Abstract

Purpose – Effective menstrual management is essential for the mental and physical well being of women. However, many women in low-income countries lack access to the materials and facilities required. They are thus restricted in their activities whilst menstruating thus compromising their education, income and domestic responsibilities. The paper aims to discuss these issues.

Design/methodology/approach – This study describes the menstrual management challenges faced by women in an emergency situation in Uganda. Totally, 50 interviews and focus group discussions were conducted with women from villages, internally displaced person (IDP) camps and schools so that the menstrual management of the host population could be compared with the IDPs.

Findings – This study showed that in IDP camps there was a significant lack of materials including soap, underpants and absorbing cloth, and facilities like latrines and bathing shelters. As a consequence women in IDP camps suffer with poor health and diminished dignity. There is also a lack of education about menstruation and reproductive health and practices are strongly influenced by cultural taboos.

Originality/value – This is the first time that the menstrual management of women in IDP or refugee camps has been studied.

Introduction

Improvements in water quality and quantity, sanitation and hygiene practices have the potential to prevent at least 9 per cent of the global disease burden (in disability adjusted life years) (Prüss-Ustún *et al.*, 2008). Menstrual hygiene is one aspect that needs to be improved and indeed this is starting to be recognized when designing sanitation programmes at both a global policy level (e.g. Gomez, 2006; Ten, 2007; Raralio and Ebo, 2009) and by non-governmental organizations (NGOs) working in the

field (International Federation of Red Cross and Red Crescent Societies, 2010). Specific examples include Bharadwaj and Patkar (2004) and Mahon and Fernandes (2010) working in India, Ahmed and Yesmin (2008) working in Bangladesh, Lal *et al.* (2007) working in internally displaced persons (IDP) camps after the Pakistan earthquake. Menstrual management is mentioned in the UNHCR's commitments to refugee women (UN High Commission for Refugees, 2001) and in commonly used reference manuals like "Engineering in Emergencies" (Davis and Lambert, 2002), but these only address menstruation briefly and whilst the importance of addressing the problem with sensitivity is stressed, no specific recommendations are made. The latest version of the Sphere Project (2011) now contains a number of specific recommendations and this has increased from previous editions. Sphere standards are internationally recognized sets of common principles and universal minimum standards in life-saving areas of humanitarian response.

Ignoring women and girls' menstrual management needs may not only impact their health but also their usual daily activities, including education, income and domestic duties. For instance, an inability to manage menstruation in schools due to inadequate toilet and bathing facilities is cited as one of the top reasons for girls' absenteeism, typically leading to them falling behind with their studies and eventually dropping out altogether (Bharadwaj and Patkar, 2004; WaterAid, 2005; Ten, 2007; Tearfund, 2009; Erulkar *et al.*, 2010). As such, it is clear that improving menstrual management is key for attaining Millennium Development Goal 3: "Eliminate gender disparity in primary and secondary education, preferably by 2005, and in all levels of education no later than 2015" which in this context overlaps with Millennium Development Goal 7, target 3 "Halve, by 2015, the proportion of the population without sustainable access to safe drinking water and basic sanitation" (United Nations, 2008). Good menstrual management relies on a supply of clean water for washing as well as adequate sanitation facilities for changing menstrual materials (Narayan *et al.*, 2001; Bharadwaj and Patkar, 2004; Lal *et al.*, 2007; Ahmed and Yesmin, 2008; Tearfund, 2009; Mahon and Fernandes, 2010; Fernandes, 2010).

The impacts of poor menstrual hygiene on health are not extensively described in the medical literature. Leegaard (1984) found that Swedish women were significantly more likely to experience regular bouts of candidiasis if they used sanitary pads rather than tampons. She also observed a relationship between positive candidiasis swabs and "spot" washing (as opposed to using a bath or a shower), though this relationship was not significant. However, later publications (Geiger and Foxman, 1996; Demba *et al.*, 2005) covering the USA and Gambia, respectively, found no relationship between menstrual practices and candidiasis. In a study of Indian women, Singh *et al.* (2001) linked reproductive tract infections more generally to poor menstrual hygiene (defined as an absent or dirty menstrual pad). Tchoudomoriva *et al.* (1998) linked urinary tract infections (UTIs) to sanitary pad as opposed to tampon use in Swedish women. Czerwinski (1996), working in the USA, found that regular washing of the genital area with soap and water is sufficient to prevent infection. None of these studies attempted to prove a link between using dirty sanitary towels and getting vaginal or UTIs, although several authors who have studied menstrual management in low-income countries have postulated that the link exists (Ahmed and Yesmin, 2008; WaterAid, 2009; Fernandes, 2010; Mahon and Fernandes, 2010).

