Beginning in May 1999, The Kate B. Reynolds Charitable Trust funded 14 programs across North Carolina under the Project IDEAL (Improving Diabetes Education, Access to care and Living) Diabetes Initiative that proposed to enhance the delivery of healthcare services to and the quality of life of underserved North Carolinians with or at risk for diabetes mellitus. Organizations that received funding included public and private, non-profit, healthcare organizations that served populations with a substantial burden of diabetes and had evidence of collaboration among community organizations as well as demonstrated sustainability and local commitment. The range of funds provided to the programs during the three years was $160,000-$275,000.

The Kate B. Reynolds Charitable Trust contracted with the Wake Forest University School of Medicine (WFUSM) Department of Public Health Sciences to develop, administer, and evaluate the initiative. An advisory committee consisting of representatives of state, federal, and private public healthcare agencies was convened by the management team at WFUSM to provide guidance in the development of the request for proposals, to review proposals received, and to provide technical assistance and continuing education to participating programs.

Each of the 14 programs developed their own unique interventions based on the needs of their community to reach their target populations. Examples of such interventions included: establishing new diabetes education and care programs in existing but underutilized physical facilities; using mobile healthcare units; creating "health depots" (off-site stations where screenings were performed and health information was distributed) in rural communities; staffing satellite sites in community pharmacies, physicians' offices, and other locales; and sending visiting healthcare professionals (e.g., diabetes educators and nurse practitioners) to low-income residential facilities. These interventions are described in more detail elsewhere.[6]

Data Collection

To measure change in quality of care, a baseline and post-intervention chart review was conducted. Since we were unable to conduct an evaluation with separate control and intervention sites, each of the programs served as their own controls, and data are presented in aggregate for the pre- and post-intervention time period. Each participating program identified their patients with diabetes from a list of patients either at their program site or at a collaborating clinic site. Patients were identified on the basis of having at least one diagnosis of diabetes in calendar year 1998 for baseline and calendar year 2001 for follow-up. Eligibility for the follow-up was based on patients who had participated in the interventions at each site. Program-specific and aggregate baseline reports were provided to each of the programs. Aggregate data for the baseline results have been published elsewhere.[7] Cases were eligible for project inclusion if they met the following criteria:

- One face-to-face encounter with a diagnosis of diabetes at baseline or follow-up, and
- Over the age of 18 as of December 31, 1998 for baseline and December 31, 2001 for follow-up.

The lists of eligible patients was provided to Wake Forest University School of Medicine staff. For programs with 60 or fewer patients, all patients were included in the evaluation. For programs with more than 60 patients, a random sample of 60 patients was selected from that site. The random sample was created using a random number generator in SAS Statistical Software Program (Cary, NC). Three of the 14 programs did not participate in the baseline evaluation, and two of the 14 did not participate in the follow-up evaluation. Data for the baseline and post-intervention are presented in aggregate.

Demographic information for project cases was gathered from patient records and imported into an electronic data collection tool developed in collaboration with the Medical Review of North Carolina (MRNC), which is the Centers for Medicare and Medicaid Services (CMS)-designated Quality Improvement Organization (QIO) for North Carolina. The tool was developed to capture information on patient characteristics and care processes from primary care medical records. Specially trained nurses and health information management personnel employed by MRNC entered data into the tool. Reliability was conducted using intra-reader assessment of a 10% sample of charts with excellent results.

Quality Indicators

Project IDEAL quality indicators were based on the national Diabetes Quality Improvement Project (DQIP)[8] and on Health Plan and Employer Data Information Set (HEDIS)[9] diabetes-related measures. The DQIP indicators represented a common set of comprehensive, evidence-based measures supported at the time of program initiation by the American Diabetes Association (ADA), the Foundation for Accountability (FACCT), the National Committee on Quality Assurance (NCQA), and the Health Care Financing Administration (HCFA). For this project, six process measures [testing for hemoglobin A1c, low-density lipoprotein (LDL)-cholesterol, nephropathy, retinopathy, hypertension, and neuropathy] and three outcome

Table 1.
Summary of Quality Indicators for Project IDEAL Evaluation

Indicator	Description	Considerations
Glycemia Assessment	At least one measurement of HbA1c during study period.	
Glycemia Control	HbA1c <9.5% on most recent test or level of control unknown.	Persons with no HbA1c test during study period were considered to not be in good control.
Lipid Assessment	At least one measurement of lipids during study period.	
Lipid Control	LDL-C <130 mg/dL on most recent test or level.	Persons with no lipid assessment in the study period were considered to not be in good control.
Nephropathy Assessment	At least one screening for diabetic nephropathy during study period via urinalysis or microalbuminuria testing (latter only if indicated).	A positive test for macroalbuminuria was considered acceptable, but a negative test for macroalbuminuria required testing for microalbuminuria. Patients with a documented history of nephropathy per medical record review were excluded from the eligible cases for this measure (the denominator).
Diabetic Retinopathy Assessment	Receiving a dilated eye exam performed by an ophthalmologist or optometrist, or having a 30-degree fundus photography read by an optometrist or ophthalmologist during study period.	Cases meeting the criteria for biennial eye exams (having any two of the following: not taking insulin; HbA1c <8.0%; no evidence of retinopathy on previous year's eye exam) were excluded from calculation of the annual eye exam rate.
Blood Pressure Assessment	At least one measurement of blood pressure during study period.	
Blood Pressure Control	Systolic blood pressure less than 140 mmHg and a diastolic blood pressure less than 90 mmHg.	Persons with no measurement of blood pressure during the study period were assumed to not have good control.
Foot Examination	Having a visual foot inspection, a pedal pulse assessment, and a sensory examination during study period.	

measures [control of: hemoglobin A1c (HbA1c), LDL-cholesterol, and blood pressure] were reported. The quality indicators chosen for this project are consistent with DQIP and HEDIS 1999 diabetes related measures with the addition of blood pressure and foot examination measures. These measures, along with the criteria for documenting compliance for each measure, are described in table 1.

Statistical Analyses

All statistical analyses were performed using the SAS Statistical software program (Version 8.0, Cary, NC). Bivariate chi-square tests were performed to determine statistical significance in the proportion of patients meeting each of the quality of care indicators. In addition, the adjusted proportions at each time period were derived by fitting a random effects logistic regression model, which took into account clinic cluster correlation and controlled for age, sex, race/ethnicity, and insurance status. The results were obtained by using the SAS macro GLIMMIX, extracting Wolfinger/O'Conell's pseudo-likelihood estimates, estimating the expected adjusted means at baseline and follow-up, and transforming back to the sample proportions.[10] The 95% confidence intervals of the differences in adjusted proportions were found by bootstrapping using the SAS macro BOOT and selecting the default 200 sub-samples. The normal approximation was used to find the upper and lower bound of the confidence intervals.[11] Additionally, the bootstrapping procedure allowed for the estimated differences in proportions to be corrected for bias. Ordinary adjusted logistic regression was also performed. As the results were similar and the variance estimates from the mixed logistic regression analyses are preferred, only the latter results are presented here.

Results

Table 2 provides demographic and medical history information for baseline and follow-up samples for the aggregate data. The racial/ethnic distribution was significantly different at follow-up compared to baseline (p=0.04), with a larger proportion in the follow-up group of whites and those classified as "other." The follow-up sample was also significantly older (p<0.001) than the baseline sample, which is reflected in the greater proportion of patients at follow-up on Medicare. Patients at follow-up were also less likely to be on insulin therapy (p=0.02).

Quality of care indicators for baseline and follow-up are described in Table 3. All indicators increased from baseline to follow-up. Testing of HbA1c significantly increased from 52.7% at baseline to 72.0% at follow-up (unadjusted difference: +19.3%; adjusted difference: +39.3%, 95% Confidence Interval [CI], 31.7-47.0%). This is a modest estimate of HbA1c testing, since this indicator refers to at least one test per year. HbA1c control increased from 39.6% at baseline to 64.9% at follow-up (unadjusted difference: +25.3%, adjusted difference: +37.5%, 95% CI, 30.6-44.4%). Since persons without an HbA1c measure were considered not in control, we only examined those with at least one HbA1c measurement. If missing values for HbA1c were ignored, control increased from 74.7% at baseline to 89.2% at follow-up. Using more intensive thresholds,[3] control to less than 8% increased from 26.0% to 55.0%, and control to less than 7.0% increased from 13.6% to 36.3%.

Measurement of lipids increased from 44.5% at baseline to 56.7% at follow-up (unadjusted difference: +12.2%, adjusted

Table 3.
Percentage of Patients Meeting Quality Indicators at Baseline and Follow-up

Quality Indicator	Baseline	Follow-up	Absolute Difference	Adjusted Difference (95% Confidence Interval)
Hemoglobin (HbA1c) Test	52.7%	72.0%	+19.3%	39.3 (31.7-47.0)
HbA1c Control	39.6%	64.9%	+25.3%	37.5 (30.6-44.4)
Lipid Assessment	44.5%	56.7%	+12.2%	19.7 (13.0-26.3)
LDL Cholesterol (LDL-C) Test	23.6%	41.8%	+18.2%	21.6 (1.5-41.7)
Nephropathy Assessment	8.0%	25.4%	+17.4%	17.0 (10.1-24.0)
Dilated Eye Exam	6.3%	7.3%	+1.0%	4.3 (1.2-7.5)
Blood Pressure Testing	77.9%	82.8%	+4.9%	19.5 (9.7-29.3)
Blood Pressure Control	37.1%	43.6%	+6.5%	7.0 (0-14.1)
Complete Foot Exam	3.3%	21.2%	+17.9%	13.2 (6.7-19.6)

difference: +19.7%, 95% CI, 13.0-26.3%). While 23.6% of the baseline sample had LDL-C within accepted levels at baseline, that indicator increased to 41.8% at follow-up. Control of LDL-C below 100 mg/dL, consistent with Adult Treatment Panel (ATP) III guidelines,[12] increased from 9.1% to 24.4%.

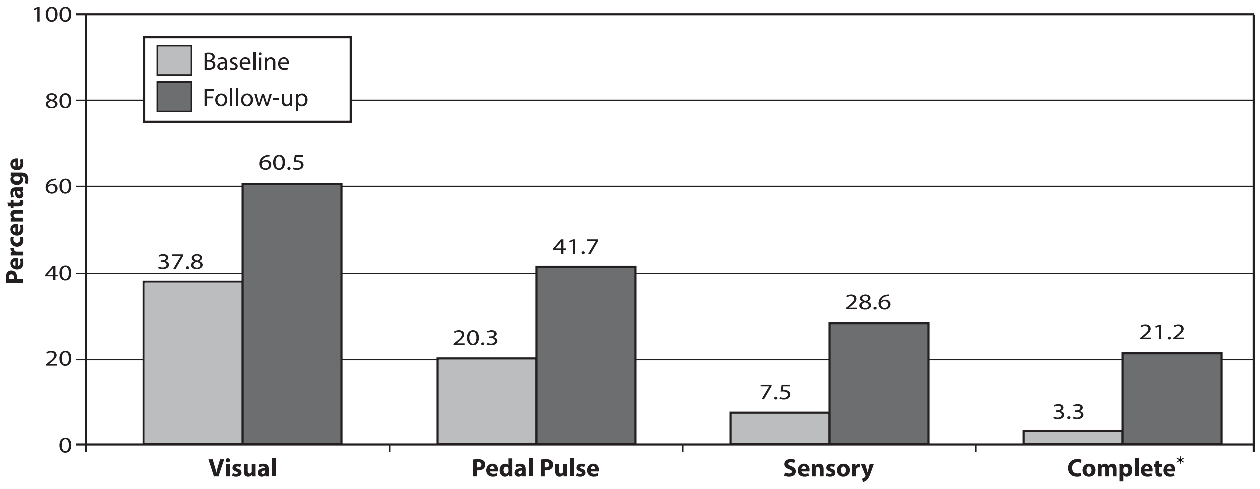
Two of the most problematic indicators identified at baseline were nephropathy and retinopathy assessment. Nephropathy assessment increased dramatically, from only 8.0% of the aggregate baseline sample to 25.4% of the follow-up sample (unadjusted difference: +17.4%; adjusted difference: +17.0%, 95% CI, 10.1-24.1%). The percentage of documented dilated eye exams only increased from 6.3% to 7.3% (unadjusted difference: +1.0%; adjusted difference: 4.3%, 95% CI, 1.2-7.5%); however, the percentage of patients receiving a recommendation for an eye examination nearly quadrupled, from 4.9% at baseline to 19.0% at follow-up (data not shown).

The vast majority of patients received a blood pressure measurement during both study periods. Blood pressure control (defined as systolic blood pressure less than 140 mmHg and diastolic blood pressure less than 90 mmHg) increased from 37.1% at baseline to 43.6% at follow-up, although this difference was not statistically significant. Using the more recent JNC VI high blood pressure recommendations[13] (systolic blood pressure less than 130 mmHg and diastolic blood pressure less than 85 mmHg), the percentage of patients with good control increased from 22.8% to 27.9%.

Foot examinations were another area of concern in the study population. Complete foot exam (having a visual, pedal pulse, and sensory exam) increased from only 3.3% at baseline to 21.2% at follow-up (unadjusted difference: 17.9%; adjusted difference: 13.2%, 95% CI, 6.7-19.6%). All three types of foot exams increased from baseline to follow-up (see figure 1). The most common examination was a visual inspection (37.8% at baseline, 60.5% at follow-up), followed by an assessment of pedal pulses (20.3% at baseline, 41.7% at follow-up).

Further examination of the control measures revealed that

Figure 1.
Distribution of Various Types of Foot Examinations among Project IDEAL Participants, Baseline and Follow-up



* Complete means having all three assessments within the study period.

few patients met all the criteria for adequate control (data not shown). Using the more stringent criteria (HbA1c less than 7%, systolic blood pressure less than 135 mmHg, and LDL-cholesterol less than 100), only 1% of patients met all of those criteria at baseline, and 5% met those criteria at follow-up. Using more conservative criteria (HbA1c less than 8%, systolic blood pressure less than 140 mmHg, and LDL-cholesterol less than 130 mg/dl), 3% met those criteria at baseline and 14% met those criteria at follow-up.

Discussion

This study showed modest to significant increases in the quality of care provided to low-income patients with diabetes among participants in a statewide diabetes initiative. This is important because the dramatic increase in the prevalence of diabetes in recent years translates to tremendous increases in future healthcare costs related to treatment of diabetes and its complications.[14] Reducing the complications of diabetes requires a strong, concerted effort from both the healthcare provider team and the individual with diabetes. While implementation of diabetes clinical guidelines, which are readily available to primary and specialty care providers, has been proven to be effective in reducing the risks associated with diabetes,[3,4] many barriers exist. Racial and ethnic differences in access to and use of healthcare services occur and disproportionately affect the underserved. Low health literacy prevents many patients from making full use of the latest treatments and up-to-date clinical information on their illness. Additionally, provider barriers such as limited clinic time with patients, inability to manage multiple guidelines, and negative perceptions of patients influence healthcare providers' implementation of diabetes care guidelines.[15]

General awareness regarding health-related issues and the benefits of accessing healthcare services could be improved through culturally appropriate community-based outreach and education programs.[16,17] However, each community will face a unique set of barriers, which precludes a one-size-fits-all solution. Healthcare delivery customized by local health leaders, but based on proven guidelines (the method demonstrated in Project IDEAL), may be necessary to achieve maximal benefits for racially diverse and medically underserved populations.

A number of studies have shown that adherence to clinical guidelines is poor for patients with diabetes, and this pattern appears to be consistent across a variety of populations. A sample of these studies is reviewed briefly here. Using the claims from Medicare beneficiaries in 1997-1999, Arday and colleagues[18] observed that only 67.8% of patients with diabetes received an annual HbA1c test, 68.3% received eye exams, and 56.8% received a lipid profile. In an assessment of quality of care among patients at 55 mid-western federally-funded community health centers, Chin and colleagues[19] found that 70% had at least one measurement of HbA1c, 26% had a dilated eye examination, and 51% had received some type of foot care. Using HMO data in California, Peters and colleagues,[20] found that 44% of patients with diabetes had received at least one HbA1c test, 48% had received a test of urinary proteins, and only 6% had received at least one foot examination. Consistent with these data, we also found low levels of adherence to diabetes care guidelines[7] in the baseline sample of low-income, largely ethnic minority patients selected for this project.

Our study has a number of limitations that must be taken into consideration. First, this study did not have a true control group, so the outcomes could have been attributed to factors other than the intervention, such as possible increased awareness of diabetes care in the community and in the healthcare arena, implementation of other local diabetes initiatives, and availability of additional healthcare resources. Also, since all sites participated in the intervention and, thus, were not blinded to treatment group as in a randomized placebo-controlled trial, there is the possibility that outcome measures were more aggressively pursued and recorded to enhance the results of the program initiative. However, this is somewhat unlikely given that systematic improvements were not shown in this study and that these data come from chart review and not from self-report by providers. In most cases, individuals coding data into the medical chart were not directly associated with the study.

The programs participating in Project IDEAL developed and implemented their own unique interventions with financial support from The Kate B. Reynolds Charitable Trust and technical support and evaluation from the Wake Forest University School of Medicine. Many opportunities for improvement were identified in the baseline data from 1998. Follow-up aggregate data revealed significant improvement for most quality indicators that supports the overall program intent: to deliver appropriate diabetes care and services to underserved North Carolinians. However, given the rather conservative assessment of quality care in this report, there is still much room for improvement. Also, the lack of an observed improvement in assessment of diabetic retinopathy indicates that this might be an area for future targeted interventions.

Conclusions

This study has a number of limitations which affect the generalizability of these results. First, there is insufficient data to test the impact of program-specific interventions. Second, the results reflect short-term changes in quality of care measures, which may not be sustained for extended periods of time. Third, these data were limited to medical chart reviews in primary care facilities, which may not adequately reflect the level of care being administered. Nonetheless, these results support the contention that programs that customize the delivery of healthcare to fit the unique needs of the community, such as demonstrated in Project IDEAL, can be successful in improving the quality of care that patients, particularly those of low-income communities, receive in primary care settings. Mechanisms for dissemination and maintenance of these approaches are needed to broaden the impact of diabetes control efforts in the population. **NCMJ**

Acknowledgements

The Project IDEAL Diabetes Initiative was supported by The Kate B. Reynolds Charitable Trust, Winston-Salem, North Carolina.

The authors wish to acknowledge the following: Dawn Doss, Assistant Project Manager, for superior work in assisting project management and program coordinators; the Project IDEAL clinic staff for their hard work toward reducing the burden of diabetes in North Carolina; the staff at the Medical Review of North Carolina and the North Carolina Baptist Hospital Health-on-Call staff, for their assistance in collection of evaluation data; and, the Advisory Committee for their role in the development and technical assistance and resources provided for this initiative:

ARTICLE

Accommodating a New Medical Profession:

The History of Physician Assistant Regulatory Legislation in North Carolina

E. Harvey Estes, Jr., MD, and Reginald D. Carter, PhD, PA

In 1967, the first graduates of the Duke University Physician Assistant Program received their certificates and began their practice. The Duke program was the first in the country to train this new professional group.[1] There was no legal framework in place for their practice, other than a ruling from the Attorney General of North Carolina that performance of delegated, physician-supervised activities by a physician assistant did not contravene the licensure laws of the state.[2,3] Other institutions were beginning programs of their own, some using the Duke model, and others a very different structure. National interest in this new manpower innovation was high, as was interest in the new profession by prospective students.[4]

Recognizing their obligation as the innovators and pioneers in physician assistant education, the parent department of the program at Duke University Medical Center, the Department of Community Health Sciences undertook the process of studying the unique problems of regulation of this new professional group and designing model legislation to implement this regulation.[1,2,5]

The process by which this model legislation was designed was unique, as was the regulatory framework which resulted. Following the development of the model, it was framed as a legislative act and considered by the North Carolina General Assembly the following year. It was passed with no major opposition.[6] This framework has served the state, the medical profession, and the physician assistant profession well for over three decades and has been the model for similar legislation in a number of other states.[7]

The purpose of this paper is to describe the process, some of the options that were considered, and some of the factors that led to a new and very unique basis for regulation of physician assistants. At the same time, it will highlight some of the characteristics of the process by which the proposed regulatory system was studied and developed. In retrospect, these appear to have heavily contributed to the favorable reception of the new regulatory process by the medical community within the state. The authors feel that recognizing these characteristics, and duplicating them, can be very useful to those with the responsibility for designing new licensure and regulatory statutes for medical occupations that may evolve in the future.

The Environment and Early Preparation

The Duke Physician Assistant Program arose from the awareness that many areas of the state, especially rural areas, were suffering from a growing shortage of physicians. The first class began in 1965, with a curriculum that resembled a shortened medical school curriculum: 12 months of pre-clinical sciences and 15 months of clinical instruction taught by medical school faculty. Interest in the program was immediate. Other medical institutions began programs of their own, some using the Duke model, and others a very different design, such as the Medex Program at the University of Washington. Entrepreneurial interest was also evident, with for-profit programs offering a certificate after only a few weeks of training. The need for standards for educational and clinical preparation of physician assistants was seen as an urgent priority, as was a framework for licensure and regulation.[5,7]

The Duke Physician Assistant Program was conceived and begun by Dr. Eugene A. Stead, then the Chair of the Department of Medicine.[8] He retired from this position in 1966, just after Duke University formed a new department—the Department of Community Health Sciences (later Community and Family Medicine)—with the first author of this paper as its chairman. The new Physician Assistant Program fit more easily into the mission and interests of this new department, and it was transferred to the new department late in 1966, before the graduation of the first class of students. This department initiated a number of studies of the new profession and also began to explore other required steps for its inclusion as a recognized component of the medical community. In addition to the looming problem of licensure and regulation, there was

E. Harvey Estes, Jr., MD, is Professor Emeritus, Department of Community and Family Medicine at Duke University Medical Center. He can be reached at eestes@nc.rr.com. Telephone 919-489-9780.

Reginald D. Carter, PhD, PA, is Associate Clinical Professor Emeritus, Department of Community and Family Medicine at Duke University Medical Center. He is Director of the Physician Assistant History Center (http://pahx.org). He can be reached at reginald.carter@duke.edu or at Box 3848, Durham, NC 27710. Telephone 919-681-3156.

the need for accreditation of educational programs and a process for testing the educational preparation of graduating students. Drs. Estes, Stead, and D. Robert Howard, Director of the Physician Assistant Program, became the planning group for these activities, with the Department of Community Health Sciences as the organizational seat of the activity.[1,9] This paper will only consider those activities related to licensure/regulation.

The federal government recognized the need for uniform standards for the profession, and early in 1969 the Department of Health, Education, and Welfare awarded a contract to the Duke Department of Community Health Sciences to develop model legislation for the regulation of physician assistants. One of the first steps in carrying out the contract was to select a project operating officer, Martha Ballenger, JD, who immediately began to review published information about licensure of medical personnel. Her findings became the basis for a *white paper*, which was used for project planning and as background information for participants in the series of conferences that followed.[2]

This white paper pointed out that the responsibility for physician and other medical occupational licensure is a state prerogative, and there are differences from state to state. Legislation for physician licensure arose in the late 19th and early 20th century to control the rampant quackery and poor medical education characteristic of that time. These licensure acts were framed in very broad and general terms, permitting physicians to carry out any act or task taught in medical school, with no restrictions. As new health professions evolved and gained acceptance, their members were granted more circumscribed licenses, enabling them to perform only those specific functions for which they were qualified by training and experience.

The paper also pointed out that the process of awarding independent licensure for a new professional group was often hotly contested by those professional groups whose professional territory was being invaded. The result was an array of professional groups within healthcare (each with a sharply defined set of authorized functions) with frequent scope-of-practice conflicts as they sought to expand their functions.

Five options were identified for discussion and debate, each with advantages and disadvantages. The "status quo" option was a continuation of the existing policy. Physicians would delegate functions to their assistant, and custom and useage would validate the process over time. This option was seen as leaving both the employing physician and the assistant vulnerable to legal action for improper delegation. Independent licensure of physician assistants was the second option. Difficulty in precisely defining the duties to be permitted was seen as a major problem with this option. The third option was to license the physician or institution that wished to utilize a physician assistant. This was seen as a new function of the Medical Board. The fourth option was create a new statute authorizing general delegation by physicians. Four states were found to have some features of legislation authorizing general delegation within their medical practice acts. Lack of protection for the public was an identified problem with this approach. The fifth and last option was to create a Committee on Health Manpower Innovations, which would report to the medical board. The Committee would evaluate and pass judgment on new types of health workers, based on the need and the ability of the applicant individual or institution to support and supervise the innovation. The need for representation by all health professions on the new Committee was recognized, but at the same time, it was predicted that each of the representatives would tend to be protective of their own turf.

No judgment was offered on the relative merits of each of these options, since this was to be the subject of open discussion and debate in the series of conferences planned for the future. The purpose of presenting options was to encourage consideration of possibilities beyond those in use at the time and to present the unique challenges of the task ahead. Chief among these was the need for flexibility while meeting the responsibility to protect the patient and the public interest.

Drafting the North Carolina Statute for Licensure and Regulation of New Medical Professionals

The next step in the process was to hold a conference on licensure/regulation of new medical professions, with physician assistants as the principal focus.[10] Representation was sought from all groups seen as having a significant interface with the new professional group. The invited participants included:

- Nationally recognized experts on licensure of health personnel, identified from their contribution to the literature on this subject;
- Representatives from medicine, nursing, and hospital administration in North Carolina, including both practicing members of these professions and members of their legal staff;
- Members of the North Carolina legislature, the North Carolina Institute of Government, and the regulatory boards governing medicine and nursing;
- Educational representatives from Duke University School of Medicine and the Physician Assistant Program;
- Members of the newly graduated classes of Physician Assistants and their employing physicians; and
- A representative of the United States Department of Health, Education, and Welfare.

The first conference was held in Durham, North Carolina, on October 26 and 27, 1969. The previously listed options were presented and discussed during the first day. It was the consensus of those present that the best approach would include a combination of several options, most closely resembling option four—a statute authorizing general delegation of functions to an assistant. For the protection of the public, it was felt that this delegatory authority should be restricted to assistants functioning under credentials and constraints reviewed and approved by the North Carolina Board of Medical Examiners. Following the conference, a group of legal consultants met to prepare a first draft of a model statute, which was circulated to all those who attended, with a request for added comments and suggested revisions. Following a rewrite incorporating several of these suggestions, the revised version was again circulated to all who had attended.

A second conference was held in Durham, North Carolina on March 1, 1970, to discuss the product of these revisions, and to discuss in detail a modification proposed by one of the legal consultants. After lengthy discussion, the "October Proposal" was endorsed by the group, and became the proposal forwarded to those responsible for framing new legislation. It was enacted into law, essentially as proposed, in the 1971 session of the North Carolina General Assembly.[6]

At the time of the previously mentioned actions, the North Carolina General Statutes, Section 90, paragraph 18, after prescribing penalties for the unlicensed practice of medicine, read:

> "Any person shall be regarded as practicing medicine or surgery within the meaning of this article who shall diagnose or attempt to diagnose, treat or attempt to treat, operate or attempt to operate on, or prescribe for or administer to, or profess to treat any human ailment, physical or mental, or any physical injury to or deformity of another person: Provided, that the following cases shall not come within the definition above recited."

This was followed by a series of permitted exceptions, including the use of home remedies within the family, the practice of dentistry by a licensed dentist, the practice of pharmacy by a licensed pharmacist, etc. The proposal was exception (14) to this definition of the practice of medicine. It read as follows:

> "(14) Any act, task or function performed at the direction and under the supervision of a physician licensed by the Board of Medical Examiners, by a person approved by the Board as one qualified to function as a physician assistant when the said act, task, or function is performed in accordance with rules and regulations promulgated by the Board."

This proposal established a two-stage method of control. Before the physician assistant could have the benefit of the protection afforded by the statute, he or she must have gained the approval of the Board, through graduation from a recognized educational program. Once approved, the assistant might subsequently demonstrate incompetence or unwillingness to perform within the limits set by the physician, or the physician might be shown to be using his assistant in an inappropriate manner. Thus, there was an implicit power of the Board to deny or revoke approval at a later time. The final clause of the exception requires the Board to promulgate rules as needed.

The model legislation had several attractive features. It avoided specificity in definition of functions allowed by assistants. The functions permitted are, in effect, any functions delegated by the physician. It placed the promulgation of rules in the hands of the Board of Medical Examiners, not the General Assembly, thereby making changes possible without the formal action of an elected body.

Since its adoption in 1971, the afore mentioned approach has had the desired effect of permitting and supporting the function of physician assistants, while safeguarding the safety of the public. It has required very minimal alteration over time, and most changes have been accomplished through changes in the rules and regulations rather than the statute.[12,13] After its enactment, a similar approach was used to permit the medical acts of nurse practitioners. Recognizing that the nurse practitioner is already acting under another licensing authority, the North Carolina Board of Nursing, the legislation added nurse practitioners to the list of exceptions to the unauthorized practice of medicine. Legislation also established a joint committee of both boards to promulgate rules and regulations for nurse practitioners, specifying that both boards must approve these rules.

Still more recently, the same model has been used to permit the function of clinical pharmacist practitioners, who are now permitted to prescribe and manage illness under rules established by a committee with membership from both boards.

The model legislation proposed in 1969-1970 thus proved its merit through its adoption in North Carolina and many other states, and it has proved a very workable and flexible in action. It has also been used as a model for other professional groups that have joined physician assistants in performing medical acts. Physician assistants now work in every medical specialty, and their functions have been accommodated as new tasks have been developed and implemented, in ways that could not have been predicted when the legislation was developed.

The Process of Development of Model Legislation

The development of the model legislation for physician assistants was a very intense process with much debate and exchange of opinion. Yet, at the end, the resulting legislation passed the North Carolina General Assembly with very little dissent. This result has caused the authors to examine the process by which it developed in more detail, and to speculate cause and effect. Several characteristics of the process of development are identified as important in achieving the successful outcome. These are presented and discussed in the following section, with the hope that they will be useful to others who wish to achieve accommodation of a new professional group into the health professions.

The following characteristics are identified as important to the outcome:

- All professional groups identified as being impacted by the new professional group, physician assistant, were represented in the group invited to develop the model legislation;
- Identified national experts, from outside the medical profession, were invited to participate and contribute to the development of ideas;
- The process emphasized, at all stages, that a major objective for the model legislation was protection of the public and the individual patient, not preservation of professional turf;
- The process permitted all participants to review prior work;

submit their own new ideas, and revise old ideas through several iterations of the developing model; and

- The process produced near unanimous agreement on the details of the model before it was sent forward.

It was obvious that the new physician assistant would interact with every other major medical professional group: nurses, hospital administrators, pharmacists, etc. For this reason, an effort was made to include each of these groups in the conference and subsequent discussions. This proved very useful in allaying anxiety and suspicions and in informing all about the provisions of the model legislation.

Physician support was an essential requirement. It was fortuitous that the president of the North Carolina Medical Society was a family practitioner from a rural area, who had seen the need for the new profession firsthand. He was also a very perceptive and innovative individual who had a very warm relationship with many members of the North Carolina General Assembly. This individual, Edgar Beddingfield, MD, had served for many years as the head of the Legislative Committee of the Medical Society of the State of North Carolina (later the North Carolina Medical Society). He was also very active as a delegate and elected officer in the American Medical Association and was very helpful later in establishing a mechanism for accreditation of physician assistant education programs through that organization.

Nursing was represented by Dr. Eloise Lewis, a senior stateswoman in this profession, and the dean of a highly respected School of Nursing. The legal counsel to the North Carolina Nurses Association was also included.

The regulatory boards for both medicine and nursing were also included, with both members and legal counsel from each. This inclusion insured that the point of view of each of these boards was expressed and understood by the other, and the usual suspicions of ill intent, based on fragmentary or distorted information, were avoided.

The inclusion of national experts on licensure of medical personnel had several important effects. Their writings were known from the preliminary research, but their presence as a part of the discussion and deliberation broadened the approach. Their presence also provided an assurance to all participants that all major issues had been considered and that the work of the committee was important. They were also tenacious defenders of the public protection requirements of the model legislation, and their presence lent authority and validity to the product developed.

The emphasis on protection of the public was unifying in many ways. Each professional group could understand that this was not an attempt to restrict or diminish other professional groups, but to serve all interests as, together, we serve our patients.

The last two points can be considered together. Every participant was invited to comment, criticize, revise, object, and contribute to the development of the model. When differences were discovered, these were discussed in detail, and a consensus obtained. When the process was finished, all felt that they had contributed and felt ownership of the product. The group included legislators who were very effective in answering questions from fellow legislators during the debates and at avoiding conflict as the North Carolina General Assembly proceeded toward passage of the measure.

Summary

The first physician assistant program in the United States was at Duke University Medical Center. This program served as a model for other institutions to begin similar educational programs, and the profession has quickly become a major source of medical services throughout the country. Less well-known is the role of Duke University and North Carolina in the development of a unique regulatory system, which also became a national model. This system has been effective in protecting the public and the patient, and has had the flexibility to adapt to changing medical practice and changing standards. The process by which this regulatory system was developed was unique, and its unique characteristics are felt to have been a significant factor in its success. Duplication of these characteristics is recommended for those who wish to incorporate new medical occupations into the larger medical community. **NCMJ**

Acknowledgements

The authors would like to gratefully acknowledge the interest and advice of Dr. Eugene A. Stead, the founder of the Physician Assistant Program at Duke University Medical Center, in the preparation of this manuscript. Dr. Stead was a critical participant in the studies and conferences cited, and he has remained an active contributor to the development and evolution of the profession over the intervening years. His friendly but persistent requests for a written record of the development of regulatory legislation led the authors, long his friends and admirers, to honor his wishes.

POLICY FORUM
The North Carolina Healthcare Safety Net

COMMENTARIES

> *"Lack of health insurance coverage decreases worker productivity; negatively affects the health of children and, thus, their ability to learn; and has unfavorable financial implications for those healthcare providers who provide care to the uninsured."*

INTRODUCTION

Policy Forum:
The North Carolina Healthcare Safety Net

For more than three years, as we have published 20 issues of the *North Carolina Medical Journal*, there have been multiple occasions when we thought the word "crisis" was an appropriate moniker for a situation of urgent importance to the health of North Carolinians or the future of the healthcare services upon which we all depend. Certainly the growing number of North Carolinians without health insurance is an alarming trend. But, when one considers the fragility of the healthcare services available to serve the needs of this rapidly increasing component of our population—now nearly one-fifth of all North Carolinians—here is yet another occasion when the word "crisis" seems appropriate.

The recent analysis of a blue ribbon Task Force on the North Carolina Healthcare Safety Net convened by the North Carolina Institute of Medicine (NC IOM) directs our attention to a set of issues many healthcare providers (individual private practice professionals, hospitals, clinics, and public health departments) have known all too well in recent years. The burden of providing free and uncompensated care to larger and larger numbers of the uninsured (for types of services that range from the everyday concerns of the "worried well" to extensive and expensive specialty care from physicians and intensive hospital services) is putting enormous pressure on providers who are legally responsible for serving all who ask for help or on volunteers who give their time and professional expertise to those unable to pay for the care they receive.

The NC IOM Task Force was ably co-chaired by Carmen Hooker Odom, MPR, Secretary of the North Carolina Department of Health and Human Services, and Sherwood Smith, Jr., JD, Chair Emeritus of Carolina Power & Light (now Progress Energy). Staff leadership was provided by Pam Silberman, JD, DrPH, Vice President of the NC IOM. Dr. Silberman and the two co-chairs, along with other colleagues at the NC IOM, have offered a detailed Issue Brief summarizing the major dimensions of the healthcare safety net problem in our state. Other members of the NC IOM Task Force were invited to discuss particular pieces of this puzzle in a series of commentaries that follow the Issue Brief.

The Task Force acknowledged that one of the most important steps that could be taken to address the problems of the uninsured would be to assure insurance coverage for greater numbers of those without such coverage. There are many strategies by which this could be done, but until healthcare insurance is universal, the uninsured will remain a health policy issue of concern.

The commentaries in this issue of the Journal give a clearer picture of those at risk by not having insurance, the complexities of state and federal regulations that govern the organization and delivery of personal healthcare services to the uninsured, the voluntary outreach of local physicians and other healthcare professionals in service to the uninsured, and the efforts of private pharmaceutical companies to make needed medicines available to those unable to afford them. In addition, the commentaries explain the tremendous burden our hospitals and local public health departments carry, as providers of last resort, through their emergency departments and clinics, respectively. The commentaries also highlight the school-based efforts in providing needed primary and preventive health services to children and adolescents with no other source of care and the way in which North Carolina's Department of

continued on page 110

continued from page 109

Health and Human Services has led the nation in the development of rural health centers to serve communities who were without access to needed primary healthcare services.

We also felt like it was important to include a recent (March 9, 2005) letter from Governor Easley to the United States Senators and Representatives of North Carolina. The letter explains how reducing the federal Medicaid match to states would affect North Carolina's healthcare safety net, and, in turn, its medically vulnerable citizens.

Serving the healthcare needs of the uninsured is a demanding job, involving thousands of healthcare professionals, hospitals, health departments, and clinics (many of whom are linked in operative networks to maximize their effectiveness and to lessen the burden on one or a few providers in each community). We hope that this issue of the Journal illustrates the enormity of the problems we face in this area. We also hope it provides some recognition for the citizenship and high-level professionalism of so many individual and institutional providers who have joined together to care for the uninsured. To all of these, we tip our hats and express our heartfelt thanks. It is hoped that in the not to distant future, the numbers of uninsured will be reduced, and some of the problems addressed in this issue of the Journal will be less of a concern than they are at the moment.

The North Carolina Healthcare Safety Net, 2005:

Fragments of a Lifeline Serving the Uninsured

Pam Silberman, JD, DrPH, Carmen Hooker Odom, MRP, Sherwood Smith, Jr., JD, Kristen L. Dubay, MPP, and Kristie Weisner Thompson, MA

In 2003, nearly 20% (1.4 million) of North Carolinians under age 65 lacked health insurance coverage.[1] Since the year 2000, more than 300,000 people have lost their health insurance—a 31% increase in the uninsured. With nearly one in five people living without insurance, North Carolina is, without a doubt, in the midst of a major healthcare crisis, and as healthcare costs continue to rise, there is little chance of an immediate respite.

Coping with the large, and still growing, number of uninsured is a national problem, but North Carolina has been harder hit than many states. As a result of recent trade relocation and downsizing, North Carolina lost a large number of manufacturing, textile, and technical jobs, which left thousands of people unemployed and uninsured. The downturn in the economy, together with the rising cost of health insurance, is making it more difficult for people to afford healthcare or healthcare insurance.

Most of the uninsured in North Carolina (62%) have annual incomes less than 200% of the federal poverty guidelines (FPG)—less than $18,620 for an individual and $47,140 for a family of four in 2004.[2] This makes it challenging for the uninsured to pay for needed healthcare. Even people who have insurance sometimes have difficulty paying for needed healthcare, but it is typically harder for the uninsured. The uninsured are less likely to have a regular source of care and are more likely to delay or forgo needed care than people with insurance coverage. The uninsured in North Carolina were far more likely than those with insurance to report that they have no person whom they consider to be their personal doctor or regular healthcare provider in 2003 (50.7% compared to 12.4%, respectively).[3] Approximately 15% of North Carolinians reported that there was a time in the last 12 months when they needed to see a physician, but could not due to cost; however, the uninsured were more likely to report this problem (41.2%) than those with insurance coverage (9.5%). Further, when the uninsured do seek care, they are generally sicker than the insured population and, as a consequence, experience poorer health outcomes.

> *"As a result of recent trade relocation and downsizing, North Carolina lost a large number of manufacturing, textile, and technical jobs, which left thousands of people unemployed and uninsured."*

What Is the Healthcare Safety Net?

The lack of health insurance coverage obviously affects the uninsured person and his or her family, but it also has a broader societal impact. Lack of health insurance coverage decreases

worker productivity; negatively affects the health of children and, thus, their ability to learn; and has unfavorable financial implications for those healthcare providers who provide care to the uninsured. The state and federal funding sources available to meet the healthcare needs of the uninsured are not keeping pace with the growing needs. The increased numbers of uninsured and inability to raise revenues from third party payers or other sources is creating significant financial strain for many safety net institutions. Without these institutions, the capacity to provide healthcare services for the uninsured and other underserved groups would be seriously undermined.

Safety net providers are those who deliver a significant amount of healthcare to the uninsured, Medicaid, or other vulnerable populations, and offer services to patients regardless of their ability to pay. They typically provide healthcare services at no charge, on a sliding-fee scale, or help make services financially affordable in some other way.

Who Are the North Carolina Safety Net Organizations?

In North Carolina, the safety net consists of federally qualified health centers (e.g., community and migrant health centers), state-funded rural health centers, local health departments, free clinics, Project Access or Healthy Community Access Programs, school-based or school-linked health centers, hospitals, and other organizations that have a central goal of providing care to patients regardless of their ability to pay (see sidebar). Many private providers provide services to the uninsured, albeit not always on a sliding-fee scale.

While some safety net resources exist in most communities, they are not always sufficient to meet the many healthcare needs of the uninsured. Some communities have multiple safety net organizations, but the system of care is fragmented. Others have a basic capacity to provide primary care services, but cannot meet the need for specialty consults or referrals, prescription medications, or more complex care. Still other communities lack even the capacity to meet the basic primary care needs of the uninsured.

The Healthcare Safety Net Task Force

In December 2003, The Kate B. Reynolds Charitable Trust funded the North Carolina Institute of Medicine to establish a Healthcare Safety Net Task Force that would examine the adequacy of the existing safety net structure. The Honorable Carmen Hooker Odom, MA, Secretary for the North Carolina Department of Health and Human Services, and Sherwood Smith Jr., JD, Chair Emeritus of Carolina Power & Light (now Progress Energy), chaired the 48-member Task Force, which included representatives of safety net organizations and provider associations, state and local elected officials and agency staff, non-profits, and advocacy organizations. The Task Force met once a month for nearly one year (March 2004-January 2005).

The goal of the Task Force was to develop a plan to better coordinate and integrate existing safety net institutions, identify

Components of the North Carolina Healthcare Safety Net

Federally Qualified Health Centers (FQHCs)

There are 23 FQHCs in North Carolina with a total of 76 delivery sites, serving more than 272,000 patients in 56 counties. FQHCs, often referred to as community or migrant health centers, provide comprehensive primary healthcare services as well as health education, preventive care, chronic disease management, oral and behavioral health services, all on a sliding-fee schedule. These centers have seen a 32% increase in the number of uninsured patients served in the past five years, serving more than 122,000 uninsured patients in 2003.

State-Funded Rural Health Centers (RHCs)

The North Carolina Office of Research, Demonstrations, and Rural Health Development in the North Carolina Department of Health and Human Services helped to establish 83 rural health centers throughout the state, with 32 of these receiving on-going support from the state. In return for the ongoing operational funds, these centers must agree to provide care to low-income uninsured individuals on a sliding-fee scale. These state-funded centers served 21,252 uninsured low-income patients in 2003.

Local Public Health Departments

There are currently 85 local health departments covering all 100 counties, with 79 of these covering single counties and six serving multi-county districts. These agencies provided clinical and preventive health services to 641,601 patients in 2003, of whom 260,603 were uninsured.

Free Clinics

These are non-profit organizations serving low-income uninsured populations by drawing on local healthcare resources and lay/professional volunteers. There are currently 60 free clinics or pharmacies in North Carolina, serving 48 communities. Most of these clinics are open one or two evenings per week and serve those needing care on a first-come, first-served basis. Free clinics served 69,320 low-income patients in 2003 (with 59,840 offered primary care services and 9,480 served in specialized clinics providing only pharmaceutical or behavioral health services).

Project Access or Healthy Communities Access Programs (HCAPs)

These are local community initiated efforts to fill gaps in the array of healthcare services available to meet the needs of the uninsured. Typically, these initiatives help link the services of traditional safety net providers to healthcare services offered by private practitioners and hospitals in the community. The Project Access model has been implemented in nine North Carolina communities in the following counties: Buncombe, Watauga-Avery, Mecklenburg, Cabarrus, Mitchell-Yancey, Guilford, Pitt, Vance-Warren, and Wake.

continued on page 114

communities with inadequate systems to care for the uninsured and underinsured, ascertain possible funding sources (nationally and locally) that can be used to expand care to the uninsured, and ultimately to expand and strengthen the capacity of healthcare providers and safety net institutions to care for underserved populations. This article provides an overview of the Task Force's findings and principal recommendations.

Are Safety Net Services Available throughout the State?

On the surface, it appears that North Carolina has a wide array of safety net organizations, located throughout the state (see map 1). However, few communities have sufficient safety net resources to meet the healthcare needs of all of the uninsured. The Task Force collected data on the number of uninsured residents receiving care in existing safety net institutions and compared this to the estimated numbers of uninsured in each county. Using these data (the percentage of uninsured with no identified source of primary care), the Task Force determined that only 25% of all the uninsured across the state receive primary care services from safety net organizations. This combined with other studies showing that the uninsured are less likely to have a regular healthcare provider and more likely to report access barriers, suggests that the healthcare safety net is not sufficient to meet the needs of the uninsured.

The percentage of uninsured served by the safety net varies widely across the state. Some counties appear to have enough safety net providers to meet the primary care needs all of their uninsured, while others appear to have none. The Task Force identified 28 counties with the least safety net capacity. Thirteen of these counties also had lower than average primary care provider-to-population ratios, suggesting that it would be difficult for the private providers to meet the primary care needs of the uninsured in these counties: Brunswick, Columbus, Davidson, Edgecombe, Franklin, Granville, McDowell, Onslow, Randolph, Rockingham, Stanly, Vance, and Wilkes. Further, access to pharmaceuticals, specialty care, behavioral health, and dental services is still a problem in many communities, including those that have adequate primary care capacity.

A few communities have been able to develop integrated systems of care to address a broader range of healthcare services needed by the uninsured. However, this is the exception rather than the rule. Most communities have fragmented systems of care for the uninsured. This is due, in part, to the difficulties in sharing patient information across providers, turf issues, and/or the need to compete for paying patients to help cover the costs of caring for the uninsured.

The Uninsured and Access to Prescription Medications

Prescription drugs are a critical component of healthcare. More than 40% of all Americans take at least one prescription drug, and 17% take three.[4] There has been a lot of public and

Sources: NC Association of Free Clinics, 2004; NC Division of Facilities Services, 2004; NC Community Health Center Association, 2004; North Carolina AHEC, 2004; Office of Research, Demonstrations and Rural Health Development, 2005; NC Institute of Medicine, 2005; NC Division of Public Health, NC Division of Medical Assistance, 2003; Area Resource File, 2003.

media attention focused on the ability of Medicare recipients to pay for needed medications, but this same problem plagues the uninsured. A 2003 Kaiser health insurance survey found that 37% of the uninsured said that they did not fill a prescription because of costs, compared to 13% of people with insurance coverage.[5]

The pharmaceutical companies have tried to address this problem by offering free or reduced-charge medications through their Patient Assistance Programs (PAPs). Nationwide, 75 pharmaceutical companies offered approximately 1,200 different medications in 2003. More than 270,000 North Carolinians accessed medications through these programs.[6] Yet, it is not always easy to obtain needed medications. Each manufacturer determines which drugs will be offered through their program and sets specific eligibility requirements. The application process can be laborious. It is often difficult for private physicians' offices as well as some smaller safety net programs to take advantage of these free medications, because of the programs' complexity. The North Carolina Foundation for Advanced Health Programs, Inc., with funding from The Duke Endowment, has developed software to assist providers and advocates in accessing appropriate PAP programs. Further, the North Carolina Health and Wellness Trust Fund has provided funding to community groups to help them develop medication assistance programs. These programs help individuals apply for free or reduced-cost medications and provide drug management to patients.

Many safety net providers also help their patients obtain needed medications, either by accessing PAPs or by offering free or reduced charge medications in-house. Despite these resources, ensuring that the uninsured obtain needed medications is still a problem. In many communities, providers are willing to volunteer to treat the uninsured, but are reluctant to do so if there is no assurance that the uninsured will be able to obtain the prescribed medications.

Collaboration and Integration

Few counties have the ability to meet the healthcare needs of all of the uninsured, regardless of how many or how few safety net organizations they have. However, there are some counties that have had more success. These counties have been able to work together to maximize their resources and to identify partners who can help in meeting the unmet healthcare needs of the uninsured.

