UNITED NATIONS CONFERENCE ON TRADE AND DEVELOPMENT

INFORMATION AND COMMUNICATION TECHNOLOGY DEVELOPMENT INDICES

United Nations New York and Geneva, 2003

www.manaraa.com

NOTE

The UNCTAD Division on Investment, Technology and Enterprise Development serves as a focal point within the United Nations Secretariat for all matters related to foreign direct investment, transnational corporations, enterprise development, and science and technology for development. The current work programme of the Division is based on the mandates set at the Tenth Conference of UNCTAD, held in Bangkok in 2000, as well as on the decisions by the United Nations Commission on Science and Technology for Development, which is serviced by the UNCTAD secretariat. In its work in the area of science and technology and development, contributing to the elucidation of global issues raised by advances in science and technology; promoting international cooperation on science and technology among Governments, enterprises and academic sectors, particularly between those of developed and developing countries and transitional economies; and promoting technological capacity-building and enhancing entrepreneurship and competitiveness in developing countries, particularly the least developed among them.

This publication seeks to contribute to the exploration of current science and technology issues with particular emphasis on their impact on developing countries.

The term "country" as used in this study also refers, as appropriate, to territories or areas; the designations employed and the presentation of the material do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory, city or area, or of its authorities, or concerning the delimitation of its frontiers or boundaries. In addition, the designations of country groups are intended solely for statistical or analytical convenience and do not necessarily express a judgement about the stage of development reached by a particular country or area in the development process.

PREFACE

In conjunction with the work programme of the Commission on Science and Technology for Development (CSTD) for the inter-sessional period 2001–2003 on "Technology development and capacity-building for competitiveness in a digital society", UNCTAD reviewed and evaluated existing work to measure ICT development from different sources, including academia, the private sector and international organizations (UNDP, UNIDO, OECD and ITU). On the basis of this earlier work, a theoretical framework has been formulated with a view to measuring ICT development, including indicators for connectivity, access, usage and policy. The framework was used to benchmark and analyse the diffusion of ICT capabilities across 160-200 countries for 1995-2001. This cross-country study compiles data and calculates ICT Development Indices for the following: connectivity (physical infrastructure for ICTs, in penetration rates of Internet hosts, PCs, telephone mainlines and mobile phones per capita); wider access to ICTs (literacy, GDP per capita and cost of local calls, as well as actual number of Internet users); usage of ICTs (incoming and outgoing telecom traffic, as an alternative to Internet data traffic flows in the absence of publicly available statistics on these); and policy environment (a wider policy framework conducive to the adoption and absorption of ICTs, which can be evaluated in terms of the presence of a domestic Internet exchange, as well as competition in the local loop, domestic long-distance and ISP markets). This study analyses country and regional rankings based on these index measurements, and reviews results over time to identify interesting trends. It also seeks to evaluate the extent and evolution of the digital divide, using basic measures of hardware equipment and numbers of Internet users in each country, to determine how the digital divide is evolving over time.

This paper was prepared by Ms. Philippa Biggs under the guidance of Mr. Mongi Hamdi of the UNCTAD secretariat. Comments were received from Ms. Lorraine Ruffing and Ms. Dong Wu. Production assistance was provided by Ms. Maria Lourdes Pasinos. The cover page was designed by Mr. Diego Oyarzun-Reyes.

Comments were also received during the various stages of preparation of the report from Sanjaya Lall, Calestous Juma, Jean Camp, Alan Porter and Larry Press, as well as from a number of CSTD members.

EXECUTIVE SUMMARY

This report analyses and evaluates information and communication technology (ICT) development using indicators of ICT diffusion across countries. It develops a conceptual framework for and selects key indicators measuring ICT development, with a specific focus on information and communication technologies (ICTs) as pervasive technologies of global impact, wide application and growing potential. Also, it benchmarks levels of existing infrastructure connectivity, as well as measures of future potential and important determinants affecting countries' abilities to absorb, adopt and make use of these rapidly evolving technologies.

The challenges in such a benchmarking exercise are manifold, in the selection of a representative set of indicators measuring the complex concept of technology development; in the "breadth versus depth" trade-off in the nature and number of these indicators; and in the integration of the results of benchmarking into policy analysis. Despite these challenges, used wisely and with caution, benchmarking can provide useful information and meaningful analysis for policy purposes. This cross-country analysis permits comparison between countries and monitoring of progress over time. Comparison with better-performing countries helps identify policies for further improvement and progression. Although benchmarking cannot investigate causation, it nevertheless allows straightforward identification based on evidence of "success stories" for closer investigation yielding policy conclusions. Approached thoughtfully, benchmarking is a useful input to policy analysis in allowing more informed and insightful study of policy and, ultimately, in promoting better, faster and more effective ICT development.

Classification of countries as falling behind, keeping up or getting ahead on the basis of rankings in these indices shows stable rankings over time, with strong regional influences apparent. As a generalization, African and South Asian countries are classified as falling behind, Latin American and transition economies as keeping up and OECD countries and South-East Asian Tigers as getting ahead. However, this classification masks considerable diversity in individual country experience, with Arab and "island States" as notable successes having good connectivity despite less competitive policy measures. Strong positive correlations are observed between connectivity and access and, to a lesser extent, connectivity and competitive telecommunications policy. Country rankings are stable and consistent over time, and in line with expectations based on income. Such stability in rankings is consistent with long-term time horizons required for telecommunications investment. It also implies that these indices are based on indicators measuring central ICT development.

The international digital divide regarding inequality in distributions of hardware equipment and Internet users across countries was also analysed and measured using Gini measures of inequality. Trends in connectivity over time suggest that, despite stable country rankings, there are small reductions in inequality in the distributions of hardware across countries, yielding the intriguing result of a diminishing digital divide. Gini analysis reveals some small, incremental reductions in inequality from highly unequal original levels. Our results show that more recent technologies such as the Internet (as measured by Internet hosts and Internet users) are more unevenly distributed relative to older technologies, such as fixed-line telephony. Our findings demonstrate "leapfrogging" in mobile telephony (with lower levels of inequality than expected, which decrease the fastest), suggesting greater potential for mobiles as more equally distributed technologies in bridging the digital divide.

However, Gini coefficients are relative measures across the whole distribution and do not identify the origins of decreasing inequality. Therefore, relative movements in rankings were analysed to identify how countries and regions are faring in basic connectivity, in order to see which countries are contributing to reducing inequality, increasing inequality or preserving the status quo. On the basis of a regional analysis of relative rankings, OECD countries were found to be more tightly bunched in the upper "tail" of the distribution, while sub-Saharan African countries continue to occupy the lower tail of the distribution. It is therefore likely that the incremental reductions in Gini coefficient derive from the centre of the distribution of hardware equipment across countries. China in particular has a steady and significant rise in relative rankings that influences the Gini coefficient strongly, since China accounts for one fifth of the world's population. It is considered that, taken together, these analyses of the digital divide and the insights derived from benchmarking provide a detailed comprehensive picture of developments in the evolution in countries' ICT development.

Overall, these reductions represent small, incremental reductions in inequality from their original high levels. There is still considerable work to be done in extending ICTs to the large majority of the world's population, so as to bring them within reach of modern communications. However, the benefits of extending ICTs to the world's rural and poorer populations may be enormous.

INFORMATION AND COMMUNICATION TECHNOLOGY DEVELOPMENT INDICES

INTRODUCTION

This report analyses and evaluates information and communication technology (ICT) development using indicators of ICT diffusion across countries. It develops a conceptual framework for and selects key indicators measuring ICT development, with a specific focus on ICTs as pervasive technologies of global impact, wide application and growing potential. Also, it benchmarks levels of existing infrastructure connectivity, as well as measures of future potential and important determinants affecting countries' abilities to absorb, adopt and make use of these new technologies.

In keeping with their complex nature and multiple applications, information and communication technologies (ICTs) may be viewed in different ways. The World Bank defines ICTs as "the set of activities which facilitate by electronic means the processing, transmission and display of information" (Rodriguez and Wilson, 2000). ICTs "refer to technologies people use to share, distribute, gather information and to communicate, through computers and computer networks" (ESCAP, 2001). "ICTs are a complex and varied set of goods, applications and services used for producing, distributing, processing, transforming information - [including] telecoms, TV and radio broadcasting, hardware and software, computer services and electronic media" (Marcelle, 2000). ICTs represent a cluster of associated technologies defined by their functional usage in information access and communication, of which one embodiment is the Internet. Hargittai (1999) defines the Internet technically and functionally as follows: "the Internet is a worldwide network of computers, but sociologically it is also important to consider it as a network of people using computers that make vast amounts of information available. Given the two [basic] services of the system - communication and information retrieval - the multitude of services allowed...is unprecedented". ICTs, represented by the Internet, deliver "at once a worldwide broadcasting capability, a mechanism for information dissemination, a medium for interaction between individuals and a marketplace for goods and services" (Kiiski and Pohjola, 2001).

ICTs have been in use for some time, for example in voice communications technology. However, recent advances such as the Internet are breaking new ground (and introducing new divisions) in the achievements and potential they offer. Cukier (1998a) notes that definition of the Internet "is very relevant to the peering debate [about the exchange of data traffic and interconnection agreements] as well as whether regulators [have] a role to play in Net matters". He points out that "the voice telecoms network is founded upon the principle of universal connectivity...The Internet, however, lacks a specific definition and it is uncertain whether the telephony model applies to it". According to this view, [spread of] "the Internet has unique important characteristics differentiating it from older technologies, such as telephony. This view has important implications for countries' policy approaches and the way in which they seek to encourage, monitor and regulate ICT adoption, interconnection and, ultimately, access."

It may be easier to define what ICTs are not: ICTs are not a panacea for development or a replacement for real-world processes. If the latter are flawed, deficient or absent, ICTs cannot make good the flaws or make up for the deficiencies. If a government process is bureaucratic, convoluted and subject to delays, moving it on-line may not make it any more efficient; and instant transmission may not necessarily make it any faster. If controls over financial systems are inadequate or missing, making systems electronic will not make them effective, and may in fact make it more difficult to trace the audit trail. This emphasizes the

importance of having well-thought-out, well-established, clear real-world processes before moving them on-line. According to this view, ICTs can be an effective "and", rather than a substitute "or".

ICTs may, however, reshape, reorganize and fundamentally restructure working methods, and ultimately the sectors in which they are used. They offer generic advantages of efficiency gains, information-sharing, communication and faster knowledge accumulation, dissemination and application, in support of the specific purposes for which they are used. They also permit new, collaborative work methods through their potential for networking. Communication and interaction between previously isolated agents pool their individually isolated resources, knowledge and experience to build a common knowledge base upon which all members can draw. ICTs can transform work and research methods by enabling group interactions based on central reserves of shared knowledge. The evidence suggests that we are still on the threshold of what ICTs may achieve, and that these collaborative networking methods will evolve further, as people learn to communicate, interact and work in new ways. This makes ICTs a very exciting "and", and one that may transform the equation altogether.

Despite the undoubted benefits offered by ICTs, significant barriers to their effective use exist in both developed and developing countries. These barriers must be addressed to allow realization of ICTs' full potential. Some barriers may be endemic (e.g. the generation gap, learning processes and gaining experience in ICTs). Developing countries face these or similar barriers to effective ICT use to a greater extent. In the *E*-Commerce and Development Report 2001, UNCTAD notes that "in developing countries, [government agencies] will have to deal with problems of telecoms infrastructure [including more restricted availability at higher prices], poor computer and general literacy, lack of awareness of the Internet and regulatory inadequacy, that also hinder other applications of the Internet there". (These obstacles are not uncommon in developed countries, with the European Union seeking to address some of these challenges.) Technological gaps and uneven diffusion in technology are not new – "older" innovations such as telephony and electricity are still far from evenly diffused - but what may be unprecedented is the potential size of the opportunity costs and benefits forgone by failure to participate in the new "digital society". Growth in the use of ICTs is highly uneven. There are significant disparities in access to and use of ICTs across countries. Developing countries risk being left further behind in terms of income, equality, development, voice and presence on an increasingly digitalized world stage. Developing countries must look forward prospectively, and participate actively in building technological capabilities to suit their needs. Technology itself also has a role to play in this. Just as technologies create them, so new innovations offer ways of bridging technological divides. Connectivity can build on existing infrastructure or bypass traditional means with technologies such as wireless. The availability of free software is transforming the information technology (IT) industry.

This report benchmarks the extent of ICT development across countries as an important contribution and input to policy-making. Benchmarking is important in measuring outcomes (but not causation) of policies, and in monitoring progress in ICT connectivity and access. It allows comparisons between countries and indicates how well countries are doing compared with others in terms of their adaptation, mastery and development of ICTs. A standard selection of indicators against which countries are measured allows comparisons and initial policy conclusions, between countries and over time. Comparison with better-performing countries helps identify policies for further improvement and progression. Although

benchmarking cannot investigate causation, it nevertheless allows more straightforward identification, based on evidence, of "success stories" for closer investigation, as an essential input to policy analysis.

