**Abstract** We investigate which factors influence 44,649 employees' decision to invest in a top retail banking group in France. We have two objectives: (i) to explore factors associated with the amount invested in the plan, and (ii) to explore whether these factors have same associations with the probability of investing more than the incentive pay i.e. being an active investor. Specifically, we focus on four parameters that have been shown to affect participation: liquidity constraints, imperfect knowledge of the plan, asset choice, and transaction costs. We confirm Engelhardt and Madrian (Natl Tax J 57:385–406, 2004) assumptions according to which such factors contribute to explain non-participation. We show that ESPP contributors have very specific and unobserved motivations, as shown with the positive correlations between error terms in the two steps of investment decisions. The existence of unobservable investment motives can be explained by a lower risk aversion, a higher time preference, or a strong willingness to participate to corporate governance.

## 1 Introduction

Over the last decades, incentive pay arrangements have become a widespread phenomenon. In the United States, it has been estimated that 38.7 million employees are concerned by such schemes, representing approximately 20% of private sector employees (National Center for Employee Ownership 2010). In France, the number of employee stocks owners has increased from 700,000 in 1998 to 2.7 millions in 2007 (French Employee Ownership Association 2009). This increased success has been driven by a permanent support from companies' executive managers and governments (Kruse 2002). Because they are usually bundled with ESPP offers, incentive pay schemes have a major influence on investment decisions. Usually, tax-free accruals of interest and tax-deductions are given for all contributions corresponding to an allocation of incentive pays. Moreover, companies usually provide matching contributions when employees invest in the ESPP.

While there has been a large interest in company-based plans savings behaviors, few research articles were dedicated to the exploration of investment behaviors in ESPP offers. Engelhardt and Madrian (2004) explain that in addition to risk aversion, four main factors can influence the decision to participate or not in ESPP offers: liquidity constraints, imperfect knowledge of the plan, asset choice, and transaction costs. Non-investors would have a lower income, a lower access to ESPP-related information, a lower willingness to invest in company stocks, and would face higher behavioral biases such as procrastination and self-defeating behavior. According to Engelhardt and Madrian (2004), these four characteristics distinguish investors from non-investors. However, Engelhardt and Madrian (2004) do not test empirically these assumptions, and to our knowledge the influence of these factors on investors' behaviors in ESPPs has not been studied from an empirical perspective. Moreover, the relationship between incentive pay mechanisms and ESPP offers remains unclear. Among investors, two main behaviors can be identified. On the one hand, some employees choose to invest an amount that is lower or equal to their incentive pay. For these employees, ESPP investment may represent a way to increase their income through tax deductions. On the other hand, some employees choose to invest more than their incentive pay, e.g. allocate to company stocks money that does not come from their job compensations. These latter employees are actually making an arbitrage in favor of their company stocks within their overall wealth. Currently, there is no evidence that these factors will have the same associations with the decision to be an active investor, e.g. invest more than their incentive pay. For these active ESPP offers investors, investment motivations may be different: their willingness to become an employee owner or to save for the future may be very important in the decision process.

In this paper, we explore the association between ESPP offers investment decisions and incentive pay mechanisms. Specifically, we study whether liquidity constraints, imperfect knowledge of the plan, asset choice, and transaction costs have same associations with the amount invested in the ESPP and the decision to become an active investor, conditional on participation. We identify characteristics associated with a higher probability of participating in the ESPP, and higher level of investment in ESPP, conditional on participation. We distinguish active investors – who invest more than their incentive pay and/or who invest the maximum amount allowed – from other investors. We consider that investment decisions results from

the following decision process: employees simultaneously decide to participate in the offer or not and (i) how much to participate, and/or (ii) to be active investors.

The determinants of ESPP participation are relatively understudied, due to the lack of availability of appropriate data. Much of the literature has focused on relatively small datasets and/or US data. This paper uses original data on 44,649 employees of a large French bank who were eligible to an ESPP offer in 2005. In this paper, we study a cross-sectional dataset describing employees' response to the ESPP offer.

We find that several proxies describing the presence of liquidity constraint, knowledge of the plan, asset choice, and transaction costs are associated with differences in the probability of investment in ESPP offers, and the conditional amounts invested. We also find the presence of a significant association between the two steps of the investment decision process: investment choice (yes vs. no) and how much to invest.