There are various levels of collaboration and integration that have occurred throughout the state, ranging from periodic meetings of safety net organizations, community planning efforts and joint projects, to more elaborate inter-organizational agreements. In some counties, the hospital has collaborated with non-profit organizations to create primary care clinics for the uninsured. In other counties, local health departments have been successful in working collaboratively with FQHCs to expand care to the uninsured. Other counties have been able to develop more comprehensive systems of care, combining the efforts of traditional safety net providers with private providers

continued from page 112

School-Based or School-Linked Health Centers

Because school-age children, especially adolescents, are not always able to access comprehensive and coordinated systems of healthcare, some schools have established school-based or school-linked health centers to provide comprehensive primary care and mental health services to students. Currently, there are 27 comprehensive centers operating in middle and high schools in the state and another 12 centers that provide primary care services delivered by nurse practitioners or physician assistants. In addition to these health centers, many schools have hired nurses that can provide more limited health services to children.

Private Physicians

Physicians in private practice are a major source of care to the uninsured; many of whom provide services for reduced fees or at no charge. A national survey of households in 2001 revealed that nearly two-thirds of the uninsured reported a private practice physician as their regular source of care, and half of these respondents reported having received services in a physician's office. There has not been a North Carolina study to document the extent to which physicians in this state provide charity care, but most would agree that this is an important component of the healthcare safety net.

Area Health Education Centers (AHECs)

As part of its mission to meet the educational needs of the state's healthcare workforce, the AHECs in North Carolina support five residency programs in family medicine, three in rural family medicine, four in internal medicine, four in obstetrics/gynecology, three in pediatrics, and three in surgery. In 2003-2004, these programs provided services to 35,427 uninsured patients.

Hospitals

Almost all (110 of 113) general acute community hospitals in North Carolina operate emergency departments, which serve as an important safety net provider of last resort, regardless of ability to pay. In 2003, the uninsured represented 10% of outpatient visits, and of those, 22% (672,799 patients) were uninsured patients making emergency room visits.

Prescription Drug Programs

The largest source of free medications for the uninsured is the Patient Assistance Programs (PAPs) offered by private pharmaceutical companies. These programs vary a great deal from one company to another in terms of medications offered, eligibility requirements, and application processes. In addition, a few communities in North Carolina have seen the development of locally-organized pharmacy assistance programs to help low-income uninsured patients obtain needed medications. These programs fill a vital gap in the overall healthcare safety net, but at present levels of funding and availability, they are not able to meet all of the medication needs of the uninsured.

of care. For example, Project Access and Healthy Communities Access Programs (HCAP) help link the services of traditional safety net providers to healthcare services offered by private providers in the community. Generally, communities that have been able to develop integrated delivery systems for the uninsured have been more successful in meeting the healthcare needs of these populations.

Although many counties have been successful in establishing collaborative arrangements across safety net organizations, others have had more difficulty. Because there is little funding available to pay directly for services to the uninsured, safety net organizations often cross-subsidize the care they provide by using revenues from other paying patients. As a result, safety net providers in some counties compete for Medicaid or North Carolina Health Choice patients or other paying patients. Further, funding sources that are limited to certain types of safety net organizations sometimes create ill-will among other organizations that also provide care to the uninsured, but have no source of funding. In addition, there are other barriers—both real and perceived—that make it difficult to collaborate. For example, state medical confidentiality laws are perceived as obstacles to sharing patient information among providers who serve the same patients at different locations.

Financing Options

Many safety net organizations receive some financing from a variety of sources, including Medicaid, Medicare, private third-party insurance, out-of-pocket payments, and charitable donations. The source and proportion of funding from different sources varies across institutions and types of organizations.

By far, Medicaid is the largest funding source for those who would otherwise be uninsured. In North Carolina, the federal, state, and county governments expended approximately $8.5 billion in SFY 2004 to cover 1.5 million low-income individuals during the year; most of these people would have been uninsured but for the Medicaid program.[7] Medicaid is also a major revenue source for many safety net organizations, including hospitals, FQHCs, rural health clinics, health departments, non-profit health clinics, school-based health centers, and other private providers who care for the uninsured. North Carolina Health Choice, the State Children's Health Insurance Program, is another major revenue stream for some safety net providers. The federal and state governments paid approximately $188 million to cover close to 175,000 previously uninsured children through North Carolina Health Choice in SFY 2004.[8]

In addition to funding for Medicaid and North Carolina Health Choice (which pays for services provided to people insured through these programs), there are limited funds available to support care for the uninsured through safety net organizations. For example, the federal government provides some funding to support operational costs for FQHCs, and the state provides limited funds to help pay for care to the uninsured through state-funded rural health centers. In addition, the North Carolina General Assembly appropriated $7 million in non-recurring funds last year (2004) to help support and expand the services available to the uninsured and medically indigent through certain safety net organizations, including FQHCs, FQHC look-alikes, public health clinics, and state-funded rural health centers. At the time this article was being written, it was still uncertain whether these funds would be continued in the 2005 budget. Some new federal funds are available to increase the number of people who can be served by federally qualified health centers through the President's Initiative for Health Center Growth; however, funding under this initiative is competitive, and North Carolina health centers have only been awarded approximately 3% of new funds over the last three years. The federal, state, and/or county governments also provide funds that offset some of the costs of providing specific services to the uninsured (e.g., child and maternal health services or services provided to people with HIV/AIDS).

While limited funding is available to help subsidize care to the uninsured, it is not sufficient to cover all of the costs, and is not well-targeted to those safety net organizations that provide the largest share of care to the uninsured. Certain safety net organizations provide a disproportionate share of care to uninsured patients, and as a result, these organizations collect a smaller share of their revenues from paying patients. This makes it harder for these institutions to pay for the care provided to the uninsured. The proportion of uninsured patients seen by different safety net providers varies across organizations:

- On average, 47.6% of the North Carolina FQHC users in 2003 were uninsured, but this varied from more than 65% in five centers, to less than 30% in seven centers.
- On average, 21% of patients in state-funded rural health centers were uninsured. This varies from more than 30% of patients who were uninsured in four state-funded rural health centers, to less than 10% of patients who were uninsured in two centers.
- The percentage of total hospital discharges attributable to the uninsured varied from a high of more than 10% in nine hospitals to a low of less than 2% in 14 hospitals; and the percentage of hospital discharges attributable to both Medicaid and the uninsured varied from a high of more than 35% in nine hospitals to a low of less than 10% in 10 hospitals.

The increased numbers of uninsured and inability to raise revenues from third party payers or other sources is creating significant financial strains for many of these organizations.

Recommendations

The Task Force formulated a set of 28 recommendations that could help strengthen and expand the capacity of healthcare safety net providers to address the healthcare needs of the growing numbers of uninsured in the state. These recommendations are fully described in the formal report issued by the North Carolina Institute of Medicine,[9] but they are generally described here.

The recommendations offered by the Task Force address four principal sets of issues facing the healthcare safety net organizations in our state. These are: (1) the need to ensure that the uninsured have health insurance coverage; (2) expanding the capacity of the healthcare safety net to meet the needs of the uninsured; (3) developing systems to better integrate existing safety net services in local communities; and (4) increasing funding to support the work of safety net providers. Brief explanations of each of these four sets of issues are offered below.

The need for additional insurance coverage for the uninsured. The primary barrier that the uninsured face in obtaining needed health services is lack of insurance coverage. Not only does lack of coverage affect the ability of individuals to access needed services, but it also affects a person's health status. To address this issue, the Task Force recommended that the North Carolina General Assembly take steps to make health insurance coverage more affordable and to expand health insurance coverage to more individuals and families who are currently uninsured. Until the uninsured have coverage, the Task Force recognized the importance of supporting and expanding existing safety net capacity to be able to meet more of the vital healthcare needs of the uninsured. In a very real sense, the healthcare *safety net* is just that, a stop-gap set of programs and voluntary efforts to minimize the effects of lack of healthcare insurance coverage for a growing segment of our population. The problems caused by lack of adequate health insurance coverage cannot be solved until most or all of those now uninsured, for all or part of a year, are included in some form of insurance to meet their healthcare needs.

The need for increased safety net capacity to address the healthcare needs of the uninsured. Because there is not unlimited funding or resources to support new or expanded safety net services across the state, the Task Force attempted to identify those communities or counties with the greatest unmet needs. The Task Force was able to collect data from some safety net providers about the number of uninsured people who received primary care services in the prior year, but these data were not uniformly available across types of safety net organizations. Data are not currently available from private practitioners, or from hospital emergency departments or outpatient clinics. Further, there are few sources of data to identify the capacity of communities to address the behavioral health, dental health, specialty, and medication needs of the uninsured. The Task Force recognized the importance of collecting these data, in order to target new resources to the communities most in need and to monitor the capacity of the safety net to address the healthcare needs of the uninsured over time. Therefore, the Task Force recommended that the North Carolina Department of Health and Human Services take the lead in monitoring services provided by public and private safety net providers across the state. In addition, the Task Force recommended that the Department, along with other safety net organizations, help develop a planning package and provide technical assistance to communities interested in expanding their safety net capacity.

The Task Force also recognized that there are barriers in existing laws that discourage some private practitioners from volunteering their time to serve the uninsured. Some private providers have expressed concern that they may be subject to a lawsuit for a bad health outcome if they provide services to the uninsured. Although North Carolina already has a Good Samaritan statute that provides protection against monetary liability, it does not currently shelter providers from the cost (either financially or emotionally) of having to defend a lawsuit. The Task Force identified a need to make the act of volunteering to serve the uninsured less of a burden, and recommended that the North Carolina Free Clinic Association work with the North Carolina Medical Society and other safety net providers to explore other ways of reducing the barrier that potential malpractice claims create to encouraging private practitioners from volunteering to serve the uninsured.

The Task Force was also concerned with assuring access to needed medications by those who are served by various safety net providers. A recommended therapeutic regimen is meaningless without the ability to follow through with access to prescribed medications. While there are some resources available to provide needed medications through the pharmaceutical companies' Patient Assistance Programs (PAPs) or through local safety net organizations, the current resources are insufficient to ensure that the uninsured can obtain necessary medications. There is also a federal program that allows certain safety net organizations to negotiate for highly discounted medication prices (called the 340B program). However, federal law restricts the 340B drug discount program to certain safety net organizations, including FQHCs, public health, and some hospitals. The deeply discounted prices are not available to free clinics, state-funded rural health centers, or other non-profit safety net organizations. Thus, the Task Force made a series of recommendations aimed at expanding the availability of low-cost or free medications to the uninsured. First, the Task Force recommended that existing programs to help low-income uninsured individuals access free or reduced-cost medications through the PAPs be expanded and that the pharmaceutical companies streamline and simplify the PAP application process. The Task Force also recommended that Congress expand the 340B drug discount program to include more safety net organizations. In addition, the Task Force recommended that state philanthropic organizations provide funding to help the North Carolina Department of Health and Human Services establish a bulk purchasing program that would help negotiate volume discounts from pharmaceutical companies for safety net organizations around the state.

Strengthening safety net integration and collaboration efforts. The patchwork of services, programs, and organizations serving the uninsured is being stretched in a number of directions as the demand for care among the uninsured has increased. Few communities in our state have been able to meet all the needs of the uninsured, regardless of how many providers of such care there are. The Task Force identified the need for increased levels of collaboration and, in some cases, the potential for the integration of services and organizations, in order to more effectively meet the needs of those served by safety net providers.

In communities with few or no safety net providers, these issues do not arise. But, in communities where multiple organizations are serving, often with overlapping efforts, the same uninsured populations, the need for collaboration is more evident. The Task Force therefore recommended a number of efforts to encourage collaboration among safety net providers and ways to encourage the involvement of professional and business organizations in these community-wide efforts.

The Task Force recognized the need to create an ongoing state-level Safety Net Advisory Council (SNAC) that can continue the work of the Task Force and encourage state-level and local safety net collaborations and integration efforts. The SNAC would be charged with collecting and disseminating "best practices" and models for service organization and delivery. Additionally, the SNAC should work with North Carolina foundations to help convene a best practices summit that would help local communities identify ways to build and strengthen their capacity to meet the healthcare needs of the growing uninsured population and reduce barriers to interagency collaboration and integration.

The Task Force also heard that existing state confidentiality laws have created barriers to sharing patient information across safety net providers—even when providing services to the same patients. The Task Force recommended that the General Assembly enact laws to clarify state confidentiality laws to ensure that safety net providers are allowed to share identifiable health information with each other when providing care to the same patients.

Increased funding to support and expand the existing safety net system. The Task Force identified four strategies that could help provide financial support for care to the uninsured: (1) ensuring that North Carolina receives its fair share of federal funding for safety-net programs, including funding from the President's Initiative for Health Center Growth and Expansion; (2) expanding state funds to support safety net organizations; (3) enhancing Medicaid reimbursement for safety net organizations, to help ensure that Medicaid reimbursement is at least sufficient to cover the costs of treating these patients; and (4) ensuring that individuals who are eligible for Medicaid enroll in the program, in order to make more limited state, local, or federal funds available to serve uninsured individuals who cannot qualify for Medicaid.

Although the Task Force spent considerable time trying to identify new sources of funding, the Task Force's highest recommendation was to maintain the state's major safety net funding source: Medicaid. As noted earlier, North Carolina has 1.4 million people who are uninsured; 62% of them have incomes below 200% of the federal poverty guidelines. The numbers of uninsured would be much larger without the existence of Medicaid and the North Carolina Health Choice programs. There is currently some discussion at the federal level about turning Medicaid into a block-grant program. This could be devastating to the state, safety net providers, and to low-income citizens of the state who rely on Medicaid to cover their healthcare needs. (See the open letter from Governor Easley on page 120-121) In addition, Task Force members felt strongly that the state was not getting its fair share of existing federal funds through the State Children's Health Insurance Program (North Carolina Health Choice), the President's Initiative for Health Center Growth (which funds FQHC health center expansion), Ryan White CARE funds for people with HIV/AIDS, or the Special AIDS Drug Assistance Program. Therefore, the Task Force recommended that the North Carolina Department of Health and Human Services and other safety net organizations work with the North Carolina Congressional delegation to: (1) oppose efforts to limit the availability of federal Medicaid funds and (2) ensure that the state receive its fair share of other funds available to underwrite health services for the uninsured.

Although new federal funds are available to expand the availability of healthcare services through FQHCs, there are barriers that prevent local health departments from applying for these funds. One such barrier is the state-required composition of local health department boards. Federal laws mandate that the governance structures of FQHCs be predominantly composed of the safety net organizations healthcare consumers; however, state law prescribes that local health departments boards be composed primarily of healthcare or other professionals. Thus, even though the populations served by health departments and FQHCs are the same, or very similar, local health departments are ineligible for this federal support. The Task Force recommended that the General Assembly give county commissioners the authority to change the local health department board composition in order to make these agencies eligible for federal funding.

The Task Force also recommended continued and expanded state funding for safety net organizations. Last year, the North Carolina General Assembly appropriated $7 million in one-time funds to expand the availability of healthcare services to the uninsured through new or existing safety net organizations: $5 million to FQHCs and $2 million for state-funded rural health centers and/or local health departments. The Task Force supported the General Assembly's efforts and recommended that this funding be expanded to $11 million on a recurring basis: $6 million for FQHCs and $5 million for state-funded rural health centers, local health departments, or other nonprofit safety net organizations with a mission of serving the uninsured.

Another need that has surfaced in many policy discussions in recent years is the need for additional school health nurses. The Task Force was aware of the important role these nurses play in meeting the primary healthcare needs of children and adolescents in our public schools. For many children, and especially for adolescents, school nurses are the only healthcare professionals they see, yet North Carolina has a shortage of such personnel. The recommended ratio of school nurses to students is 1:750; the statewide ratio in North Carolina is 1:1,918. Last year (2004), the General Assembly appropriated funds to enable the hiring of an additional 145 nurses to work in the public schools (with 65 of these positions time-limited). Even with this additional funding, there is still a need for 973 nurses to meet these recommended ratios. The Task Force recommended an additional appropriation to accomplish this goal.

The Task Force also recommended that the North Carolina Department of Health and Human Services explore options to enhance Medicaid reimbursement to safety net organizations that serve a higher than average proportion of uninsured patients and that the state ensure that local health departments—like other publicly-funded health providers—receive cost-based reimbursement for the clinical services they provide. Any new funding provided to FQHCs, FQHC look-alikes, rural health centers, hospitals, and/or health departments should be targeted toward serving the uninsured.

The Task Force suggested ways to capture savings that the state is currently realizing through implementation of the Community Care of North Carolina program (CCNC), a system that provides case management and disease management services to improve the health of Medicaid recipients with chronic or complex health problems. At the present time, local CCNC networks cannot retain any funds that are saved as a result of improved care management for these Medicaid recipients. In contrast, managed care companies that offer contract services to low-income populations are able to retain realized savings. The Task Force recommended that the Division of Medical Assistance explore the possibility of creating a system of "shared savings" with regional CCNC networks. The shared savings system would enable the networks to use their savings to support the provision of services to the uninsured.

Finally, the Task Force made a series of recommendations to ensure that uninsured individuals who are currently eligible for Medicaid are enrolled in the program. Ensuring Medicaid coverage for those who are eligible would help target the limited state funds for safety net providers toward uninsured individuals who cannot receive coverage elsewhere. National data suggest that only 72% of eligible children and 51% of eligible non-elderly adults enroll in Medicaid.[10] Many eligible individuals do not know they are eligible for coverage or are discouraged because of the stigma attached to applying for public programs. Others are discouraged because the application process is difficult to complete. The state has made significant progress in simplifying the Medicaid and North Carolina Health Choice application process for children, but the state has not yet incorporated these simplifications into the adult Medicaid application process. To address this problem, the Task Force recommended that the state streamline and simplify the Medicaid program for adults, by creating simplified application forms, extending the length of time for recertification, and exploring the possibility of eliminating the resource test for families with children (just as the state has already done for families that apply on behalf of their children only). The Task Force also recommended that the state modify Medicaid policies to make it easier for individuals with high medical expenses to qualify for Medicaid.

Summary

North Carolina is in the midst of a quiet, but growing healthcare crisis. The number of uninsured residents is rising at an alarming rate—and a faster rate than in most other states. Almost one of every five (20%) non-elderly North Carolinians have no health insurance, which means a sizeable portion of our population has unmet healthcare needs. As healthcare costs continue to increase, North Carolina is likely to continue seeing increased numbers of uninsured. Until we can dramatically reduce the volume of the uninsured, there will be a continuing and growing need for governmental, private sector, and voluntary healthcare providers to serve this population.

In this issue of the Journal, we have attempted to draw attention to the volume and variety of services, programs, and organizations involved in meeting this important healthcare need among our state's most vulnerable populations. The organizations involved in rendering these services, and the private physicians and other healthcare professionals who give of their time and talents to meet these needs, are stretched to their limits in most communities. The Task Force has recommended several concrete steps that would shore up safety net organizations' and individual providers' capacity/ability to meet these needs. Some of these steps will require rather straightforward changes in regulations and laws governing the provision of healthcare services. Others will require appropriation of funds to augment the public, private, and voluntary support now given through these safety net provider organizations in support of their efforts to serve the uninsured.

While some effort needs to be made to bring these issues to the attention of the state's Congressional delegation in Washington, DC, many of these problems should not have to wait for federal action. The needs are great, and the demands for service are increasing among those organizations and professionals who have assumed these responsibilities in counties and communities across our state. For those with healthcare insurance, these problems and their administrative complexities may seem of remote interest and concern. But, for the people who depend on the safety net services, these problems can mean the difference between health, work, and opportunity, or between disease, disability, or death. There is a genuine collective benefit to meeting the healthcare needs of the uninsured, for the health and wellbeing of a fifth of our state's population affects the health of all of us. Depending on a stop-gap, safety net to maintain the health of such a large segment of our population is a societal risk we all must confront. Failure of any part of the healthcare safety net could be detrimental to the stability of the larger healthcare system on which we all depend. **NCMJ**

State of North Carolina
Office of the Governor
20301 Mail Service Center • Raleigh, NC 27699-0301

Michael F. Easley
Governor

Governor Mike Easley sent the following letter to the entire North Carolina Congressional Delegation.

March 9, 2005

Dear United States Senators and Representatives from North Carolina:

Last week, my fellow governors and I met in Washington to discuss issues of importance to all of us, including the proposed Medicaid cuts included in the President's 2005-06 budget. Under the President's plan, $40 billion in costs would be shifted from the federal government to the states. We agreed that these proposals were not sustainable.

Like many states, the rapid growth in North Carolina's Medicaid enrollment – over 200,000 new enrollees in three years – has driven the increase in costs. As we have discussed before, our national trade policy has resulted in the loss of thousands of North Carolina jobs, and some of those families have been forced to seek Medicaid assistance to make ends meet.

Since 2001, North Carolina has taken many steps to control Medicaid costs. We have reduced provider rates and fees, denied some inflationary payments to providers, taken steps such as establishing a maximum allowable cost list and a shift to generic and over-the-counter (OTC) drugs to control costs, increased co-payments to maximum levels allowed by law, implemented technology to reduce fraud and abuse, and reduced the transitional Medicaid period by one year. Quite simply, we have exhausted many traditional cost-saving options.

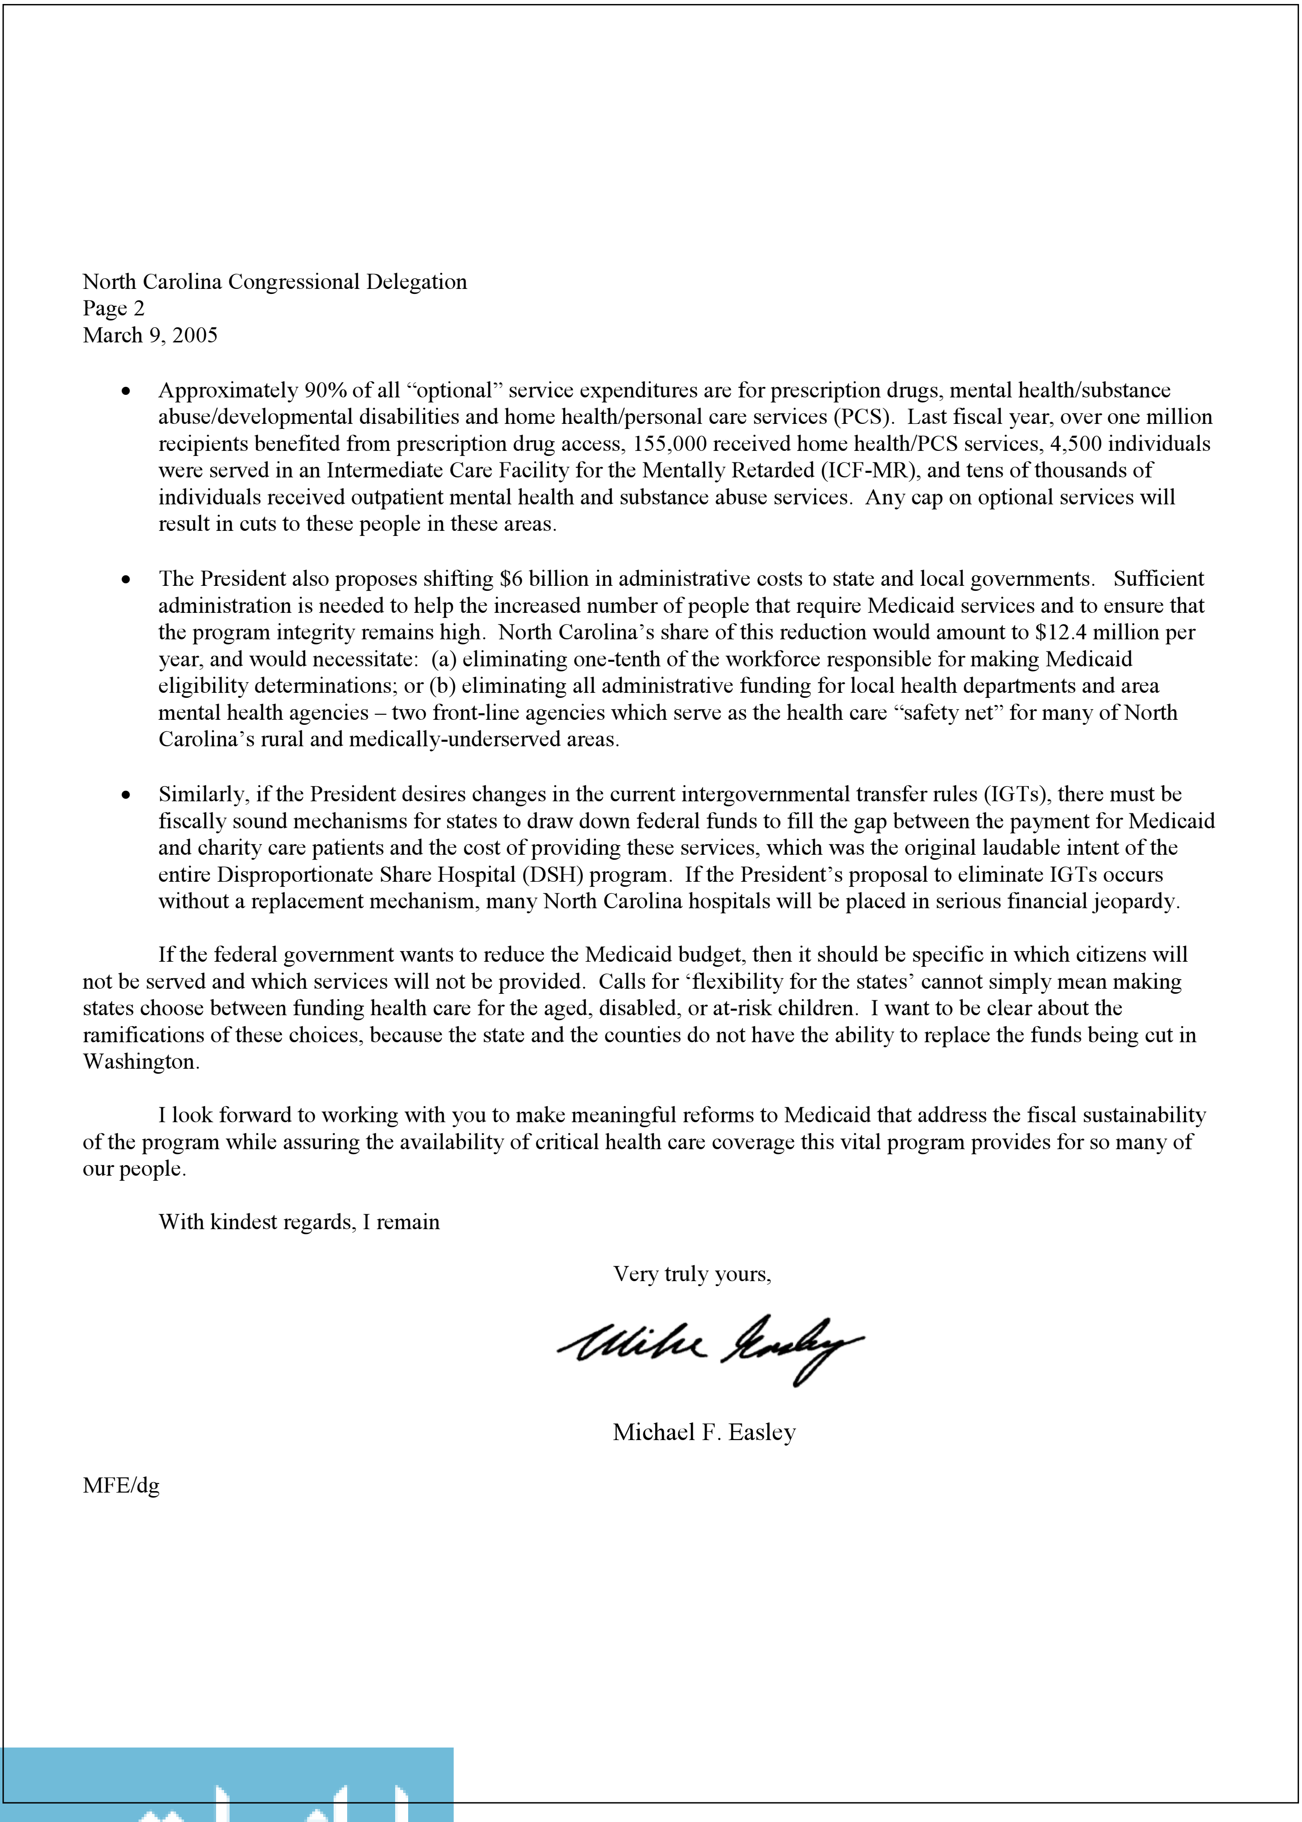
Here are the precise ramifications of some of the President's proposals to North Carolina:

- The President proposes reducing the rate of targeted case management from 62% federal share to 50% federal share. This will eliminate Medicaid case management services to an estimated 3,500 individuals.

- The President recommends a cut in the provider tax rate from a maximum of 6% to 3%. The cut in the allowable provider tax rate would cut payments to nursing facilities by $78 million and result in 600,000 fewer patient days of care provided during the year, the equivalent of 1,644 patients every day of the year.

- There is substantial discussion in Washington of controlling Medicaid costs through capping or cutting optional Medicaid services or populations. A cap or cut in optional services would require the elimination of adult dental care services that benefit 11,000 North Carolinians per month, adult optical services that benefit 3,650 North Carolinians per month, adult podiatry services that benefit 2,300 North Carolinians per month, and adult chiropractic services that benefit 1,600 recipients per month. I decided not to make these reductions in my budget recommendations this year, because these problems left untreated would result in the need for more costly medical care for these people in the future.

Location: 116 West Jones Street •Raleigh, NC • Telephone: (919) 733-5811



- Approximately 90% of all "optional" service expenditures are for prescription drugs, mental health/substance abuse/developmental disabilities and home health/personal care services (PCS). Last fiscal year, over one million recipients benefited from prescription drug access, 155,000 received home health/PCS services, 4,500 individuals were served in an Intermediate Care Facility for the Mentally Retarded (ICF-MR), and tens of thousands of individuals received outpatient mental health and substance abuse services. Any cap on optional services will result in cuts to these people in these areas.

- The President also proposes shifting $6 billion in administrative costs to state and local governments. Sufficient administration is needed to help the increased number of people that require Medicaid services and to ensure that the program integrity remains high. North Carolina's share of this reduction would amount to $12.4 million per year, and would necessitate: (a) eliminating one-tenth of the workforce responsible for making Medicaid eligibility determinations; or (b) eliminating all administrative funding for local health departments and area mental health agencies – two front-line agencies which serve as the health care "safety net" for many of North Carolina's rural and medically-underserved areas.

- Similarly, if the President desires changes in the current intergovernmental transfer rules (IGTs), there must be fiscally sound mechanisms for states to draw down federal funds to fill the gap between the payment for Medicaid and charity care patients and the cost of providing these services, which was the original laudable intent of the entire Disproportionate Share Hospital (DSH) program. If the President's proposal to eliminate IGTs occurs without a replacement mechanism, many North Carolina hospitals will be placed in serious financial jeopardy.

If the federal government wants to reduce the Medicaid budget, then it should be specific in which citizens will not be served and which services will not be provided. Calls for 'flexibility for the states' cannot simply mean making states choose between funding health care for the aged, disabled, or at-risk children. I want to be clear about the ramifications of these choices, because the state and the counties do not have the ability to replace the funds being cut in Washington.

I look forward to working with you to make meaningful reforms to Medicaid that address the fiscal sustainability of the program while assuring the availability of critical health care coverage this vital program provides for so many of our people.

With kindest regards, I remain

Very truly yours,

Mike Easley

Michael F. Easley

Federally Qualified Health Centers:
Providing Healthcare to North Carolina's Communities in Medical Need

Sonya J. Bruton, MPA

"I wouldn't trade Lincoln doctors for nothing. Whatever illnesses I have, they deal with it right away. If I have to see a specialist, they try and send me to one. They don't take chances. They always deal with my heart to make sure that it's in good condition; because, everything starts from the heart."

Sixty-four years ago, Thelma Woods was born at Lincoln Hospital—now Lincoln Community Health Center—in Durham, North Carolina. She grew up receiving care at the Center, and when she returned from New York after 30 years, it once again became her medical home. Ms. Woods discovered during a pre-employment physical that she had a blood pressure reading of 200/200. She sought care at Lincoln the next morning and learned that she had hypertension, high cholesterol, and diabetes. For three years, the medical staff helped Ms. Woods manage those conditions, and on January 18, 1993, they navigated her through a successful open-heart surgery. Today she serves as a member of the Board of Directors, and Lincoln provides medical care to Ms. Woods, her children, and grandchildren. "I think Lincoln has some of the best doctors around," she said. "I know without them caring for my health, I wouldn't be here today."

Lincoln Community Health Center is one of 23 federally qualified health centers operating in North Carolina. Federally qualified health centers (FQHCs) were created 40 years ago to respond to the reality that the poor have fewer options in the healthcare marketplace and are often shut out entirely from private medical practices. The statute authorizing the award of federal grants to health centers can be found under section 330 of the Public Health Service Act and includes a family of broad and specific health options: (1) Community Health Centers (CHCs), (2) Migrant Health Centers, (3) Public Housing Primary Care, and (4) Healthy Schools, Healthy Communities.

FQHC Defined

FQHC-designated community health centers are community-located and -operated clinics that receive federal support to care for residents living in the targeted area surrounding the center. The geographic scope may extend to zip codes or counties in an attempt to provide access to care for those in need. In order to receive federal assistance, the specified community must have a medical need. The need could be for more physicians, for more places willing to accept Medicaid/Medicare, or for a place that will care for community members who have no healthcare coverage. The care offered to these residents must include primary care services, health education, preventive care, chronic disease management, oral health, and behavioral health services. They also have to make sure that language, cultural, or economic factors neither impact a patient's ability to schedule or complete a visit nor stop them from receiving all of the follow-up services that may be needed to recover from an illness. This may mean making sure that medication or specialty services are secured. Federally-funded community health centers offer the following menu of primary care and enabling services to all patients either at the office or through a prearranged referral:

> *"FQHC-designated community health centers are community-located and -operated clinics that receive federal support to care for residents living in the targeted area surrounding the center."*

- Preventive dental services;
- Immunizations;
- Primary medical care;
- Immunizations;

Sonya J. Bruton, MPA, is the Executive Director of the North Carolina Community Health Center Association. She can be reached at brutons@ncchca.org or 2500 Gateway Centre Blvd., Suite 100, Morrisville, NC 27560. Telephone: 919-297-0012.

- Diagnostic laboratory services;
- Preventive services including prenatal, perinatal, and well-child services (such as eye, ear, and dental screenings for children);
- Cancer and other disease screenings;
- Screening for elevated blood lead levels;
- Diagnosis and treatment of communicable diseases;
- Family planning services;
- Preventive dental services;
- Emergency medical and dental service;
- Pharmacy services;
- Substance abuse and mental health services;
- Enabling services including outreach, transportation, interpreters, and case management services; and
- Services to help the health center's patients gain financial support for health and social services.

When referrals are made, health centers must coordinate and oversee the care provided to their patients, and access to care must be available through an after-hours call system or clinic hours that extend beyond the normal 9:00 am-5:00 pm work schedule.

Nationally, the community health center program was created in 1965 as part of President Lyndon Johnson's "Great Society" and "War on Poverty" initiatives. The movement came to North Carolina in March of 1970 with the creation of the Orange-Chatham Comprehensive Health Center in Chapel Hill, North Carolina. This center was followed by Lincoln Community Health Center in June of that same year.

Today there are 23 federal grantees, receiving section 330 funds, operating 76 delivery sites in North Carolina. These primary care facilities serve 56 counties and nearly 300,000 patients. In addition, there are three community-based primary care providers that are in compliance with Section 330 program requirements, but do not receive federal grant support. Instead, these centers, known as federally qualified health center look-alikes, receive:

- Drug pricing discounts;
- Special Medicaid reimbursement rates;
- Onsite Medicaid eligibility workers;
- Waived Medicare deductibles;
- Ability to waive co-payments of patients <200% of FPG;
- Medical providers through the National Health Service Corps; and
- No-cost vaccines for children.

Nevertheless, the proportion of residents without a usual source of care is much higher than the national average in North Carolina. At least one-in-five residents has no regular provider of care.[1] As a result, the push to develop more FQHCs throughout North Carolina continues. Research indicates that more health centers would significantly diminish the Hispanic/white and black/white primary care visit disparity.[2] One study recently found that a 10% increase in the number of health centers per 10,000 population would lead to a 6% increase in the probability of visiting a physician.[3] In general, expanding health center capacity reduces unmet need and increases the percent of the uninsured with a regular source of care.

Governance Structure

One of the foundations of the FQHC program is the mandate that governance of the health center organization involve a Board of Directors made up predominately of the people who use the health center's services (consumers/users). A consumer member should have used the health center services within the last two years and consider the health center his or her medical home. Health center expectations indicate that a user should be an individual who considers the health center his or her medical home for the purposes of receiving primary and preventive care.[4] For example, if upon becoming ill with the flu, an individual makes an appointment at the health center for diagnosis and treatment, the person would be considered a user of the health center's services. Conversely, if an individual uses the health center annually for a blood pressure check, but uses the services of a private physician in the community when he or she becomes sick, the individual would not be considered a health center user for the purposes of satisfying the requirement, because he or she is not using the health center as the principal source of primary healthcare. The section 330 implementing regulations state, "a majority of board members shall be individuals who are or will be served by the center and who, as a group, represent the individuals who are or will be served by the center and who, as a group, represent the individuals being or to be served in terms of demographic factors, such as race, ethnicity, sex."

From the inception of the health center program, Congress indicated that health centers should be governed predominately by the people who would care most about, and have the greatest interest in and commitment to, the scope of services offered by the health center, the health center's location and accessibility, the hours that services would be available, the programmatic priorities that the health center would pursue, etc.—the patients themselves.

Financial Stability

This year, the federal Community Health Center program celebrates its 40th anniversary. Also celebrating 40 years of service is the Medicaid program. In 1977, Dr. Karen Davis, President of the Commonwealth Fund, said, "the two programs were specifically designed to work in tandem with one another to make access to quality healthcare available to millions of Americans who previously had, at best, extremely limited access to needed care and who, as a result, experienced the worst health status among all Americans."

At 40, the FQHC program is thriving and growing under President George W. Bush's campaign to double the number of communities and people served by the end of 2006; while the Medicaid program is facing escalating costs that threaten its ability to offer coverage through the existing formula.

The weakened position of Medicaid, combined with an increasing number of uninsured, increasing healthcare costs, and downsizing of worker health benefits threaten the financial position of Community Health Centers. Approximately 25% of North Carolina health center patients are Medicaid beneficiaries, resulting in nearly 43% of North Carolina FQHC total revenues. FQHCs are left to wonder how they will continue to deliver high quality primary care to their vulnerable patients in the face of a disproportionate funding-to-need ratio environment. During this fiscal year (2005), federal grant dollars to North Carolina health centers decreased by nearly 1% across the board. Reductions to North Carolina Medicaid funding could result in increased cost sharing, forcing health centers to subsidize Medicaid using the already dwindling federal grant dollars intended for the uninsured. **NCMJ**

North Carolina State Government and the Healthcare Safety Net:

Building the Nation's Most Extensive Network of Rural Health Centers

Torlen L. Wade, MSPH, and Andrea D. Radford, MHA

Since its inception in 1973, the North Carolina Office of Research, Demonstrations, and Rural Health Development has worked to transform government into a catalyst for improving access to quality and cost-effective healthcare services for underserved residents of North Carolina. Under the leadership of its founding director, James D. Bernstein, the Office adopted a state/local partnership approach and made community investment the cornerstone of its improvement strategy. Bernstein focused on five key philosophies that have remained the guiding principles of the Office's partnership initiatives over the last 30 plus years:

- Ownership is vested with community participants;
- Roles and responsibilities of all participants, both community and governmental, are clearly defined;
- In-depth technical assistance is provided on a continuous basis;
- Accountability is clear and measured; and
- Meeting patient and community needs remains the focus of all activities.

Jim Bernstein believed strongly that if improvement in care or service was the goal, then those who were responsible for making it happen must have ownership of the improvement process. State government could not merely issue edicts or dangle money; it had to engage in meaningful partnerships, be prepared to make long-term investments in communities and nurture the leadership needed to deliver the desired improvements.

Community Involvement

The Office began to apply these principles in its initial rural health development work. When the Office was founded in 1973 as the Office of Rural Health Services, it was charged by the North Carolina General Assembly with assisting North Carolina's rural areas in tackling a critical shortage of primary healthcare services in their communities. As large numbers of aging general practitioners retired in the early 1970s, they were not being replaced by younger physicians. The prospects for North Carolina's isolated rural communities to attract replacements were dim. The programs to train the new specialty of family practice physicians were just getting underway, and the competition for the few physicians available was intense. Meeting the growing rural healthcare crisis required new strategies and new infrastructure.

To help rural communities address these challenges, the Office promoted two important structural changes to North Carolina's healthcare delivery system. The first structural change was the development and use of community nonprofit boards, comprised of local residents, as the owners and operators of their community's healthcare program. To support this level of

"State government could not merely issue edicts or dangle money; it had to engage in meaningful partnerships, be prepared to make long-term investments in communities and nurture the leadership needed to deliver the desired improvements."

Andrea D. Radford, MHA, is a Primary Care Operations Consultant for the North Carolina Office of Research, Demonstrations, and Rural Health Development. She can be reached at andrea.radford@ncmail.net.

community involvement, the Office designed and developed a comprehensive set of support services that helped make community ownership and direction a reality. By building a cadre of specialized technical expertise, the Office was able to assist interested communities in establishing nonprofit corporations, organizing fund raising campaigns, designing and building facilities, recruiting and hiring staffs, and overseeing medical operations. The combination of community leadership and the comprehensive technical assistance delivered by the Office was a highly effective approach in making medical care available to their residents for many rural communities. What was viewed as a radical development in the early 1970s is an integral component of North Carolina's medical landscape today. More than 80 community-owned rural health centers developed with Office of Rural Health assistance now serve approximately 350,000 North Carolinians across the state.

Using Physician Extenders

The second structural change that was a centerpiece of the Office's initial efforts to increase access to healthcare in rural communities was the reliance on non-physician primary care providers—family nurse practitioners and physician assistants—to provide needed medical services. Major changes in medical practice and reimbursement rules and regulations were initiated to enable these non-physician primary care providers to practice in medical offices geographically removed from a supervising physician. Family nurse practitioners and physician assistants became, and still are, important providers at many rural health centers.

Key Programs Serving the Medically Vulnerable

The principles from which the Office of Rural Health developed over 30 years ago in addressing access to care in rural communities across the state are now used to guide the Office and its partners in bringing about improvement in other healthcare areas that target the underserved and medically vulnerable, including:

- *Community Care of North Carolina*. Managing the care of Medicaid recipients through community health networks that are organized and operated by local physicians, hospitals, health departments, and departments of social services. The 15 Community Care networks, serving more than 600,000 Medicaid recipients, are putting in place the management systems needed to achieve long-term improvement in the quality, cost, and health outcomes of recipient care;
- *Medical Assistance Plan (MAP)*. Providing direct funding for primary care services to indigent patients served by nonprofit providers in high-need counties;
- *Prescription assistance*. Improving providers' ability to access free and low-cost medications for their low-income patients; and
- *Farmworker healthcare*. Targeting the unique healthcare needs of seasonal and migrant farmworkers across the state by building up local delivery systems in high-impact areas.

Future Planning

As the Office of Research, Demonstrations, and Rural Health Development moves into the 21st century, it looks to build on the legacy of community ownership and collaboration established as guiding principles in the early days of the Office. Establishing and sustaining successful safety net providers still requires the active participation of the community to be served and coordination with existing healthcare providers. Challenges seen in the early days of the Office, key physicians retiring with no one to replace them, and medical students choosing specialty practice over primary care, are re-emerging and call for creative solutions that require communities, providers, and government agencies to work together. The needs of North Carolina's uninsured and medically vulnerable citizens are greater than current resources. Collaboration among both communities and healthcare providers is critical to avoid duplication of effort, to develop programs that are sustainable over time, and to use limited resources wisely. While common problems plague the safety net as a whole, each community has its own unique set of circumstances and offers its own unique set of resources to tap into. The time-tested philosophy of community-driven healthcare avoids a one-size fits all solution and seeks to work with a community to maximize the impact and effectiveness of existing resources and to assist them in designing workable approaches to healthcare needs. This philosophy of community-driven healthcare is one of the key factors that allowed North Carolina to build and sustain the nation's most extensive network of rural health clinics. **NCMJ**

Free Clinics in North Carolina:
A Network of Compassion, Volunteerism, and Quality Care for Those without Healthcare Options

Olivia Fleming, MA, and John Mills, CAE

Ida and her husband Jim both worked full-time. Ida's job did not provide health insurance, but Jim paid extra so his insurance policy would cover both of them. Jim developed multiple sclerosis, which progressed rapidly causing Jim to lose his job. Despite their limited financial resources, they were able to continue his insurance through COBRA. Unfortunately, they did not have the resources to continue hers. Ida was faced with managing her hypertension without insurance. She turned to Urban Ministries Open Door Clinic (ODC) in Raleigh for treatment and medication. A routine screening mammogram revealed a lump in Ida's breast. Uninsured and frightened, she turned again to the ODC. ODC coordinated care and, within a month, Ida had a mastectomy and had begun a chemotherapy regimen. One year later, Ida is cancer-free and has found a new job with healthcare benefits, leaving the ODC with an opening for another person in need without other healthcare options.

Nancy, a young woman in her late 20's, came to ODC because she didn't feel well. Diagnosis: diabetes mellitus. Her hemoglobin A1c was 15, and other clinical measures were similarly high. Nancy entered ODC's specialized diabetes management program, the Diabetes Care and Risk Reduction Program. By meeting regularly with a certified diabetes educator; making significant changes in her eating and exercise habits; and receiving medications, a glucometer, and test strips at no charge, Nancy has brought her hemoglobin A1c to 5.2 and other clinical measures are in line. She is able to move toward her goal of getting pregnant, something that six months ago was not advisable due to her health status.

Approximately 1.4 million North Carolinians are uninsured, and that number is larger when statistics include individuals who lack health insurance at a given point during the year. It is a common misconception that low-income individuals are eligible for Medicaid coverage. To be eligible, one must fit into a few limited categories, such as being pregnant, being under 18 years of age or younger, age 65 and older, or before being disabled. There are also maximum resource and income levels allowable for each category. Simply being poor does not qualify one for governmental healthcare. Free clinics are a community response to the crisis facing these uncovered individuals. The clinics are by no means a comprehensive solution, but they represent a compassionate, economical, and proven source of healthcare. More than 50% of free clinic patients are employed, many working more than one job to make ends meet. However, they work for low wages and for employers who do not offer affordable healthcare insurance. It is in this environment that concerned individuals began to seek ways to improve access to healthcare in their communities.

> *"More than 50% of free clinic patients are employed, many working more than one job to make ends meet."*

What is a Free Clinic?

Free clinics rely on community collaboration and the spirit of compassion that leads persons to volunteer their services to assist their less fortunate neighbors. Free clinics in North Carolina reflect the needs and resources of their individual communities. There is no template, yet there are similarities. They are non-profit organizations, directed by concerned community leaders. Typically, the clinics provide services through a

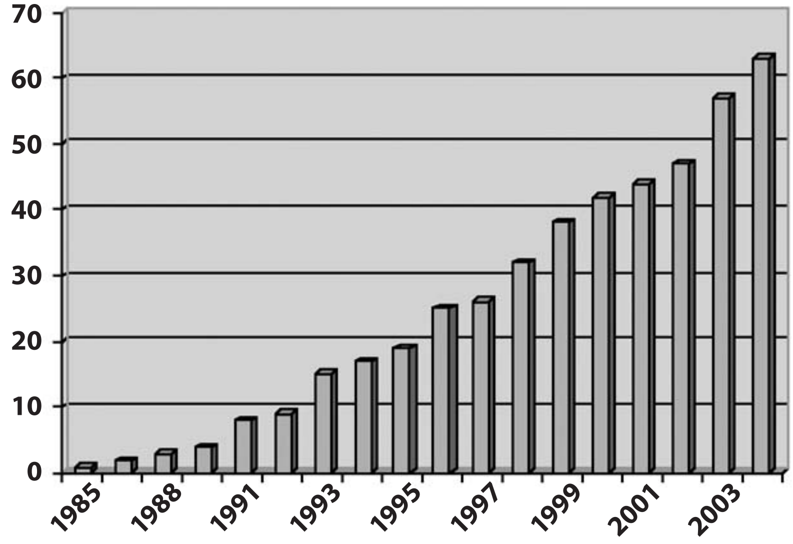
Olivia Fleming, MA, is the Director of The Open Door Clinic, a program of Urban Ministries of Wake County, Inc. She can be reached at ofleming@urbanmin.org or PO Box 26476, Raleigh, NC 27611-6476. Telephone: 919-256-2167.