Although research in the area of menstrual management in low-income countries has grown recently, it is principally focused on school girls (Narayan *et al.*, 2001; Bharadwaj and Patkar, 2004; WaterAid, 2005, 2009; Adhikan *et al.*, 2007; Ten, 2007;

Deo and Ghattargi, 2005; Kirk and Sommer, 2006; Dasgupta and Sarkar, 2008; Anibue *et al.*, 2009; Dhingra *et al.*, 2009; Erulkar *et al.*, 2010; Sommer, 2010; McMahon *et al.*, 2011; Thakre *et al.*, 2011; Kamaljit *et al.*, 2012; Shanbhag *et al.*, 2012). There are only four studies published on menstrual management in mature women in low-income countries (Ahmed and Yesmin, 2008; Fernandes, 2010; Mahon and Fernandes, 2010; Sommer, 2012).

A review of academic and grey literature highlights that research into menstrual management in IDP camps was been largely ignored until Sommer's 2012 review paper, and even this highlights the need for more case study evaluations. For example von Roenne *et al.* (2010) describe in detail the formation and evolution of the reproductive health group in Guinea where nurses and midwives who had been forced to escape the conflicts in Sierra Leone and Liberia provided reproductive health services to their fellow refugees. However, their services seemed to only include antenatal care, postnatal care, family planning and sexually transmitted infection care, with no mention of any assistance on menstrual management. There is only one further study that addresses the issue: a short article on bathing shelters erected in IDP camps following the Pakistan earthquake (Lal *et al.*, 2007). They consulted the women on how to build shelters that would facilitate good menstrual hygiene. The women requested that "menstruation units" for washing and drying their menstrual cloths should be included within the screened bathing blocks, so that no one would know that the women were entering the blocks for that purpose. Such blocks were subsequently constructed and received positive feedback.

Thus, there is a clear need for a study focusing on the menstrual management practices and perceived needs of women in IDP camps. This research compares menstrual management between women in IDP camps, neighbouring villages and schools in Katakwi district of Uganda. As the disaster had a slow onset, comparing IDP women and girls in the camps with non-IDP women and girls settled in the same area highlights the differences in menstrual management. There are four research focus themes: menstrual materials; menstrual management facilities; education about menstruation; and daily life during menstruation. By comparing women in IDP camps to women in neighbouring villages, it is possible to assess how living in camps provides additional menstrual management challenges, compared to women living in villages. With this enhanced understanding of the challenges girls and women face, the paper recommends suitable changes to sanitation programmes designed for emergency situations.

In order to make recommendations, it was necessary to understand how sanitation planning in emergency camps occurs. The ideal situation is described by Davis and Lambert (2002). At the operational field level, a sub-group is responsible for sanitation planning. This may include a government public health authority, UN agencies, NGOs, private sector members (such as construction or excavation contractors) and representatives of the affected community. This group meet regularly. The group identifies the resources that need to be mobilized to meet sanitation needs; plan and implement a response; and monitor and evaluate progress making adjustments to the programme if necessary. In order to carry out these tasks effectively, they need to collect information about people's sanitation needs and how they should be addressed. Techniques for collecting information include interviewing, brainstorming, direct observation, participatory mapping, ranking and questionnaires. For example, community members could be asked to rank latrine criteria (such as privacy, distance from home, ease of cleaning) so the most suitable latrine types can be selected.