The remainder of the paper is organized as follows. Section 2 reviews the relevant literature on employees' investment behaviors. Section 3 describes the methods used and Section 4 reports the results obtained. Section 5 presents a discussion of our empirical results, and Section 6 concludes.

## 2 Literature review

Our paper aims at investigating the factors associated with the ESPP offer participation. Specifically, we explore the association between the presence of liquidity constraint, imperfect knowledge of the plan, asset choice and transaction costs with the decision to invest and the level of employee's ESPP offer investment decision.

### 2.1 Liquidity constraint

DeGeorge et al. (2004) show that labour income and financial wealth are major determinants of participation in France Telecom's first ESPP offer. Liquidity constraints can be driven by labour income, which depends on human capital. The current value of human capital is often modeled as a function of the current labor income, its rate of growth, and the temporal horizon during which it will be paid.

According to Jappelli (1990), the probability of facing liquidity constraints is a decreasing function of age, wealth and current income. Moreover, Jappelli and Pagano (1994) show that household credit and mortgage can be used as indicators of liquidity constraints. The nature of the job contract (permanent or temporary) may also affect investment in the ESPP since unemployment threats may motivate investment decisions of risk averse employees who wish to cover themselves against future risks.

### 2.2 Imperfect knowledge of the plan

Engelhardt and Madrian (2004) emphasize how ESPP imperfect knowledge can result in non-participation, because some employees may face troubles to understand the plan's features and make uninformed decisions on participation. Previous researches (Engelhardt and Madrian 2004; DeGeorge et al. 2004) provide evidence that communication dealing with the ESPP offer within the firm may be critical and

that ESPP-related information is usually lacking. Engelhardt and Madrian (2004) explain that financial seminars are usually given to provide 401(k) plan information, leaving little time to ESPP-related information.

Finally, firms can affect employees' investment decisions in their company stocks (see Benartzi et al. 2007 for a review). Huberman et al. (2007) find that the plan-level policy, measured by the availability of matching contributions schemes, increases employees' participation in 401(k) plans. Aubert and Rapp (2010) underline that employees' risk exposure in company-based saving plans may become problematic if employers play an important role in investments process.

### 2.3 Asset choice

Another reason for non-participation discussed by Engelhardt and Madrian (2004) is the availability of company stocks outside the ESPP. According to Engelhardt and Madrian, employees may not see ESPP offers as an opportunity to increase their gross compensation, but rather as a mean to incorporate company stocks into the overall savings portfolio. To investigate this explanation, they examine the relationship between the receipt of stocks options and participation in the ESPP. But they find little support that participation in the ESPP decreases when company shares are available elsewhere through stocks options.

Benartzi and Thaler (2001) explain that investors may distinguish company stocks from other assets, e.g. consider ESPP as a separate investment option. Huberman et al. (2007) find that 401(k) savings rates increase when company stocks is offered as an investment option especially among low-income employees. Poterba (2003) explains that the cost of poor diversification due to massive investments in company stocks is concerning. Poterba suggests that most employers should develop education seminars to improve employees' education on risks, returns and diversification or hand out informed consent forms for employees whose 401(k) is highly concentrated in company stocks.

### 2.4 Transaction costs

Engelhardt and Madrian (2004) finally mention procrastination as a potential cause of non-participation in the ESPP. Procrastination is a particular type of self-control problem investigated by Thaler and Shefrin (1981). In standard time value of money calculation, one dollar saved today would be perceived to be worth exponentially more in decades from now. Contrarily, procrastination means that individuals are hyperbolic discounters applying high discount rates to the near term and lower discount rates to the future (Mitchell and Utkus 2004). In the French context, this effect may be higher since participants' contribution to the ESPP must be frozen during a 5-year period. This restriction does not apply to American ESPP participants who are allowed to sell out the shares the same day they buy them.