The International Telecommunication Union (ITU) notes in its 2002 World Telecommunications Development Report that "over the last few decades, virtually every country has succeeded in improving its telecommunications sector. Thus, every country can show that its particular blend of policies has been successful". This implies that using absolute scores and absolute growth rates, nearly every country would register a gain in telecommunications infrastructure. The ITU concludes that "it is only by making international comparisons that it is possible to show which policies have been more successful than others...For this reason, an approach based on comparative rankings may be more meaningful than one that uses absolute growth rates". UNCTAD therefore uses a methodology based on a comparative analysis of relative rankings, rather than absolute scores. Indeed, with respect to ICT development, it is unclear what the reference points for absolute scores would be. Unlike in the case of literacy or life expectancy, there are no clearly established upper ceiling limits for ICT capacities. In this report, UNCTAD adopts a comparative approach based on relative country rankings to identify countries that are making progress in ICT development and those which are being left behind in the digital divide.

1. THEORETICAL FRAMEWORK AND LITERATURE REVIEW

In conjunction with the Commission on Science and Technology for Development (CSTD), UNCTAD reviewed and evaluated existing work to measure ICTs from different sources, including academia, the private sector and international organizations (UNDP, UNIDO, OECD and ITU). This section provides a brief discussion of some of the main conceptual issues arising from a review of the literature on approaches to the measurement of ICT development.

Literature review of issues relating to ICT indices

The theoretical model and selection of indicators determine the quality and predictive power of the indices based thereon. A good example of a comprehensive, well-thought-out model which considers causation in technological development is the Industrial Performance Scoreboard (2002) of the United Nations Industrial Development Organization (UNIDO). Conversely, absence of or deficiencies in a model constrains and limits the scope of observations possible (e.g. the Economic Intelligence Unit's earliest e-readiness indicators yield only limited policy insights, owing to the lack of a theoretical framework in their first formulation). Press (1999) observes that "in tracking diffusion of the Internet, one must choose a balance between breadth and depth". He concludes that with a complex concept such as the Internet, "an index may be more robust than a [single] indicator in measuring a qualitative concept" (Press, 1999, p. 5). This introduces the idea of a composite cluster of associated technologies. The selection of these technologies and the indicators measuring them have important consequences for the study's results and conclusions. The United Nations Development Programme (UNDP) uses a broad selection of technological indicators in its Technological Achievement Index (2001). UNDP's indices for agricultural and manufacturing technologies have the advantage of enabling UNDP to characterize

developing countries by technological criteria relevant to those countries' industrial achievements. Inclusion of older innovations permits longitudinal comparisons over time back to 1970.

In this report, UNCTAD opts for a narrower, more focused subset of indicators of ICTs. This restricts our time period to 1995 onwards, consistent with Hargittai (1999), who notes that use of the Internet only really became widespread after 1993. The selection of indicators also relates to the size of the country sample. For more basic connectivity indicators, 200 countries have been assessed. For more specialized data, notably for use of ICTs, samples are restricted to mostly OECD and South Asian countries. There is thus a "breadth versus depth" trade-off in the selection of indicators. This trade-off shows how standardized, detailed data are not available for large numbers of countries. From a practical perspective, if a wider sample coverage is sought, more basic indicators must be chosen for the index. For more detailed indicators such as usage and ICT take-up statistics, specialized data are only available for a smaller subset of countries. Furthermore, this type of data is most likely to come from country case studies, rather than the high-level, standardized data UNCTAD presents here. In the trade-off between "breadth versus depth", this study opts necessarily for breadth in number of countries, in pursuit of its cross-country benchmarking aims.

UNCTAD (1991) distinguishes between input, output and performance-related indicators for technology indicators as a whole. However, it is increasingly unclear to what extent this distinction applies in respect of ICT indicators. Is a personal computer (PC) to be viewed as an input (e.g. as a necessary piece of equipment for dial-up Internet access), as an output (e.g. in regression analysis, which has sought to explain the diffusion of PCs, as in Caselli and Coleman, 2001) or as part of the phenomenon to be studied? The distinction between input and output indicators (e.g. UNDP, 2001) finds a parallel in similar distinctions between exante and ex-post indicators (e.g. World Economic Forum, 2001), and determinants and performance indicators (e.g. UNIDO, 2002). It also partly relates to the sequential view of technology, in which one technology forms a basis or input to another in predefined steps. For example, UNDP (2001) justifies the inclusion of telephones and electricity as indicators in its Technological Achievement Index since "they are needed to use newer technologies and are pervasive inputs to a multitude of activities". Alternatively, technologies may be viewed as synergistic, in which a cluster or spectrum of technologies is necessary as simultaneous inputs to an outcome technology, for example electricity, digital code, PC or modem for Internet access. The question of whether inputs into the process of technology development are considered sequential as in UNDP (2001), or synergistic as in the "cluster" approach of McConnell International (2000, 2001), determines the form of index adopted (See section 2.2, "Index methodology").

Views of sequential and synergistic technologies partly reflect views of causation. Indices are not capable of determining or quantifying causation, for which more sophisticated statistical techniques are required. Causation may be conceptually embodied in the theoretical framework; for example, UNIDO (2002) distinguishes between "Determinants" and indicators of "Industrial Performance" and investigates causation by methods that include regression and cluster analysis. Indices provide a ready means of measuring a standard set of "symptoms", rather than their wider, more complex "causes". There is likely to be significant endogeneity within this model, which indices are not equipped to analyse.

The indigenous nature of technology is a consideration for some studies. The original Capacity for Innovation Index of Porter and Stern (1999) distinguishes between countries where "companies obtain technology by pioneering their own new products and processes", which receive the highest scores, and countries where "companies obtain technology exclusively from foreign countries", which receive less credit. This method values domestic innovation as more valuable than imported technology and diminishes the value of international technology transfer (TT), despite evidence to the contrary, for the success of channels of imported technology (notably Asian NIEs, such as the Republic of Korea). The World Economic Forum (WEF) also distinguishes between domestic and foreign technology in its study of national competitiveness, on the basis that "evidence suggests that without strong domestic technological activity, heavy dependence on foreign technologies leads to limited and shallow technology transfer" (WEF, 2000). The Mosaic Group (1996) assesses "indigenization" in its IT Capacity Framework, defined as the national origins and staffing of technology with indigenous personnel. However, in its subsequent "Global Diffusion" of the Internet framework, the Mosaic Group (1998) assesses worldwide diffusion of technology as a stand-alone, independent package that countries can import and apply, and no longer considers the national origins of technology, R&D or human capital.

To what extent it is relevant to talk of the national origins of a global technology such as the Internet is an intriguing question. The Economist Intelligence Unit notes that "the Internet is global, but local conditions matter" (EIU, 2001). "National" and cultural influences are apparent in the readiness with which consumers adopt new technology and in issues of multinational corporations (MNC) operations and foreign investment in technology transfer. There is an important role for the State in the development of policy and the telecoms and business environment. Governments can influence access to technology through connectivity, control over access and censorship. Important policies include telecoms policy and regulation, import policy, FDI, MNCs and technology transfer, political openness/censorship, e-governance, e-leadership, education, research, stable macrofundamentals and the legal environment. The academic question of the origins of technology has its practical significance in the adoption of national economies as the basic unit of analysis (see section 2, "ICT Development Indices").

Our review of work carried out to evaluate countries' ICT capabilities revealed a consistent underlying theoretical framework of indicators of connectivity, access, policy and usage across most studies, irrespective of the viewpoint from which they are written, as illustrated in table 1. UNCTAD uses the theoretical framework in table 1 to approach the measurement of ICT development and adopts this framework in the formulation of the ICT Development Indices, as described in the next section.

| Index | UNCTAD (2002) | Mosaic Group (1998) | Mosaic Group (1996) | McConnell International (2001, 2000) | Economist EIU (2001, 2000) | Harvard University Guidelines (2000) | ITU (2001) |

ICT Development Indices

2. ICT DEVELOPMENT INDICES

The Index of ICT Diffusion is a simple arithmetic average of scores on the quantitative Connectivity and Access indices. Qualitative variables for policy indicators are presented separately for 2001–2002. The telecom usage index was reviewed and analysed, but is not presented, as telecom traffic showed a different profile and did not appear representative of Internet use. These indicators represent a selective subset of the full set possible, with other indicators omitted owing to limited data availability or difficulties in their measurement.

| Index/dimension | Indicators | Sources | |
|--|---|------------------------------|--|
| 1. Connectivity | • Internet hosts per capita | • All data series from ITU | |
| | • Number of PCs per capita | and compared with World Bank | |
| | • Telephone mainlines per capita | data for accuracy check) | |
| | • Cellular subscribers per capita | | |
| 2. Access | • Internet users per capita | • ITU | |
| | • Literacy (% population) | • UNSD | |
| | • GDP per capita | • World Bank | |
| | • Cost of a local call | • ITU | |
| 3. Policy | • Presence of Internet exchange | • UNCTAD research | |
| (Presented separately, as relates to 2001–2002) | • Competition in local loop telecoms | • ITU | |
| <i>Tetales to 2001–2002)</i> . | Competition in domestic long-distance | • ITU | |
| | • Competition in ISP market | • ITU | |
| Usage: Telecom traffic (Analysed separately but not presented, as profile | • International incoming telecom traffic (minutes per capita) | • ITU | |
| appears unrepresentative and it is unclear to what extent this reflects global diffusion of ICTs and the Internet) | • International outgoing telecom traffic (minutes per capita) | • ITU | |

Table 2. Construction of the ICT Development Indices

Appendix 1 presents the ICT Development Indices, the Index of ICT Diffusion and country rankings for 2001, 2000 and 1999 for all countries with data available. Indices and rankings for 1998 and 1995 were also calculated and are analysed in appendix 2.

2.1. ICT INDICATORS

2.1.1 Connectivity

Connectivity is narrowly defined as the physical infrastructure available to a country, as distinct from broader factors determining access (e.g. literacy, cost). It represents the basic "limiting factor" regarding access to and use of ICTs – without the essential physical hardware, ICT use is not possible. UNCTAD defined narrow "connectivity" as the minimum set of measures necessary for ICT access, comprising Internet hosts per capita, PCs per capita, telephone mainlines per capita, and mobile subscribers per capita. This excludes supporting infrastructure (such as electricity supply and transport), affordability and broadband access (which may be currently more relevant to developed countries, but is expected to become increasingly important to all countries in the future). McConnell International notes that "a multitude of factors must be in place...a weakness in any one can degrade a country's ability to take advantage of the economic potential of the Internet". This view sees connectivity as a cluster of technologies with synergies, rather than precedence, between different types of infrastructure. This is in contrast to UNDP's sequential logic of "old" (telephony and electricity) as opposed to "new" innovations (hosts, PCs) and "leapfrogging" between stages with an underlying sequential order.

1. Internet hosts per capita

The number of Internet hosts has been adopted as a measure of the Internet penetration of a country and the degree of national "connectivity". Network Wizards define a host as follows: "A domain name that has an IP address (A) record associated with it. This would be any computer system connected to the Internet (via full or part-time, direct or dial-up connections) i.e. nw.com, www.nw.com". OECD (2002) considers that "host count is the most precise available data on the presence of Internet in a country". Cross-country regression work has mainly used this variable as the most representative variable of Internet diffusion, for example Hargittai (1999), Kiiski and Pohjola (2001), and Robinson and Crenshaw (1999).

An increasing number of Internet hosts implies increased ability to handle, service and store large amounts of data. However, difficulties include:

- Ambiguity and overlap with Internet server functions: hosts may include name servers, mail servers and file servers;
- Measurement methods and difficulties in allocating hosts to nations.

Hosts are assumed to be in the country shown by their country code (e.g. .nl for Netherlands). However, "there is not necessarily any correlation between a host's domain name and its location. A host with a .NL domain name could easily be located in the U.S. or any other country. Hosts under domains EDU/ORG/NET/COM/INT could be located anywhere. There is no way to determine where a host is without asking its administrator" (Network Wizards). This is a major problem, with anomalous results; for example, the top country for Internet host penetration as at July 1999 was the Pacific island of Niue (ITU, 2001). The Solomon Islands had no hosts according to the July 1999 Networks Wizards survey, but has been connected to the Internet since 1996. The United States ranks 44th in

Internet penetration on the basis of the .us code. Most hosts in the United States use .com, .net or domains other than .us (ITU, 2001).

A single computer may host several domain names and a single domain name might be hosted by a group of computers (ITU, 2001). Figures have been adjusted for the physical location of the hosts. Data are subject to revision and there are often discrepancies between different surveys. In July 1999, OECD nations owned 93 per cent of hosts (Press, 1999).

