## ABSTRACT

Guntur, Bharath C. M.S., Purdue University, May 2013. Airline Yield Model Simulating Current Industry Standard Yield. Major Professor: Denver W. Lopp.

The aviation industry is a capital-intensive market, which depends on huge investments to start and operate an airline company. For airlines to achieve a competitive return on their investments, they depend on developing and maintaining a strong customer base. In order to do so, they implement various strategies to attract customers to improve market share. For airlines to be profitable and sustain competitive markets, various financial factors need to be considered. Among these factors is “yield,” which is the focus of this research project. The project analysis explores the development of a yield model from daily-published airline fares, examines data and determines if a reliable model can be developed which will correlate strongly with the monthly-published domestic airline yield report of the Airlines for America (A4A). Finally, the research seeks to answer the question as to whether or not a model can be used for predicting yield value close to the A4A yield report prior to its release.

## CHAPTER 1. INTRODUCTION

Airlines are one of the most highly utilized modes of transportation in terms of logistics. Airlines have limited inventory per trip. If an aircraft leaves the ground with empty seats, the flight has lost the potential for added revenue, resulting in increased costs. Therefore, airline management attempts to maximize profits per trip by increasing revenue and reducing associated costs by optimizing utilization of the inventory. Yield, quantified as the revenue in cents or dollars per seat mile, is one such measure that helps airlines determine the revenue generated by each paying passenger for each mile flown.

### 1.1 Statement of Purpose

Currently, a common standard used for reference in the airline industry is the Airline for America (A4A) published monthly domestic yield report, (issued approximately the 20<sup>th</sup> of each month). Because ticket fares, the economy, and customer demand are highly volatile on a daily and monthly basis, analyzing yield data published on a daily and monthly basis could possibly assist interested parties gain a more holistic approach to understanding the current and future direction and outlook for airline yields.

Beneficiaries could include airlines, large travel associations and travel managers, credit card businesses, and banks, among others. This could also be very important for stock analysis of airlines and other businesses, as the yield data may reflect current financial results of airlines' monthly revenue potential. This research explores various parameters in developing a yield model based upon United States (U.S.) domestic published daily fares.

### 1.2 Significance

Airlines are huge capital investment businesses and in order to generate revenue, they need to understand the market, schedules, prices, and passenger demand for all routes. Yield is one of the financial factors that measures revenue generated per passenger seat mile. This is determined by dividing the ticket revenue with total passenger miles. If a strong correlation of a monthly yield developed using daily published fares to the A4A report can be determined, it may be possible to design a prediction model for interested parties to obtain a more real time data reference in making financial, operational, or investment decisions.

### 1.3 Scope

This project will involve developing a monthly yield as a foundation in developing a prediction model of A4A yield values at the end of each month prior to A4A publication. The daily yield representation requires collecting a data sample of routes, published daily fares along the sample routes, passenger volume along these routes, and route distances. Once the fare values are tracked using an Excel spreadsheet,

the sample daily yields along the sample routes will be determined. Daily yields for sample routes will be calculated and averaged to obtain the corresponding monthly yield. These monthly data results will be compared with corresponding A4A monthly values to determine a correlation factor. A statistical analysis will be conducted to determine a regression model for predicting A4A monthly yield.

#### 1.4 Research Question

Can a yield model be developed from daily-published airline fares that could simulate current airline industry yield?

#### 1.5 Assumptions

The following assumptions are considered for this model

- Airlines for America yield values will be considered the standard yield value for the airline industry.
- Passenger daily demand is assumed to be the same for each month.

#### 1.6 Limitations

The limitations of this study are:

- The airline routes determined in the yield model are limited to top 250 passenger routes within United States.
- The data is restricted to the top two airlines that hold nearly 70 to 80 percent market share along these routes.

### 1.7 Definitions

*Cost per Available Seat Mile (CASM):* “The average cost of flying an aircraft seat (empty or full) one mile. Often referred to as a ‘unit cost’ measurement. Calculated as Total Operating Expenses/Total Available Seat Miles” (Southwest, 2012, ¶6).

*Revenue Passenger Mile (RPM):* “One paying passenger flown one mile. Often referred to as the airline industry’s measure of ‘traffic’” (Southwest, 2012, ¶14).

*Revenue Passengers Carried:* “The number of Origination and Destination paying passengers” (Southwest, 2012, ¶13).

*Revenue per Available Seat Mile (RASM):* “Total Operating Revenue per seat (empty or full) flown one mile. Often referred to as a ‘unit revenue’ measurement. Calculated as Total Operating Revenues/Available Seat Miles” (Southwest, 2012, ¶12).

*Yield:* “The average amount of revenue received per paying passenger flown one mile. Calculated as Total Operating Revenues/Revenue Passenger Miles” (Southwest, 2012, ¶10).

### 1.8 Abbreviations

*A4A:* Airlines for America

*ATA:* Air Transport Association, Inc.

*ATPCO:* Airline Tariff Publication Company

*BTS:* Bureau of Transportation Statistics

*CASM:* Cost per Available Seat Mile

*FAA:* Federal Aviation Administration

*RASM:* Revenue per Available Seat Mile

*RITA:* Research and Innovative Technology Administration

*RMS:* Revenue Management Systems

*RPM:* Revenue Passenger Mile

*RRPM:* Revenue per Revenue Passenger Mile

### 1.9 Summary

Yield is one of the financial measurements used by airlines and interested parties in analyzing revenue and available inventory in an airline route system. A4A publishes an actual industry standard yield value of US domestic airlines on the 20<sup>th</sup> of every month. This study explores the possibility of developing a monthly yield model, which can be used to predict the monthly A4A yield value with low error, prior to A4A publication.

## CHAPTER 2. LITERATURE REVIEW

### 2.1 Literature Review Approach

This review of literature begins with an introduction to yield, its definition, and its importance for airlines and other parties. This study, *Airline yield model simulating current industry standard yield*, approaches the concept of developing a yield model that generates daily yield data and comparing the model with the A4A yield value. The literature review covers a range of sources and the information gathered from these sources to develop the yield model.

### 2.2 Introduction

In order to stay competitive, many airlines started using financial measurements such as RPM, CASM, and RASM, and yield to understand current and future market demand growth. Each term listed above is an influential variable of revenue management within the airlines. External factors also affect airlines' revenue, including price competition and fuel prices. As stated, yield is one of the influential factors for airline decision making.

Today, most airlines use yield to determine the current market fares for routes and to predict future demand along each route or industry as a whole. Airlines currently use yield information published by the A4A organization (A4A, 2012).

## 2.3 Yield

Yield, according to the Oxford dictionary, in financial terms, “is the amount of money brought in/generated” (2012). It is exactly what it sounds like, but in airline terminology, there is a slight change in the yield definition; it is the average revenue generated by commuting a passenger for one mile. It is expressed in cents per passenger mile or cents per passenger kilometer. In aviation, yield is referred to in many different terms, such as revenue per revenue passenger mile (Vasigh, Fleming, Mackay, 2010), revenue yield per revenue passenger mile (Southwest Airlines, 2012), and revenue per passenger mile (American Airlines, 2012). However, each refers to the common definition of, the average amount of revenue received per passenger flown one mile.