Other transaction costs may be associated with investing in an ESPP. According to Degeorge et al. (2004), search costs deterred employees to invest in the ESPP offered by France Telecom in 1997. This cognitive cost includes the time and effort of analyzing and understanding the rules of the ESPP. The transaction costs may also result from switching money from an existing savings plan provided outside the

company to the sponsor's plan. Gale and Scholz (1994) explain that this cost is less burdensome for richer employees.

## 2.5 Motivations for exploring ESPP investment behaviors

The difficulty with exploring investment behaviors in ESPPs has been described in previous research (Aubert and Rapp 2008, 2010). From a theoretical perspective, the challenge arises from the fact that ESPPs introduce a link between working and saving contracts. This correlation between human capital and portfolio risks is absent in most of theoretical models of expected utility. Such models usually consider that risks associated to human capital and financial portfolio are independent. However, in the case of an ESPP investment, this assumption cannot be applied because employees are supposed to buy their company stocks.

Another explanation of potential divergence between theory and empirical evidence comes from the existence of biases in savers' economic rationality. Standard saving and consumption models describe investment behaviors using two parameters of preferences: risk aversion and time preference. According to the theory, savers prefer flexibility, i.e. the possibility to proceed to portfolio adjustments (Kreps 1979). The reliability of both parameters is debated by the behavioral approach. Investors can hardly follow coherent saving strategies based on their lifecycle because of two main reasons (Benartzi and Thaler 2004; Madrian and Shea 2001). First, some savers are not foresighted, and cannot plan their long term financial resources. Second, some households are impatient and cannot respect their own saving rules. These households display strong preferences and need for current income.

Because investments in ESPPs are constraining (early withdrawal restrictions for instance), they may be more attractive for foresighted but impatient agents who wish to self-control (Thaler and Shefrin 1981). However, potential threats involving the correlation between human capital and portfolio risks may discourage risk-averse investors. Instead of trying to reshuffle their assets in order to balance risk and performance, some savers may retain the same investment patterns over time, even if it leads them to face huge portfolio risks. Such rigid saving patterns may result from inertia behaviors (Benartzi and Thaler 2002).

Huberman et al. (2007) show that plan participation increases with compensation, and that matching contributions have higher impact on poorest employees. Such a result can be explained by the fact that low-income employees are more likely to face liquidity constraints, and are therefore more sensitive to matching mechanisms. Aubert and Rapp (2008, 2010) showed that factors such as human capital, gender and place of residence affect investment decisions in company-based savings plans.

## 3 Methods

### 3.1 Data

The sample is an original dataset collected in August, 2005 from a French CAC 40 index listed bank. Data were collected after this bank offered to its employee the opportunity to invest in an ESPP in June, 2005. Our data describe employees' response to that offer. Similar offers occurred in this company in 2001 and 2003. The

eligibility was extended to all employees that had been hired at least two months before the offer occurred, and to retired employees. Eligible employees were able to invest up to 25% of their gross compensation to purchase their company stocks at a price equal to 85% of its fair market value. ESPP investors become shareholders of the firm they work for.

Incentive pay and sponsors' plans contributions were bundled, and framed by four main rules. Employees had to choose between getting the incentive pay in cash and have it included in their taxable income; or having the money put into the plan and excluded from their taxable income. Amounts invested in the ESPP were blocked for a 5-year period (until 2010). Early-withdrawals were possible under specific conditions such as lay-off, divorce or bankruptcy. The maximum amount each employee could contribute to the offer was €40,000.

### 3.2 Sample characteristics

Our sample includes 44,649 employees eligible to the 2005 ESPP. Contributors' socio-demographic characteristics include age, tenure, hierarchical rank in the bank, gender, type of contract (permanent or temporary), education, and place of residence. We also have information on the bank's department each employee works for. Financial information includes incentive pays earned in 2005, annual gross salary, contributions in the 2005 offer, and balance of the employees' ESPP before the 2005 offer. We exclude 1,287 employees who have missing values regarding their hierarchical rank in the bank. Our final sample consists of 43,362 employees eligible to the offer

### 3.3 Model specification

Our objectives are to explore whether liquidity constraints, imperfect plan information, asset choice, and transaction costs are associated with (i) amounts invested in the ESPP and (ii) the probability of being an active investor, conditional on participation. Because of non-randomness of participation choices, our analyses may face the presence of selection bias. As ESPP investments introduce a correlation between employees' human and financial capital they are more risky than other financial investments. It can therefore be assumed that ESPP contributors have a lower risk aversion than non-investors.