2. PCs per capita

Telephone lines and *personal computers* are key components for Internet access before 3Generation and WAP mobile access become widely available, with significant implications for ICT adoption. Current access methods include dial-up access, using a telephone line, PC and modem. PCs therefore represent an upper limit for Internet access. Caselli and Coleman (2001) use the number of computer imports as a measure of "computer technology adoption".

PC estimates are available for developed countries, but measurement may be unreliable. Most ITU data are estimates of PC stocks from sales or import data. This is inaccurate for developing countries, where shipment data are scarce and significant channels for PC imports are omitted (e.g. smuggling, grey market, local assembly). Increased PC penetration rates should increase ICT connectivity. This is purely a numerical count and gives no indication of the power or quality of PCs, the use made of them or by which access method (e.g. shared Internet access, with multiple users for single PC).

3. Telephone mainlines per capita

This is a relatively reliable, basic "limiting factor" of connectivity and representative of potential, if not actual, levels of "dial-up" access. ITU statistics include telephone subscribers plus the number of payphones (data from telecom authorities or operators). Increased availability of telephone mainlines should increase Internet connectivity, assuming that dial-up access is available. However, this does not give an indication of the speed, reliability or cost of the connection, which are important considerations.

It is also important to be aware of the proxy variables that may be implicit in this measure. Telephone networks typically require large investments, and so average national income and the public resources available play a significant role in determining connectivity on a national basis. Population distribution, urban/rural dispersion and underlying geographical factors are important determinants of the extent of telephone networks; for example, Nepal and Cambodia have geographically limited mainline networks, while Turkey's is widely distributed.

4. Mobile subscribers per capita

Mobile connectivity and this measure will become increasingly important in the future. Current methods of Internet access emphasize PC-based applications, with 3G and WAP less widely adopted. Inclusion of mobiles allows leapfrogging in, for example, Cambodia (ITU case study, 2002) to be counted. However, the ITU notes that the Cambodian Government has neglected fixed lines, which are "more important for Internet access at this time".

Inclusion of both fixed and mobile telephones reflects forms of ICT access that are important now and will remain so in the future.

2.1.2 Access

Jensen (2000) considers Internet connectivity from a more technical telecommunications perspective, noting that it "requires more than simply installing phone cables...the Internet is dependent on the telephone network ([comprising] cost of the line and cost of local and long-distance charges), availability and affordability of access equipment...and pervasiveness of telematics (mix of hard/software with human/organizational skills and knowledge transfer)". This introduces a broader definition of access and the factors determining use of ICTs, beyond narrowly defined connectivity.

1. Number of Internet users

This is an *ex-post* measure of the level of Internet use achieved by a nation in realized access to the Internet. However, Nua surveys and ITU (2001) point out different survey methods and definitions of Internet 'users':

Inhabitants > awareness > ICT access > users > subscribers

The number of *subscribers* paying for Internet access is more precise than the number of users and implies a certain degree of usage in terms of realized actual users. It is also more measurable, but may not reflect full usage as it omits free or shared access. For developing countries, subscribers may constitute "elite" consumers and fail to include common types of usage (e.g. shared access and cybercafes).

Nua collects its data from national surveys that do not use consistent methodology, thus reducing their comparability. For consistency, UNCTAD used ITU estimates of Internet users, weighted by population to yield Internet users per capita. The estimates in ITU surveys are consistently lower than those in SangoNet surveys (Nua). However, to test how representative ITU estimates are, countries were ranked and compared using Nua and ITU user estimates. Comparison of rankings revealed similar country profiles across both sources so, irrespective of actual indicator values, we can have confidence in the country rankings.

2. Literacy

In the absence of widely available voice protocols, text-based protocols remain the most widely used Internet applications. Language barriers and illiteracy have been identified as common obstacles to Internet access. Language has been modelled using dummy variables for English-speaking former colonies (Robinson and Crenshaw, 1999). However, the rapid growth of other languages on the Internet means that the importance of this obstacle to access is diminishing all the time. According to GlobalReach, 43 per cent of on-line users and 68.4 per cent Web content use English, down from 80 per cent of Web-pages in English in the late 1990s. Literacy remains a pervasive barrier to access, particularly for developing countries. Basic literacy represents an important *ex-ante* capability for Internet access, of which only a small subset may be realized as the proportion of Internet users. "Depth" measures of human capital, such as tertiary education, are considered less relevant for basic Internet access. We therefore included basic literacy in our index as an important determinant of access.

3. Cost of a local call

Prices are an important measure and determinant of access, since people will not use the Internet if they cannot afford it. In Europe, the practice of per minute billing has been considered a major obstacle to Internet adoption (Center for Democracy & Technology, 2002). Some countries may have high Internet connectivity (e.g. high telephone and PC penetration) but relatively low user levels. The most widely used Internet access method is dial-up (U.S. Internet Council, 2000), with the following main charges:

- 1. Telephone charges (line rental and/or call charges paid to the PTO);
- 2. Internet access charges (paid to the ISP).

Internet pricing comparisons are complex (depending upon method of access, time and frequency of use), change rapidly and are often available only for developed countries. Given data constraints for developing countries, we adopted the cost of a local call as the most representative indicator of cost of access. However, *telephone charges* issues include the following:

- Local call charges: some telephone operators do not charge directly for local calls (including operators in North America and New Zealand). This has been considered an integral factor key to the expansion of ICTs in North America (Information Society, quoted in Center for Democracy and Technology, 2002);
- Operators may include a proportion of "free" local calls in subscription charges;
- Charges may be fixed regardless of call duration;
- Local call charges may differ depending on the time of day or the day of week, or whether the call is for Internet access;
- Operators may provide discounted calls to user-specified numbers.

The reduced cost of calls should facilitate the expansion of access to ICTs.

4. GDP per capita

Income is another key determinant of access and people's ability to afford hardware investment and ongoing call costs (that are often a significant proportion of the cost in accessing the Internet). \$1 an hour charged by a cybercafe is unaffordable for people whose average income is \$2 per day. Average national income is also a proxy variable for a country's level of development, often implicitly related to a country's level of investment and thus its connectivity and infrastructure. Kedzie (1997) notes that "economic development is a leading candidate for a compounding factor that affects both democracy and electronic communication networks simultaneously". However, in his study of democracy and interconnectivity based on simultaneous equations analysis growth in Internet nodes, "statistical test results do not support...economic development as a confounding third variable... neither democracy nor GDP proves to influence interconnectivity strongly".

2.1.3 Policy

The Policy Index relates to 2001–2002, as these data are current and ITU gives "real-time" data. Retrospective comparison is made with the other indices for 1995–2000. However, the stability of the rankings emerging (see section 3, "Discussion of results") gives us confidence that these are valid comparisons to make.

1. Presence of Internet exchanges

Abramson (2000) defines Internet exchange (IX) points – also called network access points (NAPs) or metropolitan area exchanges (MAEs) – as physical installations created by third parties to facilitate traffic exchange between ISPs. Telegeography defines IX as "services created to facilitate on-site interconnections between independent or third-party Internet networks". This definition can be ambiguous: ITU considers that Egypt has access to the functions of an IX (ITU, 2001), but Egypt is not listed as having an IX (Telegeography).

Internet exchanges are important for permitting domestic exchange of within-country traffic, without using valuable international bandwidth. Abramson (2000) notes that IX "provide focal points for local traffic exchange, enhancing local Internet infrastructure and reducing dependence on international links". Establishing an Internet exchange is an important policy decision in the allocation of resources for developing countries, keeping domestic Internet traffic within the country and saving international bandwidth for other uses.

For the majority of developing countries, Internet exchanges are nationally based, that is one per country (e.g. Kenya IX, Indonesia IX). Some countries have multiple exchanges serving major urban centres (e.g. Capetown IX, Johannesburg IX). In the United States, IX operate primarily at the State level or serve major urban centres, where MAE may be a more appropriate name.

Our policy variable is a dichotomous variable (1 for an IX, 0 for its absence) since, for the majority of developing countries, the establishment of an IX is a major step. The additional benefits arising from further exchanges at the urban level may be considered marginal. The establishment of an IX may also be indicative of a proactive ICT policy outlook.

2. Competition in the local loop/domestic long distance

Competition in a country's telecoms sector is an important policy choice. Current thinking holds that monopolies may hinder rapid development and advocates liberalization of the telecoms sector in promoting new entry and competition, lowering prices and expanding access. The OECD (2001) concludes that "countries that moved early to liberalise telecoms have much lower telecoms costs and a wider diffusion of ICTs than countries that were late to take action" (p. 9). It recommends that countries "facilitate the diffusion of ICT, by increasing competition in telecoms and technology (p. 22)...[with] policies to unbundle the local loop and improve interconnection frameworks" (p. 24). The structure and policy developments in the telecoms market affect the diffusion and absorption of ICTs within a country. Gorman and Malecki (2000) observe that "regulation and lack of telecommunication competition make it more expensive to operate through Asian and European providers (Gorman and Malecki, 2000; Cukier, 1998a). The high cost of infrastructure and connections in Europe makes a circuit from Washington DC to Paris, London or Stockholm cost less than direct lines (Paltridge, 1999). Although prices are

dropping as competition increases, leasing capacity on many intra-European leased lines remains more expensive than trans-Atlantic routes (Paltridge, 1999)".

However, evidence from the cross-country regression studies is conflicting. Kiiski and Pohjola (2001) found that Internet access cost best explained growth in computer hosts per capita; however, competition (lack of monopoly) in telecoms markets proved insignificant. This is in sharp contrast to Hargittai (1999), who found that monopoly in the telecoms sector had a considerable negative impact on Internet connectivity in OECD countries (but not via reduced prices in access costs, which proved statistically insignificant).

Competition in the local loop describes a country's telecoms market structure and government policy towards telecoms, irrespective of whether competition actually results in reduced prices. Based on data from ITU T-Reg Unit, our index scores competition in the local loop as 1, partial competition as 0.5, duopoly as 0.25 and monopoly as 0. It is important to be aware of the implicit value judgements inherent in this scoring system. The "monopoly" score of 0 does not recognize the potentially beneficial effects conferred by a "benign monopoly". SingTel is widely recognized to have been an efficient, proactive incumbent in Singapore's telecoms sector, with important benefits for the adoption of ICTs in Singapore (ITU, 2001). This contrasts with the Nepal Telecommunications Company in Nepal, which "was not customer-orientated in pricing, bandwidth or service" (ITU, 2000). In future work, the clear-cut monopoly/competition distinction could be replaced by analysis of actual country practice.

3. Competition in the ISP market

The ITU defines web servers as installations that provide end-user access to the Internet, disseminate information and sell products and services (ITU, 2001). However, Cukier (1998) identifies four different types of ISP — backbone, downstream, webhosting and online service providers. Competition in a country's ISP market is important for the domestic diffusion of ICTs. Competition in Internet service provision may reduce prices and installation time, and improve quality and availability of different services and customer care, thereby enhancing access. The beneficial effects of a vibrant ISP market are illustrated by Indonesia and Egypt, each with in excess of 60 ISPs, as opposed to Cambodia and Viet Nam, where a limited number of ISPs and higher market concentration arguably result in higher prices and reduced customer service (ITU case studies).

The number of ISPs in a country has been used as an indicator of market liberalization. However, as there are at least four different types of ISP (Cukier, 1998), the number of ISPs may be difficult to define and establish. Furthermore, markets may be fast-changing and there may be no legal requirement for ISPs to register. Also, it is necessary to distinguish between licensed ISPs and operational ISPs. This makes ISP counts inaccurate in large, liberalized markets. The number of ISPs has not been used in our index. UNCTAD uses ITU's T-Reg unit data to define this variable as a simple dichotomous variable (competitive scored as 1, monopoly as 0), rather than a continuous scale based on the number of ISPs.

2.1.4 Usage (omitted from the Index of ICT Diffusion)

UNCTAD sought to investigate Internet traffic data. However, these data are commercially sensitive for ISPs, who did not respond positively to our data requests. This is consistent with OECD (1998), which notes that an "absence of data on Internet traffic flows between

countries". Abramson (2000) notes that "meaningful Internet traffic statistics do not yet exist", despite widespread use of telephone traffic data. ITU (2001) notes that "Internet traffic data are scarce. Where available, they are compiled by telecom operators, ISPs, and some government agencies. Internet average daily usage in minutes reveals wide variations in average usage times across countries".