### 2.3.1 Yield Segmentation

Yield can be separated into various classes as categorized by Bureau of Transportation Statistics (2012) listed below:

- Type: There are primarily two types of yield in the aviation industry. First is passenger yield, which is expressed in cents per revenue seat mile/kilometer, and generated by carrying revenue passengers. The second type is the cargo yield generate by carrying cargo/freight, expressed in cents per ton mile/ton kilometer. For this research project, the focus is on the U.S. domestic passenger segment of the airlines.
- Class: Since there are various classes on board a flight, such as business, first, economy, and economy plus, yield can be separately obtained for each class of fare. For example, airlines designate business and first-class passengers as high

yield passengers, as they pay a premium price for tickets and service aboard a flight. The model developed will cover all the ticket classes for selected routes.

- Route: Airlines can individually predict the average yield for a given route. For instance, long-range routes average yield will approach the same yield as short-range flights with more frequencies.
- Airline: Airlines as a whole can determine their individual yield along all the routes with all the fare classes as illustrated in the Figure 2.1 below, detailing a bar chart with yield values on the vertical axis and the airlines on the horizontal axis.

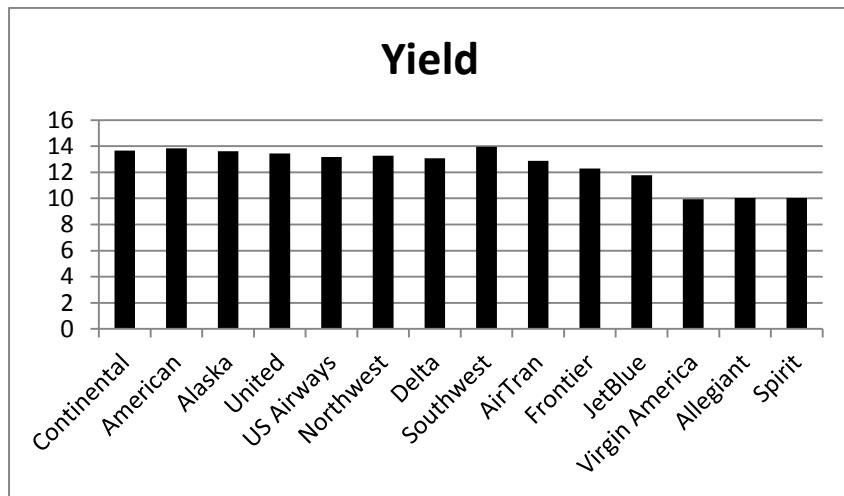

Figure 2.1 United States Airlines' Yield 2008 (data extracted from BTS, 2012).

- Airlines as a group: In the United States, airlines have been grouped into various groups such as regional, low-cost, and network carriers, depending on their fare structures, airport origin and destination, and yearly passenger traffic. Table 2.1 illustrates yield data on a quarterly basis for the year 2008.

Table 2.1 *Yield Generated by Domestic Airline Groups in Cents per Seat Mile* (Bureau of Transportation Statistics, 2009).

4Q 2008 Rank	Airline Group	1st Quarter 2008	2nd Quarter 2008	3rd Quarter 2008	4th Quarter 2008
1	Regional	22.4	23.5	21.8	19.4
2	Low-Cost	12.5	12.6	13.0	13.5
3	Network	13.1	13.5	14.0	13.3
	21-Carrier Total	13.6	14.0	14.3	13.7

- Industry as a whole: By combining data from airlines, routes, and classes, the yield can be determined for the airline industry as a whole. Figure 2.2 lists the yield plot between United States domestic airline yield and international yield.

For the purpose of this study, only passenger domestic yield is used.

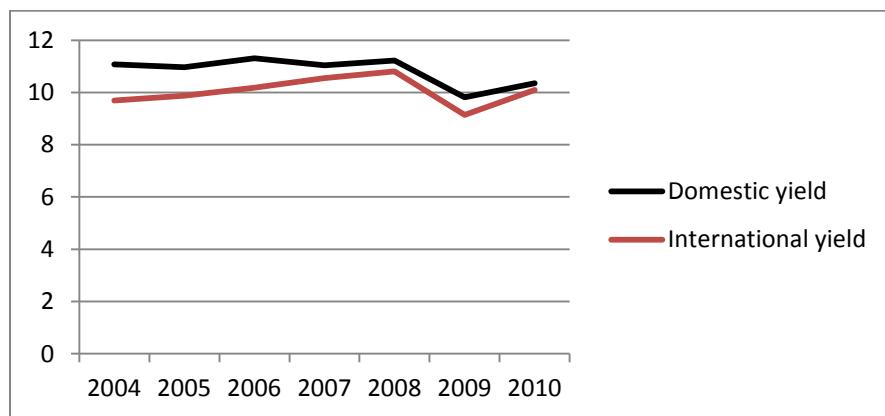

Figure 2.2 United States Domestic Airline Yield vs. International Airline Yield (data extracted from Bureau of Transportation Statistics, 2010).

### 2.3.2 Yield Equation

In simple terms, yield can be calculated by using the Equation 2.1, as defined by Bijan, Ken, & Liam (2010).

$$Yield = \text{Total Passenger Revenue (R) / Total Revenue Passenger Miles (RPM)}$$

(Equation 2.1)

Total passenger revenue (R) is the total amount of money generated by flying passengers along a route or with an airline. Total Revenue passenger miles (RPM), as illustrated in Equation 2.2, represents the product of the miles times the number of revenue passengers flown along the route or with the airline, respectively (Bijan, Ken, Liam, 2010).

$$\text{Revenue Passenger Miles (RPM)} = \text{No. of Passengers Flew} * \text{Distance along the Route}$$

(Equation 2.2)

For instance, if an aircraft having a capacity of 100 seats flew a distance of 900 miles with 85 revenue passengers and by operating the flight, RPM is  $85 * 900 = 76,500$ , and the operating revenue reported along this route is \$14,000, then yield is  $R/RPM = 14,000/76,500 = \$0.183/RPM = 18$  cents per passenger mile.

There are various other types of formulas also being utilized by the industry. In his book, *Straight and Level: Airline Financial Economics* (2008), Stephen Holloway calculates yield for a given route as shown in Equation 2.3

$$Yield = (\text{Operating Revenue}) / \text{Traffic}$$

(Equation. 2.3)

### 2.3.3 Factors Affecting Yield

There are various factors that influence yield characteristics, as mentioned by Stephen Holloway (2008, p 183). They are:

- Fare Structure: Since there are different fare classes for a route, yield brings uniformity and gives the average fare for all units sold along a route. The three main fare structures are first class, business and economy. However, in the airline industry, there could be more than eight types of fare structures for a given route.
- Traffic Mix: With different fare structures across a cabin, there exist different traffic mixes associated for the price that will influence the yield. There are three different characteristics that affect the traffic mix:
  - Demand Characteristics: Business travel vs. pleasure/leisure travel.
  - Price elastic vs. inelastic situations: Lower fares for inelastic situations, (i.e., booking a flight two to three months prior). For example, booking a flight at the last minute will result in high prices, as there likely exists increased demand.
  - Protecting space for last-minute, high-yield passengers: High-yield customers are mostly business class passengers that are willing to pay a premium price for the ticket.
- Length of haul: Distance along the route. The longer the distance between airports, the lower the yield as revenue needs to be spread across a greater RPM in comparison to short haul flights.