#### 3.3.1 Determinants of amount invested, conditional on participation

Since we have data on participants and non-participants, we address potential selection bias problems using the Heckman's two-steps procedure (Heckman 1979). The first step of the model can be written as:

$$p_i = I(z_i\gamma + v_i \geq 0) \quad (1)$$

The  $I(\cdot)$  function equals 1 if the employee  $i$  invests in the offer and is zero otherwise. We assume that the error terms in the selection equation,  $v$ , has zero-conditional mean and follows a standard normal distribution.

The second step of the model is given by:

$$\log(y_i) = x_i\beta + u_i \tag{2}$$

We observe  $\log(y_i)$  if  $p_i = 1$ . Equation 2 can be written as:

$$E[\log(y_i)|p_i = 1, x_i] = x_i\beta + \sigma_u\lambda(z_i\hat{\gamma}) + u_i \tag{3}$$

where  $\sigma_u$  is the standard error of the disturbance  $u$ , and  $\lambda(\cdot)$  is the inverse Mills ratio (IMR). The IMR is estimated as the prediction of the binomial probit (Eq. 1) in the first step and used as an explanatory variable in the second step. The second step uses an Ordinary Least Square (OLS) linear regression where the dependent variable is the logarithm of invested amounts.

The selection function has a set of explanatory factors  $z_i$  that are a superset of  $x_i$ . Indeed, Woolridge (2009) explains that two-steps regressions need a variable that is associated with selection (decision to invest or not) but that is not associated with amounts invested. This exclusion restriction is recommended as the IMR can be highly correlated with the elements of  $x_i$ . In that case, it would be very difficult to separate sample selection from misspecification. To prevent potential multicollinearity problems between the IMR and other covariates, we control for one more right-hand side variable in the first step than in the second steps. This identification variable represents mean ESPP investments in former offers per department. It is relevant for the choice to invest or not in the ESPP offer, as it can be assumed that employees working in departments with investments in former ESPP offers have a higher probability of participating in new offers (Duflo and Saez 2002). This variable is not associated with the level of investment.

### 3.3.2 Determinants of being an active investor, conditional on participation

To determine the probability of being an active investor, we use a binomial probit model with selection (Van de Ven and Van Pragg 1981). The formulation is written as:

$$\begin{aligned} y_1^* &= x_1\beta_1 + u_1 \\ y_2^* &= x_2\beta_2 + u_2 \\ \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} &\sim N \left\{ \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix} \right\} \end{aligned} \tag{4}$$

where latent variable  $y_1^*$ , which measures whether the employee invests more than his incentive pay, or up to the €40,000 participation limit, depends on factors  $x$ , and the binary outcome  $y_1 = 1$  arises when  $y_1^* > 0$ .

In this model,  $y_{1i}$  is observed only when the selection equation has a value of 1, e.g. when the employee participates in the ESPP:

$$y_{2i} = (x_{2i}\gamma + u_{2i} > 0) \tag{5}$$

The potential correlation between the error terms of the two equations is measured with the parameter  $\rho$ . Rejecting the null hypothesis for  $\rho$  indicates the presence

of selection, e.g. a dependence across estimated equations. In the first steps, we control for an identification variable measuring the mean number of investors in the offer per department. This variable is associated with the probability of investment in the offer but it is not associated with the probability of being an active investor. Finally, the significance of interaction terms in Probit models is measured using likelihood ratio (LR) tests.