Background and methodology

The district of Katakwi in North East Uganda (see Figure 1 for location) was selected for the research because this region contained both villages and IDP camps in close proximity, enabling a comparison of menstrual management in different settings to be made. At the time of the research (2005 and 2006), Katakwi was affected by two ongoing conflicts. First, the area suffered from incursions by the Lord's Resistance

Figure 1.
The location of the study area, Katakwi District, within Uganda

Note: In 2007 (after the field study was completed) the district was split into two, Katakwi and Amuria

Army, which had a record of murder, torture, rape and abduction. Second, there were violent attacks from neighbouring Karamoja. This started as cattle rustling, but in more recent times included rape and murder (International Displacement Monitoring Centre, 2005). All the camps had more women than men, with the proportion of women for individual camps ranging from 51 to 62 per cent. Lutheran World Federation (LWF) staff reported that this imbalance was caused by men being killed, abandoning their families or being away in the army or towns where they are seeking work.

The research took place over June and July 2005 and 2006 by two female researchers. Totally, 13 IDP camps were chosen in conjunction with LWF. They varied in size (from around 400 to 2,000 people) and length of existence (two to five years). Levels of security in the camps also varied according to the LWF staff. Camps were selected from the north, south east and west parts of the district in order to give a representative view. Four villages and fourteen schools were selected due to their close proximity to the IDP camps. The rationale for selecting a range of camps with a variety of characteristics was to get a clear picture of the diversity of menstrual management challenges faced. Some of the newer or more insecure camps may not have experienced as much intervention on menstrual management from NGOs as the older or more secure camps. In smaller camps interventions may be more likely to filter to household level, conversely larger camps may attract the attention of more NGOs.

Since the research took place the situation has changed radically, and it became safe for the camps to be dispersed and people to return home.

This piece of research is primarily applied in nature, seeking to solve a particular problem, and began in an exploratory rather than descriptive or explanatory manner (Neuman, 1997), asking “what are the differences between menstrual management in IDP camps, neighbouring villages and schools?” It then evolved into action research, treating knowledge as a form of power to empower and attempting to improve conditions (Neuman, 1997) through making recommendations for design changes to sanitation programmes in Katakwi. Further recommendations based on wider principles appropriate for emergency sanitation planning globally are also made.

In order to generate the richness of data required, in-depth qualitative interviewing was adopted as the chosen methodology, as opposed to, for example more quantitative techniques such as questionnaires (Rubin and Rubin, 1995). Such an approach seeks to build trust and openness through empathy, and recognizes that the interviewer is not a neutral actor but a participant in an interviewing relationship, with their emotions and cultural understandings having an impact on the interview (Monaghan and Just, 2000).

This research therefore borrowed from two main theoretical areas: feminist research and postmodernism. First, feminist research, because of the emphasis on subjective, empathetic, process oriented, inclusive approaches, combined with the flexibility to choose research techniques across boundaries between academic fields (e.g. Lather, 1991). Second, postmodernism, in recognition that knowledge takes numerous forms and is unique to particular people, therefore a certain methodological self-consciousness is necessary which recognizes that language is an inadequate vehicle for expressing any sort of “reality” (e.g. Bernard, 2006; Hall, 1973; Robson, 2002).

In order to minimize bias as part of this chosen methodology, or allow for the effects of it where it occurred, reflexivity on the part of the researchers was necessarily an integral activity. This involved the interviewers asking multiple sides of a story and empathizing with conflicting points of view, even if those were not shared by the interviewer. In this type of research it is impossible to eliminate bias, but if the researchers are fully aware that they may be biased then they can try and minimize it.

Groups of women and groups of girls were interviewed to enable as many of their opinions as possible to be heard in a short space of time. Women were asked to volunteer for the focus group discussions whilst girls were selected by the senior women teacher in each case. The purpose of the research was explained to the participants, and their consent to participate in the research was sought. Any who did not want to participate left the group at this point, although they could leave at any point during the focus group. No men were present so the women could talk at ease if they wanted to, or remain quiet. No names were recorded so the participants' anonymity was assured. The interviewer sat on the floor with the participants to avoid any feelings of intimidation. The focus group discussions started with a round of introductions, and translation was done by a LWF social worker (for the women) or a senior woman teacher for the school girls. Whilst a discussion guide had been prepared, informal discussion covered the issues in a culturally appropriate way. Discussions were recorded and notes were taken. No full names were recorded, to respect confidentiality.

