ACKNOWLEDGEMENT

First all ultimate thanks are due to "ALLAH" who without his aid, the present work could not have been done.

It gives me immense pleasure to express my deep sense of gratitude and appreciation to Prof. Dr. Ali Abd El Maksoud El Hosary Professor of Agronomy, Fac. of Agric., Benha Univ. for suggesting the problem, their supervision and kindly help and encouragement during the course of the study and unlimited help during preparing and writing the manuscript. Their sincere contribution is very well appreciated and will be sentimentally memorable.

Sincere appreciation is also due to Dr. Mahmoud El-Zaabawy El-Badawy Associated Prof. of Agronomy Fac. of Agric., Benha Univ. for suggesting the problem, valuable scientific supervision advice, continuous help and for the revision of the manuscript.

Sincere thanks to Prof. Dr. Assad Ahmed Hamada Head Research in field crops Res. Inst. Agric. Res. Cent. Giza. for suggesting the problem, valuable advice, supervision and continuous help throughout the experimental work, and the preparation of the manuscript.

I didn't deny the great help and facilities offered from Mr. Ahmed A.A El-Hosary Ass. Lecturer of Agronomy Fac. of Agric., Benha Univ. for continuous help throughout this study.

I didn't deny the great help and facilities offered from all staff members of Experiment and Research Station of Moshtohor, Benha University, Qalyubiya Governorate, EGYPT.

At the end and at the beginning gratefulness and thanks are due to my father, mother, brothers and sister.

INTRODUCTION

1. INTRODUCTION

Maize (*Zea mays* L.) is one of the most important cereals in Egypt due to its vast grown area, total production and cash value. It is essential for human consumption and livestock. Moreover, it is also used for industrial purposes such as manufacturing starch and cooking oils. Many efforts are devoted nowadays to increase its productivity through genetical improvement.

The ultimate goal of most breeding programs is the production of improved hybrids for commercial use through the evaluation of line genotypes for high yielding ability.

Evaluating inbred lines is of prime importance for hybrid production. Therefore, nature and number of tester parents to be used for evaluating inbred lines is still an important step. The top crosses test with abroad and narrow base testers is the most common procedure for the evaluating process. The top cross method of maize breeding has been used to evaluate inbred lines for general combining ability (GCA) and specific combining ability (SCA). **Davis (1927)**, **Jinkins (1935)** and **sqargue (1939)** suggested the method of early testing that greatly effected by the nature and number of testers needed for efficient evaluation of inbred lines. **Sprague and Tatum (1942)** was the first to partition the total combining ability effects of the lines into GCA and SCA. The choice of suitable tester is important to maximize information on evaluating inbred lines for combining ability

The main objectives of the present work were:

- 1) To evaluate some inbred lines of maize.
- 2) Provide information of suitable testers for testing of inbred lines.
- 3) To estimate general and specific combining ability for several traits of maize.
- 4) To estimate heterosis percentage for grain yield relative to S.C. G.155, Pioneer 3080 and T.W.C. G. 352 as checks.

REVIEW OF LITERATURE

2. REVIEW OF LITERATURE

The available literature concerning this study can be reviewed under the following headings:

- 2.1. Nature and number of testers.
- 2.2. Combining ability effects.
- 2.3. Genotypes x environmental interaction.
- 2.4. Heterosis.

2.1. Nature and number of testers.

The problem confronting breeders is the number of testers required for efficient evaluation of lines for GCA. Selecting suitable testers is the first and important step in evaluating inbred lines in maize breeding program. Review on the nature of testers is presented as follows:

Davis (1927) was the first to suggest the use of inbred, open pollinated varieties as a method for evaluating maize inbred lines.

Al-Naggar *et al.* (1997) studied effectiveness of different testers; narrow, medium and broad genetic base in evaluating combining ability of inbred lines of maize. They concluded that inbred tester sd.7 was the most powerful tester for the maximization of mean grain yield of the test crosses. The single cross tester S.C. 10 was the best based on the ability to reduce the magnitude of interaction variance of test cross x environment and provide of favorable SCA effects. They suggested that narrow or medium base testers are useful for evaluation of GCA of lines.

Abdel-Sattar (1998) top crossed twenty-four inbred lines were divided into two groups. First group (Consisted of 12 inbred lines) to each of Giza-2, T.W.C.310 and D.C 215 giving a total of 36 top crosses. Second group was top crossed to each of Giza-2, D.C. 204 and S.C. 10 giving a total 36 top crosses. They found that the testers D.C. 215 and T.W.C. 310 in the first set gave highest positive GCA effects for grain yield and number of kernels/ row. However the tester S.C.10 was the best general combiner for grain yield/ plant and its components in the second set.

Soliman and Sadek (1998) top crossed ten white maize inbred lines with three line testers and they found that the tester inbred line Gm.30 showed the highest significant GCA estimate for grain yield.

Sultan (1998) top crossed fourteen yellow maize inbred lines with two line testers, i.e. Gm-1002 and Gm-1004 and considered the two testers as best testers in classification inbred lines into high vrs low yielding ability.

Sadek et al. (2000) top crossed twenty white maize inbred lines to each of two line testers, i.e. Sd-7 and Sd-63 and they found that the tester line Sd-7 was the best combiner for grain yield while the tester inbred line Sd-63 showed desirable GCA effects for earliness and shortness.

Soliman et al. (2001) top crossed fourteen S_3 yellow maize inbred lines derived from the wide genetic base population Giza-45 (Ev-3) to each of three yellow maize inbred testers, i.e. Gz-638, Gm-1002 and Gm-1021. They found that inbred tester Gm-1021 manifested highest average performance of grain yield compared to test crosses of Gz-638 or Gm-1002.

Venkatesh et al. (2001) carried out line x tester analysis to determine the combining ability of modified single cross hybrids through their crosses and they inferred that among the sister line crosses used as female parents, $(A_1 \times A_1^-)$, $(A_7 \times A_7^-)$, $(A_8 \times A_8^-)$

8), ($A_{10} \times A_{10}^-$) and ($A_{11} \times A_{11}^-$) are the best general combiners. Among the exotic testers that were used CML 290 had to be the best combiner. The indigenous tester CM111 widely used in the Indian maize program also showed its potential as a good tester.

Dodiya and Joshi (2002) mated twenty diverse advanced stage lines of maize with three inbred lines (testers) in Line x tester design and they found that T_1 had desired significant GCA effects for 100-grain weight and harvest index but best combiner for ear size and Stover yield. T_3 had desired significant GCA effects for grain yield and Stover yield.

Amer et al. (2003) crossed new seven yellow inbred lines of maize with four testers i.e. The inbred line L-121, two promising single crosses (Sk-21 and Sk-22) and one three way cross (T.W.C. 351) and they found that the inbred tester L-121 showed the best desirable GCA effect for grain yield and ear length. Moreover, the testers, S.C. Sk-21 and S.C. SK-22 were the best general combiners for ear height and ear diameter.

Abdel-Sattar (2004) crossed five inbred lines of maize in three levels of inbreeding (S_3 , S_4 and S_5) to each of three different testers, i.e. S.C 122, T.W.C 310 and T.3057. He reported that the best parental tester for different traits were the broad genetic tester T.W.C.310.

Aly (2004) crossed thirty nine yellow and white inbred lines (S_8) of maize to each of the two testers, i.e. D.C. Dahab and synthetic variety Giza-2. He found that Dahab had desirable GCA effects for most of studied traits and this may be attributed to it had a narrower genetic base than Giza-2.

Amer (2004) top crossed eighteen new white inbred lines of maize to the three testers, i.e. Line Sk-7001/8, S.C. Sk-17 and Giza-2. He reported that the tester inbred line Sk-7001/8 had desirable significant GCA effects for short plant and ear position. While, the tester S.C. Sk-17 had desirable significant GCA effects for earliness, short plant, grain yield, ear length and

ear diameter. Giza-2 as a tester had downer favorable genes for no. of rows/ ear and 100- kernel weight (g.).

Ibrahim and Motawei (2004) top crossed fourteen inbred lines of maize to the three testers, i.e. Sk-7001/8, S.C.Sk-17 and Gz-2. They found the inbred tester Sk-7001/8 showed the best desirable GCA effects for number of rows/ ear. Moreover, the tester S.C. SK-17 was the best combiner for grain yield and number of kernels/ row. While the tester Gz-2 was the best general combiner for earliness and short plants.

Mosa (2004) top crossed new white twenty seven inbred lines of maize to the two testers. i.e. homozygous inbred line GM-4 and heterozygous promising single cross sakha-1. the studied traits were silking date, plant and ear heights, grain yield, ear length, ear diameter, number of rows/ ear, number of kernels/ row and 100 kernel weight. He found that top crosses involving heterozygous S.C. Sk-1 as a common tester showed the heighest means for all traits and the widest range for all traits except plant height compared with top crosses involving homozygous inbred line Gm-4 as a common tester. Consequently, the heterozygous S.C. Sk-1 was the best tester for evaluating the inbred lines in top crosses. The heterozygous S.C. SK-1 as tester was the best general combiner for grain yield, ear length, number of rows/ ear, number of kernels/ row and 100-kernel weight. While the homozygous inbred line Gm-4 as tester was the best combiner for silking date, plant and ear heights and ear diameter.

Mosa et al. (2004) top crossed nine inbred lines of yellow maize to the three testers i.e. L-121, S.C. Sk-52 and composite - 21 and they found that the parental testers that exhibited better general combining ability were L-121 for grain yield/ plant. S.C. Sk-52 for number of rows/ ear and ear position and composite- 21 for number of kernels/ row.

Abd El-Moula (2005) Top crossed twenty yellow maize inbred lines (S₄) to each of three testers, i.e. Gz-45 (base

population) and two elite inbred lines (Gm-1001 and Gm-1004). He found that the tester lines Gm-1001 was the best combiner for grain yield and no. of ears/ 100 plants. While, the tester Gm-1004 showed desirable GCA for shortness and tester pop-45 for earliness and shortness.

Ibrahim and Osman (2005) top crossed new fifteen white inbred line of maize with the two tester lines, i.e. Sids-63 and Sakha-9195. They indicated that the tester line Sk-9195 had desirable significant GCA effects for earliness, ear length, number of rows/ ear, 100-kernel weight and grain yield (ard/fed). While, the second tester (Sd-63) had favorable genes for ear diameter.

Motawei et al. (2005) crossed twenty-nine inbred lines of yellow maize derived from S₅ generation with two genetically diverse inbred testers. The top-crosses were divided into two different sets: set-I included 28 top-crosses and set-II included 30 top crosses. They found that the tester Gm-1001 was a good general combiner for ear position, no. of rows/ear and ear diameter in the two sets of top crosses and for grain yield in set II. While tester line sk-6241 had favorable alleles for days to 50% silking, no. of ears/100 plants and no. of kernels/ row.

2.2 Combining ability:

Combining ability of inbred lines in the ultimate factor determining future usefulness of the lines for hybrids. combining ability initially was general concept considered collectively for classifying an inbred line relative to its cross performance.

Al-Naggar et al. (1997) found that the inbred testers Sd-7, Sd-86 and S.C. 10 gave the highest GCA effects for grain yield. The range between low and high estimates of SCA effects for grain yield was widest for Sd-7 followed by S.C.10.

Abdel-sattar (1998) top crossed twenty-four inbred lines were divided into two groups. First group, (consisted of 12

inbred lines) to each of Giza-2, T.W.C. 310 and D.C. 215. Second group was top crossed to each of Giza-2, D.C. 204 and S.C. 10. The studied traits were grain yield/ plant, plant height, ear height, ear length, ear diameter, number of rows/ ear and number of kernels/ row. He found that the variance associated with SCA was more important than σ^2 GCA for all traits in two sets revealed that the non-additive component of gene action had the major role in the inheritance of all traits.

Sultan (1998) top crossed fourteen yellow maize inbred lines with two line testers, i.e. Gm-1002 and Gm-1004 to estimate GCA and SCA for days to 50 % silking, plant height, ear position (%), number of ears/ 100 plants, ear length and diameter, number of rows/ ear, number of kernels/ row, 100-kernel weight and grain yield were calculated. He found that variance magnitude due to GCA was higher than that due to SCA. This indicated that additive genetic variance was the major source of variation responsible for the inheritance of grain yield and other agronomic traits.

El-Zeir (1999) mated ten maize inbred lines to four testers and found that additive genetic effects among lines were the major source of genetic variance responsible for all studied traits except ear height and ear length.

El-Zeir et al. (2000) top crossed seventeen inbred lines of maize to two testers. They found that non-additive genetic variance play an important role in the inheritance for grain yield, ear length, number of kernels/ row and weight of 100-kernel. While the additive genetic variance played an important role in the inheritance for silking date, plant height, ear height and number of rows/ ear.

Gado (2000) crossed seventeen yellow maize inbred lines with two testers, i.e. Gm-2 and Gm-9. He estimated GCA and SCA for days to 50 % silking, plant height, ear height, ear length, ear diameter, number of rows/ ear, number of grains/ row, 100-grain weight and grain yield (ard./fed.). He indicated

that the additive genetic variance was the major source of variation responsible for the inheritance of these traits.

Sadek *et al.* (2000) top crossed twenty white maize inbred lines to each of two line testers, i.e. Sd-7 and Sd-63. They estimated GCA and SCA for grain yield, days to 50% silking, no. of ears/ 100 plant and plant and ear heights. They found that variance magnitude due to SCA was higher than that due to GCA. This indicated that non-additive genetic variance was the major source of genetic variation responsible for the inheritance of grain yield and other traits.

Soliman (2000) top crossed sixteen yellow maize inbred lines to each of three different testers. i.e. Gz-45 and two elite inbred lines, Gm-1001 and Gm-1021. He estimated GCA and SCA for grain yield, number of days to mid silking, plant height, ear position and number of ears/ 100 plants. He found that the magnitude of σ^2 SCA among lines for grain yield was larger than that of σ^2 GCA. On the contrary σ^2 GCA was greater than σ^2 SCA for the other traits.

Barakat(2001) top crossed sixteen white maize inbred lines to each of the two line testers, i.e. Sd-7 and Sd-63 to estimate GCA and SCA for days to 50% silking, plant height, ear height, number of ears/ 100 plants, grain yield / plant and per feddan, ear length and diameter, number of rows/ ear and 100-kernel weight were calculated. He found that variance magnitude due to GCA was higher than that due to SCA. This indicated that additive genetic variance was the major source of variation responsible for the inheritance of grain yield and other agronomic traits.