- Intensity of competition: Price competition from other airlines will highly influence yield for a given airline. As most customers are leisure travelers, they prefer low-ticket prices, thereby affecting yield for the airline.
- Network design: Hub and spoke vs. point-to-point network of routes. Yield here, is mostly affected by the distance between airports.

The above provides insight in to the makeup of yield and the parameters that affect the yield, in this study cause and effect of the parameters were not analyzed.

### 2.3.4 Yield and Other Terms

There is a misconception between average fare and yield. Average fare is the average amount of money spent by the passenger along a route, expressed in dollars per passenger, while yield is the average fare per unit of output sold, expressed in cents per passenger mile. By selecting average fare, one can obtain only the average revenue per passenger for a route, and that cannot be compared with another route as distance could vary, or capacity could vary. Yield gives average revenue per passenger mile. This can be easily compared between two different routes, or two different market segments or more on a per distance basis. Average fare values are only affected by the number of passengers and cost of the tickets published by the airlines, while yield values are based on the price of tickets, number of passengers, and the distance between the origin and destination.

On the contrary to yield being important to airlines, author Perry Flint in *Air Transport World* (1995) suggests that airlines should not focus on passenger yield, as they cannot control it, but rather they should consider RASM (Revenue per Available

Seat Mile) which can play a major role in airline profits. Yield can be affected by ticket prices: as ticket prices go up; fewer people fly along the route, and yield values will decrease. The converse is true, for yield with increased ticket fares, RASM will increase. Since there is a restriction in capacity, load factor is the key for profit. Flint states that yield is what people are willing to pay for the fare. This perspective holds that yield mostly likely will change with a change in ticket prices, but will not be affected by increasing or decreasing passenger demand along the routes.

Yield management is another term, which provides insight into the importance of yield measurement. In the airline industry, yield management is an important concept that is used in relation to yield in obtaining the revenue model for each flight flown. Yield has demand variable in it, while yield management does not generate demand, but it simulates it. The functional aspects of yield management are, according to Page & Connell (2006):

- Market Segmentation;
- Price Management;
- Demand Forecasting;
- Availability and/or capacity management; and
- Reservation/negotiations.

The main function of yield management is that it “determines how much of each product (fare class for each origin/destination) to sell” (Mak, 1992, p.9). By effective implementation of yield management practices, airlines can be successful and can generate maximum revenue by selling the product at the right time for the right price and to the right customer.

Yield is one of the determining variables used in revenue management systems (RMS) by almost all airlines; to make decisions about ticket prices, and to plan for the future depending on the current yield trend. One of the key aspects of the RMS is to generate more revenue for each of the product sold; in airline industry, it is to maximize revenue earned per each seat sold from each flight. This can be achieved by maximizing yield, (i.e., selling seats at the cost of average yield for flight or higher than that). If the tickets are sold at prices that cause yield for that ticket to be lower than the average yield, then the airlines could opt to not sell the ticket and rather fly an empty seat (Holloway, 2008).

### 2.3.5 Yield Forecast

Commercial aviation is one of the important sectors of today's economy. In 2009, commercial aviation contributed about 4.9 percent of Gross Domestic Product (GDP) (Federal Aviation Administration, 2011). Boeing forecasts there will be an increase in passenger demand over the next few years, which will in turn lead to an increase in airline revenue. With an increase in revenue, airline yield would likely increase. The Federal Aviation Administration forecasts that the average yield for fiscal year 2012 will increase by 1.2 percent (March 8, 2012), while IATA predicts there will be a 1.7 percent increase in global passenger yield values, as airlines are maintaining tight capacities onboard the flight (ATW, 2012). An airline organization group called Airlines for America publishes the industry standard for the yield values.

By analyzing the possibility of developing a prediction tool for monthly A4A yield reports, the aviation could have an additional tool in making decision.

## 2.4 Airlines for America

Airlines for America (A4A), previously called Air Transport Association of America, Inc. (ATA), was the first trade organization of America's airlines. The primary goal of this association is to create and support aviation business environment, and to sustain the global airline competition. A4A also provides support that improves aviation safety and security. A4A serves as a platform between the air carriers, the US governmental bodies and few private sectors. There are in all, 16 key departments within the association that serve and address all major aspects of aviation. Nearly, 90 percent of U.S air traffic both passenger and cargo, are transported by A4A affiliated members (2012, 1¶).

Yield is defined by A4A as follows: "Passenger 'yield' is a commonly used metric representing the average fare paid by customers to fly one mile (revenue passenger mile or RPM). It is a key indicator of the price of air travel and is a weighted average expressed in cents" (A4A, 2012, 1¶).

A4A calculates the yield from operating revenue and total revenue passenger miles data provided by its member airlines. The yield value is published on the 20<sup>th</sup> of every month for the previous month data. In this thesis, the plan is to develop a daily yield model from the published fares by the airlines and that could also project the daily trend and future yield values. In order to develop a new yield model in comparison with the A4A published yield Figures, prices values, passenger demand, and distance along the routes information need to be gathered. Price values of routes are gathered from Airline Tariff Publishing Company (ATPCO); passenger demand and distance along routes are gathered from the Bureau of Transportation Statistics (BTS).

## 2.5 Bureau of Transportation Statistics

The Bureau of Transportation Statistics (BTS) was established in 1992 under the Intermodal Surface Transportation Efficiency Act of 1991 as a statistical agency. In 2005, BTS merged with the Research and Innovative Technology Administration (RITA). BTS's role as a statistical agency is as follows (Bureau of Transportation Statistics, 2012, 5¶):

- Is policy-neutral-an objective broker for the facts;
- Covers all of transportation; BTS is cross-modal in nearly everything we do;
- Does independent data collection and analysis, but BTS also serves all the other modes to help them be more effective and efficient;
- Sets standards for transportation data;
- Has special statutory protections (essentially the same as those for Census Bureau and Bureau of Labor Statistics) for the confidentiality of data we collect; and
- Have unique competencies in statistics, economics, information technology, geographic information systems, and transportation.

The data and statistics section on the BTS website covers topics related to aviation with additional modes of transportation statistics. For this study historical airline traffic data (number of passengers on each route) and the route distances were gathered from the BTS website. With nearly 28,000 flight daily across US, a sample of top 250 passenger routes with top two major market share by airlines were selected to develop the monthly yield using BTS data.

## 2.6 Air Tariff Publishing Company

Air Tariff Publishing Company (ATPCO) is solely owned by 16 U.S. and international airlines. ATPCO serves as an electronic clearinghouse for fares and changes posted by the airlines. ATPCO was established in 1940s when fares were regulated by the government. Following airline deregulation in 1978, many airlines started tracking competitive prices for a given route and adjusting their fares accordingly to obtain maximum customer market. “ATPCO serves as the airfare data provider for more than 450 airlines worldwide, which together represent 97 percent of scheduled commercial air travel. With customers on six continents in 165 countries, our airline customers range from large intercontinental network carriers to small regional companies. Fares from all these airlines are sent to another set of our customers, the global distribution systems (such as Sabre, Amadeus, Travelport, and ITA Software) and other computer reservation systems that use our data to issue tickets” (ATPCO, 2012, 2¶).