Issues raised in these discussions were triangulated with other available information such as individual interviews with other key informants. Key informants included teachers, NGO workers and health professionals. Observations were made in the camps, villages and schools according to a checklist which included a description of the design, the function, appearance, smell and items available (soap, water and basins). Following the interviews, the recordings were transcribed and common themes are described in the results section.

Details of the variety of interviews conducted can be found in Table I. Altogether the research includes:

- ten focus group discussions with up to 45 women each in IDP camps;
- three focus group discussions with up to 25 women each in villages;
- 16 focus group discussions of up to 15 girls aged nine to 20 in 14 schools, accompanied by a female teacher;
- eight interviews with senior or head teachers; and
- nine interviews with health workers.

The camps were selected from all parts of the region, and the selected camps varied in size and age. However, it was not possible to select camps on the basis of ethnicity, area of origin of residents, socio-economic status, levels of education or literacy, and hence there is a possibility that the camps were not representative. Although the authors are confident that through data triangulation and attention to matters of bias, accurate data has been gathered, the different culture and language of data gatherers compared to respondents may have resulted in some attitudes and opinions having been lost in translation. These factors may also have affected the girls' and women's willingness to express their problems and fears in front of each other, or in front of their teachers. However, these effects were minimized to the extent of not distorting the data presented. It should also be noted that by their nature, focus group discussions can be dominated by the opinions of one or two individuals, and may not reflect the majority view. However, they do allow opinions to be gathered from a lot of women in a short space of time, and can be less intimidating than a face-to-face interview.

This was a piece of exploratory research into the experiences of girls and women about menstrual management. It is based on the theory that the subjects of the research have real experiences which can be elicited by a sympathetic and sensitive

researcher, and those experiences and perceptions deserve to be heard and documented. It is an ontological approach which combines objectivism and realism, and an epistemological approach which is a blend of interpretivism and critical realism.

Results

In each of the following sections, the three contexts of villages, schools and camps are compared for each of the four menstrual management themes.

Description, demographics, activities

The thirteen IDP camps visited were densely populated with mud-brick or thatch huts situated, on average, less than ten metres apart. Seven or eight people, both male and female, and often only distantly related, lived in each dwelling. Bathing facilities (for washing) and latrines (for urinating and defecating) were communal and generally located around the periphery of the camps, but well within sight for security reasons.

Each camp had at least one borehole within 200 m of the edge of the camp.

In villages, mud-brick homesteads were typical. Built with land surrounding them, these were occupied by one family (up to seven or eight people) with dividing walls for men and women. Each homestead had its own bathing facility within the compound.

The daily activity of female residents involved caring for children, collecting firewood and water, cooking and farming. These activities were similar in both village and camp life, though more arduous in the camps due to more dependent household members (often orphans) and no formal land to farm.

The average school size in the research region was 581 pupils. Female school attendance decreased with age at all of the schools. For example, at two of the primary schools investigated, the female drop out rate over the first seven years was 75 and 66 per cent, respectively. At a secondary school, there was a 97 per cent reduction in numbers from the first to the sixth year and at another secondary school, there was a reduction of 42 per cent over just one academic year. Early marriage was the most

prevalent reason given by the girls for dropout, but lack of money for scholastic and menstrual materials was cited as another reason by girls and teachers in two of the fourteen schools.

Menstrual materials

Almost all of the women interviewed used cloth from old, worn clothes to absorb their menstrual blood, or more rarely, cloth bought from a health clinic. However, out of the 29 focus group discussions, 17 specifically commented that they found the use of cloth to be ineffective due to poor absorption, discomfort and leakage. The cloth, which lasted anywhere from one to six months depending on age at time of first use as a menstrual cloth, was held in place by a waistband (see Figure 2) or, less frequently, by underpants. Some more affluent village women or school girls used disposable sanitary pads with underpants. These cost between \$1 and \$1.85 for a packet of 12 pads, but were not available from the markets in Katakwi.

In camps, there was great difficulty in procuring cloth, and women often had to resort to using rags found outside the home, such as discarded head-cloths used by women carrying water containers from boreholes. Users stated this practice was undesirable and is not practised in the villages where all cloth was sourced from within the home. In four of the schools either cotton cloth or sanitary pads were available to girls in an emergency, but these were bought using government funds. In the other schools, there were insufficient funds for such an emergency service:

[We use] old clothing, but if we don't have any we take rags that somebody has dropped in the rubbish pit (Women, Aketa Camp).