John Mills, CAE, is the Executive Director of the North Carolina Association of Free Clinics. He can be reached at John@NCFreeClinics.org or 3447 Robinhood Road, Suite 312, Winston-Salem, NC 27106. Telephone: 336-251-1111.

combination of paid staff and volunteers—physicians, nurses, pharmacists, laboratory personnel, and support personnel. They share other common characteristics:

- *Free care.* There is little to no charge for services or prescriptions.
- *Target population.* The target population includes people who have low-incomes and are uninsured (i.e., have no health insurance, no Medicare, no Medicaid, no Veterans Benefits). Low-income determinations are made by the individual clinic and range from 100-200% of federal poverty guidelines.
- *Core values.* Delivery of high-quality, compassionate care based on a belief that lack of income should not prevent access to healthcare. Free clinics place strong emphasis on providing non-judgmental, compassionate care while respecting the dignity and self-worth of every patient.
- *Volunteer driven.* The majority of services are provided by volunteers, who receive no compensation for their services.

Figure 1.
Growth of Free Clinics in North Carolina



Volunteerism is the major difference between free clinics and other safety net providers. Services are provided by individuals who are at the free clinic because they want to be. Volunteers consistently say that they receive more than they give in their encounters with patients. Physicians, with no managed care constraints or productivity requirements are able to practice medicine as they see fit. It reminds many of them of the practice setting that lured them into medicine in the first place. A collegial atmosphere exists in free clinics, with frequent communication and interchange about patients among nurses, physicians, and pharmacists. This atmosphere, with leading professional provider volunteers, results in the delivery of high-quality medicine to free clinic patients.

Development of Free Clinics in North Carolina

In the 1970s, concerned physicians began free clinics in the Winston-Salem area. Those clinics operated from area churches, but were not able to sustain operations and closed in the late 1970s.

In 1985, Dr. Don Lucey and other community physicians developed a free clinic, the Open Door Clinic, at the Urban Ministries in Raleigh after recognizing that lack of health and resulting poor health status were causes of unemployment and increased the potential of homelessness. Urban Ministries Open Door Clinic is one of over 60 free clinics serving uninsured North Carolinians at the present time (see figure 1).

"It's places like this that renew your faith in humanity."

North Carolina leads the nation in the number of free clinics with 53 medical clinics, approximately 25 with state-licensed pharmacies (10 with stand-alone pharmacies or pharmacy programs). In 2003, North Carolina's free clinics served more than 69,000 patients, dispensed 450,000 prescriptions, and provided $50 million in healthcare services.

Free Clinic Services

North Carolina's free clinic services vary by community, depending on needs and resources of the individual communities. Services may include the following:

- Medical—acute episodic medical treatment; management of chronic diseases,
- Dental,
- Pharmacy,
- Laboratory and other diagnostic tests,
- Physical therapy,
- Podiatry,
- Behavioral health,
- Medical specialty services—including ophthalmology, orthopedics, cardiology, and dermatology among others, and
- Social work.

Even though services are provided at no charge, most free clinic patients receive the full-range of services needed for their medical condition. Patients receive medical care, laboratory services, referrals for other diagnostic or therapeutic services, health education, prescription medications, and specialty care. If a needed specialist is not available on-site, most free clinics have arrangements for community physician specialists to see patients in their offices.

Patients are emotionally invested and touched by the concerned and high-quality care they receive in these free clinics. As one Urban Ministries Open Door Clinic patient recently stated, “It’s places like this that renew your faith in humanity.”

Financials and Free Clinics

Free Clinics receive no federal or state funding. Because they receive no revenue from their patients, free clinics must turn to their communities for support. They are funded with cash and in-kind donations from a variety of sources including:

- Individual contributors,
- Churches,
- Businesses,
- Hospitals,
- United Way, and
- Foundations.

In 2004, free clinics raised over $13 million from private funding sources. Because they use volunteer providers and secure donated supplies, medication, and ancillary services, free clinics were able to leverage these gifts into over $50 million in healthcare services to their patients.

In 2004, the Blue Cross and Blue Shield of North Carolina Foundation announced a five-year, $10 million grant to the North Carolina Association of Free Clinics for the support of existing free clinics and the creation of new clinics in underserved areas.

Challenges Facing Free Clinics

North Carolina’s free clinics face multiple challenges as they continue to offer compassionate healthcare services to those without other options, including:

- *Meeting changing demographics*. Providing culturally appropriate services to diverse racial/ethnic populations is challenging. Access to interpreters in rural areas of the state is increasingly difficult.
- *Volunteer recruitment and retention*. Free clinics’ dependence on volunteers for service delivery requires them to continually recruit and retain licensed volunteer providers.
- *Finances*. Sustaining funding to operate the clinics once they have been operating for several years is challenging. Start-up grants are generally available, but they are short-term funding solutions.
- *Infrastructure issues*. Lack of funding to support staff is an issue. Most clinics operate with small staffs who must recruit, retain and support volunteers, and develop and maintain systems to ensure high-quality care delivery.
- *Liability concerns of volunteers*. While there is no history of a malpractice suit brought against a North Carolina free clinic, the specter of liability is prominent in the minds of most volunteer providers. Clinics must find an affordable solution for offering liability protection for providers.

Free clinics do not profess to be the answer to the crisis of access to healthcare for North Carolina’s uninsured, but they are a continuing stop-gap measure until there is a more comprehensive funding stream for indigent medical care. As Don Lucey, MD, states, “In 1985, when we started Open Door Clinic, we thought we’d be around for only a couple of years, until the country dealt with this problem of access to healthcare. Twenty years later, we’re still waiting.” **NCMJ**

COMMENTARY

Local Physicians Caring for Their Communities:

An Innovative Model to Meeting the Needs of the Uninsured

Gillian K. Baker, MHA, Alan T. McKenzie, and Paul B. Harrison, MPH

"Thank you for saving my feet, and my life." Those words warm the heart of the physicians who care for Joe.

About a year ago, Joe was not feeling well. He felt something was wrong, but he knew he did not have the money to go to the doctor, so he tried not to worry about it. However, as his health began to deteriorate, a friend told him about how physicians in his county will take care of him, even if he cannot pay. A local project coordinates healthcare for folks like Joe, who do not have insurance and cannot afford to go to the doctor.

Joe was very excited about the possibility of being able to get the much-needed healthcare and applied for the project. Joe met the criteria and was accepted into the project and assigned to a primary care provider. On Joe's initial visit to the doctor it was discovered that he has diabetes. Through the project, Joe is able to get the medical care, tests, medications, and supplies he needs to get and keep his diabetes under control. In addition, it was discovered that the disease has caused sores on Joe's feet that, which without the care of a specialist, could result in Joe's feet needing to be amputated. Through Joe's visit to a specialist, his feet have gotten better, and he has been able to avoid an amputation.

In your county a project like this might be called Project Access, or Appalachian Healthcare Project, or maybe Community Care Plan, but it is all the same—physicians donating their time and talents to do what they do best—helping those who are sick.

There are now many counties throughout North Carolina that have volunteer physician care projects, and the number of them continues to grow in North Carolina and throughout the country. For example, Charlotte/Mecklenburg County began officially serving patients through its Physicians Reach Out initiative in late 2004. But, it all began in Asheville, in 1994, when a grant from the Robert Wood Johnson Foundation started Project Access. The premise of these projects is that local physicians participate in a volunteer medical service program designed to meet the medical needs of residents who have no health insurance and have incomes typically below 150% to 200% of the poverty guidelines. Hospitals also donate care to patients enrolled in such projects. The projects coordinate donated inpatient and outpatient services and pay for limited outpatient medication requirements.

In Buncombe County, the Buncombe County Medical Society administers the first Project Access program, which serves as a model for replications throughout the state. Private physicians can participate in one of two ways in Buncombe County: (1) They can commit to serve patients at one of the safety net clinics, and/or (2) They can agree to see a certain number of patients in their office per year. Eighty percent of the physicians in private practice have agreed to participate in the program. Primary care providers agree to see 10 uninsured

> *"The premise of these projects is that local physicians participate in a volunteer medical service program designed to meet the medical needs of residents who have no health insurance, and incomes typically below 150% to 200% of the poverty guidelines."*

Gillian K. Baker, MHA, is the Director of the Appalachian Healthcare Project. She can be reached at gillianb@charter.net or 155 Furman Road, Suite 7, Boone, NC 28607. Telephone: 828-263-9493.

Alan T. McKenzie is the CEO of the Buncombe County Medical Society. He can be reached at alan@bcmsonline.org or 304 Summit Street, Asheville, NC 28803. Telephone: 828-274-6989.

Paul B. Harrison, MPH, is the Executive Director of the Wake County Medical Society. He can be reached at pharrison@wakedocs.org or 2500 Blue Ridge Road, Suite 312, Raleigh, NC 27607. Telephone: 919-783-0404 ext. 23.

low-income patients, and specialists agree to see 20 patients per year. Local hospitals donate all lab tests and inpatient and outpatient services. Patients who visit a specialist (or a primary care doctor) in their private office can obtain their medications through a county-funded medication assistance program.

In an effort to document the care being delivered by the project, the County Medical Society processes standard insurance claims forms voluntarily submitted by physicians, hospitals, and pharmacies to document which services were provided and the value (i.e., the usual cost) of the services. Patients referred by private physicians have their eligibility determined through the Medical Society. The average program enrollment period is approximately six months, but this varies based on the patient's needs and length of time that he or she is uninsured.

These projects help address problems associated with donated care including: physicians concern that they would be inundated with requests; patient eligibility, differentiating which patients could afford to pay; and concern that uninsured patients would be able to obtain needed medications or diagnostic services. In addition, the project office eases some of these concerns by verifying patient need and distributing patient referrals equitably among many different providers. This helps spread the burden/risk of caring for the uninsured. In addition, reminder phone calls are made to reduce no-shows and help ensure that patients can obtain specialty and ancillary services and needed medications.

Today people with incomes below the allowed Federal Poverty Level have access to comprehensive care through a network of primary care clinics and private physicians seeing patients in their practices and in the hospital. There is a system of specialty care referral, free pharmacy, and other services. Doctors are routinely donating their time and talent to provide treatment for diabetes and hypertension and perform procedures like heart surgery, knee surgery, and even brain surgery. All of this is done in their private practices and at local hospitals without regard to a patient's ability to pay.

Physician Leadership Role

Project Access initiatives are dependent on physician leadership and the identification of local physician champions. Physician leadership develops and executes all aspects of physician recruitment in an organized volunteer care program. The message of the physician champion is straightforward: the indigent population needs to have better care, and the only way it will be delivered is if the medical community contributes to this care in a way that does not unfairly tax any individual provider. All segments of the healthcare delivery system need to participate, and there needs to be organization, documentation, and controls to ensure the system is treating those in need (both economically and medically) as efficiently and effectively as possible. With a commitment from a significant portion of the medical community, the process can move forward.

Physicians are recruited to participate in the project. By the point of project implementation, 35% to 100% of the physicians in each of the counties where the project is active have joined the effort. Primary care physicians agree to accept 10-12 patients as their responsibility. Specialty physicians agree to accept 20-24 patients per year from the program. Local medical societies, hospitals, health departments, county governments, departments of social services, and area pharmacies have participated in these initiatives to varying degrees based on program location.

Why Physicians Participate

Physicians report great satisfaction from the personal rewards they receive as a result of the service they are providing to the community. They note that the image of their medical community has been enhanced through the positive publicity that the program brings to the profession as a whole, as well as individual participants. This increased awareness of the significant contributions physicians make to the safety net has, in turn, led to increased credibility and political and social influence in their community and at the state and national levels.

There is renewed camaraderie and pride in the medical profession and commitment to the general welfare of their communities. These physicians have discovered that by working together in their communities they can make a difference. They have improved the health of their communities and their profession.

Clearly, physician leadership at the local level produces dramatic results: enhanced healthcare delivery, improved health of communities, and a renewal of the only inexhaustible resource of the healthcare delivery system—the compassion of its caregivers.

Measuring Outcomes

Access to Continuum of Care Increases

In Buncombe County during 2004, of the 210,000 total population, there were approximately 38,000 uninsured. Of the uninsured, approximately 65% (or 25,000 residents) had incomes below 200% of the federal poverty guidelines. Amazingly, over 24,000 of these estimated 25,000 low-income uninsured patients were seen at least once in a safety net clinic or in a private primary care physician's office during that calendar year. Of these, 2,800 were referred for specialty care, hospital services, and/or medications beyond the scope of services available in these free clinics and community clinics. Ninety-three percent of all county residents now report having a medical care home.

Health Status of Uninsured Improves and Charity Costs Decrease

Community-wide health assessments conducted in Buncombe County found that the uninsured were more likely to report being in good or excellent health than the insured. The uninsured were also less likely to report using the emergency room than the insured. Of the patients served through Project Access, 25% reported improved productivity on the job, and 17% reported reduced absenteeism. Per patient charity care costs decreased, perhaps related to improved health status and increased access to primary and preventive care services fostered through the collaboration of private doctors, hospitals, safety net clinics, and area pharmacies. Area hospitals have documented an average of $3 million annually in avoided charity care costs.

History of Replication

In late 1998 Buncombe County Medical Society was selected from nearly 1,700 applicants to receive the prestigious Ford Foundation Innovations in American Government Award. With that award came a commitment by the Medical Society to help others replicate its system of care. As a result of the experience gained by the Buncombe County Medical Society, it has now developed a sophisticated approach to helping communities adopt and adapt the Project Access model to their unique circumstances; and thereby, dramatically expand access to care in their communities by better organizing existing resources. Using Project Access as a model, many North Carolina counties have operational systems, including Avery, Watauga, Mitchell, Yancey, Wake, Mecklenburg, Pitt, Cabarrus, Guilford, Forsyth, Caldwell, Vance and Warren Counties, while others have secured necessary funding and are in the process of organizing their systems. Nationally, there are project access systems operating in dozens of communities, such as Wichita, Kansas; Spokane, Washington; Austin, Texas; and Marquette, Michigan. A more comprehensive listing with links to program web sites may be accessed at www.apanonline.org.

Project Access can be replicated in both rural and urban settings such as these projects in Wake and Watauga-Avery Counties.

Appalachian Healthcare Project: A Rural Model

While the Project Access model is easier to establish in communities with large provider bases and existing safety net providers, Project Access models have been established in less resource-rich environments as well. The first rural Project Access program, the Appalachian Healthcare Project, serves Watauga and Avery Counties. Watauga County has a population of 42,857 people with 25 primary care providers and 60 specialists. Avery County has a population of 17,610 with 17 primary care providers and two specialists.

In the spring of 2000, the only place for low-income uninsured patients to receive care was the hospital emergency department. There were no safety net organizations or free clinics providing comprehensive primary care. The Appalachian Healthcare Project was made possible by the commitment of the medical communities in these two counties. Each provider pledged to see anywhere from 12 to 24 patients per year. In addition, the local hospitals offered inpatient, outpatient, and diagnostic services to Appalachian Healthcare Project patients. The commitment of the medical community allows the patient load to be distributed equitably among the physicians. Since the project was implemented in April 2001, approximately 600 people have been served. On average, there are about 200 active patients at any time. In 2004, the medical community provided nearly $2 million in medical care and medications to Appalachian Healthcare Project patients.

Wake County Project Access: An Urban Model

Urban volunteer service programs, like Project Access, are dependent on community stakeholders working collaboratively for the "common good." In this instance, the presence of six physician champions during the 12-month planning period persuaded leaders of the three hospital corporations and 450 physicians to sign on as participating providers.

The program has allowed the medical community to document the volume of donated care for patients who would not likely be able to pay for services. For this reason, hospital-based physicians and hospital corporations could only gain by their participation in Project Access, which has been strongly supported by local private practice physicians.

The project works collaboratively with an array of primary care safety net clinics, the health department clinics, hospital emergency departments, and private practice physicians. Since its inception in late 2000, Project Access of Wake County has enrolled 5,030 patients and has generated $20 million in donated care provided by physicians and hospitals. Operating expenses, including the cost of outpatient medications, account for $1 million, which yields a ratio of cost-to-donated care equal to $1:$20.

Current Needs for State Policy Development and Funding

Nationally, over 70% of physicians report providing charity care to the uninsured, yet this remains an often-overlooked component of our state's safety net services to the uninsured. In the absence of more thoughtful policies at the state level, the "specialty care" gap between primary care safety net services and hospital-based services will continue to widen, and many more patients will "fall through the cracks."

While scant state or federal policy has been developed to support continued private physician practice-based charity care, communities are stepping forward and producing dramatic gains in access, improved health, and reduced costs in serving the uninsured. These communities are investing in:

- Creating accountable safety net systems that improve the health of the uninsured and demonstrate significant returns on investment through reduced community costs and improved business productivity from healthier workforces.
- Building and sustaining physician-led administrative support that better organizes and celebrates physician charity care.
- Strategic planning that creates a healthcare safety net providing the full continuum of needed services.
- Systems that assure that uninsured patients receive the medications prescribed by physicians.
- Outcomes measurement systems that document the return on community investment.

State and federal policies are needed to help communities with these needed investments. In addition, the North Carolina Institute of Medicine North Carolina Healthcare Safety Net Task Force Report[1] calls for careful analysis of the

North Carolina's Good Samaritan legislation to assure that it provides appropriate liability protection for doctors donating their care to the uninsured, in particular to assure that this protection extends to cover doctors who are seeing patients for free in their private practices. Current legislation provides protection for patients who are referred by community clinics, but the protective legislation does not clearly extend its coverage to doctors who are participating in organized systems of charity care and seeing patients (for free) in their practices who may not have been referred by a clinic.

Conclusion

While our healthcare finance system cannot be based on charity, care donated by private physicians is a vitally important, yet vastly undervalued, component of our state's healthcare delivery system. Clearly charity care exists and will exist for the foreseeable future. Strategic investment in better organizing and integrating this care has been demonstrated to produce significant return on investment and public policy should be pursued to deliver this care effectively. **NCMJ**

The Hospital Emergency Department:
An Anchor for the Community's Healthcare Safety Net

Jeffrey S. Spade, CHE

North Carolina's community hospitals have a long respected tradition of undergirding the health and welfare of citizens and communities across the state, wealthy or poor, urban or rural, healthy or frail. One hundred thirteen (113) community hospitals provide needed healthcare services for North Carolina's 100 counties, ensuring local community access for both basic healthcare requirements and more complex interventions and therapies. North Carolina's community hospitals are also a prime anchor of the safety net that protects the state's most vulnerable citizens: the elderly, those with chronic disease, the poor, the disadvantaged, and the uninsured. Without a local hospital, many North Carolina communities would struggle to maintain even the most basic health services.

The North Carolina Healthcare Safety Net Task Force Report[1] by the North Carolina Institute of Medicine effectively describes the increasing burden of the uninsured and the poor, while documenting the "frayed edges" and the "worn patches" that shore up the state's healthcare safety net. While hospitals represent the virtual anchors of the safety net, hospital emergency departments are the ever-present backbone of the safety net's architecture. Emergency departments are often the first line of defense against community epidemics, like influenza and respiratory diseases, a provider of hope and life for citizens faced with debilitating disease or life-threatening injury, and a provider of last resort when no other avenues for healthcare seem available.

North Carolina Emergency Departments Carry a Huge Burden

In 2003, North Carolina hospitals provided emergency services to 3,433,432 patients, an increase of 21% percent over five years (see figure 1). North Carolina's rate of increase exceeds the national growth in emergency visits, which increased 11.6% over the same five-year period.[2] In a national survey completed in 2002 by the Centers for Disease Control, abdominal pain, chest pain, and fever were the most commonly recorded principal reasons for an emergency visit, accounting for one-fifth of all emergency visits. The most frequently reported diagnoses were contusions, acute upper respiratory infections, open wounds, and abdominal pain. Diagnostic/screening services, procedures, and medications were provided at 86.8%, 43.2%, and 75.8% of emergency visits, respectively. Additionally, 12% of emergency visits result in hospital admission; and more than one-third of patients admitted to the hospital are first treated in the emergency department.[3]

Figure 1.
North Carolina Hospital Emergency Visits, 21% Increase in Visits Since 1999

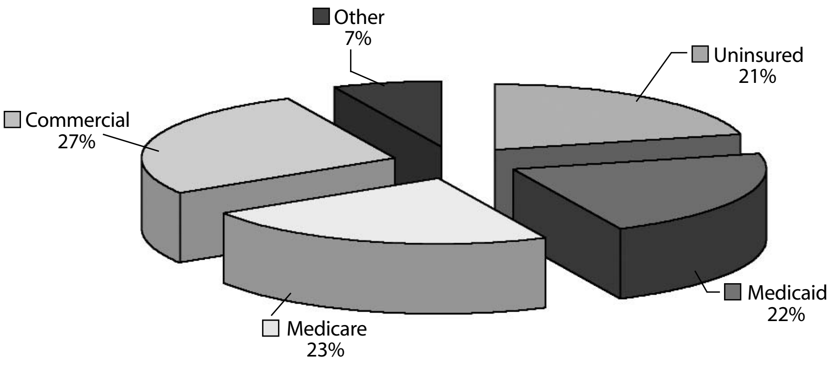
Figure 2.
North Carolina Hospital Emergency Visits by Payment Type in 2004



Total Emergency Visits for North Carolina Hospitals in 2003 = 3,433,432

emergency visits were by those with Medicaid; and 27% of the emergency visits in 2004 were covered by commercial insurance (see figure 2). The rate of uninsurance (21%) in North Carolina's emergency departments is greater than the national rate (16%). Furthermore, North Carolina's hospitals experience higher use of emergency services by the poor and elderly (Medicare and Medicaid) and lower rates of commercial coverage than the average emergency department nationally. Fifty-six percent (56%) of North Carolina's emergency visits occur in urban hospitals and 44% in rural hospitals. North Carolina's large hospitals, those with 200 licensed beds or more, accounted for 64% of emergency department admissions in 2004. North Carolina's largest hospitals, those hospitals with 400 or more licensed beds, serve the greatest proportions of uninsured and poor emergency care patients (23% uninsured and 26% Medicaid, respectively, 49% combined). For the average North Carolina hospital, the uninsured and poor account for 43% of the emergency admissions.[4]

The Multiple Roles of Hospital Emergency Departments

In the National Hospital Ambulatory Medical Care Survey by the Centers for Disease Control (CDC), the authors state, "the primary role of the hospital emergency department is the treatment of seriously ill and injured patients. However, the emergency department provides a significant amount of unscheduled urgent care, often because there is inadequate capacity for this care in other parts of the healthcare system. The emergency department also serves as referral site for other providers to evaluate and stabilize patients."[5]

A May 2004 study published by the CDC examined the characteristics of emergency departments serving high proportions of safety net patients. Interestingly, the study defined a "high-burden safety net emergency department" as having greater than 40% combined services to Medicaid and uninsured emergency patients. Given that the average North Carolina hospital emergency department treats 43% uninsured and Medicaid patients combined, many North Carolina emergency departments would readily meet the CDC definition as serving a high burden of safety net patients.

Furthermore, the CDC study found that emergency departments serving high proportions of poor and uninsured patients have a greater proportion of visits made by children and minority residents; have higher percentages of non-urgent and 'urgent, but primary care-treatable' cases; and higher percentages of cases that left the emergency department without being treated. Of note, the CDC study found that the percentages of 'emergent conditions that were avoidable with preventive care' were not significantly different between hospital emergency departments with varying (high versus low) proportions of the uninsured and poor. In addition, hospital emergency departments with higher proportions of uninsured patients had lower percentages of emergency cases that were 'avoidable with primary care' in comparison to hospitals with high proportions of Medicaid visits to the emergency department.[6]

Comparable data describing the use, characteristics, and demographics of emergency departments and patients in North Carolina are lacking. Therefore the appropriateness of emergency department admissions and the reasons for seeking emergency care by vulnerable populations, such as the poor and the chronically ill, are not well documented.

However, recent developments will improve the understanding of emergency care in North Carolina. A new partnership between the North Carolina Division of Public Health (NCDPH) and the North Carolina Hospital Association (NCHA), with support from two nationally prominent information technology companies, Solucient and MercuryMD, organized and developed the North Carolina Hospital Emergency Surveillance System (NCHESS). The main purpose of the NCHESS partnership is to capture near real-time emergency care data to quickly assess and manage public health or population health emergencies.

Biodisaster preparedness is the reason NCHESS was developed. Because of this unique and successful partnership, North Carolina is the first state in the country to develop and implement this advanced biopreparedness warning system. An important and valuable by-product of the NCHESS development will be the collection and analysis of emergency department diagnoses, trends, demographics, and outcomes. In the near future, NCHESS will help the state's healthcare systems and providers understand the usage trends in emergency services and, in turn, be able to design interventions and healthcare access models to improve community health. NCHESS will greatly contribute to the understanding of the adequacy of the healthcare safety net in North Carolina.

Emergency Department Care: Often Inappropriate and Expensive When No Alternatives Exist

While specific North Carolina data are unavailable, national studies routinely conclude that providing care for non-emergent or primary care-treatable conditions in emergency settings is expensive, sometimes inappropriate, and often inefficient. The federal Agency for Healthcare Research and Quality (AHRQ) recently published a study examining the health and economic costs of the lack of preventable primary care for diabetes patients. The study estimates nearly $2.5 billion in savings annually if patients received more appropriate primary care for diabetes complications.[7] Community Care of North Carolina networks across the state have documented reductions in emergency department usage by patients with chronic diseases, namely asthma and diabetes, when the local and regional primary care systems collaborate to improve and support chronic disease management in the community setting.

A national study by the Center for Health System Change concludes that uninsured citizens rely on emergency departments for one-fourth (25%) of their ambulatory care visits, compared to 8% for the privately insured population.[8] The authors posit that the greater reliance by the uninsured on emergency departments for primary care is likely due to a decline in access to office-based providers. The same study indicates, however, that contrary to popular wisdom, uninsured patients are not driving the increased use of hospital emergency departments. Instead, privately insured patients and Medicare beneficiaries accounted for two-thirds of the overall increase in emergency department visits, nationally, between 1996 and 2001.[8]

The Center for Health System Change suggests that capacity constraints experienced by office-based providers, combined with a loosening of managed care restrictions, may contribute to the increase in non-urgent emergency visits, a trend apparent in all payer segments. The Center's 2003 Issue Brief states, "other research shows that more patients are having difficulty making appointments with their doctors, and more people have long waits for appointments. For their part, more physicians report having inadequate time to spend with their patients and are increasingly closing their practices to some new patients, despite spending more time in direct patient care activities. With extended hours and no appointment necessary, emergency departments increasingly may be viewed by many patients as more convenient sources of primary care than their regular physicians. For uninsured patients, emergency departments are one of the few remaining primary care options."[8]

A 2005 report by the National Association of Community Health Centers tracks the federal government's plan to place federally-funded community health centers serving the poor and uninsured into every poor county in the United States. The report identifies 47 poor counties in North Carolina, divided into 20 counties with a community health center (CHC) and 27 North Carolina counties without a CHC.[9] With the rising numbers of uninsured and poor in North Carolina, the ability of the public system of care (health departments, CHCs, indigent care clinics, rural health clinics and centers, free clinics, etc.) to accommodate the increasing indigent care burden is certainly being stretched.

Hospital emergency departments are increasingly the last remaining reliable and routinely available source of primary healthcare in many North Carolina communities. If the uninsured visit rate of 21% is applied to the emergency visits tabulated for North Carolina in 2003 (3.43 million emergency visits), then North Carolina hospitals experienced more than 721,000 uninsured emergency visits in 2003. Adding in Medicaid, hospital emergency departments provided care for nearly 1.5 million uninsured or poor North Carolina residents in 2003.

> *"Emergency departments are often the first line of defense against community epidemics..., a provider of hope and life for citizens faced with debilitating disease or life-threatening injury, and a provider of last resort when no other avenues for healthcare seem available."*

The Emergency Medical Treatment and Active Labor Act (EMTALA) of 1986 has had a profound effect on hospital emergency departments. EMTALA requires emergency departments to screen and stabilize all patients that present to the emergency department regardless of ability to pay. The federal government does not guarantee such expansive access to any other segment of the healthcare system. Thus, emergency departments are often viewed as the ultimate safety net providers, ensuring a minimum level of care and services regardless of the patient's disease category, background, ethnicity, immigration status, or insurance class. While EMTALA is viewed as an unfunded federal mandate and presents enormous compliance issues for the hospitals, the concept of the hospital emergency department as a guaranteed source of immediate healthcare is important and vital to sustaining and improving community health.

Challenges Faced by North Carolina Hospitals' Emergency Departments

It is comforting to know that North Carolina's hospitals and emergency departments are a solid anchor and backbone for the state's healthcare safety net. However, regardless of the strength and commitment of community hospitals to emergency care, hospitals face many difficulties in maintaining this important aspect of the safety net anchor. Among the issues that impact hospital emergency departments are reasonable and adequate financing, increasing volumes of uninsured patients, access to capital for expansion and technology enhancements, adequate physician coverage for unassigned and uninsured patients, the unstable nature of mental health reform in the state, the rapid influx of immigrants and foreign-born citizens requiring care, and the rising cost of malpractice insurance premiums. Several of these issues are worthy of further examination.

> *"...the concept of the hospital emergency department as a guaranteed source of immediate healthcare is important and vital to sustaining and improving community health."*

Financing the Care of the Uninsured. Operating and maintaining a modern, fully equipped, adequately staffed and appropriately sized emergency department is an expensive proposition. Yet, emergency care is such a basic and essential aspect of community health networks that almost every community hospital in North Carolina offers emergency care. The primary financing mechanism for emergency departments is insurance coverage for health services. For the average North Carolina hospital, one in five patients (21%) is uninsured, with very little or no resources to pay for their care. Another 45% of emergency care is provided to Medicare and Medicaid patients. Obviously, maintaining adequate levels of reimbursement, especially from the government payers, Medicare and Medicaid, is essential if hospital emergency departments are to remain viable and accessible. Cutting hospital payments in Medicare and Medicaid, especially at a time when the numbers of uninsured residents are rising, will definitely impact the quality and availability of essential, yet expensive hospital services such as emergency departments. In the federal 2006 fiscal budget, Medicaid expenditures are under attack, threatening the ability of the state of North Carolina to adequately fund its Medicaid program. The retraction or reduction of Medicaid funding by the federal government cannot be allowed. This one factor alone, inadequate Medicaid funding, is a major threat to North Carolina's healthcare safety net.

Malpractice Insurance Costs. The rapid rise of malpractice insurance premiums also hampers the emergency department safety net. Some North Carolina hospitals and physicians have experienced malpractice premiums increases of 300% or more over the past few years. The malpractice cost increases are so dramatic and expensive that some physicians can no longer afford to cover certain services, such as labor and delivery, or even general surgery. Also emergency department back-up coverage is often considered a high-risk, high-liability service, which can influence the cost and/or availability of malpractice insurance, driving physicians to curtail or drop emergency department coverage from their privileges. Losing community physicians from the coverage panel for the hospital emergency department is a serious problem. Having fewer physicians available for emergency patients, especially those patients who present at the hospital without a regular physician, means that hospital emergency departments may be unable to provide care for some very basic, yet essential, healthcare services. Solving or at least abating the malpractice crisis in North Carolina will give some respite to hospitals and health providers that struggle daily to maintain adequate emergency care coverage.

Growth of the Numbers of Uninsured. The expanding ranks of the uninsured in North Carolina cannot be ignored either. The loss of manufacturing, tobacco, and textile jobs in North Carolina will continue to push the number of uninsured residents into record territory (almost 20% of residents under age 65 in 2004). Uninsured residents frequently do not have a regular source of primary healthcare. Thus, uninsured residents may seek primary care in hospital emergency departments, often too late, after a treatable condition has progressed into a true emergency. If the rate of increase of the uninsured continues at the current pace, then hospital emergency departments may be one of the few remaining care settings available for uninsured patients. A hospital emergency department with 30% or more of its care provided to uninsured patients and 20% or more emergency care being provided to Medicaid patients is at serious risk for financial failure.

Mental Health Reform. Mental health reform is a vastly important issue for hospital emergency departments. The state of North Carolina is currently undergoing major reforms to the mental health system. As a result, the mental health system in North Carolina is very fragile; not enough providers, too few community-based services, inadequate reimbursement, uneven insurance coverage, and an increasing demand for service. The rate of uninsurance is 70% higher for mental health visits to the emergency department than the average emergency visit. If mental health reforms, such as the development of community service alternatives and mental health reimbursements, are not adequate or incomplete, then hospital emergency departments will be overwhelmed with patients requiring care for mental health conditions. In fact, many hospital emergency departments across the state already report significant increases in patients requiring mental health service with few options for community referral.

The Need for Expanded Primary Care Options. Besides preserving and protecting Medicaid funding, one major solution is recommended to help maintain the hospital emergency department's strength and viability as a safety net anchor: the commitment to create and maintain multiple and additional community access points for primary care service for the uninsured, the poor, and the vulnerable. Community health centers, rural health clinics and centers, public health departments, free clinics, mental health centers, and community physician practices must be developed and supported in close collaboration with the local care networks, especially in the neediest communities and counties. If additional primary care access points for the uninsured are not developed and funded, then hospital emergency departments will become increasingly crowded, suffer from inadequate staffing and less advanced equipment and technology, and require more financial subsidies. **NCMJ**

COMMENTARY

Our Healthcare System Is Failing

J. Douglas Yarbrough, MBA

What do we think when we hear about someone who has no health insurance coverage? Our first thought is that they may not get the care they need. Then we wonder if they could lose their savings and/or incur massive debts if they or someone in their family has a catastrophic illness. This should concern us, but this is not the whole picture. In reality, providing medical care for the uninsured is an even greater problem for our healthcare delivery system. In fact, it is crippling our system; and if left unresolved, it will destroy our system. Nationally, there are approximately 44 million people without medical coverage. Another 38 million have inadequate coverage. That means approximately 28% of the United States population is without adequate healthcare coverage.[1]

With some exception, uninsured people pay very little of the cost of providing their healthcare at the hospital level. For years, we in the hospital industry have referred to the uninsured as "self-pay." For financial purposes, we classify our patient receivables as Medicare, Medicaid, other government, commercial, or self-pay. We informally refer to self-pay as "no-pay." That is because we collect a very small percentage of what we charge the uninsured. Many of them are classified as charity care, and a large portion of their care is written off. Some uninsured patients have the ability to pay, but decide not to, and their balances become bad debts. Some fall into a monthly payment category where they make very small monthly payments (without interest). How do hospitals deal with the cost of the uninsured? Like any business, we pass it on to the paying customers. It becomes a piece of overhead. Call it what you want, but it is a part of the total cost, and somebody has to pay for it.

> *"How do hospitals deal with the cost of the uninsured? Like any business, we pass it on to the paying customers."*

From a financial perspective, accounting for healthcare is much like accounting for any other type of service. We must have enough revenue to cover our costs. If we cannot make a profit, we cannot replace worn out plant and equipment or invest in the latest technologies. However, there is one difference unique to the healthcare field. That is the enormous amount of free care and under-paid care we deliver. We must charge each patient more to recover the unreimbursed cost of care provided to the uninsured and "government payers." As a result, hospitals write off 40-50% of what they charge.

Hospitals Are Underpaid by Medicaid and Medicare

Let me explain why government payers present another unique problem for healthcare providers. Earlier I referred to the classification of patients as Medicare, Medicaid, other government, commercial, or self-pay. In North Carolina, hospitals are not receiving enough payments from government payers to cover the cost of treating government-pay patients. Medicare payments to hospitals are not based on what hospitals charge, and, in most cases, do not cover the true cost of providing the care. Imagine owning a business where your customers walk in, take your product or service, and then tell you what they are willing to pay. Why can Medicare do this? Medicare covers half of the patients that come to our hospitals. Medicare is the number one payer by far; they can virtually enforce any payment system they choose, and hospitals have no choice but to accept. Historically, the Medicare program has grown much more than government estimates, and they had to come up with payment systems that allow them to meet their budget. For the first 18 years of Medicare's existence, the program paid hospitals for the "cost" of the care provided. However, since 1983, the payments have been slowly declining in relationship to the actual cost of providing care, and now hospitals are receiving less in payments than the actual cost of the care. How do hospitals recover this shortfall? Simple: they pass it on to other payers.

Unfortunately, Medicaid, the second largest payer for many

J. Douglas Yarbrough, MBA, is President and CEO of Duplin General Hospital, Inc. He can be reached at dyarbrough@dgh.org or PO Box 278, Kenansville, NC 28349. Telephone: 910-296-0941.

hospitals, has been doing the same thing as Medicare. They are paying less to hospitals than the cost of providing care to Medicaid patients. Hospitals are burdened with yet another class of payer that does not cover the cost of care provided. What do hospitals do to cover that short fall? Obviously, the same remedy is to pass that on to other payers. Unfortunately, the only payers remaining are commercial insurance carriers. Insurance companies have historically paid hospital bills based on billed charges rather than a government imposed payment scheme.

Insurance Companies Demand Deep Discounts

In recent years the number of commercially insured patients has dwindled. With factories closing and workers attracted to jobs with little or no insurance coverage, the problem is exacerbated. Employers have reached the boiling point with health insurance costs, and they are beginning to increase employee deductibles and coinsurance, passing the cost on to their employees. The insurance companies are tired of paying the shortfall for all the other payer classes. Consequently, insurance companies are beginning to negotiate deep discounts and alternative payment systems. This creates a great dilemma for hospitals. There is no one left to absorb the cost of the uninsured.

Hospitals Are Left with Few Acceptable Business Options

Many hospitals in North Carolina have run out of ways to recoup the cost of providing free care, and they are now losing money on their bottom lines. Where does the money come from to fund those losses? Like any business, losses come out of surplus—surplus that should be used to replace worn out plant and equipment and purchase new technologies. Hospitals operate in a high-tech, labor-intensive environment, and they cannot survive without the latest technologies. When a hospital uses its surplus to fund loses from operations, sooner or later, they have either to cut services drastically or close. Unfortunately, we have some hospitals in North Carolina that are now in that situation. We also have many hospitals that are currently losing money and will be in that situation if nothing is done to break the cycle.

How do we break the cycle? If hospitals were like other businesses, they would simply discontinue unprofitable services, add profitable lines, lay off employees, and certainly stop giving away their services. As we all know, none of these solutions will work for hospitals, particularly the not-for-profit community hospitals. We are not here simply to make a profit. The services we provide are essential to the community. Our mission is to improve the health of our community, regardless of patients' ability to pay, regardless of how profitable or unprofitable the service is. We are the last place for many patients to go. We are their "safety net." Our emergency rooms are full, and we will continue to take care of them as long as we can. Unfortunately, under the current system, our days are numbered.

Suggestions for Change

So, what are we going to do? I will share a few of my suggestions. First, we, meaning all of us, providers of care, insurance companies, Medicare, Medicaid, etc., must quit playing the blame game. We are in this fix because we have spent the last four decades blaming each other for these problems. Our problems will continue until we all come together and take equal responsibility for fixing them. Hospitals and healthcare providers should not be the fall guys in the system. The enormous burden of the uninsured must be borne by all of us.

Second, we need meaningful reform on the legal side of healthcare. Regardless of who is right or wrong about tort reform, the legal climate is terrible. At one time in this country, many of our physicians came from physician families. Now, physicians are encouraging their kids to go into other fields. The fear of malpractice suits, complicated billing and payment systems, and government regulation is discouraging new physicians from going into private practice. In order to have enough physicians in rural areas, hospitals are forced to contract with physicians as employees or guarantee them a fixed income. This further depletes hospital resources and puts them at financial risk.

A very large hidden cost in our system is the increasing volume of unnecessary diagnostic testing. Fear of being sued is the number one reason why physicians order so many tests. The number of MRIs, CT scans, x-rays, etc. are growing each year, simply because physicians are afraid not to order them. One lawsuit can destroy a physician's livelihood. Most physicians feel trapped in a system where sensible, conservative medicine can no longer be practiced. Defensive medicine is costing us a fortune.

Last, we must educate our communities. Not only do we all need education on healthier lifestyles and preventive medicine, but also we must learn to make wise choices about our care. We must also learn to form reasonable expectations about our healthcare system. Everyday, I am amazed at the level of dedication exhibited by our healthcare workers. They are compassionate and caring. They work around the clock to be here whenever we need them. But, medicine is not an exact science, and people are not perfect. We need to take the profiteering out of our legal system. **NCMJ**

Public Health Departments:
The Under-funded Provider of Last Resort

George F. Bond, Jr., MPH, and Wanda L. Sandelé, MPH

To understand a healthcare safety net, perhaps we should begin by reflecting back on our days as children at the circus watching that daring young girl on the flying trapeze and her strong "catcher," both poised 50 feet above the floor. The only thing standing between them and certain death is that thin rope safety net just above the floor. With that image in mind, three basic characteristics of a safety net stand out. First, it is *effective* in avoiding certain death, it must work! Second, it should offer *complete* coverage. A net, covering 90% of the arena is useless to those who fall on the 10% not covered. Third, the *net must always be there*. Do you recall when the ringmaster called for the removal of the net for the last five minutes of the act just to heighten tension and excitement in the audience? When the poles holding up the net were removed, it fell to the ground and *there effectively was no safety net!*

> *"Public health is known as the 'silent miracle' because the process of preventing epidemics, assuring food safety, and providing clean water is invisible and, all too often, taken for granted."*

Let us now turn our thoughts from the circus to an examination of the healthcare safety net in North Carolina. When most healthcare professionals define the healthcare safety net, they include payment sources such as Medicaid and Health Choice; they include rural health centers and free clinics; and they almost certainly will include federally qualified health centers (FQHCs) and FQHC look-alikes. Rarely is the local health department mentioned in these definitions, even though the evidence clearly shows them to be an integral part of the net and indeed the "provider of last resort" in many North Carolina counties.

Effective?

Traditional safety net providers would like to be 100% effective in providing care for the uninsured and underinsured. Sadly, however, they are seriously under-funded by state and federal sources to respond to that need. Their funders, and indeed their own balance sheets, tell them that they need to be self-sufficient. Thus, when times get tough, co-pays, deductibles, and lab fees go up by necessity, and sometimes patients without a payment source are turned away. Last year, local health departments provided more than $11 million in un-reimbursed prenatal care alone to low-income clients who could not pay for their healthcare. When community health centers have to turn away patients because of mounting operational deficits, those patients go to the *local health department*.

Complete Coverage?

Community health centers are located all over North Carolina, but coverage is still incomplete. In western North Carolina, for example, there are community health centers in Hot Springs, Asheville, and Hendersonville; but beyond that line, there is not a single community health center in any of our eight western-most counties. Those eight counties tend to be poor, they have high unemployment rates, and they meet virtually any definition of medical need. Probably because of

Wanda L. Sandelé, MPH, is the Craven County Director of Public Health. She can be reached at wsandele@co.craven.nc.us or Craven County Health Department, PO Drawer 12610, New Bern, NC 28561. Telephone: 252-636-4960.

their sparsely populated nature these counties have not been attractive sites for new community health centers. However, every single one of those eight counties has a *local health department*! Local health departments last year provided an estimated *$40 million of uncompensated care*!

The Net Is Always There?

Across North Carolina, community health centers have grown up as independent, freestanding organizations with consumer boards. While independence has advantages, it leaves community health centers financially vulnerable because they are not connected to a "deep pocket" such as a county government, a hospital, or a university. Thus, when the local economy stumbles, cash flow constricts, and there are only limited reserves from which to draw. Either fees have to go up, or costs have to come down. Either way, access for the low-income patients is threatened. Our rapidly increasing Hispanic population faces financial challenges as well as language barriers to health access. Health departments are required by the Civil Rights Act to serve this challenged population. There is a local health department within a 30-minute drive of every resident in every county in North Carolina.

We should all be proud of our fine system of community health centers working tirelessly in our state delivering quality healthcare. However, we cannot say in good faith that those traditional safety net providers alone form an impervious healthcare safety net. In fact, there are large holes in that net, both in terms of eligibility and geography. There is, however, a system already in place with buildings that deliver healthcare in every single county in North Carolina. There is at least a minimal level of healthcare staffing on the payroll of a "deep pocket" that either already provides, or has the potential to provide, primary care to the uninsured and underinsured in every county. There is already access to at least some basic level of clinical service in all 100 counties from Hanging Dog in the west to Hatteras on the coast. That system is our 85 *local health departments*. We believe that the current value and future potential of health departments as safety net providers have largely been overlooked.

Public health is known as the "silent miracle" because the process of preventing epidemics, assuring food safety, and providing clean water is invisible and, all too often, taken for granted. Public health is the "provider of last resort." The term suggests that the local health department somehow miraculously picks up the loose ends when the private sector either finds certain services or segments of the population unprofitable or inconvenient. "Provider of last resort" also suggests that the care is of lesser quality and only a temporary, desperate measure that must suffice until something better comes along. The truth is that thousands of citizens receive high-quality clinical service from their local health departments, perhaps because they have an overdue balance at their private provider, or since no other provider accepts Medicaid, or maybe because of their transportation and language challenges. We in public health are honored to be able to fill some of today's gaping holes in the safety net.

Because we are required to complete a Community Health Assessment every four years, health departments learn about access problems through our data gathering and analysis. A health department that chooses to embrace the function of "provider of last resort" unfortunately positions itself to operate continuously in a crisis mode, especially when the economic climate or the personality of the healthcare community changes. Most health departments do not have large primary care programs, but maintaining even a small clinical program assures capacity and allows for rapid expansion to greater volume when circumstances dictate. Such was the case in one eastern North Carolina county where the only two obstetrical practices merged and decided that they could not see pregnant women covered by Medicaid. Overnight, the prenatal workload at the health department more than tripled. This could not have been accomplished on such short notice if the program did not already exist. Since expansion is always easier than absolute creation, local health departments struggling to serve the low-income population have more than once questioned why a brand new community health center gets approved, funded, and built right down the street when the dollars could better be spent shoring up their existing program.

The explanation for this apparent lack of collaboration lies both in federal regulations and in state law. The system of FQHCs, begun in the 1960's to extend primary care access, did not allow North Carolina health departments to fulfill that vital community role, even though a number were already major providers of such services in their communities. By federal regulation, an FQHC must have a board with a majority of consumers. Standing in direct opposition, North Carolina statutes do not currently permit a board of health, which governs the health department, to exist in that form. That artificial barrier to FQHC status needs to be removed. We are pleased that the North Carolina Healthcare Safety Net Task Force Report[1] contains a recommendation for the removal of the legal barrier that prevents health departments from becoming FQHCs.

Adequate Funding

The real problem with the safety net lies not at the feet of the providers. The problem is that *no one has adequately funded care* for the uninsured at the federal, state, or local levels. It matters not whether the organizational structure is run by a consumer-dominated board, a hospital board of trustees, or a board of health—somebody has to be willing to "foot the bill" for those who cannot pay. Even though the public health department directors are prone to complain about other members of the safety net who are not seeing their "fair share" of the indigent, in reality, the only way any of us are able to see the uninsured is through a combination of donations or local appropriations and the very skillfully orchestrated practice of cost-shifting. Even though health department staff are government employees, they still must be paid, they still have to buy medical supplies, and there must be phones and heat in the building. County Commissioners in some counties have chosen to support their local health departments in the provision of medical service to the uninsured. That does not render medical care at the health department free; it just means that someone has accepted a responsibility to pay for care not covered by insurance. All we really need in this state to complete our safety net and make it impervious—stretching from the mountains to the shore—is funding for the uninsured. We already have a voucher system available to some providers to pay for the uninsured. If that program could be expanded significantly, if federal dollars can be attracted to support new FQHCs, and if statutory barriers to FQHC status for local health departments could be removed, then North Carolina, as a state, with all the safety net providers working together as a system, can and will address the needs of those who currently are denied routine access to our healthcare system.

In a nation that long ago walked on the moon and currently supports over 125 heart transplant centers, surely we can muster the political will to solve the problems with our safety net. Health departments can play a significant role in the implementation of that solution. President Bush has proposed a dramatic increase in the numbers of community health centers across the nation. Federal dollars of this magnitude have not been available for many, many years. We must aggressively act on this historic funding opportunity. We must also pledge to work together to develop a reliable funding stream to cover uninsured patients.