Dubey *et al.* (2001) crossed fifteen diverse early maturing white seeded inbred lines of maize with three testers. The data were recorded on grain yield and maturity traits. They reported that the ratio of σ^2 SCA/ σ^2 GCA was greater than one for all

characters. This indicated the preponderance of non-additive variance in the expression of traits under study.

Mahmoud *et al.* (2001) crossed nineteen white maize lines to each of two elite inbred tester lines Sd-7 and Sd-34 to estimate combining ability effects for grain yield/fed., days to mid silking, plant height and ear placement (%). They reported that non-additive was more important than additive gene action in the inheritance of grain yield, whereas additive gene action was comprised most of the genetic variance of other studied traits.

Soliman *et al.* (2001) top crossed fourteen S₃ yellow maize inbred lines to each of three yellow maize inbred testers. The studied traits were grain yield, silking date, plant height and ear position. They found that the magnitude of the ratio of general to specific combining ability variance ($\sigma^2 GCA/\sigma^2 SCA$) revealed that the additive Component of gene action had the major role in the inheritance of all traits.

Soliman *et al.* (2001) top crossed eighteen yellow maize inbred lines to each of three broad genetic base testers namely pop.-59E, pop. 21 and pop.-Fat-3 to estimate the combining ability effects and determine the type of gene action for grain yield. They indicated that the magnitude of dominance ($\sigma^2 D$) gene effects was more important than additive ($\sigma^2 A$) genetic effects in controlling that trait.

Amer *et al.* (2002) reported that non additive genetic variances played an important role in the inheritance for grain yield and number of kernels/row. While the additive genetic variance played an important role in the inheritance for silking date, plant and ear height, ear length, ear diameter, number of rows/ ear and weight of 100-kernel.

Dodiya and Joshi (2002) mated twenty diverse advanced stage inbred lines of maize with three inbred lines (testers) in line x tester design. The studied traits were grain yield/plant,

plant height, days to 50% brown husk, ear size, 100 grain weight, stover yield and harvest index. They found that higher values of σ^2 SCA than σ^2 GCA (pooled) for all characters in all environments indicated the importance of non-additive variances in control of all the characters studied.

Joshi *et al.* (2002) crossed fifteen diverse early maturing white seed colour inbred lines of maize with three testers in line x tester design. The data were recorded on yield and yield contributing traits. They indicated that the expression of both GCA and SCA were influenced by the environmental fluctuation for these traits, A higher proportion of σ^2 SCA between σ^2 SCA and GCA also indicated that the additive x non-additive and non-additive interaction were significantly higher among the hybrids which would be important in the hybrids.

Amer *et al.* (2003) crossed seven new yellow inbred lines of maize with four testers and they found that additive was more important than non-additive genetic variance for all traits.

El-Shenawy *et al.* (2003) indicated that the σ^2 GCA played a greater portion in the inheritance of ear length, number of rows/ear, silking date, plant height and ear height. While, σ^2 SCA played the major role in the inheritance of grain yield and number of kernels/ row.

Abdel-sattar (2004) indicated that the ratios of GCA/SCA through all self generations showed the greatest role of dominance variance (σ^2 D) than of additive variance (σ^2 A). Lines contributed much more than the testers to the total genetic variation.

Aly (2004) crossed thirty nine yellow and white inbred lines of maize to each of two testers D.C. Dahab and synthetic variety Giza-2. He reported that the magnitude of σ^2 SCA was larger than that of σ^2 GCA for all studied traits at both locations and

combined data indicated the non-additive was found to be more important than additive gene effect for all studied traits.

Amer (2004) top crossed eighteen new white inbred lines of maize to three testers, i.e. line, S.C. Sk-17 and Giza-2 to estimate combining ability for silking date, plant height, ear position, grain yield (ard./ fed.), ear length, ear diameter, number of rows/ear, number of kernels/row and 100-kernel weight. He mentioned that the additive type of gene action was more important than non-additive type of gene action in inheritance of all studied traits except ear position and ear diameter.

Ibrahim and Motawei (2004) mentioned that the additive genetic variance was more important for grain yield, weight of 100 grain, plant height and ear height. While, non-additive genetic variance was an important for number of kernels/row, ear diameter and silking date.

Mahmoud and Abd El-Azeem (2004) top crossed twenty three yellow inbred lines of maize to two testers, i.e. Gm-1004 and Gm-1021. GCA and SCA as well as genetic parameters estimated for days to 50% silking, plant height, ear height and grain yield traits were calculated. They found that the magnitude of σ^2 GCA (additive genetic variance) for all traits was larger than that of σ^2 SCA (non-additive genetic variance).

Mosa (2004) reported that the non-additive type of gene action were important in controlling the behavior of silking date, plant height, grain yield, ear length, number of kernels/row and 100 kernel weight. While the additive type of gene action played the major contribution in the inheritance of ear height, ear diameter and number of rows/ear.

Mosa et al. (2004) top crossed nine inbred lines of yellow maize to the three testers. The data were recorded for grain yield /plant, number of rows/ ear, number of kernels/row and ear position (%). They reported that additive genetic variance

(GCA) was predominating than non-additive genetic variance (SCA) in the inheritance of all traits.

Abd El-Moula (2005) top crossed twenty yellow maize inbred lines (S_4) to each of three testers, i.e. Gz-45 (base population) and two elite inbred lines, Gm-1001 and Gm-1004. The studied traits were grain yield, days to 50% silking, plant and ear heights and no. of ears/ 100 plants. He reported that variance magnitude due to SCA was higher than that due to GCA. This indicated that non-additive genetic variance was the major source of genetic variation for the inheritance of grain yield and other traits.

Ibrahim and Osman (2005) top crossed new fifteen white inbred lines of maize with two tester line. The data collected were days to 50% silking, plant height, ear height, ear length, ear diameter, number of rows/ ear, number of kernels/ row, 100-kernel weight and grain yield. They indicated that additive gene action was more important than non-additive one in the inheritance for all of the studied traits.

Motawei *et al.* (2005) reported that the additive genetic variance (σ^2 GCA) played an important role in the inheritance of ear position%, no. of rows/ ear and ear diameter in the two sets and days to 50% silking, no. of ears/ 100 plants and 100 kernel weight within set-I. Mean while, non-additive genetic variance was more important in the expression of grain yield, no. of kernels/ row and ear length in the two sets.

2.3. Genotype x environment interaction:

El-Hosary (1988) studied 20 new inbred lines by top cross method in maize. He found that the interaction between years and both types of combining ability were highly significant for all traits except plant height.

Sedhom (1992) studied thirty two inbred lines by top cross method. He found that the interaction between specific

combining ability and environment was much higher than those of general combining ability for most studied traits.

Sedhom (1994) evaluated seven inbred lines using ten different testers and found that specific combining ability x years interaction was higher than that of general combining ability x years interaction for all traits except silking date, revealing that non additive gene effects seemed to be more affected by environment rather than additive ones.

Shehata et al. (1997) crossed five inbred maize lines with five narrow base elite inbred testers. They found that the interaction between entries (genotypes) by locations and its components, i.e. parent x location, crosses x location and parent vs. crosses x location were highly significant differences for all studied traits.

Sultan (1998) top crossed fourteen yellow maize inbred lines with two line testers. He found that both inbreds and testers significantly interacted with environments in case of grain yield and some other traits and indicated that the interaction of GCA by location was markedly higher and positive for grain yield and other traits.

El-Zeir (1999) mated ten maize inbred lines to four testers and found that the interaction between genotypes x locations for most attributes were significant.

El-Zeir et al. (2000) crossed seventeen inbred lines of maize with two testers. They found that additive type of gene action was found to be more affected by environment than non-additive type of gene action in most cases.

Gado (2000) evaluated seventeen yellow maize inbred lines using two testers and found that the interaction of inbreds with environment was significant in case of ear length and grain yield. Also significant interaction of testers with environment was also detected for number of days to 50% silking, plant height, ear height and ear diameter. The interaction of GCA by

locations was higher and positive for grain yield and other traits except silking date, ear length and number of grain/ row.

Sadek *et al.* (2000) evaluated white maize inbred lines with two line tester. They found that both inbreds and testers significantly interacted with environments for most traits. Also, the interaction of SCA by location was higher than that of GCA ones for all studied traits.

Soliman (2000) crossed sixteen yellow maize inbred lines with three different testers. He found that the interaction of both lines and testers with locations were highly significant for grain yield, days to mid silking. Also, mean squares due to tester x location interaction was significant for plant height.

Barakat (2001) evaluated sixteen white maize inbred lines with two line testers. He found that both inbreds and testers significantly interacted with environments in all traits except plant height, ear height and number of ears / plant. However, the interaction of environments x lines x testers was significant for only grain yield/ plant and /feddan and ear length. Also, the interaction of GCA by locations was markedly higher and positive for grain yield and other traits.

Mahmoud *et al.* (2001) evaluated nineteen white maize lines with two elite inbred tester lines. They reported that non-additive gene action was affected more by environmental conditions than additive gene action for all studied traits.

Soliman *et al.* (2001) top crossed fourteen S₃ yellow maize inbred lines to each of three yellow maize inbred testers. They found that the magnitude of the interactions between σ^2 SCA x location was generally higher than σ^2 GCA x location for the studied traits except grain yield.

Amer *et al.* (2002) evaluated eight inbred lines of maize to four testers. They found that additive type of gene action was more affected by environment than non-additive type of gene action for all studied traits except ear length and ear diameter.

Dodiya and Joshi (2002) they found that environments played important role in the expression of GCA and SCA variance. The performance of the parents and their GCA effects varied in different environments which may be attributed to genotype x environment interaction.

Amer *et al.* (2003) evaluated seven new yellow inbred lines of maize to four testers. They found that additive more interacted by location than non-additive variance for grain yield, ear length, no. of rows/ear and no. of kernels/ row traits. While non-additive more influenced by location than additive variance for days to mid-silk, plant height, ear height and ear diameter traits.

EL-Shenawy *et al.* (2003) top crossed eight maize inbred lines to four testers. They found that the interactions were significant for most studied traits and the interaction between σ^2 GCA x location was greater than σ^2 SCA x location interaction for all studied traits except number of rows/ear.

Aly (2004) crossed thirty nine yellow and white inbred maize lines to two testers. They found that the variance interaction of σ^2 GCA x location were larger than those of σ^2 GCA_T x location for studied traits indicated that the σ^2 GCA for inbred lines was more affected by environments than for testers. Also, the combined data revealed that variance of σ^2 GCA x location interaction was either negative or smaller than variance of σ^2 SCA x Location interaction for all traits under study. these results indicated that non-additive type of gene action is more affected by environmental conditions than variance due to additive effects.

Ibrahim and Motawei (2004) top crossed fourteen inbred lines of maize to three testers. They reported that non- additive genetic variance was more affected interacted by locations than additive genetic variance for all studied traits except number of kernels/ row and ear diameter.

Mahmoud and Abdel-Azeem (2004) top crossed twenty three yellow inbred lines of maize to two testers. They found that the interaction of lines x location was highly significant for grain yield and significant for ear height. Tester x locations interaction was highly significant for ear height. Also, the interaction of lines x testers x locations was highly significant for grain yield.

Mosa (2004) crossed twenty seven inbred lines of maize to two testers. He found that a line x locations interaction was significant for all traits except number of rows/ear and 100-kernel weight. While testers x locations and line x testers x location interaction were not significant for most traits. The non-additive types of gene action were more sensitive to environmental differences than additive types of gene action for most traits.

Mosa et al. (2004) evaluated nine inbred lines of yellow maize to three testers. They reported that the non-additive genetic variance showed obvious interaction with locations for grain yield / plant, number of rows/ear and number of kernels/row.

Abd El-Moula (2005) top crossed twenty yellow maize inbred lines to each three testers. He found that the interaction of SCA with location was markedly higher than that of GCA ones for all studied traits.

Ibrahim and Osman (2005) evaluated new fifteen white inbred lines of maize to two tester lines. They reported that Genotypes x location interaction was significant for some traits i.e. grain yield, 100-kernel weight and ear height.

Motawei et al. (2005) crossed twenty-nine inbred lines of yellow maize with two genetically diverse inbred testers. They found that the magnitude of σ^2 SCA was more affected by location in most studied traits and σ^2 GCA was more sensitive

to locations than σ^2 SCA in the inheritance of days to 50% silking within two sets.

Seiam (2007) top crossed ten maize inbred lines to three inbred tester. He found that variation due to lines x locations interaction was highly significant for all studied traits. The variation due to tester x locations interaction was also significant for yield and plant height. The variation due to interaction of line x tester x location was highly significant for all studied traits.

2.4. Heterosis:

Shehata et al. (1997) crossed five maize inbred lines with five narrow base elite inbred testers. They found that one single cross (Gm-2 x Sd-35) gave the highest mean value and out yielded the recommended check single cross 10 by 4% while four hybrids (Gm-1 x Sd-7), (Gm-1 x Sd-35), (Gm-2 x Sd-34) and (Gm-5 x Sd-7) gave insignificant mean values grain yield/plant or feddan relative to S.C. 10. The five single crosses surpassed and out yielded the two check hybrids S.C.9 and S.C. 103 by 15%. The highest value of heterotic effects relative to mid and better parent were obtained from the crosses, i.e. (Gm-1 x Sd-7), (Gm-1 x Sd-35), (Gm-2 x Sd-35), (Gm-3 x Sd-35), (Gm-3 x Sd-62), (Gm-3 x Sd-63), Gm-5 x Sd-7), (Gm-5 x Sd-35) and (Gm-5 x Sd-63) for grain yield and its components, significant negative heterotic effect for earliness were observed for the previous single crosses.

Soliman and Sadek (1998) top crossed ten white inbred maize lines with three inbred testers. They found that top cross (Gm-26 x Gm-30) out yielded the check hybrid Giza 10 by 7.9, 3.3 and 5.9 % at Sakha, Sids and their combined data , respectively.