UNCTAD investigated existing data on telecom traffic as an indicator of usage. Telephone technologies form part of the ICT technological cluster. They are, however, mature technologies with established uses and may not be representative of usage patterns for more recent ICTs, including the Internet. Our usage index of telecom traffic is calculated as the average of incoming/outgoing telecoms traffic (minutes per capita population):

Usage index = (incoming traffic + outgoing traffic)/2

The results from our usage index based on telecom traffic reveal the interesting phenomenon of "offshore islands". These are a small but important sub-category of "island states" (including the Cayman Islands, the Bahamas and Bermuda) specialized in service industries such as offshore banking and financial services, which lend themselves to the use of ICTs. Renata Lebre La Rovere (1996) points out in her excellent review of Brazilian banking that "a bank's production process is particularly suited to benefit from IT diffusion, since it is organized around the storage and transfer of information". Banking is particularly suitable for automation and computerization because of the high volume of repeat transactions involved. These island economies specialized in banking have high PC and telephone penetration rates. However, their importance is apparent in the telecom usage statistics, where they have the highest average incoming/outgoing telephone traffic, exceeding that of many larger economies (see section 3, "Discussion of results").

The extent to which this phenomenon of usage patterns based on telecom traffic is representative of Internet data traffic flows is questionable. Comparison of country rankings in telecom traffic with rankings based on the number of Internet users (regardless of type of usage) reveals little similarity in country rankings. UNCTAD therefore retained this index separately and did not include it in the Index of ICT Diffusion. Current telecom traffic may suggest future patterns of usage of ICTs and how these more recent technologies may mature. However, for the time being, UNCTAD considers usage patterns based on its analysis of telecom traffic volumes to be less representative of ICT usage patterns, and has excluded the Usage Index from the ICT Development Indices.

2.2. INDEX METHODOLOGY

Index methodology

Edgeworth (1925) defines an index number as "a number [that] shows by its variations the changes in a magnitude which is not susceptible either [to] accurate measurement itself or [to] direct valuation in practice". Press (1999) observes that "in tracking diffusion of the Internet, one must choose a balance between breadth and depth" and concludes that "an index may be more robust than a [*single*] indicator in measuring a qualitative concept" (p. 5). This view of a cluster of technologies is consistent with that of the Mosaic Group, which suggests that individual technologies need to be evaluated, since countries seldom exhibit uniform capabilities across the broad spectrum of ICTs. Measures of breadth and depth are needed — a dilemma which the Mosaic Group resolves by the use of Kiriat or "wheel and

spoke" diagrams (Press, 1999) to reflect technology as a "multi-faceted concept". UNCTAD has reflected this balance between breadth and depth through use of an aggregate index with component sub-indices.

However, there are dangers inherent in the use of a disaggregated index. The Mosaic Group observes in its "Framework Analysis" paper (1997) that "while it is tempting to derive a single index to reflect a country's IT capability, such an approach is unlikely to provide the depth of understanding needed for policy decision-making". Press (1997) explicitly warns against the dangers of averaging, or "reducing a [*multi-faceted*] capability diagram down to a single number" (i.e. area), since capability diagrams with the same total area may have very different shapes, that is countries exhibit different profiles across the spectrum of ICT technological capabilities. Press (1999) notes further challenges for Internet indices: [they] "should be orthogonal, each measuring an independent aspect of the state of the Internet in a nation, but it is difficult to define indices that are both comprehensive and uncorrelated". Simple averaging of indicators in an index implicitly assumes equal weighting of indicators and the possibility of offset of one indicator by another (i.e. connectivity is assumed to be equivalent to access and policy). GIT (2000) notes that an "additive model implies that strength on any one of these dimensions could compensate for weakness on another".

Whether inputs into the process of technology development are considered sequential, as with UNDP (2001), or synergistic, as in the "cluster" approach of McConnell International (2001), determines the form of index adopted. A sequential concept of technological inputs implies an additive model in which factors with implied equivalence may offset each other. In other words, strength on one aspect can compensate for weakness on another, as above. This is also the perspective within which the idea of "leapfrogging" fits. For instance, Cambodia's lack of fixed mainlines may not matter, as its high mobile penetration rate is likely to offset this, implying "leapfrogging" by "skipping a step" in the sequence. In fact, determinants do not have the same or equivalent influence over IT capability. Connectivity is a limiting factor, while government policy impacts upon IT capability and may result in lower IT capability for a well-connected nation (e.g. in comparing Pakistan with India, the positive impact of early liberalization of telecoms licences is seen on Internet growth in Pakistan, compared with slower growth under public monopoly, private monopoly and finally liberal privatization in India).

Conversely, a synergistic view of a critical mass of associated technologies essential for a country's advancement in technology implies a multiplicative model in which weakness in any one input may hinder and impede effective development on the basis of non-equivalent inputs. This is the view put forward by McConnell International (2001) in the context of the Internet, stating that a multitude of factors must be in place in order to take full advantage of the economic potential of the Internet, and that weakness in one area can seriously obstruct the realization of potential benefits. GIT (2000) also describes a synergistic view of technological development by highlighting the fact that all four dimensions in its model, namely national orientation, socio-economic infrastructure, technological infrastructure and productive capacity, have to be strengthened for a nation to enhance its technology-based export competitiveness.

Despite these two differing views and methodologies, indices have usually followed simple additive averaging models. UNCTAD also opts for such a model mainly for two reasons. First, our review of work to date indicated that results calculated using both methodologies do not differ significantly from each other. Second, the additive model is more widely used

because of its relative simplicity. UNCTAD uses the aggregated index approach, with component indices (similar to UNDP's HDI). Countries' overall scores may be disaggregated into component indices of interest, permitting finer discernment between nations with different profiles across the spectrum of ICT capabilities. Attention should not focus on final index scores, but on scores across country profiles.

Relative or absolute indices

The ITU notes in its 2002 World Telecommunications Development Report that "over the last few decades, virtually every country has succeeded in improving its telecommunications Thus, every country can show that its particular blend of policies has been sector. successful". In absolute scores, therefore, nearly all countries will show increases in telecommunications connectivity. The ITU concludes "it is only by making international comparisons that it is possible to show which policies have been more successful than others...For this reason, an approach based on comparative rankings may be more meaningful than one that uses absolute growth rates" [italics added]. The ITU argues that relative growth rates are more insightful for policy analysis than absolute growth rates. UNCTAD therefore uses a methodology based on relative rankings, rather than absolute scores. Using relative rankings, countries' index scores are calculated as a proportion of the maximum score achieved by any country in any one year (see next section). This method has the advantage that reference points derive from real-world achievements realized by any country (listed in appendix 5). However, it has the drawback that reference countries change year on year, thus reducing inter-year comparability. Only country rankings can be compared between years, consistent with the ITU's recommendations, rather than direct comparisons of countries' scores (since the reference points are changing). In this report, UNCTAD adopts a comparative approach based on comparisons of relative country rankings between years to identify countries that are making progress in ICT uptake, and those that are being left behind in the digital divide.

Evidence from other studies illustrates some issues that may arise using relative indices. GIT (2000) notes that relative indexing "is a relative scaling so that an apparent 'decline' over time or low score is only relative to other countries". GIT's HTI "are *relative* indicators. Hence, a 'decline' on an indicator does not imply an actual drop, just that competing countries have advanced faster". Thus, "Germany is considerably closer to other leading nations than to the U.S. and Japan...this distancing is not due to any decline in Germany, but rather to the remarkable gains by the U.S" (GIT 2000). UNIDO (2002) also notes that "movements in rankings are relative, not absolute. Many [countries] like Kenya are not particularly technology-intensive exporters – they move up the scale because their exports are more complex than their other measures relative to other countries in their vicinity".

These observations support the idea that, in general, it is more meaningful to talk about countries' rankings than about a country's index score. Countries tend to group or "bunch" together (particularly around the centre of the index distribution), where a score interval of 0.1 may be equivalent to several places in the rankings. Conversely, countries that stand out in the lead or fall behind in the tails of the distribution may have relatively large gaps between country scores, such that a significant improvement in index score is necessary in order to catch up leaders, or for those behind to catch other countries up. In general, it will thus be more meaningful to talk about countries' rankings than about their absolute index scores.

Reference points

The question of approach in using relative versus absolute indices is closely connected with the issue of reference points. Indices with absolute scores are calculated as a proportion of fixed reference points. This has the advantage of permitting direct year-on-year comparability of scores (although, for the reasons cited above, the significance of a country's score depends upon its place in the index distribution), but it is unclear what these reference points should be for ICT achievements. With some indicators, maximum achievements are relatively straightforward: for example, 100 per cent literacy rate, 100 per cent Internet user rate. For other indicators, maximum achievements are less obvious. Mobile penetration may reach over 100 per cent (e.g. for subscribers with more than one phone, or two Subscriber Identification Module cards per phone). There are no established a priori ceiling limits for Internet host penetration.

The problem of an outlying "star performer" is also illustrated in GIT's work, where the country with the maximum reference value forges ahead. "The U.S. increased [its electronics production] by \$71B from 1996 to 1999. The U.S. position is so strong that even China's remarkable doubling of electronics production from \$33B to \$65B increases its score only from 12 to 19" (out of 100). This is partly apparent from appendix 5, where the maximum reference values for ICT parameters are increasing at very rapid rates. The use of fixed reference values, as happened with UNDP's HDI, could resolve this problem. However, with fast-changing ICT indicators, it is not evident what these fixed reference values should be (compared with life expectancy/literacy, where well-established upper ceiling values exist).

Indicator scores methodology

Scores are derived as an index relative to the maximum and minimum achieved by countries in any indicator:

Index score = (Value – Minimum)/(Maximum – Minimum)

Since the minimum value achieved is zero¹ for most indicators, scores amount to a percentage of maximum values:

Index score: = (Value – 0)/(Maximum – 0) = Value / Maximum

Maximum reference values are given in appendix 5 for connectivity. Indicators for which minimum values were not zero were telecoms traffic and telephone mainlines. However, these scores were calculated as a percentage of maximum values for consistency. Appendix 1 presents the Index of ICT Diffusion calculated on the basis of the Connectivity and Access Indices for 2001, 2000 and 1999. On the basis of these rankings, countries are classified as "falling behind" (FB), "keeping up" (KU) and "getting ahead" (GA) corresponding to first, second and last thirds in rankings. Segmental analysis was carried out in appendices 3 and 4 for 2001, dividing countries into these categories on the basis of rankings. This permits

¹ The statistically desirable property of "reversibility" that the index calculated forwards and the index calculated backwards should be reciprocals of each other (Fisher, 1922), namely, is not fulfilled owing to use of arithmetic averages in the indices. Use of "zero" minimum values means that this "reversible property" yields mathematically undefined answers (reciprocals of zero). However, that does not have significant consequences for this index.

categorical analysis of results by income level, region or culture. It also allows analysis of the scatter of observations, with frequency given in brackets after the title.

Additive model and averaging

There is no a priori logic for weighting indicators in their aggregation into the index. Simple averaging of indicators in an index implicitly assumes equal weighting of indicators and the possibility of offset of one indicator by another (i.e. mobiles are assumed to have equal importance to telephones, PCs and Internet hosts; connectivity is assumed to be equivalent to access and policy). GIT (2000) notes that an "additive model implies that strength on any one of these dimensions could compensate for weakness on another". This is consistent with a sequential view of ICTs, rather than a synergistic one (where any weakness in the cluster reduces overall technological capabilities, i.e. a multiplicative model as discussed previously).

Furthermore, use of simple averages across scores results in averaging effects. GIT (2000) recognizes that "a given indicator combines several scores [so] typically no country will score 100 on the resulting indicators". In general, distributions are averaged into the centre of the scoring range. Averaging effects are noted by UNIDO (2002), which recognizes the possibility of "offset...at least for some countries [where] use of two benchmarks together biases the results against them in that their average capabilities appear lower".

Time period

Hargittai (1999) notes that "the World Wide Web was invented only in 1990 and web browser in 1993, [which] significantly accelerated [the Internet's] spread both in the U.S. and internationally. Significant Internet diffusion is observed worldwide only in the past few years". UNCTAD therefore compiled indicators and calculated indices for 1995, 1998, 1999, 2000 and 2001. ICT Development Indices and Connectivity Indices are presented for 2001, 2000 and 1999. The Policy Index relates to 2001–2002, as ITU's data are constantly updated. Comparisons with the Policy Index are thus retrospective.

Unit of analysis

Our units of analysis are nation States, countries or territories defined by national boundaries. Technological hubs, or "centres of excellence" with extensive hinterlands (Telegeography, quoted in UNDP's HDR, 2001) are aggregated into national-level statistics and it is important to be aware of the significant averaging effect this has on our results. Adoption of nations and territories as our unit of analysis gives added pre-eminence to Singapore, as both a nation state and a "large city" (ITU, 2000), compared with, for example, a lower ranking for India, comprising Bangalore as a technological hub. Were New York or Bangalore to be separated out from their hinterlands, very different results would emerge. New York has more Internet hosts available to it than the whole of Sub-Saharan Africa, which means that a city ranking, or ranking of nations by cities, would yield different results. The survey by Telegeography (2001) gives some indication of what a ranking by cities looks like.