### 3.3.3 Variables

Our independent variables of interest are factors describing the presence of liquidity constraint, knowledge of the plan, asset choice, and transaction costs. The set of individual characteristics included in our models are therefore related to these four factors. Liquidity constraint is measured by gross income (continuous, in logarithm), incentive pay (continuous, in logarithm), and the presence of a permanent contract (vs. temporary contract). We create a proxy variable to measure whether employees have a position within the human resources department, which is in charge of implementing the ESPP offer. This proxy captures information dealing with the knowledge of the plan. We also control for a variable measuring the number of previous offers to which employees were eligible in the past (two ESPP offers occurred before 2005). This variable allows us to capture additional information dealing with ESPP knowledge, assuming that employees with previous eligibility had better knowledge. To measure the influence of asset choice on the investment decision, we create a continuous variable indicating the proportion of the plans sponsored by the company (including previous ESPPs and the company savings plan) invested in company stocks. Transaction costs, e.g. indirect cost of understanding the ESPP offer rules is measured with a variable describing financial expertise. This variable is a proxy that measures whether the employee has a job requesting financial knowledge within the bank: investment department, asset management department, insurance department, private equity department, and finance department.

We also control for additional socioeconomic characteristics that have been shown to be associated with investment behaviors. Most of these variables can be associated with at least one of the four investment factors described above. We create a continuous variable indicating the difference between 2005 and employees' hiring date (tenure). Potential gender differences are studied using a dichotomous variable whose value was 1 if the employee was a man, and 0 if not. The variable education is a dummy variable which value is one if the employee holds a Masters' Degree, and 0 if not. A dichotomous variable measured employees' hierarchical rank  $\geq 6$ ; range 0–10) in the company. The Masters' Degree variable measures general skills, when financial knowledge, hierarchical level, and nature of the job are three variables that capture specific skills. We control for a variable describing whether the employee is living in the Paris area (vs. living in other part of France). Indeed, Balligand and Foucault (2000) show that employees in the Paris area have a higher probability of holding company stocks.

Finally, we control for three interaction terms:  $Age \times Age$  captures potential non-linearity of investment with age,  $Tenure \times Age$  measures the interaction between tenure and age, and  $Male \times Paris$  captures interactions between residency and gender. Significance of these interaction terms in non-linear regressions are estimated with likelihood ratio tests.

### 3.4 Sensitivity analyses

Sensitivity analyses explore how endogeneity biases could influence our regression results, and focus on potential multicollinearity issues. Variables such as education, type of contract, salary, and incentive pay are likely to be simultaneously determined with investment. These variables are determined by unobservable factors such as ability or risk appetite, which are likely to be correlated with error terms in our regressions, raising problems of omitted variable biases. To deal with such problems, we tried to identify a set of instrumental variables that were associated with endogenous variables but independent from the error term. However, we were not able to find satisfactory instruments. We therefore decided to present for each model two different regressions using sets of variables that included: (i) only the variables that are safely exogenous (age, Paris region, male, and interaction terms), and then (ii) the variables for which endogeneity can be suspected.

Many of the variables that are determined by ability are likely to be collinear. For instance, education, wage, and tenure could introduce multicollinearity. Potential problems of multicollinearity between independent variables are assessed using the Variance Inflation Factor (VIF). Test values are high in regressions that controlled for interaction terms. However, our postestimation tests provide evidence that all VIF values are lower than 3 when we exclude these terms. According to Craney and Surlis (2002), multicollinearity problem arises beyond a VIF value of 10. Consequently, such a problem is only driven by the presence of interacted variables. We ran additional regressions without these terms, which provided similar results for all variables (only the sign of the coefficient associated with age changed), and concluded that multicollinearity issues do not affect our results. To provide an idea of how severe the multicollinearity issue is, we provide a correlation matrix among all right-hand side variable. In additional sensitivity analyses (not reported in the paper but available upon request), we ran regressions that controlled for these variables one by one, in order to get additional information of how severe the multicollinearity issue is in our models.

Finally, we ran the models without and with the inverse Mills ratio in order to be able to check the direction of the bias when selection is not controlled for, and we ran models where the age and tenure variables were broken into dummies, to further assess potential non-linear effects with these variables (not reported in the paper but available upon request).