El-Zeir (1999) mated ten maize inbred lines to four testers. He found that four single crosses (P4 x Sd-7), (P9 x Sd-62), (P10 x Sd-62) and (P7 x Sd-63) gave the highest mean values

for yield and yield components in addition to earliness and shorter plants with low ear placement than the check hybrid S.C 10.

El-Zeir *et al.* (2000) top crossed seventeen inbred lines of maize to two testers. They found that top crosses Sk-7005/10 x Sd-7 and Sk-7005/11 x Sd-7 gave the higher mean values for yield and yield components. In addition to earliness, shorter plant and ear height than the check hybrid single cross-10.

Sadek *et al.* (2000) top crossed twenty white maize inbred lines to each of two line testers. They found that eleven out of 40 top crosses exhibited significantly positive SCA effects for grain yield. Further more, six out of those eleven top crosses, i.e. (Gm-4 x Sd-7), (Sd-1011 x Sd-7), (Gm-12A x Sd-7), (Sd-1006 x Sd-63), (Sd-1007 x Sd-63) and (Sd-98-9 x Sd-63) out yielded the commercial check S.C.10 (Best check) by 23.5, 19.8, 15.1, 11.7, 9.1 and 8.1 %.

Soliman (2000) top crossed sixteen yellow maize inbred lines to each of three different testers, i.e. Gz-45 and two elite inbred lines. He showed that 12 out of 48 top crosses surpassed significantly positive SCA effects. Five of them L-14, L-4, L-3 and L-7 crossed with inbred line Gm-1021 and (L-14 x Gm-1002) manifested highly significant over yielded the commercial hybrid S.C. 161 (30.27 ard./ fed.) by 28.9, 27.1, 19.3, 18.8 and 16.3%.

Mahmoud *et al.* (2001) crossed nineteen white maize inbred lines to each of two elite inbred tester lines. They indicated that the most superior cross (L-14 x Sd-34) possessed highly significant and positive SCA effects and manifested significantly out yielded (36.77 ard./ fed.) the best commercial hybrid S.C. 10 (34.51 ard./ fed.) by 6.5%. Also, this cross was insignificantly different from S.C. 10 for the other studied traits.

Soliman *et al.* (2001) top crossed fourteen yellow maize inbred lines to each of three yellow maize inbred testers. They

found that Gm-1021 crossed to inbreds L-10, L-2 and L-7 produced the best single crosses which significantly out yielded the yellow commercial check hybrid S.C.161 (30.60 ard./fed.) by 22.9, 18.3 and 16.7 %.

Amer et al. (2002) mated eight inbred lines of maize to four testers, i.e. Sd-34, S.C.Sk-1, S.C.122 and T.W.C. 322. They reported that one top cross (Gm-4 x S.C. Sk1) produced yield of 31.51 ard./ fed. and surpassed these of commercial hybrids S.C.122 (27.69) and T.W.C. 322 (27.23) ard./ fed. Mean while nine top crosses (Sd-63 x Sd-34), (Sk-8202 x Sd-34), (Sk-8375 x Sd-34), (Sk-8375 x (T.W.C 322), (Gm-4 x S.C. 122), (Sd-63 x Sk-1), (Sk-8375 x S.C. Sk-1), (Sk-8375 x S.C. 122) and (Gm-4 x T.W.C 322) were not significant compared to S.C. 122 and T.W.C 322 for grain yield and most desirable traits.

Amer (2004) top crossed eighteen white inbred lines of maize to three testers, i.e. line Sk-7001/8, S.C. Sk-17 and Giza-2. He found that two single crosses i.e. Sk-7/15 x Sk-7001/8 (37.62 ard./ fed.) and Sk-7/28 x Sk-7001/8 (36.22 ard./ fed) were significantly superior than the commercial S.C. 10 (33.40 ard./fed.) for grain yield and most agronomic traits. Also, three T.W.C. ie. S.C. Sk-17 x Sk 712 (37.41 ard./ fed.), S.C. Sk-17 x Sk- 7/15 (37.07 ard./fed.) and S.C. Sk-17 x Sk-7/28 (35.26 ard./fed.) were significantly superior than the commercial T.W.C. 310 (32.30 ard./ fed.) for grain yield and most agronomic traits.

Ibrahim and Motawei (2004) top crossed fourteen inbred lines of maize to three testers i.e. Sk-7001/8, S.C. Sk-17 and Gz-2. They found that two top crosses Sk-63-32 x S.C. Sk-17 and Sk-63-32 x Sk-7001/8 did not differ significantly from the check variety S.C. 10. Moreover, fourteen top crosses exhibited significant differences than check variety T.W.C. 310.

Mosa (2004) top crossed white twenty-seven inbred lines of maize to two testers, i.e. inbred line Gm-4 and single cross Sk-1. He indicated that four single crosses i.e Sk-5015/7 x Gm-4

ard./fed)., Sk-5017/19 x Gm-4 (34.75 ard./ fed)., Sk-5015/4 x Gm-4 (32.98 ard./ fed) and Sk-5016/14 x Gm-4 (32.82 ard./ fed). Were superior for grain yield compared to S.C. 10 (32.68 ard./fed).

Mosa et al. (2004) top crossed nine inbred lines of yellow maize to three testers i.e. L-121, S.C. Sk-52 and composite-21. They found that the desirable heterotic effects for grain yield / plant relative to the check S.C. 155 were recorded for top cross Sk-7070 x L-121 (24.65%). Whereas, the highest heterosis values relative to the check T.W.C. 352 were detected for the top crosses Sk-7070 x L21 (28.82%) and Sk-7078/2 x L121 (17.73%).

Abd El-Moula (2005) top crossed twenty yellow maize inbred lines to each of three testers, i.e. Gz-45 and two elite inbred lines. He found that crosses L-2, L-10, L-11, L-13, L-15 and L-18 x Gm-1001 were the most superior and promising single crosses, since they outyielded the commercial check S.C. 155 by 40, 15.2, 26, 29.3, 30.8 and 20.7 %.

Ibrahim and Osman (2005) top crossed fifteen white inbred lines of maize with two tester line. They found that two single crosses i.e. Sk. 9195 x Sk-5027/6 (32.16 ard./ fed.) and Sk-9195 x 5037/15 (31.44 ard./ fed.) did not differ significantly than the commercial hybrid S.C. 10 (31.39 ard./ fed.) for grain yield and some agronomic traits.

Motawei et al. (2005) crossed twenty-nine inbred lines of yellow maize with two inbred testers. They found that one top cross (Sk-5001/11 x Sk6241) out yielded the best check S.C. 155. Meanwhile, in set-II one top cross (Sk-5001/26 x Gm-1001) was superior than the two checks and two crosses (Sk-5001/17 x Sk-6241) and (Sk-5001/18 x Gm-1001) were superior than the check Pioneer 3080 of grain yield.

Seiam (2007) top crossed ten white maize inbred lines to three inbred testers. He found that crosses of lines no. 1, 3, 6 and

8 across testers ranged from 27.98 to 31.35 ard./ fed. and significantly out yielded the highest yielding check S.C. 10 (26.77 ard./ fed.) by 5.7, 17.1, 6.35 and 4.5 % , respectively .

MATERIALS & METHODS

3. MATERIALS AND METHODS

The experimental work of this study was carried out at the Experiment Research Station of Moshtohor, Benha University, Qalyubiya Governorate, Egypt during the two successive seasons 2006 and 2007.

Plant materials

- 1- A total of twenty (*Zea mays* L.) yellow inbred lines were developed by Prof. Dr. Ali Abd El-Maksoud El-Hosary Prof. of Agronomy, Fac. of Agric., Moshtohor, Benha Univ. and were used to establish the experiment materials for several characters among inbred lines under study. These lines were selected on bases of yielding ability and other desirable plant aspects. The plant materials were selected with a wide range of diversity for several traits.
- 2- Three testers of yellow maize were used in this investigation to make all possible line x tester crosses. The three testers used in this study were chosen to represent wide difference in relation to the tested lines. i.e. (Gem. Pop.) representing broad genetic base, single cross (El-Hosary 101) representing approximately narrow genetic base and the inbred line 100 representing narrow genetic base. The code number, names and origin of these inbred lines and testers are present in (Table 1).
- 3- Three check varieties were used in this investigation their names are single cross Giza 155, S. C. Pioneer 3080 and three way cross Giza 352.

Field experiments

In the first summer season 2006 seeds of the twenty inbred lines and three testers were split sown on 25th May, 30th May and 8th June to avoid differences in flowering time and to secure enough hybrid seed. All possible top crosses combinations were made between the twenty inbred lines and three testers by hand method giving a total of 60 top crosses.

Each top cross was constituted by collecting pollen from 40-50 protected tassels, representing the tester, then top crossing into protected silks of 15 plants, representing the inbred lines by hand pollinating.

In the second summer, season 2007 two adjacent experiments were conducted on two sowing dates. i.e. 15th June and 4th July. In each experiment the twenty inbred lines, three testers and their 60 top crosses as well as the three check hybrids (S.C. G.155 and S.C. Pioneer 3080 and T.W.C. G.352) were grown in a randomized complete block design with three replications. Each plot consisted of two ridges of 5 m length and 70 cm width. Each hill was spaced 25 cm apart with two kernels planted per hill and later thinned to one plant per hill. The plots were irrigated after sowing. The second irrigation was given after 21 days from sowing. The plants were then irrigated at intervals of 10-15 days. The plots were informally fertilized at the rate of 120 kg of nitrogen per faddan given before the first and second irrigations. The other cultural practices of maize growing were properly practiced.

Characters studied

Data for the following traits were recorded on ten individual guarded plants chosen at random from each plot, except for days to 50% pollen shedding, days to 50% silking and maturity dates where the plot mean basis were used.

A. Agronomic characters

- 1- Days to 50% pollen shedding (tasseling date) was recorded as the number of days from sowing to the day when 50 percent of the plants tasseled.
- 2- Days to 50% silking (silking date) was recorded as the number of days from sowing to the day when 50 percent of the plants silked.
- 3- Plant height (cm) was measured from soil surface to the top of tassel.
- 4- Ear height (cm) was measured to the nearest centimeter from soil surface to the top ear node.
- 5- Leaf area of upper ear (cm²) was computed according to the formula; farther ear leaf length x farther ear leaf width x 0.75.
- 6- Ear husk degree was measured before harvest by using 1-9 Scale; where scores of 1, 2, 3, and 4 was given when the kernels of top ear were appeared about 4, 3, 2 and 1cm, respectively. Score 5 was given when the kernels of top ear don't shown and the husk longer equal to zero. Scores 6, 7, 8 and 9 were given when the husk was longer than the top of the ear 1, 2, 3 and 4 cm, respectively.
- 7- Maturity date was recorded as the number of days from sowing to the day when all husks of ears turned brown.

B. Yield and yield components

- 1- Ear length (cm).
- 2- Ear diameter (cm).
- 3- Number of rows/ear.
- 4- Number of Kernel/ row.
- 5- Weight of 100-kernel (g).
- 6- Ear weight/plant.

- 7- Grain yield per plant (g) adjusted at 15.5 % moisture content.
 8- Shelling percentage was computed as $100 \times (\text{grain weight} / \text{ear weight})$.

Analysis of data in the experiment

Statistical analysis.

An ordinary analysis of variance was firstly performed for all traits in each sowing date to test the significant of all genotypes. Homogeneity of error variance was tested for each trait. This test revealed the validity of combined analysis of both sowing date for all studied traits. When differences among top crosses were found significant, line x tester analysis according to **Kemphorne (1957)** was done for each sowing date and combined over them (Table 2 and 3).

Table (2): Source of variation and degree of freedom for top crosses to each three testers at each sowing date.

S. O. V.	d.f
Replications	r- 1
Crosses	fm- 1
Lines	f- 1
Testers	m- 1
Lines x testers	(f-1)(m-1)
Error	(r-1)(fm-1)
Total	rfm-1

Where: r = Number of replications, m = Number of testers and f = Number of lines

Table (3): Combined analysis of variance of the two sowing dates and the expectations of mean squares.

S. O. V.	d.f	E.M.S
sowing date (D)	D-1	
Reps / sowing date	D (r-1)	
Crosses	fm- 1	
i) inbred	f- 1	$M_1 \sigma^2 e + r \sigma^2 fmD + rm \sigma^2 fD + rD \sigma^2 fm + rm \sigma^2 f$
ii) Testers	m- 1	$M_2 \sigma^2 e + r \sigma^2 fmD + rf \sigma^2 mD + rD \sigma^2 fm + rD \sigma^2 m$
iii) inbred x testers	(f-1)(m-1)	$M_3 \sigma^2 e + r \sigma^2 fmD + rD \sigma^2 fm$
Crosses x sowing date	(fm-1)(D-1)	
i) inbred x sowing date	(f-1)(D-1)	$M_4 \sigma^2 e + r \sigma^2 fmD + rm \sigma^2 fD$
ii) Testers x sowing date	(m-1)(D-1)	$M_5 \sigma^2 e + r \sigma^2 fmD + rf \sigma^2 mD$
iii) inbred x testers x D	(m-1)(f-1)(D-1)	$M_6 \sigma^2 e + r \sigma^2 fmD$
Error	D(r-1)(fm-1)	$M_7 \sigma^2 e$

Where:

D: sowing date.

$\sigma^2 fD$: variance due to inbred x sowing date interaction.

$\sigma^2 f$: variance due to inbreds.

$\sigma^2 mD$: variance due to tester x sowing date interaction.

$\sigma^2 m$: variance due to testers.

$\sigma^2 fmD$: variance due to inbred x tester x sowing date interaction.

$\sigma^2 mD$: variance due to inbred x tester interaction.

Estimation of general and specific combining ability effects:

The model used to estimate general and specific combining ability effects of the ijk th observation was:

$$X_{ijk} = \mu + \hat{g}_i + \hat{g}_j + \hat{s}_{ij} + e_{ijk}$$

Where:

μ = overall population mean

\hat{g}_i = GCA effect of the i th male parent (tester).

\hat{g}_j = GCA effect of the j th female parent (inbred).

\hat{s}_{ij} = SCA effect of ij th cross combination.

e_{ijk} = the error associated with the X_{ijk} observation.

I = number of male parent (tester) = 1, 2, ...m.