Bridges.org (2001) observes that *international digital divides* have been assessed by comparisons of connectivity hardware between countries (PCs, hosts, servers, telephones), whereas *domestic digital divides* are assessed by measures of access by different groups (ethnicity, gender, age, income). The concept of disparities in access to ICTs is the same in

both cases, but the unit of analysis as the nation state determines the choice of variables and method. The Mosaic Group (1996) measured the 'indigenisation' of IT capability, or "involvement by nationals...in installation, use, operation, maintenance, management and adaptation of technology...performed by indigenous personnel". Its later (1998) theoretical framework assesses absorption of ICT technologies as independent, stand-alone technologies. The national origin of technology is not considered. Analysis of technology along national lines measures "national differences" in the adoption and absorption of IT. However, whether such differences are national or cultural may be indeterminate (boundaries of nation States and culture may coincide, but this is not always the case). Expatriate communities are often important in promoting technological adoption in their homelands (e.g. communication needs of overseas Vietnamese, the accumulated human capital of Indian software specialists in United States).

National size effects

GIT (2000) notes that the Innovation Index of Porter and Stern (1999) "is normalized (per capita measures), whereas [GIT's] is not (most of the statistical components reflect national totals). HTI address national technological competitiveness without particular concern for an economy's size". However, it does not explore the consequences of this for its results. In fact, this may introduce bias into results. UNIDO (2002) notes that "the use of a population deflator works against large countries, but remains a good way to adjust for country size". This may be particularly true for infrastructure, where a certain minimum threshold infrastructure in the network may be required, irrespective of the size of the country. Further expansion of the network may result in economies of scale in larger countries, resulting in proportionately reduced levels of infrastructure per capita. Population dispersion and geographical dispersion of the network are intimately related to country size. It is unlikely that these effects can be corrected for; however, it is important to remain aware of their existence and the fact that averaging measures across per capita population may implicitly work against larger countries, lowering their relative rankings.

In fact, the most important consequences of using normalized per capita measures in our Indices arise for developing countries. Where countries have high rates of population growth, Indices based on per capita indicators of telecommunications development mean that any growth in telecommunications infrastructure must outstrip population growth to result in an improved indicator value and index score. This may explain why in appendix 5, the minimum values for some per capita connectivity measures remain close to zero. For certain countries, absolute gains in telecommunications infrastructure are failing to keep up with the increase in their population, resulting in unchanged infrastructure per capita values.

Data omission effects

The treatment of data omissions is central in determining the results of an index. In calculating the Indices, final scores must be adjusted for the number of data observations and weighted, so as to eliminate the impact of data omissions. Failure to do so effectively "dilutes" the final index score by the number of omissions. However, data omissions are more likely for poorer countries. This poses a problem for our results, the extent of which is unclear. For some indicators (e.g. telephone mainlines and mobiles, in the Connectivity Index), 201 countries have been covered to a reasonable extent. However, some indicators (e.g. local call costs, in the Access Index) have more limited data availability that varies from year to year. Rodriguez and Wilson (2000) note that their "results almost surely err on the

side of optimism, as countries with poor or no available data are most likely to be the same countries that are being left behind by the information revolution". This caution also applies to our study. The omission of primarily poorer countries with low data availability means that absent or negligible observations are omitted. Our sample essentially comprises those countries with a degree of connectivity infrastructure in the first instance. This introduces bias from sample truncation into our findings, but it is difficult to establish the extent of this bias or how to correct it.

3. DISCUSSION OF RESULTS

The results in this section are discussed by:

- 1. Income (UNDP codes of high-, middle- and low-income, others);
- 2. Regional groupings (UNDP codes of Eastern Europe and the Commonwealth of Independent States (CIS), OECD, Arab States, East Asia, South Asia, Latin America and the Caribbean, sub-Saharan Africa, others);
- 3. Other regions, where geographical factors are important (e.g. "island states").

Comparisons are also made between:

- 4. Connectivity and Access Indices and their relationship in appendix 3;
- 5. Policy and Connectivity Indices to study the impact of policy in enhancing ultimate connectivity in appendix 4;
- 6. Evolution of indices over time;

as important comparisons within the ICT Development Indices. Since telecommunications policy is expected to impact mainly upon user numbers and cost variables in the Access Index, and less so on other variables of literacy and income, this comparison was not analysed in detail. Positive correlations between sub-indices in appendix 2 are illustrated by the overweight positive diagonals in appendix 3. Random scatters of observations would yield equal weightings across boxes. However, frequency of observations (given by the figures in brackets) illustrates a positive correlation in weightings. The high correlations in our results may suggest that the Indices are measuring consistent indicators of central "technological development". However, indices do not address the question of causation. These indicators may also represent proxy variables for key drivers underlying technological development (e.g. average income and/or level of development, levels of investment). Causation cannot be determined by correlations and should be investigated by more sophisticated statistical techniques such as regression.

1. Income

UNDP codes were used to classify up to180 countries into four categories of high-/middle-/low-income and "others" for ICT Indices. To some extent, this analysis is partly dependent upon these classifications. Analysis of ICT rankings reveals that:

22

| Index of ICT Diffusion | 2001 | 2000 | 1999 | 1998 | 1995 |
|---------------------------|------------------|------------------|----------------------|------------------|----------------------|
| High: Best | United States 1 | United States 1 | Norway 1 | Norway 1 | Finland 1 |
| Worst | Qatar 45 | Bahamas 48 | Qatar 37 | Bahamas 55 | Bahamas 46 |
| Average | 18.6 | 18.7 | 17 | 18 | 17 |
| Middle: Best | Rep. of Korea 23 | Rep. of Korea 23 | Rep. of Korea 21 | Rep. of Korea 26 | Rep. of Korea 26 |
| Worst | Albania 161 | Albania 176 | Eq. Guinea 144 | Gabon 142 | Egypt 154 |
| Average | 77 | 82 | 73 | 74 | 78 |
| Low: Best | Armenia 62 | Indonesia 72 | Tajikistan 50 | Ukraine 66 | Viet Nam 61 |
| Worst | Eritrea 171 | Eritrea 180 | Central Af. Rep. 159 | Niger 159 | Central Af. Rep. 156 |
| Average | 132 | 137.6 | 126 | 128 | 120 |
| Others: Best | Macao (China) 31 | Guam 25 | Greenland 27 | Greenland 25 | Macao (China) 28 |
| Worst | Sol. Islands 167 | Sol. Islands 174 | Vanuatu 148 | Sol. Islands 141 | Saint Lucia 143 |
| Average | 109.4 | 106 | 84 | 76 | 70 |

Table 3. Analysis of the Index of ICT Diffusion by income

Average rankings conform to expectations. "High" income countries consistently capture the top rankings, with an average ranking of 17–18.7. This average ranking is 55–60 places ahead of "middle" income countries, which have a consistent average ranking between 73 and 81 over the period 1995–2001. "Low" income countries show some decline in average ranking over this period, from 120 to 132 in 2001. "Others" are too varied to yield meaningful conclusions. This pattern is apparent from the Connectivity Index for 200 countries using these categories:

 Table 4. Analysis of the Connectivity Index by income

| Connectivity Index | 2001 | 2000 | 1999 | 1998 | 1995 |
|-----------------------|------------------|---------------------|-------------------|---------------------|------------------|
| High: Best | United States 1 | United States 1 | United States 1 | Finland 1 | Finland 1 |
| Worst | Brunei 82 | Bahamas 62 | Bahamas 64 | Bahamas 62 | Qatar 57 |
| Average | 21.2 | 22.5 | 23.6 | 22.6 | 22.5 |
| Middle: Best | Rep. of Korea 26 | Rep. of Korea 29 | Rep. of Korea 28 | Rep. of Korea 28 | Rep. of Korea 30 |
| Worst | Gabon 155 | Djibouti 159 | Eq. Guinea 183 | Eq. Guinea 165 | Eq. Guinea 170 |
| Average | 86.5 | 94.3 | 97 | 97.5 | 99.5 |
| Low: Best | Georgia 89 | Ukraine 100 | Ukraine 100 | Ukraine 98 | Armenia 90 |
| Worst | Niger 193 | DR of the Congo 200 | Guinea-Bissau 201 | DR of the Congo 201 | Chad 201 |
| Average | 158.6 | 163.7 | 165 | 165 | 163 |
| Others: Best | Bermuda 11 | Bermuda 5 | Bermuda 5 | Bermuda 7 | Bermuda10 |
| Worst | Somalia 195 | Afghanistan 199 | Afghanistan 197 | Afghanistan 200 | Yugoslavia 200 |
| Average | 94.6 | 85.6 | 81 | 81.6 | 111 |

"High" income countries again capture the top connectivity rankings, with an average ranking of 21–23.6. This average ranking is 77 places ahead of that of "middle" income countries, whose constant average ranking improves from 99.5 to 86.5 from 1995 to 2001. "Low" income countries also show some improvement in average ranking over this period

from 163 to 158.6. Again, "others" is too varied a category to draw meaningful conclusions. These results are however constrained by the broadness of these categories — for example, Djibouti, Gabon, Equatorial Guinea and Côte d'Ivoire are classified as middle-income countries, and Georgia, Ukraine and Armenia as low-income countries. The definitions of these categories constrain possible conclusions, and so it is interesting to look at narrower regional classifications for more focused analysis.

2. Regional groupings

UNDP codes were used to classify up to 180 countries into eight categories of Eastern Europe and CIS, OECD, Arab states, East Asia, South Asia, Latin America and the Caribbean, sub-Saharan Africa and "others". Analysis of ICT diffusion rankings by these categories reveals that:

| Index of ICT Diffusion | 2001 | 2000 | 1999 | 1998 | 1995 |
|--------------------------------------|--|--|---|--|---|
| 1. OECD: Best | United States 1 | United States 1 | Norway 1 | Norway 1 | Finland 1 |
| Worst | Mexico 75 | Mexico 73 | Mexico 72 | Mexico 71 | Mexico 116 |
| Average | 22.2 | 22.7 | 22 | 21.5 | 27 |
| 2. EE & CIS: Best | Slovenia 27 | Slovenia 28 | Slovenia 30 | Estonia 28 | Slovenia 27 |
| Worst | Uzbekistan 166 | Albania 176 | Azerbaijan 140 | Azerbaijan 140 | Uzbekistan 142 |
| Average | 94.8 | 107.6 | 71 | 70 | 78 |
| 3. LAC: Best | Bahamas 44 | Costa Rica 46 | Barbados 38 | Uruguay 45 | Guyana 41 |
| Worst | Belize 128 | Belize 131 | Dominican Rep. 120 | Dominican Rep. 125 | Bolivia 146 |
| Average | 71.7 | 77.6 | 79 | 79.5 | 78.6 |
| 4. E. Asia: Best Worst Average | Hong Kong (China) 9 Cambodia 169 88.7 | Hong Kong (China) 8 Cambodia 179 89.3 | Hong Kong (China) 8 Myanmar 146 80 | Hong Kong (China) 11 Lao PDR 156 77 | Hong Kong (China) 11 Mongolia 153 74.5 |
| 5. Arab: Best | UAE 25 | UAE 26 | UAE 26 | UAE 29 | Kuwait 31 |
| Worst | Yemen 140 | Yemen 145 | Sudan 127 | Yemen 128 | Egypt 154 |
| Average | 88.8 | 91 | 80 | 82 | 89 |
| 6. S. Asia: Best | Maldives 70 | Maldives 70 | Maldives 56 | Maldives 77 | Maldives 86 |
| Worst | Bangladesh 148 | Bangladesh 154 | Bangladesh 133 | Sri Lanka 134 | Nepal 137 |
| Average | 111.6 | 113.3 | 104 | 113 | 112 |
| 7.SSA: Best | Mauritius 57 | Mauritius 65 | Mauritius 54 | Mauritius 50 | Mauritius 39 |
| Worst | Eritrea 171 | Eritrea 180 | Niger 159 | Niger 159 | Central Af. Rep. 156 |
| Average | 126.3 | 131.3 | 127 | 126.4 | 117 |
| Others: Best | Israel 22 | Israel 21 | Israel 20 | Israel 17 | Israel 19 |
| Worst | Sol. Islands 167 | Sol. Islands 174 | Vanuatu 148 | Sol. Islands 141 | Saint Vincent & G 143 |
| Average | 98.8 | 99.3 | 74.4 | 66 | 62.5 |

 Table 5. Analysis of the Index of ICT Diffusion by regional grouping

Average rankings conform to expectations. OECD countries consistently capture the top rankings, with average ranking improving from 27 to 22.2 from 1995 to 2001. Eastern Europe and CIS also improve in average ranking from 78 to 71 from 1995 to 1999, but decline afterwards to 94.8 in 2001. Latin American and Caribbean countries have a consistent ranking of 78.6–79 from 1995 to 1999, which improves to 71.7 in 2001. "East