## 4 Results

### 4.1 Descriptive statistics

Table 1 provides descriptive statistics of the 43,362 employees of our sample. Among them, 42.93% are men, mean age is 45.10 years (SD: 10.61), 54.62% live in the Paris region (SD: 8.04), 84.69% have a permanent contract (SD: 36.01), and 3.92% hold a Masters' Degree (SD: 19.41). Mean tenure is 16.30 years (SD: 13.64), the mean number of previous ESPP offered to these employees is 1.61 (SD: 0.75), and 35.00% (SD: 31.68%) of the company based savings is invested in company stocks. Mean gross income and incentive pay are respectively €35,360 (SD: 21,552) and €4,356

**Table 1** Summary statistics

Variable	Mean	Std. dev.	Min	Max
Male	0.429	0.495	0	100
Age	45.103	10.61	10	71
Paris	0.546	0.498	0	100
Permanent contract	0.847	0.36	0	100
Masters' degree	0.039	0.194	0	100
Number of previous offer	1.615	0.745	0	2
Tenure	16.303	13.64	0	45
Income	35,359.976	21,551.575	1	650,000
Incentive pay	4,355.572	28,329.835	0	18,000,000
Human resources department	0.213	0.409	0	100
Financial expertise	0.0671	0.250	0	100
Hierarchical rank $\geq 6$	0.427	0.495	0	100
Investment (yes vs. no)	0.460	0.4984	0	100
Amount invested	3,990	6,747	0	40,000

(SD: 28,330). Among the employees of our sample, 21.31% (SD: 40.95) hold a position with privileged access to the ESPP offer information, 6.71% (SD: 25.02) have better financial expertise, and 42.70% are in the upper hierarchical categories. Finally, less than half of the sample invested in the ESPP (46.02%, SD: 49.84), with a mean invested amount of €3,990 (SD: 6.747).

#### 4.2 Bivariate analyses

Table 2 reports results of bivariable analyses comparing characteristics of investors vs. non-investors, and active investors vs. regular investors. Investors (19,957 employees representing 46.02% of total) have different characteristics than non-investors

**Table 2** Mean characteristics of non-investors, investors, and active investors

Variable	Non investor	Investor	Passive	Active
Overall	0.530	0.460***	0.597	0.402***
Male	36.78	50.14***	38.97	48.79***

*Legend:* 1 Male, 2 Age, 3 Age × Age, 4 Paris, 5 Male × Paris, 6 Permanent contract, 7 Masters' degree, 8 Number of previous offers, 9 Tenure, 10 Tenure × Age, 11 log(income), 12 log(incentive), 13 Percentage invested in ESPP, 14 Human resource, 15 Financial expertise, 16 Hierarchical rank ≥6

(53.98% of employees). They are more likely to be male, to be younger, to live in the Paris region, to hold a permanent contract and to hold a Master's Degree. Investors are also richer than non-investors: they have greater gross income (respectively, €41,838 vs. €29,837) and they receive larger incentive pay (respectively; €7,217 vs. €1,916). Finally, new investors are more likely to have invested in previous ESPPs than non-investors, they have better financial expertise, and they are better hierarchically ranked. In Table 2, we also compare active investors (40.28% of investors) to employees who invest an amount smaller than their incentive pay (59.72% of investors). Active investors are more likely to be male, to be younger, to live in the Paris region, to have higher tenure, to hold a Masters' Degree, to have invested in previous ESPPs, and to have greater gross income and incentive pay. Active investors are also more likely to have invested in former ESPP offers, they have a better access to the 2005 ESPP information, a better financial expertise and a higher hierarchical rank in the company.

#### 4.3 Correlation matrix

Table 3 describes the correlation matrix of all independent variables selected in our analyses. Large correlations involve age, tenure, permanent contract, and the number of previous ESPPs employees were eligible to. Income and incentive pay are highly correlated with gender, living in the Paris region, and education. The human resource variable is correlated to age, permanent contract, income, and tenure.

#### 4.4 Factors associated with the conditional amounts invested

Tables 4 and 5 provide results obtained after Heckman (columns (1) and (2)) and conditional OLS regressions (column (3)). Our variables measuring the presence of liquidity constraint (income and incentive pay) have positive and significant associations with the probability of investing in the offer, and the conditional

amount invested. Knowledge about the offer, when measured with human resource department occupation, is not associated with the probability of investing in the offer, but it is significantly associated with the conditional amount invested. However, the variable measuring the number of previous offers to which employees were eligible in the past has a negative association with the probability of investing in the ESPP offer, and with the conditional amount invested (Heckman). The variable describing asset choices through the percentage invested in previous ESPPs has a positive and significant association with both the probability of investing in the offer and the conditional amount invested. The absence of transaction costs, measured with the variable describing the presence of financial expertise, has positive and significant associations with the probability of investing in the offer, and the conditional amount invested. Other factors significantly associated with the probability of investment and/or with the conditional amount invested are: tenure (−), male (+), Masters' Degree (+), and higher hierarchical category (+).