We use old clothes, sometimes we find rags by the borehole (Women, Amursia Camp).

[We use] old clothes and if we do not have those we pick them up from the rubbish and wash them (Women, Ongongoja Camp).

Source: Sketch by Ross Tierney based on a photograph taken during fieldwork

Figure 2.
A menstrual cloth tied
with a waistband

All women interviewed stated a preference of using well fitting underpants to hold material in place, but these were expensive and difficult to obtain. Older women preferred to use clean, dark coloured cotton cloth which would not show stains, whereas younger women, who had occasionally used disposable pads which they had been given by schools, health clinics or NGOs, expressed a desire to use pads for reasons of comfort, absorption and freedom of movement. To continue using disposable pads, many older girls worked to raise money to pay for them in addition to their scholastic materials. The girls worked in other people's gardens, sold produce in the market or brewed local beer. When a menstrual cloth or disposable pad is no longer useable it is disposed of in a pit latrine, or if no latrine is available, it is buried.

Five of the 14 schools had received cotton cloth from NGOs. Whilst the cloth was considered effective for their emergency needs, it did not suffice on its own. The girls lacked soap and basins to wash the cloth and tight fitting pants to hold the cloth. However, once the cloth had deteriorated and been disposed of, no further cloth was available so girls in camps had to resort to rags again. Another five schools had received sanitary pads from NGOs and teaching staff noted improved school attendance. At one school the supplies were running low and there was no sign of replenishment. At the other schools, the girls reported no problems in the disposal of pads, although the supply of pads had only just started.

Menstrual management facilities

In order to manage menstruation with dignity, private areas and facilities (soap and buckets) are required for washing and drying cloths in close proximity to latrines or bathing areas. In the camps, there were not enough basins or soap, and they were not able to bathe once a day as they were in the villages:

We also need more basins, the ones we have now are broken and we have to wash everything in them – our rags, our babies. Everything is put into the same basin (Women, Palam Camp).

Cloths are usually changed up to three times a day. In villages, women wash their used cloth within the homestead bathing facilities using a separate family basin. The cloth is then dried outside in the sun. They feel comfortable doing this because their dwellings are sufficiently separated from each other. However, the situation in camps and at schools is reported as significantly worse.

At all the camps visited the women did not have enough privacy to cope with their menstrual periods hygienically or with dignity. Common problems included broken or absent doors on latrines and bathing shelters, which forced women to wash and change rapidly or in the dark. The cloths were then hung indoors on the eaves of their dwellings, sometimes covered with another cloth to hide it from other family members. The cloths do not dry quickly but women feel that there is no alternative because it is not acceptable to hang their cloths outside in view of other families, especially men and boys:

Village life was different, we had privacy. We were able to wash and dry the rags outside. We dried the rags on the roof [of the dwelling] or in the bush and we were less exposed (IDP woman, Amursia Camp).

In the village we were able to wash and hang the rags anywhere without shame, in the camp that is very difficult (IDP woman, Ngariam Sub-County Camp).

In the villages we had freedom and space to dry the rags outside the huts. Here [in the camp] we have no privacy to dry the rags, we are forced to hang them in the house. We also have to wait until evening to wash the rags (IDP woman, Milmil Camp).

A consequence of the poor drying facilities is that women resort to wearing damp cloths. Medical professionals interviewed reported repeated use of damp cloths leads to health problems such as rashes, fungal infections and UTIs. Damp cloth is also more uncomfortable to wear and rubs against the skin causing open sores, which are vulnerable to infection. Medical staff at the camps confirmed that numerous women suffer from candidiasis, a fungal infection that can be caused by poor hygiene. The women rarely seek medical advice for these problems, which are only noticed when they are examined for another medical problem. Health centres can provide free antibiotics to treat UTIs but medication for candidiasis must be bought from drug stores. This is relatively expensive at \$1.50 for a typical course of treatment.