Asian countries" is a diverse category, encompassing Asian Tigers (e.g. best-performing Hong Kong (China) at 11–8) and Cambodia, the Lao People's Democratic Republic and Myanmar as countries falling behind. East Asia shows some decline in average ranking over this period from 74.5 to 88.7. Arab countries are similarly diverse, encompassing countries getting ahead (such as the United Arab Emirates and Kuwait) and countries falling behind (Yemen and Sudan), and have roughly constant ranking over this period, with average ranking varying between 80 and 90, and 88.8 in 2001. South Asia also shows an improvement from an average of 112 in 1995 to 104 in 1999, before slipping back to 111.6 in 2001. Sub-Saharan Africa's average ranking is consistently last but stable from 117 in 1995 to 126.3 in 2001, although its best performers — Mauritius and South Africa — generally rank between 50–65. "Others" is a varied category. These trends are again apparent from the connectivity rankings (see also the regional groupings in the section on the digital divide):

| Connectivity Index | 2001 | 2000 | 1999 | 1998 | 1995 |
|---|---|--|--|---|--|
| 1. OECD: Best | United States 1 | United States 1 | United States 1 | Finland 1 | Finland 1 |
| Worst | Mexico 74 | Mexico 88 | Mexico 93 | Mexico 97 | Mexico 95 |
| Average | 22 | 25.4 | 26.6 | 27 | 29 |
| 2. EE/CIS: Best Worst AverageSlovenia 25 Kyrgyztan 175 | | Slovenia 28 | Slovenia 31 | Slovenia 36 | Slovenia 40 |
| | | Tajikistan 153 | Tajikistan 152 | Albania 152 | Albania 158 |
| | | 96.9 | 99 | 95.7 | 92 |
| 3. LAC: Best | Bahamas 49 | Barbados 59 | Barbados 57 | Barbados 55 | Barbados 51 |
| Worst | Nicaragua 147 | Nicaragua 147 | Nicaragua 145 | Nicaragua 144 | Nicaragua 142 |

| 4. Arab: Best | UAE 30 | UAE 35 | UAE 39 | Qatar 51 | Kuwait 44 |
| Worst | Sudan 164 | Sudan 169 | Sudan 172 | Sudan 178 | Sudan 187 |
| Average | 103 | 107.4 | 109 | 108 | 108 |
| 5. E.Asia: Best Worst Average | Hong Kong (China)12 Myanmar 188 106 | Singapore 11 Myanmar 192 111.4 | Hong Kong (China)12 Myanmar 184 114 | Hong Kong (China)11 Myanmar 186 115 | Hong Kong (China)13 Myanmar 180 113 |
| 6. S. Asia: Best Worst Average | Islamic Rep. of Iran 97 Bangladesh 184 148.3 | Islamic Rep. of Iran 104 Bangladesh 190 153.6 | Islamic Rep. of Iran 101 Bangladesh 185 150 | Islamic Rep. of Iran 99 Bangladesh 189 150 | Islamic Rep. of Iran 101 Bangladesh 191 151 |
| 7.SSA: Best | Mauritius 57 | Mauritius 69 | Mauritius 75 | Mauritius 70 | Mauritius 79 |
| Worst | Somalia 195 | DR of the Congo 200 | Guinea-Bissau 201 | Chad 201 | Chad 201 |
| Average | 156.7 | 162 | 166 | 166 | 167 |
| 8. Others: Best | Bermuda 11 | Bermuda 5 | Bermuda 5 | Bermuda 7 | Bermuda 5 |
| Worst | Afghanistan 194 | Afghanistan 199 | Afghanistan 197 | Afghanistan 200 | Afghanistan 198 |
| Average | 90.4 | 83 | 78.7 | 79 | 77.8 |

 Table 6. Analysis of the Connectivity Index by regional grouping

For 1995–2001, average connectivity rankings conform to expectations and show remarkable consistency between periods. Furthermore, the same countries are consistently best or worst in their categories, which partly reflects the long time scales needed to significantly improve levels of infrastructure. OECD countries consistently capture the top rankings, with average

ranking improving from 29 to 22 from 1995 to 2001. Eastern Europe and CIS show a decline in average ranking from 92 to 99 from 1995 to1999, and an improvement thereafter from 99–90 (overall unchanged), while Latin American and Caribbean countries show a steady improvement in average ranking from 100 to 86.4. In terms of connectivity, Arab countries outperform East Asian countries (the reverse is true of wider ICT access and diffusion), with average Arab connectivity of 108–103 (compared with 113–106 for East Asia). Arab countries encompass countries "getting ahead" (UAE, Qatar and Kuwait) and Sudan as their worst-performer, although Sudan improves steadily from 187 to164. East Asian countries include best-performing Hong Kong, China (between 11 and 13) and Myanmar as the worst-performing (at 180–192). South Asia has a constant average of around 150, with the consistent best-performer, the Islamic Republic of Iran, and lower-performing Bangladesh. Sub-Saharan Africa's average ranking is consistently last but shows some improvement, from 167 to 156.7, with the best performers — Mauritius and South Africa — generally ranking between 57 and 85. Chad and Guinea-Bissau are the lowest performers at 201. "Others" is again a varied category.

3. Other regions

Regional classifications are reflected in the above UNDP categories of Eastern Europe and CIS, OECD, Arab States, East Asia, South Asia, Latin America and the Caribbean, and sub-Saharan Africa. However, for our purposes, further interesting results emerge from the Usage Index of telecom traffic, where the importance of "island economies" is also apparent. These are small, relatively remote but highly connected islands such as Cayman Islands and Bermuda, specialized in service industries. They score highly in connectivity, beyond what might be expected from their geography, but in line with their specialization in ICT-intensive service sectors. The negative impact of geography is also evident, for example in respect of Nepal and Bhutan, where mountainous terrain prevents extensive network infrastructure. These countries score poorly in the regional classification of South Asia, and the satellite technology that can help overcome such terrain is not included in our index.

4. Connectivity and Access Indices – appendix 3

Connectivity and access show high correlations of 0.786 (2001), 0.764 (2000), 0.776 (1999), 0.833 (1998) and 0.686 (1995), as shown in appendix 2. The strong correlation of the Access Index (comprising users, literacy, call costs and average income) with connectivity is embodied in the Index of ICT Diffusion, as the average of these two indices.

Appendix 3 illustrates this correlation, with countries lying mainly on the positive correlation diagonal and less so on the inverse diagonal. It is expected that good connectivity provides a basic foundation for and enhances good access (GDP income is an important underlying determinant of both access and connectivity infrastructure). Good access despite poor connectivity is counter-intuitive against expectations — only one country has good access (Costa Rica, owing to good literacy rates and low call costs), with 15 countries having adequate access despite poor connectivity. Despite their relative rarity, these countries exemplified by Costa Rica illustrate the possibilities for Governments to enhance access beyond narrowly defined ICT connectivity with good literacy and low call costs. Transition economies generally enjoy strong literacy and education, thus improving access. Connectivity decreases as one moves further eastwards from Central and Eastern Europe towards the Central Asian republics. This contrast is observed in the rankings in appendix 3. The absence of good connectivity may make widespread access difficult to achieve, with a

large "vicious circle" (FB Con, FB Acc), populated largely by African and Asian subcontinent countries.

5. Policy and Connectivity Indices – appendix 4

The scores of the Policy and Connectivity Indices show a reasonable correlation in appendix 2 of 0.516 (2001), 0.4297 (2000), 0.430 (1999), 0.426 (1998) and 0.403 (1995), although this is a retrospective comparison to make, since the policy variable relates to 2001–2002. This may also explain the decreasing correlation the further back one goes in time. The positive diagonal in appendix 4 is again overweight in country observations, as expected from these correlations.

Segmental analysis of rankings presented in appendix 4 illustrates strong regional groupings. The "GA Con-GA Pol" box contains primarily OECD countries, engaged in a "virtuous circle" with competitive telecoms sectors and good infrastructure. "GA Con-KU Pol" contains Mediterranean and some Eastern European countries. "GA Con-FB Pol" contains Arab and island States with good infrastructure, but less liberalized telecommunication policies. It is important to note that for offshore islands with small populations, a competitive telecoms sector may not be appropriate, contrary to the value judgements implicit in the scores.

The "KU Con-GA Pol" box contains mostly Latin American and some Asian countries that may have implemented competitive policies, but have yet to witness the full benefits. The middle segment, "KU Con-KU Pol", contains the bulk of Central and Eastern European countries that have been cautious about or delayed telecom sector reforms. African countries dominate the last third of rankings in the connectivity column.

However, countries in the "FB Con-GA Pol" box offer the most potential. These are countries that may have recently implemented reforms (e.g. India, in the transition from monopoly to a more liberal market structure) and are waiting to reap the benefits, or countries that have had competitive market structures for some time, but lack the resources to invest heavily in infrastructure. However, a coherent competitive policy framework is in place, and these countries may therefore be in a position to profit from their policies in the future. These regional groups in rankings highlight different types of economies under consideration and suggest that policy recommendations must be tailored to the different types of economy.

6. Evolution over time

Comparison of the Indices reveals that country rankings are relatively stable year on year. Comparisons of progress in country connectivity between years demonstrate relatively little movement between categories. This is consistent with high correlations between years:

| Index of ICT Diffusion | 2001 | 2000 | 1999 | 1998 | 1995 |
|------------------------|------|--------|--------|--------|--------|
| 2001 | 1 | 0.9918 | 0.9507 | 0.9476 | 0.9084 |
| 2000 | | 1 | 0.9591 | 0.9590 | 0.9182 |
| 1999 | | | 1 | 0.9849 | 0.9421 |
| 1998 | | | | 1 | 0.9553 |
| 1995 | | | | | 1 |
| Connectivity Index | 2001 | 2000 | 1999 | 1998 | 1995 |
| 2001 | 1 | 0.9617 | 0.9554 | 0.9483 | 0.9112 |
| 2000 | | 1 | 0.9893 | 0.9798 | 0.9461 |
| 1999 | | | 1 | 0.9893 | 0.9579 |
| 1998 | | | | 1 | 0.9789 |
| 1995 | | | | | 1 |
| Access Index | 2001 | 2000 | 1999 | 1998 | 1995 |
| 2001 | 1 | 0.9867 | 0.8133 | 0.8297 | 0.7057 |
| 2000 | | 1 | 0.8211 | 0.8488 | 0.7167 |
| 1999 | | | 1 | 0.9338 | 0.7725 |
| 1998 | | | | 1 | 0.8000 |
| 1995 | | | | | 1 |

 Table 7. Correlations within Indices between years

These high correlations are consistent with "considerable stability in Industrial Performance Scoreboard rankings...supporting the argument that capability building is a slow and incremental process" (UNIDO, 2002). They could thus reflect the long-term nature of investments and prolonged time scales involved in expansion of telephone mainline networks. This also suggests that it may be difficult to break out of a "vicious circle", but that benefits conferred by establishing a "virtuous circle" with competitive policies may be long-term.

Appendices 3 and 4 provide a segmental categorization of rankings for 2001. Only 2001 is presented, but a review of movements over the period 1995–2001 yields further insights. China moved up the connectivity rankings from the lowest third in rankings to the middle third in 1998, following liberalization of its telecoms sector to full competition in long-distance and partial competition in its local loop. China also experienced considerable inward investment in this period. India and Pakistan remain in the last third for connectivity. "The growth of telecommunications infrastructure in S.Asia has not been demand-driven, unlike that of other countries where the infrastructure has been built and services operated by private investors...but almost entirely investment-driven, dependent on priority level...from limited public resources...[In India] connectivity remains low and unevenly distributed" (Indian *Economic and Political Weekly*, 1999). However, different policy paths were

pursued: "In Pakistan, the private sector dominates; in India the government [was] monopoly service provider [until the end of 1998/early 1999]; in Nepal, high cost of international communications was circumvented by a country-wide Intranet". These different policy paths do not appear to have had a strongly differentiated impact on respective connectivity. (Note, however, that India subsequently liberalized its telecom sector, which accounts for its maximum policy score of 4 in 2001–2002). Reforms and later benefits in connectivity are also strongly differentiated in the former USSR. In keeping with the studies of economies in transition by the World Bank and the European Bank for Reconstruction and Development, the sharp contrast between the CEE and Central Asian regions is observed in our rankings. In the next section, we analyse the evolution of connectivity indicators from 1995 to 2000, which are of particular importance owing to their relation to the digital divide.

4. THE DIGITAL DIVIDE

In their review of work carried out to assess the digital divide, Bridges.org (2001) observes that the digital divide between countries has typically been assessed by counts of hardware and connectivity (such as hosts, PCs, telephones and mobiles). The distribution of data on these variables was analysed to investigate how it evolves, so as to see whether the "uneven diffusion" of technology (UNDP) is increasing or decreasing over time. Definitions of the "digital divide" include:

- 1. Absolute measures: the absolute gap between the most advanced country with the highest hardware concentrations and the country with the lowest;
- 2. Relative measures: measures of whether the distribution as a whole is growing more convergent or less convergent with time;
- 3. Categorical measures: whether the group of "low-income" countries is converging with (relative to) the group of "high-income" countries.
- 4. Convergence: relative convergence or divergence in rates of growth of hardware, as investigated by Rodriguez and Wilson (2000).