On an average daily basis ATPCO processes up to nearly 130,000 fare change requests. During busy times it processes up to nearly two million changes (Wensveen, 2011). The top 250 passenger route samples were selected for this study; the fares along these routes from August 2009 through November 2012 were gathered from ATPCO database. Once the data was obtained for the past data, daily fares for the routes are tracked on a daily basis to keep update with information and to develop a yield model.

## 2.7 Summary

In order to develop a new yield model in predicting A4A yield, sample routes, daily fares, passenger demand, and distance along the routes, information needs to be gathered. Daily fares of the routes are gathered from Airline Tariff Publishing Company (ATPCO); sample routes, passenger demand and distance along routes are gathered from the Bureau of Transportation Statistics (BTS).

## CHAPTER 3. METHODOLOGY

### 3.1 Data

To develop a yield model the following information was necessary in determining and updating the predicted airline yield:

- Routes city pairs;
- Passenger traffic along routes;
- Distance between the origin and destination cities along the routes; and
- Daily published fares by the airlines for the routes.

Routes, passenger traffic and distance between the routes are collected from the Bureau of Transportation Statistics (BTS) database, where airlines report their data. Daily-published fares were obtained from the Airline Tariff Publication Company (ATPCO), a company which publishes updated fares from airlines several times a day for each route.

### 3.2 Sampling

Under the Form 41 section on the BTS website, all the routes with passenger traffic and distance between the airports that airlines fly within US domestic and international markets have been recorded. For this project, the routes were restricted to top 250 passenger routes within U.S. domestic.

Initially, once the data had been downloaded from the BTS website, using Excel, duplication of the city pairs were removed from the dataset, as ATPCO tracks all routes as one –way. For example, a flight from Indianapolis International Airport (IND) to Los Angeles International Airport (LAX) would be considered the same as a flight from LAX to IND airport. The passenger traffic along these routes would be added to give total passenger demand along the route segment for each month.

The datasets of the city pairs have been arranged in descending order of the passenger traffic for all the months. The top 250 routes were selected. These 250 routes resembled nearly 26 percent of the total commercial air traffic population throughout the United States. Due to the restrictions with ATPCO, all the 250 routes were simplified into 127 one-way routes.

The selected route city pairs were used in the ATPCO database to obtain information about published fares by the two airlines along these routes from August 2009 through November 2012.

### 3.3 Process

From the sample 127 domestic routes and the published economy fares from the ATPCO database, the determined routes were downloaded. The data involved could range fare changes from single fare to several hundred per route on any given day. So in order to simplify the process, daily average fare was determined for each route. Then passenger information are gathered from the BTS database. Though BTS does not track the passenger on a daily basis, they were reported on monthly basis. In order to get a representative and weighted factor of daily passengers flown on the routes, the total

monthly passenger were averaged evenly across the month depending on the number of days in that month. Once the daily average fares and the daily passenger were determined, the daily revenues were calculated by multiplying the daily average fare and the daily passengers for each route. The daily revenue for all the routes was added to give the total daily revenue across the top 250 sample routes. The total daily passenger miles were determined by multiplying daily passenger along each route with the distance along these each routes, then the daily passenger miles along each are added to give total daily passenger miles. The total daily revenue for the system was then divided by the total daily passenger miles to give daily yield which is the weight average of the distance and the ticket fares. The daily yield values were then averaged on monthly basis to get one single value for each month. The calculated monthly yields were then compared to the industry standard yield published by Airlines for America. The dependent variable was A4A yield values, while the calculated monthly yields from the daily published fares served as the independent variable.

### 3.4 Regression Analysis

After the method to find the monthly yield was developed then regression analysis was performed on the data to best predict the monthly industry standard A4A yield values. As stated above in the literature review, A4A publishes each month data on the 20<sup>th</sup> of the following month. A regression analysis was conducted to simulate the industry yield and used it to predict 20 days beforehand each A4A monthly value.