#### 4.5 Factors associated with the conditional probability of being an active investor

Tables 6 and 7 report results from Heckprob regressions (columns (1) and (2)) and the probit regressions (column (3)). Income has a significant positive association with the conditional probability of being an active investor. However, we find evidence

of a negative association between incentive pay and the conditional probability of being an active investor. In the Heckpro model, privileged knowledge about the offer, measured by the variable describing whether the employee works in the human resource department, is not significantly associated with the conditional probability of being an active investor. However, this variable is significant at the 10% level

**Table 7** Probability of being an active investor, conditional on participation (all variables)

in the conditional probit model (–), and eligibility to former offers has a negative association. Employees who invested in former offers (and do not face access choice limitations) have higher probability of being active investors. In the conditional probit model, employees with lower transaction costs, e.g. with better financial expertise, have a lower probability of being active investors. In Table 7, other factors associated with the conditional probability of being an active investor are: age (+), male (+), tenure (–), and higher hierarchical category (+). Finally, our interaction terms (*Tenure* × *Age*; *Male* × *Paris*) have positive and significant associations with the probability of investing in the ESPP and the conditional probability of being an active investor.

## 5 Discussion

Originally, ESPPs were introduced in France to provide an opportunity to employees to get involved in their firm's management. In France, employees who participate in these plans are allowed to elect board employee directors. Over the past decades, shareholding has increased a lot in France (+10% between 1997 and 2007) and ESPPs have become very popular in France. Previous research (Arrondel and Masson 2007) provided evidence that French shareholders have specific profiles: they work in the private sector, have a high-level of qualification, and belong to an older part of the population (50–59 years old). Our results must be interpreted regarding to that specific context.

### 5.1 Main findings

We find a positive association between amounts invested and education level: compared with other employees, employees holding an Masters' Degree have higher ESPP investments. It can be argued that our education variable is based upon the degree observed and only captures general human capital information. However, additional variables (hierarchical rank and financial expertise) that capture specific skills also have a positive association with ESPP investments.

We find the presence of a novelty effect: savers invest larger amounts if they have never had an access to the ESPP offer. However, this effect is tempered by the fact that employees who already invested in previous ESPPs had higher amounts invested and higher probability of being active investors. Age has an important association with investment decisions. Oldest employees may adopt offensive investment patterns because retirement is an early withdrawal motive. Results for the cross-variable between age and tenure show that this effect is blurred by age, that is, the effect of time with the company diminishes with age. As employees reach retirement age, they are able to withdraw funds without penalty, even if they have participated in the offer soon before they leave. Employees who have been working for a long time in the firm are aware of tax benefits resulting from an investment in the ESPP. Their learning-by-doing background leads them to maximize the gain linked to tax benefit, e.g. they have a lower probability of being active investors. Moreover, employees who have spent more time in the bank may be more concerned by corporate governance issues.

The positive relationship between permanent contracts and investment behaviors shows that risk on labor income seems to deter employees to invest in their company

stocks. This result differs from previous researches on French data underlining the existence of a positive correlation between job uncertainty and investment in stocks (Arrondel and Masson 2007). As one of ESPP goals is to associate employees with the company's development, it can be assumed that employees who hold permanent contract are more likely to get involved in corporate governance.

The presence of significant correlation between error terms obtained in 2-steps regressions confirm that unobserved variables have a huge influence on investors' choices. There are two possible economic interpretations of this result, which come from the influence of two factors that are usually very difficult to observe in empirical studies. The significant Heckman's lambda can be interpreted by the fact that ESPP investors have a lower risk aversion than non-investors, which influences the amounts of wealth they decide to allocate into these plans. Moreover, finding significant correlations between both steps may reflect differences in time preference between investors and non-investors. Some investors may have lower time preference than non-investors and may therefore be more likely to choose investments that are blocked for a 5-year period.