Forty years ago, President John F. Kennedy challenged the nation to put men on the moon by the end of the decade. We need that same kind of bold political leadership in North Carolina to answer the problems of the uninsured. The uninsured cannot solve the dilemma of access to care for all North Carolinians. They do not speak for themselves with a loud political voice. In fact, they may not speak at all, or they could speak in a foreign tongue. However, we can and we must speak for them! **NCMJ**

Pharmaceutical Companies Meet the Needs of the Poor and Uninsured:

An Important Element in the Healthcare Safety Net

J. Andrew Hartsfield IV, JD

> *"I am writing to say that I really appreciate the help you gave me in getting my medications. . . You may not realize how life-saving you are. . . I can never thank you all enough for helping me when I so desperately needed it."*
>
> — Excerpt from patient letter to GlaxoSmithKline

Our government spends hundreds of billions of dollars on healthcare entitlement programs every year, the largest programs being the federal Medicare program for senior citizens and the disabled; the federal/state Medicaid program for low-income patients; and the State Children's Health Insurance Program for children, up to age 19, who are not already insured. Despite the scope of these programs, there are many low-income people who do not qualify for any of them. These people depend on the complex and vast array of sometimes confusing public and private programs that make up the healthcare safety net.

As part of their commitment to improving access to medicines, pharmaceutical companies play an important and essential role in helping low-income, uninsured, and other vulnerable populations get the medicines they need as part of this safety net.

At GlaxoSmithKline, we do not want a lack of insurance coverage or financial means to put a patient at risk by causing them to either not fill a prescription or to fill it through unsafe channels. Thus we—like most other major pharmaceutical companies—offer programs designed to ensure that vulnerable populations get the prescription drugs they need.

Pharmaceutical Industry Patient Assistant Programs

More than six million patients across America received more than 22 million free or discounted medications with a wholesale value topping $4.17 billion from pharmaceutical companies last year.[1] Expanded outreach efforts continue to increase use of these programs.

The industry also launched an innovative program that serves as a clearinghouse for the more than 275 public and private prescription assistance programs available. Augmenting these efforts, the industry's trade association, PhRMA, launched a new web site, www.pparx.org, making it much easier to learn about the many different public and private programs available and to identify ones that can help patients on an individual basis. These efforts are designed to increase awareness of and enrollment in existing programs.

As part of these efforts, GlaxoSmithKline's patient assistance programs, Bridges to Access and Commitment to Access™, provided over $372 million worth of prescription medicines to eligible low-income, uninsured patients in the United States

> *"As part of their commitment to improving access to medicines, pharmaceutical companies play an important and essential role in helping low-income, uninsured, and other vulnerable populations get the medicines they need as part of this safety net."*

J. Andrew Hartsfield IV, JD, is Vice President of Public Policy and Advocacy at GlaxoSmithKline. He can be reached at andy.2.hartsfield@gsk.com or PO Box 13398, Research Triangle Park, NC 27709-3398. Telephone: 919-483-7667.

during 2004. In North Carolina alone, more than 25,900 patients received medicines worth nearly $20 million from GlaxoSmithKline.[2] Importantly, GlaxoSmithKline's programs also provide a bridge for patients, offering coverage under the program during the time a patient applies to other programs, such as the AIDS Drug Assistance Program, where waiting lists and delays can often mean a long wait for the patient.

The success of GlaxoSmithKline's and the industry's programs are rooted in the local support of community health groups, physicians, and many others. Working together, these partnerships reach out to vulnerable individuals, conduct training sessions on enrollment, and spread the word that help exists for people who need it.

Discount Card Programs

Pharmaceutical company patient assistance programs are one important part of the safety net, but there is also help for patients who don't qualify for these programs due to income. Many pharmaceutical companies also offer free discount card programs through which qualified individuals can receive significant discounts on their medicines. A few programs are highlighted below.

Orange Card℠

GlaxoSmithKline introduced the Orange Card℠ in 2001. It was the first such manufacturer discount card offering significant savings for low-income senior citizens. More than 175,000 seniors, including 13,000 North Carolina seniors, have an Orange Card℠. Through the Orange Card℠, qualifying seniors can get their GlaxoSmithKline medicines at a savings of about 20-40% off the usual price paid. To qualify, Medicare beneficiaries must have no public or private prescription drug insurance and have an income under $30,000 for a single person or under $40,000 for a couple.[*]

Together Rx Card™

Soon after the launch of the Orange Card℠, seven pharmaceutical companies created the Together Rx™ free prescription drug savings program. Together Rx™ is a discount card through which the participating manufacturers offer savings of approximately 20-40% off their brand-name medicines. Patients can save on more than 155 FDA-approved medicines, and some pharmacies offer savings on generics as well. Medicare enrollees who have no other prescription drug coverage and earn less than $28,000 ($38,000 for couples) are eligible.[†]

Resources for Drug Assistance

America's pharmaceutical companies want patients to be able to get the best and safest medicines available. For low-income patients there are a number of resources and programs available to help. Here are some web sites that provide information on programs and eligibility requirements:

HelpingPatients.org
www.helpingpatients.org

GSK Orange Card℠
www.OrangeCard.com

Together Rx Card™
www.Together Rx.com

Together Rx Access Card™
www.TogetherRxAccess.com

Bridges to Access™
Bridgestoaccess.gsk.com

Commitment to Access™
commitmenttoaccess.gsk.com

Medicare
www.medicare.gov

Nearly 1.5 million seniors, including more than 75,000 North Carolina seniors, have a Together Rx™ card, and to-date seniors have saved over $700 million on their medicines.

Both the GlaxoSmithKline Orange Card℠ and the Together Rx™ card will be available until the Medicare prescription benefit takes effect in 2006.

Together Rx Access Card™

The Orange Card℠ and the Together Rx™ card programs provide savings for low-income Medicare beneficiaries. Yet, there are millions of Americans who lack health insurance that don't qualify for Medicare. In January, GlaxoSmithKline and nine other major pharmaceutical companies introduced an innovative program to fill that gap and help many of those uninsured. The Together Rx Access Card™ helps Americans without prescription drug coverage better afford their medications by providing them with meaningful savings on many brand-name and generic products—at local pharmacies.

To be eligible, individuals must not be eligible for Medicare, have no prescription drug coverage (public or private), and

---

[*] Income limits may be different in Alaska and Hawaii; GlaxoSmithKline (GSK) expects Orange Card℠ participants to realize out-of-pocket savings ranging from 20-40% of the price individuals without drug coverage would usually pay their pharmacies for GSK medicines. Actual savings will vary depending on a pharmacy's customary pricing for a specific GSK medicine. GSK offers Orange Card℠ participants direct savings on their outpatient GSK prescription medicines equal to 25% of our wholesale list price. See application for important details and limitations.

[†] This program is for Medicare enrollees who have an annual income that is less than $28,000/singles ($38,000/couples) and do not have prescription drug coverage (public or private); this range of savings reflects the savings presently offered. Savings may vary depending on a pharmacy's customary pricing for a specific medicine and the savings offered by the participating company that makes it. (Participating companies independently set the level of savings offered and drugs included in the program. Those decisions are subject to change.) Income limits may be different in Alaska and Hawaii.

have a household income equal to or less than $30,000 for a single person, $40,000 for a family of two, or $50,000 for a family of three.[‡] Participants can expect to save about 25-40%—and sometimes more—off the usual pharmacy price paid on these prescription products. More than 275 FDA-approved prescription products, as well as a wide range of generics, from 10 major pharmaceutical companies are included in the program, including dozens of medicines used to treat diabetes, hypertension, high cholesterol, cancer, allergies, asthma, arthritis, and depression, which are among the most common conditions affecting Americans. Together Rx Access™ could benefit approximately 80% of the 45 million Americans—including more than eight million children—who are uninsured and don't have prescription drug coverage.

Ninety-eight percent of pharmacies nationwide will accept the Together Rx Access™ Card. The goal of the Together Rx Access Card™ is to help the millions of Americans without prescription drug coverage gain access to the prescription products they need and to help them take care of what's most important—their health. Since January, Together Rx Access™ has enrolled more than 300 uninsured North Carolinians.

Medicare Prescription Drug Benefit

One of the most important recent efforts to increase access to healthcare was the enactment by Congress of a Medicare prescription drug benefit. Enrollment for the Medicare prescription drug benefit begins in November 2005, and it is an important change in the nation's healthcare safety net. Beginning in 2006, Medicare beneficiaries will have access to a benefit that will cover outpatient prescription drugs. The benefit will be administered by private prescription drug plans, and seniors will have a choice of which plans to join. The new program is especially beneficial to low-income patients. They will get full coverage with minimal copays and will not have to pay premiums or deductibles. Every low-income senior citizen should take advantage of the new Medicare prescription drug benefit. Also, seniors with high prescription drug costs can benefit from the catastrophic coverage offered under the new benefit.

Until the prescription drug benefit goes into effect, there are Medicare prescription drug discount cards available. These cards offer discounts on prescription drugs and can charge a premium. But again, for low-income seniors, these cards are a great deal. Qualifying low-income seniors can get a card with up to $600 already available for them to use toward the purchase of prescription drugs.

Conclusion

Lack of access to even basic medication and healthcare facilities is a situation nobody should experience. GlaxoSmithKline recognizes the importance of our nation's healthcare safety net and is committed to playing a role in helping people avoid this crisis. No single organization can produce a solution; we will continue to work with other stakeholders to improve the health of our nation and improve our healthcare system. **NCMJ**

[‡] Savings may vary depending on the pharmacy's customary pricing for each product and savings offered by the participating company that makes it. Participating companies independently set the level of savings offered and the products included in the program. Those decisions are subject to change. Income limits may be different in Alaska and Hawaii.

COMMENTARY

Free Prescriptions? Yes, There Is a Way!

Margaret P. Elliott, MPA

There may not be such a thing as a free lunch, but you can get your prescription medication free if you qualify. Just ask the Martin family. I'll never forget their story. This couple's niece called from Ohio to our free pharmacy to see if anyone could help her aunt and uncle whom she discovered were paying $700 per month for their prescription medications. To make matters worse, she learned that they were paying for them by charging the cost of their medications on a credit card. In debt, reaching beyond their ability to ever pay it back, the Martins turned to Crisis Control Ministry in Winston-Salem, which houses North Carolina's first state-licensed free pharmacy.

In one hour's time, after an interview to determine the couple's financial situation, the Martins were enrolled as certified clients of our pharmacy, and able to have their $700 worth of prescriptions filled for free! In addition, our pharmacy was spared the cost of their medications, thanks to the drug assistance programs offered by the pharmaceutical companies who manufactured the couple's medications. By completing applications that verified their inability to pay, our staff helped steer this couple through the guidelines of programs that vary depending on the company. Their medications were mailed to a local physician and dispensed to the couple at our free pharmacy.

Just six years ago this scenario was very different. Every day the free pharmacy staff faced very real challenges to meeting the needs of the individuals who visited us and could not afford their life-sustaining prescription medications. Even though we purchased medications, some were just too expensive to buy. If we happened to have received some sample donations from local physicians, we called it providential and were grateful to have the donation to dispense. Unfortunately, that didn't happen every day. We had to ask some patients to call back later to see if we received the medications. We had to tell others that we just didn't have their medication, and we couldn't afford to buy them, even at a discount wholesale price.

In 2000, the annual budget for Crisis Control Ministry's free pharmacy in Winston-Salem was $400,000. Four years later, we operated on less than half that budget, with costs offset by donated drugs. In 2003-2004, we dispensed nearly 34,000 prescriptions, 21% more prescriptions than in 2000—medications valued at over $2.1 million on a $197,000 budget thanks to pharmaceutical donations from local nursing homes and our participation in helping patients enroll in pharmaceutical companys' Patient Assistance Programs (PAPs). In 2004, our free pharmacy received $423,000 worth of drugs from drug manufacturers—drugs that we earlier had purchased or simply could not afford to provide.

Many people are no longer able to afford their medications due to the rising cost of prescription drugs. These individuals may be eligible for the patient assistance programs and discounts offered by pharmaceutical companies, but these programs are complicated. They are all different, and it is not always easy to get the information you need to use them.

> *"One of the most important roles we play as advocates and human service providers is educating and helping our neighbors in need to access the services that are available to them."*

Pharmaceutical manufacturers have designed programs to serve the most financially needy patients, those who lack health insurance or financial resources, and those who have exhausted all other options to cover needed medications. Though these programs are very beneficial, locating information and navigating through the complex application process is sometimes an overwhelming task.

The majority of brand name as well as generic medications are available through PAPs. Although eligibility requirements vary according to manufacturer, there are requirements that typically must be met:[1]

Margaret P. Elliott, MPA, is the Executive Director of Crisis Control Ministry, Inc. She can be reached at melliott@crisiscontrol.org or 200 East Tenth Street, Winston-Salem, NC 27101-1512. Telephone: 336-724-7875.

- *United States Residency.* Depending on the program, some companies simply require that patients be permanent residents of the United States. Others require that they reside in the United States legally and others require United States citizenship.
- *No prescription coverage.* The patient must not be covered or eligible for coverage under any public or private insurance that covers prescriptions.
- *Low income.* Each company has its own eligibility standards regarding income. Most will not provide assistance to patients with monthly incomes that exceed 200% of the federal poverty guidelines.
- *Chronic medical conditions.* Patients who require on-going medication to treat chronic medical conditions are typically the only patients who will qualify for assistance. Since the application process may take several weeks, these programs are usually not appropriate for acute medication needs.

Benefits of Patient Assistance Programs

There are many benefits of PAPs to patients, healthcare providers, communities, and drug manufacturers. Patients are provided access to much needed, sometimes life-sustaining, prescription medications for free or at a reduced cost. This enables the patient to use his or her remaining financial resources to provide for other basic life needs, such as food and shelter. The patient experiences less emotional stress and, with the provided medication, has improved health.

Healthcare providers benefit because the patient stays compliant with a recommended course of treatment. There are fewer trips to the emergency room and fewer admissions into nursing homes. Sample medications can be used for other purposes.

The community benefits by supporting safety net providers who help provide access to the PAPs. Resources saved can be directed toward other needs in the community.

Drug manufacturers, who are not required to offer these programs, benefit with PAPs by providing an opportunity to contribute to improved patient outcomes. PAPs also allow companies a marketing opportunity, help with public relations efforts, and offer potential tax deduction.

Details of Patient Assistance Programs[1]

Individual Programs. The complexity of accessing free medications through PAPs is revealed in the challenges one faces while completing the applications. The eligibility criteria, system of medication delivery (either to the patient, the physician, or accessed through a voucher to use at a retail pharmacy), and application forms are different for each program. Safety net providers, such as free clinics or social workers, assisting patients with the process must learn the criteria of each company's program.

Access to forms. Most forms are available on the pharmaceutical company's website or through specialized software that accesses the forms. Some forms must be requested each time a patient is identified. Waiting to receive a form in the mail only delays the application process.

Citizenship/Residency requirements. Many programs require patients to be legal residents or United States citizens to be eligible for PAPs. This serves as a barrier in communities that seek to serve undocumented residents or those who are not yet citizens.

Frequent changes. The application process, the medications covered, and the eligibility criteria can change quite often; therefore, it is imperative that healthcare providers keep up with them in order to complete the patient enrollment forms correctly.

Long waiting times. It is not unusual for a patient to wait four to six weeks to receive medication ordered through a PAP. During these waiting periods, healthcare providers and safety net providers must seek other ways to access medications to provide for the immediate needs of the patient.

Reapplication required. Many programs provide only a 90-day supply of medication and require the patient to reapply for the next supply. This requires a tremendous amount of organization and reminder cues to ensure continuity of care for enrolled patients.

Detailed documentation. Supporting documentation necessary to qualify for patient assistance programs sometimes includes pay stubs, tax returns, or a letter from the Medicaid office verifying that the patient was denied enrollment in that program.

Conclusion

Though the process of acquiring free medications from pharmaceutical providers is tedious and time consuming, the cost savings to safety net providers is worth the effort. One of the most important roles we play as advocates and human service providers is educating and helping our neighbors in need to access the services that are available to them. The safety net providers in our state are aptly described as being part of a patchwork system of responders who attempt to meet the needs of individuals and families who lack financial resources and are part of the growing number of uninsured. I recently was invited to meet with the presidents of two local hospitals. One of them had never even heard of patient assistance programs offered by pharmaceutical manufacturers. I was not so surprised. I am the first to say that the patchwork of services such as those provided at free clinics and free pharmacies across the state are not the long-term solution for the uninsured population. In the meantime, until the political process allows for affordable health insurance for all of our residents, we safety net providers become experts at pooling our resources and at figuring out ways to serve the economically poor families whose healthcare needs would otherwise be unmet. **NCMJ**

Integrating Multiple Service Providers in Service to the Poor and Uninsured:

The Critical Conditions for Effective Collaboration

Thomas G. Irons, MD

Roberta Burgess, a HealthAssist Nurse Case Manager, was made aware through community contacts that Mary M. was in trouble. An employed but uninsured 49-year old woman who lived alone in a mobile home, she had become morbidly obese and was about to lose her job. She was woefully under-medicated and rapidly progressing toward disability and irreversible cardiovascular disease. Roberta made a home visit, finding Mary barely able to rise from of her chair or walk without assistance. With the help of Lynn Howard, a project social worker, she found Mary a walker and, with her, embarked on a journey of recovery. First it was necessary to control her diabetes, hypertension, and hyperlipidemia. Regina Coyle, a nurse practitioner, saw her in a series of clinic visits, prescribed appropriate medications, and placed Mary on a carefully limited exercise and weight-loss program. Meanwhile, HealthAssist team members were making contacts with several community and state agencies. The progress toward recovery was slow but continuous, and in 2004 Mary had successful gastric bypass surgery, funded by the North Carolina Division of Vocational Rehabilitation Services. As of this writing, she is employed full-time and soon will require no HealthAssist services. Roberta said recently, "She came by to see me and I hardly recognized her. She looked wonderful!"*

*HealthAssist is the original program component of the Eastern Carolina Community Health Consortium (ECCHC).

> *"In no case has complete integration been approached, but many have achieved broad-based, genuine collaboration among diverse entities."*

For a long time now, I have, on a few moonless nights every year, fished a flounder net in the lower Pamlico River. Because of its large and flexible 5 1/4 inch mesh, it spares most other fish, and the flounder's physiology allows him to rest on the bottom until I remove him. Around mid-July and extending into mid-September, blue crabs become a serious problem. The ones I usually catch are free-swimming as "doublers," meaning they are occupied with the business of reproduction. They get themselves all wrapped up, and I often must break a strand to get them out. One broken monofilament strand doubles the size of the hole formed by the mesh, and pretty soon, as we say Down East, I've got "holes you could walk through." One might say, stretching the metaphor a bit, that the fisherman's success depends on the "connectedness" of his net. Once it gets really "holey," he'll still catch a few flounders, but most will escape. The healthcare safety net is disturbingly similar. At best it is a fragile, "patchwork array," with certain relatively consistent components, the compromise of any one of which can create a major service gap. A brief look at those components might be helpful.

The Components of the Healthcare Safety Net

Most communities of medium-to-large size have at least one free clinic and even some small rural areas have found ways to provide limited, part-time free health services. In addition to primary care services, these entities often provide medication support, ranging from sample distribution to helping clients access drug company programs and/or purchasing and distributing limited

medications. In some cases, pharmaceutical assistance is provided, but there is no direct healthcare. Public health departments, in addition to their traditional prevention-focused programs, provide a range of primary care services ranging from minimal to comprehensive, the outstanding example of the latter being in Buncombe County. These exceptional programs notwithstanding, few public health departments can provide medication support outside that required for management of sexually transmitted diseases, pregnancy prevention, and tuberculosis. The community health centers often referred to in this report as federally qualified health centers (FQHCs) are the most economically viable model for comprehensive indigent health services, and some across the state have done so with remarkable effectiveness. Greene County Health Care, headquartered in the tiny rural community of Snow Hill, recorded encounters with over 18,000 people last year. They offer comprehensive primary care including prenatal services, dental care, and an award-winning Latino outreach program. Still, despite the so-called "President's Initiative," new center applications are highly competitive, and regulations prohibit establishing centers in many areas. Private physicians carry a share of this burden as well, depending upon variables such as workload of insured patients, the availability of volunteer "off time," and the availability of Project Access-like programs that allow them to provide donated services within an organized structure. Public hospitals, of course, bear a huge "charity care" burden. There are many other community organizations and agencies, both public and volunteer, providing human services that are essential to improving the health of low-income people.

> *"Early on, we agreed on a simple sentence that captures the essence of this element: 'We will do what is right, we will do it well, and we will do it together.'"*

How Likely Is Collaboration or Integration to Occur?

Across the board, these services are rarely integrated, though notable exceptions exist. Among them, Community Care of North Carolina (CCNC) has had the greatest impact. Thanks in large part to the visionary leadership of Allen Dobson, MD, President of Community Care of Cabarrus County, and James D. Bernstein, founding Director of the state's rural health program, CCNC has managed to contain Medicaid cost increases, while significantly improving health outcomes and provider and patient satisfaction. Using a nurse case management strategy and depending upon volunteer physician leadership, it has helped communities across the state coordinate services to Medicaid recipients. There are a number of local examples, often operating in coordination with CCNC. Many have been temporarily funded under the United States Health Resources and Services Administration Healthy Communities Access Program (HCAP). These include, but certainly are not limited to, the Eastern Carolina Community Health Consortium (ECCHC), headquartered in Greenville, the above-mentioned Buncombe County coalition, and a similar one operating in Cabarrus County. In no case has complete integration been approached, but many have achieved broad-based, genuine collaboration among diverse entities.

The Essential Elements of Community-Level Collaboration

As I have traveled around the state to advise others engaged in this work, I have spent many hours reflecting on the elements of successful programs. The following five components are, I believe, the essential ones:

- *The Right Kind of Leadership.* Organizational self-interest ("turf") and mutual mistrust are the absolute enemies of collaboration. Public service and charitable entities are far from immune to these and cannot easily set them aside. One who leads these coalitions must be generally well-known, absolutely trustworthy, and have the maturity to put aside personal biases and respond in a non-reactionary way to negative or confrontational situations. Often these are physician leaders, like Allen Dobson in Cabarrus, Lindsey De Guehery in Wilson, and many others.

- *A Clear, Simple, and Continually Reinforced Value.* Collaborators must agree upon a common value that can be easily articulated. In the eastern North Carolina group, we agreed that all are committed to improving the health status of poor and low-income people, *period*. When conflict has arisen or our spirits have lagged, we have stopped and asked, "What are we here for?" reinforcing this core value. Early on, we agreed on a simple sentence that captures the essence of this element: "We will do what is right, we will do it well, and we will do it together."

- *A Source of Funding.* Many would list this component first. I do not for two reasons. First, acquiring funding before genuine collaboration has been achieved is a sure prescription for failure. All of us who are engaged in this work can cite numerous examples. Secondly, it is not only possible to build a coalition of committed partners with little or no outside funding, it is essential. If the entities involved are not committed to each other and the coalition's core value, the program will fail whatever its financial condition. On the other hand, programs that can demonstrate in a grant application or site visit that genuine collaboration is present are far more likely to be funded.

- *Inclusiveness.* No community is likely to be successful in bringing all stakeholders to the collaborative table. Still, coalitions should make it their goal to do so. In building the ECCHC, we faced numerous threats. Perhaps the most serious one was the historically strained relationship between the components of the University Medical Center and Greene County Health Care (GCHC). Program leaders recognized early on that GCHC could bring extraordinary strength to the coalition, and GCHC leaders, likewise, saw the need for healthy partnership. Solving this problem required clear communication about issues of disagreement and demonstrated commitment from both parties to rebuilding trust. This was slow and difficult work, but its success was assured from the beginning by the mutual commitment of leaders from both entities to effective collaboration. Much of this work was done in a highly productive series of private meetings between the GCHC Executive Director, Doug Smith, MBA, and this author. In another example, these same entities are cooperating in the construction of a 15,000 square foot community health center in northern Pitt County, with GCHC agreeing to operate the center as an expansion site. This expansion could compromise an important program operated by the Pitt County Health Department, its prenatal care clinic. Because the Pitt County Health Director, Dr. John Morrow, is an active coalition leader, discussions among the appropriate parties were held early on and the potential conflict averted.

- *Flexibility.* Finally, successful coalitions, like my flounder net, must have sufficient flexibility to stretch as much as possible without tearing. Sudden changes in political priorities, funding streams, population need, etc., are inevitable. Such flexibility requires a constant reinforcement of the mission and an underlying spirit of optimism, a belief that doing what is right will ultimately be both successful and rewarding.

My own observation, as one coalition leader, is that I am responsible for upholding this spirit among our partners, and to work continually to praise and thank those who do the day-to-day work. When I find myself discouraged, I remember our vision, and say to myself, often aloud, "We will do what is right, we will do it well, and we will do it together." **NCMJ**

COMMENTARY

Rising Student Health Needs Require a School Safety Net

Leah M. Devlin, DDS, MPH, and Marilyn K. Asay, RN, MS

The fourth grader was lethargic and gray. Thin to begin with, he had lost six pounds in the past four to six weeks. After two days of very reduced alertness in class, the school guidance counselor and the boy's teacher contacted the school nurse. The nurse, newly hired by the school district as its first-ever nurse, reviewed the boy's symptoms and called his mother for permission to check his blood sugar. The nurse then contacted a local pharmacist who donated blood sugar testing supplies that same day. With a blood sugar of 578 mg/dl, the nurse urged the mother to seek immediate medical attention for her son. The boy was hospitalized and diagnosed with Type I Diabetes. In collaboration with the boy's physician, mother, and teacher, the nurse subsequently began preparing for the boy's return to school by developing a care plan and training the teacher, principal, and counselor in monitoring the student's self-care. The teacher reports that thanks to the school nurse, who identified this child's diabetes and managed his successful reentry into school, this student is "back to his normal self, has more energy, and is learning better."

> "...each of North Carolina's school nurses [are] responsible on average for approximately 1,900 students, ...rather than the nationally recommended 1:750..."

A freshman came into his high school's health center for a sick visit. While there, the staff asked him to complete a health risk questionnaire in order to get more information about his risk-taking behaviors and conditions. The multi-disciplinary team at the center (which includes a nurse practitioner, nurse, mental health professional, nutritionist, and health educator) treated the young man for high blood pressure, rosacea, and acne and provided mental health and weight management counseling. He was enrolled in the North Carolina Health Choice Program (North Carolina's State Children's Health Insurance Program) and received glasses from the Lens Crafters Gift of Sight Program. By integrating and delivering his medical and mental health services at the school-based health center, this student was able to miss very little school while receiving multiple services, and his mother missed very little work. He is now a senior with a brighter future ahead of him.

At a metropolitan high school, the school nurse splits her attention between two boys. A 16-year-old football player has fallen and may have re-injured a broken ankle. A 15-year-old freshman, taking medication for both bipolar disorder and attention deficit hyperactivity disorder, is feeling light-headed. The nurse examines the students, calls the parents, and assists in coordinating primary care and specialty providers. Across town in another school, with no school-based nurse, the health needs of students are addressed as best as possible by teachers, secretaries, and administrators.

These true stories are but three examples of the variety of health concerns that students bring with them to school each day. These health problems impact their ability to be successful in school and require that the school healthcare safety net be strengthened. The needs of students have also changed dramatically in the past ten years, creating increased demands for appropriate care while at school. For example, the North Carolina Annual School Health Services Report for Public Schools for 2003-2004 reported that:

Leah M. Devlin, DDS, MPH, is the State Health Director, Division of Public Health, North Carolina Department of Health and Human Services. She can be reached at leah.devlin@ncmail.net or 1915 Mail Service Center, Raleigh, NC 27699-1915. Telephone: 919-715-7081.

Marilyn K. Asay, RN, MS, is the State School Nurse Consultant, Division of Public Health, North Carolina Department of Health and Human Services. She can be reached at marilyn.asay@ncmail.net or 1928 Mail Service Center, Raleigh, NC 27699-1915. Telephone: 919-715-3298.

- Over 161,000 (12%) students suffer from chronic illnesses or special healthcare needs (diabetes, asthma, seizure disorders, etc.).
- More than 14,000 students needed one or more invasive procedures performed during the school day (nebulizer treatments, tube feedings, urinary catheterizations, tracheostomy care, blood glucose monitoring, and the management of insulin pumps, etc.).
- At least 7% of students received medications at school, including controlled substances.

In addition to the growing numbers of children with complex health problems that often require intensive management at school, the prevalence of risk-taking behaviors continues to be elevated. These include substance abuse, homicide, suicide, child abuse and neglect, and developmental problems such as Attention Deficit Hyperactivity Disorder (ADHD). Mental health issues such as anxiety, depression, school refusal, anger, and eating disorders are increasing and are affecting attendance, school performance, and student well being. Prevention programs have become a greater focus in schools, as the obesity epidemic is affecting children and adolescents at earlier ages. One in four North Carolina teens and one in five children ages five to 11 years of age are now overweight. The ability to learn at school is directly related to the status of a student's health. "Students who are hungry, sick, troubled, or depressed cannot function in the classroom, no matter how good the school,"[1] according to the Carnegie Council on Adolescent Development. Students who drop out of school experience more health problems, delayed employment, and poverty. Data from the United States Bureau of the Census underscore that high school dropouts have the lowest expected lifetime earnings compared with workers at all other levels of educational attainment. It is well documented that people in poverty are less likely to have access to healthcare and less likely to engage in healthy lifestyles. The Council of Chief State School Officers and the Association of State and Territorial Health Officials have jointly noted this interdependency between health and education by suggesting that "healthy kids make better students and better students make healthy communities."[2]

> *"The absence of a strong safety net of nurses in North Carolina's schools represents one of our most critical missed opportunities to help children be successful."*

The School Nurse as a Safety Net "First Responder"

When nurses are present in the school, parents often rely on them as first responders for early identification, referral, and follow-up for their children's primary care needs. Often the school nurse is the first person a parent seeks out in order to make a decision about the need for health services. "Go see the school nurse, and if she thinks you are sick enough to go to the doctor, tell her to call me." With each of North Carolina's school nurses responsible on average for approximately 1,900 students (often scattered over a minimum of three to four schools), rather than the nationally recommended 1:750, it is very difficult to provide the level of safe care needed and to assist families in locating and using local healthcare resources. Teachers and other school staff are asked to assume more and more health related responsibilities, and school nurses are expected to provide training and on-going supervision for these individuals.

The North Carolina General Assembly, understanding the school nurse's role in the development of healthy students who are more likely to achieve academic success, appropriated money for the School Nurse Funding Initiative (SNFI) to the Division of Public Health in 2004. The Initiative included an annual state appropriation of $4 million to fund 80 permanent positions and approval of Maternal and Child Health Bureau funds of $3,250,000 annually for 65 time-limited (two-year) positions. Governor Easley has called for 165 additional nurses in the budget over the next two years. Many of these nurses will work in Child and Family Support Teams to further link children at-risk to community services

School Health Centers: A Second Safety Net for Some Schools

With regard to comprehensive services for adolescents, the safety net in most communities is thin. While access to comprehensive services has improved for some adolescents in the state, most service delivery remains fragmented and categorical, with treatment for illness, sports physicals, mental health services, or counseling for nutrition concerns all being provided at different locations. School-based and school-linked health centers located on or easily accessible to school campuses have brought comprehensive, "one-stop-shopping" opportunities to adolescents and a focus on emerging health problems. The obesity epidemic, for example, is receiving increased attention in these centers as evidenced by the requirement for state-funded health centers to include a body mass index (BMI) performance measure.

With parental permission, students can receive help in these health centers for a variety of medical and psychosocial needs. Currently, there are 27 comprehensive centers operating in middle and high schools in the state and another 12 centers that provide primary care services delivered by nurse practitioners or physician assistants.

Health Is Academic

With high school graduation rates falling in North Carolina from 64% in 1990 to 60% today, it is essential that every student has access to healthcare and the opportunity to develop healthy behaviors so they can learn and graduate. The absence of a strong safety net of nurses in North Carolina's schools represents one of our most critical missed opportunities to help children be successful. Closing the health disparity for children is a critical strategy to close the achievement gap. We must ask ourselves, "Have we done all that we can to make certain that children and teens are ready and able to learn supported by healthy families?" North Carolina is now answering this question under the leadership of the Governor, the General Assembly, the State Board of Education, local schools, and health departments with their respective boards. The State Board of Education is also requiring all districts to create School Health Advisory Councils bringing parents, healthcare providers, and community organizations to the school health table as well. This momentum is critical, for it will take all of us working together to strengthen the school health safety net and thereby our children's chances for success in school. **NCMJ**

AHEC Teaching Clinics in Service to the Uninsured

Thomas J. Bacon, DrPH

One of the primary reasons for establishing the North Carolina Area Health Education Centers (AHEC) Program in the early 1970s was to create a statewide infrastructure to expand the training of primary care physicians in the state. With support from the North Carolina General Assembly, AHEC today supports eight residency programs in family medicine, four in internal medicine, four in obstetrics and gynecology, three in pediatrics, and three in surgery. These programs employ 260 full-time faculty and 285 residents, which is nearly 15% of the total number of residents in training in the state.

These AHEC residency programs, in close partnership with their community teaching hospitals, provide a significant amount of safety net care throughout North Carolina. As with teaching programs across the country, the clinics operated by these residencies and teaching hospitals take all patients, regardless of ability to pay. In addition, the teaching services serve as the means to admit patients to hospitals that come through the emergency room and have no regular physician. Frequently, these patients do not have insurance coverage.

> *"...AHEC residencies work closely with other safety net providers to create better systems of care."*

During 2003-2004, AHEC teaching services provided more than 450,000 outpatient visits and more than 184,000 inpatient visits of care. Nearly 100,000 of these outpatient visits were for uninsured patients, and more than 36,000 of the inpatient visits were for uninsured patients. AHEC clinics also have high numbers of Medicaid and Medicare patients, and the reimbursement rates of both public programs have not kept up with the rising costs of care.

Beyond their own clinics, AHEC residencies work closely with other safety net providers to create better systems of care. Most work closely with health departments to improve the safety net, including rotating residents to health department clinics, coordinating and in some cases integrating health department and AHEC clinic services, and seeking grants to establish new models of care. In some AHECs, such as Wilmington, faculty lead outreach clinics in surrounding rural counties to expand access for the uninsured. In Fayetteville, the AHEC hosts the regional child abuse clinic, and supports HIV/AIDs and other outreach clinics in nearby rural counties. AHEC faculty have taken the lead in developing new community-wide safety net programs, such as the role Mountain AHEC faculty played in establishing Project Access in Asheville.

The workforce development role of AHEC residencies is also critical to maintaining and strengthening the safety net services in the state. AHEC residencies were initially established to expand statewide capacity to train physicians to meet the physician workforce needs of underserved communities. Data from the past 25 years indicate that the AHEC residencies are effectively fulfilling that mission. Over 1,500 residents have graduated from AHEC primary care residencies, and two-thirds of them have remained in North Carolina to practice. In addition, graduates of AHEC residencies are more likely to settle in rural and other underserved communities than graduates of residencies at a university medical center.

As with other safety net providers, AHEC and hospital-based clinics face a number of financial challenges. The number of uninsured patients seeking care continues to grow as employer-based health insurance becomes more expensive and less available. State appropriations for AHEC and other related programs have declined over the last four years, and federal grant support via the Bureau of Health Professions has also declined. At the same time, costs for malpractice premiums, new technology, and recruiting and retaining faculty have all increased.

In spite of the challenges, the AHEC Program remains committed to maintaining and strengthening its statewide network of primary care residencies. As the population of North Carolina continues to grow at a rate faster than the national average, it may be necessary to further expand the number of residency positions to assure that the physician supply for the state remains adequate to meet the growing needs of our population. **NCMJ**

COMMENTARY

Who is at Risk of Losing Safety Net Healthcare?

Adam G. Searing, JD, MPH

Ms. McDaugherty, a 30-year-old widow with two children, works as a waitress. Her job pays enough to put her income slightly above eligibility for the North Carolina Medicaid program ($11,425 annually), but offers no health insurance coverage. Her earnings of roughly $1,000 a month are quickly used to pay for rent and utilities for an efficiency apartment ($700), food ($150), and public transportation ($100).

Just as she was starting to get on her feet economically, less than a year after she lost her husband, Ms. McDaugherty found a lump in her breast. Tests performed at a community clinic found that she had a malignant tumor that had already spread to her lymph nodes.

Since her income is slightly above the federal poverty level, she can only qualify for Medicaid as an "optional benefitiary" because she has been diagnosed with breast cancer. Because of Medicaid, Ms. McDaugherty was able to see a specialist who advised her that she needed a lumpectomy, followed by chemotherapy and radiation treatment. The Medicaid program currently covers all of Ms. McDaugherty's cancer treatments, including medications for the side effects of chemotherapy, which help her continue working part-time.

As an "optional beneficiary," she would be one of the first to completely lose health coverage as a result of federal or state budget cuts to Medicaid, since her income is slightly above poverty level. Even if coverage is continued, North Carolina could select a narrow list of services that would be covered for people like her. For example, the state might limit the drugs that help control the side effects of her cancer drugs and allow her to work.[i]

Strengthening the Safety Net, Covering the Uninsured, Controlling Health Costs

Three years ago I wrote an article for the *North Carolina Medical Journal* entitled "The Uninsured and Medicaid."[1] I surveyed the Medicaid program and the situation of the uninsured, noted the drivers of rising costs, the necessity of denying healthcare to people currently covered by Medicaid to achieve truly substantial cost savings called for by proposed state budget cuts, and the need for new revenue to sustain the program in a time of economic downturn so that even more people would not join the ranks of the uninsured.

To borrow an apt example from a noted health policy researcher,[2] Bill Murray in the movie "Groundhog Day" and I have much in common as I address this issue again for the Journal. Medicaid costs continue to increase along with general healthcare costs and as we ask the program to absorb more people who have lost insurance. Substantial budget cuts are proposed by the federal government that could only be covered by denying Medicaid coverage to tens of thousands of North Carolinians.[3] Once again, we need to find new revenue in order to address growing health costs and the growing numbers of the uninsured. Finally, there are no detailed plans for reform under consideration by political leaders in North Carolina.

Although the problems are the same today as they were in 2002, they could be much worse. Unlike many states, North Carolina chose to enact incremental tax increases over the last three years so we could maintain state health, education, and other vital services for our residents. While there have been some cuts, we have avoided the examples of states as diverse as Oregon, Texas, and Mississippi, where hundreds of thousands of vulnerable seniors and children have joined the ranks of the uninsured after being cut from Medicaid coverage.

Still, the picture in North Carolina is grim. New reports show that from 2000 to 2003, over 457,000 North Carolinians

---

[i] This example is based on a real person and was developed by FamiliesUSA and the North Carolina Health Access Coalition. See "The Bush Administration's Proposed Structural Changes to Medicaid: Hurting Real North Carolinians," www.familiesusa.org.

Adam G. Searing, JD, MPH, is Project Director for the North Carolina Justice Center's Health Access Coalition and Health Co-Chair for the Covenant with North Carolina's Children. He can be reached at adam@ncjustic.org or PO Box 27167, Raleigh, North Carolina 27611-7167. Telephone: 919-856-2568.

have lost health insurance due to rising health costs and the economic downturn—one of the highest rates in the country.[4,5] Over 300,000 people have joined the ranks of the uninsured since 2000, and we have added over 230,000 people to Medicaid. Premiums for employer-based plans in North Carolina have risen by 43.4% between 2000 and 2003.[4] A family health insurance plan in North Carolina now costs about $9,000 per year.[5] There are now 1.5 million people on Medicaid in North Carolina and 1.4 million people without health insurance.

When people talk about health reform, they often imagine a magic bullet that will decrease health costs, extend coverage, and not cost any more than we spend right now. Over the last 70 years, no magic bullet has appeared, although many have been proposed. The current crop includes medical malpractice changes, health savings accounts, a single payer health system, and electronic medical records. While each of these ideas probably has some positive aspects, none of them is either politically feasible or will really have any appreciable effect on the underlying problems our health system faces.[7,8,9,10] To really address the growing numbers of the uninsured, our overstrained safety net, and rising health costs, reform in North Carolina must take a different path.

Successfully strengthening the safety net in North Carolina means three mountains must be climbed. First, our tax system must be reformed so it collects (consistently from year-to-year) the revenue necessary to fund the public health safety net services we already have. Second, we must collect more revenue through the tax system to cover people now currently uninsured and make health insurance more affordable for those who are already insured—both reforms the public says it wants. Third, we need to develop a plan for reform that businesses, advocates for the uninsured, policymakers, and other stakeholders can support.

Reforming the Tax System to Fairly Meet the Health Needs of North Carolinians

Health and related human service programs account for approximately 25% of North Carolina's state budget spending. The majority of this spending is on safety net programs like Medicaid, Health Choice, and other health and child development programs.[11] All but about 5% of other state government spending goes for education, justice, and public safety programs. That nearly 95% of state spending is for these public services should not be surprising. Education, healthcare, and justice services all enjoy broad popular support among North Carolinians. For example, a recent survey of North Carolina voters shows that 87% support Medicaid to fund healthcare for low-income people in the state.[12]

North Carolina's tax system has not kept pace with the public's interest in funding these key state services. This is not an argument that more revenue needs to be generated from taxes, just that the current laws on the books mean that the tax burden is distributed unfairly and cannot respond to our growing state population. Our tax system is antiquated and so full of loopholes that it does not fund state needs over time and is easily affected by economic downturns. An example of this is the sales tax that extends to most products while not covering services people increasingly buy instead of products. The person who used to pay sales tax on the purchase of a lawn mower now pays no sales tax on the purchase of a lawn mowing service. Because of problems like this, “families earning less than $15,000 in North Carolina pay the greatest share of their income [10.9%] in state and local taxes while the top 1% of income-earners pay the lowest share of their income [6.3%] in taxes.”[13]

> *“...our tax system must be reformed so it collects (consistently from year-to-year) the revenue necessary to fund the public health safety net services we already have.”*

Another example of why we need tax reform is the shift of the tax burden away from corporations to individuals.[14] As revenues from corporate taxes decline, the state must look to individuals to make up the difference, often with inequitable results. A major Fortune 500 company in North Carolina, BB&T, had basically no state income tax liability (0.1%) from 2001-2003 despite making $4.6 billion in profits.[15] Without reform of our tax system, we will not have the money to fund current state safety net programs that have broad public support, like Medicaid and Health Choice, much less enough money to make improvements in the future.

Generating Revenue to Strengthen and Expand the Safety Net

A reformed tax system would better keep up with the growth of state safety net programs and services now available. However, any expansion to address the problems facing the safety net or to extend coverage to the growing uninsured population will need new revenue.

Recently a group of farmers came to demonstrate at the General Assembly in Raleigh with two demands: (1) keep and increase tax breaks for farmers, and (2) make health insurance more affordable.[16] This call highlighted one of the main obstacles to strengthening the safety net and addressing the problem of the uninsured—people want the government to do something to make healthcare more affordable and accessible, but they believe they pay too much for government services already and want lower taxes. These two goals are simply not compatible.

Strengthening North Carolina's Medicaid and other safety net programs to insure parents of already covered children would begin to reduce North Carolina's uninsured rate. This costs money. Ideas like establishing a statewide reinsurance pool for employees in small businesses with extremely high health bills could reduce small business health premiums significantly. This costs money. Allowing medically uninsurable North Carolinians to buy into state health plans would reduce the numbers of uninsured. This costs money.

Any one of these reforms is achievable within the context of North Carolina's $15 billion budget, but at least some new revenue will have to be generated to meet these needs and the public's other priorities in education and public safety. The bottom line is that for significant health reforms to have a chance, people who want health reforms must also advocate for a tax system that will generate enough revenue to fund reforms.

Steps to Strengthen the Safety Net and Expand Health Insurance Coverage

Developing a plan to strengthen the safety net and extend affordable health coverage is the easy part, once enough revenue has been raised to achieve real reforms. Proposals abound, but funding them is always the critical component. The following proposals would each individually slash the number of people without health insurance. Enacting all of them would elevate North Carolina to the status of a national leader in reducing the costs of health insurance for business and individuals, while extending coverage to the uninsured.

- Expand Medicaid and North Carolina Health Choice (children's health insurance) to offer affordable coverage to low-income parents of children currently covered if a family's income is under 200% of federal poverty guidelines ($31,340 annual income for a family of three).
- Direct more funding to safety net health centers like community health centers, rural health centers, and public health clinics to enable them to expand and provide services to the growing number of people either uninsured or covered by Medicaid.
- Allow childless adults, children, and parents to buy into the state employees' health insurance plan if their income is below 300% of federal poverty guidelines ($47,010 annual income for a family of three). Charge premiums on a sliding-fee scale with families and individuals who have higher incomes paying the full cost of coverage.
- Establish a state high-risk insurance pool that would subsidize coverage for people who, because of a health condition, cannot find affordable coverage anywhere else.
- Start a state reinsurance pool for small and mid-size businesses that would take over paying for the health costs of any employee whose medical bills exceeded $50,000. By removing the risk of paying for catastrophic care, employer health premiums would drop, and coverage would become more affordable.

Treading water is simply not acceptable. As costs mount in tandem with calls to cut Medicaid, North Carolina's major health safety net program; as employers find they can no longer afford coverage for employees; and as the numbers of uninsured grow, we cannot simply stand by. Federal action is unlikely, and North Carolina must begin to address the problem of affordable health coverage and the uninsured on its own. Without action by the federal government, it is unlikely that North Carolina will be able to completely strengthen the healthcare safety net and extend health coverage to 100% of people without health insurance. However, indifference in Washington is no excuse for North Carolina not beginning to address these serious problems with its own innovative solutions. **NCMJ**

Take Note

Book Review:

Scientific Publications by Walter Kempner, MD: Volume II. Radical Dietary Treatment of Vascular and Metabolic Disorders. Edited by Barbara Newborg, MD. Gravity Press, Durham, NC, 2004. 557 pages.

For this reviewer, this volume is a trip back to 50 years ago, when Dr. Kempner was the most renowned clinician at Duke University Medical Center. He is best known as the originator of the rice diet, and the first to demonstrate that severe hypertension and glomerulonephritis could be successfully treated by its application and that malignant hypertension, a common, largely fatal diagnosis of that time, could be treated and reversed.

The book is not a biography, nor is it a discussion of his radical dietary therapy. It is a collection of his scientific papers, plus those of other closely associated team members at Duke. It is of special interest to readers of this Journal and North Carolina physicians, because most of the earlier Kempner papers were published in the *North Carolina Medical Journal* in the early 1940's. The volume also includes papers about Kempner by physicians who knew and worked alongside him, such as Morton Bogdonoff, Jay Skyler, and Eugene Stead, all of whom contributed to a symposium in Kempner's honor in the *Archives of Internal Medicine* in 1974 on the occasion of his retirement from the Duke faculty.

These papers are remarkable in many ways and worth reading. They reflect the limited knowledge base of that time relating to hypertension and kidney disease, and they also reflect the meticulous and detailed data collection and recording that are a part of Kempner's legacy. There are extraordinary before and after pictures of ocular fundi showing the resolution of papilledema and chest films showing reversal of cardiomegaly. These are so dramatic that they caused some well-known physicians of the time to doubt their validity. They also demonstrate the effective use of flow sheets in patient care, long before these became popularized as part of the problem-oriented record.

It is regrettable that these papers cannot portray the personality and power of this remarkable man. He began his career as a bench scientist, working in the laboratory of the famous Otto Warburg in Germany, and continued his studies of cellular physiology in his early years at Duke. He became a clinician again during World War II, when many of the Duke faculty departed to join the Duke hospital unit in England. His early successes with the rice diet were published and noted, but his earliest presentations were not well received. Such success in the treatment of diseases previously considered incurable was too good to be believed! His patients—most of whom came to him after receiving a death sentence from their physicians at home, and most of whom returned home much improved, and even "cured"—were his staunch supporters and returned to his care over and over again, bringing their friends and making him a wealthy man. Many at Duke were jealous of his success, and it is said that the recruitment of Eugene A. Stead, Jr., MD, to Duke in 1946 was favored by those who thought that Stead would force him out. Instead, Stead recognized the importance of his work and adopted his techniques for his own patients, which is documented in Stead's comments in this volume. Stead defended and supported Kempner, and he, in turn, provided Stead, in his earliest years at Duke, with the financial means to develop his department into a world leader.

Kempner's diet was a combination of severe sodium, fat, and protein restriction, which was found to benefit a number of significant morbid conditions: hypertension, kidney disease, vascular disease, diabetes, obesity, etc. The development of diuretics, potent antihypertensive drugs, and cholesterol reducing agents, plus the difficulty of remaining on this difficult and different diet, made the rice diet less important and even outmoded in the opinion of some, but he was never convinced that any of these "advances" were more beneficial to the patient than his diet. Clearly, much of his success reflects the strength of conviction and a personality that helped motivate his patients to remain on the diet. This complex and remarkable man deserves full credit as the first physician to offer a ray of hope to those with several previously irreversible illnesses, to which the papers in this compilation give convincing documentary evidence.