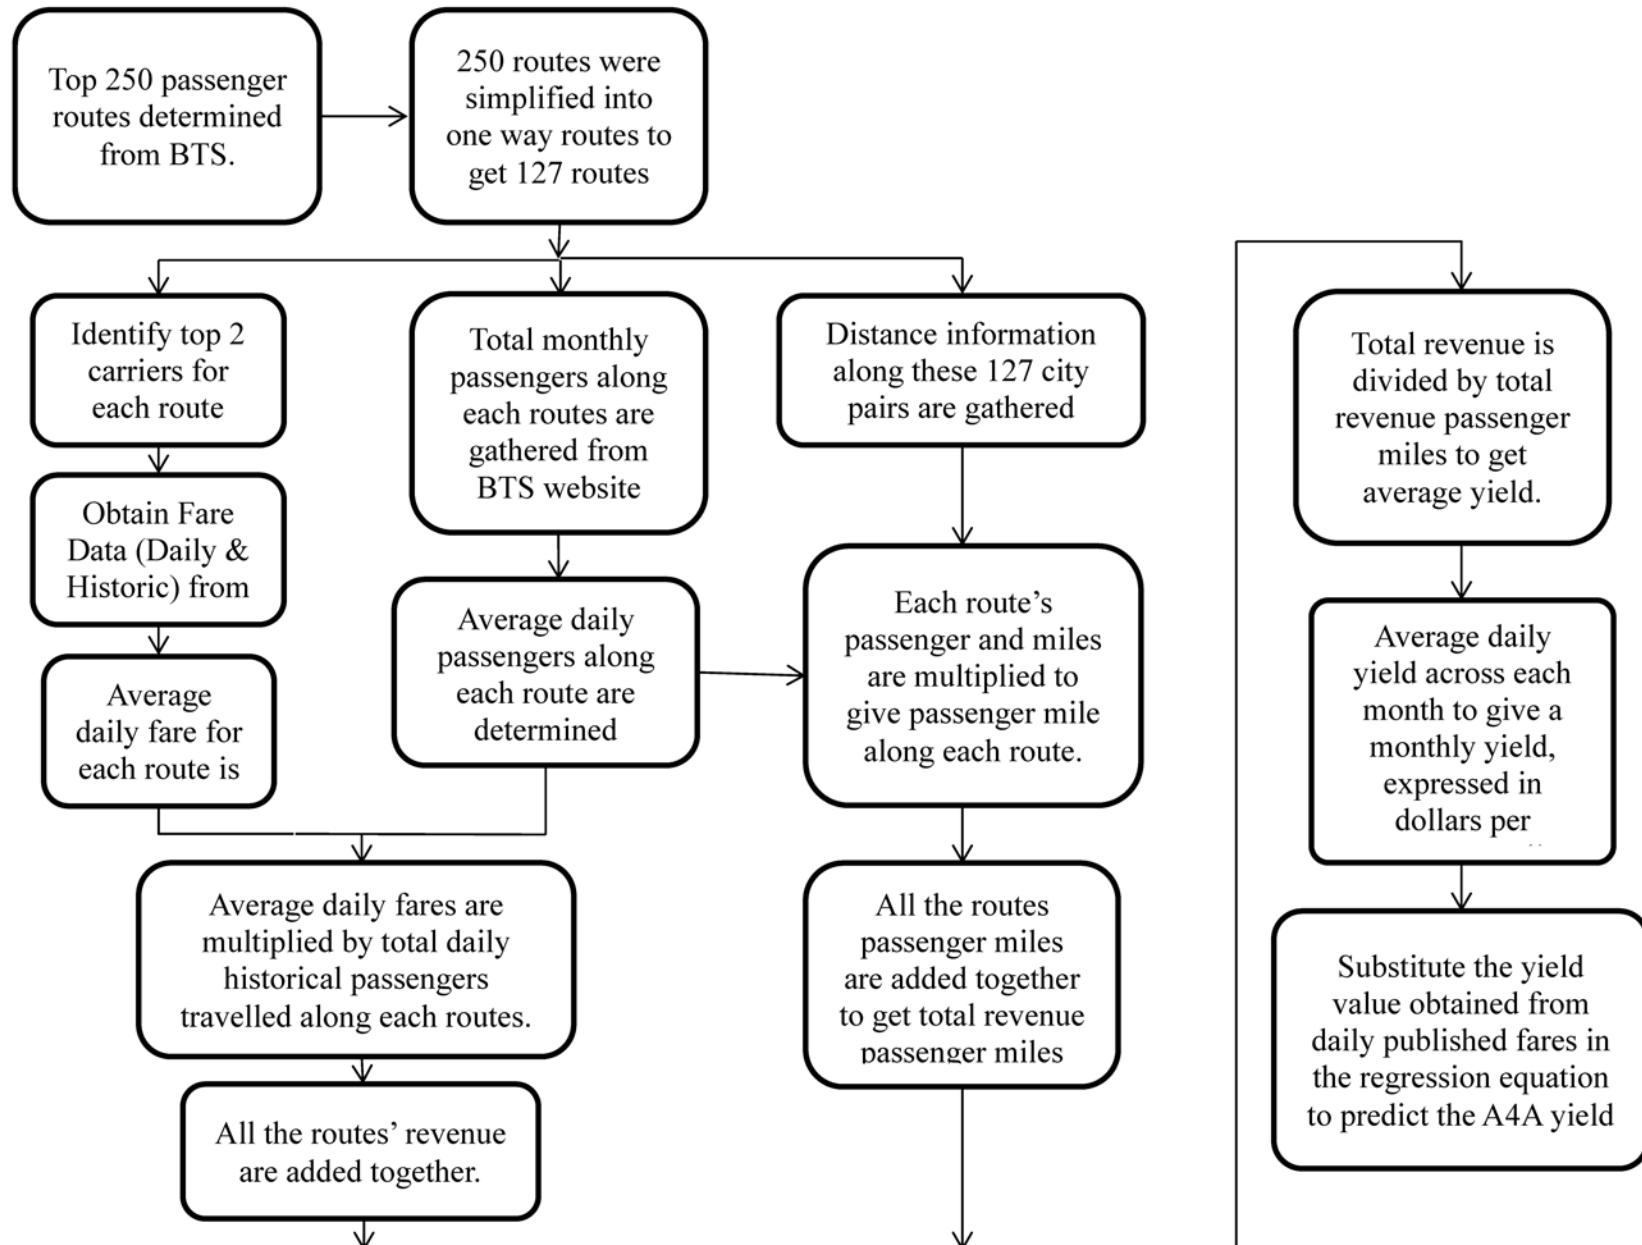

Figure 3.1 Methodology Flow Chart

### 3.5 Summary

This study was in search of developing a model for predicting A4A monthly values. In creating a model, a correlation analysis was performed to analyze the trend between actual A4A yield values and the yield values developed using daily published fares. A best fit regression model was developed to predict a close estimate to the actual A4A by the end of each month.

## CHAPTER 4. RESULTS

In this chapter, the data and the statistical results for the model are presented and discussed. The chapter begins with the basic descriptive statistics of both dependent and independent variables and concludes with the results and tests about the data. Hereon, yield values are expressed in dollars per seat mile.

The monthly yields calculated from the ATPCO daily-published fares by the airlines and the current industry standard A4A yields are represented in the Table 4.1, for the 37 months between August 2009 and August 2012.

**Yield (ATPCO):** Represent monthly yield values calculated from daily-published fares from ATPCO database expressed in dollars per seat mile.

**Yield (A4A):** Industry standard monthly yield values as published by A4A expressed in dollars per seat mile.

The independent variable in the Table 4.1 above is the Yield value obtained from the ATPCO data and the dependent variable is the industry standard A4A yield value.

#### 4.1 Statistical Analysis of the Data

The statistical and graphical summary of the monthly Yield (A4A) and Yield (ATPCO) from the Table 4.1, have been represented in Figure 4.1 and Figure 4.2 respectively. The graphical summary of the data in the Figures 4.1 and 4.2 below, show that Yield (A4A) and Yield (ATPCO) have followed the normal probability with skewness. The Box plots below the normal probability plot illustrates that there were no outliers in each of the datasets.