In six of the schools where facilities were observed, the facilities were also inadequate and girls were not willing to change their menstrual material whilst at school. Common problems stated included: lack of soap; no water close at hand; no area available for drying cloths; no bathing facilities; and too few latrines. Water was available at all schools but if located away from the latrines the girls had to carry water across the school drawing unwanted attention. The number of latrines relative to girls was also significantly below the government and Sphere Project (2011) standards. The ratio of girls to facilities (mixed and girls) averaged at 70:1 across the ten schools, compared to 40:1 (Government of Uganda standards) and 20:1 (Sphere Project, 2011). Some of the latrines had been destroyed by animals. Some girls who lived close to the school ran home to change their cloth and thus remained in school. Others did not attend school during their menstrual period and thus fell behind academically and increased the likelihood of dropout. Other girls remained in school but did not change until the end of the school day. As a result they ran the risk of smelling, leaking, being in discomfort and getting an infection:

Most of them [schoolgirls] stay at home. It is very difficult to come to school when they have their menstruation because they don't have the facilities to change their underpants, the sanitary pad they don't have, they don't have money for buying them, so most start using rags which are very difficult to maintain and even to wash. So most of them stay away (Senior Woman Teacher, Obulengorok Camp School).

We would like bags for carrying such things [as menstrual materials] because we just have 'kaveras' (plastic bags) like we use to go to the market, but when we just use 'kaveras' the boys can grab them thinking it is cassava we are bringing from home. We would like bags with locks' (Girls at Obulengorok Camp Primary School).

[...] we are embarrassed to transport rags to and from school. We have no bags to put *them* in (Girls at Adere Primary School).

Education about menstruation

Many menstruation myths can be dispelled through appropriate, targeted education. Some of the myths encountered during this research included:

- a menstruating woman should not go to the groundnut field as this will bring a bad harvest;
- a missed menstrual period indicates HIV/AIDS;
- cloths must not be burnt, or discarded where others may find them as this may bring misfortune to the woman; and
- if a pad is discarded in a latrine, the girl will not reproduce.

The primary route of education about menstrual management is through schools. In all of the schools investigated, girls were taught about menstruation, though the quantity and quality of teaching varied significantly. Topics comprised one or all of the following: personal hygiene, managing menstrual materials and the biological menstrual cycle. The importance of educating girls about menstruation was widely acknowledged by both male and female teachers. Yet despite this, there was a general consensus amongst NGO staff, health staff, government officials and teachers that girls did not know enough about menstruation and still believed myths. This was confirmed by the basic questions asked by primary and secondary schoolgirls during the focus group discussions. From the senior nursing officer's experience, many girls still did not know: what periods were; why females have them; what can be expected (regularity, extent of bleeding and what is abnormal); how to cope with period pain; what menstrual materials are effective; and how to manage materials (transporting when soiled, washing and drying, and disposal).

Girls in nine of the ten focus groups that addressed the issue were not prepared for their first period. They did not know what it was and feared it was another sickness. In rural areas and in camps, girls were less aware and more bashful about menstruation.

Only four of the 14 schools stated that boys were taught the basics about menstruation including the practicalities involved. In these schools, girls and teachers explained that the incidence of teasing had fallen. However, there were still reports of teasing if girls had a problem with menstruation. When asked if they would like a local nurse to come and talk to them about menstruation, the girls generally responded positively. Four schools already had a visiting nurse to undertake medical examinations and talk about health but the nurse did not always talk about menstruation. In eight out of ten schools asked, the older girls spoke to the younger girls about issues of growing up, like menstruation, and it was believed an effective means by which the younger ones could learn. One of these schools had a more formal arrangement, referring to child-to-child teaching. There was no significant difference in educational practises between menstruation between schools attended by IDPs and schools with no IDPs.

Approximately half of the girls were taught about menstruation at home, with no significant difference observed between the camps and the villages. This task fell to the women in the family. The remaining girls learnt about menstruation only at school. The impression from all adult participants in the research was that most parents or guardians do not sufficiently educate their girls about menstruation. Poor menstruation education at home was attributed to poverty and ignorance, as many parents would not have received any education about menstrual management themselves. The situation is compounded by unfamiliarity with modern materials and inability to provide girls with necessities such as menstrual materials, pants, a basin, soap, and sometimes painkillers. In the towns, parents were generally more educated and aware of the issues that affected girls' education than in rural areas.