J = number of female parent (inbred) = 1, 2, ...f

K = number or replication = 1, 2, ... r

The individual effects were estimated as follows:

a) GCA for inbred lines:

$$\hat{g}_i = \frac{X_{i..}}{tr} - \frac{X_{...}}{Itr}$$

Where:

$X_{i..}$ = total of all i th female (inbred) parent over all male parents (testers) and replications.

$X_{...}$ = total of all females (inbreds) over all males (testers) and replications.

b) GCA for testers:

$$\hat{g}_t = \frac{X_{t...}}{I r} - \frac{X_{...}}{I t r}$$

Where:

$X_{t...}$ = total of the t th male (tester) parent over all females (inbreds) and replications.

I = number of Lines

t = number of testers, r = number of replication

c) Specific combining ability effects:

$$\hat{s}_{ij} = \frac{X_{it}}{r} - \frac{X_{i.}}{I r} - \frac{X_{.j}}{I r} + \frac{X_{...}}{I t r}$$

Where:

X_{it} = total of the it th hybrid combination over all replications.

Stander error for combining ability effects:

$$\text{S.E. (GCA for inbred lines)} = \sqrt{(Me / r t D)}$$

$$\text{S.E. (GCA for testers)} = \sqrt{(Me / r I D)}$$

$$\text{S.E. (SCA effects)} = \sqrt{(Me / r D)}$$

$$\text{S.E. } (\hat{g}_i - \hat{g}_j) \text{ inbred} = \sqrt{(2 Me / r t D)}$$

$$\text{S.E. } (\hat{g}_i - \hat{g}_j) \text{ tester} = \sqrt{(2 Me / r I D)}$$

$$\text{S.E. } (\hat{s}_{ij} - \hat{s}_{kl}) = \sqrt{(2 Me / r D)}$$

Where:

D = number of sowing dates.

Me = error variance.

Estimation of variance components:

The following variance components were estimated based on the expectations of the mean squares of combined analysis (Table 3).

$$\text{i) } \sigma^2_f = \frac{M1 - M3 - M4 + M6}{rmD}$$

$$\text{ii) } \sigma^2_m = \frac{M2 - M3 - M5 + M6}{rfD}$$

$$\text{iii) } \sigma^2_{fm} = \frac{M3 - M6}{rD}$$

$$\text{iv) } \sigma^2_{fD} = \frac{M4 - M6}{rm}$$

$$\text{v) } \sigma^2_{mD} = \frac{M5 - M6}{rf}$$

$$\text{vi) } \sigma^2_{fmD} = \frac{M6 - M7}{r}$$

Where:

σ^2_f = Variance due to inbreds.

σ^2_m = Variance due to testers.

σ^2_{fm} = Variance due to inbred x tester interaction.

σ^2_{fD} = Variance due to inbred x Sowing date.

σ^2_{mD} = Variance due to tester x Sowing date.

σ^2_{fmD} = Variance due to inbred x tester x Sowing date.

The covariance of half-sibs (H.S.) and the covariance of full-sibs (F.S.) were estimated as follows:

$$\text{Covariance H.S.} = \frac{m \sigma^2 f + f \sigma^2 m}{m + f}$$

$$\sigma^2 fm = (\text{Cov. F.S.} - 2 \text{Cov. H.S.})$$

$$\text{Covariance F.S.} = \sigma^2 fm + 2 \text{Cov. H.S.}$$

$$\sigma^2 \text{GCA} = \text{Cov. H.S.} = \frac{m \sigma^2 f + f \sigma^2 m}{m + f}$$

$$\sigma^2 \text{SCA} = (\text{Cov. F.S.} - 2 \text{Cov. H.S.}) = \sigma^2 fm$$

$$\sigma^2 \text{GCA} \times \text{sowing date} = \frac{m \sigma^2 fD + f \sigma^2 mD}{m + f}$$

$$\sigma^2 \text{SCA} \times \text{Sowing date} = \sigma^2 fmD$$

Heterosis:

Heterosis for each trait was calculated for each individual top cross as the percent deviation of F₁ mean performance from either S.C. G. 155, Pioneer 3080 and T.W.C. G. 352 average values for each experiment as well as the combined data as follows:

$$\text{The check variety heterosis (heterobeltosis)} = \frac{\text{F1} - \text{Check variety}}{\text{Check variety}} \times 100$$

Appropriate L.S.D values were computed according to the following formulae to test the significance of these heterotic effects.

$$\text{L.S.D. for heterosis relative to check variety} = t \times \sqrt{\frac{2MSe}{r}}$$

Where:

t: is the tabulated t value at a stated level of probability for the experimental error degree of freedom and r: is the number of replications.

RESULTS & DISCUSSION

4. RESULTS AND DISCUSSION

4.1. Analysis of variance:

Analysis of variance for the studied traits in separate planting dates as well as the combined analysis is presented in (Table 4). Test of homogeneity revealed the validity of the combined analysis over both sowing dates. Sowing dates mean squares were significant for all traits except number of rows/ ear, number of kernels/ row and shelling percentage, indicating over all differences between the two sowing dates, with mean values in early sowing being higher than those in late sowing for all traits except ear husk (Table 5). The increase in these traits at early sowing date may be due to the prevailing of favorable temperature and day length leading to greater vegetative growth, yield and its components of corn plants. Therefore, the first sowing date seemed to be non-stress environments. These results are in harmony with those obtained by **Nawar *et al.* (1998)**, **El-Hosary and El-Badawy (2005)**, **El-Hosary *et al.* (2006)** and **Sedhom *et al.* (2007)**.

Crosses mean squares were significant for all the studied traits at both sowing dates as well as the combined analysis except ear diameter at early sowing date, indicating the wide diversity between the parental materials used in the present study. Significant crosses x sowing date mean squares were obtained for all traits except ear height, ear husk, and ear diameter, revealing that the tested crosses varied from each other and ranked differently from sowing date to another.

Lines mean squares were significant for all traits at early and late sowing dates as well as the combined over them, indicating the wide diversity among those inbred lines. Significant lines x sowing date mean squares were detected for all traits except tasseling date, ear height, ear husk, ear diameter and shelling%.

These findings indicate that parental inbred lines differ in their mean performance in most traits.

Significant mean squares due to testers were obtained for all traits in both sowing dates as well as the combined analysis except maturity dates at both sowing dates as well as the combined analysis, tasseling date, silking date, leaf area, ear diameter, number of kernels/ row at early sowing, and ear length at early sowing date and the combined analysis. Such results indicated a wide range of variability among parental testers. In addition, lines mean squares were much higher than those of testers for most studied traits. Such results revealed that lines contributed much more to the total variation as compared to testers. Therefore, the total GCA variance was due to inbred lines for most traits. Also, the interaction between tester x sowing date mean squares were significant for silking date, leaf area, ear length, ear diameter, no. of kernels/ row, ear weight/ plant, 100-kernel weight and grain yield/ plant. This indicated that the testers behaved somewhat differently from one sowing date to another.

Significant line x tester mean squares were obtained for all traits except ear diameter at both sowing dates as well as the combined analysis, ear husk, number of rows/ ear and number of kernels/ row at late sowing date and shelling percentage at early sowing date. Significant interaction between line x tester x sowing date mean squares were obtained for tasseling and silking dates, plant height, leaf area, no. of rows/ ear, 100-kernel weight, shelling percentage, ear weight/ plant and grain yield/ plant.

Results & Discussion

4.2. Mean performance

Mean values of top crosses along with three hybrid checks (T.W. G 352, S.C. Pioneer 3080 and S.C. G 155) for all the studied traits in both sowing dates as well as their combined data are presented in (Table 5).

Results in (Table 5) showed that the mean performance of tasseling date was significantly lower than the best earlier check variety by one, twenty four and eighteen top crosses at early, late sowing dates as well as the combined analysis, respectively. The top cross $T_1 \times L_1$ at early sowing date had earlier than the best check variety S.C. Pioneer 3080. While, the top crosses $T_3 \times L_{14}$, $T_1 \times L_1$ and $T_3 \times L_{16}$ gave the lowest mean values compared with other genotypes at late sowing date. The top crosses $T_1 \times L_1$, $T_1 \times L_{13}$ and $T_3 \times L_{14}$ gave the lowest mean values for tasseling date at the combined data.

For silking date, zero, twenty six and fifteen top crosses exhibited significantly earliness than the earlier check variety at early, late sowing dates as well as the combined, respectively. The top crosses $T_1 \times L_1$, $T_1 \times L_{13}$, $T_2 \times L_{12}$ and $T_3 \times L_{10}$ gave the lowest mean values for this trait at the combined data.

Regarding maturity date, forty six, thirteen, forty seven top crosses expressed significantly earliest than the earlier check variety. From breeder point of view, the previous mentioned top crosses seemed to be of prime importance since earliness in maize hybrids is a must avoid destructive pests. The top crosses $T_1 \times L_1$, $T_1 \times L_6$, $T_2 \times L_7$, $T_2 \times L_9$, $T_2 \times L_{10}$, $T_2 \times L_{18}$, $T_3 \times L_6$, $T_3 \times L_{10}$ and $L_3 \times L_{12}$ expressed the lowest significant values of maturity date and it were the earliest among the studied top crosses at the combined analysis.

Regarding plant height, twenty one, fiveteen and twenty top crosses expressed significant lowest values as compared with the best check variety T.W. G 352 at early, late sowing date as well as the combined analysis, respectively. The top crosses $T_1 \times L_{10}$, $T_1 \times L_{12}$, $T_1 \times L_{18}$, $T_2 \times L_9$ and $T_2 \times L_{15}$ in the early sowing

date, T₂xL₉, T₁xT₁₃ and T₁xL₁₅ at late sowing date and T₁xL₁₀, T₁xL₁₅, T₁xL₁₈, T₂xL₉, T₂xL₁₅ and T₃xL₁₄ at the combined analysis were the best among the studied crosses since they expressed the lowest significant values of this trait (Table 5).

As for ear height, eight, zero and nine top crosses showed significant lowest values as compared to best check variety (G155) from the three check hybrids at early, late sowing dates as well as the combined analysis, respectively (Table 5).

The three top crosses T₁xL₁₀, T₁xL₁₈, T₂xL₉ and T₂xL₁₅ at the combined analysis which had the best values for plant height showed also the most desirable values for ear height. Therefore, these top crosses are prospective in maize breeding program.

For leaf area, fourteen, six and sixteen top crosses were significantly superior to the best check variety at early, late sowing dates and the combined analysis, respectively. Moreover, the seven top crosses T₁xL₆, T₁xL₁, T₂xL₂, T₂xL₁₂, T₃xL₁, T₃xL₉, T₃xL₁₅ and T₃xL₁₆ were the best among all studied crosses since they expressed the highest significant values of this trait in the combined analysis over both sowing dates (Table 5).

Regarding ear husk, none of the top crosses surpassed significant compared to the best check variety in both sowing dates and the combined data. However, the most top crosses exhibited insignificant values of ear husk compared with the best check variety (Table 5).

As for ear length one, ten and six top crosses exhibited significant higher than the best check variety at early, late sowing dates as well as the combined data, respectively. The top crosses T₁xL₁₄, T₂xL₃, T₂xL₁₁, T₃xL₁₁ and T₃xL₁₈ at the combined analysis exhibited significantly higher mean values as compared to the best check hybrid S.C. Pioneer 3080.

For ear diameter, none of the top crosses significantly surpassed the best check hybrid at early, late sowing date and the combined analysis. However, the check hybrid S.C. Pioneer 3080 gave the highest value for this trait but without superiority

than most top crosses in both sowing dates as well as the combined data.

For number of rows/ ear, the top crosses $T_2 \times L_5$ at early sowing date; $T_2 \times L_4$, $T_3 \times L_5$ and $T_3 \times L_6$ at late sowing date; and $T_1 \times L_{13}$, $T_2 \times L_5$, $T_3 \times L_5$ and $T_3 \times L_6$ at the combined analysis, exhibited significant higher than the best check hybrid.

For number of kernels/row, with the exception of crosses $T_1 \times L_3$, $T_2 \times L_{11}$, $T_2 \times L_{20}$, $T_3 \times L_{16}$, $T_3 \times L_9$ and $T_3 \times L_{12}$ at late sowing date, none of top crosses surpassed the best check hybrids in early, late sowing date as well as the combined analysis. Also, the best check variety S.C. Pioneer 3080 recorded the highest no. of kernels/ row but without superiority over that recorded by most top crosses for this trait in both sowing dates as well as the combined over them.

Regarding 100-kernel weight, the top crosses $T_1 \times L_1$, $T_1 \times L_3$, $T_1 \times L_{12}$, $T_3 \times L_3$ and $T_3 \times L_{10}$ at early sowing date; $T_1 \times L_{12}$, $T_2 \times L_3$, $T_2 \times L_{15}$, $T_3 \times L_3$, $T_3 \times L_{13}$ and $T_3 \times L_{19}$ at late sowing date and $T_1 \times L_1$, $T_1 \times L_7$, $T_1 \times L_{12}$, $T_2 \times L_3$, $T_2 \times L_{15}$, $T_3 \times L_3$ and $T_3 \times L_{19}$ at the combined analysis exhibited significantly higher than the best check hybrid S.C. G 155.

For ear weight, one, thirty three and five top crosses out yielded the best check hybrid. Also, it is clear that the most desirable top crosses were obtained from the crossing between T_1 and each of inbred lines L_{13} and L_{17} and T_2 and each of inbred lines L_5 , L_{10} and L_{12} at the combined data.

As for shelling percentage, none of the studied top crosses significantly exceeded that of the best of check hybrid. However, the most top crosses did not significantly from the best check hybrid.

Regarding grain yield/ plant, the highest mean values were recorded by S.C. Pioneer 3080 at early sowing date, but without significant superiority over those of hybrids $T_1 \times L_{13}$, $T_1 \times L_{17}$, $T_2 \times L_5$, $T_2 \times L_{10}$, $T_2 \times L_{12}$ and $T_2 \times L_{14}$. While, twenty six and three top crosses exhibited significantly higher than the best

check hybrid S.C. Pioneer 3080 at late sowing date and the combined analysis, respectively.

The best top crosses were $T_1 \times L_{13}$, $T_1 \times L_{17}$ and $T_2 \times L_{12}$ at the combined data. Also, eight top crosses at combined analysis did not differ significantly than the best check hybrid.

From such results it could be concluded that the previous top crosses could be efficient and prospective in maize breeding programs since they expressed significant desirable effects for grain yield and for one or more of yield components.