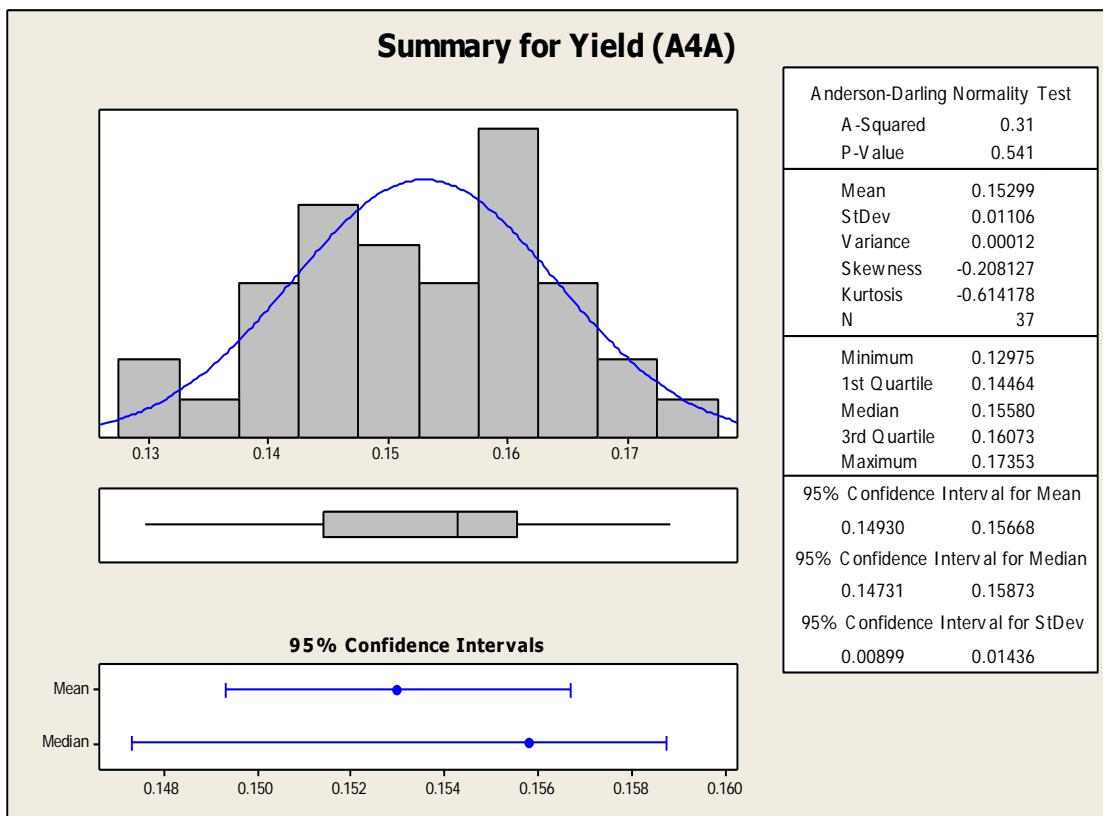

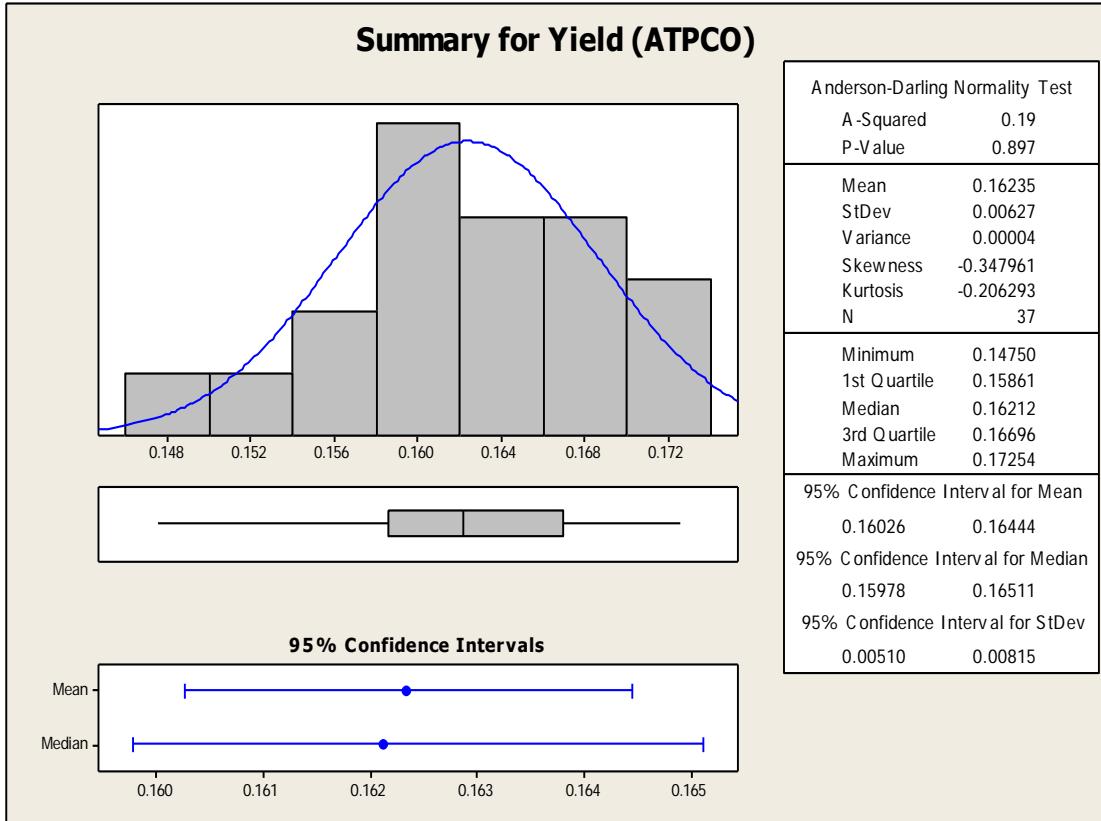

Figure 4.1 Descriptive Statistics of the Industry Standard A4A Yield

*Figure 4.2 Descriptive Statistics of the Monthly Yield Values Developed from ATPCO Daily Published Fares*

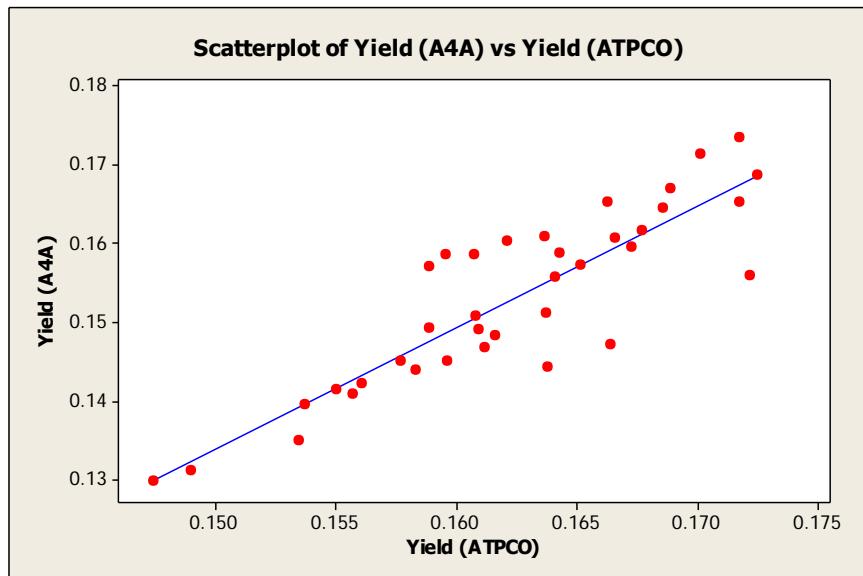

A Pearson correlation was determined between the Yield(A4A) and Yield (ATPCO) data, and the correlation as noted in the Table 4.2 was 0.878, designating that there was a strong correlation between the dependent and independent variable and was statistically significant with a p-value of zero.

*Table 4.2: Pearson Correlation Between Yield (A4A) and Yield (ATPCO)*

Pearson Correlation between Yield (A4A) and Yield (ATPCO)	0.878
P-Value	0.00

#### 4.2 Regression Analysis

As the correlation had a strong trend, a scatterplot between the dependent and the independent variable was plotted and shown in Figure 4.3. The graph represented that there was a linear trend between the dependent and independent variable. The blue line in the graph demonstrated a regression line which best fits the model between yield (A4A) and Yield (ATPCO).

*Figure 4.3 Scatterplot of Yield (A4A) vs. Yield (ATPCO) With Regression Line*

The blue regression line in the Figure 4.3 was calculated by the regression analysis function in Minitab software, and represented by the Equation 4.1 as noted below.

$$Yield (A4A) = -0.0982 + 1.55 \cdot Yield (ATPCO)$$

(Equation 4.1)

As mentioned above, the Minitab software exhibited a set of regression results as noted in Figure 4.4. From the data, “R square,” was calculated which reflects the coefficient of determination, preliminary used for data to measure the proportion of

explained variance to the total variance of Yield (A4A). The R-Square result was 76.40 percent, or 0.7640 if expressed between 0 and 1 (statistical terms), providing a reasonable level of confidence the model would predict the data using the regression equation.