## 5.2 What determines non-participation?

Our results confirm Engelhardt and Madrian (2004) assumptions according to which liquidity constraints, imperfect knowledge of the plan, asset choice, and transaction costs contribute to explain non-participation. Our results also show that ESPP contributors have very specific and unobserved motivations, as shown with the positive correlations between error terms in the two steps of investment decisions. It can be assumed that ESPP investors differ from other investors because they have a strong motivation to buy their own company stocks: the opportunity to participate in the corporate governance. Some employees may choose to invest because they are concerned by the company's management. In this case, investment would reveal another aspect of people's aversion. Cohen (2008) suggests that being loyal employees affects employees' investment decision about their company stocks in 401(k).

## 5.3 Limitations

Our paper has several limitations. We were not able to measure matching contributions and the amount of tax-deductions, which have been shown to have important influence on investment behaviors. Gale and Scholz (1994) provide evidence that matching contribution mechanisms are associated with increased investments in company-based saving plans. We were not able to measure the association between tax incentives that are bundled with incentive pays investment and investment behaviors. It is likely that non-participants have lower interest in tax-incentive associated with ESPP investments due to the level of their overall taxable income. However, previous research has showed that the relationship between tax incentives and saving behaviors is uncertain (Börsch-Supan 2004). According to Engen and Gale (1997), tax incentives in ESPPs can sometimes be lower than tax incentives found in other investment plans. Hausman and Poterba (1986) show that tax incentives could actually be associated with a slight decrease in private savings.

This paper uses cross-sectional dataset collected in 2005, after the company's stocks price has increased during four consecutive years. This may be a limitation of our findings since Benartzi (2001) found that past returns are key determinants of employees' investment in their company stocks. Future research may ideally use panel-data controlling for stocks price historical returns or focus on cross-sectional data collected during the context of a bear market. Our data were collected in a financial institution. It can be assumed that employees working in affiliates such as investment bank, funding bank, and private equity bank have a good financial knowledge. This feature may explain why in our sample human capital is overall positively correlated with investment in ESPPs. Indeed, studying a bank implies that most employees have a good basic knowledge of finance, so the interpretation of some variables is less straightforward. Specifically, higher tenure could be associated with better financial expertise. In Table 7, column (3), we find that employees with financial expertise have a lower probability of being active investors. Such employees have doubtlessly access to information dealing with much more lucrative financial products offered by their company such as stocks options. This result can be explained by the assumption of bounded rationality. Employees who have strongest financial knowledge may choose not to invest in ESPPs because they can find less constraining investment opportunities and a better diversification of risks. Because of the specificity of our sample, our results may not be generalized to other companies.

## 6 Conclusion

This paper provides an innovative study of ESPP contributors' investment strategies, distinguishing active investors from other investors. This approach allows comparing two different investment behaviors that are associated with the willingness of investing in company stocks. We test Engelhardt and Madrian (2004) assumptions about the determinants of non-participation. Liquidity constraint is measured by gross income, incentive pay, and tenure. In order to assess the employees' knowledge of the plan, we identify which department of the company each employee belongs to and how many ESPPs they have been eligible to. Concerning the asset choice, we know how much employees contributed to ESPP investments in the past. Finally, we make the assumption that transaction costs are lower for employees holding a job requiring financial expertise.

We find that the presence of liquidity constraint, imperfect knowledge of the plan, asset choice, and transaction costs are related to the investment decisions. Specifically, employees facing liquidity constraints are less likely to invest in the ESPP. Knowledge about the plan is positively associated with the willingness to invest: employees who work in the company's department in charge of organizing the ESPP offer have a greater invested amounts. Employee owners have higher probability of being active investors, showing that asset choice is associated with investment decisions. Finally, lower transaction costs are associated with higher investment probabilities, and higher conditional amounts invested.

We find the presence of a novelty effect, as the largest amounts invested were by employees who have not already been eligible to previous offers. The existence of unobservable motives of investment can be explained by a lower risk aversion, a higher time preference, or a strong willingness to participate to corporate

governance. Some investors may only be motivated by a short-term interest, or the willingness to prepare themselves to future risks such as unemployment.