The fluctuations of hybrid performance from sowing date to another were detected for most traits. These results would be due to significance of the interaction between hybrids and sowing date.

Table (5): mean performance of the testers and line x tester and check varieties in both sowing dates as well as the combined over them.

4.3. Analysis of variance for combining ability:

The estimation of variance due to general combining ability (σ^2 GCA) and specific combining ability (σ^2 SCA) along with their interaction with sowing dates are presented in (Table 4) Results indicated that σ^2 SCA was more important than σ^2 GCA for all studied traits in both sowing dates as well as the combined analysis except tasseling date and number of rows/ ear in the combined analysis, ear diameter at early sowing date and ear husk at late sowing date σ^2 GCA= σ^2 SCA revealing that additive and non additive gene effects was similar for controlling this trait . These results indicated that the largest part of the total genetic variability associated with those traits was the result of non – additive type of gene action. The importance of non-additive gene action in controlling such traits was reported by **El-Hosary (1989)** for ear length, ear diameter, number of rows/ ear, number of kernels/ row and grain yield/ plant, **Sedhom (1994)** for ear length and ear diameter; **Soliman (2000)** and **Mahmoud *et al.* (2001)** for grain yield ; **Amer *et al.* (2002)** for grain yield and number of kernels / row ; **El-Shenawy *et al.* (2003)** for grain yield and number of rows / ear; **Mosa (2004)** for silking date , plant height , grain yield , ear length , number of kernels / row and 100-kernel weight ; **Abd El-Moula (2005)** for grain yield , 50% silking , plant height and ear height ; **Motawei *et al.* (2005)** for grain yield , number of kernels / row and ear length.

The magnitude of the interaction between specific combining ability and sowing dates was much higher than that of general combining and sowing dates for all traits except ear height, ear husk and number of rows/ ear. These results led to the conclusion that non-additive gene action was more biased by the interaction with environments than the additive effects. Such results are in agreement with those reported by **El-Hosary (1985)**, **Sedhom (1992 and 1994)**, **Al-Naggar *et al.* (1997)**, **Soliman (2000)**, **Sadek *et al.*(2000)**; **Mahmoud *et al.*(2001)**; **Soliman *et al.*(2001)**; **Amer *et al.*(2003)**; **Aly (2004)**; **Mosa**

(2004) ; Ibrahim and Motawei (2004) ; Mosa *et al.* (2004) ; Abd El-Moula (2005).

For the exceptional traits, the magnitude of σ^2 GCA x sowing date interaction was higher than that of σ^2 SCA x sowing date revealing that additive and additive x additive gene action interacted more with the environment than the non additive component. Similar results were reported by El-Hosary (1989), Sedhom (1994), Sultan (1998), El-Zeir *et al.* (2000), Gado (2000), Barakat (2001), Amer *et al.* (2002), El-Shenawy *et al.* (2003).

4.3.1 General Combining ability effect:

The general combining ability effects (\hat{g}_i) of testers and parental inbred lines for all traits in both sowing dates as well as the combined analysis is presented in (Table 6).

From the breeder's point of view, high negative values for tasseling, silking and maturity dates as well as plant and ear heights along with high positive values for yield and its components would be useful for maize breeding program.

Testers:

Results in (Table 6) indicated that the tester T_1 (L_{100}) exhibited significant desirable (\hat{g}_i) effects for plant and ear heights and 100-Kernel weight at early, late sowing dates, as well as the combined data, ear diameter, ear weight / plant and grain yield / plant at late sowing date and the combined data; and ear length at late sowing date. Also, it gave significant undesirable or insignificant (\hat{g}_i) effects for other cases.

The parental tester S.C. (El-Hosary 101) expressed significant positive (\hat{g}_i) effects for leaf area and shelling percentage at late sowing date and the combined data and ear husk at early sowing date and the combined data; ear weight, grain yield/ plant and 100-Kernel weight at early sowing date. Also, it gave significant positive (undesirable) (\hat{g}_i) effects at late sowing date and the combined data for tasseling date and late sowing date for silking date. However, it gave insignificant (\hat{g}_i) effects for other cases.

Parental tester (Gem. Pop.) expressed significant desirable (\hat{g}_i) effects for number of rows/ ear in both sowing dates and the combined data; leaf area at late sowing date; tasseling date and silking date at late sowing date and the combined data. Also, it gave significant undesirable or insignificant (\hat{g}_i) effects for other cases.

Inbred lines:

six, four and four inbred lines expressed significant and negative (\hat{g}_i) effects for tasseling date at early, late sowing dates as well as the combined analysis, respectively.

For silking date seven, four and six inbred lines gave significant negative (\hat{g}_i) effects at early, late sowing dates and the combined over them, respectively. The parental inbred lines L_1 and L_{13} exhibited the highest (\hat{g}_i) effects for tasseling and silking dates in both sowing dates as well as the combined data. Moreover, both inbred lines L_1 and L_{13} were the best combiners for both traits together.

Consequently, they could be utilized in developing new hybrids characterized by earliness in flowering.

For maturity date, the parental inbred lines L_6 and L_{10} seemed to be the best combiners for earliness in both sowing dates as well as the combined analysis. Consequently, they could be utilized in developing new hybrids characterized by earliness in maturity.

Regarding plant height, seven, five and seven inbred lines gave significant negative (\hat{g}_i) effects at early, late sowing dates as well as the combined data, respectively. The best inbreds in general (\hat{g}_i) effects were L_2 , L_9 , L_{10} , L_{15} and L_{18} in both sowing dates and the combined analysis.

On the other hand, L_6 , L_{19} , L_4 and L_5 gave significant positive (\hat{g}_i) effects for plant height in both sowing dates and the combined data. Therefore, they could be of great value in breeding programs for developing new hybrids with highest plant stature for forage crops..

For ear height, six, two and four inbred lines exhibited significant negative (\hat{g}_i) effects at early, late sowing dates as well as the combined data, respectively. The inbred lines L_9 and L_{15} were the best combiners for both traits (plant and ear heights). Therefore, they could be of great value in breeding programs for developing new hybrids with short plant stature.

For leaf area, six, eight and nine inbred lines exhibited significant positive (\hat{g}_i) effects at early, late sowing dates and the combined analysis, respectively. From these lines, the three inbred lines L₁, L₂, L₁₁ and L₁₆ were good combiners for this trait in both sowing dates and the combined analysis. Therefore, they could be of great value in breeding programs for developing hybrids with highest leaf area of upper ear increased forage crops and grain yield.

The inbred lines L₂, L₉ and L₁₇ expressed significant positive ear husk in both sowing dates as well as the combined analysis.

Regarding ear length, the best general combiners which had significant positive (\hat{g}_i) effects was L₁₁ in both sowing dates as well as the combined analysis. While, L₁₉ exhibited significant positive (\hat{g}_i) effects in both sowing dates as well as the combined data for ear diameter.

Results in (Table 6) showed that the best general combiners which had significant and positive (\hat{g}_i) effects for number of rows/ ear was the inbred L₅, L₆ and L₁₃ in both sowing dates as well as the combined data.

For no. of Kernels/ row, the best general combiners which had significant and positive (\hat{g}_i) effects were the parental inbred lines L₁₁ and L₁₂ in both sowing dates and the combined over them.

Regarding 100-kernel weight, seven , five and seven parental inbred lines exhibited significant positive (\hat{g}_i) effects at early, late sowing dates and the combined analysis, respectively .However , the most desirable (\hat{g}_i) effects for this trait were detected for the parental inbred lines L₃ followed by L₁₉ in both sowing dates and the combined data.

For shelling percentage, four, two and five parental inbred lines exhibited significant and positive (\hat{g}_i) effects at early, late sowing dates as well as the combined analysis, respectively.

Moreover, the most desirable combiner for this trait was L₁₈ in both sowing and the combined analysis.

Seven, ten and nine parental inbred lines for ear weight / plant; six, eight and seven parental inbred lines for grain yield/ plant exhibited significant positive (\hat{g}_i) effects at early, late sowing dates as well as the combined analysis, respectively. Moreover, the most desirable combiners for ear and grain yield/ plant were the inbred lines L₅ and L₁₃ in both sowing dates and the combined analysis.

From the previous results it could be concluded that the parental inbred lines L₅ and L₁₃ should be of great values in breeding programs for improving grain yield and its components and earliness (L₁₃). Also, it is clear that the parental inbred line which exhibited significant desirable (\hat{g}_i) effects for grain yield/ plant might express the same effects for one or more of traits contributing grain yield. For example, parental inbred line L₁₃ expressed significant desirable (\hat{g}_i) effects for grain yield/ plant, ear weight/ plant, number of rows/ ear, plant height, tasseling and silking dates. While, L₅ gave significant positive (\hat{g}_i) effects for grain yield/ plant, ear weight/ plant, no. of rows/ ear and plant and ear heights (grain or fodder yield).

Table (6): General combining ability effects of testers and inbred lines for all the studied traits.

4.3.2 Specific combining ability effects:

Specific combining ability effects of the top crosses for all traits in both sowing dates as well as the combined analysis are presented in (Table 7).

Significant and negative SCA effects for tasseling date in top crosses; $T_1 \times L_1$, $T_2 \times L_{15}$ and $T_2 \times L_{19}$ at early sowing date; $T_1 \times L_7$, $T_1 \times L_{19}$, $T_2 \times L_3$, $T_2 \times L_{12}$, $T_3 \times L_2$, $T_3 \times L_{10}$, $T_3 \times L_{14}$ and $T_3 \times L_{16}$ at late sowing date, and $T_1 \times L_1$, $T_2 \times L_3$, $T_2 \times L_{19}$, $T_3 \times L_{10}$ and $T_3 \times L_{14}$ at The combined analysis. The most desirable SCA effects for this trait were detected for the top cross $T_2 \times L_3$ followed by the crosses $T_3 \times L_{14}$ and $T_2 \times L_{19}$. This means that the immediate use of line 3 and 19 as a parent of three way cross with S.C (S.C El-Hosary 101) could be recommended.

Also, in (Table 7) showed that the tester (Gem. Pop). expressed the highest number of significantly negative SCA effects especially at late sowing date and the combined analysis in their crosses and showed the highest negative SCA effects for tasseling date at late sowing and the combined analysis. Also, exhibited the widest range of SCA effects -2.41 to 2.70 at late sowing date and -1.31 to 1.75 in the combined analysis.

Regarding to silking date, three, two and zero top crosses exhibited significant and negative SCA effects were obtained for the tester T_1 (L_{100}), T_2 (S.C El-Hosary 101) and T_3 (Gem.pop.), respectively at early sowing date; Three, three and three top crosses at late sowing gave significant negative SCA effects in the same order. While, one, three and three top crosses gave significant negative SCA effects in the same order at the combined analysis. Moreover, the most desirable SCA effects for this trait were obtained for the top crosses $T_1 \times L_1$ at early sowing date; $T_2 \times L_3$ and $T_2 \times L_{12}$ at late sowing date and the combined analysis. Meanwhile, the tester T_2 (S.C El-Hosary 101) gave the best SCA effects for this trait. While, T_3 (Gem. pop.) had the widest range of SCA effects for this trait at late sowing and the combined analysis. However, T_1 (L_{100}) expressed the widest range of SCA effects for this trait at early sowing date. It could

be concluded that the tester T_2 (S.C El-Hosary 101) was the best among all tester for silking date since it exhibited the largest number of significantly negative SCA effects over both sowing dates and the combined analysis. Also, the tester T_3 (Gem. pop.) expressed the widest range of SCA effects at late sowing date and the combined analysis.

Regarding to maturity date, one, zero and one at early sowing date; two, zero and two at late sowing date and one, two and three top crosses at the combined analysis exhibited significant negative SCA effects for tester T_1, T_2 and T_3 , respectively. Also, the cross $T_1 \times L_1$ at early ,late sowing date and the combined analysis, $T_3 \times L_{15}$ at early sowing date and the top cross $T_3 \times L_{17}$ at late sowing date and the combined analysis had the most desirable \hat{S}_{ij} effects for this trait.

For plant height, five, five and four top crosses at early sowing date; six, three and three top crosses at late sowing date and five, four and four top crosses at the combined analysis expressed significant negative \hat{S}_{ij} effects for the tester T_1 (L_{100}), T_2 (S.C El-Hosary 101) and T_3 (Gem. pop.), respectively. The highest desirable \hat{S}_{ij} effects to short plants were detected by cross $T_1 \times L_3$ and $T_1 \times L_{10}$ in both sowing dates as well as the combined analysis. In addition this tester expressed the largest number of significantly negative \hat{S}_{ij} effects and had the widest range of \hat{S}_{ij} effects for this trait. In this respect, **Zambezi et al. (1986)** pointed out that inbred testers are preferred over broad base testers and mentioned two practical reasons for preferring inbred line (narrow base) testers to broad – base testers. First, sampling errors are likely to occur with heterogeneous testers. Second, use of an inbred line or (single cross) tester may permit quicker utilization of new lines in commercial hybrids, especially if the tester is already in commercial use.

For ear height, the top crosses $T_1 \times L_4$, $T_2 \times L_{15}$, $T_2 \times L_{16}$, $T_2 \times L_{17}$, $T_3 \times L_3$, $T_3 \times L_{14}$ and $T_3 \times L_{15}$ at early sowing date; $T_1 \times L_{11}$, $T_2 \times L_{16}$, $T_3 \times L_3$, $T_3 \times L_{14}$ at late sowing date and $T_1 \times L_{11}$, $T_1 \times L_{18}$, $T_2 \times L_9$, $T_2 \times L_{15}$, $T_2 \times L_{16}$, $T_2 \times L_{17}$, $T_3 \times L_3$ and $T_3 \times L_{14}$ at the

combined analysis, expressed significant negative \hat{S}_{ij} effects. However, the most desirable \hat{S}_{ij} effects were detected for the top crosses $T_2 \times L_{16}$, $T_3 \times L_3$ and $T_3 \times L_{14}$ at early, late sowing dates as well as the combined analysis, respectively. The T_2 (S.C El-Hosary 101) exhibited the largest number of desirable \hat{S}_{ij} effects (4 crosses). While, the T_3 (Gem. pop.) expressed the widest range between \hat{S}_{ij} effects at both sowing dates as well as the combined analysis. This may suggest the immediate use of T_2 (S.C El-Hosary 101) as parents in the development of three way crosses to improve ear height.