North Carolina Voluntary State Registry of Advance Healthcare Directives

In 2001, the North Carolina General Assembly passed legislation authorizing the NC Secretary of State to create a voluntary on-line registry of advance healthcare directives for the benefit of the citizens of the state and their healthcare providers under circumstances where immediate access to such directives would be needed. Citizens wishing to register their notarized directives may place three types of healthcare directives and an organ donor card on the Internet web site maintained by the Office of the Secretary of State at the following Internet location:

http://www.secretary.state.nc.us/ahcdr/

Those wishing to take advantage of this service by filing their information by mail may get information to facilitate their registration by calling 1-919-807-2000. Forms are provided for:

- Health Care Power of Attorney
- Declaration of Desire for Natural Death (Living Will)
- Advance Instruction for Mental Health Treatment
- Organ Donor Card

"Sallie" and others just like her provide 80% of all long-term care

One of every 5 adults in NC is caring for someone age 60 or older.

How can healthcare providers help?

- ▲ Ask your patients and those accompanying them if they have responsibilities providing care for someone
- ▲ Use the Caregiver Self-Assessment developed by the AMA at http://www.ama-assn.org/ama/pub/category/5037.html

Refer patients and caregivers to local resources

- ▲ North Carolina's Family Caregiver Support Program can provide help for caregivers of persons 60 or older.
- ▲ To locate local resources through your Area Agency of Aging visit http://www.dhhs.state.nc.us/aging/fcaregr/fcjobs.htm http://www.fullcirclecare.org and http://www.eldercare.gov/

Uninsured and Underinsured Adults in North Carolina

The United States spends more per capita on healthcare than any other industrialized nation. It is also the only industrialized nation that provides no universal healthcare for its citizens. Therefore, there must be a "safety net" of healthcare providers who cover the uninsured and underinsured. The United States spends billions of dollars treating the uninsured once their health problems become too severe to be ignored. The uninsured receive less preventive care, are diagnosed with more advanced disease, and receive less therapeutic care once diagnosed than the insured. In North Carolina, preventive services for the uninsured are most often provided by local public health departments and community and migrant health centers.

The North Carolina Behavioral Risk Factor Surveillance System (BRFSS) is a random telephone survey of persons ages 18 and older. Each year, a question is asked about whether the respondent has health insurance. In 2004, several questions were included to address the issue of underinsurance. Following are selected BRFSS data on the uninsured and underinsured, weighted to reflect the entire adult population of the state.

- 17% of North Carolina adults had no health insurance.
- Among persons ages 18-24, those with less than a high school education, and those with household income less than $25,000, approximately 30% had no health insurance.
- 65% of Hispanic adults had no health insurance—35% of English-speaking Hispanics and 75% of Spanish-speaking Hispanics.
- 41% of uninsured adults reported that there was a time in the last 12 months when they needed to see a doctor, but could not due to the cost, compared to 10% of adults with health insurance.
- 35% of uninsured diabetics reported that there were times in the past 12 months when they were unable to obtain testing supplies and diabetes medicines due to the cost, compared to 9% of diabetics with health insurance.
- 51% of uninsured adults reported that they have no personal doctor or healthcare provider, compared to 12% of adults with health insurance.
- Among the BRFSS respondents who did have health insurance, 17% reported that they had to give up some living expenses in the last year to pay healthcare costs.
- Among those with health insurance, 18% reported that they took a tax deduction for healthcare expenses on their federal tax return, 16% said that someone in their household had problems paying medical bills, and 13% said that their household had been contacted by a collection agency about owing money for medical bills.
- Among those with health insurance, 20% said that their total out-of-pocket healthcare expenses (including health insurance premiums) were more than $5,000 during the past year, including 5% who said they spent more than $10,000.

New Directions in End-of-Life and Palliative Care

The following was previously published in the Raleigh News & Observer, March 27, 2005 and is reprinted here with permission.

Reaching for reassurance at the end of life

CHAPEL HILL—"What would you do?" I've been asked this question hundreds of times since I started medical school in 1983. I was asked it as a medical student, as a surgical resident, as a trauma surgeon, a critical care specialist, and as the director of an ICU in a rural North Carolina hospital. I've been asked it about a variety of issues, but most commonly I've been asked it by families who were making end-of-life decisions about their loved ones.

Should they put a feeding tube in their grandmother, now too demented to eat? Should they donate the organs of their brain-dead son? And what about their father and his massive stroke—should they disconnect him from the ventilator?

"What would you do?"

For years, this question made me nervous. It was a relic of the old days, before I came along, when doctors had all the answers, when we simply went ahead and did what we thought was right without much input from patients and their families. I didn't train in the era of paternalism. I trained in the era of patient autonomy, so when families asked, "What would you do," I thought that they were asking me what they should do, as if there were some kind of objectively right answer, separate from the wishes of the people for whom they were speaking.

For years, I sidestepped this question. I told families that I didn't know what I would do in their situation. I said you never knew what you would do until you were the one that was having to do it. In fact, however, this was often a lie. Generally, I knew what I would have done: I wouldn't have put in the feeding tube, I would have donated the organs, I would have turned off the ventilator.

But for years I didn't tell people that. I didn't want them to do what I wanted them to do. I wanted them to do what the patient would have wanted. I thought that injecting my own opinion would make them think more about me and less about the patient, that the possibility of doing something their doctor disagreed with would only make their decision more difficult.

Over time, though, I began to notice something. I wasn't the only person hearing "What would you do?" Families asked nurses too, and they asked the nursing assistants whose job it was to bathe the patients, change their sheets, empty their catheters, turn them side to side to prevent them from developing pressure sores. When I moved to rural North Carolina, the family meetings at which we discussed all this expanded to include "church family" and the patients' ministers. They faced the question too: "What would you do, Reverend?"

After a while, I began to realize that the families weren't actually asking what they should do. In fact, most of them already had an idea about what they should do. Most of them felt they should withdraw life support, because the majority of my families knew that somewhere along the line, the patient had told his brother or his wife or his daughter or his mother something about not wanting to be kept alive by tubes and machines.

And so I came to understand that the families weren't asking what they should do. Instead they were asking us all for permission to actually do it—permission to withdraw life support and allow the patient to die. They weren't asking for legal permission—they knew it was legal. But they were asking for true social sanction. They wanted to know that other families did this, that people from the church wouldn't think of them as murderers, that their neighbors wouldn't fault them when the word got out.

Families were also asking for reassurance that the patient wouldn't suffer. They needed to believe that if they elected to withdraw support, we could continue to comfort patients and alleviate their suffering as they moved toward death.

Families asked nurses and nursing assistants as often as they asked me, because they knew the nursing staff well. They had seen the nurses rub lotion on the patient's dry feet. They had seen the aide comb out the patient's matted hair. They had watched techs readjust tape and bandages and tubes and IV lines so they didn't tug and tear at the patient's fragile skin. Family members, watching this, were touched by the staff who cared the most for their family member. When they asked staff members what they would do, they chose the ones that they trusted most. They chose ones that they knew would never have done anything that would have increased the suffering of the patient.

I am dismayed that the president and Congress, particularly the physician members of Congress, have elected to intervene in the Terri Schiavo case. The physicians above all should understand the delicate, carefully wrought relations of trust that are an essential part of patient care and decision-making, especially at the end of life. The name-calling and grandstanding that have accompanied this case will only make it more difficult for families in the future to make end-of-life decisions.

Just as sadly, I think, they will cause families who have already had to make these painful decisions to question themselves and the decisions for which they so plaintively begged reassurance.

Elizabeth Dreesen, MD, is a fellow of the American College of Surgeons and a specialist in surgical care. Formerly the Medical Director of the Critical Care Unit of the Lincolnton Medical Center and in private practice, she is now on sabbatical in Chapel Hill. She can be reached at 919-967-3529.

Alzheimer's Disease and Family Caregivers

To the Editor

Your January/February 2005 issue (66:1) of the *North Carolina Medical Journal* is truly overwhelming because of: the staggering numbers of us who will have one day, by current projections, Alzheimer's Disease; the depiction of the incredible amount of sad work involved in care giving; the financial burdens families must bear; the description of the pathos/grieving associated with being around these patients; and because of the paucity of policy options available to North Carolina or the United States.

Sixteen million people afflicted with dementia by 2050 will clearly require a carefully planned/well-funded system of organized, standardized care. Such a system can only be achieved by the design/construction of a very large number of Alzheimer domiciliaries patterned after the concept of tuberculosis in sanitaria as built in the late 1800s-early 1900s. Patchwork of respite options, as in the table from Karisa Derence's commentary will not suffice and almost certainly would not prevent bankruptcies within families, churches, or governmental agencies. Of course building a multitude of structures for patient's with TB had the notions of "healthy" food/air contributing positively to the treatment of and the need for isolation to prevent contagion as a powerful force to get the policymakers to act.

For Alzheimer's dementia, the impeti are the logistics of financing such care, defining the care to be provided, and the recruitment of an adequate sized army of caregivers. Remember, some of the requirements of these 16 to 50 million folk will be: housing; feeding; protection from cold/heat; prevention of injury to self/others while permitting maximum freedom to pace, wander, or babble early on in the disease; preserving some activities of daily living for as long as possible; cleanliness; and dignity; however society chooses to define it by then. Such requirements extrapolate into the need for unique interiors/furnishings for this kind of housing. Then, there are the matters of: choking/feeding for many who can't chew or swallow or have lost the ability to use knife/fork/spoon; air handling of odors, washability of repeatedly soiled every day items (beds, bedding, chairs, walls, floors, etc.), and an endless supply of diapers, diaper changers/diaper disposals to mention just a few. Finally, in the last trimester of the illness our hosts and their staff will have to make hard decisions about how/whether to treat malnutrition, dehydration, skin breakdown, urinary tract infections with resistant organisms, pneumonia, sepsis; exacerbations of the other chronic medical conditions that were on the problem list before the onset of dementia or developed during the dementia; and the occasional intercurrent acute surgical event.

No matter how such "hotels" are financed, whether at the state or federal level, there will still be a need for volunteerism beyond any exhibited in this country to-date. As an aside, we must not limit such volunteerism by requiring bureaucratic certification in feeding, bathing, dressing, or walking with these cognitive invalids. Indeed, perhaps we will need a form of universal subscription (say between the junior and senior years of high school) to swell the ranks of caregivers.

There are, of course, many objections to this proposal, such as: how much dare we spend on a structured solution lest we siphon funds away from the promise of a cure by research or from the cost of a truly effective chronic treatment; the unfair requirement in some less populated states that visitors might have to travel for a day to visit a relative or loved one; and the logistical problem of who will and how to decide about eligibility for admission. Perhaps a happy long-term concern will be what to do with all that new construction once the disease joins the list of easily preventable or successfully treatable disorders. If we're optimistic, then we should plan on multipurpose structures and consider geography accordingly.

Be assured that despite the anticipated letters and outcry by social scientists, politicians, clergy, and ethicists to what appears to be a calloused practical solution to a challenge of staggering proportions, there will be millions of relatives clamoring to get a loved one admitted when the institution is as conceptualized in my mind and as it could/should be.

"If we build them, they shall come!"

Harold R. Silberman, MD, FACP
Professor Emeritus
Duke University Medical Center
Durham, NC

The North Carolina Institute of Medicine
Since January 2002,
Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

North Carolina MEDICAL JOURNAL

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

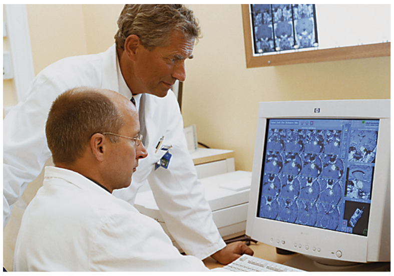
A partnership that's working for eastern North Carolina



Better tools mean better care

Cooperation and vision are bringing leading-edge technology to help patients in eastern North Carolina who are diagnosed with brain lesions. Pitt County Memorial Hospital has received state approval to buy and install a Leksell Gamma Knife, one of medicine's newest and most powerful tools for the treatment of brain tumors and other neurological conditions. The Leksell Gamma Knife is the most recent addition to the hospital's growing armamentarium of leading-edge diagnostic and treatment technology.

The project, which is expected to be operational in the fall of this year, is the result of careful collaboration and planning involving the hospital, the Leo W. Jenkins Cancer Center, the Brody School of Medicine Department of Radiation Oncology and private physician practices including Eastern Neurosurgical and Spine Associates, Eastern Radiologists and Carolina Radiation Medicine.

The Brody School of Medicine, University Health Systems and private physicians are working together to make things happen — in the community, in the region and in the state.

PHYSICIAN
LEADERSHIP
INSTITUTE

*Advancing Excellence
in Healthcare*

THE PHYSICIAN LEADERSHIP INSTITUTE IS NOW ACCEPTING CANDIDATES.

The University of North Carolina at Chapel Hill's Kenan-Flagler Business School and Medical Review of North Carolina, Inc., introduce a new educational program in the Carolinas exclusively for physicians. Designed to empower physicians to meet the challenges of our rapidly evolving healthcare system, the Institute offers eight different modules over four weekend sessions. All classes will be taught by both university faculty and nationally recognized experts. The first session begins the weekend of September 30th, 2005, at the Paul J. Rizzo Center, conveniently located in Chapel Hill.

SESSION DATES

SEP 30 – OCT 2, 2005 | DEC 2 – 4th, 2005 | JAN 13 –15, 2006 | MAR 31 – APR 2, 2006

MODULE 1 -	Welcome, Program Orientation and Understanding the Changing Role of Physician Leadership in the 21st Century
MODULE 2 -	Self-Awareness and Communication Skills
MODULE 3 -	Systems Thinking and Tools for Problem Solving
MODULE 4 -	Leading Change and Influencing People
MODULE 5 -	Negotiations and Consensus Building
MODULE 6 -	Conflict Management
MODULE 7 -	Quality and Financial Management
MODULE 8 -	Strategic Leadership for Creating a Vision Focused Future

To nominate a physician, or to learn more about applying for this program, please contact Jill Blalock, MPH, at jblalock@ncqio.sdps.org or call toll-free (800) 682-2650, ext. 2004.

Enrollment is limited to 50 physicians. Please contact us to reserve your space.

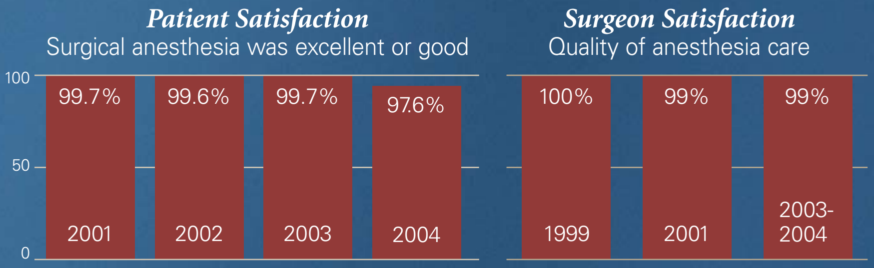
www.physicianleaders.org

We Measure Satisfaction One Patient At A Time

Southeast Anesthesiology Consultants and Southeast Pain Care Are Dedicated To Patient and Surgeon Satisfaction.

One patient at a time. Everyone talks about exceeding expectations, but Southeast Anesthesiology Consultants and Southeast Pain Care do more than talk.

Through ongoing patient surveys, we measure the satisfaction levels of our 70,000 anesthesia and 30,000 chronic pain patients each year. In addition, we survey our surgical colleagues every other year for their assessment of our performance.



Patient Satisfaction

Surgical anesthesia was excellent or good

Surgeon Satisfaction

Quality of anesthesia care

Patient and surgeon satisfaction results are audited by a third party and are statistically significant.

Patient and surgeon satisfaction surveys are crucial elements in our comprehensive Continuous Quality Improvement program, which also includes 50-point quality checklists on every patient we treat. It's all part of our dedication to Assuring Safety and Administering Comfort, one patient at a time.

Managing Chronic Health Conditions Through Member Health Partnerships

Diabetes, asthma, kidney disease, fibromyalgia, migraine or heart disease. When a patient receives the news that they have any one of these chronic conditions, chances are that they will want to learn everything they can about it.

At Blue Cross and Blue Shield of North Carolina, we want our members to learn how to better manage their chronic conditions, as well as get the facts on how they can live a healthier lifestyle. We want to help them sort through the information overload that they will likely encounter, and get them up-to-date information about their specific condition when they need it.

That's why we offer Member Health Partnerships℠. Designed to educate our members about their individual health concerns, these customized programs also help reduce the health risks that may develop with a chronic condition.

With educational resources, self-management tools, condition-specific quarterly newsletters and even financial incentives, members will benefit from the knowledge they can gain from these free, confidential programs. They can also speak with specially trained nurses, who can assist them in understanding their treatment options and help them get the most out of their office visits with you.

In addition to conditions such as asthma, diabetes or heart disease, we also offer a Member Health Partnerships program for expectant mothers with prenatal care issues.

If you have Blue Cross and Blue Shield of North Carolina patients who would benefit from any of our Member Health Partnerships programs, encourage them to call us at **1-800-218-5295** or visit us online at ***bcbsnc.com*** for more information.

For more than 71 years, our members and participating doctors have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's stable, reliable and largest health insurer.

Innovative health care designed around you.℠ | *bcbsnc.com*

ARTICLE

Health-related Quality of Life among North Carolina Adults with Diabetes Mellitus

Deborah Patrick Wubben, MD, MPH, and Deborah Porterfield, MD, MPH

Abstract

Background: *Previous research on health-related quality of life among people with diabetes used subgroups of diabetics who were not representative of a larger population and long questionnaires that are not practical for surveillance.*

Objective: *To identify people with diabetes in North Carolina who are at risk for a poor quality of life based on demographic and medical characteristics using surveillance data.*

Methods: *Analysis of Behavior Risk Factor Surveillance System data from North Carolina, years 1998 through 2001, to examine associations between demographic and medical characteristics among people with diabetes and four different health-related quality-of-life outcome indicators, including general health status, physically unhealthy, mentally unhealthy, and functionally limited days. The demographic and medical characteristics studied were age, sex, ethnicity, marital status, education, income, health insurance, obesity, duration of diabetes, and insulin use. These same characteristics were also tested for independent associations with functionally limited days.*

Results: *Ethnicity and gender were not associated with any of the quality-of-life measures among people with diabetes. Those younger than age 65 were more likely to have mentally unhealthy days, but age was not related to the other outcomes. A household income of less than $20,000 was related to poor general health and greater than one week each of physically unhealthy, mentally unhealthy, and functionally limited days. Subjects with a high school education or less, no health insurance, and those not married or cohabiting had at least one poor health-related quality-of-life outcome. Obesity, duration of diabetes of ten or more years, and insulin use were also associated with at least one poor quality-of-life outcome. The only characteristic that was independently related to the number of functionally limited days was income. People with diabetes of working age and with low incomes were more likely to have greater than one week of functionally limited days (aOR = 10.3; 95% CI = 4.9-21.5).*

Conclusions: *Our results suggest an association between poor quality of life and low-socioeconomic status among people with diabetes in North Carolina.*

Background

This study's objective was to determine if there are demographic and/or medical characteristics that can identify North Carolinians with diabetes who are at risk for a poor health-related quality of life. Using general quality-of-life measures, people with diabetes consistently rate their health status worse than those without diabetes.[1-8] Not only is quality of life an important health outcome as a measure of well-being, but people's subjective perceptions of health are also related to more conventional health outcomes such as mortality and healthcare use.[9-11]

As we consider interventions to improve health-related quality of life among people with diabetes, information about which subgroups have a poor quality of life may help us target our resources and interventions more effectively.

Previous research among people with diabetes has helped identify possible demographic and medical characteristics related to physical and mental quality of life. Other investigators have associated age, sex, marital status, education, income, and insurance status with health-related quality of life among people with diabetes.[8,12-19] Many researchers have failed to observe a relation between ethnicity and quality of life among people

Deborah Porterfield, MD, MPH, is the Program Director for the Preventive Medicine Residency Program in the Department of Social Medicine at the University of North Carolina at Chapel Hill. She is also a medical epidemiologist for the North Carolina Department of Health and Human Services. She can be reached at deborah_porterfield@unc.edu or at CB 7240, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7240. Telephone: 919-966-7499.

with diabetes.[12,14,17,20,21] However, research using *Healthy Days** surveillance data among a general population sample found that Hispanics and blacks were more likely to have a poor health-related quality of life compared to whites.[1] Other researchers have associated a number of comorbid diseases, such as obesity,[2] cardiovascular disease,[2,16,22] arthritis,[21,22] chronic lung disease,[22] and depression,[20,21,23,24] with poor quality of life among people with diabetes. Diabetes complications, duration of diabetes, and use of insulin are also related to quality of life in most studies.[7,12-17,20,21,25-30]

Nevertheless, prior studies yield conflicting results and may not be generalizable since almost all used clinic-based populations. The only population-based research on quality of life among people with diabetes in the United States was a study by Glasgow et al. using a marketing sample population.[12] Other population-based studies of people with diabetes were done in Europe, where healthcare entitlement is universal and population characteristics differ significantly from the United States.[2-4,7,8,13-15,23] In the clinic-based studies, most researchers used a select group of patients seen at diabetes clinics,[16,17,20-22,24,25,31-33] patients with specific diabetes complications,[26-29] or patients who participated in clinical trials.[30,34,35]

In addition, previous research has used quality-of-life measures that are time and labor intensive and, therefore, not suitable for tracking large population groups. Currently, the Medical Outcomes Study Short-Form General Health Survey is the most widely used generic measure of health-related quality of life in clinical research.[10] This survey consists of physical, social, and role functioning scales as well as measures of mental health, perceptions of overall health, and pain intensity. Although this instrument is extensively used and reliable, it is impractical to use for population surveillance because of its length. In addition, the scales do not provide the kind of concrete measures of health-related quality of life that policy makers need to calculate the associated economic and social costs.

Asking about quality of life in the Behavioral Risk Factor Surveillance System (BRFSS)[9] allows for the collection of continuous, comparable data on large population groups. Likewise, asking for the number of unhealthy days provides a concrete measure of poor quality of life that can be used to quantify costs, thereby allowing employers, legislators, and health and social welfare agencies to understand better the impact of diabetes mellitus on quality of life.

Researchers have used the *Healthy Days* questions from the BRFSS to compare patients with diabetes mellitus to the general population.[1] However, no study has looked for identifiable subgroups of patients with diabetes who are at risk for poor quality of life as defined by *Healthy Days*. By using a state population-based survey with the *Healthy Days* questions, policy makers can quantify the costs associated with poor health-related quality of life and perform future analyses to track changes.

Methods

Design

This cross-sectional study evaluates the associations between multiple demographic and medical characteristics with health-related quality of life among people with diabetes in North Carolina. Our protocol was assessed by the North Carolina Public Health Institutional Review Board and was determined to be exempt from review.

Sample and Setting

Our sample of people with diabetes in North Carolina was from the BRFSS, a state-based, random-digit-dialed telephone survey of civilian, non-institutionalized adults age 18 and older. Response rates in the North Carolina BRFSS, calculated as the number of completed interviews divided by the number of eligible units, ranged from 56.2% in 2001 to 61.7% in 1998. The final BRFSS data were weighted to adjust for sampling probabilities and non-response rates.[34]

We identified adults with diabetes by "yes" responses to the question, "Have you ever been told by your doctor that you have diabetes?" Females with only a history of gestational diabetes were not included in the analyses. Due to the relatively small number of adults with diabetes per year, we combined data from years 1998-2001 (n = 1,035).

Measures

Based on our literature review, we included a number of independent variables thought to be related to poor health-related quality of life. The demographic characteristics included age, sex, ethnicity, marital status, education, income, and insurance status. Ethnicity was dichotomized into white and non-Hispanic versus non-white and/or Hispanic (the majority of whom were English-speaking). The medical characteristics included obesity, duration of diabetes, and use of insulin. Due to the survey's limitations, certain medical comorbidities as well as complications of diabetes could not be included in our analyses.

We used *Healthy Days* to measure health-related quality of life. Earlier analyses of the BRFSS core *Healthy Days* questions in representative surveys of adults show these measures to be internally consistent, accurate identifiers of population groups with poor quality of life and concurrently valid when compared with a self-rated health measure for all adults.[9] For example, a Centers for Disease Control and Prevention (CDC) study using national BRFSS data adjusted for age found a "tenfold difference in *unhealthy days* between adults reporting excellent versus poor general health."[9]

Our study examined four separate outcomes: general health rating, physically unhealthy days, mentally unhealthy days, and number of days with functional limitations due to poor physical

---

* To track health-related quality of life among state populations, the CDC developed a measure called *Healthy Days* for its BRFSS. Using four basic questions, this measure asks about a person's self-rated health and evaluates physical health, mental health, and functional health by assessing the number of unhealthy days in the past month.

or mental health. The questions for each of these outcomes were (1) "Would you say that, in general, your health is excellent, very good, good, fair, or poor?" (2) "Now thinking about your physical health, which includes physical illness and injury, for how many days during the past 30 days was your physical health not good?" (3) "Now thinking about your mental health, which includes stress, depression, and problems with emotions, for how many days during the past 30 days was your mental health not good?" and (4) "During the past 30 days, for about how many days did poor physical or mental health keep you from doing your usual activities, such as self-care, work, or recreation?" We then dichotomized the last three of these outcomes based on our examination of the responses, which suggested seven days as an appropriate cutoff. We postulated that one week of unhealthy days would represent a major impact on both the respondent and, for example, the respondent's employer.

Results

Descriptive Data

Table 1 shows the characteristics of adults with diabetes in North Carolina as determined by the BRFSS samples from 1998-2001. Using the weighted data, the majority of the sample are female, white, younger than 65 years, currently married or living with a partner, have household incomes greater than $20,000 per year, completed more than a high school education, have health insurance, are obese, were diagnosed with diabetes less than ten years ago, and do not use insulin.

Our study analyzed the four different health-related quality-of-life outcomes asked by the BRFSS among adults who reported a diagnosis of diabetes (see Table 2). Overall, an equal proportion of adults in North Carolina with diabetes rated their health as excellent, very good, or good (49%) compared to those who rated their health as fair or poor (51%). The overall mean for physically unhealthy days was 9.3 per month, for mentally unhealthy days 4.5 per month, and for functionally limited days 5.7 per

Table 2.
Average Scores for Healthy Days Outcomes among North Carolina Adults with Diabetes

Measure	Percent or Mean number of days	Median number of days	Percent < 7 days
Self-reported health status:			
fair or poor	51%	N/A	N/A
excellent, very good, or good	49%	N/A	N/A
Number of days during the past 30 days that physical health was not good	9.3	1.0	66
Number of days during the past 30 days that mental health was not good	4.5	0	84
Number of days during the past 30 days that poor physical or mental health restricted activities	5.7	0	77

month. However, the unhealthy days outcomes were all greatly skewed, with the median number for each at zero or one day per month. The majority of the sample (range 66-84%) reported seven or fewer unhealthy days for each unhealthy days outcome (physically unhealthy days, mentally unhealthy days, and functionally limited days).

Associations between Demographic and Medical Characteristics with Healthy Days

Table 3 shows the differences in health-related quality of life by the independent variables of sex, ethnicity, age, marital status, income, education, insurance status, obesity, duration of diabetes, and use of insulin. In this table, the subgroups with an asterisk are significantly different (based on Pearson's chi-square at the $p < 0.01$ level). Of the demographic characteristics, socioeconomic variables were associated with the greatest differences in quality of life. Gender and ethnicity were not associated with any of the dichotomized quality-of-life outcomes. Respondents less than age 65 and not currently married or living with a partner were each associated with more than one week of mentally unhealthy days. However, people with diabetes were significantly more likely to have a poor quality of life on all of the outcomes if they had a lower-household income (all p-values < 0.001). The other two socioeconomic characteristics, education and insurance, were also strongly related to a poor quality of life. Those with less education and those with no health insurance were more likely to have a poor quality of life on three of the four outcomes.

All of the medical characteristics we included showed an

association with at least one of the *Healthy Days* outcomes. Obesity was associated with more than one week of functionally limited days. A longer duration of diabetes was associated with more physically limited days. Insulin use was associated with a poor general health rating and greater than one week of physically unhealthy days, in addition to more mentally unhealthy and functionally limited days.

We found no strong independent association between most of the socioeconomic and medical characteristics and functionally limited days. The only characteristic that was independently related to the number of functionally limited days was income. Subjects with an annual household income of less than $20,000 were more likely to have greater than one week of functionally limited days ($p < 0.001$). However, due to an interaction between income and age ($p=0.002$), an income of less than $20,000 showed a stronger association with more than one week of functionally limited days among persons with diabetes who were younger than 65 (aOR=10.3; 95% CI 4.93-21.5) than among those who were 65 and older (aOR=1.9; 95% CI 0.7-5.1).

Conclusions

In this study, the majority of adults with diabetes in North Carolina rate their health-related quality of life as good and report less than a week of physically unhealthy, mentally unhealthy, and functionally limited days. However, our study also identified subgroups with poor quality of life, based on only a few demographic and medical characteristics. The greatest differences were between socioeconomic groups—those of lower socioeconomic status reported more mentally, physically, and functionally unhealthy days and had a lower general health rating. We found that, of the demographic and medical characteristics studied, an annual household income of less than $20,000 was the only one associated with poor quality of life on all of the outcome questions. People with less education and no health insurance were also strongly disposed to be physically unhealthy and likely to report more functionally limited days. Less education was related to a poor health rating and no health insurance to mentally unhealthy days, while low income was the only characteristic independently associated with greater than one week of functionally limited days, especially among those of working age (younger than 65 years of age). The finding of a significant loss of functional days among people with diabetes who have low incomes should be of importance to policy makers since this reflects the number of days people say that they are unable to work or do their usual activities. Further investigations could determine if it is the type of work (e.g., physical labor)—or poor access to healthcare that is most closely associated with a loss of functional days among low-income people with diabetes.

A strong association between low income and poor health-related quality of life is also consistent with the results of other research. Using the Healthy Days measures, a study among the general population found that people with household incomes below the federal poverty guidelines had the lowest quality of life on all outcomes measures, including being more likely to report fair or poor health, having more physically and mentally unhealthy days, and having more functionally limited days.[1] A comprehensive and representative study by Glasgow et al. of health-related quality of life among people with diabetes in the United States, showed a similar association between lower incomes and worse quality of life for each scale of physical, social, and mental health in the Medical Outcomes Study quality-of-life measure.[12] This study of a national sample of diabetic adults was similar to our North Carolina sample, in terms of age range, gender distribution, and health insurance status. However, in the Glasgow et al. sample only 47% of the subjects had more than a high school education, compared to 61% in our North Carolina sample; and the majority of the Glasgow et al. sample had higher incomes than those in our sample of North Carolinians. Nevertheless, both studies found the same associations between less education and low income with a poor health-related quality of life. In addition to these associations, Glasgow et al. found strong, independent associations between more medical comorbidities and more diabetes complications with poor physical and mental quality of life[12]—associations that our study could not assess because of survey limitations. Future surveillance using the BRFSS should include important predictor variables, such as questions regarding chronic disease diagnoses and diabetes complications, on an annual basis.

Our study is not designed to prove that any of the demographic and medical characteristics are a cause of poor health-related quality of life. Nevertheless, important associations can help identify groups based on these demographic and medical characteristics that are likely to be experiencing a poor quality of life and that need to be targeted for interventions. Some of the variation in quality of life by different demographic groups may reflect differences in interpretation of questions. Furthermore, since the BRFSS excludes households without telephones and the institutionalized, it may possibly exclude a portion of the population with a low-socioeconomic status and under-represent severely impaired adults.

Similar to other research on quality of life among people with diabetes, this study includes only those who have been diagnosed and is not designed to include the estimated 30% of people who have diabetes but are unaware of it.[38] The data collected through the BRFSS also relies on self-report, but researchers have found a high agreement between the self-report and medical report of common medical conditions, including diabetes, both in the elderly and other population groups.[39,40] In addition, the overall response rate for the BRFSS in North Carolina was only 56-60%, which could therefore introduce sampling bias; however, the sample is weighted to adjust for different response rates between demographic groups. Among this sample of people with diabetes, less than 5% refused to answer each question relating to the independent variables and outcomes studied, except for household income, which almost 25% did not report. Although those older than 65 were more likely to refuse to report their income level, the proportion of each *Healthy Days* outcome was not statistically significantly different between those who answered their income-level question and those who did not. Therefore, we can say that there was no difference in quality of life between responders and non-responders.

The North Carolina Division of Public Health is interested in quality-of-life surveillance for people with diabetes in order to track health disparities and target its resources. Prior research on health-related quality of life among people with diabetes identified likely associated demographic and medical characteristics. However, these studies, done mostly among clinic populations, yielded conflicting results, and many of them used long, detailed, research tools that are not feasible for surveillance research.

The results of our study are strengthened by the use of a random, population-based, annual state survey and the reliability and validity of the quality-of-life outcome measures. Compared to the research measures used in previous studies, *Healthy Days* is a short, policy-relevant quality-of-life measure. By using surveillance data with easy-to-administer questions regarding quality of life, public health professionals can track how well we are meeting the *Healthy People 2010* goals of increasing the quality and years of life.[41] Since the *Healthy Days* outcomes are included in each state's annual Behavior Risk Factor Surveillance System,[9] studies can also be done of subpopulations with other chronic diseases, such as asthma or arthritis, as well as studies that compare quality of life between people with different diseases and in different states. By measuring the number of days where quality of life is limited due to poor health, *Healthy Days* allows policy makers to calculate the associated economic and social cost of poor quality of life. The results of our study provide information that public health practitioners can use to target resources and interventions to those people with diabetes in North Carolina who are most at risk for a poor quality of life. **NCMedJ**

ARTICLE

Protecting Workers from Secondhand Smoke in North Carolina

Marcus Plescia, MD, MPH, Sally Herndon Malek, MPH, Donald R. Shopland, Christy M. Anderson, and David M. Burns, MD

Abstract

Background: *Exposure to job-related secondhand smoke represents a significant, but entirely preventable occupational health risk to non-smoking workers. This article examines trends in smoke-free workplace policies in North Carolina. We also examine whether workers comply with such policies.*

Methods: *Data from the Census Bureau's Current Population Survey were analyzed from 1992 through 2002. Trends for North Carolina workers are compared with workers nationally, and trends are presented by age, race, gender, and type of worker.*

Results: *North Carolina ranks 35th in the proportion of its workforce reporting a smoke-free place of employment. The proportion of workers reporting such a policy doubled between 1992 and 2002. Females were more likely to report a smoke-free work environment (72.0%, CI +/-2.6) than males (61.2%, CI +/-4.6%). Blue-collar (55.6%, CI +/-5.5) and service workers (61.2%, CI +/-8.4), especially males, were less likely to report a smoke-free worksite than white-collar workers (73.4%, CI +/-2.6). Compliance with a smoke-free policy does not appear to be an issue, only 3.2% of workers statewide reported someone had violated their company's nonsmoking policy.*

Conclusion: *While some progress has been made in North Carolina to protect workers from secondhand smoke, significant disparities exist. Smoke-free policies can make a significant difference in reducing exposure to airborne toxins and their associated diseases, and these protective public health policies have not been shown to reduce business revenues. Much has been done to assure the health and safety of workers through public health policy. However, opportunities to protect North Carolina workers from the health effects of secondhand smoke are limited by a preemptive state law.*

Key Words: *Secondhand smoke, environmental tobacco smoke, occupational status, public health policy, CPS, NCI.*

Introduction

A series of authoritative reports have conclusively demonstrated that exposure to secondhand smoke is a significant health threat to non-smokers, increasing the risk for lung cancer, coronary artery disease, asthma and other lung diseases, and Sudden Infant Death Syndrome.[1-5] New evidence indicates there are health risks for even a brief exposure to secondhand smoke for individuals with preexisting heart disease. In Helena, Montana, a comprehensive local ordinance that banned smoking in all indoor public places, including worksites, was associated with a 40% decline in hospital admissions for acute myocardial infarction during the six months the ordinance was in effect, only to rebound after the ordinance was suspended following a legal challenge.[6] The Helena study prompted the Centers for Disease Control and Prevention to review the literature and to issue a commentary on the public health risks of secondhand smoke, stating, *"All patients at risk of coronary heart disease or with known coronary artery disease should be advised to avoid all indoor environments that permit smoking."*[7]

David M. Burns, MD, works with the University of California at San Diego, San Diego, CA.

The United States workforce has undergone fundamental change in workplace smoking restrictions. Fifteen years ago the United States Congress banned smoking aboard all commercial airlines[8] out of concern for the health of flight attendants who were routinely required to work in the smoking section of the aircraft. At least 11 states* have now enacted comprehensive legislation mandating that most places of employment, including restaurants and/or bars, be smoke-free. These states join hundreds of local communities that have passed totally smoke-free workplace ordinances.[9]

In this important area of occupational health protection, states with historical, economic, and political ties to tobacco, like North Carolina, have traditionally lagged behind other states and the nation.[10] The purpose of this article is to examine trends in smoke-free workplace policies in North Carolina. The data presented are from the Census Bureau's Current Population Survey (CPS).** Trends in the state are compared with trends nationally and among select surrounding states. We also examine the degree to which workers in the state comply with rules that prohibit smoking at their place of employment.

Methods

The CPS is a continuous monthly survey that has been conducted by the Census Bureau for the Bureau of Labor Statistics since 1940, focusing on labor force indicators for the civilian non-institutionalized population of the United States ages 15 and older. In 1992, the National Cancer Institute (NCI) sponsored a 40-item Tobacco Use Supplement to the CPS, which included, among other items, questions about official workplace smoking policies and the nature and characteristics of those policies. The Supplement was conducted over four time periods, 1992-1993, 1995-1996, 1998-1999, 2001-2002. The monthly CPS sample consists of approximately 56,000 eligible housing units in 792 sampling areas. All strata are defined within state boundaries, and the sample is allocated among the states to produce state, Census region and division, and national labor force estimates, keeping the total sample size to a minimum. Response rates to the CPS labor force core questionnaire is about 95% and between 85-89% for the NCI Tobacco Use Supplement.

Worker Eligibility Criteria

Routine labor force questions from the CPS core were used to determine each respondent's employment status and to categorize each worker into a standard occupational group. Because the primary area of interest for this report was the extent of official workplace smoking policies for indoor working environments in North Carolina, additional questions were used to identify eligible respondents. To be included in the analysis, individuals must have been 15 years of age or older and (1) employed either full- or part-time at the time of interview, (2) employed outside the home but not self-employed, (3) not working outdoors or in a motor vehicle, (4) not traveling to different buildings or sites, and (5) not working in someone else's home. Applying these criteria produces 10,773 eligible indoor workers for further analysis.

Definition of Smoke-Free

All eligible respondents were queried, "Does your place of work have an official policy that restricts smoking in any way?" (note: about 2% of subjects responded "don't know" and were excluded from the analyses). Those who responded "yes" were also asked: "Which of these best describes your place of work's smoking policy for indoor public or common areas, such as lobbies, restrooms, and lunch rooms?" and "Which of these best describes your place of work's smoking policy for work areas?" Response choices for each were: "Not allowed in any …" "Allowed in some …" or "Allowed in all …"

Workers who reported that their employer had an official policy that restricted smoking and did not permit smoking in any public or common areas or in the work area, were considered to be working in a smoke-free environment. This definition is identical to that used in other national and state-based reports.[9-13] For compliance, only workers with smoke-free policies were included in the analysis.

Statistical Analysis

Statistical analyses were performed using Statistical Analysis Systems software, version 8.02.[14] Supplement weights, adjusted for overall Supplement non-response and Supplement self-response only, were produced using a special algorithm developed by the Bureau of Labor Statistics.[15] Sudaan was used to compute standard errors and 95% confidence intervals (or margin of error) using the replicate weights that the Census Bureau constructed using Fay's methods.[16]

Results

The percentage of the North Carolina indoor workforce covered by a smoke-free workplace policy has increased over the ten-year period 1992 through 2002 (see Table 1). Less than a third of the state's workforce was smoke-free in 1992-1993, but by 2001-2002, slightly more than two thirds were reporting this level of protection. The trend toward smoke-free worksites

* States that have enacted comprehensive laws, the date of passage and setting affected: California (restaurants 1995, bars 1998), Maryland (workplaces and restaurants 1995), Delaware (workplaces, restaurants and bars 2002), New York (workplaces, restaurants and bars 2003), Massachusetts (workplaces, restaurants and bars 2004), Utah (restaurants 2005), Florida (restaurants 2003), Connecticut (restaurants 2003, bars 2004), Idaho (restaurants 2004), South Dakota (workplaces 2002) and Maine (restaurants and bars 2004).

** The federal government's primary data source for labor force statistics. These data cover the ten-year period 1992 through 2002.

Table 1.
Comparison of Workplace Policy Trends in North Carolina with Neighboring States and the Nation and State Rank in 2001-2002

Percent of indoor workers 15 years of age and older reporting a smoke-free workplace

State and (rank in 2001-02)	**1992-1993** % (CI)[1]	**1995-1996** % (CI)	**1998-1999** % (CI)	**2001-2002** % (CI)
North Carolina (35)	**30.8 (± 2.1)**	**54.4 (± 2.3)**	**61.0 (± 2.6)**	**67.3 (± 2.5)**
Tennessee (39)	36.0 (± 2.1)	53.0 (± 2.8)	63.0 (± 4.2)	66.1 (± 3.6)
South Carolina (43)	37.7 (± 3.2)	58.3 (± 4.5)	63.8 (± 2.6)	65.4 (±4.3)
Georgia (47)	46.7 (± 3.5)	56.7 (± 4.7)	66.1 (± 2.8)	63.3 (± 3.3)
Virginia (24)	43.7 (± 2.6)	62.2 (± 3.3)	70.6 (± 2.3)	71.2 (± 2.3)
All United States workers	**46.3 (± 0.4)**	**63.4 (± 0.4)**	**69.0 (± 0.4)**	**70.9 (± 0.4)**

CI = 95% confidence interval or margin of error

increased substantially during the initial three-year survey period, increasing 77% between 1992-1993 and 1995-1996, but just 24% over the next six years. As of 2001-2002, North Carolina ranks 35th among all the states in the proportion of its workforce reporting a smoke-free place of employment.

Smoke-free policies vary considerably by age and gender of the worker, with younger workers, particularly males ages 15-24, reporting lower rates of smoke-free policies (40.7% CI +/-12) than middle age male workers age 40-54 (62.0% CI +/-7.4) and older male workers age 55-64 (72.5% CI +/-10.7). Thus, less than 50% of male workers ages 15-24 are likely to be currently covered by a smoke-free policy, the lowest rate of any age group in the state, and this low rate of coverage has not changed in absolute terms since 1995-96. Overall, females are currently more likely to report a smoke-free work environment (72.0% CI +/-2.6) than males (61.2% CI +/-4.6). Rates are similar among blacks and whites throughout the 1992-2002 time period. The rates are slightly lower for Hispanic workers but these differences are not statistically significant.

While consistent progress has been observed in the effort to protect workers from job-related secondhand smoke in the state, some workers are less protected than others (see Table 2). Blue-collar and service workers are considerably less protected than white-collar workers. In 2001-2002, 52.4% (CI +/-5.8) of male blue-collar workers and 47.5% (CI +/-14.2) of male service workers were smoke-free, compared to 73.4% (CI +/-14.2) of all white-collar workers. This difference persisted across all four time periods. Females, regardless of occupational category, reported higher rates of smoke-free policies than males.

Table 2.
Trends in Smoke-Free Policies in North Carolina by Type of Worker

Type of worker	**1992-1993** % (CI)[1]	**1995-1996** % (CI)	**1998-1999** % (CI)	**2001-2002** % (CI)
White-collar	38.3 (+/-2.1)	63.0 (+/-2.8)	68.5 (+/-2.8)	73.4 (+/-2.6)
Blue-collar	18.3 (+/-2.8)	41.6 (+/-5.0)	48.5 (+/-5.4)	55.6 (+/-5.5)
Service	29.5 (+/-4.8)	43.1 (+/-6.2)	48.6 (+/-7.6)	61.2 (+/-8.4)

CI = 95% confidence interval or margin of error.

Note: Throughout the manuscript we refer to three major occupational groups, white-collar, blue-collar and service workers. While no official definition exists for these workers, on the CPS public use data file, the Census Bureau "recodes" some 500 individual occupations into 14 major groups. Examples of white-collar occupations include people employed as managers, accountants, clerical workers, engineers, teachers, physicians, etc., blue-collar workers include carpenters, mechanics, assembly line workers, bus and truck drivers, tailors, etc; and examples of service workers are, food service workers, health technicians, personal and protective services (firefighters, guards, police), etc.

Table 3 provides estimates for smoke-free workers in the state who reported someone had violated their company's smoke-free policy in the two weeks prior to interview by smoking in their work area. Only a small percentage of the state's workforce reported a violation of a smoke-free policy over the six-year time period examined. Furthermore, compliance with such policies appears to be improving, with noncompliance decreasing from less than 5% in 1995-1996 to just 3.2% in 2001-2002, a level of compliance equal to that seen among workers nationally. Blue-collar and service workers report slightly higher rates of noncompliance than white-collar workers, a trend also observed nationally, although none of these differences are statistically significant. Despite the rapid increase in smoke-free workplace policies among workers in the state, in 2001-2002, 96.8% of all workers with such a policy indicated their place of employment was in compliance with that policy.

Discussion

The importance of secondhand smoke as a significant health risk to workers cannot be overstated. Finnish researchers calculated mortality among workers for several major diseases

Table 3.
Compliance with Smoke-Free Workplace Policies among North Carolina Workers Compared to Workers Nationally by Type of Worker and Gender and % of Workers Reporting Someone Violated Workplace Policy in Past Two Weeks.

	1995-1996				1998-1999				2001-2002

related to secondhand smoke and estimated that such exposures were responsible for 2.8% of all lung cancer deaths, 4.5% of deaths from asthma, and 3.4% of all coronary heart disease deaths.[17] Other investigators have demonstrated that food service workers experience a lung cancer death rate that is 50 percent higher than the general population even after controlling for active smoking.[18] More recently, the Centers for Disease Control and Prevention has estimated that secondhand smoke is a cause of 38,000 premature deaths annually in the United States, the majority from cancer and heart disease,[19] although millions more are made ill and lose work from asthma, pneumonia, bronchitis and other respiratory problems.[4]

When smoking is permitted in indoor environments, the quality of the indoor air quickly becomes unhealthy, not only for workers, but patrons and visitors alike. When smoking is eliminated, improvements in air quality are almost immediate, even in heavily polluted bars and restaurants. Air quality researcher James Repace recently measured the levels of particle-bound polycyclic aromatic hydrocarbons (PPAH) and fine particle respirable suspended air pollutants (RSP) in eight hospitality venues in Delaware just prior to and several weeks after a statewide clean indoor air law was implemented.[20] PPAH levels in the eight venues prior to implementation of the statewide ban averaged five times the level found in outdoor air, while the average level of RSP was 15 times the level allowed in outdoor air under the United States National Ambient Air Quality Standards (NAAQS). Implementation of the law was associated with a 90-95% reduction in both RSP and PPAH levels. Similar results have been observed elsewhere.[21,22] Repace calculated that to bring a typical bar with average smoking prevalence into compliance with the NAAQS for fine particle air pollutants would require more than 80 air changes per hour.[22]

In North Carolina, opportunities to protect workers from the health effects of secondhand smoke through public health policy are limited by a preemptive law. In 1993, the state legislature passed a law that required state-controlled buildings to set aside 20% of their space for smoking and prohibited local regulatory boards from enacting stronger provisions unless the legislation was enacted before the state law would take effect in October of that year.[23] A total of 105 local ordinances were in effect by the October date, 89 of which had been fast tracked to beat the deadline. A legal challenge to one ordinance, contending that boards of health are not elected officials and do not have the authority to rule on this particular issue, was eventually appealed to the North Carolina District Court. The subsequent ruling invalidated almost all of the 89 newly enacted ordinances,[24] forcing most communities to suspend legal enforcement of their ordinances.

Some progress has been made within the state to protect workers from the health effects of secondhand smoke through voluntary efforts, but such efforts have created significant differences in coverage between different categories of workers. The local Health Directors Association initiated an aggressive statewide education campaign encouraging local governments and others to adopt smoke-free policies in 1993,[25] and North Carolina Project ASSIST began educational campaigns to encourage businesses to adopt voluntary policies.[26] As a result, the proportion of the state's workforce reporting a smoke-free place of employment increased from three-in-ten workers in 1992-1993 to nearly seven-in-ten workers by 2001-2002, with most of the increase occurring during the time of the state-sponsored educational campaign.