UNCTAD used the first three of these methods to analyse indicators of hardware connectivity and numbers of Internet users. These are only basic indicators of the digital divide, which may be defined with more sophistication as access to and use of ICTs. It may not be the amount of hardware that is most important, but ultimately the use that is made of this hardware and overall changes in the way the economy works. However, analysis of connectivity as the basic "limiting factor" with regard to ICT access and of actual numbers of Internet users evaluates bottlenecks and disparities in the initial stages of access to ICTs.

1. Absolute measures

In appendix 5, which presents basic statistics describing indicator data populations, absolute measures of the digital divide reveal steadily increasing maxima, medians and averages across all populations over the period 1995–2000. These populations indicate rapidly increasing maximum observations as the countries in the lead continue to forge ahead as "star performers". In contrast, minimum observations remain at or close to zero in most

cases. This is explained by these data describing per capita penetrations. Absolute gains in telecommunications sectors cited by the ITU are negated by gains in populations in some developing countries. It is often this "absolute perceived gap" that is cited in popular observations about the digital divide — the gap between the most ICT-developed economies and the least ICT-developed appears to be wide, obvious and growing.

In terms of relative disparities, the evidence is rather more mixed. The distributions of indicator populations are highly skewed, as indicated by significant standard deviations (as a percentage of mean) and discrepancies between the median and mean (both measures of central tendency, but the mean is more influenced by outliers). Appendix 5 indicates that skewness in these distributions of averaged indicator penetrations per capita is decreasing marginally over time. The picture is one of digital leaders forging ahead in their absolute lead; however, newcomers may be catching up in terms of relatively less skewed distributions of hardware across countries, on the basis of average hardware penetrations across countries as the basic unit of analysis.

Such average scores are only partially representative, however. These indicators are averages of total hardware equipment divided by total population for each country. They do not take account of the relative proportion of the world's population living in each country. The Gini measure of inequality weights the distribution of hardware equipment or Internet users by the relative proportion of the world's population for each country to produce a relative population-weighted measure of inequality.

2. Relative measures: Gini coefficients

Preliminary analysis of Gini coefficients of inequality in levels of hardware equipment across nations reveals that levels of inequality in the distribution of hardware equipment are very high at 0.7–0.9, approximately twice the average level of income inequality observed for countries (between 0.3 and 0.4). Inequality in the distribution of technology across countries is undoubtedly high and substantial. Gini coefficients further reflect the relative age of the technologies, with greater inequality observed for more recently introduced technologies, such as Internet hosts (around 0.91) and Internet users (between 0.87 and 0.73). Internet users are more evenly distributed than either PCs or Internet hosts, which emphasizes that access may differ from basic connectivity to the Internet. Telephones, as the oldest technology examined, consistently have the lowest Gini coefficients of all these technologies from 0.69 to 0.57 over the period 1995–2001. Mobiles are a notable exception to the age rule, with lower Gini coefficients than expected given the relative youth of this technology, which further decrease the fastest, from 0.82 to 0.66 over the period 1995-2001. This reflects the rapid catch-up and "leapfrogging" in mobile technology noted by ITU and UNDP. The "digital divide", as measured by hardware equipment and Internet users, is undoubtedly wide and substantial, but may be differentiated according to different types of technology.

| Variables | 2001 | 2000 | 1999 | 1998 | 1997 | 1996 | 1995 |
|-------------|--------|--------|--------|--------|--------|--------|--------|
| Internet | 0.9157 | 0.9205 | 0.9166 | 0.9137 | 0.9126 | 0.9022 | 0.9102 |

| Table 8. Gini coefficient | s (figures in bracke | ts give numbers of countries) |
|---------------------------|----------------------|-------------------------------|
|---------------------------|----------------------|-------------------------------|

The question of how the "digital divide" is evolving, and whether it is growing or decreasing over time, is more complex. Gini analysis reveals relatively little overall change in the inequality of these distributions, with their evolution over time representing small, incremental reductions from their highly unequal levels. However, Gini coefficients as relative measures across the whole distribution do not identify exactly where contributions to reducing inequality come from. Given that Gini measures are weighted by population, countries with substantial populations, such as China and India, have greater influence in determining the overall Gini coefficient. It is doubtful that contributions to reducing inequality derive from the tails of the distribution. As described from the absolute measures, "best performers" are in fact increasing their lead, whilst some countries in the lower tail remain at or close to zero. Thus, these reductions in inequality are likely to derive from the centre of the distribution, with Gini coefficients reflecting the greater importance of more populated countries, and China in particular.

In the next section, UNCTAD analyses relative movements in regional categories of rankings to identify how countries and regions are faring in basic connectivity, and to determine which countries are contributing to reductions in inequality, increasing inequality or merely preserving the status quo. It is considered that, taken together these relative measures of the digital divide and the insights derived from benchmarking provide a more detailed picture of the evolution of countries' ICT development.

3. Categorical measures: Relative movements in country rankings

Country rankings have two main characteristics: their current level and trend over time. To analyse relative movements in country rankings, connectivity rankings were divided into quartiles of "Excellent" (1–50 places); "Good" (51–100); "Poor" (101–150) and "Disadvantaged" (151–201). Trends in connectivity rankings from 1995–2001 were assessed to determine whether they were "Improving", "Similar" or "Declining". In a sample of 201 countries, if 100 is taken as the median, the impact of trends in inequality on the status quo may be viewed as:

| Level | Trend | Relative impact on inequality | | |
|----------------|-----------|--|--|--|
| Excellent | Improving | Exacerbates inequality | | |
| (50 countries) | Similar | Preserves the status quo | | |
| | Declining | Reduces inequality: trend towards median | | |
| Good | Improving | Exacerbates inequality | | |
| (51 countries) | Similar | Preserves the status quo | | |
| | Declining | Reduces inequality: trend towards median | | |
| Median | _ | 100 th place | | |
| Poor | Improving | Reduces inequality: trend towards median | | |
| (52 countries) | Similar | Preserves the status quo | | |
| | Declining | Exacerbates inequality | | |
| Disadvantaged | Improving | Reduces inequality: trend towards median | | |
| (49 countries) | Similar | Preserves the status quo | | |
| | Declining | Exacerbates inequality | | |

 Table 9. Relative movements in country rankings

(This is judgemental and not an exact science: countries may be "borderline" between categories, and move from one to another, accounting for the inexact numbers of countries in each category.) The conclusions from such a review depend very much on the regional classifications. UNDP classifications of regional and cultural groupings were used. Analysis of country rankings by categories reveals the trends described below.

1. OECD countries

Consistent with the observations in section 3 about regional rankings, OECD countries consistently rank as the best-performing countries in terms of ICT development. They have only "excellent" or "good" connectivity and always take first place (Finland, replaced by the United States) as having the highest possible ranking, but with decreasing minimum rankings from 95th to 74th place (Mexico). Consequently, the OECD average ranking decreases from 29 to 22 place from 1995 to 2001. Only three OECD countries show marginal declines in rankings (Finland, Australia and Canada), reflecting loss of first-mover advantages and catch-up by other OECD countries. The standard deviation in rankings decreases correspondingly from 26 to 18, indicating a more closely bunched grouping at the upper end of the distribution. OECD countries are effectively differentiating and separating out from the body of the distribution of country rankings, in an increasingly polarized distribution of hardware across countries with the OECD countries ahead.

2. Eastern European countries and the Commonwealth of Independent States

Eastern European countries and the Commonwealth of Independent States demonstrate considerable polarization within their region. The best ranking improves (Slovenia rockets up the rankings, from 40th place to 25th place from 1995 to 2001). However, minimum rankings slip from 158th place in 1995 (Albania) to 175th place in 2001 (Kyrgyztan Republic). This leaves their overall average ranking unchanged, between 92 and 90, but leads to a steady increase in Eastern European and CIS standard deviation in rankings, from 18 to 40. The Eastern European and CIS region demonstrates increasing polarization and variation, around approximately the same mean. (It is worth noting that variation would be

further increased if Poland, Hungary and the Czech Republic were to be categorized under the CEE region, rather than under the OECD).

3. Latin America and Caribbean

Latin American and Caribbean countries show a steady improvement in average ranking from 100 to 86.4. Barbados and Bahamas have stable rankings at around 51–49th from 1995 to 2001. The minimum ranking (Nicaragua) declines slightly from 142th to 147th place from 1995 to 2001. Despite unchanged maximum and minimum rankings, 10 other countries have improving rankings (including Costa Rica, Brazil and Jamaica) and 12 countries have similar rankings, resulting in an improving average. Standard deviation remains the same at 25. Overall, Latin America retains a stable distribution around a slowly improving average.

4. Arab countries

Arab countries encompass best-performing Qatar, Kuwait and the United Arab Emirates (UAE), whose rankings improve from 44th to 30th place, and Sudan with the lowest ICT development, although Sudan improves steadily from 187th to 164th place from 1995 to 2001. This does not impact on the average ranking and standard deviation, which remain unchanged at around 108 and 41 respectively. Four countries (Bahrain, Jordan, Sudan and UAE) do better; four countries' performance declines over time (Algeria, Djibouti, Kuwait and Syrian Arab Republic). Overall, the contribution of Arab countries is therefore to maintain the status quo, with no major contributions to reducing inequality.

5. East Asia

East Asian economies include best-performing Hong Kong (China) and Singapore (between 11 and 13) and Myanmar as the worst-performing, declining from 180 to 192 from 1995 to 2001. This leaves the overall average unchanged at 113–111 between 1995 and 2001, although there is some improvement to 106 in 2001, while the standard deviation hovers around 55. However, the most remarkable individual success story in East Asia is China, which rockets up the rankings in connectivity from 136th place in 1995 to 93rd in 2001. Given that it is host to one fifth of the world's population, China's steady rise in relative ranking contributes substantially to the reduction in inequality showed by the Gini coefficients.

6. South Asia

South Asian countries are all in the lower two quartiles of rankings and demonstrate no real change overall, essentially preserving the status quo. The best maximum ranking varies between 101 and 97 (Islamic Republic of Iran) from 1995 to 2001, and the lowest between 191 and 194 (Bangladesh). This leaves overall average ranking preserved at 151–148 in the lower tail of the distribution, while standard deviation remains the same around 30. India, the most populous country with one sixth of the world's population, shows a slight improvement in ranking from 158 to 151 between 1995 and 2001. This may reinforce the reductions in Gini coefficient, representing a small reduction in inequality, but it seems likely that overall the South Asian region does not contribute to any major changes in overall inequality.

7. Sub-Saharan Africa

Africa demonstrates a wide variation in performance, between best-performing Mauritius, which improves from 79th place to 57th place from 1995 to 2001, and the bulk of sub-Saharan African countries in the lower tail of the distribution, including Chad, Guinea-Bissau, Congo and Somalia, which occupy last place. The overall average ranking shows a small improvement in rankings, from 167 to 157, while standard deviation in rankings increases to reflect the growing variation from 28 to 32. Overall, there is thus an increasing deviation about a minimally improving average. However, African countries remain clustered towards the bottom of the distribution, so that the overall contribution of sub-Saharan Africa is to maintain the status quo, with no major contributions to reducing inequality.

5. CONCLUSIONS AND WAY FORWARD

There are different aspects to "multi-faceted" technology clusters, and ICTs may be measured from several perspectives. Measurement across multiple aspects is necessary in order to give rounded country profiles across the spectrum of ICT capabilities. On the basis of a review of previous work, UNCTAD chose connectivity, access, usage and policy as key components in the measurement of ICT development across countries. In this study, UNCTAD measures countries' technological profiles using an aggregated index of ICT diffusion, with component indices for connectivity, access and policy in the ICT Development Indices.

These different aspects are related, with strong positive correlations observed between connectivity and access and, to a lesser extent, competitive telecoms policy and connectivity. This suggests that these Indices measure central measures of "technological development", although causation cannot be addressed with benchmarking indices. The qualitative policy index contains an implicit value judgment in favour of competition in the telecoms sector, which does not allow for "benign monopolies" or small economies where economies of scale may be appropriate. The policy index is, however, correlated with connectivity, which implies beneficial effects for telecoms liberalization in terms of improved connectivity.

Classification of countries as falling behind, keeping up and getting ahead on the basis of the ICT Development Indices shows consistent rankings over time, with high correlations between periods. This partly reflects the long-term nature of infrastructure investments and policy reforms. Rankings are in line with expectations based on previous performance and income. Strong regional influences are apparent. In terms of relative rankings, African and South Asian countries are classified as falling behind, Latin American and transition economies as keeping up, and OECD countries and some South-East Asian Tigers are getting ahead. However, this masks considerable diversity in individual success stories, such as Costa Rica and China, and the notable successes achieved in connectivity by Arab and island States, despite less competitive telecom policies. For island States, this may arise, however, from their geographical situation and specialization in service industries.