Leaf area of upper ear, the cross $T_1 \times L_6$, $T_1 \times L_9$, $T_1 \times L_{20}$, $T_2 \times L_2$, $T_2 \times L_4$, $T_2 \times L_{12}$, $T_3 \times L_{15}$ and $T_3 \times L_{16}$ at early sowing date; T_1 and each of L_4 and L_8 ; T_2 with each of L_2 , L_{10} and L_{12} ; and T_3 with each of L_9 , L_{15} , L_{17} and L_{18} at late sowing date and T_1 with each of L_6 , L_8 and L_{20} ; T_2 and each of L_2 , L_{10} , L_{12} and L_{14} ; T_3 and each of L_9 , L_{15} , L_{16} and L_{18} , gave significant positive \hat{S}_{ij} effects. However, the other top crosses exhibited either significant negative or insignificant \hat{S}_{ij} effects.

The top cross $T_1 \times L_9$ at early sowing date and the combined analysis and $T_1 \times L_{18}$ and $T_1 \times L_{19}$ at the combined analysis gave significantly positive \hat{S}_{ij} effects for ear husk. However, the other top crosses gave either significant negative or insignificant \hat{S}_{ij} effects for this trait.

For ear length, the top crosses $T_1 \times L_{14}$, $T_2 \times L_3$, $T_2 \times L_5$ and $T_3 \times L_{10}$ at early sowing date; $T_1 \times L_9$, $T_2 \times L_3$ and $T_2 \times L_{20}$ at late sowing date; $T_1 \times L_{14}$, $T_2 \times L_3$, $T_3 \times L_{10}$ and $T_3 \times L_{18}$ at the combined analysis expressed significant positive \hat{S}_{ij} effects. However, the most desirable \hat{S}_{ij} effects were detected for the top cross $T_2 \times L_3$ at both sowing dates as well as the combined analysis.

For ear diameter, the top cross $T_2 \times L_{12}$ at the combined analysis gave significant positive \hat{S}_{ij} effects. However, the other top crosses gave either significant negative or insignificant \hat{S}_{ij} effects for this trait.

For number of rows/ ear, the top crosses $T_1 \times L_{13}$, $T_1 \times L_{14}$, $T_2 \times L_6$ and $T_3 \times L_{10}$ at early sowing date; $T_1 \times L_{13}$, $T_2 \times L_4$ and $T_3 \times L_6$

at late sowing date and $T_1 \times L_{13}$, $T_2 \times L_4$, $T_2 \times L_6$, $T_3 \times L_3$ and $T_3 \times L_{10}$ at the combined analysis, exhibited significantly positive \hat{S}_{ij} effects. While, the other top crosses gave either significant negative or insignificant \hat{S}_{ij} effects. The most desirable \hat{S}_{ij} effects were obtained from top cross $T_3 \times L_{10}$, $T_2 \times L_4$ and $T_1 \times L_{13}$ at early, late sowing dates as well as the combined analysis, respectively.

Regarding number of kernels/ row, the top crosses $T_1 \times L_{16}$ and $T_3 \times L_{16}$ at early sowing; $T_1 \times L_{18}$, $T_2 \times L_{15}$ and $T_2 \times L_{20}$ at late sowing date; and $T_1 \times L_5$, $T_1 \times L_{16}$, $T_2 \times L_{15}$ and $T_2 \times L_{20}$ at the combined analysis exhibited significantly positive \hat{S}_{ij} effects for this trait. The rest top crosses showed either significant negative or insignificant \hat{S}_{ij} effects.

Five, three and five top crosses at early sowing date; seven, four and five at late sowing date; seven, three and seven at the combined analysis expressed significant positive \hat{S}_{ij} effects for 100-kernel weight for the T_1 , T_2 and T_3 , respectively. Moreover, the most desirable \hat{S}_{ij} effects for this trait were obtained for the top crosses $T_1 \times L_1$, $T_1 \times L_{12}$ and $T_1 \times L_{12}$ at early, late sowing dates as well as the combined analysis, respectively.

It could be concluded that the tester L_{100} was the best among all testers for this trait since it exhibited the largest number of significant positive \hat{S}_{ij} effects, in addition this tester T_1 expressed the best \hat{S}_{ij} effect over all crosses and had the widest range of \hat{S}_{ij} effect. In this respect, **Zambezi *et al.* (1986)** pointed out that inbred testers are preferred over broad base testers and mentioned two practical reasons for preferring inbred line (narrow base) testers to broad-base testers. First, sampling errors are likely to occur with heterogeneous testers. Second, use of an inbred line or (single cross) tester may permit quicker utilization of new lines in commercial hybrids especially if the tester is already in commercial use.

Concerning ear weight, seven, eight and nine top crosses at early sowing date; eight, seven and seven at late sowing date; eight, seven and nine top crosses at the combined analysis expressed significant positive \hat{S}_{ij} effects for T_1 , T_2 and T_3 ,

respectively. The most desirable \hat{S}_{ij} effects were recorded for the top crosses $T_1 \times L_{17}$ and $T_2 \times L_5$ at early sowing date; $T_1 \times L_{18}$, $T_2 \times L_{12}$ and $T_3 \times L_9$ at late sowing date; and $T_1 \times L_{13}$ and $T_2 \times L_{12}$ at the combined analysis.

Regarding shelling percentage, the top crosses $T_2 \times L_{19}$ at early sowing; $T_1 \times L_3$, $T_2 \times L_9$, $T_2 \times L_{18}$ and $T_3 \times L_{13}$ at late sowing date; $T_1 \times L_{13}$, $T_2 \times L_9$, $T_2 \times L_{18}$, and $T_3 \times L_{13}$ at the combined analysis exhibited significant positive \hat{S}_{ij} effects. The other top crosses exhibited either significant negative or insignificant \hat{S}_{ij} effects for this trait.

For grain yield/ plant, five, seven and six top crosses at early sowing date; six, six and six top crosses at late sowing date; seven, six and eight top crosses at the combined analysis for testers T_1 , T_2 and T_3 , respectively. The best \hat{S}_{ij} effects were obtained from top crosses $T_1 \times L_{17}$, $T_2 \times L_5$, $T_2 \times L_{12}$ and $T_3 \times L_{15}$ at early sowing date; $T_1 \times L_{18}$, $T_2 \times L_{12}$ and $T_3 \times L_6$ at late sowing date; $T_2 \times L_{12}$ and $T_1 \times L_{17}$ at the combined analysis. Furthermore, the tester T_2 (S.C El-Hosary 101) exhibited the widest range between \hat{S}_{ij} effects for this trait at the combined analysis. Therefore, the immediate use of lines L_4 , L_5 , L_{10} and L_{12} as parents in the development of three way crosses with T_2 (S.C El-Hosary 101). Also, the immediate use of lines L_7 , L_{13} and L_{17} as parents in development of single crosses with T_1 (L_{100}).

Table (7): Specific combining ability effects for all top crosses at separate sowing dates as well as the combined analysis.

4.4. Heterosis:

Heterosis for grain yield/ plant was computed for individual top crosses as the percentage increase of hybrid performance relative to T.W. G 352, S.C. Pioneer 3080 and S.C. G 155 at early, late sowing date and the combined over them (Table8).

Eight, forty one and twenty top crosses expressed significant and positive heterotic effects in early, late sowing dates as well as the combined analysis relative to T.W. G 352. However, most desirable heterotic effects were detected for the top crosses $T_1 \times L_{13}$, $T_1 \times L_{17}$, $T_2 \times L_5$, $T_2 \times L_{10}$, $T_2 \times L_{12}$ and $T_3 \times L_{10}$ at both sowing dates and the combined analysis. The useful heterotic effects relative to T.W. G 352 ranged from -31.8 to 17.42, -11.63 to 65.32 and -17.12 to 30.62% at early, late sowing dates and the combined over them, respectively.

Regarding useful heterotic effects relative to S.C G 155, zero, fifty eight and nineteen top crosses exhibited significant and positive values for grain yield/ plant at early, late sowing dates as well as the combined analysis, respectively. Eight top crosses at early sowing dates did not differ significant compared S.C. G 155. However, the best heterotic effects were obtained for the top crosses $T_1 \times L_7$, $T_1 \times L_{13}$, $T_1 \times L_{17}$, $T_2 \times L_4$, $T_2 \times L_5$, $T_2 \times L_{10}$ and $T_2 \times L_{12}$ in the combined data. The useful heterotic effects relative to S.C. G 155 ranged from -39.37 to 4.38, -11.29 to 106.82, and -17.49 to 30.03% at early, late sowing dates and the combined analysis, respectively.

Regarding useful heterotic effects relative to S.C. Pioneer 3080 Zero, twenty six and three top crosses exhibited significant and positive values for grain yield/ plant at early, late sowing date as well as the combined analysis, respectively. Also, five, twelve and eight top crosses did not differ significant compared S.C. Pioneer 3080 in the same order. Insignificant useful heterotic effects in these top crosses revealed that a hybrid program based on these materials may be useful for testing under different location and years. However, the best useful heterotic

effects were obtained for the top crosses $T_1 \times L_{13}$, $T_1 \times L_{17}$ and $T_2 \times L_{12}$ in the combined data. The heterotic effects relative to S.C. Pioneer 3080 ranged from -41.09 to 1.42, -39.22 to 41.69 % and -28.62 to 12.49% at early, late sowing dates as well as the combined analysis. Hence, it could be concluded that the previous top crosses offer possibility for improving grain yield in maize. Many investigators reported useful heterosis for yield in maize *Shehata et al. (1997)*, *Mahmoud et al. (2001)*, *Amer et al. (2002)*, *Mosa et al. (2004)* and *Abd El-Moula (2005)*.

Table(8): Heterosis for grain yield relative to T.W. 352 at first and second sowing date as well as combined analysis.

SUMMARY

SUMMARY

The main objectives of the present work were to evaluate inbred lines of maize through Line x tester analysis.

The experimental work of this study was carried out at the Experiment Research Station of Moshtohor, Benha University, Qalyubiya Governorate, Egypt during the two successive seasons 2006 and 2007.

A total of twenty (*Zea mays* L.) yellow inbred lines were used to establish the experiment materials for several characters among inbred lines under study. These lines were selected on bases of yielding ability and other desirable plant aspects. The plant materials were selected with a wide range of diversity for several traits. Three testers of yellow maize were used in this investigation to make all possible line x tester crosses. The three testers used in this study were chosen to represent wide difference in relation to the tested lines. i.e. (Gem. Pop.) representing broad genetic base, single cross (Elhosary 101) representing approximately narrow genetic base and the inbred line 100 representing narrow genetic base. Three check varieties were used in this investigation their names are single cross Giza 155, S. C. Pioneer 3080 and three way cross Giza 352.

In the first summer season 2006 seeds of the twenty inbred lines and three testers were split sown on 25th May, 30th May and 8th June to avoid differences in flowering time and to secure enough hybrid seed. All possible top crosses combinations were made between the twenty inbred lines and three testers by hand method giving a total of 60 top crosses.

Each top cross was constituted by collecting pollen from 40-50 protected tassels, representing the tester, then top crossing into protected silks of 15 plants, representing the inbred lines by hand pollinating.

In the second summer, season 2007 two adjacent experiments were conducted on two sowing dates. i.e. 15th June and 4th July. In each experiment the 60 top crosses as well as the three check hybrids (S.C. G.155, S.C Pioneer 3080 and T.W.C. G.352) were grown in a randomized complete block design with three replications.

Recorded data were days to 50% tasseling (tasseling date), days to 50% silking (silking date), maturity date, plant height (cm), ear height (cm), leaf area of upper ear (cm²), ear husk, ear length (cm), ear diameter (cm), number of rows/ear, number of kernel/row, weight of 100-kernel (g), ear weight/plant, grain yield per plant (g) adjusted at 15.5 % moisture content and shelling percentage was computed as 100 x (grain weight /ear weight). Line x tester analysis was used according to Kempthorne (1957).

The results of the present study could be summarized as follows:

A) Analysis of variance

Sowing dates mean squares were significant for all traits except number of rows/ ear, number of kernels/ row and shelling percentage.

Crosses mean squares were significant for all the studied traits at both sowing dates as well as the combined analysis except ear diameter at early sowing date. Significant crosses x sowing date mean squares were obtained for all traits except ear height, ear husk, and ear diameter.

Lines mean squares were significant for all traits at early and late sowing dates as well as the combined over them. Significant lines x sowing date mean squares were detected for all traits except tasseling date, ear height, ear husk, ear diameter and shelling%.

Significant mean squares due to testers were obtained for all traits in both sowing dates as well as the combined analysis except maturity date at both sowing dates as well as the combined analysis; tasseling date, silking date, leaf area of upper

ear, ear diameter, number of kernels/ row at early sowing, and ear length at early sowing date and the combined analysis. In addition, lines mean squares were much higher than those of testers for most studied traits. Such results revealed that lines contributed much more to the total variation as compared to testers. Therefore, the total GCA variance was due to inbred lines(GCA variance) for most traits.

The interaction between tester x sowing date mean squares were significant for silking date, leaf area of upper ear, ear length, ear diameter, no. of kernels/ row, ear weight/ plant, 100-kernel weight and grain yield/ plant.

Significant line x tester mean squares were detected for all traits except ear diameter at both sowing dates as well as the combined analysis; ear husk, number of rows/ ear and number of kernels/ row at late sowing date and shelling percentage at early sowing date. Significant interaction between line x tester x sowing date mean squares were obtained for tasseling and silking dates, plant height, leaf area of upper ear, no. of rows/ ear, 100-kernel weight, shelling percentage, ear weight/ plant and grain yield/ plant.

B) Mean performance:

The top cross $T_1 \times L_1$ at early sowing date had earlier than the best check variety S.C. Pioneer 3080. While, the top crosses $T_3 \times L_{14}$, $T_1 \times L_1$ and $T_3 \times L_{16}$ gave the lowest mean values compared with other genotypes at late sowing date. The top crosses $T_1 \times L_1$, $T_1 \times L_{13}$ and $T_3 \times L_{14}$ gave the lowest mean values for tasseling date at the combined data.