However, significant disparities exist. While more than seven-in-ten white-collar workers in the state work in smoke-free settings, blue-collar and service workers lag significantly behind, and blue-collar workers are more likely than other workers to be exposed to other hazardous agents in the workplace. The smoke-free rate among service workers in North Carolina is similar to the rate reported by service workers nationally in 2001-2002, although male service workers in the state report significantly lower rates of smoke-free policies than other workers (less than 50% are smoke-free). Many of these workers are employed in the food service sector of the economy. A recent study of 38 major occupations showed food service workers were the least protected from job-related secondhand smoke. Just 28% of waiters/waitresses and 13% of bartenders report working under a smoke-free workplace policy.[27] According to the Bureau of Labor Statistics, 275,000 North Carolinians were employed in restaurants and bars in August 2004 compared to 160,000 at the beginning of 1990, an increase of 70%, making it one of the more significant and fastest growing segments of the state's workforce.[28] More than 50% of these workers are women. Given the low level of smoke-free policy coverage among service workers in the state and nationally, it is likely that a large proportion of the quarter-million bar and restaurant workers in North Carolina are also at risk from job-related secondhand smoke.

There is evidence that suggests immediate improvements in the health status of bar and restaurant workers after implementation of a smoke-free law. Eisener et al.[29] in a study of 53 California bartenders, documented improvements in pulmonary function and respiratory symptoms one month after a statewide smoke-free law went into effect. Sargent et al. observed a 40% reduction in hospital admissions for acute myocardial infarctions in Helena, Montana following implementation of a smoke-free ordinance that included bars and restaurants.[6] The elimination of secondhand smoke from all hospitality venues, such as bars and restaurants, could have a significant impact on the health of this large and growing segment of the state's workforce.

Smoke-free policies do not hurt business revenue, even in restaurants and other hospitality venues. Recently published economic analyses in California, New York, and elsewhere have clearly demonstrated that smoke-free laws are essentially revenue neutral, that is, they neither increase nor decrease revenue when implemented.[30-35] In 2003, Scollo and colleagues[36] reviewed 97 studies on the economic impact of smoke-free policies, including studies funded by the tobacco industry. None of the 60 independently funded studies found any significant, long-term economic effects associated with smoking bans in restaurants and bars. Of the 27 studies that controlled for other economic factors and used objective measures to assess impact, none showed a negative effect. Zagat, the world's leading provider of survey-based consumer dining behavior, found that 72% of 110,000 American restaurant-goers surveyed for its 2005 poll indicated their eating-out habits would not change if smoke-free policies were put into effect in restaurants, while 26% said they would eat out more often, versus only 3% who said they would eat out less often.[37]

The findings of this study are based on a series of cross sectional surveys conducted by the US Census Bureau for its Current Population Survey (CPS) and covering the period 1992 through 2002. Information on official worksite smoking policies is based on responses obtained from employees and not worksite managers or business owners. Data derived from workers are likely more accurate than a survey consisting of responses from workplace managers or owners for several reasons. First, almost all surveys of worksites published to date,[11] exclude small businesses from their sampling frame, yet, according to the Census Bureau, small companies (<50 employees) employ 42% of all workers and make up more than 95% of all businesses in the US. Thus, worksite surveys provide an incomplete picture of worksite smoking policies. Second, worksite surveys typically rely on a response from a single individual, usually a company official, who responds for the entire company. In the COMMIT trial consisting of 11 communities of varying size in North America, Glasgow et al,[38] reported that individual workers reported rates of smoke-free policies that were lower than those reported by management-level representatives. Finally, the CPS has an excellent track record for obtaining accurate worksite and employment data. Since 1940 the CPS has been the federal government's main data source for monthly labor force statistics.

The primary purpose of this paper was to focus on differences in smoke-free policies by examining a number of demographic and employment variables as a means of highlighting which workers are currently not protected from the dangers of secondhand smoke in North Carolina. Multivariate analysis could provide some insight regarding which factors are independently associated with workplace smoking policy but such analysis is beyond the scope of this report. Variables such as age, gender, type of worker, work site and smoking status could serve as confounders of specific trends reported in this study. Previously published data demonstrate that smokers report significantly lower rates of smoke-free policies than nonsmokers.[11] Smokers tend to be younger and less educated than nonsmokers and blue-collar and service workers report significantly higher cigarette use rates than white-collar workers.

Conclusions

Second hand smoke is a well-established health hazard. While some progress has been made in North Carolina to protect workers from secondhand smoke, significant disparities exist. Smoke-free policies can make a significant difference in reducing exposure to airborne toxins and their associated diseases and these protective public health policies have not been shown to reduce business revenues. Much has been done to assure the health and safety of workers through public health policy. However, opportunities to protect North Carolina workers from the health effects of secondhand smoke are limited by a preemptive state law. **NCMedJ**

INTRODUCTION

Policy Forum:
Innovations in Primary Care Practice

The July/August 2002 issue of the *North Carolina Medical Journal* gave topical focus to "The Place of Primary Care." The papers in that issue of the Journal provided a general overview of the evolving role primary care plays in the ever-changing American healthcare sector. The last paper in that issue, by Warren P. Newton, MD, MPH, Professor and Chair of the Department of Family Medicine at the University of North Carolina School of Medicine, raised questions about the attractiveness of medicine as a profession (primary care practice in particular) in an age of increasing pressure from managed care and governmental insurance programs, as well as at a time of increasing commercialization of medical science and practice. These pressures and added complexities may be making these fields less attractive to future medical school applicants and graduates.

Now, three years later, we have invited Dr. Newton and several colleagues from across the state who practice (or study) primary care to describe some of the recent developments in this field that are enabling practitioners to better serve their patients' primary care needs, while at the same time assuring their own personal, professional, and financial goals. Most of these papers were generated from discussions taking place in a fall 2004 conference on "innovations in primary care practice" named in honor of the late Robert Huntley, MD.*

These papers describe six specific categories of developments in the organization and practice of primary care. Although these ideas are often described as "innovations" in this field, they are not new ideas for the most part. Rather, it is the recent attention they have received as strategies for improving quality of care and assuring the professional and financial viability of primary care practice that makes them important.

These six categories of developments include: (1) efforts to downscale the size and complexity of practice organization with an emphasis on low-overhead operations; (2) the infusion of electronic health records in primary care practice; (3) the use of disease management protocols for the major categories of chronic conditions seen in primary care practice; (4) the use of *Advanced Access* scheduling as a way of increasing the efficiency of small practice organizations; (5) community-wide, collaborative care delivery models to meet the increasing burden of caring for the uninsured and underserved; and (6) the use of electronic communication with patients via e-mail and other uses of the Internet. There is no doubt that each of these developments reflects the changing nature of available technology and the contemporary pressures on primary care practice organizations. They also signal new directions in how primary care practitioners relate to their patients as well as the potential for significant improvement in the effectiveness and quality of some aspects of care.

Other information contained in this issue of the Journal describes the supply and distribution of primary care practitioners in our state and the important trends in this regard.

As always, we hope that the discussion of these issues will elicit comments and observations from our more than 25,000 readers.

ISSUE BRIEF

New Developments in Primary Care Practice

Warren P. Newton, MD, MPH, C. Annette DuBard, MD, and Thomas H. Wroth, MD, MPH

The great paradox of modern American medicine is the coexistence of stunning achievement in biomedical knowledge and technology, alongside our failure to meet the basic healthcare needs of a substantial proportion of the population. As the bridge between technical advances in medicine and the real lives of patients, primary care physicians find themselves stretched thin by patient demand for greater responsiveness to urgent care needs, lack of time to deliver preventive services, and the increasing complexity of chronic disease management. Communities in North Carolina and throughout the country are facing a relentless escalation of healthcare costs, with an alarming rise in the proportion of the population without health insurance. Simultaneously, the physicians serving these communities face increasing costs and decreasing reimbursement, with mounting pressure to see more patients in less time, or to limit the types of patients they care for, in order for their practices to survive.[1]

"...physicians serving these communities face increasing costs and decreasing reimbursement, with mounting pressure to see more patients and less time, or to limit the types of patients they care for, in order for their practices to survive."

The Aim of this Issue of the Journal

In response to these challenges, primary care is rapidly evolving, as healthcare providers explore new ways of responding to patient needs while also making their practices more efficient and effective. These innovations are the foci of this issue of the *North Carolina Medical Journal*.

Revisiting the history of general practice in North Carolina offers insight into contemporary primary care delivery, and allows us to examine whether the structure of primary care that has evolved in our communities is adequately equipped to address the needs of the population being served. Our own review of this history suggests that primary care practice requires substantial systematic change to remain viable and to provide adequate access to quality healthcare. Against the background of this historical overview, we will present ways in which practices across the state are rising to the challenge of improving access and quality while decreasing costs, and discuss implications for future strategic initiatives, policies, and research.

It is well-established that community-based primary care practices play a key structural role in the care of the population. Kerr White, T. Franklin Williams, and Bernard Greenberg first established this with their classic 1961 paper on "The Ecology of Medical Care," derived from their work here in North Carolina, which demonstrated that the vast majority of patient care takes place in community-based outpatient practices, substantially distinct from care received in hospitals and academic

Warren P. Newton, MD, MPH, is the William B. Aycock Professor and Chair of Family Medicine at the University of North Carolina at Chapel Hill. His major interest is in the organization and effectiveness of care. He can be reached at warren_newton@med.unc.edu or CB 7595 Chapel Hill, NC 27599. Telephone: 919-966-5600.

C. Annette DuBard, MD, is a family physician practicing with Piedmont Health Services, Inc. and a preventive medicine resident in the Department of Social Medicine, UNC School of Medicine. She can be reached at annettedubard@hotmail.com or CB 7240, Chapel Hill, NC 27599-7240. Telephone: 919-643-1674.

Thomas H. Wroth, MD, MPH, is a family physician and preventive medicine resident at UNC School of Medicine. He can be reached at tomwroth@mindspring.com or Department of Family Medicine, CB 7595, Chapel Hill, NC 27599. Telephone: 919-966-3711.

health centers.[2] Larry Green more recently updated and confirmed this conclusion (see Figure 1).[3]

It is further evident that the strength of the organization of primary care has a major impact on the health of the population. Barbara Starfield conducted a series of studies in the early 1990s to measure the integration and impact of primary care systems around the world, and found that countries where primary care is most firmly established as the foundation of the care delivery system have not only the best health outcomes for the population, but the least expensive care.[4-9] Within the United States, counties with more primary care providers have lower mortality rates.[10] Similarly, states with higher ratios of specialists to the population have both higher healthcare expenses and lower-quality care for the Medicare population, while states with more generalists have lower spending and use more effective care.[11] The structure and processes of community-based primary care practice in North Carolina, then, warrant a closer look.

Looking Back: A History of Community Practice in North Carolina

Today's community-based primary care practices have evolved from a model that dates back at least a half-century. In 1952, there were just over 2,000 general practitioners in North Carolina, with a ratio of approximately 5,000 patients per primary care physician.[12] The health status of North Carolinians was poor at the time: 40% of whites and 60% of blacks were found unfit for the military draft during the World War II—the highest percentage of draft rejections of any state in the country. Leading causes of death included cancer, stroke, and heart attack; but deaths from tuberculosis, accidents, and premature births were also much more common.[13]

In 1953, 75% of North Carolina physicians were in solo practices. Most primary care physicians offered hospital care and obstetrics, and one-in-ten performed major surgeries. Most physicians practiced out of small offices—often in a drug store or in a practice facility attached to their home—offering preventive care and treating respiratory infections, injuries, cardiovascular and infectious diseases, and other conditions. Fifty-two percent offered walk-in care, sometimes without appointment systems. Office staff was minimal, with perhaps a single nurse or assistant, and less than half of practices had their own x-ray and electrocardiogram (EKG) equipment. Record-keeping was sporadic; 11% did not keep clinical records and 47% kept notes that consisted only of the diagnosis or treatment.[14]

Community clinicians in 1953 worked 50 hours-a-week seeing patients in the office, not including on-call and after-hours work. Most had office hours on Saturdays, and a remarkable 11% also kept Sunday hours. In addition, most doctors visited patients in the hospital and made house calls. Fees were low, about $3 per visit, contributing to an annual salary of about $16,000.[14]

The population of North Carolina has nearly doubled in the last 50 years. While the number of family physicians today is only slightly more than the number of general practitioners in the 1950s, the addition of internists, pediatricians, and obstetricians to the primary care ranks has netted a ratio of about 1,200 patients to each primary care practitioner.[15] As Table 1 shows, the mortality of influenza/pneumonia, non-vehicular accidents, premature births, and tuberculosis have all decreased substantially over the past half-century. Deaths due to cancer have increased dramatically, as have deaths due to chronic lung disease, chronic diabetes, and Alzheimer's disease.[16] This explosion of chronic disease has had a large impact not only on mortality, but on the distribution of demand for patient care. While preventive care visits are still common, the proportion of visits for chronic conditions, such as cardiovascular disease, diabetes, and musculoskeletal disorders, has risen considerably (see Figure 2).[17]

The organization of primary care practice has also changed dramatically. Solo practices, which once accounted for three-quarters of all community practices, have largely been replaced by group practices. While health insurance only covered about 12% of patients in 1950, 73% of patients today are covered by Blue Cross Blue Shield, Medicare, Medicaid, or health maintenance organizations.[18] As a consequence of changing needs of

the population, the dramatic development of office-based technology, and the spread of insurance reimbursement, staffing ratios have gone up dramatically. The ratio of one nurse or assistant to one physician in the 1950s increased to an average ratio of 4:1 or 5:1 by 2004. The resulting increase in overhead is a key feature of the business model of modern primary care. Today's community clinicians have cut their office hours down to about 44 hours-a-week or less, with weekend hours much less extensive and house calls exceptional. The number of patients seen each week has dropped from an average of 170 to 95. Fees have risen to a mean of $71 per office visit,[19] while the median salary of all primary care physicians is now $153,231[20]—both representing dramatic increases far beyond inflation.

What are the lessons of this history? First, the primary care practices of the past were designed for short, problem-focused visits that addressed acute infectious disease, trauma, and well-person care. Consequently, practices were organized around rapid triage for relatively simple problems, with short appointments emphasizing diagnostic tests, brief treatments, and education. Most of the care delivered was provided by the doctor. In contrast, primary care practices of the future need to provide chronic disease management in addition to acute care and more comprehensive preventive services. In order to do chronic care well, Wagner and colleagues at Group Health Cooperative of Puget Sound have argued for an emphasis on patient self-management support, planned regular visits with care-giving teams, linkages to community resources, and evidence-based clinical decision support,[21-24] all of which require system redesign on an organizational level, rather than merely motivating behavioral change on the part of individual providers. It must be recognized, however, that the role of primary care is not limited to chronic disease. A key element of primary care's contribution to the health of the population and to cost control is its multiple missions—to provide preventive services and urgent care as well as chronic care.

Second, the traditional business model for primary care is failing. Public demand and the broad penetration of health insurance (compared with the 1950s) has allowed a great expansion of practice costs related to staff and clinician salaries, spurred by increases in office technology and the need to capture reimbursement from a complex array of payers. The last decade has seen great additional increases in overhead costs, in terms of staff salaries, Health Insurance Portability and Accountability Act (HIPPA) and other regulatory compliance, and now electronic health records. Reimbursement has not kept up with these expenses, and sectors of practice that were previously critical to financial viability, such as office laboratories, have been tightly restricted. Primary care practices have always had to attend closely to overhead costs; now they must rethink their overhead radically and look for innovative ways to maximize clinical efficiencies through technology and the reorganization of care systems.

Looking Around: A Broken Primary Care System

It is important to understand that many aspects of our current primary care system—and thus the bulwark of the health of the population—are broken. Despite dramatic economic growth since 1990, North Carolinians are finding it increasingly difficult to access regular and continuous primary healthcare services. According to the 2004 North Carolina Behavioral Risk Factor Surveillance System, almost one-in-five adults in North Carolina lack health insurance, with rates of insurance coverage much lower among racial and ethnic minorities. Twelve percent of insured adults and 51% of uninsured adults report not having

> *"...practices across the state are rising to the challenge of improving access and quality while decreasing costs..."*

a personal physician or other healthcare provider. Approximately 17% of all North Carolina adults report that they could not get needed medical care at some point during the last 12 months due to cost.[25,26] Concomitantly, the health status of the population is worsening. Those without health insurance or a usual source of care receive fewer preventive services[27] and experience higher mortality rates and worse clinical outcomes for chronic conditions.[28]

The national Institute of Medicine (IOM) has argued persuasively that the quality of American healthcare falls far short of expectation.[29,30] While much attention has been given to patient safety and quality of care in inpatient settings, there is ample evidence of a quality chasm in primary care as well. In a recent random sample, only slightly more than half of adults received recommended care for prevention, acute episodes, or treatment of chronic conditions.[31] Similarly, more than half of patients with diabetes,[32] hypertension,[33] high cholesterol,[34] congestive heart failure,[35] chronic atrial fibrillation,[36] asthma,[37] depression,[38] and tobacco addiction[39] are managed inadequately.[40]

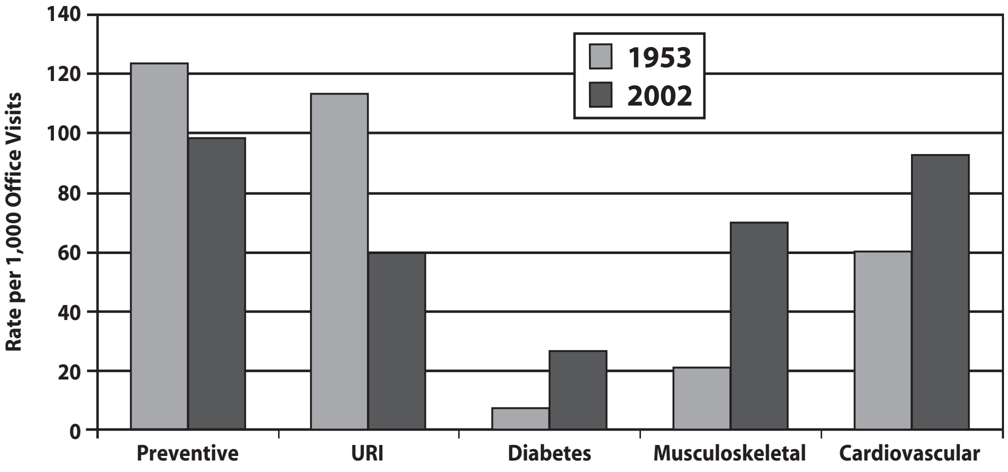
Nationwide, disparities in healthcare access and quality related to race, ethnicity, and socioeconomic status are pervasive. Disparities have been well documented in preventive, acute, and chronic care across many clinical conditions; and across many care settings, including primary care.[41] In North Carolina, African Americans have persistently higher death rates from heart disease, stroke, and diabetes than whites;[42] conditions which are largely preventable with early detection of risk factors and good chronic disease management. Disparities may be attributable, in part, to differential access to quality primary care. A recent study showed that among Medicare patients, 80% of visits for African American patients in this country represent care provided by only 22% of physicians. Physicians caring for African American patients are less likely to be board-certified, and less likely to have access to specialty consultation, diagnostic imaging, and arrangements for non-emergency hospital admissions.[43]

As concerning as these trends are, there is reason to believe that conditions will worsen. While advances in medical technology, such as organ transplantation, thrombolytic therapy, or anti-HIV pharmaceuticals receive wide publicity and acclaim, the prevalence of key health conditions, such as diabetes, hypertension, high cholesterol, obesity, and sexually transmitted disease, continues to rise.[44-46] Furthermore, the healthcare safety net itself is in danger. Often unrecognized is that primary care practices form a huge component of the safety net for the poor and uninsured. Nationally, nearly two-thirds of the uninsured report a private practice physician as their regular source of care,[47] a far greater number than traditional "safety net" institutions such as academic health centers, community health centers, and county health departments. As primary care practices fight for survival, there will be a tendency to jettison patients with a relatively less desirable source of reimbursement—the uninsured or, increasingly, Medicare and Medicaid.

Looking Ahead: Innovations in Primary Care

During the last few years, the leading professional organizations in family medicine,[48] general internal medicine,[49] and pediatrics[50,51] have performed substantial studies of what the future of their disciplines will hold. The Future of Family Medicine project[48]—a broad scope effort which involved all family medicine professional organizations, conducted extensive

Figure 2.
Office Visits[1] for Common Diagnoses in North Carolina, 1953 vs. 2002



[1] Preventive visits include well child care, well adult care, prenatal care. URI includes upper respiratory infection, pharyngitis, bronchitis, sinusitis. Musculoskeletal includes arthropathy, spinal disorders, rheumatism. Cardiovascular includes coronary heart disease, hypertension, congestive heart failure, hypercholesterolemia.

Sources: Peterson et al, An analytical study of NC general practice 1953-1954. J Med Educ, 1956; and Woodwell et al, National Ambulatory Medical Care Survey: 2002 summary, CDC.

survey research, obtained substantial participation from employers and insurers, and tested its economic model—has attempted to define a "New Model of Practice"—including the scope, philosophy, organization, and business model of practice. Table 2 contrasts the New Model of Practice to Traditional Practice.

Practices that include all features of the "New Model of Practice" do not yet exist—nor is there consensus that all elements of the new model are necessary. There have been, however, great efforts to develop and test new models of primary care that respond to the changing needs of the population and the demands placed on practices. This special issue of the *North Carolina Medical Journal* highlights examples of recent developments in the delivery of primary care from our own state that show promise in advancing access to quality care or enhancing the financial viability of community practices. Our experience is that many of the innovators are working in relative isolation, often below the radar of academic medical centers traditionally focused on improving the efficacy of care. We believe that broader networking and public discourse will help move the process along. It is the intent of this Journal issue to spur dialogue, not about whether primary care needs fundamental change, but rather how to do it in such a way that access and quality of care are improved while ensuring a viable primary care delivery system.

It is important to set some bounds on the discussion. A premise of this issue is that it is unrealistic to look to individual physicians alone to rectify the pervasive issues of access and quality in primary care. Work from the Duke University Department of Community and Family Medicine has illustrated quite clearly the impossibility of incorporating all evidence-based preventive and chronic care guidelines into our current modes of practice. To fully achieve current recommendations for an average panel of 2,500 patients, a physician would have to dedicate 7.4 hours per working day to preventive services alone (to the exclusion of acute and chronic care).[52] As emphasized in the IOM Quality Chasm Report, "Trying harder will not work. Changing care systems will."[29]

A second premise of this issue is that our focus is limited to office-based primary care in community settings. Dentistry and public health have been largely excluded from the American concept of primary care for at least two generations, and the marketplace has further "carved out" a large component of mental healthcare in recent years. The rapid spread of hospitalists, especially in urban centers, also has potential to fundamentally alter relationships between primary care practices, hospitals, and communities. Finally, entities outside of primary care, notably large businesses and insurers, are increasingly developing programs of disease management that overlap with initiatives

Table 2.
Traditional versus New Model of Practice

Traditional model	New model
Systems often disrupt the patient-physician relationship	Systems support continuous healing relationships
Care is provided to both sexes and all ages; includes all stages of the individual and family life cycles in continuous, healing relationships	Care is provided to both sexes and all ages; includes all stages of the individual and family life cycles in continuous, healing relationships
Physician is center stage	Patient is center stage
Unnecessary barriers to access by patients	Advanced Access by patients
Care is mostly reactive	Care is both responsive and prospective
Care is often fragmented	Care is integrated
Paper medical record	Electronic health record
Unpredictable package of services is offered	Commitment to providing directly and/or coordinating a defined basket of services
Individual patient oriented	Individual and community oriented
Communication with practice is synchronous (in person and by telephone)	Communication with practice is both synchronous and asynchronous (e-mail, Web portal, voicemail)
Quality and safety can be assumed	Processes are in place for ongoing measurement and improvement of quality and safety
Physician is the main source of care	Multidisciplinary team is the source of care
Individual physician-patient visits	Individual and group visits involving several patients and members of the healthcare team
Consumes knowledge	Generates new knowledge through practice-based research
Experience-based	Evidence-based
Haphazard chronic disease management	Purposeful, organized chronic disease management
Struggles financially, undercapitalized	Positive financial margin, adequately capitalized

presented in these articles. Though rarely acknowledged, the implications of these trends are substantial, and have been only partially evaluated. We recognize, but cannot address fully, the need for further dialogue about the role of practices in these larger issues of public health promotion, prevention, and disease management.

Addressing the Business Model: Low-Overhead Models of Practice

In recent years, much attention has been given to the rapid spread of practices developed to counter the failing business model of traditional primary care. Examples include hospitalist practices, in which the hospital bears the vast majority of costs of staff and systems, exclusive nursing home practices, and niche practices limited to home care. In this issue, Dr. Brian Forrest's practice provides a representative example of the concept of dramatically reduced overhead extended to traditional primary care office practice.[53] Traditional primary care practices have among the highest overhead rates of any office-based medical practice—often exceeding 50-60%. Dr. Forrest and others have been able to demonstrate the practical consequences of reducing overhead below 25% of total costs: appointment lengths of 30 minutes, with greater time to address prevention and chronic disease, improved patient satisfaction, and the opportunity to see people who can not afford traditional care. The expense break-even point of three-to-five patients per day is remarkable, and Dr. Forrest's attention to the sources of overhead, from staffing to facility maintenance, is instructive to anyone working in a traditional environment. Given the rapid escalation of copays and deductibles, the experience of Dr. Forrest's patients is instructive: they pay less out-of-pocket for a history and physical exam, as well as standard and screening tests than would be required for copays under many insurance companies. It is important to note that Forrest and others do not yet offer data about overall cost and quality of care over time. Still, the experience of his practice and others like it raises the question of the incremental value of oversight and quality interventions that insurers provide—how much does it cost and how much is it worth?

"...it is unrealistic to look to individual physicians alone to rectify the pervasive issues of access and quality in primary care."

Low-overhead practices are not yet for everyone, however. While Forrest and others have been successful in specific settings, with favorable demographics and a charismatic clinical leader, other primary care providers attempting to adopt the model have failed. It is important to learn what factors influence success, and how such practices can be integrated into a larger local health systems, including hospitals and specialty care. Similarly, it will be important to develop the model further with more explicit attention to chronic disease management and care outcomes. The most important priority, however, is to explore the viability of the model among more disadvantaged populations. Dr. Steven Crane describes early experience with low-overhead practices targeting indigent patients, and discusses challenges to implementing this model in underserved communities.[54]

Advanced Access Scheduling: Doing Today's Work Today

Advanced Access, also known as Open Access, refers to a way of organizing a practice to allow much improved access to care. The basic premise is that patients should be able to get an appointment the same day that care is needed. This requires a fundamentally different approach to patient scheduling—practices must anticipate demand to assure that enough open slots are available for same-day requests. The transition to Advanced Access is challenging—requiring substantial changes to clinician templates, front-desk routines, and telephone protocols, with a difficult period of "working down the backlog" in which both previously scheduled appointments and same-day appointments are being seen.[55,56] Successful practices report a significant reduction of missed appointments, improved financial performance, and significant improvements in patient and physician satisfaction. In this issue of the Journal, Drs. John Anderson and Carlos Sotelango provide a case study of the transition to Advanced Access in a family medicine practice, with an illustration of the use of metrics and iterative process improvement methods key to successful implementation.[57] Dr. Greg Randolph's commentary addresses potential advantages and problems in extending the Advanced Access model to subspecialty practice.[58]

Several unanswered questions remain, however, about the feasibility of Advanced Access scheduling in varied settings. First, how robust is the business model? How long do financial benefits last? Advanced Access requires specific and potentially costly infrastructure—can the practice environment afford it? Will local insurers pay for combined services, such as preventive and acute care, provided at the same visit? Such features, while appreciated by physicians and patients alike, are not sustainable without reimbursement. A second issue is the incorporation of chronic disease care into Advanced Access. Patient-driven appointment scheduling may improve patient satisfaction, but patients with chronic disease and other conditions need regularly scheduled visits—whether or not the patient takes the initiative to ask for them. We may need to move beyond Advanced Access to a concept of organized access, to incorporate both patient-demanded access and practice-initiated visits for focused chronic disease care.

Disease Management in the Primary Care Setting

Recognition that the majority of patients with chronic illness do not receive optimal treatment has motivated the redesign of primary care around improved chronic disease management in recent years. The chronic care model, as envisioned by Edward Wagner and colleagues at Group Health Cooperative of Puget Sound, posits that higher-quality care necessitates "system reform in which informed, activated patients interact with prepared, proactive practice teams."[23] Innovation in chronic care disease management has six interrelated components: support for more effective patient self-management beyond traditional didactic patient education; clinical information systems to include patient registries and treatment planning reports, delivery system redesign with coordination of multidisciplinary caregivers; clinician decision support through evidence-based practice tools; healthcare organizational support for chronic disease improvement; and integration of community resources.[59]

Several practice models for improving chronic disease management have emerged in recent years, traditionally focusing on high-cost diseases such as diabetes, congestive heart failure, and asthma. Many disease-specific chronic care management initiatives have been shown to improve clinical outcomes and reduce healthcare costs or lower the use of more costly healthcare services.[24,60,61] Successful models can be found in a wide variety of practice settings, including integrated delivery systems (such as Group Health Cooperative of Puget Sound in Washington, or Kaiser Permanente of Northern California), private practices, and community health centers.[23] Such initiatives typically emphasize patient self-management support, and may involve case management or interdisciplinary team approaches, group visits, or planned disease-focused visits, reminder systems and physician performance feedback, and enhanced clinical decision support through technology.[23,62-65]

Despite these promising examples, chronic care model components have not been widely adapted into individual practice settings. Internal and external obstacles to practice redesign, related to time and money, present major challenges to community practices. Additionally, a focus on a single chronic disease state may be both counter-intuitive and counter-productive in community practice. Primary care patients typically arrive with multiple concerns unrelated to their chronic disease and often have multiple co-morbidities that influence care and outcomes, such as coexisting disease, poverty and underinsurance, and language difficulties or illiteracy. Unlike targeted disease management programs, family physicians are faced with the management, on average, of more than three problems per encounter (with an average of 4.6 problems per encounter for diabetic patients).[66] It is important to recognize, then, that tailoring disease management programs to patients seen by community-based primary care practitioners, rather than by specialty groups or academic centers, will require further research and refinement.[67]

For this issue of the Journal, Drs. Thomas Wroth and Joseph Boals have provided a commentary[68] that focuses on improvement of asthma in a community pediatric practice, and illustrates how a rapid cycle quality improvement approach can significantly improve both process and outcome measures of quality. Dr. Samuel Weir reviews the experience of Sandhills Pediatrics and describes the broader lessons learned for developing disease management programs in primary care.[69]

Electronic Health Records

The paper medical record utilized by the vast majority of primary care providers has many disadvantages, including illegibility, inaccessibility to multiple providers of care at the time and place needed, and segmentation with multiple volumes and multiple storage sites. Comprehensive electronic health records (EHR) include not only the clinical record (with problems, medication lists, health maintenance information, reminder systems, and population health improvement capacity), but also scheduling systems and support for billing and electronic communication with insurers, pharmacies, and patients. Electronic health records hold great promise for improving both quality of care and clinical efficiency.[70,71]

Other countries have implemented highly successful national programs to promote EHR use. In Australia, 70% of general practitioners used computers in their consulting rooms in 2000 compared to 15% in 1997. In England, 98% of general practitioners have access to EHR; nearly all use it for prescription refills, and 30% report that their practices are paperless.[72] There are signs that similar transitions are coming in the United States. The American Academy of Family Physicians (AAFP)and its Center for Health Information Technology has led a national initiative to promote electronic health records, leading to a dramatic change in the market for EHRs, including falling costs and market recognition that transition costs are substantial, national efforts to develop standards for EHRs among vendors, and the Center for Medicare and Medicaid Services' initiatives regarding the nature of the continuity record and the development of pay for performance reimbursement. The AAFP currently estimates that 12% of their members use EHRs, and that this will rise to 50% within two years. The use of EHR is beginning to grow in other specialties as well.

It is important to note that the comprehensiveness of the computerized record is key to its cost-effectiveness. Replacing dictation cost and filing clerks reduces the expense structure in the practice; facilitating Advanced Access scheduling and pay for performance premiums also add income. As a part of the Future of Family Medicine initiative, the Lewin group was commissioned to assess the economic feasibility of a "New Model Practice." In an economic analysis of the new model of practice compared with best available estimates for current private practices, the EHR accounted for the single greatest positive change to clinician compensation, and most of the income gain that made the new model practice financially vigorous.[73]

It is also important to understand that current technology is clearly transitional; there is a great divide between office-based systems (and their vendors) and large hospital-based systems of care. Substantial organizational, regulatory and technical barriers to bridging this gap exist. Early efforts to raise the technical standards of communication between office and hospital systems have been seen, but it will be impossible to fully track outcomes without easy-to-use interfaces between offices and many other sources of data relevant to patient care, such as hospitals, nursing homes, pharmacies, insurers, and health departments.

The front-end costs of implementing an electronic health record present an insurmountable barrier to many community practices, despite the promise of long-term cost savings for most practices and an eventual decrease in total United States healthcare costs with widespread application of this kind of information technology.[73] The national Institute of Medicine has argued that government and large private purchasers of healthcare should provide incentives to practices to make such changes, and such initiatives are becoming more common.[62]

Dr. Karen Smith's commentary in this issue of the Journal[74] describes the transition to an EHR in her practice, in a relatively poor, largely African-American rural community. It is clear that the transition to EHR is a major event in the lifecycle of a practice, and that the costs are large, both in direct expenses and in organizational efforts. Dr. Smith currently serves as the President of the North Carolina Academy of Family Physicians, and she has made adoption of EHRs the focus of her presidential efforts across the state. Dr. Edward Ermini provides further perspective on the development of EHRs and the creation of a national health information network.[75]

Electronic Communication with Patients and Payers

Rapid advances in information technology now allow integration of the electronic health record with common practice management activities and billing systems, including electronic communication with payers, leading to considerable reduction in practice administrative costs. In a similar way, communication with patients via e-mail offers an attractive way to enhance patient-centered care and to improve access and timeliness of interventions. E-mail communication between patients and providers allows for closer surveillance of disease status or response to therapy, tracking of the receipt of clinical preventive services or consultative care, and rapid feedback of test results.

Applying such technology, however, incurs substantial costs to the clinical practice and to the individual practitioner. The acquisition of equipment that can make it possible for physicians and office staff to interact through e-mail with patients from multiple locations, and perhaps through wireless connectivity, requires the investment of resources and the acquisition of minimal skills in the use of such technology. Perhaps more importantly, it remains unclear how physicians can be reimbursed for the time required to respond to and document patient-initiated e-mail correspondence. Similar issues arose as communication with patients via telephone expanded dramatically.

Dr. Spencer's commentary in this issue of the Journal[76] describes the initial experience of establishing a web-based interface with patients in a family medicine setting. His report makes it clear that setting up e-mail communication is much more involved than just having e-mail contact with patients. In addition to privacy issues, many different functions must be served by the interface, such as arranging appointments, referrals, and pharmacy refills, which are most effectively addressed by non-physician staff. Dr Komives's serves as the Senior Medical Director for Network Services at Blue Cross and Blue Shield of North Carolina. Her commentary discusses advances in electronic communication between clinicians and patients.[77]

New Delivery Models for Community-Based Care

Beyond practice-based clinical and administrative initiatives, an increasing number of primary care providers are participating in external initiatives to improve comprehensive disease management or reduce barriers to care in their communities. Individual practices, especially solo or small group practices and rural or community health centers, often lack sufficient internal resources to conduct major quality improvement initiatives or evaluate and adapt new innovations for their practice settings. In recent years, federal and state agencies have developed programs through which health centers or practices can participate in collaborative networks addressing specific issues in patient care. The intent is to build strategic partnerships and develop infrastructure and expertise for the incorporation of new evidence-based models of care into clinical practice. The federal Bureau of Primary Health Care collaboratives, targeting community health centers serving underserved populations, have focused on preventive services and chronic disease management (cancer screening, diabetes, depression, asthma, and cardiovascular diseases) as well as center operation (Advanced Access and patient flow redesign).[78] Similarly, the state-based North Carolina Chronic Disease Management Collaborative has assisted private and not-for-profit primary care practices in implementing comprehensive diabetes and cardiovascular disease management models, achieving substantial improvements in evidence-based clinical processes and clinical outcomes since January of 2003.[79]

An extension of these ideas has led to the development of regional networks involving all primary care clinicians, county health departments and hospitals in particular geographic regions. The stimulus for these initiatives has come from the North Carolina Medicaid Program in the North Carolina Department of Health and Human Services (NC DHHS). Over the last ten years, the Division of Medical Assistance in the NC DHHS has developed models of regionalized care focused on quality improvement and cost control. Currently, 3,000 physicians throughout North Carolina are participating in the Community Care of North Carolina (CCNC) initiative. This program provides community infrastructure and management tools to allow providers to more effectively implement evidence-based clinical care and more efficiently utilize community resources. With the involvement of all providers in a region, these networks provide an opportunity for substantial changes in the organization of care in a community, such as increased after-hours care availability in private offices and centralized immunization programs at the local health department. An external evaluation of the overall community care model by Mercer estimated approximately $120 million of savings to Medicaid as the result of community-based population management.[80] A savings of $4.6 million in savings were realized between 2000-2002 from the asthma and diabetes disease management programs alone.[81,82] CCNC programs have demonstrated clearly that it is possible to improve patient care and decrease costs.

Dr. Allen Dobson's commentary in this issue of the Journal[83] describes the development of the CCNC pilot program in Cabarrus County, underscoring the new organizational structures necessary to re-organize care in a community, the challenges to organizing care in this way and the early outcomes in that county. Dr. Charles Willson, President-Elect of the North Carolina Medical Society, describes the development of a similar CCNC model in Pitt County.[84] CCNC programs are now being implemented in every county in North Carolina.

The Outlook for Primary Care

Community-based primary care clinical practice appears to be at a crossroads in its history, resulting from the simultaneous demands of a rapidly increasing population of patients in need of timely acute, preventive, and chronic care; and the pressure to operate within ever narrower bounds of financial accountability and cost constraint. Add to these pressures the growing expectation that physicians will provide the very best, evidence-based diagnostic and therapeutic interventions, and one has a recipe for extreme frustration among primary care specialties whose financial margins are already minimal. Despite the commitment of primary care physicians to the provision of high-quality care to their patients, deficiencies in healthcare access and quality are widespread and pervasive, and the long-term viability of current practice models may be in question. Hence, innovative ideas about how to redesign certain basic aspects of primary care practice, and how to combine the resources of healthcare providers at the community level, are worthy of serious examination.

In this issue of the Journal, several contributing authors have offered illustrations of recent developments addressing the organizational aspects of primary care practice. Examples range from narrowly focused, practice-based improvements in patient flow or communication, to comprehensive, clinical quality improvement initiatives, to sweeping community-wide reorganization of care. What these innovations share is a recognition of the critical need for fundamental changes in primary care, and a commitment to better serve patients and communities.

While visionary clinical leaders are critical to the successful negotiation of current challenges to primary care, primary care practices do not shoulder the responsibility for addressing the needs of the population alone. There is a great need for health research to move beyond the traditional questions of efficacy and effectiveness to questions of population health impact, which requires attention to the development, dissemination, implementation, and maintenance of improved practice arrangements. Active planning for the diffusion of valid research findings into routine clinical practice is necessary to close the gap between the academic generation of knowledge and the clinical care of the patient.[85,86] Conversely, it has been said that "to obtain more evidence-based practice, we need more practice-based evidence."[87] Until a solid evidence base exists for clinical and administrative primary care practice innovations, progress toward the goals of improved quality and access to care for communities, and improved operational margins for practices, is likely to be slow and sporadic.

Policymakers and other stakeholders in health system costs, such as employers, hospitals, private insurers, Medicare, and Medicaid, also have an interest in improving primary care systems. Creating a favorable business case for innovation in primary care requires that the long-term cost savings that result from improved preventive and chronic care accrue to the organization paying for the improvements.[24] Any substantial innovation in healthcare practice requires an initial investment of time and money. Clinical information systems, which play a central role in streamlining administrative efficiencies and providing a framework for improved preventive services delivery, chronic disease management, and practice-based continuous quality improvement, are particularly expensive and difficult to implement for many practices. Community practices need a financial environment that helps them to implement positive change. Arguably, third-party payers and other stakeholders who invest in primary care practice innovation, by offsetting start-up costs or rewarding superior performance with increased reimbursement rates, will reap the rewards through improved health status of the population served and decreased dependence on more costly care for avoidable complications.

Conclusions

Community practices today are the direct descendants of general practice in the 1940s and 1950s, although the health and healthcare problems faced by today's communities are quite different. Primary care must change radically to survive the financial pressures of today's healthcare environment while addressing widespread systematic deficiencies in healthcare access and quality. Visionary clinical leaders have demonstrated innovative ways to improve the financial margins of their practices, improve access to timely care for their patients and communities, and deliver higher quality care for patients with chronic disease. Refinement and diffusion of such innovations will require greater investments of both research and capital, with the active and creative engagement of all of us who desire better health for our communities. **NCMedJ**

Low-Overhead Practice Models and the Uninsured:

Harnessing the Power of Small Scale to Address Large Unmet Health Needs

Steven D. Crane, MD

Despite a decade of extraordinary economic growth and low unemployment, fewer Americans had health insurance in 2000 than at the beginning of the decade. One third of working North Carolinians (2.5 million people) between the ages of 18 and 64 are not covered by health insurance.[1] Minorities are much less likely to have insurance; 40% of Hispanics and 20% of African Americans lack insurance compared to 12% of whites. Furthermore, lower-income Americans are more likely to be uninsured; 30% of those making less than $25,000/year, compared with 8% of those making more than $75,000, lack insurance. Insurance makes a difference. Those without insurance seek needed care less often, are less likely to receive preventive services, and have poorer health outcomes.[2] About 18,000 Americans die each year of treatable diseases because they don't have healthcare coverage.[3] Most of the uninsured are employed full-time, and nearly one fourth work for firms with more than 500 employees.[4] Two thirds have household incomes of $25,000 or more [140% of the federal poverty guidline (FPG)].

Private physicians provide 75% of ambulatory care for uninsured patients.[5] Given that substantial system-wide health reform is unlikely to occur in the foreseeable future, the private sector will likely remain an important part of the healthcare safety net. Nevertheless, financial pressures are eroding charity care in the private sector. Primary care physicians widely report that managed care/Medicare changes have substantially increased overhead in outpatient practices, reducing time with patients and increasing physician dissatisfaction.[6] The number of United States-trained medical students choosing careers in primary care has steadily declined for the last five years.[7] Although there are likely multiple reasons for this decline, the perception that primary care is a less satisfying medical career is probably an important one.

Examples of Low-Overhead Solo Practices

Gordon Moore, MD, has demonstrated that a primary care practice can dramatically lower costs by "going solo," hiring no staff, and using technology and lean systems to manage a practice's "non-physician" tasks.[8] This allows longer, more meaningful interactions with patients, improved ability to address their chronic needs, while maintaining a salary in excess of $150,000 and averaging only 12 patient visits per day (or about half the daily volume for most family physicians). Innovative use of electronic medical records, communication technology, and Advanced Access scheduling[*] allows patients unparalleled access to their primary care physician, improving the quality of their care, and enhancing professional satisfaction. Closer to home, Dr. Brian Forrest has demonstrated similar results from a practice opened in April 2002. Patients are charged a flat office visit of $45. Lab tests are charged based on cost and yield the practice a small net profit of $15 per test. The practice nets $165,000 per year with a practice volume of 15 patients a day/44 weeks a year. Both of these practice examples share a

> *"Although this practice model may be very appealing, physicians will encounter many barriers to actually opening such a practice."*

---

[*] Advanced Access scheduling is a patient-scheduling model that emphasizes the provider seeing patients on the same day the patient calls for an appointment.

Steven D. Crane, MD, is the Program Director for the Hendersonville Family Practice Residency Program. He can be reached at Steve.crane@pardeehospital.org or 741 6th Avenue West, Hendersonville, NC 29739. Telephone: 828-696-1255.

low-volume, low-overhead model approach, but differ in that Dr. Moore accepts insurance whereas Dr. Forrest accepts only cash payments for services and allows patients with insurance to file their own claims for reimbursement if they wish. Both practices are located in urban areas.

Dr. Kate Sloss of Bat Cave, North Carolina has established a high-volume, low-overhead model in an isolated rural community. Although she employs three staff members (to Moore's none and Forrest's one), her overhead is still substantially below Medical Group Management Association benchmarks[9] for family physicians and enables her to see 15% of her patients on a sliding-fee basis ($10 per visit) and a large proportion of Medicaid and Medicare patients, with less than 15% commercial or management care coverage. She achieves these cost reductions from a lower rent structure through a community church, very low capital costs through donated or used equipment and furniture, and administrative overhead that is paid through lab revenue from a local provider group with which she is affiliated.

Each of these practices shares some very important features. First, they are solo practices providing personalized service to patients with Advanced Access scheduling. Each reports high levels of patient satisfaction, due to Advanced Access scheduling, and higher physician satisfaction, because they are able to focus more of their attention on taking care of patients' needs and less on managing complex organizations. Second, precisely because these practices have lower overhead, they report profitability at volumes or in locations that more traditional practices would find difficult. Finally, although each practice approaches the revenue side of the practice differently, the revenue is sufficient, given the practice model, for the physician to enjoy a competitive net income.

Will Providers Who Use Low-Overhead Models Continue to Provide Quality Care to the Uninsured?

Low-overhead practice models could play an important role in addressing the failings and gaps in the present system of primary care for the uninsured. As noted above, two thirds of families without health insurance have incomes greater than $25,000 (or 140% above FPG) and potentially could pay the cost of primary care if it were more reasonably priced, as it may be through achieved low-overhead practices. Because one third of all adults aged 18 to 64 in North Carolina do not have health insurance, this population represents a great untapped market for primary care in nearly every community. Physicians choosing to establish these types of practices could choose to locate nearly anywhere and quickly become profitable.

While it may be inevitable that these types of practices will become more commonplace as experience with the model grows, it is not at all clear if the practices will serve the needs of the uninsured or if they will produce the type of quality and breadth of services called for by the Future of Family Medicine Project.[10] Practitioners in low-overhead practices may very well either continue to provide care to the insured population, enjoying higher incomes with less stressful work styles, or to those uninsured with higher incomes who can afford higher out-of-pocket fees for "concierge" type service.[11] It is also unclear if solo practitioners will perform any better with regard to quality, safety, or evidence-based practice standards than those in more traditional practice models. It is quite likely that without the peer oversight and role-modeling, which may occur in group practices, practitioners may perform less well in these areas.

Barriers to Implementing a Low-Overhead Model

Although this practice model may be very appealing, physicians will encounter many barriers to actually opening such a practice. First, as in any practice, there are a myriad of details and tasks that need to be successfully completed before opening the doors. These include developing a business plan, securing working capital, finding a location, negotiating a lease or building purchase agreement, finding equipment and supplies, setting up accounting and financial procedures, and developing an array of necessary forms, to name a few. Family physicians just graduating from residency, or even those who have previously practiced in a group where such details are managed by others, may lack the confidence, experience, or entrepreneurial spirit to start such a solo practice. Second, because this practice model is innovative, banks may be reluctant to extend business loans to someone wishing to start such a practice. Finally, although the idea of having more professional control may be appealing, many may fear becoming professionally isolated. Medical training is typically done in large organizations, and a physician's previous patient care experiences are likely always to have been part of a larger group.

For the low-overhead practice model to meet the needs of low-income patients or isolated communities, it will need to accommodate those who have public-funded insurance, such as Medicare and Medicaid. For instance, Dr. Forrest's practice accepts no insurance and charges a flat rate of $45 per visit. This may be both affordable and a bargain for moderate-income patients, but neither to low-income patients who have Medicaid or Medicare and no physician. Under present Medicare and Medicaid rules, Dr. Forrest couldn't easily begin taking such insurance and continue serving his uninsured clients at a lower rate. Sliding-fee scales for low-income patients and cash discounts may be acceptable ways to accommodate both payment systems into a low-overhead practice, but would probably require further clarification if this model is to become more widespread. Although accepting Medicare and Medicaid would add some complexity and cost to a low-overhead practice, it would nevertheless add some robustness to the model by allowing a more diverse and medically needy patient population.