#### **Regression Analysis: Yield (A4A) versus Yield (ATPCO)**

The regression equation is  
 $\text{Yield (A4A)} = -0.0982 + 1.55 \text{ Yield (ATPCO)}$

Predictor	Coef	SE Coef	T	P
Constant	-0.09823	0.02319	-4.24	0.000
Yield (ATPCO)	1.5474	0.1427	10.84	0.000

S = 0.00537201    R-Sq = 77.1%    R-Sq(adj) = 76.4%

#### Analysis of Variance

Once the residuals were determined, the residual data for Yield (A4A) were plotted as shown in Figure 4.5. The Versus Order plot in the Figure 4.5 plotted the residuals listed in Table 4.3.

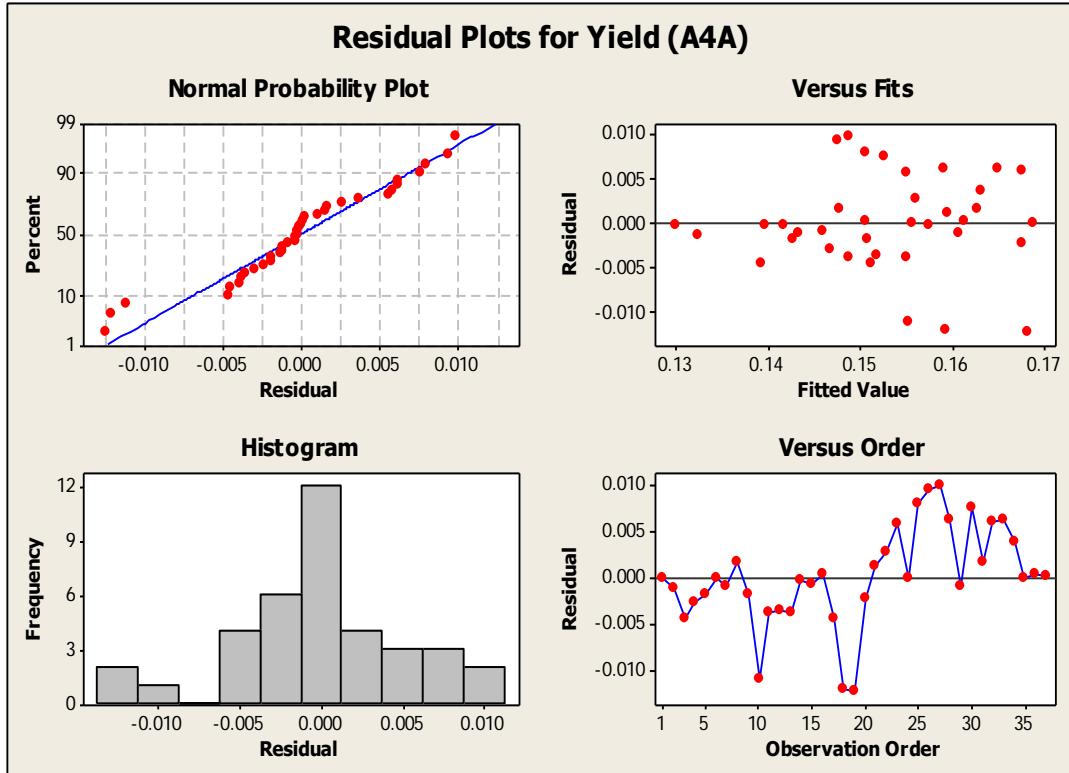

Figure 4.5 Residual Plot Without Indicator Variable

Looking at the versus order plot, there was a shift in the mean, most of the data from the first 20 observations predicted data was over-estimated as compared to the industry standard yield values as published by A4A, and for the balance of the observations was under-estimated. This shift in means suggested additional regression analysis may provide an improved prediction model. In reviewing the data gathered from ATPCO database, it was determined that the fares modified three times each day and do not report the exact count for the number of seats sold at each price. Therefore, an indicator variable was introduced to offset the mean shift. If the real A4A data was higher than \$0.156/seat mile, it was indicated by 1 or else 0. The main role of the Indicator Variable was to reduce the difference between predicted and the Actual A4A values.

Using the indicator variable and the data from Table 4.1, another regression equation was developed and is as noted below in Equation 4.2, and the regression analysis has been shown in Figure 4.6.

$$\text{Yield (A4A)} = -0.0221 + 1.05 \text{ Yield (ATPCO)} + 0.0106 \text{ Indicator}$$

(Equation 4.2)

#### **Regression Analysis: Yield (A4A) versus Yield (ATPCO), Indicator**

The regression equation is

$\text{Yield (A4A)} = -0.0221 + 1.05 \text{ Yield (ATPCO)} + 0.0106 \text{ Indicator}$

Predictor	Coef	SE Coef	T	P
Constant	-0.02213	0.01605	-1.38	0.177
Yield (ATPCO)	1.0486	0.1008	10.40	0.000
Indicator	0.010633	0.001252	8.49	0.000

S = 0.00308534 R-Sq = 92.6% R-Sq(adj) = 92.2%

Indicator	1	0.0006864

*Figure 4.6 Regression Analysis of Yield (A4A) and Yield (ATPCO) With Indicator Variable*

From the above analysis which used the indicator variable, it can be interpreted that “R square,” coefficient of determination had increased from 0.7640 to 0.9920. 92.20 percent of the time, the predicted variance can be explained by the actual A4A yield variance. On substituting the yield values generated from ATPCO data fares in the regression Equation 4.2, the new predicted values using indicator variable, expressed in

dollars per seat mile, were listed below in Table 4.4 below, along with the residuals. The residuals values ranged from -0.0057 and 0.005568

A new scatterplot of residuals was plotted with the A4A yield values and was shown in the Figure 4.7.