For silking date, the top crosses $T_1 \times L_1$, $T_1 \times L_{13}$, $T_2 \times L_{12}$ and $T_3 \times L_{10}$ gave the lowest mean values for this trait at the combined data.

Regarding maturity date, the top crosses $T_1 \times L_1$, $T_1 \times L_6$, $T_2 \times L_7$, $T_2 \times L_9$, $T_2 \times L_{10}$, $T_2 \times L_{18}$, $T_3 \times L_6$, $T_3 \times L_{10}$ and $L_3 \times L_{12}$ expressed the lowest significant values of maturity date and it were the earliest among the studied top crosses at the combined

analysis. For number of rows/ ear, the top crosses T₂xL₅ at early sowing date; T₂xL₄, T₃xL₅ and T₃xL₆ at late sowing date; T₁xL₁₃, T₂xL₅ and T₃xL₅ at the combined analysis exhibited significant higher than the best check hybrid. For number of kernels/row, with the exception of crosses T₁xL₃, T₂xL₁₁, T₂xL₂₀, T₃xL₆, T₃xL₉ and T₃xL₁₂ at late sowing dates, none of top crosses surpassed the best check hybrids in early, late sowing dates as well as the combined analysis. For 100-kernel weight, the top crosses T₁xL₁, T₁xL₃, T₁xL₁₂, T₃xL₃ and T₃xL₁₀ at early sowing date, T₁xL₁₂, T₂xL₃, T₂xL₁₅, T₃xL₃, T₃xL₁₃ and T₃xL₁₉ at late sowing date and T₁xL₁, T₁xL₇, T₁xL₁₂, T₂xL₃, T₂xL₁₅, T₃xL₃ and T₃xL₁₉ at the combined analysis exhibited significantly higher than the best check hybrid S.C. G 155. For shelling percentage, none of the studied top crosses significantly exceeded that of the best of check hybrid. For grain yield/ plant, the highest mean values were recorded by S.C. Pioneer 3080 at early sowing date but without significant superiority over those of hybrids T₁xL₁₃, T₁xL₁₇, T₂xL₅, T₂xL₁₀, T₂xL₁₂ and T₂xL₁₄. While, twenty six and three top crosses exhibited significantly higher than the best check hybrid S.C. Pioneer 3080 at late sowing date and the combined analysis, respectively. However, the best top crosses were T₁xL₁₃, T₁xL₁₇ and T₂xL₁₂ at the combined data.

C) Combining ability:

Results indicated that σ^2 SCA was more important than σ^2 GCA for all studied traits in both sowing dates as well as the combined analysis except tasseling date and number of rows/ ear in the combined analysis and ear diameter at early sowing date and ear husk at late sowing date σ^2 GCA = σ^2 SCA revealing that additive and non additive gene effects was similar for controlling this trait .

The magnitude of the interaction between specific combining ability and sowing dates was much higher than that of interaction between general combining and sowing dates for all traits except ear height, ear husk and number of rows/ ear.

C) 1. General Combining ability effect

Testers:

The tester T₁ (L 100) exhibited significant desirable (\hat{g}_i) effects for plant and ear heights and 100-Kernel weight at early and late sowing dates as well as the combined data; ear diameter, ear weight/plant and grain yield/plant at late sowing date and the combined data, and ear length at late sowing date.

The parental tester S.C. (Elhosary 101) expressed significant positive (\hat{g}_i) effects for leaf area of upper ear and shelling percentage at late sowing date and the combined data and ear husk at early sowing date and the combined data; ear weight, grain yield/ plant and 100-Kernel weight at early sowing date, Also, it gave significant positive (undesirable) (\hat{g}_i) effects at late sowing date and the combined data for tasseling date and late sowing date for silking date. However, it gave insignificant (\hat{g}_i) effects for other cases.

Parental tester (Gem. pop.) expressed significant desirable (\hat{g}_i) effects for number of rows/ ear in both sowing dates and the combined data; and leaf area of upper ear at late sowing date; tasseling date and silking date at late sowing date and the combined data. Also, it gave significant undesirable or insignificant (\hat{g}_i) effects for other cases.

Inbred lines:

The parental inbred lines L₁ and L₁₃ exhibited the highest (\hat{g}_i) effects for tasseling and silking dates in both sowing dates as well as the combined data. Moreover, both inbred lines L₁ and L₁₃ were the best combiners for both traits together. For maturity date, the parental inbred lines L₆ and L₁₀ seemed to be the best combiners for earliness in both sowing dates as well as the combined analysis. For number of rows/ ear the lines L₅, L₆ and L₁₃ were the best combiners inbred lines in both sowing dates as well as the combined data.

For no. of Kernels/ row, the best general combiners which had significant and positive (\hat{g}_i) effects were the parental inbred

lines L₁₁ and L₁₂ in both sowing dates and the combined over them. The most desirable (\hat{g}_i) effects for 100-kernel weight this trait were detected for the parental inbred lines L₃ followed by L₁₉ in both sowing dates and the combined data. The most desirable combiners for ear and grain yields/ plant were the inbred lines L₅ and L₁₃ in both sowing dates and the combined analysis.

C) 2. Specific combining ability effects:

For tasseling date the most desirable SCA effects were obtained for the top crosses T₁xL₁, T₂xL₁₅ and T₂xL₁₉ at early sowing date; T₁xL₇, T₁xL₁₉, T₂xL₃, T₂xL₁₂, T₃xL₂, T₃xL₁₀, T₃xL₁₄ and T₃xL₁₆ at late sowing date, and T₁xL₁, T₂xL₃, T₂xL₁₉, T₃xL₁₀ and T₃xL₁₄ at The combined analysis. Regarding to silking date, the most desirable SCA effects for this trait were obtained for the top crosses T₁xL₁ at early sowing date; T₂xL₃ and T₂xL₁₂ at late sowing date and the combined analysis. For maturity date, the top crosses T₁xL₁ at early, late sowing date and the combined analysis; T₃xL₁₅ at early sowing date and the top cross T₃xL₁₇ at late sowing date and the combined analysis had the most desirable \hat{S}_{ij} effects for this trait. For number of rows/ ear, the top crosses T₁xL₁₃, T₁xL₁₄, T₂xL₆ and T₃xL₁₀ at early sowing date; T₁xL₁₃, T₂xL₄ and T₃xL₆ at late sowing date and T₁xL₁₃, T₂xL₄, T₂xL₆, T₃xL₃ and T₃xL₁₀ at the combined analysis had the most desirable \hat{S}_{ij} effects for this trait. Regarding number of kernels/ row, the top crosses T₁xL₁₆ and T₃xL₁₆ at early sowing; T₁xL₁₈, T₂xL₁₅ and T₂xL₂₀ at late sowing date; and T₁xL₁₆, T₂xL₁₅ and T₂xL₂₀ at the combined analysis exhibited significantly positive \hat{S}_{ij} effects for this trait. The most desirable \hat{S}_{ij} effects for 100-kernel weight were obtained for the top crosses T₁xL₁, T₁xL₁₂ and T₁xL₁₂ at early, late sowing dates as well as the combined data, respectively. Concerning ear weight, the most desirable \hat{S}_{ij} effects were recorded for the top crosses T₁xL₁₇ and T₂xL₅ at early sowing date; T₁xL₁₈, T₂xL₁₂ and T₃xL₉ at late sowing date; T₁xL₁₃ and T₂xL₁₂ at the combined analysis. For grain yield/ plant, the best \hat{S}_{ij} effects were obtained

from top crosses $T_1 \times L_{17}$, $T_2 \times L_5$, $T_2 \times L_{12}$ and $T_3 \times L_{15}$ at early sowing date; $T_1 \times L_{18}$, $T_2 \times L_{12}$ and $T_3 \times L_6$ at late sowing date; $T_2 \times L_{12}$ and $T_1 \times L_{17}$ at the combined analysis.

D) Useful heterosis:

Regarding useful heterotic effects relative to S.C G 155, zero, fifty eight and nineteen top crosses exhibited significant and positive values for grain yield/ plant at early, late sowing dates as well as the combined analysis, respectively. The eight top crosses at early sowing dates did not differ significant compared S.C. G 155. However, the best heterotic effects were obtained for the top crosses $T_1 \times L_7$, $T_1 \times L_{13}$, $T_1 \times L_{17}$, $T_2 \times L_4$, $T_2 \times L_5$, $T_2 \times L_{10}$ and $T_2 \times L_{12}$ in the combined data. The useful heterotic effects relative to S.C. G 155 ranged from -39.37 to 4.38, -11.29 to 106.82, and -17.49 to 30.03% at early, late sowing date and the combined analysis, respectively.

Regarding useful heterotic effects relative to S.C. Pioneer 3080 Zero, twenty six and three top crosses exhibited significant and positive values for grain yield/ plant at early, late sowing date as well as the combined analysis, respectively. However, the best useful heterotic effects were obtained for the top crosses $T_1 \times L_{13}$, $T_1 \times L_{17}$ and $T_2 \times L_{12}$ in the combined data. The heterotic effects relative to S.C. Pioneer 3080 ranged from -41.09 to 1.42, -39.22 to 41.69% and -28.62 to 12.49% at early, late sowing date as well as the combined analysis.

ARABIC SUMMARY

المخلص العربى

أجريت هذه الدراسة بهدف تقييم مجموعة من سلالات الذرة الشامية الصفراء و قد أجريت هذه الدراسة فى محطة البحوث و التجارب الزراعية بمشهر - جامعة بنها خلال موسمى الزراعة ٢٠٠٦, ٢٠٠٧.

اشتملت هذه الدراسة على عشرون سلالة صفراء متباعدة وراثيا و مستنبطة لقدرتها الإنتاجية العالية و صفاتها الأخرى المرغوبة.

استخدمت لهذه الدراسة ثلاثة كشافات من الذرة الصفراء هى (عشيرة- جميلة) ذات قاعدة وراثية عريضة و هجين فردى (El-Hosary 101) و السلالة النقية (L100) ذات قاعدة وراثية ضيقة و استخدمت ثلاثة هجن للمقارنة هى (هجين فردى جيزة ١٥٥, هجين فردى ببونير ٣٠٨٠ و هجين ثلاثى ٣٥٢).

وفى موسم ٢٠٠٦ تم زراعة العشرين سلالة و الثلاثة كشافات فى ثلاثة مواعيد للزراعة للتغلب على الاختلافات فى مواعيد التزهير و الحصول على كمية حبوب كافية و تم إجراء كل التهجينات الممكنة بينهما و الحصول على ٦٠ هجين قمى و فى موسم صيف ٢٠٠٧ تم تقييم جميع الهجن القمية و عددها ٦٠ هجينا بالإضافة إلى ثلاثة هجن للمقارنة فى ميعادين للزراعة ١٥ يونيو، ٤ يولييه باستخدام تصميم قطاعات كاملة العشوائية فى ثلاثة مكررات.

وكانت الصفات تحت الدراسة هى:-

عدد الأيام من الزراعة حتى ظهور ٥٠% من النورة المذكرة و المونثة، عدد الأيام من الزراعة حتى النضج، ارتفاع النبات، ارتفاع الكوز، مساحة ورقة الكوز العلوى، طول أغلفة الكوز، طول الكوز، قطر الكوز، عدد صفوف الكوز،

عدد حبوب الصف، وزن ١٠٠ حبة، وزن الكوز و الحبوب للنبات، النسبة المئوية للتقريب.

و قد أجرى التحليل الإحصائي طبقاً لطريقة كمبثورن عام ١٩٥٧ و يمكن تلخيص أهم النتائج فيما يلي:

(١) تحليل التباين.

١- كان التباين الراجع إلى مواعيد الزراعة معنوي لكل الصفات ماعدا عدد صفوف الكوز، عدد حبوب الصف و النسبة المئوية للتقريب.

٢- كان التباين الراجع إلى الهجن معنوي لكل الصفات في ميعادى الزراعة و كذلك التحليل التجميعي بينهما ما عدا صفة قطر الكوز في الميعاد المبكر للزراعة.

٣- كان التباين الراجع إلى تفاعل الهجن \times مواعيد الزراعة معنوي لكل الصفات ماعدا ارتفاع الكوز و طول أغلفة الكوز و قطر الكوز.

٤- كان التباين الراجع إلى السلالات معنويًا لكل الصفات في ميعادى الزراعة و كذلك التحليل التجميعي بينهم.

٥- كان التباين الراجع إلى السلالات \times مواعيد الزراعة معنويًا لكل الصفات ماعدا صفة ميعاد طرد النورة المذكورة و ارتفاع الكوز و طول أغلفة الكوز و قطر الكوز و النسبة المئوية للتقريب.

٦- كان التباين الراجع إلى الكشافات معنويًا لكل الصفات في ميعادى الزراعة و كذلك التحليل التجميعي لهما ما عدا ميعاد النضج في كل من ميعادى الزراعة و التحليل التجميعي. وميعاد طرد النورة المذكورة و المؤنثة و مساحة ورقة الكوز و قطر الكوز و عدد الحبوب في الصف في الميعاد المبكر و طول الكوز في الميعاد المبكر و التحليل التجميعي. بالإضافة إلى ذلك كان التباين

الراجع إلى السلالات عالية عن التباين الراجع إلى الكشافات لكل الصفات المدروسة. لذلك كان التباين الكلي للقدرة العامة على التألف راجعا إلى تباين القدرة العامة على التألف للسلالات.

٧- كان التفاعل بين الكشافات x السلالات معنويا لكل الصفات تحت الدراسة عدد قطر الكوز في ميعادى الزراعة و التحليل المشترك, طول أغلفة الكوز, عدد صفوف الكوز و عدد الحبوب في الصف في الميعاد المتأخر و نسبة التقريب في الميعاد المبكر. بينما كان التفاعل بين السلالات x الكشافات x مواعيد الزراعة معنوي بالصفات ميعاد طرد النورة المذكورة و المؤنثة, ارتفاع النبات, مساحة ورقة الكوز, عدد صفوف الكوز, وزن ١٠٠ حبة والنسبة المئوية للتقريب ووزن الكوز و الحبوب للنبات.