Access to Specialty Care

Even if these practices could help improve access to primary care for a substantial portion of the uninsured population, lack of health insurance still limits access to more expensive specialty or inpatient services. If a person requires expensive inpatient or specialty care to return to work (or to health) they face a "Sophie's Choice" of getting the care and facing financial ruin, or not getting the care and facing worse health. Strategies that just address the affordability of primary care neglect this critical aspect of access for the uninsured. Uninsured families are likely to remain one illness or injury away from financial ruin if they require such care in order to return to health. According to bankruptcy experts, medical bills contribute to about one-in-five personal bankruptcies, and the states with the highest filing rates tend to have larger-than-average populations of uninsured.[12]

Benefits in Creating Networks

A network of semi-autonomous, low-overhead practices specifically targeting high-need areas and populations could harness the promise of this low-overhead model in addressing the larger goals and needs of the healthcare system. A network could help reduce costs by allowing for group purchase arrangements, sharing of management expertise, and providing start-up know-how and capital. These highly innovative practitioners could also share their solutions to the daily practice tasks, thereby improving efficiency for all in a shorter time frame. A network could help provide professional support and accountability by reporting clinical outcomes for chronic conditions and preventive care, raising the general standard of care in such practices. The lessons learned from this practice model in improving access, patient and physician satisfaction, lowering costs, and clinical outcomes could lead to wider system improvements, if there was an efficient mechanism for monitoring and reporting these innovations.

A network of such practices potentially in partnership with third-party payers could also spur the development of an innovative insurance product that coupled high-deductible catastrophic coverage (generally available at about half the premium of traditional preferred provider organization policies) with a prepaid primary care allowance. Such a primary care prepayment structure of even $15 per month could allow these low-overhead practices to achieve similar revenue and utilization rates, but allow primary care to be even more accessible while giving working families substantial protection from ruinous medical costs. This insurance product could help small businesses extend employer-based coverage for primary care at a much lower cost than is presently available even through group purchase arrangements.

Improving access, reducing racial and economic disparities in health status, and improving patient outcomes should be high priorities of healthcare reform. Efforts to expand health coverage or expand subsidized healthcare centers are expensive and unlikely to be undertaken in a climate of other pressing national concerns. Although other individual practitioners may adopt a similar low-cost practice model, as demonstrated by the experience of Drs. Moore and Forrest, unless the model specifically targets underserved populations in the network context, health outcome improvements will be sporadic. And unless there is a mechanism to share the risk of catastrophic illness, the uninsured will remain excluded from the benefits of expensive care that can restore health and function.

Success of this type of practice could encourage the use of this model to serve unmet needs in many communities. Demonstrating that low cost and sustainability, coupled with accountability to achieve measurable outcomes, may hasten the development of such networks elsewhere using locally available resources. **NCMedJ**

Access Healthcare:
A Model to Provide Improved Access to High-Quality and Affordable Healthcare

Brian R. Forrest, MD

The Access Healthcare model is based on a combination of new and vintage approaches to patient care that work together to provide reasonable solutions to some of the current problems in the healthcare system. The hypothesis of the Access Healthcare model is that if practices can decrease overhead and collect payments at the time of service (i.e., eliminating practice-based insurance billing), then they can reduce fees and increase revenue.

I performed an evaluation of several existing North Carolina family medicine practices and then opened a practice based on a model that would address some of the problems that had been observed. This commentary describes the Access Healthcare model and discusses what has been learned from it.

Background

The Access Healthcare model began as an observational study of existing practice models in the piedmont and triad areas of North Carolina. This particular evaluation began five years ago (2000) and involved several different practices and more than 50 providers. Various types of offices were studied, including a large group practice, a small group practice, and a multi-specialty group practice. The main aspects observed were patient flow, time spent in the waiting room, billing, patient check-in and check-out, verification of insurance, and DNKAs (number of patients who did not keep their appointment). For 42 of the providers, the average charge was $93 per patient visit, the average collection was $39 per patient visit, and the total average overhead was $50 per patient visit. Even though this is an average, it represents an $11 loss per patient seen. Additional study over a 16-month period and review of other innovative approaches from articles in *Family Practice Management, Family Practice News, American Medical Association News*, local newspapers, and magazines, helped me conceptualize the Access Healthcare model.

For three and a half years, the Access Healthcare practice (located in Apex, North Carolina) has provided continuity care for more than 2,000 patients. Practice overhead is consistent at 25%. Charges/collections average $65 per patient. The net practice profit is $48 per patient.

The $65 average is made up of the $45 office visit added to the average lab and supply cost of about $20 per patient. This means that the supplies and labs are paying the overhad and the office visit charge is basically the net profit for each provider. This makes it possible to charge less, see fewer patients, and still net a higher reimbursement per encounter than most providers due to the reduced overhead and higher collections. Also, it only takes about three to four patients per day to break-even (and pay overhead costs) with this model.

The Access Healthcare Model Key Concepts

Patient Cost and Charges. At Access Healthcare, costs are less than half what they are in other practice settings, which results in patient charges being significantly lower. Since practice costs are lower, these savings can be passed on to the patient. Cost reductions come primarily from reduced overhead, which normally accounts for 50-60% of a "traditional" practice's costs. Patients understand and appreciate the shared cost savings and are, therefore, more likely to return and to "spread the word." Word of mouth from satisfied patients represents the largest new patient referral base for the practice.

Collections. With patients expected to pay the full balance at the time of service, collection rates are two times that of other practices.[1] The net result of collecting the payment sooner and reducing the costs associated with collecting the revenue is a collection rate of more than 99% after three and a half years.

Office Visit Length. The true joy in practicing medicine is spending time with patients and helping them with their health problems. In most practices, the high volume of patients that must be seen reduces the time a clinician can spend with each patient. The Access Healthcare model helps optimize patient

Brian R. Forrest, MD, is the founder of Access Healthcare, PA. He can be reached at questions@acchealth.com or 1031 W. Williams St., Suite 106, Apex, NC 27502. Telephone: 919-363-0190.

encounters by increasing the amount of time the provider can spend with each patient. Being able to spend enough time with the doctor is the top reason that most patients give for returning to the practice. People are willing to spend money on something they value, and they value time with the doctor. This is truly a win-win situation for both the doctor and the patient.

Patient Satisfaction. If patient demand is a barometer for patient satisfaction, then patients are very satisfied with this model of care. The practice averages 15 new patients per week, even when no advertising is taking place. Anecdotal evidence also gives us reason to believe the patients are satisfied. In many informal encounters in the town where the practice is located, patients report a high level of satisfaction and persons who have never been to the practice report that they have heard very positive things about Access Healthcare.

The Access Healthcare Model: Implementation

In April 2002, I opened the Access Healthcare Practice in Apex, North Carolina. Apex is a mix of suburban and rural, well-insured and uninsured, and self-employed and under-employed. Within a two-mile radius of the Access Healthcare office are million dollar houses and the local community health center—affluent and indigent. This population mix is reflected very evenly in the practice. Roughly 30% of the patients served in this practice have no insurance at all. Fifty percent have traditional prescription and copay coverage. Another 20% are catastrophically insured with high deductibles or hospital-only coverage.

Decreasing Overhead. Decreasing overhead is crucial to making Access Healthcare viable. Staff size is usually the largest burden for practice overhead. The Access Healthcare practice has one staff person per provider rather than the normal 4.6 per provider, which is the national average.[2] Cross training and investment in each employee is crucial, and keeping turnover low is a must. Each medical office assistant is responsible for scheduling, check in/out, phones, referrals, chaperoning exams, and setting up basic tests like urinalysis and streptococci tests for the provider.

The provider has responsibilities, which are not typical in other practices, such as providing their own phlebotomy, giving injections, and returning and making patient phone calls with lab results. While these activities reduce costs, they also contribute to high patient satisfaction, as the patients are not "handed-off" to others, and they receive lab results very quickly.

Operational costs have also been reduced. Since there is no insurance to file, no billing equipment or software is necessary. Only one computer is needed for scheduling, accounting, and word processing. Due to lower patient volume, minimal inventory is required so there is no concern for wasted storage space or expired medications.

Utility costs are kept low by turning off lights that are not in areas being used and by operating the thermostat on a timer. Easy listening radio run over a wireless intercom for background music saves hundreds of dollars per year over "Muzac" type services.

The Access Healthcare practice even provides its own janitorial services. All duties are split among employees (including the physician). Many practices pay $10,000-$15,000 per year on these services. Access Healthcare employees are asked if they would rather have that amount divided and added to salaries for 15 minutes of work per day or hire someone to do it. Everyone always answers the same way.

Technology can cut costs too. A four-line phone system that uses wireless technology is utilized so the traditional key system with hard-wired lines is not needed. This saved about $7,000 in initial phone costs and has required no maintenance. This system also has an advanced digital answering system that can triage calls and page the provider, so there is no need for an operator or an answering service.

Setting Fees. After analyzing the cost and charge ratios from the practices studied, a flat office-visit fee was initially set at $40 per patient visit (now $45). Whether a patient is in the office for five minutes or 50 minutes, the basic charge is the same for visits with Current Procedural Terminology (CPT)® codes 99211-99215.* The average office visit at the Access Healthcare practice is 30 minutes. The model works because the average visit at a primary care practice is a code 99213 (a 30-minute visit with a problem-focused history and exam and a low-complexity medical decision). Over time, if the practice gets $45 for both a 90-minute physical and a 20-minute visit, this will equate to the average charge for a code 99213.

> *"The true joy in practicing medicine is spending time with patients and helping them with their health problems."*

The Access Healthcare practice charges patients an additional fee for lab tests (based on cost), but pays the lab company directly for the tests. Payment-in-full to the lab companies is certain because Access Healthcare is able to pay companies without rejecting claims due to incorrect ICD-9 codes or diagnosis/CPT mismatch. Lab companies are able to pass on some savings they

---

* Clinicians use the CPT series of codes 99211-99215 to describe the five levels of intensity for evaluation and management services provided in office or other out-patient settings for established patients. For example, a 99211 could be a five-minute visit with a nurse, and a 99215 would be an extensive evaluation and physical exam of multiple medical problems that could take an hour or longer.

realize from not incurring the expenses of billing patients or insurance companies, and their payment is guaranteed. For these reasons, discounts may be as much as 50-90% off list price, which means most patients pay an average of $20-25 for lab tests that would have cost more than $100 if the lab company billed the patient or the insurance company directly.

Scheduling patients. Advanced Access scheduling is used at Access Healthcare. This is beneficial in several ways. For the practice, Advanced Access scheduling cuts lost productivity and revenue from "DNKAs." Advanced Access scheduling also increases the practice's revenue by attracting patients that might otherwise go to urgent care or to the emergency department for non-emergent care. Patients appreciate being able to see their primary care provider on a "same-day" basis when needed, especially when going to an urgent care or emergency department can be much more costly for them. This increases patient satisfaction and patient loyalty to the practice. Many patients who need brief encounters such as flu shots and blood draws appreciate seeing the physician and having minimal wait times for these services.

The scheduling template is filled by scheduling eight to ten patients a day for appointments and leaving the rest of the day for same day call-in or walk-in patients. Normally, same day call-in/walk-in patients fill DNKA patient slots. This arrangement allows each full-time provider to treat 15-16 patients each day—a lighter patient load than for providers in a traditional practice. This means a less hectic office. It makes it easier to maintain privacy, cuts the risk exposure for medical mistakes and malpractice, and allows time for adequate documentation during the workday rather than dictating at the end of the schedule.

House Calls. Access Healthcare has gone back to yesteryear by reinstating house calls. This can be done without the contractual restrictions for charges that exist in insurance agreements. It is a joyful way to practice medicine, and physicians around the country are going back to it. House calls are great for homebound patients who are unable to get other physicians to come out to their house. The Access Healthcare practice charges a $150-cash rate for house calls.

Patient Billing. The Access Healthcare model makes it easy for patients to know what their bill will be and increases the underinsureds' ability to pay at time of service. One reason for this is that all charges are clearly identified on an *a la carte* sign in the waiting room.

However, a major portion of the patients have health insurance. When the practice opened, it was anticipated that 90% of patients would be uninsured. However, as the word of mouth about Advanced Access and hour-long office visits spread, patients who could submit their own insurance and get reimbursed (preferred provider organizations, State Employees, etc.) began to fill the practice. These patients now represent the majority (about 65%) of the practice.

Many insurance co-payments for urgent care visits are $50 now—more than a code 99215 at Access Healthcare—and some plans' office-visit co-payments are $35 or $40, which is very close to the office-visit charge at Access Healthcare. For most plans, patients can simply submit their Access Healthcare encounter form/receipt, and their insurance company will reimburse them (less their respective copay for out of network providers). While most physicians say they wait months on reimbursement from insurance companies, most Access Healthcare patients report receiving reimbursement within a few weeks. In the current healthcare system, this is due to the fact that physicians have surrendered their power to insurers by signing contracts. However, patients, who are the clients of the insurer, have the real power. If claims were denied or delayed to patients who filed, those patients would likely pick another insurer or pressure their employer to do so.

> *"Most patients have a very positive reaction to this ... Insured patients value increased access and longer visits ... Uninsured patients are ... charged a fraction of what they are charged at an office that accepts insurance."*

Medicare. The Balanced Budget Act of 1997 gives physicians and Medicare patients the freedom to privately contract outside the Medicare system. If a physician opts-out of Medicare, he or she agrees to bill patients directly and forgo any payments from Medicare. Once out, the physician may not submit claims to Medicare for any Medicare patients for a two-year period. Since Access Healthcare has never taken Medicare, the practice can treat Medicare patients as long as Medicare patients sign a private contract with the physician/practice stating that no charges incurred at Access Healthcare can be billed by the practice or by the patient to Medicare.

Patient Reaction. Most patients have a very positive reaction to this practice model. Insured patients value increased access and longer visits more than the inconvenience of filing their own insurance. Uninsured patients are also very receptive to this model. They are charged a fraction of what they are charged at an office that accepts insurance. Uninsured patients at traditional practices are often paying more for healthcare than anyone else, when they should be the ones getting discount care. This occurs since practices that file insurance have to charge the uninsured the same or higher rates due to insurance contracts and increased overhead.

Outcomes: Retention of patients has been outstanding with greater than 98% of all patients keeping Access Healthcare as their primary care provider after three years. There only have been around 15 hospitalizations out of this patient population exceeding 2,000 over last three years, despite the fact that many patients have multi-system diseases and 10% are more than 65 years of age. Because of the time spent with patients, providers can practice with good continuity and within current treatment guidelines. The practice participated in a study being conducted by Wake Forest University based on chart audits, which found that, for diabetes and hypertension management, the Access Healthcare practice is in the upper echelon of practices' adherence to current recommended standards.

On several occasions, estimates of the "normal-visit cost" for an insurance-accepting practice have been done, and it has been determined that insurance companies saved approximately $25,000 per month on average and that the insured (as a group) have paid $400 to $500 per month in higher out-of-network copays. The uninsured (as a group) saved $5,000 to $10,000 per month in out-of-pocket expenses over what they might have paid at a conventional practice.

Conclusion

We have learned several lessons. From the beginning, the Access Healthcare practice should have clearly explained and marketed the fact that insured patients could file their own claims and receive reimbursement for treatment at the practice. Many patients are surprised to find out that if they send in the encounter form they get a check back in a couple of weeks. The practice would have benefited from more thorough market research (e.g., local demographics, major employers, etc.) as well.

There are potential drawbacks to this model. One potential drawback is working with insured patients who need out-of-network referrals. This can be a hassle when services require prior approval from an "in-network" primary care provider. For some patients, the co-pay may be higher for an out-of-network provider, and this is the biggest reason for patient attrition, though attrition has been very low. Having a small staff means there is less reserve if illness or turnover occurs. However, the practice is fortunate to have many well-trained volunteers who can step in when needed.

Access Healthcare has been fiscally sound from day one and has never taken out loans for any operating expense. All start-up costs were taken care of through savings accumulated for nine months prior to opening. Expansion plans are under consideration with the potential for several new Wake County locations. The providers at the Access Healthcare practice hope that other physicians will adopt innovative practice models to improve their satisfaction, bottom line, and, most of all, patient care in the coming years. **NCMedJ**

Creating a National Health Information Network:

The Importance of Individual Provider Participation

Edward B. Ermini, MD

Paper kills when it is used to compose medical records, according to Newt Gingrich.[1] He is not alone in voicing that opinion. Powerful leaders including Hillary Rodham Clinton, Patrick J. Kennedy, William H. Frist, and President George W. Bush agree that the current paper charting system used by most medical offices is a problem that needs to be corrected. Our government is currently creating a National Health Information Network (NHIN) that will connect physicians, patients, labs, and hospitals securely and seamlessly. The NHIN will make it easier to evaluate and improve the quality of healthcare delivery systems. Patients will be able to view and supplement their medical record over the Internet and interact with components of the network. Clinicians will be able to manage disease more efficiently, resulting in fewer medical errors and mistakes. The success of this network will depend upon whether medical groups of eight or fewer providers participate, since these groups deliver the largest proportion of healthcare in the United States.

> *"The success of this network will depend upon whether medical groups of eight or fewer providers participate, since these groups deliver the largest proportion of healthcare in the United States."*

The concept of the "paperless office" has been discussed for more than 20 years, and it is an idea that has been slow to materialize. Many early adopters of electronic medical record (EMR) systems have had bad experiences. A combination of technology that was difficult to use and providers resistant to changing their ways has kept the digital office from reaching widespread use. Early EMR systems offered little in the way of compatibility with other systems, often relying on proprietary software that required frequent upgrades and revisions. It has been said that 50% of EMR installations have failed, and experts attribute those failures to a lack of planning, training, and ongoing support through the transition and afterward. Vendors were focused on sales, and physicians had unrealistic expectations about the ease of transition. The workflow changes that were needed in order for the systems to work were never implemented, leading to failure and lost revenue. Most providers now acknowledge that computerized medical records will play a role in the future, but many feel compelled to wait as long as possible to adopt them. There is reluctance to put forth the money and effort now because more powerful systems and financial incentives will likely be available in the future.

Early adopters of EMR systems often saw computers as an efficient way to generate complete office notes that would meet the documentation criteria created by government regulations. Although many offices were able to store records electronically, notes had to be printed or faxed when other providers needed information. Electronic communication between providers was hindered by proprietary software that was incompatible with programs developed by other vendors. With less than 20% of practices utilizing electronic records, it was unlikely that other offices would have the capability to accept digital data if it were made available.

Creating Data Transfer Standards

In order to achieve interconnectivity between physician offices, our government realized that data transfer standards were necessary. In other areas of commerce such as transportation, telecommunications, and banking, the government has set the national standards in order to let developers know how to design their products. The goal was to make medical records available to providers through processes similar to those used by

Edward B. Ermini, MD, is in the private practice of otolaryngology in Lumberton. He can be reached at eermini@carolina.net or 4303 Ludgate Street, Lumberton, NC 28358. Telephone: 910-738-4226.

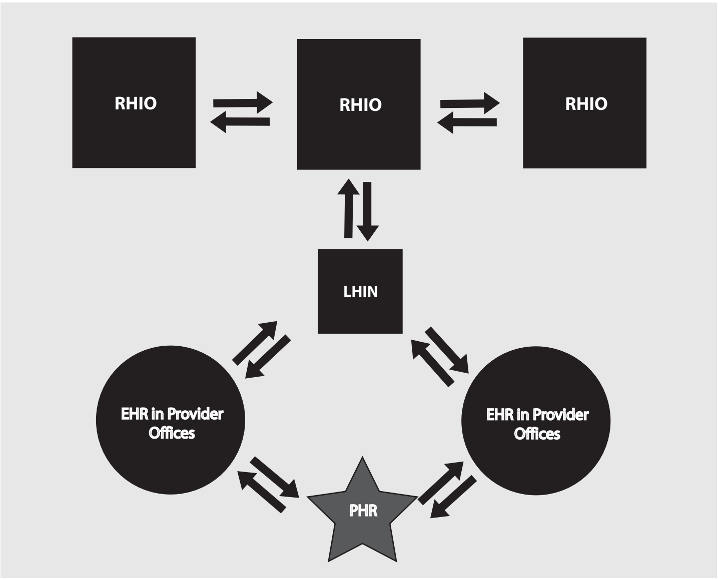
banks to share account information for automatic teller machines.

Organizations like Health Level 7® (HL7) have been working for years on data transfer standards. Most vendors distributing sophisticated software packages use versions of these standards already. In 2004, Secretary of Health and Human Services Tommy Thompson announced the creation of the Office of the National Coordinator for Health Information Technology (ONCHIT), and named David J. Brailer, MD, PhD, to the position. The coordinator is responsible for promoting widespread use of the NHIN by 2010. One of Dr. Brailer's first tasks was to create the Commission for the Certification of Electronic Medical Record Systems. This summer, the first vendors will receive certification. Certification means that the system will be able to exchange data at a minimal level between other certified systems. It opens the way for a National Health Information Network.

The basic components of the Health Information Network will be the electronic health record (EHR) and the personal health record (PHR). The EHR will be created in provider offices or hospitals and will generate and store clinical encounter information. For the first time in history, patients will participate in the creation of their own medical records through the PHR. Elements of the PHR will be imported into the EHR during a clinical visit. The complete EHR will be portable and available through the National Health Information Network with necessary safeguards to protect patient privacy.

The NHIN will be composed of Local Health Information Networks (LHIN) and Regional Health Information Networks (RHIO) linked via the Internet (see Figure 1). Health information will not be stored in one massive central data storage area. Instead, a partnership between patients, hospitals, and providers will allow the National Health Information Network to exist. RHIOs are now emerging in several parts of the country as a way of promoting the development of LHINs. For example, a North Carolina RHIO is being proposed by the North Carolina Healthcare Information and Communications Alliance (NCHICA) and will likely stimulate health infrastructure development in our state.

Figure 1.
National Health Information Network



The Advantages of a National Health Information Network

There are tremendous advantages for clinicians if a National Health Information Network is created. By using a certified EHR system, a healthcare provider should be able to obtain current medication lists, drug allergy information, demographics, labs, and x-rays instantly through the Internet. These data elements can then be automatically incorporated into an accurate medical record. After the office visit, prescriptions can be checked against formularies and then sent directly to pharmacies. Referring physicians will be able to check the progress of a patient's visit to a specialist without having to wait for the notes to be delivered. Records will be available instantaneously, and the faxing and copying that goes on now in most offices will become a thing of the past. The number of clean insurance claims should go up, and rejections by payers will become less common. When one considers the amount of time the average office spends tracking down labs and x-rays, checking insurance and demographic information, and creating a chart for a new patient, the advantages become apparent. Further financial benefits will come from reduced chart storage costs, payroll and transcription savings, and easier compliance with government regulations. Billing and scheduling components are also available in most commercial systems. Quality outcome measures will also be easier to evaluate with a computerized database. EHR systems will also help prevent medical errors by providing decision support capabilities that check for errors and remind clinicians to perform certain tasks. Links to libraries, disease registries, and "best practice" recommendations also will be available.

Conversion Challenges Faced by Clinicians

The backbone of the NHIN will be the private physicians in small medical groups. The migration from paper to electronic records for this group requires unique financial and technical challenges. Without access to large information technology (IT) budgets and network technical support, any system they adopt must be inexpensive, secure, and reliable. The conversion from paper to electronic medical records will take more than the purchase of hardware and software to be successful. Since most clinicians were trained at a time where computers were not an essential part of medical documentation, the advantages of office automation may not be recognized and appropriately exploited. Education, technical assistance, and a change in the way clinicians organize their workflow will be important components of any successful effort to create a useful National Health Information Network.

It is unlikely that significant health information technology adoption will occur in small medical groups without some type of financial incentive. Current proposals to stimulate IT adoption include payments of three to six dollars per patient visit[2] and lower co-pays for patients visiting offices with electronic records systems. Less attractive incentives may come as reduced fees for those practices without computerized records. Market forces generated from patients, insurances companies, and industry are also expected to encourage IT adoption. One reason for these market forces is the amount of money the NHIN is expected to trim from the healthcare budget of the United States. It is estimated that a functioning network could save insurers $112 billion per year in the ambulatory care setting alone.[3]

> *"It is estimated that a functioning network could save insurers $112 billion per year in the ambulatory care setting alone."*

There are several ways of providing inexpensive systems to small clinician groups. The Application Service Provider (ASP) model allows clinicians to use a computer in their office to link to a large server hosted at a secure, remote location via the Internet. The ASP maintains the server, updates the programs, and maintains IT support in exchange for a low fee from the clinician. Groups needing more control than an ASP allows may opt for purchasing their own server and programs. This approach carries the responsibility and expense of providing upgrades, support, and security. Small groups usually lack the financial and technical resources to properly maintain this type of network. Larger groups of physicians or even clinician co-operative groups can band together to purchase "enterprise" versions of software that allow the organization to act as its own ASP. Legal counsel is recommended for these ventures since federal laws could be inadvertently violated if the network were used as a vehicle for creating referrals, price-fixing, or gaining financial advantage.

Options for Electronic Health Record Systems

Not all existing EHR systems are expensive. One of the best EHR systems, VistA, is available for a minimal charge from the government. With millions of taxpayer dollars, the VistA system was developed for the Veterans Administration (VA). In 2004, Secretary Thompson announced that it would be made available to the public.[4] Current versions of VistA are written in a language called MUMPS, which is not widely used by programming specialists. The VA is upgrading the VistA system in stages. Groups like OpenVistA™ have tried to convert VistA to a LINUX-based product in order to allow easier implementation by the medical community. The government is also creating a version of the software called VistA-Office EHR, which will soon be available for private use. All of these are expected to be compatible with the NHIN. Also worth mentioning is *open*EHR®, an international project under development by a team of volunteer programmers. If successful, it will provide a sophisticated software system accessible to any healthcare provider on earth.

Of course, the big question about all of these free systems is the level of support available. Sources for training and maintenance will have to be provided before any of these will attain widespread acceptance by small medical practices.

Patient Safety and Healthcare Quality

The report "*To Err is Human*"[5] pointed out that there were frequent errors in hospitals causing adverse events. It also illustrated the need to have a reliable source of data for assessing performance in the medical community. Although the numbers so widely quoted from this report were obtained by extrapolating a relatively small number of actual hospital cases, it has produced many good ideas for quality improvement. The American Hospital Association and the American Medical Association have embraced the *100,000 Lives Campaign*[6] recently launched by the Institute for Health Improvement. In North Carolina, the Medical Review of North Carolina, Area Health Education Centers, North Carolina Medical Society, North Carolina Medical Board, North Carolina Institute of Medicine, and North Carolina Healthcare Information and Communications Alliance, Inc., as well as various specialty organizations are all instituting programs to improve quality through health information technology. Clearly, electronic health record systems figure to play prominently in future solutions for improving healthcare quality.

The development of the NHIN may be the most important breakthrough to affect the medical profession in decades, and it may occur with little physician input. Ironically, it is the reluctance of physicians to adopt information technology systems that is slowing the creation of the NHIN. At some point in the future, payers and patients will demand that physicians utilize the NHIN. There will be a "tipping point," where providers must link up to the network in order to stay competitive in their fields. When that occurs, the NHIN will become essential in the practice of medicine. **NCMedJ**

Transformation of a Dinosaur:

Revising Healthcare Documentation

Karen L. Smith, MD

Healthcare in America is entering a new phase. Electronic health records (EHRs) will eventually replace the paper records we have used for years. Healthcare consumers are demanding cost-effective services and high-level quality. To meet these demands and survive in this high-cost industry, we must find ways to make healthcare delivery more efficient and cost effective. Physician organizations recognize that this change must occur in every entity which provides medical services. Physician offices, outpatient facilities, and hospitals should have the capability to communicate in an efficient manner. Using ERs would facilitate more effective communication. Modernizing the health records is also a way to improve patient safety and healthcare quality. With electronic health records, the complete patient record is reduced to computerized format. This complex information would be maintained in a secure database, yet be readily available at the time of need. The following account provides an example of how an electronic health record could make it easier for healthcare providers to provide time-sensitive healthcare to patients.

> *"With electronic health records, the complete patient record is reduced to computerized format."*

How an Electronic Health Record Could Save a Life

Mr. Joe is a 59-year-old man who is employed as a small engine repairman at a local plant. He and his wife were eagerly awaiting the news of their first grandson from their daughter in Iowa. His daughter and son-in-law began their law careers five years ago and had attempted to conceive for at least three years. The news finally came, so the grandparents took the first flight out. Mrs. Joe noted that her husband was having difficulty keeping pace as they walked steadily toward the gate. Once on the plane, he slept the entire six hours. They were greeted by their son-in-law, who whisked them to the hospital to see the baby. Just as they exited the nursery, Mr. Joe collapsed. He was rushed to the emergency room and eventually admitted to the coronary care unit. His family learned that his heart was enlarged, but he did not have a heart attack. In all the excitement, Mrs. Joe suddenly remembered that her husband had a rare condition, which his mother also had. She could not remember the name, but knew his mother was on prolonged steroid therapy, until she entered remission. Mrs. Joe decided she would call her family physician to obtain this important information. Since it was Saturday, she was concerned she may not be able to reach her doctor, especially at 2:00 am. Even if Mr. Joe's physician answered the call, he may have to provide answers to her questions based on memory (unless he had an electronic health record).

From memory alone, Mr. Joe's physician will not be able to disclose his latest lab results, vital signs, body weight, last electrocardiogram (EKG) reading, last chest x-ray results, or even the last date he was seen. The physician may or may not remember the historical information about Mr. Joe's mother. The physician then must decide if he should awaken his spouse, get dressed, and go into his solo practice to retrieve Mr. Joe's records. This is a frustrating dilemma for physicians. How many times has his own individual and family life been interrupted due to this ethical dilemma? He makes the same choice he has made many times in the past—to retrieve this information now in order to prevent a delay in therapy. Upon arrival to his office, he must locate the paper chart, which is not in its correct place. He searches the front office, the billing staff, and, finally, his own desk. The chart is found on his desk with a message from Mrs. Joe regarding the need for a prescription refill prior to travel. He opens the chart only to discover the last clinical note has not been filed since these reports must come in from the transcriptionist. The physician now searches his pocket for the number given to him by the telephone answering service. It is 4:00 am before he can call the Iowa hospital. When he calls, the physician learns that Mr. Joe had an abrupt change in his condition 15 minutes ago.

Karen L. Smith, MD, FAAFP, is in private practice in Raeford, North Carolina. Dr. Smith is also the current President of the North Carolina Academy of Family Physicians. She can be reached at schw1960@earthlink.net or 929 West Prospect Avenue, Raeford, NC 28376. Telephone: 910-904-1695. Web address: www.karensmithmd.com.

This scenario may have proceeded differently if the physician's records were readily accessible. Electronic health records would allow the physician to review each patient's chart without leaving the home. The physician could turn on the computer wait five minutes for the system to warm up, make the call to Iowa, and answer questions with confidence. He could share the EKG, labs, and chest x-ray results with the Iowa physicians. These results could even be faxed to Iowa for review and comparison. Mr. Joe's family physician could also confirm the date and time all prescription refills were sent to the pharmacy, and he could confirm Mrs. Joe's report by acknowledging that her husband has a condition called sarcoidosis with cardiac manifestations. According to the chart, Mr. Joe responded to a three-month course of prednisone three years ago with no further exacerbations since that time. Mr. Joe's prior episode responded rapidly once a bolus dosage and subsequent dosages were given to him. He did well and was discharged to his home five days later. The Iowa physicians would appreciate this information, and Mr. Joe's physician could be back asleep by 2:30 am.

Since the advent of electronic health records entered the healthcare scene, the choice to implement or defer use remains with the individual physician. The average Joe really can not persuade his or her doctor to adopt electronic health records. The average Joe actually represents the doctor, his family, the patient, and all others who play a role in his or her daily well-being. Let's face it, if we find ourselves in medical crisis, one of the first individuals called will be our family physician to provide the trusted information. Due to the state of healthcare in North Carolina, family physicians are responsible for many lives, and providing quality healthcare is paramount in that responsibility. This responsibility has been accepted by the profession as part of the discipline's transition, noted in the Future of Family Medicine,[1] which states, "Family physicians are committed to fostering health and integrating healthcare for the whole person by humanizing medicine and providing science-based, high-quality care. To remain true to this statement of identity, while continuing to meet the needs of patients and society in a changing healthcare environment, family medicine must promote innovation in the delivery of clinical services and in the education of clinicians." Chief among the multifaceted responsibility of providing patient-centered care, will be ensuring that every citizen has a medical home and that physicians use tools such as electronic health records.

Electronic Health Records Have Advantages for Patients and Healthcare Providers

The benefits of electronic records are noted beyond the standard access to clinical information. The record is documentation of every encounter the patient has with the physician's office. This includes a request for records from the patient's insurer or consulting physician. The individual's billing and financial information can be accessed in the same format in order to verify existence of healthcare coverage. The record is also used to track preventive health information (i.e., need for mammogram, pap smears, prostate or colon screening). Documentation of this nature helps reduce potential duplication of services and unnecessary testing, which, in turn, may help to reduce the healthcare financial costs that are now spiraling out of control.

A physician's professional and family life can be enhanced with organized and efficient documentation. Electronic health records would allow the physician to reduce after-hours time spent completing and reviewing records. This time is often taken away from personal family time, which can disrupt spousal and family relations. The doctor may even be neglecting his/her own personal health needs due to lack of time in the business day. Physicians who utilize time-management strategies with strict requirements for patient care schedules and controlled access after hours are sometimes criticized. The technique is effective for separating personal and professional life, but fails to solve the problem of limited time. Inefficiencies of the traditional medical practice have stripped valuable hours from the daily schedule. Electronic health records are a way to recover badly needed time for the physician and his/her staff.

What's the Hold Up?

This is a no brainer. So what is the delay? Implementation of electronic records requires commitment by the individual doctor, practice, or hospital group. The physician must bear this expensive financial endeavor. In addition, time is required to teach the physician and staff how to use their selected system. The practice must dedicate time and money in order to gain time in the long run. Medical practices that pursue this challenge would benefit from incentive payments to assist with the financial aspect. Insurers (both patient care and medical malpractice carriers) should recognize practices that utilize electronic health records with increased payments and decreased premiums, respectively.

An electronic health record is merely a component of a larger plan to transform healthcare to a discipline that can respond to the needs of the public. Every person should have access to high-quality, equitable care. Every person should be able to identify their own physician and be assured that the physician has adequate resources to care for their needs. The implementation of electronic health records is beyond the individual doctor. It will require the support of the entire community. **NCMedJ**

Application of Quality-Improvement Methods in a Community Practice:

The Sandhills Pediatrics Asthma Initiative

Thomas H. Wroth, MD, MPH, and Joseph C. Boals IV, MD

Asthma is the third leading cause of preventable hospitalization in North Carolina and frequently leads to school absence, parental work absenteeism, and childhood disability.[1] Although there is evidence that appropriate use of controller medicines and self management education improves outcomes in children with asthma, a recent national study demonstrated that most individuals with asthma do not receive recommended care.[2] While disease management programs have been developed to improve care for those with chronic diseases, such as asthma, their interventions often fail to be integrated into care provided in primary care practices. Community practices are ideally situated to lead disease management efforts, but face barriers such as lack of time, poor reimbursement, lack of available staff, and inadequate information technology.[3] Although barriers do exist, effective methodologies have been used to improve care in busy practices, such as measuring performance and providing feedback, and using Plan-Do-Study-Act (PDSA)[4] cycles to test improvement strategies. *Plan* includes initial problem identification, probable causes of the problem, potential solutions and data needed to evaluate them, and improvement goals. *Do* involves implementing a solution and collecting the data needed to evaluate the impact of the solution. *Study* requires further data analysis to develop conclusions—what happened when we made that change? *Action* involves either further study or action that comes out of the data analysis. In this commentary, we describe one pediatric practice's experience using quality improvement methods to improve asthma care.

The Practice

Sandhills Pediatrics is a rural, private practice in Southern Pines, North Carolina with approximately 37,000 patient visits per year. The practice is staffed by six pediatricians (five full-time and one part-time) and two pediatric nurse practitioners. The payer mix includes 50% Medicaid, and the practice is enrolled in AccessCare, one of North Carolina's Medicaid managed care networks. AccessCare provides case management services to Medicaid recipients and also supports practice-based quality improvement for asthma. At the start of the project in 1998, the practice estimated that they cared for approximately 1,400 children with asthma. That year, 19 of these children were hospitalized, and 216 were seen in the emergency department with the primary diagnosis for asthma. The aim of the project was to improve outcomes in asthma care, including reducing emergency department visits and hospitalizations due to asthma.

Organizing and Collecting Baseline Data

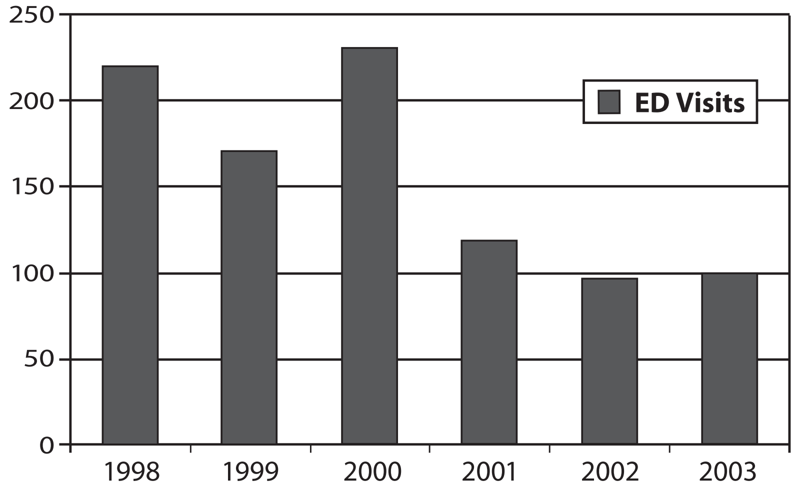
A practice team was initially formed consisting of all providers and several nurses. The practice team adopted the 1997 clinical practice guidelines from the National Heart,

> *"While disease management programs have been developed to improve care for those with chronic diseases, such as asthma, their interventions often fail to be integrated into care provided in primary care practices."*

Thomas H. Wroth, MD, MPH, is a family physician and preventive medicine resident at UNC Chapel Hill. He can be reached at tomwroth@mindspring.com or Department of Family Medicine, CB 7595, Chapel Hill, NC 27599. Telephone: 919-966-3711.

Joseph C. Boals IV, MD, is a practicing pediatrician at Sandhills Pediatrics in Southern Pines, North Carolina. He can be reached at jboals@nc.rr.com or 195 West Illinois Avenue, Southern Pines, NC 28387. Telephone: 910-692-2444.

Figure 1.
Emergency Department Visits, 1998-2003



Lung, and Blood Institute's (NHLBI) Asthma Education and Prevention Program (NAEPP)[5] to improve care. A case manager from the Medicaid managed care program assisted the team with performing chart audits and reporting performance data. Based on the results of a baseline chart audit, the practice team focused on improving four measures: staging patients as severe-persistent, moderate-persistent, mild-persistent, or mild-intermittent asthma; providing spacers and peak flow meters ("hardware"); using a written action plan; and ensuring that those with persistent asthma were prescribed long-term control medications.

At the beginning of the project, a chart audit was performed on children enrolled in the AccessCare program. The audit found that less than 10% of the charts had documented staging, a written action plan, spacers and peak flow meters, or that long-term control medications were prescribed. It was clear that there was substantial variation among providers in how they cared for their patients with asthma.

Educating the Team

The first phase of the intervention involved educating the practice team about the NHLBI guidelines and the potential impact of following the guidelines on the practice population. The practice team and AccessCare staff developed written action plans with embedded asthma guidelines. AccessCare provided patients with the education booklet called *One Minute Asthma*.[6] The practice team met approximately once a month, with most meetings being unscheduled and informal. After several months, a follow-up chart audit was performed. While there was improvement in the use of long-term control medications, spacers, and peak flow meters, fewer than 20% of children were staged and given action plans. The practice team postulated that physicians were not staging patients and using action plans because there was not enough time during the visit.

Strategies to Improve Care

In an effort to overcome time constraints that limited the provider's ability to provide complete asthma care, the team created "standing orders" so that other team members could provide certain aspects of care. Nurses were given the responsibility for teaching patients how to use peak flow meters and how to fill out a portion of the action plan. In order to facilitate the staging of patients, the action plan form was revised to include a staging tool. One of the other strategies used by the team was to provide the performance data to both the providers and the practice. The performance data of individual physicians were also displayed, creating a "healthy" competition among providers. The next round of chart audits indicated that practice behavior had begun to change. Greater than 80% of the charts audited had documentation of staging, use of action plans, prescribed long-term control medications when appropriate, and use of peak flow meters and spacers.

Outcomes

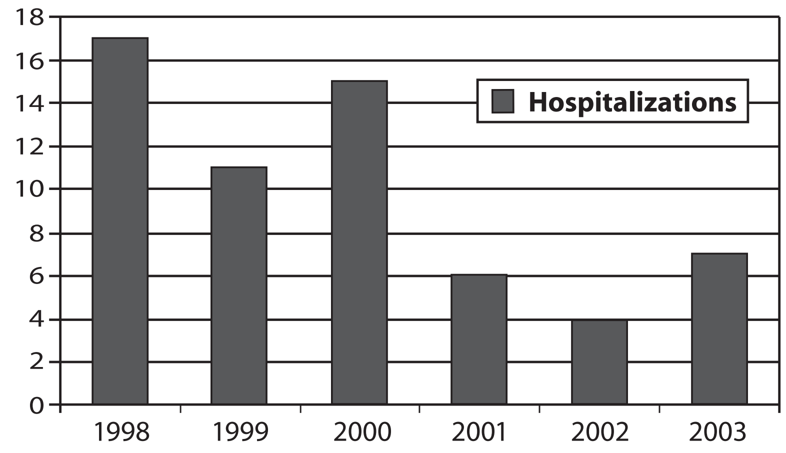
Pediatric asthma emergency department visits and hospital admissions were tracked yearly from 1998 to 2003. Data were obtained on Sandhills Pediatrics' patients, age two-to-17 years with the primary or secondary diagnosis of asthma. Over the project time period, there was a 48% reduction in emergency department visits and a 62% reduction in hospital admissions for asthma (see Figures 1 and 2).

Summary

This case study demonstrates the use of quality improvement methods to improve asthma care in a busy community practice. The practice used disease-management strategies, such as population identification, self-management education, and performance measurement and feedback. The practice then applied several practice-based quality improvement methods, such as PDSA cycles, to improve care. From 1998 to 2003, process measures, such as staging of asthmatics, use of long-term control medications, use of peak flow meters and spacers, and use of action plans, improved. There was also a substantial decrease in emergency department use and hospitalizations among patients with asthma.

Although there have been several studies demonstrating the efficacy of disease management strategies, most lack generalizability to community practices.[7] Often, interventions are so intensive and cumbersome, that they are unlikely to be replicated in primary care settings. Researchers have been unable to determine which components of the interventions are most effective and replicable. Furthermore, many studies of disease management strategies enroll participants who lack the co-morbidities seen in

Figure 2.
Asthma Hospitalizations, 1998-2003



community practice. There are also few studies of disadvantaged populations that face other barriers to care, such as lack of transportation, poor access to specialists, and medical illiteracy.

In this case study, there were several unique factors that enabled the practice to improve care for this population. The AccessCare case manager who worked with the practice not only provided data and feedback to the practice team, but also served as an improvement "coach," often pushing the team and facilitating many of the improvement efforts. AccessCare's approach is in contrast to many of the commercial disease management companies' "carve out" models that do not sufficiently involve providers or practices in their interventions. The other necessary ingredient for success in this project was organizational leadership and support. The leaders of the practice saw beyond the usual metrics of patient visit counts and relative value units (RVUs) to embrace the concept of population health: the notion that practices are not only responsible for providing acute, episodic care in the office, but also for improving health outcomes in the community in which they serve. Other important factors included ensuring a basic agreement among providers on the need for improvement and frequent communication about the goals of the project. Although the champions of the project tried to minimize formal meeting time, there was frequent informal communication between team members. In the future, there is a need to develop other approaches to stimulate these endeavors in community practices, such as "pay for performance" programs, continuing education credit, and tying maintenance of board certification to quality improvement initiatives. **NCMedJ**

Disease Management in Primary Care:
Rapid Cycle Quality Improvement of Asthma Care

Samuel S. Weir, MD

What can we learn from the Sandhills Pediatrics' asthma care experience?[1]

The first lesson is that primary care-based disease management programs can dramatically improve outcomes of care. Not surprisingly, an organized, explicitly designed approach to caring for special populations leads to improved outcomes of care. Sandhills Pediatrics successfully *carved into* their practice "a systematic, population-based approach to identify persons at risk, intervene with specific programs of care, and measure clinical and other outcomes."[2]

> *"The Sandhills experience can teach the rest of us the key ingredients and how to organize them to improve population outcomes in primary care."*

This is an important lesson because in the mid to late 1990s many in the managed care community lost faith in practicing physicians doing what Sandhills Pediatrics has done. Managed care executives turned to *carve out* solutions from emerging disease management vendors. These vendors developed programs that bypassed the traditional healthcare delivery system and used externally based case managers or other resources to reduce costs and improve outcomes related to chronic diseases.[3]

It's clear that a specifically designed disease management program can improve outcomes for those with chronic disease. But how do we carve these successful programs into existing practices? Viewed from the perspective of operations research, Sandhills Pediatrics becomes a laboratory with very important lessons for the rest of us. The Sandhills experience can teach the rest of us the key ingredients and how to organize them to improve population outcomes in primary care.

Leadership

The first and arguably most important ingredient is leadership. Leadership must be persistent and able to defuse nearly certain initial resistance to build an effective team of colleagues and office staff. The image to get in your mind here is that of the Energizer Bunny®—leadership that keeps going and going and going.

Organizational Support

A second crucial ingredient for successful disease management is organizational support. Notice that Sandhills has been involved in several improvement initiatives around preventive care, access, oral rehydration, and attention deficit disorder. Clearly this is an 'early adopter' medical practice! In each of these efforts, the practice had the support of a larger organization helping them improve their practice. Practices need a guide, a support network, and a larger context in which to view their work. In this case, Dr. Boals had the support of the AccessCare network of practices. AccessCare is a non-profit organization committed to improving quality of care and reducing costs of care for state Medicaid beneficiaries.[4] Other third-party payers might take notice of this innovative approach to working with practices to improve quality and reduce costs of care.

Measuring Practice Performance

A third vital ingredient to build a successful disease management program is measurement of practice performance. As with Sandhills pediatrics, this can involve time-consuming chart reviews. In their case, an AccessCare staff member did the chart reviews. Identifying a non-clinician member of the staff who can be trained to do the chart reviews on an ongoing basis may be a way for practices to achieve this.

Samuel S. Weir, MD, is the Director of Quality Improvement for the Department of Family Medicine at the University of North Carolina School of Medicine. He can be reached at sam_weir@med.unc.edu or CB 7595 Chapel Hill, NC 27599. Telephone: 919-966-3711.

Hand-in-hand with a commitment to measure practice performance is the courage to face the results squarely. Many clinicians feel challenged and threatened when they begin to see this kind of data and will question the measurement strategy and the data quality rather than begin to look for ways to improve. A measurement plan that is simple and transparent can quiet the critics and refocus attention on performance improvement.

Team Approach

A fourth necessary ingredient to building a successful practice-based disease management program is a team approach to care. I don't think it is an accident that Drs. Wroth and Boals described significant improvement after the nurses in his practice began to participate in asthma care by 'automatically' doing peak flow measurements and writing action plans for patients with a diagnosis of asthma. This expansion of the nursing role within a practice is a common theme of successful disease management programs. Prerequisites to this include a practice culture that is open to learning new skills and applying those skills in expanded roles within the practice.

Focus on Process

A final ingredient to building successful carve-in disease management programs is a focus on the process of care. What happens when a patient with asthma visits the practice? Who is going to do what? Where? When? With what resources?

These ingredients: leadership, organizational support, measurement of practice performance, a team approach to care, and a focus on the process of care have been identified as common elements of successful clinical microsystems in studies done across the United States.[5] How should these ingredients be combined? The recipe for successful disease management in primary care practices calls for the proper mixing of these ingredients over time.

Rapid cycle quality improvement combines these ingredients in repeated cycles of planning, doing, studying, and acting (PDSA) cycles.[6] *Planning* includes initial problem identification, probable causes of the problem, potential solutions and data needed to evaluate them, and improvement goals. *Doing* involves implementing a solution and collecting the data needed to evaluate the impact of the solution. *Studying* requires further data analysis to develop conclusions—what happened when we made that change? *Action* involves either further study or action that comes out of the data analysis. Rapid cycle quality improvement leads back to a better understanding of the problem and more planning.[7]

This cyclical process of improvement was well-illustrated in commentary by Drs. Wroth and Boals. Their first cycle of improvement involved physician and nurse education and the provision of pre-printed action plans and patient education materials. They began planning for a second cycle of improvement by increasing education, making peak flows and filling out action plans 'automatic' within the practice, and reporting individual clinician outcomes. These steps led to a dramatic improvement in outcomes. A third cycle of improvement led them to create an evening asthma clinic for 'well-asthma' visits once a month.