A review of the evolution of the digital divide, defined by hardware equipment and numbers of Internet users, was undertaken using absolute measures, Gini coefficients and analysis of movements in country rankings. Taken together, this review suggests small, incremental reductions in inequality in the distributions of hardware and Internet users across countries,

yielding the intriguing result of a diminishing digital divide. Our results show that more recent technologies such as the Internet are more unevenly distributed relative to older technologies, such as fixed-line telephony. Our findings also demonstrate "leapfrogging" in mobile telephony (with lower levels of inequality than expected, given the youth of this technology, which decrease the fastest), suggesting greater potential for mobiles as more equally distributed technologies in bridging the digital divide.

From regional analysis of relative rankings, UNCTAD reviewed levels of and trends in connectivity for different regions. Our results show that the "tails" of the distributions are becoming more polarized, with OECD countries becoming more tightly bunched at the front of the distribution and differentiating out ahead from the body of the distribution of countries. Conversely, sub-Saharan African countries remain grouped at the lower end of the distribution. These patterns are also found in and consistent with the absolute scores, where "best performers" are in fact increasing their lead, whilst some countries in the lower tail remain at or close to zero (appendix 5). The incremental overall reductions in relative inequality observed using Gini coefficients derive from the centre of the distribution, and China in particular, which accounts for a fifth of the world's population and shows a steady and significant rise up the rankings.

In future work, it would be interesting to compare the UNCTAD ICT Development Indices and the changes in the rankings therein with other indices (for example, UNIDO's Infrastructure Index, McConnell International's and EIU's connectivity rankings). In further work, the challenging question of causation could be addressed to forge a link between the trends in outcomes observed and underlying policy measures implemented in practice. Regression work could include a consideration of economies' sectoral composition, in the technological structure of services and exports and channels of technology transfer, as important drivers of and influences on countries' uptake and absorption of ICTs.

6. APPENDICES

The following appendices are presented:

- 1. Appendix 1 ICT Development Indices (2001, 2000 and 1999), listed by country and by ranking;
- 2. Appendix 2 Correlation tables of component indices;
- 3. Appendix 3 Comparison of Connectivity/Access Indices for 2001;
- 4. Appendix 4 Comparison of Connectivity/Policy Indices for 2001;
- 5. Appendix 5 Descriptive statistics;
- 6. Appendix 6 Connectivity Index (2001, 2000 and 1999).
- 7. Appendix 7 Data definitions and sources.

Appendix 1 presents ICT Development Indices and the Index of ICT Diffusion calculated as discussed above, in the section on index methodology for 2001, 2000 and 1999.

Appendix 2 presents correlation tables for the three main component indices (Connectivity, Access and Policy Indices) calculated using the correlation function in Excel for the years 1995, 1998, 1999, 2000 and 2001.

Appendices 3 and 4 represent a relative analysis of rankings in the Connectivity/Access Indices and Connectivity/Policy Indices for 2001, by comparing and categorizing countries as falling behind (FB), keeping up (KU) and getting ahead (GA). For connectivity, countries were divided into thirds, with the first third (1-67) classified as getting ahead, second third (68-124) as keeping up and the last third (125-201) as falling behind. For access, countries were also divided into thirds, with the first third (1-53) classified as getting ahead, second third (54-106) classified as keeping up and the last third (107-156) as falling behind. For policy, thirds closely corresponded to scores, so that the first third includes policy scores in excess of 0.5, the second third 0.5/ x >0 and last third scores of zero. This allows the segmental classification and analysis of Connectivity with Access Index and Connectivity with Policy Index, to determine whether there is any correlation and correspondence between them.

Appendix 5 provides exploratory data analysis for base data populations of Internet hosts, PCs, telephones and mobiles to present a preliminary analysis of the digital divide.

Appendix 6 provides a separate listing of the Connectivity Index, for 2001, 2000 and 1999.

2001 CONNECTIVITY VERSUS POLICY PLOT OF RANKINGS

Appendix 5. Descriptive statistics

This appendix provides descriptive statistics for the populations of variables. According to Bridges.org (2001), the international digital divide has typically been assessed by counts of hardware and connectivity (hosts, PCs, telephones, mobiles). The distribution of these variables can be analysed to investigate their evolution over time, to see whether "uneven diffusion" (UNDP) is in fact increasing or decreasing over time.

| Measure | Hosts | PCs | Telephones | Mobiles |
|----------------|--------|--------|------------|---------|
| 1995 values | | | | |
| Maximum | 422 | 328 | 737 | 227 |

Appendix 7. Data definitions and sources

- 1. **Internet hosts**: Internet hosts are the number of computers with active Internet Protocol addresses connected to the Internet, per 10,000 people. Source: ITU.
- 2. **Personal computers**: Personal computers are the estimated number of computers designed to be used by a single individual, per 1,000 people. Source: ITU.
- 3. **Telephone mainlines**: Telephone mainlines are the estimated number of telephone mainlines, per 1,000 people. Source: ITU.
- 4. **Mobile phones**: Mobile phones are the number of mobile phone subscribers, per 1,000 people. Source: ITU and UNSD population estimates.
- 5. **Internet users**: Number of Internet users per 1,000 people. Source: ITU.
- 6. **Literacy**: Literacy rate calculated as the inverse of the illiteracy rate. Source: World Bank and UNCTAD.
- 7. **GDP per capita**: Gross domestic product per capita. Source: World Bank.
- 8. **Cost of a local call**: Estimated cost of a 3-minute local call in US dollars. Source: ITU.
- 9. **Telecom traffic outgoing**: Estimated number of minutes outgoing traffic. Source: ITU.
- 10. **Telecom traffic incoming**: Estimated number of minutes incoming traffic. Source: ITU.
- 11. **Internet Exchange**: Presence of an Internet Exchange (IX) point, defined by Telegeography as "services created to facilitate on-site interconnections between independent or third-party Internet networks". Source: Telegeography.
- 12. **Competition in local loop**: Full/partial competition, duopoly, monopoly. Source: ITU T-Reg Unit.
- 13. **Competition in long-distance**: Full/partial competition, duopoly or monopoly. Source: ITU T-Reg Unit.
- 14. **Competition in ISP market**: Whether the ISP market may be described by full/partial competition, duopoly or monopoly. Source: ITU T-Reg Unit.

SELECTED UNCTAD PUBLICATIONS ON SCIENCE AND TECHNOLOGY

(For more information, please visit www.unctad.org/stdev on the web)

A. Individual Studies

Science and Technology Diplomacy: Concepts and Elements of a Work Programme. 33 p. UNCTAD/ITE/TEB/Misc.5. Free-of-charge.

Transfer of Technology for Successful Integration into the Global Economy: A case Study of Embraer in Brazil. 61 p. UNCTAD/ITE/IPC/Misc.20. Free-of-charge.

Transfer of Technology for Successful Integration into the Global Economy: A Case Study of the South African Automotive Industry. 34 p. UNCTAD/ITE/IPC/Misc.21. Free-of-charge.

Transfer of Technology for the Successful Integration into the Global Economy: A Case Study of the Pharmaceutical Industry in India. 52 p. UNCTAD/ITE/IPC/Misc.22. Free-of-charge.

Coalition of Resources for Information and Communication Technologies. 92 p. UNCTAD/ITE/TEB/13. Free-of-charge.

Key Issues in Biotechnology. 20 p. UNCTAD/ITE/TEB/10. Free-of-charge.

An Assault on Poverty: Basic Human Needs, Science and Technology. 327 p. ISBN 0-88936-800-7. (Joint publication with IDRC).

Compendium of International Arrangements on Transfer of Technology: Selected Instruments. Sales No. E.01.II.D.28. \$45.

Foreign Direct Investment and Transfer of Technology in India. 150 p. Sales No. E.92.II.A.3. \$20.

Information Technology and International Competitiveness: The Case of the Construction Services Industry. Sales No. E.93.II.D.6. \$25.

Investment and Innovation Policy Review of Ethiopia. 115 p. Sales No. E.01.II.D.35. \$25.

Knowledge Societies: Information Technology for Sustainable Development. 323 p. Sales No. GV.E.98.0.11. \$19.

Making North-South Research Networks Work. 48 p. UNCTAD/ITE/EDS/7.

Missing Links: Gender Equity in Science and Technology for Development. 371 p. ISBN 0-88936-765-5. (Joint publication with IDRC).

On Solid Ground: Science, Technology and Integrated Land Management. 66 p. ISBN 0-88936-820-1. (Joint publication with IDRC).

Technological Capacity-Building and Technology Partnership: Field Findings, Country Experiences and Programmes. Sales No. 95.II.D.6. \$22.

The Science, Technology and Innovation Policy Review: Colombia. 161 p. Sales No. E.99.II.D.13. \$42.

The Science, Technology and Innovation Policy Review: Jamaica. 156 p. Sales No. E.98.II.D.7. \$23.

Transfer and Development of Technology in Developing Countries: A Compendium of Policy Issues. Sales No. E.89.11.D.17. \$19.

Report of the Workshop on the Transfer and Development of Environmentally Sound Technologies (ESTs). Sales No. E.94.11.D. 1. \$10. (Joint publication with the Government of Norway. Oslo, Norway.)

B. ATAS Issue Paper Series

ATAS Issue 12: The Role of Publicly Funded Research and Publicly Owned Technologies in the Transfer and Diffusion of Environmentally Sound Technologies. 405 p. Sales No. E.00.II.D.37. \$45.

ATAS Issue 11: New Approaches to Science and Technology Cooperation and Capacity Building. 417 p. Sales No. E.99.II.D.4. \$40.

ATAS Issue 10: Information Technology for Development. 558 p. Sales No. E.95.11.D.20. \$75.

C. Technology for Development Series

Electronic Commerce and Music Business Development in Jamaica: A Portal to the New Economy? 45p. Sales No. E.02.II.D.17.

Changing Dynamics of Global Computer Software and Services Industry: Implications for Developing Countries. 51 p. Sales No. E.02.II.D.3. \$15.

Partnerships and Networking in Science and Technology for Development. 46 p. Sales No. E.02.II.D.5. \$15.

Do Environmental Imperatives Present Novel Problems and Opportunities for the International Transfer of Technology? 21 p. Sales No. E.95.II.D.11. \$10.

Emerging Forms of Technological Cooperation: The Case for Technology Partnership. Sales No. E.96.II.D.1. \$19.

New Technologies and Technological Capability-Building at the Enterprise Level: Some Policy Implications. 39 p. Sales No.E.95.II.D.24. \$10.

Promoting the Transfer and Use of Environmentally Sound Technology: A review of **Policies.** 53 p. UNCTAD/DST/12. \$19.

Science and Technology in the New Global Environment: Implications for Developing Countries. 56 p. Sales No. E. 95.II.D.14. \$19.

United Nations publications may be obtained from bookstores and distributors throughout the world. Please consult your bookstore or write to:

United Nations Publications

QUESTIONNAIRE

Information and Communication Technology Development Indices

In order to improve the quality and relevance of the work of the UNCTAD Division on Investment, Technology and Enterprise Development, it would be useful to receive the views of readers on this and similar publications. It would therefore be greatly appreciated if you could complete the following questionnaire and return it to:

Readership Survey UNCTAD Division on Investment, Technology and Enterprise Development United Nations Office at Geneva Palais des Nations Room E-10054 CH-1211, Geneva 10 Switzerland

1. Name and address of respondent (optional):

| 2 | Which | of the | following | hest (| describes | vour | area of | work? |
|----|---------------|--------|-----------|--------|-----------|------|---------|-------|
| ∠. | vv men | or the | Tonowing | Dest | acscribes | your | area or | WOIK! |

| Government | ? | Public enterprise | ? |
|--------------------------------|---|----------------------|---|
| Private enterprise institution | ? | Academic or research | ? |
| International organization | ? | Media | ? |
| Not-for-profit organization | ? | Other (specify) | |
| | | | |

3. In which country do you work?

4. What is your assessment of the contents of this publication?

| Excellent | ? | Adequate | ? |
|-----------|---|----------|---|
| Good | ? | Poor | ? |

5. How useful is this publication to your work?

Very useful ? Of some use ? Irrelevant ?

- 6. Please indicate the three things you liked best about this publication:
- 7. Please indicate the three things you liked least about this publication:
- 8. If you have read more than the present publication of the UNCTAD Division on Investment, Enterprise Development and Technology, what is your overall assessment of them?

| Consistently good | ? | Usually good, but with some exceptions | ? |
|--------------------|---|--|---|
| Generally mediocre | ? | Poor ? | |

9. On average, how useful are these publications to you in your work?

| Very useful ? | Of some use ? | Irrelevant? |
|---------------|---------------|-------------|
| | | |