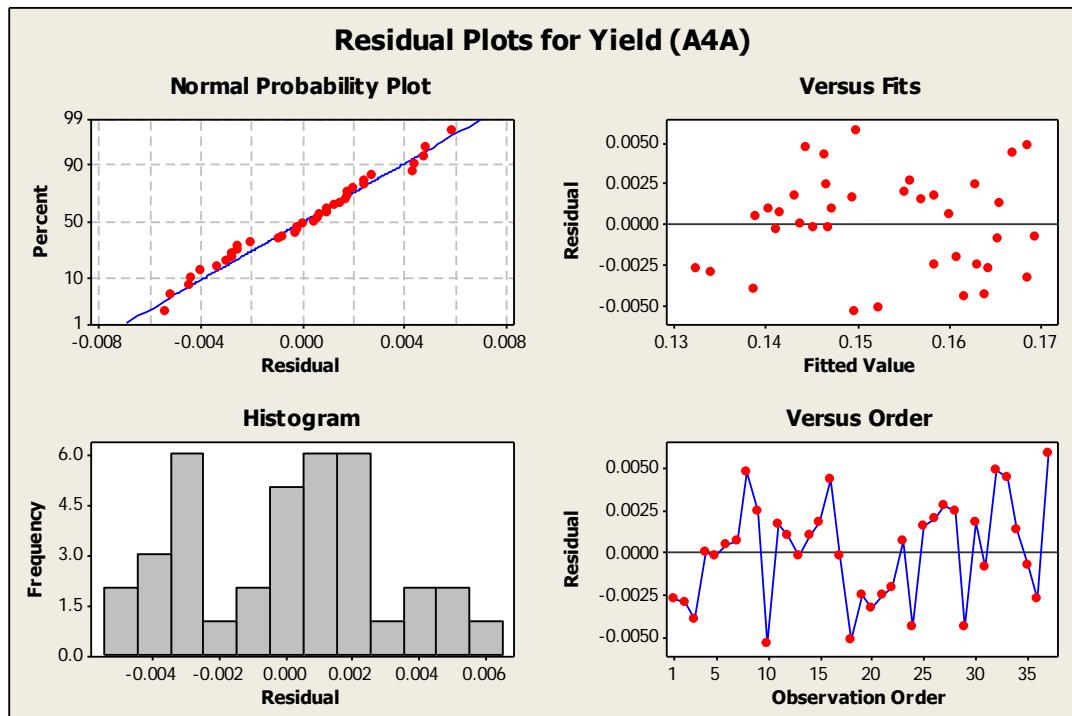

Figure 4.7 Residual Plot With Indicator Variable

Table 4.5 shows the comparison between the regression equation developed with and without the indicator variable.

Table 4.5 *Regression Analysis With and Without Indicator Variable*

	Without Indicator Variable	With Indicator Variable
Regression Equation	Yield (A4A) = -0.0982+1.55 Yield (Model)	Yield (A4A) = - 0.0221 + 1.05 Yield (Model) + 0.0106 Indicator
R-Square	0.7640	0.9220
Range of Residuals	-0.01282 to + 0.009412	-0.0057 to +0.005568

#### 4.3 Testing

The regression analysis with the indicator variable was determined to be an improved model over the simple linear regression in predicting the A4A yield values for each month. Once the model was developed using the 37 data points listed in Table 4.1 with the indicator variable, the model was tested on the consecutive next three months from September 2012 through November 2012 while holding the regression equation constant. The results of the prediction for the following months from September 2012 through November 2012 have been listed in Table 4.6 below and were compared with actual A4A published yield values.

Another regression model was developed with changing regression equation keeping dataset constant for 37 months. In this, if a new month was added to the dataset, the first month was removed, keeping the sample size same across the regression equations. The results of changing regression equation for the next three months have been detailed in the Table 4.7.

Table 4.6 Results from Testing the Model With Constant Regression Equation

Month	Regression Equation	Adjusted R-Square	Yield(ATPCO)	Predicted A4A yield	Actual A4A Yield	Residual
September 2012	Yield (A4A) = - 0.0221 + 1.05 Yield (ATPCO) + 0.0106 Indicator	0.9220	0.16953	0.155907	0.1561	0.000193
October 2012	Yield (A4A) = - 0.0221 + 1.05 Yield (ATPCO) + 0.0106 Indicator	0.9220	0.17094	0.167987	0.1644	-0.003587
November 2012	Yield (A4A) = - 0.0221 + 1.05 Yield (ATPCO) + 0.0106 Indicator	0.9220	0.17243	0.169552	0.1651	-0.004452

Table 4.7 Results from Testing the Model With Changing Regression Equation

Month	Regression Equation	Adjusted R- Square	Yield (ATPCO)	Predicted A4A yield	Actual A4A yield	Residual
September 2012	Yield (A4A) = - 0.0221 + 1.05 Yield (ATPCO) + 0.0106 Indicator	0.9220	0.16953	0.155907	0.1561	0.00193
October 2012	Yield (A4A) = - 0.0164 + 1.01 Yield (ATPCO)+ 0.0107 Indicator	0.9140	0.17094	0.166949	0.1644	-0.00255
November 2012	Yield (A4A) = - 0.0048 + 0.943 Yield (ATPCO) + 0.0107 Indicator	0.9050	0.17243	0.168501	0.1651	-0.003402

The results above predicted with constant regression equation and changing regression equation both exhibited a close prediction to the actual A4A yield value for the months of September 2012 through November 2012. The constant regression equation has an increasing error over the course of time and also has a residual value compared to the changing regression equation. This suggests, as new monthly data was added to the constant regression equation; the data on which the regression equation was developed would reduce the impact of actual yield movements for future months. Developing an updated changing regression equation with the recent 37 month data would increase sensitivity of yield movements and provide a more realistic and closer value to the actual A4A yield.

#### 4.4 Summary

With best use of the available information, the regression model developed with a revolving indicator can best predict the industry standard A4A yield values at the end of each month, i.e., 20 days ahead of the A4A publication. A regression equation with changing datasets would assist in a more accurate prediction of the A4A value.

## CHAPTER 5. DISCUSSION AND CONCLUSION

Yield, as stated above in the literature review, is the willingness of a customer to pay for a mile along a route. By using the published fares from ATPCO database, a method was developed using Microsoft Excel software to publish the yield values at the end of each month, which were then correlated within a high confidence rate with the industry standard A4A yield value. The regression analysis from the results section demonstrated a model could be developed which represented the predicted yield value of the A4A yield with an adjusted R-square greater than 0.90.

The current yield model developed using simple linear regression analysis with changing dataset and indicator variable is better serving in close predictions of A4A values. While predicting the A4A yield value at the end of each month, substitute zero and one values individually into the updated regression equation developed from the previous 37 months of data. If the predicted A4A value is less than \$0.156/seat mile in either case, always consider zero as the indicator variable. If in both the cases, the predicted A4A yield value is always greater than \$0.156/seat mile consider value one as the indicator variable.

For the current regression model developed using the indicator parameter, the values zero and one are determined based on the predicted A4A value. For future consideration it is suggested to develop an indicator parameter based on the Yield (ATPCO) values or trends. Another analysis that could be considered for future development is forecasting A4A yield values based on repetitive trends, as shown in Figure 4.7 in the versus order plot.

### 5.1 Conclusion

Yield has been discussed as proportional to the total revenue generated from the route or a system and inversely proportional to the passenger miles (Equation. 2.1). Yield is one of the financial key terms that help airlines determine customers' behavior for a change in airfare along a route. Airlines try to generate maximum revenue per flight on any given route, which can be attained when the yield is at its optimum point for the route. Considering yield as a system, the domestic airline yield, will determine how the airlines are performing, i.e., if there will be an increase or decrease in revenue by looking at the yield trend over the years. Domestic airline yield values could be beneficial in assisting not only the airline companies but also credit card companies and the investors to understand the airline market and future growth.

One goal of this study was to determine models that could simulate industry standard yield values. By using variables, such as the top 250 domestic passenger routes, total monthly passengers flown along these top 250 routes, published fares for these routes from the ATPCO data and the distance along the city pair routes a method was developed using Excel Software to determine monthly yield values. A regression model was developed using the Minitab Software, with the monthly A4A yield values and yield

values developed using the published fares for the routes, to predict the A4A yields. By making the best use of the available information the developed regression model was found to predict the actual A4A yield with an R-square value greater than 0.90.

To address the research question, it has been shown that an alternative model can be developed from daily published fares that could simulate industry standard A4A yield values.