Daily life during menstruation

The women and girls are very fearful that the "rags" are obvious to others or that they may loosen and fall. In one group, women described moving and sitting in strategically careful ways in order to "maintain themselves".

In the camps more than half of the interviewed women stated that they had had to remain in their homes for some part of their menstrual period because of abdominal pain and shame due to lack of sufficient menstrual material to protect from staining their clothes. At these times neighbours and children help with daily chores such as

water collection. This sometimes meant that girls were kept away from school in order to care for the household. Conversely, in the villages women rarely remained indoors during their menstrual period. This was because their rags dried more quickly enabling them to change more frequently and feel more confident about being in public. They also said that neighbours are not near enough to be called on for help.

Teaching staff in eight of the schools reported that girls missed school during their menstruation. The main reasons cited were abdominal pain, fear of teasing and that they would not be able to “maintain themselves”. According to the teachers interviewed, if girls miss four days a month, they fall behind academically increasing the likelihood of dropout. Of the five schools with good attendance during menstruation, four schools had recently received pads from NGOs to give to the girls. There did not seem to be any particular policy targeting schools containing IDPs for this intervention. The fifth school was Kokorio Primary School, serving local village (no IDPs) where the girls interviewed were unusually confident, open and willing to talk about issues on menstruation. They had markedly different experiences and attitudes towards menstruation from their peers in other schools. They never missed school during their menstrual period and they used the latrines to change rags during the school day. They carried their menstrual materials to and from school in black plastic bags and claimed not to be teased or bothered by boys when going to the latrines with the bags; and they were not afraid of staining their clothes. It may be possible to attribute the difference in attitude and behaviour found at Kokorio to one or more of the following:

- the school latrines were clean, and had strong metal doors, with large working locks;
- the girls’ latrines were well separated from those of the boys; and
- both boys and girls at Kokorio had received sex-education classes and had talked about “growing-up” issues in class.

Discussion

There is a clear and compelling basis for intervention in menstrual hygiene management. Females unable to manage their menstruation feel undignified by the sights, smells, teasing, discomfort and infections that can result. Productive time spent at work and school suffers.

It was observed that women in the camps faced greater challenges than women in the villages. Specifically, they found it difficult to procure menstrual cloths and they had a lack of privacy to change their cloths and wash and dry them. This latter challenge is a factor of the camps’ cramped conditions and inadequate provision of sanitation. The lack of space to dry the cloths has further impacts as it means that women cannot change cloths regularly and are forced to remain in the home, not outside doing productive activities. The use of damp cloths potentially leads to urinary tract and vaginal infections. Attempts to address menstrual management by the NGO working in the camps were hampered by a lack of time, research and capacity. Further research is needed to understand the constraints which prevent appropriate support being made to displaced women and girls.

Preferences for different types of menstrual materials can vary within a community. NGOs typically treated girls and women the same despite differing preferences (girls wanted pads, women cloth) but acted in the best interests of all (by giving cloth) considering the facilities available and financial sustainability.

Disposable pads are still prohibitively expensive. Tearfund (2009) estimated that buying sanitary pads for one woman would cost 10 per cent of a poor family's monthly income. It is likely that more people will use pads in the future as they become more affordable and popular with women. If they dispose of them down the latrine, consideration needs to be made for the larger pit size required. The impact of disposable pads on the solids accumulation rate in pits is not known and requires further research. In non-emergency situations, women are able to dispose of disposable pads with other solid waste, bury them or burn them (Ten, 2007; Dasgupta and Sarkar, 2008; Dhingra *et al.*, 2009; Water Aid, 2009; Fernandes, 2010; Mahon and Fernandes, 2010) but this may not be possible in IDP camps. This situation may be improving with the introduction of Makapads in Uganda. These are locally manufactured pads which sell for around half the price of other brands. They are made from 99 per cent local materials, with the main raw material being papyrus reeds, which grow abundantly across the country (Ishingoma, 2006). However, they have been reported as being insufficient for the heaviest menstrual flows (Sommer, 2012). They were not available on the market at the time of research.