(ب) متوسط الأداء

١- كان الهجين القمي $T_1 \times L_1$ ابرك الهجن مقارنة بالهجين الفردي بيونير ٣٠٨٠ في ميعاد طرد النورة المذكورة في الميعاد المبكر بينما أظهرت الهجن القمية $T_1 \times L_1$, $T_3 \times L_{16}$, $T_3 \times L_{14}$ فروق معنوية عن الهجن الأخرى في الميعاد المتأخر و كان افضل الهجن القمية في التحليل التجميعي هي $T_1 \times L_1$, $T_1 \times L_{13}$, $T_3 \times L_{14}$ لصفة ميعاد طرد النورة المذكورة

٢- أظهرت الهجن القمية $T_1 \times L_1$, $T_1 \times L_{13}$, $T_2 \times L_{12}$, $T_3 \times L_{10}$ فروق معنوية لصفة ميعاد طرد النورة المؤنثة في التحليل التجميعي.

٣- كانت الهجن القمية $T_1 \times L_1$, $T_1 \times L_6$, $T_2 \times L_7$, $T_2 \times L_9$, $T_2 \times L_{10}$, $T_2 \times L_{18}$, $T_3 \times L_6$, $T_3 \times L_{10}$, $T_3 \times L_{12}$ أفضل الهجن بالنسبة لصفة ميعاد النضج في التحليل التجميعي .

٤- أظهرت الهجن القمية $T_1 \times L_{14}$, $T_2 \times L_3$, $T_2 \times L_{11}$, $T_3 \times L_{11}$, $T_3 \times L_{18}$ فى التحليل التجميى فروق معنوية عالية مقارنة بأفضل هجين فردى للمقارنة بيونير ٣٠٨٠ وذلك بالنسبة لصفة طول الكوز .

٥- لم تظهر أى من الهجن القمية فروق معنوية مقارنة بهجن المقارنة فى كلاً الميعادين وأيضاً التحليل التجميى لهما وذلك لصفة قطر الكوز .

٦- أظهرت الهجن القمية $T_2 \times L_5$ فى الميعاد المبكر, $T_2 \times L_4$, $T_3 \times L_5$, $T_3 \times L_6$ فى الميعاد المتأخر, $T_1 \times L_{13}$, $T_2 \times L_5$, $T_3 \times L_5$ فى التحليل التجميى فروق معنوية عالية عن أفضل هجين للمقارنة لصفة عدد صفوف الكوز .

٧- أظهرت الهجن القمية $T_1 \times L_3$, $T_2 \times L_{11}$, $T_2 \times L_{20}$, $T_3 \times L_6$, $T_3 \times L_9$ فى الميعاد المتأخر أفضل قيمة بالنسبة لصفة عدد حبوب /الصف ولم يتفوق أى هجين قمى على هجن المقارنة.

٨- بالنسبة لصفة وزن المائة حبة أظهرت الهجن القمية, $T_1 \times L_{12}$, $T_1 \times L_3$, $T_1 \times L_{12}$, $T_2 \times L_3$, T_2 , $T_3 \times L_{10}$, $T_3 \times L_3$, $T_1 \times L_1$, $T_1 \times L_1$, $T_1 \times L_7$, $T_3 \times L_{15}$, $T_3 \times L_3$, $T_3 \times L_{13}$, $T_3 \times L_{19}$ فى التحليل التجميى فروق معنوية عن أفضل هجين مقارنة لهذه الصفة (هجين فردى جيزة ١٥٥).

٩- أعطى الهجين الفردى بيونير ٣٠٨٠ أعلى قيمة لمحصول النبات الفردى فى الميعاد المبكر بدون تفوق معنوى عن الهجن القمية $T_2 \times L_5$, $T_2 \times L_{10}$, L_{12} بينما اعطت ستة و عشرون و ثلاث هجن قمية زيادة معنوية فى المحصول عن أفضل هجن المقارنة هجين فردى بيونير ٣٠٨٠ فى الميعاد المتأخر و التحليل المشترك على التوالى. و كانت الثلاثة هجن

المباشرة و المتفوقة هي $T_1 \times L_{13}$, $T_1 \times L_{17}$, $T_2 \times L_{12}$ فى التحليل المشترك.

ج - القدرة على التألف :-

- أوضحت النتائج أن القدرة الخاصة على التألف كانت أكثر أهمية من القدرة العامة وذلك بالنسبة لكل الصفات فى ميعادى الزراعة وأيضاً التحليل التجميعى لهما ما عدا صفة ميعاد طرد النورة المذكرة وعدد صفوف الكوز فى التحليل التجميعى وكذلك صفة قطر الكوز فى الميعاد المبكر .

- كان قيمة التفاعل بين القدرة الخاصة على التألف \times مواعيد الزراعة أعلى من تفاعل القدرة العامة على التألف \times مواعيد الزراعة بالنسبة لكل الصفات ما عدا ارتفاع الكوز ، طول أغلفة الكوز ، وعدد صفوف الكوز .

ج ١ - القدرة العامة على التألف :-

- الكشافات

- أعطى الكشاف T_1 (السلالة ١٠٠) تأثيرات معنوية للقدرة العامة على التألف لصفة ارتفاع النبات ، ارتفاع الكوز ، وزن ١٠٠ حبة فى كلا الميعادين وكذلك التحليل التجميعى لهما و صفة قطر الكوز ، وزن الكوز للنبات ، ومحصول الحبوب للنبات فى الميعاد المتأخر والتحليل التجميعى و صفة طول الكوز فى الميعاد المتأخر .

- أعطى الكشاف الهجين الفردى تأثيرات موجبة ومعنوية للقدرة العامة على التألف لصفات مساحة ورقة الكوز ، النسبة المئوية للتفريط فى الميعاد المتأخر والتحليل التجميعى و صفة طول أغلفة الكوز للميعاد المبكر والتحليل التجميعى ووزن الكوز ومحصول الحبوب للنبات ووزن ١٠٠ حبة فى الميعاد المبكر . وأيضاً أعطى تأثيرات موجبة ومعنوية (غير مرغوبة) للقدرة العامة على

التألف بالميعاد المتأخر والتحليل التجميحي لصفة ميعاد طرد النورة المذكورة
وفى الميعاد المتأخر لصفة ميعاد خروج النورة المؤنثة .

- أعطى الكشاف (عشيرة- جميزه) تأثيرات موجبة ومعنوية للقدرة العامة على
التألف لصفة عدد صفوف الكوز فى كلا ميعادين الزراعة والتحليل التجميحي
لهما و صفة مساحة ورقة الكوز فى الميعاد المتأخر و صفة ميعاد خروج
النورة المذكورة والمؤنثة فى الميعاد المتأخر وكذلك التحليل التجميحي لهما .

- السلالات

- أظهرت السلالتان L_{13} , L_1 تأثيرات سالبة وعالية المعنوية للقدرة العامة على
التألف لصفة عدد الأيام حتى ظهور ٥٠ % من النورة المذكورة والمؤنثة فى
كلا الميعادين وأيضا التحليل التجميحي لهما .

- أظهرت السلالتان L_{10} , L_6 تأثيرات سالبة وعالية المعنوية للقدرة العامة على
التألف لصفة ميعاد النضج فى كلا الميعادين وأيضا التحليل التجميحي لهما .

- أظهرت السلالة L_{11} فى كلا ميعادين الزراعة وأيضا التحليل التجميحي لهما
تأثيرات موجبة ومعنوية للقدرة العامة على التألف لصفة طول الكوز . بينما
أعطت السلالة L_{19} تأثيرات موجبة ومعنوية للقدرة العامة على التألف لصفة
قطر الكوز فى كلا ميعادين الزراعة وأيضا التحليل التجميحي لهما .

- أظهرت السلالات L_{13} , L_6 , L_5 تأثيرات موجبة ومعنوية للقدرة العامة على
التألف لصفة عدد صفوف الكوز فى كلا ميعادين الزراعة وأيضا التحليل
التجميحي لهما .

- أظهرت السلالة L_{11} يليها L_{12} فى كلا ميعادين الزراعة وأيضا التحليل
التجميحي لهما تأثيرات موجبة ومعنوية للقدرة العامة على التألف بالنسبة لصفة
عدد حبوب الصف .

- بالنسبة لصفة وزن المائة حبة أظهرت السلالة L_3 يليها L_{19} في كلا ميعادى الزراعة وأيضا التحليل التجميى أفضل تأثيرات للقدرة العامة على التآلف لهذه الصفة .

- أظهرت السلالتان L_{13} , L_5 أفضل تأثيرات للقدرة على التآلف لصفتين وزن الكوز ومحصول الحبوب للنبات فى كلا ميعادين الزراعة وأيضا التحليل التجميى لهما .

(ج) ٢ - القدرة الخاصة على التآلف :-

- أمكن الحصول على أفضل تأثيرات للقدرة الخاصة على التآلف بالنسبة لصفة عدد الأيام حتى ظهور ٥٠% من النورة المذكورة فى الهجن القمية التالية $T_1 \times L_{19}$, $T_2 \times L_{12}$, $T_2 \times L_3$, $T_1 \times L_{15}$, $T_2 \times L_{19}$ فى الميعاد المبكر و $T_3 \times L_{16}$, $T_3 \times L_{14}$, $T_3 \times L_{10}$, $T_3 \times L_2$ فى الميعاد المتأخر و $T_1 \times L_1$, $T_2 \times L_3$, $T_3 \times L_{14}$, $T_3 \times L_{10}$, $T_2 \times L_{19}$ فى التحليل التجميى. كما أمكن الحصول على أفضل تأثيرات للقدرة الخاصة على التآلف لصفة عدد الأيام حتى ظهور ٥٠% من النورات المؤنثة فى الهجن التالية $T_1 \times L_1$ فى الميعاد المبكر, $T_2 \times L_3$ فى الميعاد المتأخر وأيضا التحليل التجميى لهما.

- أمكن الحصول على تأثيرات للقدرة الخاصة على التآلف بالنسبة لصفة ميعاد النضج فى الهجن التالية $T_1 \times L_1$ فى الميعاد المبكر و المتأخر وكذلك التحليل المشترك, $T_3 \times L_{15}$, $T_1 \times L_1$ فى الميعاد المبكر و الهجين $T_3 \times L_{17}$ فى الميعاد المتأخر وأيضا فى التحليل التجميى لكلا الميعادين.

- بالنسبة لصفة عدد صفوف الكوز أعطت الهجن القمية التالية أفضل تأثيرات للقدرة الخاصة على التآلف $T_3 \times L_{10}$, $T_2 \times L_6$, $T_1 \times L_{14}$, $T_1 \times L_{13}$ فى الميعاد المبكر ; $T_3 \times L_6$, $T_2 \times L_4$, $T_1 \times L_{13}$ فى الميعاد المتأخر ; $T_3 \times L_{10}$, $T_3 \times L_3$, $T_2 \times L_6$, $T_2 \times L_4$ فى التحليل التجميى .

- أمكن الحصول على أفضل تأثيرات للقدرة الخاصة على التآلف لصفة عدد حبوب الصف في الهجن القمية التالية $T_1 \times L_{16}$, $T_3 \times L_{16}$ في الميعاد المبكر ; $T_1 \times L_{13}$, $T_2 \times L_{15}$, $T_2 \times L_{20}$ في الميعاد المتأخر ; $T_1 \times L_5$, $T_1 \times L_{16}$ في الميعاد المتأخر و $T_2 \times L_{20}$, $T_2 \times L_{15}$ في التحليل التجميعي لكلا الميعادين .

- بالنسبة لصفة وزن المائة حبة أظهرت الهجن القمية $T_1 \times L_1$, $T_1 \times L_{12}$, $T_1 \times L_{12}$ تأثيرات موجبة للقدرة الخاصة على التآلف في الميعاد المبكر و المتأخر و كذلك في التحليل المشترك فلى التوالى.

- أمكن الحصول على أفضل تأثيرات للقدرة الخاصة على التآلف لصفة وزن الكوز للنبات في الهجن القمية التالية

$T_1 \times L_{17}$, $T_2 \times L_5$ في الميعاد المبكر ; $T_3 \times L_9$, $T_2 \times L_{12}$, $T_1 \times L_{18}$ في الميعاد المتأخر ; $T_2 \times L_{12}$, $T_1 \times L_{18}$ في التحليل التجميعي .

- أمكن الحصول على أفضل تأثيرات للقدرة الخاصة على التآلف لصفة محصول الحبوب للنبات في الهجن القمية التالية $T_3 \times L_5$, $T_2 \times L_{12}$, $T_2 \times L_5$, $T_1 \times L_{17}$ في الميعاد المبكر ;

$T_3 \times L_6$, $T_2 \times L_{12}$, $T_1 \times L_{18}$ في الميعاد المتأخر $T_1 \times L_{17}$, $T_2 \times L_{12}$; في التحليل التجميعي لهما .

(د) قوة الهجين :-

- أمكن الحصول على أعلى قوة هجين مرغوبة لمحصول الحبوب للنبات بالنسبة للهجين الفردى جيزة ١٥٥ في الهجن القمية التالية

$T_2 \times L_{10}$, $T_2 \times L_5$, $T_2 \times L_4$, $T_1 \times L_{17}$, $T_1 \times L_{13}$, $T_1 \times L_7$ في التحليل التجميعي .

- تراوحت قوة الهجين بالنسبة للهجين الفردي جيزة ١٥٥ من -٣٩,٣٧ إلى ٤,٣٨ ،
-١١,٢٩ إلى ١٠٦,٨٢ ، -١٧,٤٩ إلى ٣٠,٠٣ % فى كلا من الميعادين
المبكر والمتأخر وكذلك التحليل التجميعى بينهما على الترتيب .

- أمكن الحصول على أعلى قوة هجين مرغوبة لمحصول الحبوب للنبات بالنسبة
للهجين الفردي بيونير ٣٠٨٠ فى الهجن القمية التالية $T_{1 \times L_{13}}$ ، $T_{1 \times L_{17}}$ ،
 $T_{2 \times L_{12}}$ فى التحليل التجميعى .

- تراوحت قوة الهجين بالنسبة للهجين الفردي بيونير ٣٠٨٠ بين -٤١,٠٩ إلى
١,٤٢ ، -٣٩,٢٢ إلى ٤١,٦٩ ، -٢٨,٦٢ إلى ١٢,٤٩ % فى كلا
الميعادين المبكر والمتأخر والتحليل التجميعى بينهما على الترتيب .

التحليل الوراثى لبعض الهجن القمية للذرة الشامية

رسالة علمية مقدمة من