For improvements to menstrual hygiene to be sustained, the community at large needs to be sensitized to the importance of girls' education and issues like menstruation. Whilst of course women have been managing their menstruation for generations in their villages, living in the camps means they cannot manage their menstruation in the usual way, and hence education about menstruation becomes as important as providing suitable facilities.

Menstruation must not remain a taboo subject if women and girls are to manage themselves better and avoid unnecessary health problems, disrupted education and low self-esteem. However, efforts to include menstrual hygiene education in primary schools in Bangladesh were resisted by policy makers as it was seen as against norms and values (Nahar and Ahmed, 2006), and development workers in India were worried that introducing the subject could damage relations with the community (Mahon and Fernandes, 2010). Menstruation is not only a taboo in Uganda; Ten (2007) describes how menstruation is a taboo across Asia and Africa, and Dhingra *et al.* (2009) and Fernandes (2010) describes the restrictions on women in India. If women are embarrassed about their menstruation they will take extreme steps to disguise it, including hiding their menstrual rags so they do not dry properly. Again, this is not exclusive to Uganda, and has been observed in Nepal (WaterAid, 2009), Bangladesh (Bharadwaj and Patkar, 2004; Ten, 2007; Ahmed and Yesmin, 2008) and India (Dhingra *et al.*, 2009).

Although the schools were all day schools, the girls needed to bathe each time they changed their cloth so bathing facilities are essential. However, they were absent in the schools visited in this study. If female teachers and girls continue to use cloth, bathing shelters are necessary for privacy, personal hygiene and to avoid embarrassment from leaking. The facilities need only be basic structures made out of local materials but must include a system for drainage to prevent stagnant surface water. However, LWF (2006) found that 15 per cent of schools in Katakwi and Amuria did not have separate stances for boys and girls and that 40 per cent of school latrines in Katakwi and Amuria districts did not comply with government design specifications.

Conclusions and recommendations

The menstrual hygiene needs of women and school girls have been gravely overlooked in both relief and development programmes forcing them to cope with their menstrual management in any way possible. This has negative impacts on the dignity and mobility of women and school girls. Davis and Lambert (2002) recommend that communities are

consulted at all stages in the planning, monitoring and evaluation of a sanitation programme in emergency camps. This research has shown that women and girls in the IDP camps of Katakwi were not sufficiently consulted about their menstrual needs, which has been reflected in the poor menstrual management practices they have been forced to adopt.

Simply providing menstrual material is an insufficient way of addressing menstrual management in schools and camps. Explanations are required of how to use and manage the material, and key messages should be regularly reinforced. Menstruation places extra demands on female consumables, so there is also a need for additional tight pants, soap and basins. Furthermore, a sufficient amount of gender sensitive sanitation infrastructure is fundamental in schools and camps, including private, clean and secure latrines and bathing shelters, with a nearby water supply for handwashing and bathing.

An emergency situation can erode the social fabric of communities. As such, particular care is often placed on ensuring effective education and emotional and financial support for those affected. For women and girls, menstrual management education is essential to ensure an understanding of the biology of menstruation, and in particular, how to achieve the best menstrual hygiene and when to seek medical help. Boys should not be excluded from menstrual education as an increase in their understanding helps reduce the embarrassment and exclusion of girls and women during their menstrual period. Parents and carers of children also need to be informed about the importance of teaching girls about menstruation at home, offering emotional and financial support, and providing appropriate sanitation facilities.

Changes are required to the design of sanitation programmes so that menstrual management of women and girls is effectively addressed. First and foremost consultation is required with school girls, teachers, women and the wider community about menstrual hygiene needs. Menstruation is seen as a taboo subject and must be dealt with sensitively. Cultural perceptions of menstruation and their implications on interventions should not be ignored but understood and catered for appropriately. Stakeholders should be more involved in participatory design and monitoring of the provision of facilities.

It is recommended that national and international emergency response guidelines on menstrual hygiene interventions should promote financially and environmentally sustainable solutions, including:

- consultation with girls and women regarding their menstrual needs, including what non-food items they require and what bathing facilities they would like;
- training in the use of menstrual materials;
- non-food items to include tight pants, soap and basins;
- private, clean and secure latrines with water available nearby; and
- education of both boys and girls in menstrual biology and hygiene.