Unfortunately, Sandhills Pediatrics and its remarkable improvements in asthma care remain the exception rather than the norm. The task for many of us is to emulate their efforts in our own practices across the state. **NCMedJ**

Implementing Advanced Access in a Family Medicine Practice:

A New Paradigm in Primary Care

John B. Anderson, MD, and Carlos A. Sotolongo, MD

Triangle Family Practice is a family medicine group that has been part of the Duke University Health System since 1995. There are eight physicians and three physician assistants/nurse practitioners in the group that is located in suburban Durham. Growth in this area of Durham has resulted in a significant influx of new patients to the practice. In 2001, the practice was seeing almost 300 new patients a month. The wait for an annual physical appointment was an average of 90 days, with one provider booked out to 180 days (see Figure 1). Patients were unhappy because they were unable to see their usual provider, the staff was dissatisfied at having to continually bargain with patients over appointments, and the providers were struggling to keep up with the demand. Everyone realized that something had to be done, as this had become an untenable situation.

We became aware of the concepts and principles of Advanced Access scheduling after attending an Institute for Healthcare Improvement meeting and realized that this approach could address the issues we were having at Triangle. Advanced Access is based on the premise of doing "today's work today" and that it is not necessary to make patients wait, either for appointments or while they are in the office. The old paradigm is that we can create capacity in today's schedule by pushing work into the future.[1] The result is that all the routine or non-urgent requests are scheduled out for weeks hoping to make space for those patients who need to be seen today. Our schedules end up full with last months work, and patients have to convince the staff they are sick enough to be seen today. Patients are often unable to see their usual provider, they have to wait for preventive and chronic illness care, and they routinely miss appointments that are scheduled weeks and months into the future. The practice's financial performance suffers because of the high no-show rate and the large number of low-acuity visits. Patient and staff satisfaction are also poor as a result of the constant haggling for appointments and inefficiencies in the office.

The decision was made to use Triangle Family Practice and Butner-Creedmoor Family Medicine as pilot practices prior to implementing Advanced Access across all the practices that make up Duke's primary care network, Duke University Affiliated Physicians (DUAP). What follows is a description of how we implemented these concepts at Triangle from the spring of 2001 until spring of 2002. The group participated in a Breakthrough Learning Series Collaborative sponsored by the Institute for Healthcare Improvement on Advanced Access and

Office Efficiency with other primary care practices from around the country. The collaborative approach was helpful in that we learned from expert faculty, but also were able to share experiences and strategies with other practices.

Implementing Advanced Access Scheduling

The challenge that confronted Triangle was how to take the "high-leverage" changes, outlined elsewhere in this Journal and in the literature, and apply them to their own situation.[1,2] The decision was made early in the process to close the practice to new patients so as to allow the providers to work down their "backlog" of patients that were scheduled out into the future. This process can take anywhere from six weeks to six months, but is a crucial step in the process of creating capacity to see patients on a same-day basis. We also began to examine several long-standing policies regarding the way our schedules were managed. There were rules in place as to how many physicals could be scheduled in a day and multiple appointment types structured in an attempt to "manage" the demand from patients for visits. Providers were scheduled as "walk-in" doctors so they could see acute care patients. Scheduling providers on a walk-in basis disrupts continuity and further restricts the physician's availability to see his or her own patients. In addition, the practice had no idea of what the demand for appointments was and no idea of what individual provider panel sizes might be.

> *"Patients were unhappy because they were unable to see their usual provider, the staff was dissatisfied at having to continually bargain with patients over appointments, and the providers were struggling to keep up with the demand."*

Involving Staff and Providers in the Process

The practice created an internal team that participated in the collaborative. The team met on a weekly basis to plan the necessary changes and to analyze the data collected to measure the impact of these changes. They began to measure their demand for appointments so as to compare it with their capacity to see patients. They also tracked their no-show rate, their cycle time (how long it takes a patient to move through the office), and their patient and staff satisfaction. We use the third-next available appointment for a physical as our measure of access with the goal being able to get this down to same day availability. As mentioned earlier, Triangle's was out to 90 days. One of the biggest challenges faced by Triangle's team was convincing the staff and providers of the need to change and adopt this new approach. This was accomplished by involving them in the process, and sharing the data from the practice and testing changes prior to their implementation.

The practice was able to create significant capacity in their schedule by reducing their appointment types to two, 15, and 30 minutes. The scheduling rules, such as only four physicals per day, were removed, and the primary question staff had to answer when patients requested an appointment was whether the patient's provider was in the office that day. Once providers began to see their own patients, more could be done at each visit, and patients did not have to be seen as often. We began to employ a concept called "max-packing," which entailed doing as much as possible for patients when they are in the office and not having them return for another appointment. This frees up the future schedule and raises the acuity level of that visit. Care teams were created in the practice that also included schedulers and medical record personnel. These teams would "huddle" each morning before patients were scheduled to plan the day's work, synchronizing patient information with the appropriate provider. The care teams were geographically co-located to help facilitate real-time communication between nurses, providers, and schedulers on the phone with patients. As appointment availability increased, the need for phone triage decreased, and those nurses could be given other tasks in the office.[3]

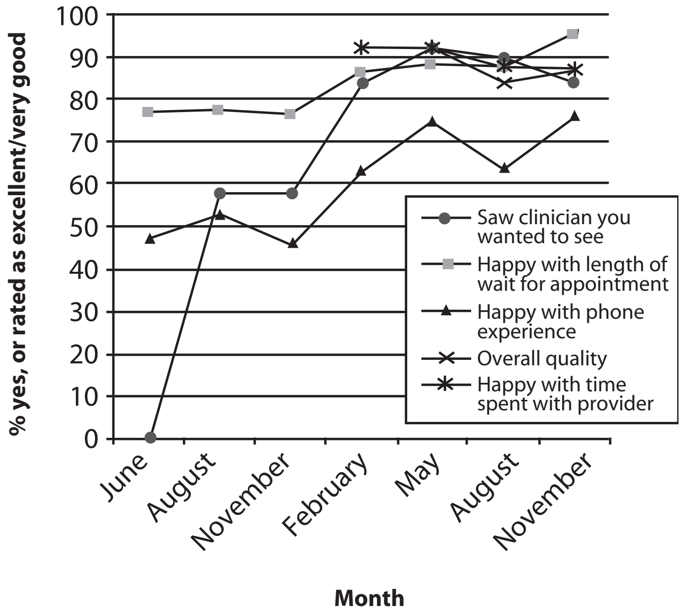
Making Adjustments

Once the practice was able to collect and understand its demand for appointments data, over-paneled providers could shift some of their patients to other providers. We learned that Mondays and Fridays are high-demand days, so we were able to "shape" the demand and book return appointments at less busy times. Patients who needed to return for follow-up were given appointments, but because we had availability, we did not have to schedule patients for "just in case you're not better" appointments. The practice also developed contingency plans for when providers were on vacation or at times of high demand for appointments. There were some concessions made with the scheduling of physicals due to the high demand for some of our female providers. We did limit this number to six-a-day, and they were scheduled on the hour so as not to occur back to back.

Conclusion

As a result of implementing Advanced Access, the practice can now measure its availability in terms of one-to-two days.

Figure 2.
Patient Satisfaction, June 2001-December 2002



Patient satisfaction has improved dramatically (see Figure 2), the staff finds this a much more satisfying place to work, and the providers feel less stressed and better able to take care of patients. The practice has enjoyed financial success and has been able to grow its market share. The changes associated with Advanced Access cannot be implemented without significant work and effort, but the resulting success has positioned the practice to respond to the changing landscape that lies ahead for primary care medicine. **NCMedJ**

Where Next for Advanced Access:

Will It Be Embraced by Specialties?

Greg D. Randolph, MD, MPH

A Brief History of Advanced Access

Advanced Access, sometimes referred to as Open Access (see page 199), is a set of principles designed to help practices reduce waiting times for appointments and reduce office-waiting times, two common access barriers in healthcare today. The Advanced Access approach to practice management and scheduling was originally developed by Mark Murray, MD, MPA, and Catherine Tantau, RN, at Kaiser Permanente in the early 1990s.[1] Many if not all of the strategies were derived from the experience of other industries[2]—though cleverly adapted to healthcare.

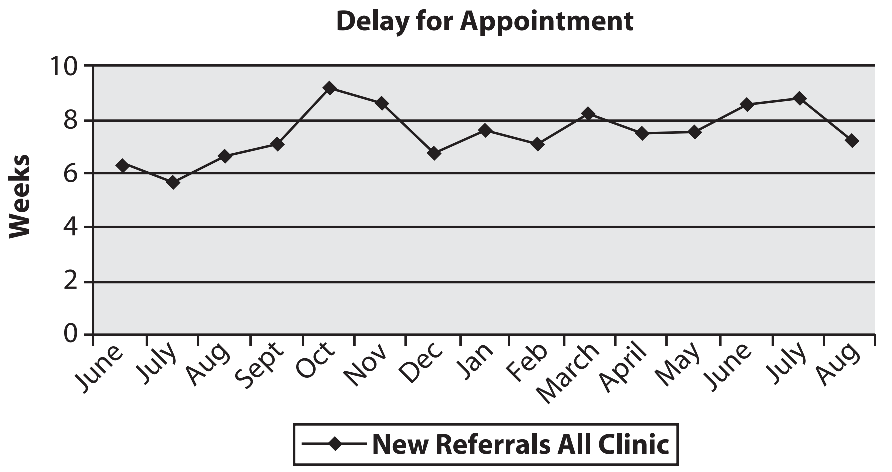
In the mid-1990s, Murray and Tantau began a partnership with the Institute for Healthcare Improvement (IHI), a nonprofit organization devoted to the spread of improvements in healthcare. Together with the IHI, Murray and Tantau have been involved in spreading Advanced Access to thousands of practices, primarily in primary care settings.[3,4] The improvements in care documented by Triangle Family Practices in this issue are important drivers of the increasing appeal of this approach in primary care.

More recently, the IHI, the Veterans Health Administration, and the National Health Service in the United Kingdom have developed methods for widespread dissemination of Advanced Access to thousands of practices. These large scale efforts have included specialty settings. However, adoption of Advanced Access by specialty practices has been slow and generally limited to a small number of organizations and geographic areas.

Access Problems in Specialties

There is certainly a need for attention to reduce delays for specialty care. Local data from the University of North Carolina Chapel Hill Pediatric Subspecialty Clinics (see Figure 1) is typical of the delays for new referrals to many specialties. Unfortunately, it is quite common for new specialty referrals to reside on waiting lists that are several months long.

Figure 1.
Delays for Appointments for New Referrals from the UNC-Chapel Hill Pediatric Subspecialty Clinics, June 2003-August 2004



There are several potential causes for these delays. One is the increasing concern about national shortages in the pediatric subspecialties.[6] There may be local shortages among some adult specialties too, even though the national supply appears adequate. Waste and inefficiency in many subspecialty clinics are another potential cause.[3] In addition, just as in primary care settings, there is a common mindset in specialty settings that it is okay for patients to wait—more alarming, waiting is often viewed as

Greg D. Randolph, MD, MPH, is Assistant Professor of Pediatrics at the Center for Children's Healthcare Improvement, University of North Carolina at Chapel Hill. He can be reached at randolph@unc.edu or CB 7226, Chapel Hill, NC 27599-7226. Telephone: 919-843-7224.

an indication that "we are the best."[7] As long as waiting is viewed as acceptable or even desirable, there will be a major barrier to redesigning practice systems to allow more timely care.

Principles of Advanced Access Are Generalizable

There is no reason to believe that principles of Advanced Access (see Table 1) cannot be applied to specialty settings. They are applicable to industries outside healthcare like Wal-Mart, General Motors, and Starbucks (where these principles were first applied), so why not to specialty care? Indeed, through the IHI's Pursuing Perfection project, Cincinnati Children's Hospital is successfully applying these principles to pediatric subspecialties.[8] Similarly, the Veterans Health Administration has had success spreading these principles to adult specialties.[9]

> *"Advanced Access, sometimes referred to as Open Access, is a set of principles designed to help practices reduce waiting times for appointments and reduce office-waiting times, two common access barriers in healthcare today."*

Specialty clinics can reduce appointment backlog, reduce appointment types, and manage bottlenecks just as primary care practices can. However, with increasing experience in specialty clinics, we are learning where some of these principles need to be applied slightly differently. For example, to balance demand and supply, specialty clinics need to address the number of new patients subspecialty clinicians are assigned (based on current numbers managed, full-time equivalents, expertise, etc.) rather than panel size (as in primary care). In addition, in order to reduce demand, primary-specialty partnerships are very important for specialists (e.g., to establish referral criteria and to design systems to promote prompt return to the primary care setting).

Table 1.
Advanced Access Principles

Principle	Examples
Balance appointment supply with patient demand	• Predict appointment supply by accounting for holidays, vacations and non-clinical work • Predict patient demand for appointments by collecting appointment data
Work down the backlog (waiting list)	• Distinguish between "good" (planned care) and "bad" (delayed care) backlog • Measure the extent of the backlog and make a plan for reducing it, including a start and end date
Reduce appointment types	• Reduce number of appointment types • Standardize appointment lengths (e.g., consider 30-minute appointments for all visits)
Plan for contingencies	• Increase capacity at peak times • Plan for predictable seasonal increases in appointment demand
Reduce future patient demand	• Maximize activity at appointments to reduce future demand • Extend intervals for return appointments
Manage the bottlenecks	• Identify bottlenecks in clinic flow • Drive unnecessary work away from the bottlenecks
Synchronize patient, provider, and information	• First AM and PM appointments start on time • Patient registration done by phone if confirming patient appointment
Predict and anticipate patient needs at the time of the appointment	• Use regular "huddles" to anticipate and plan for contingencies in schedule • Use notepads, whiteboards, flag systems, etc. to communicate during the day
Optimize rooms and equipment	• Use "open rooming" to maximize flexibility • Standardize supplies in all rooms and have stocked at all times
Use continuous flow strategies	• Do this moment's work now (e.g. dictate immediately after visits) • Use scheduled pauses to apply continuous flow approach to non-appointment activities (e.g. returning phone calls)

What's Ahead?

In the near future, it is reasonable to expect that the demand for specialty access improvements will accelerate. The growing body of research that suggests that Advanced Access decreases no-show rates, improves patient satisfaction, improves staff satisfaction, increases physician productivity, and increases revenues in primary care will likely accelerate the spread of this approach among primary care practices in the United States.[4,10-15] As more primary care practices adopt Advanced Access, these practices and their patients will begin to turn their attention to timely access for specialty care. Indeed, we have already witnessed this phenomenon in some areas of the country. In addition, market forces will likely apply pressure to specialty practices to improve patient satisfaction—reducing delays for specialty care will be an important way to address these market forces.

As the experience with Advanced Access increases in specialty settings (through the experiences of "early adopters"), the feasibility and the advantages of this approach will become clearer to a greater number of potential adopters in specialty settings.[16] The spread of Advanced Access to specialty practices could reach in to the thousands within the next five years, based on the experience of primary care we have witnessed. However, spread will ultimately depend on a small number of "early-adopter" practices to try and succeed with this relatively new innovation in healthcare scheduling and practice management. A number of groups, including the IHI and The Center for Children's Healthcare Improvement, are trying to assure this indeed does occur. **NCMedJ**

Community Care of North Carolina:
Saving State Money and Improving Patient Care

Charles F. Willson, MD

It was a morning in January, flu season, and I was already a half a dozen patients behind as I entered the exam room and saw Heather lying in her mother's lap, tugging for air.

Heather was a frequent flyer at our office, well known to the doctors and staff for her bad asthma. At age four, she knew the fearful regimen of subcutaneous epinephrine injections given every 15 minutes until the wheezing broke or, even worse, an admission to the hospital for intravenous (IV) aminophylline. Usually her grandmother brought her, but today it was her mother, a thin young woman who looked older than her years.

Heather was in respiratory distress, nares flaring, deep intercostal retractions, tugging with her neck muscles with each breath. I quickly counted her respirations, 64 per minute. Worst of all, she looked tired, barely lifting her head from her mother's breast to look at me. The nurse had already laid out the epinephrine and syringes. I gave the first epinephrine injection subcutaneously with little resistance from Heather. Instead of waiting to see if she improved, I left the room to call the hospital for a bed for Heather. The second and third injections brought little improvement and a lot of tachycardia. As I handed her a set of admissions orders, I explained to Heather's mother that she would need to be admitted to hospital for IV therapy and a chest x-ray. She nodded in agreement.

> *"...the only way to curb the spiraling cost of healthcare in our country is to prevent that which is preventable and catch the rest in its earliest stages through a well-planned system of primary care with access for all the people..."*

Off I went into the next exam room. Around lunchtime, I received a call from the emergency department (ED). Heather had been sent there from the admissions office. She was being admitted to the pediatric intensive care unit (ICU). Off I went to the hospital. Heather had just reached the ICU when I got there. Her blood gases showed significant carbon dioxide retention. With the help of the anesthesiologist, we had her intubated, taking the load of breathing off that thin little frame.

That afternoon, I learned that Heather and her mom had walked the two miles to my office in sub-freezing temperatures. Instead of going directly to the hospital, her mother had walked her home to get her pajamas. As I listened to the story in disbelief, the social worker related that Heather's mom was a heroin addict and perhaps it was more than pajamas she went home for. Clearly, a healthcare delivery system that relied on the parent to decide when to come to the office, how to get there, and how to follow the treatment plan was not meeting the needs of Heather and her two brothers.

The Old Model

The primary care model I learned in medical school and residency in the seventies and practiced in the eighties and nineties could best be described as "snap shot" medicine. We saw the patient briefly in the office, made a diagnosis, and, most often, wrote a prescription. Getting the prescription filled, taking the medicine, and returning for follow-up, if things weren't going better, were left to the patient. Little attempt was made to find out if the patient could afford the medicine, understood the instructions, or could comply with the treatment regimen. If things didn't go well or if the patient didn't return for follow-up, it was probably

Charles F. Willson, MD, is a Clinical Professor of Pediatrics at the Brody School of Medicine at East Carolina University. Dr. Willson also serves as Medical Director and Chairman of the Steering Committee for the Pitt County Community Care Plan and President of the Eastern Carolina Health Organization. He can be reached at willsonc@mail.ecu.edu or Brody 3E139, 600 Moye Boulevard, Greenville, NC 27834. Telephone: 252-744-3041.

his or her own fault. We didn't even have a system of identifying who hadn't shown up for their appointment each day. Was no news, good news? Few physicians had resources or systems to follow their patients over time or to determine the outcomes of their patient care in the aggregate. Physicians had no data comparing their practices with their peers'. The default standard was "medico-legal." If you didn't get sued, you were probably doing "okay."

The New Model

In Crossing the Quality Chasm,[1] the Institute of Medicine of the National Academies outlined the desired characteristics of a new model for healthcare delivery in our country:

- Care is based on a continuous healing relationship.
- Care is customized according to patient needs and values.
- The patient is the source of control.
- Knowledge is shared and information flows freely.
- Decision-making is evidence-based.
- Safety is a system priority.
- Transparency is necessary.
- Waste is continuously decreased.
- Cooperation among clinicians is a priority.

In the late eighties and nineties when health maintenance organizations (HMOs) arrived in North Carolina, many healthcare leaders thought the HMOs would bring system improvements. The upside for a pediatric generalist was that well-child care finally became a covered benefit. The downside was that the reimbursement rates were a percentage of your usual charge or, even more worrisome, a capitation rate associated with patient risk level (How could I be responsible for my patients' costs and outcomes? We all knew patients weren't very compliant.). Some insurers actually gave us performance data, comparing us with other pediatricians in their network. These data were often linked with financial withholds and highly suspicious of being another way of further decreasing reimbursement. There was little effort to enhance my ability to care for my patient.

Physicians in practice needed a new model that would supply the resources necessary to provide a "continuous healing relationship." We needed practical education on how to implement "evidence-based" best practices. We needed an office-based computer system that could track and aggregate our clinical information. We needed believable, practice-specific utilization data from the insurers. Most of all, we needed specially trained office personnel (case managers) who could be our eyes, ears, and arms to follow our most medically and socially complex patients once they left the office.

The Medical Home

While the medical model is founded on the physician-patient relationship, the community-based primary care model is based on the medical home. A medical home is a well-planned primary care practice that strives to meet the broad spectrum of healthcare needs of its patients from simple acute illnesses to preventive health maintenance visits through referrals to specialists for complex and chronic conditions. Using evidence-based disease management protocols and knowledge of where additional services can be accessed in the community, the region, the state, and even the nation, the physicians and staff of the medical home can advise the patient on what services are needed or recommended for any given medical question or complaint. Over time, a "continuous healing relationship" is developed. By catching illness early and encouraging healthy lifestyle changes, the medical home brings great value and comfort to its patients during periods of illness and stress in their lives. In Community Care of North Carolina (previously called Carolina Access II/III), our medical home model is made powerful thanks to the enhanced resources the primary care physicians are given to help manage their patients. These resources are disease management protocols, case managers, and practice-specific utilization data. Many healthcare leaders refer to our model as an "enhanced primary care case management model (E-PCCM)."

A Brief History of Carolina Access

During the early 1990s, North Carolina Medicaid Director Barbara Matula created a partnership with primary care physicians called Carolina Access. She wanted improved rates of well-child care (HealthChecks) and decreased unnecessary use of the emergency department as a source of primary care. By committing to be on-call 24 hours-a-day, seven days-a-week, 365 days-a-year for their Medicaid patients, the primary care practice would receive a case management stipend of $2.50 per member per month. Triage nurses at the local ED would call the patient's on-call physician and describe the patient's complaint, condition, and vital signs. If the Medicaid patient was stable and could be safely seen in their medical home, the patient would be referred there. In the first year, Carolina Access decreased ED charges by 10%. Unfortunately, the Health Care Financing Administration [HCFA, now the Center for Medicare and Mediciad Services (CMS)] that had given a waiver to North Carolina to implement Carolina Access, took away this option with the Emergency Medical Treatment and Active Labor Act (EMTALA)* in 1995. EMTALA regulations erected major barriers to triaging patients back to their primary care offices.

---

* "In 1986, Congress enacted EMTALA to ensure public access to emergency services regardless of ability to pay. Section 1867 of the Social Security Act imposes specific obligations on Medicare-participating hospitals that offer emergency services to provide a medical screening examination (MSE) when a request is made for examination or treatment for an emergency medical condition (EMC), including active labor, regardless of an individual's ability to pay. Hospitals are then required to provide stabilizing treatment for patients with EMCs. If a hospital is unable to stabilize a patient within its capability, or if the patient requests, an appropriate transfer should be implemented." Available at http://www.cms.hhs.gov/providers/emtala/default.asp. Accessed June 13, 2005.

Carolina Access II

By 1996, with North Carolina Medicaid costs again skyrocketing at double-digit yearly growth figures, the North Carolina legislators were again looking for a cost containment mechanism. Commercial HMOs told legislators they could save the state 10% in the first year, if legislators would turn the North Carolina Medicaid program over to the HMO industry. For a $2.5 billion program, that was an attractive offer. Another option, offered by a group of large hospitals in North Carolina with high Medicaid usage, was to form a consortium to take over Medicaid. Both the HMO- and the hospital-consortium plans included 15-20% overhead costs, while North Carolina Medicaid only cost the Division of Medical Assistance (DMA) 4% in overhead. Converting to a program with higher overhead would mean there would be less money for direct patient care and services.

Recognizing that physician orders, prescriptions, and treatment plans generate more than 70% of Medicaid costs, then Secretary of the North Carolina Department of Health and Human Services H. David Bruton, MD, proposed a direct partnership between Medicaid providers in the communities and the state Division of Medical Assistance. His recipe for success was rewarding physicians for working harder and smarter. Medicaid programs in other states had low-participation rates by physicians due to reimbursement rates that didn't cover the office expense of seeing the Medicaid patient. Why not enlist physician participation by rewarding them with a $2.50 per member per month case management fee and paying them a fee schedule that more than covered costs (95-100% of Medicare rates)? Nine pilot sites were funded across the state. The enhancement of Carolina Access into disease and case management was named Carolina Access II.

A Brief History of the Community Care Plan of Pitt County

In June 1996, Secretary Bruton presented his vision of a physician-led healthcare system to a meeting of our local physician organization, Eastern Carolina Health Organization (ECHO). He explained that the healthcare middle men brought little value, but extracted 15-20% of the healthcare dollar. He called for a partnership between physicians and the state to bring improved access to care, measurable quality, and cost-effectiveness. His goal was to decrease yearly cost increases for Medicaid from the 15-20% level down to 8% by the fiscal year 2000. He asked that local provider groups submit proposals to his office on how to accomplish his goals. In January 1997, our Physicians Hospitals Organization (PHO), University Medical Center Health (UMC Health), submitted a detailed proposal for a county-wide partnership of the physicians, hospital, health department, and department of social services to manage the care of Medicaid patients in Pitt County. Cabarrus County, under the leadership of L. Allen Dobson, Jr., MD, submitted a similar model. My practice, Greenville Pediatric Services, had been invited to join a large statewide pediatric group model (AccessCare), but we declined. To be an effective alternative to the HMO model, we needed projects that covered all Medicaid patients in the area. While 70% of Medicaid patients are children, they generate only 30% of the costs. Adults and disabled patients comprise 30% of Medicaid patients, but they generate 70% of the costs. For this reason, we speculated that the pediatric network would not be inclusive enough to control total Medicaid costs. Secretary Bruton agreed, designating our more inclusive, county-wide model as Carolina Access III. Carolina Access II included other pilots that cared for only portions of the Medicaid population.

Financing the Pilot Programs

Administrative costs for the pilots were funded by an additional $2.50 per member per month. Our fiscal entity receiving these funds was the local PHO. A project coordinator, a part-time medical director (me), and case managers were hired. A steering committee was empowered by the PHO to run the pilot. The steering committee was loosely constituted, with each partner being represented (i.e., physicians, hospital, health department, and department of social services). Decisions are by consensus. Over the last six years, I recall only one formal vote by the steering committee, and it was unanimous. Care management committees were formed to identify the clinical issues that should be addressed, as well as to implement best practices developed by the statewide medical directors group.

With the Carolina Access roots into decreasing unnecessary ED utilization, our first challenge was to encourage our patients to use their medical homes as the first contact for care. In partnership with the hospital, a nurse advice phone line (HealthDirect) was developed. Every Carolina Access family, received a refrigerator magnet with the office phone number and the HealthDirect nurse advice-line number. Also, we created a community pediatric after-hours clinic that was staffed by a pediatrician (either from private practice or the medical school) and several residents. This after-hours clinic operates from 6:00 pm to 10:00 pm every night of the year, including weekends and holidays. With these two initiatives, we decreased ED visits by Medicaid patients under age 21 by 17% in our first year (fiscal year 1999). Importantly, our parents and patients appreciated the convenience of these alternatives to the long waits in the ED.

The Physician Champion

Much of the success of Carolina Access can be directly traced to physician involvement at all levels. Each pilot program in Carolina Access II/III had a medical director committed to the vision of a primary care-directed, evidence-based healthcare delivery system for North Carolina Medicaid patients as articulated by Secretary Bruton. Medical directors meet every two months to review statewide data and discuss innovative programs initiated at the pilot level. At the practice level, we try to identify a physician champion who will attend our local care management meetings and be the catalyst to implement disease management initiatives in his or her practice. As our county-wide model has evolved into a regional network, we have realized the need for a physician champion in each medical community. This physician champion receives a small stipend for a few hours of work each month (e.g., arranging and attending local steering committee meetings and interpreting the utilization data provided to individual practices). Physicians across North Carolina should feel an ownership in the success of Community Care of North Carolina.

Disease Management

Disease management tools were developed by a statewide medical directors group. Utilization data gleaned from charges showed that the North Carolina Medicaid program had high costs for pediatric asthma patients from ED use and hospitalization. In 1995, the national Institute of Medicine published guidelines[2] for management of children with asthma, so we felt we could adapt those guidelines for our use and get physician buy-in fairly easily. The results were impressive. Over the first four years of the program, utilization data showed we saved $27.5 million in reduced ED and hospital charges to North Carolina Medicaid. Diabetes management was the second disease tackled. Congestive heart failure is now being addressed through a more top-down approach. Several networks have initiated other disease management initiatives based on need and enthusiasm for tackling a perceived clinical problem. Buncombe County developed a Depression in Adults Initiative. In Pitt County, we are addressing attention deficit hyperactivity disorder and children with complex and chronic disease.

Case Management

In AccessCare, each pediatric practice has a case manager on site to assist in patient education and to overcome complex barriers to the successful implementation of the treatment plan. In our county-wide model, we've found great value in assigning our case managers to a primary care practice, but housing the case managers in a central location where they can learn from each other and cover each other's patients during holidays and vacations. We employ one case manager for every 3,300 patients, with each case manager actively following 100 to 200 patients at a given time. Referrals for case management are made directly by the practicing physicians, as well as by high-risk/high-cost patients identified by utilization data. Patients who frequently utilize the ED also receive calls from our case managers to assess reasons for the ED visit and schedule follow-up with the medical home.

Other case managers exist throughout the healthcare system. Our case managers often take referrals and then hand off the active management to other case managers located at health departments, departments of social services, mental health centers, early intervention programs, and the Children's Development Services Agencies. With these precious resources, we cannot afford to overlap services.

Implementing Evidence-Based Practice

Why do physician offices change how they practice? Every physician I know wants to practice the best medicine he/she can, and generally thinks they are. A physician won't change because Chuck Willson says he or she needs to, and especially not when a faceless bureaucrat in Raleigh or Washington, DC tells them to. Typically, physician offices will change if they can see opportunities for improvement. We've learned that practice-specific data will identify opportunities for a practice to improve. For example, when I told one Pitt County practice that their ED rate was four times the county average, the practice joined the community after-hours clinic consortium. Within a few months, their ED rate was better than the county average. While utilization data from claims are instructive and often compelling, we perform chart audits in the practices to assess compliance with disease management initiatives. We found early on that ED visits for asthma are correlated with a practice's asthma guideline compliance and office hours on weekends. When I first audited my own charts, I found that fewer than 50% of my asthma patients were staged or had a peak flow management plan as recommended by NIH guidelines. What a rude awakening for a physician champion!

Community Care of North Carolina

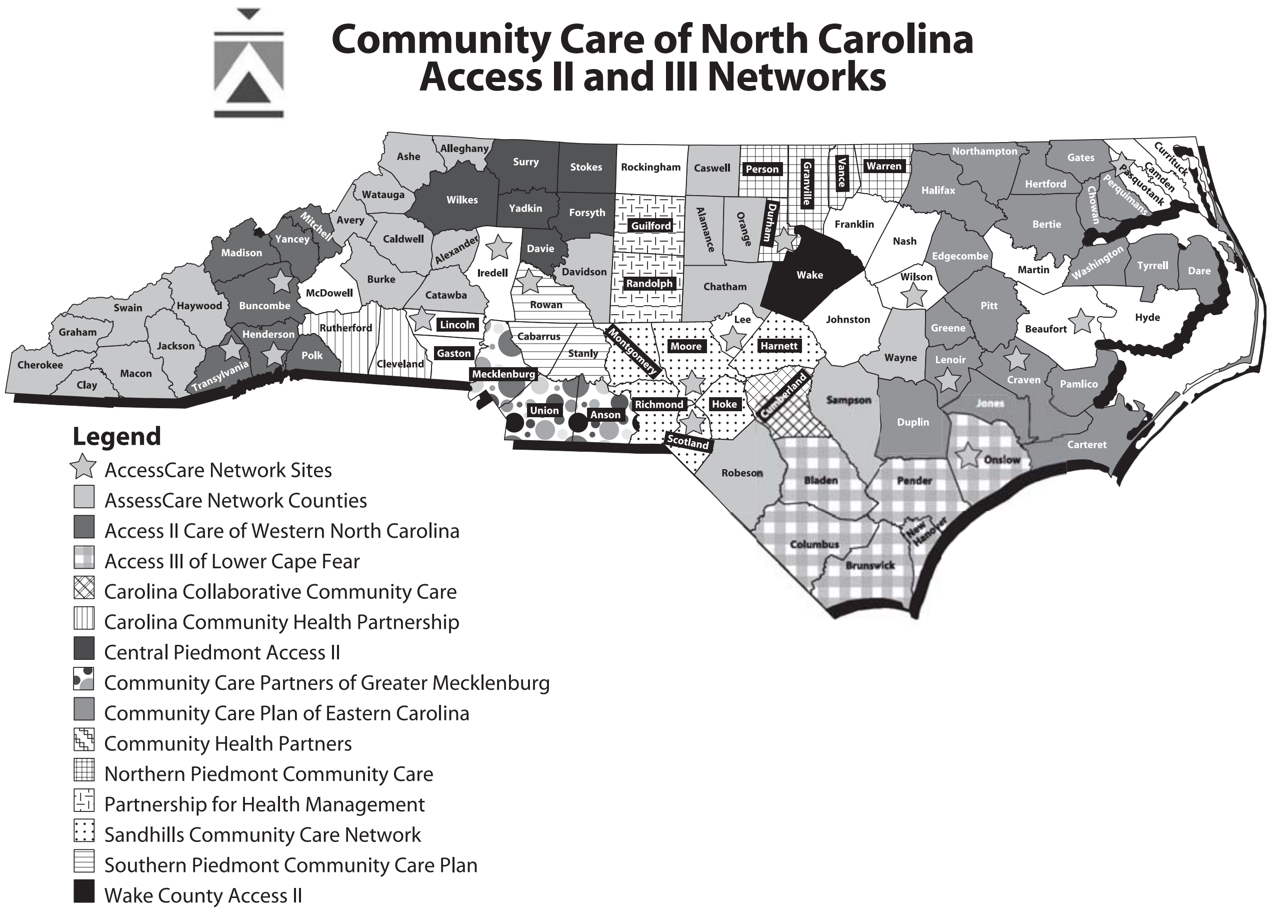
When Secretary Carmen Hooker Odom took over the North Carolina Department of Health and Human Services in 2000 after Governor Easley's re-election, she renamed Carolina Access as Community Care of North Carolina (CCNC). She also deemed the county-wide model as the preferred model and asked that it be implemented statewide by 2006. The Pitt County CCNC model became the Community Care Plan of Eastern Carolina (CCPEC). We help counties develop local partnerships for implementation of the enhanced primary care case management model. Since community healthcare is dependent on local resources, we recruit a physician champion as clinical director and form a local steering committee with representatives from the hospital (if there is one), health department, and department of social services. The local steering committee hires a project director and the case managers with funds being passed through our fiscal entity (now AccessEast, a not-for-profit corporation that evolved out of the PHO). CCPEC is now operating in 16 counties across eastern North Carolina (see map).

The Value of a Primary Care Network

Community Care of North Carolina works because it provides a network of enhanced primary care medical homes for North Carolina Medicaid patients. These enhancements are financial, data, and disease/case management. High-quality care is being delivered in a timely fashion in the least costly setting. Once the statewide network is complete, opportunities will exist to look at specialist care for North Carolina Medicaid patients with the same goals of improving access to care, measuring utilization and quality, and enhancing cost-effectiveness.

Conclusion

To achieve best outcomes for the individual patient, a primary care medical home empowered with disease management and



case management resources provides the "continuous healing relationship" envisioned by the national Institute of Medicine. A community network of these enhanced medical homes, linked into a regional network, can really start to deliver improved care for entire populations of patients, whether aggregated by insurance coverage (or lack of) or by disease processes. These networks become a platform to launch new and innovative care management programs.

As I think about Heather, my hope is that under our new CCNC model, she would have been in case management, her transportation issues identified, her mother's drug addiction addressed, and a pediatric ICU admission with intubation could have been avoided. Once our practices have mastered the evidence-based care of disease, my hope is that we, as primary care physicians, can turn our attention to the genetic and lifestyle issues that lead to disease. Primary care physicians need to assess the health and risk factors of their patients and give them a map to sustained good health until age finally intervenes with a peaceful death. I dream that the medical homes of the future will provide "prospective care" as outlined by R. Sanders Williams, MD, Dean of the Duke University School of Medicine, at a 2004 United States Department of Health and Human Services symposium in Baltimore. Truly, the only way to curb the spiraling cost of healthcare in our country is to prevent that which is preventable and catch the rest in its earliest stages through a well-planned system of primary care with access for all the people of our state and nation.[3] Community Care of North Carolina is a major step in that direction. **NCMedJ**

Cabarrus County:

A Study of Collaboration

L. Allen Dobson Jr., MD, and Torlen L. Wade, MSPH

While recent attention has been paid to office-based interventions to improve care, innovations in population-based healthcare have had an arguably larger impact on the health of the population. The experience of healthcare providers and community organizations in Cabarrus County, one of the original Community Care of North Carolina (CCNC or Medicaid Access III) pilots and early Healthy Community Access Program (HCAP) federal grantees, demonstrates two important innovations in population-based healthcare: primary care case management of the Medicaid population and integration and collaboration of safety net providers to care for the uninsured. CCNC, now expanded to cover the majority of the state, has had remarkable success statewide by ensuring a medical home for every Medicaid recipient, fostering community-wide collaboration around improved systems of care and employing disease management strategies to improve care. These principles applied statewide have resulted in remarkable improvements in asthma care, decreased hospitalizations, and a resultant savings of $124 million for state fiscal year 2004 for women and children covered by Medicaid.[1] HCAP grants and the Project Access model of Buncombe County have been used to improve volunteerism and coordination of care for the uninsured. Although every community is different in terms of resources and stages of healthcare systems development, this description of Cabarrus County's experience may define principles and elements of successful provider collaboration and system change.

History

Cabarrus County has a long history of excellent medical care; often beyond that expected in a community of its size. From the early days when textiles dominated the local economy, Northeast Medical Center (then Cabarrus Memorial Hospital) had a close tie to the textile industry and, in particular, with Cannon Mills. Charles A. Cannon served as Chairman of the Board of Directors of Cabarrus Memorial Hospital and was an early champion of high-quality healthcare. This close relationship continues today as the Cannon Foundation and Charitable Trusts supports the hospital and many worthwhile health-related projects. One early example was the medical education affiliation with Duke University supported by the Cannon Charitable Trusts, which improved physician continuing medical education and helped recruit many of the early specialists to the community. In the 1980s and early 1990s, in response to rising healthcare costs, there were attempts at healthcare integration through development of a health maintenance organization (HMO) and other managed care endeavors. Although these initiatives were not successful over the long term, they did set the necessary groundwork and provided valuable experience among physicians and other healthcare providers for working together.

Background of Collaboration

Cabarrus County and its many healthcare providers and agencies had a number of successful collaborations prior to more formally organizing as Cabarrus Community Care Plan, Inc. (CCCP) to locally manage Medicaid recipients and to coordinate the care of the uninsured. Some notable examples of early collaboration include:

- The *Community Free Clinic*, founded in 1994 by two retired physicians, Drs. George Liles and David Lockhart, receives wide community and provider support and plays a significant role in CCCP by providing a site for eligibility determination, medical care, and pharmacy services for the uninsured.
- The Cabarrus Family Medicine Residency Program, a collaborative venture between Northeast Medical Center, its medical staff, and the physicians of Cabarrus Family Medicine, was developed in 1996 to increase the supply of primary care physicians in Cabarrus County and rural communities in North Carolina.

L. Allen Dobson Jr., MD, is the Assistant Secretary for Health Policy and Medical Assistance for the North Carolina Department of Health and Human Services, and Past Chairman of Cabarrus Community Care Plan, Inc. He can be reached at allen.dobson@ncmail.net or 2501 Mail Service Center, Raleigh, NC 27699-2501. Telephone: 919-855-4100.

Torlen L. Wade, MSPH, is the director of the North Carolina Office of Research, Demonstrations, and Rural Health Development. He can be reached at torlen.wade@ncmail.net or 2009 Mail Service Center, Raleigh, NC 27699-2009. Telephone: 919-733-2040.

- The Logan Community Family Resource Center was a 1997 collaborative effort between municipal, health, law enforcement, and local government to provide needed services to the medically at-risk, minority population of the Logan community.
- Cabarrus Human Services Center opened in 1998 and includes Piedmont Behavioral Healthcare (mental health agency), Cabarrus Health Alliance (health department), and the department of social services under one roof. Co-location of these agencies has promoted access to care and ease of service.

> *"One of the keys to CCCP's success was the inclusive nature of the organization. While keeping the key providers of care at the center of the organization, there was balanced decision-making and building of trust among the entire medical community."*

Other notable community organizations that resulted from community collaboration include: Healthy Cabarrus (1998), Mental Health Association of Cabarrus County (1998), Latino Advocacy Council (1999), Parish Nurse Program (1997), Medical Assistance Enrollment Network (1995), and others.

Organization

In 1998, the community informally organized and applied to become one of the first Access III Medicaid pilots. Access III networks were defined as full-county initiatives that included the majority of physicians providing Medicaid services, the local hospital, the health department, and the department of social services. The goals of the network were to:

- Work directly with those community providers who have been caring for Cabarrus County's Medicaid recipients.
- Build a public and private partnership where community providers can work together to cooperatively plan for meeting patients' needs and where existing resources can be used most efficiently.
- Put in place local systems and supports that are needed to achieve long-term improvements in quality, cost, and access for Medicaid recipients; including implementing evidenced-based practice, disease management, case management, high-cost service management, and feedback and accountability.

In 2000, after a community needs assessment identified unmet medical needs for the uninsured, Healthy Cabarrus convened a task force to apply for the new federal HCAP grants available to communities to improve care for the uninsured. This application and the subsequent award became the pivotal point in the formal organization of Cabarrus Community Care Plan, Inc., a 501(c)3 (not-for-profit) corporation.

From the beginning, CCCP's governance structure included both providers of care and community organizations. A large Board of Directors represented physicians, the hospital, mental health, the health department, social services, free clinic, schools, dentists, and other community agency/organization representatives. A smaller executive committee provided day-to-day oversight. As with each CCNC network, Medicaid provided a $2.50 per member per month fee to the network to provide for management support. The HCAP grant provided needed project assistance in developing and delivering care to the poor uninsured. The network hired "care managers" who had a broad responsibility in assisting providers and patients. Another key function of the network was development of a Medical Management Committee, representing the major primary care practices charged with being the medical home for patients. Their role was development and implementation of disease management and utilization management initiatives at the practice and community level. In Cabarrus, that function fell to an already established disease management group at Northeast Medical Center. CCCP's role was to support and coordinate existing resources, rather than develop new infrastructure. One of the keys to CCCP's success was the inclusive nature of the organization. While keeping the key providers of care at the center of the organization, there was balanced decision-making and building of trust among the entire medical community.

Ongoing Projects

In addition to projects implemented as part of statewide Medicaid disease management efforts, CCCP was able to pilot new initiatives for the state and also work on local initiatives. Examples of statewide projects include asthma disease management, diabetes disease management, Prescription Advantage List (more cost effective prescribing), emergency department utilization reduction, and high-cost/high-risk case management.

CCCP was also part of initial pilot programs for the dental screening and fluoride varnish project in the zero-to-three-year-old Medicaid population, therapy services utilization management, poly-pharmacy in the nursing home project (which reduced and improved medication use among nursing home patients), and the current depression and mental health integration initiatives.

Examples of local projects include a community-wide attention deficit disorder (ADD)/attention deficit hyperactivity disorder (ADHD) management project tracking 1,481 students with ADD/ADHD; expansion of the dental care system for the poor and uninsured; and the HCAP grant, which funded the community-wide system for care of the uninsured. Through the HCAP program, 1,400 uninsured individuals received care in 2004, representing more than $2 million dollars in free physician services, and $1.2 million in free medication.

Notable Results

Although each of the above projects has shown improvements based on community and practice report cards, the most significant community results have been with regard to diabetes. Practice-based disease management for diabetes in Cabarrus County was initially championed by Dr. Doug Kelling, a local internist. His early work led to the development of a disease management center supported by NEMC. The Disease Management Center established a diabetes registry that tracks over 6,000 diabetic patients. The data measurements include hemoglobin A1C, low-density lipoprotein cholesterol, blood pressure, eye exams, aspirin, ACE inhibitor use, and monofilament exams. Patients are followed in the registry regardless of insurance type or extent of coverage. These data, in addition to practice improvement data, are collected and allow evaluation of care of the uninsured and Medicaid recipients compared to the privately insured population.[2]

The bankruptcy and subsequent closure of the largest employer in Cabarrus County, Pillowtex, created the largest layoff in North Carolina history. The increasing uninsured population combined with ongoing medical needs of former Pillowtex employees, and a growing Latino population for which disease management data indicated a lack of adequate access to care, significantly exceeded the community's ability to provide care. In response to this, CCCP led the effort to open and secure funding for a new Community Health Center

CCCP's efforts in managing the Medicaid population have resulted in significant cost savings for the state and local community. This is clearly the most significant success to-date. Despite having a higher than average per patient cost in 2001, CCCP was able to show an overall decrease in per patient Medicaid cost over the next three years of 5% (or $18.4 million). This measure best approximates utilization and is compared to a 10% increase for the state over the same period. Based on state estimates, total Medicaid expenditures in Cabarrus County, likewise, were less than would be expected over the same period and resulted in a savings of more than $1.01 million in local tax revenue.[3] Continued improvement is expected as CCCP begins management activities for the aged and disabled populations covered by Medicaid and other populations.

Lessons Learned

There are some basic principles that can be drawn from the Cabarrus experience as well as experiences in other CCNC communities.

- Community ownership is a *must* if these efforts are to be effective.
- A "medical home" for every patient remains the backbone for improving healthcare quality and access.
- You can't do it alone. Partnership, inclusiveness, and collaboration are keys to success.
- You must develop and support systems that change care at the practice and community levels.
- Physician leadership of the care improvement process is essential for long-term success.
- You have to measure outcomes. You get what you measure, but it is important to start measuring *something*, even if it is a single measure.
- Early success builds trust and makes future initiatives easier.
- Lasting change will take time and reinforcement.

Improvements in care quality, access, and savings seem to be additive (i.e., the totality of care improvement at the community level seems to be greater than the individual initiatives).

The promise of a more integrated community health system based on a primary care medical home and collaborative systems of care at the local level is attainable and should help prove the value of further development of the Community Care of North Carolina program. **NCMedJ**

Clinician-Patient E-mail Communication:

Challenges for Reimbursement

Eugenie M. Komives, MD

I inadvertently entered the world of electronic communication with patients in my former practice when a staff member suggested putting some of my business cards in the exam rooms. I was not aware that she had used the version with my e-mail address on them until I started receiving unsolicited e-mail from patients. Most of the patients who proactively chose to communicate with me via e-mail did so appropriately—they asked general questions, needed prescription refills, and/or had non-urgent problems. I removed the business cards before the volume of users got "out-of-hand," and the experiment came to a natural end when I left the practice for a job at Blue Cross and Blue Shield of North Carolina as Medical Director for the State Health Plan.

Why Should Electronic Consultations Be Reimbursed?

The core question regarding the issue of electronic clinician-patient communication that both patients and insurers should answer is, "Why should I start paying for something I used to get for free?" Electronic clinician-patient communication offers a number of advantages. For the patient, the advantages might be enhanced convenience (e.g., avoiding a long wait on the telephone, multiple phone transfers, uncertainty as to whether the prescription was called into the pharmacy, and/or making un-necessary trips to the clinician). I certainly would be willing to pay a fee for the convenience, and I suspect I am not unique in this regard.

"Why should I start paying for something I used to get for free?"

A different set of reasons might prompt insurers to consider reimbursing clinicians for this service. Payers are more likely to value innovations that reduce healthcare costs, improve the quality of care for members with chronic disease (regardless of whether or not costs are reduced or stable), and improve member satisfaction for the service offered.

Technology Links Patients, Providers, Payers, and Pharmacies

Research has found that many patients value these services and are willing to pay at least a nominal amount of money for their availability.[1,2] Thus far, at least one study explores the value proposition for electronic clinician-patient communication services from the insurers perspective.[3] This study involves a product called RelayHealth® and was conducted by Stanford University and the University of California–Berkeley.

RelayHealth® is a secure, Web-based, Health Insurance Portability and Accountability Act (HIPAA)-ready platform that can facilitate electronic clinician-patient interaction. RelayHealth® includes an algorithm-driven clinical interview process called a webVisit®, which facilitates electronic communication between patients, healthcare professionals, payers, and pharmacies. Through this type of program, patients can consult their clinicians with specific questions or requests, and clinicians can respond with the assistance of medically-reviewed, guideline-based content and can even attach patient education materials from an online library. Other patient-oriented features include prescription renewal, appointment scheduling, obtaining lab results or referrals, and access to self-care information. Possibilities for clinicians include: a program that coordinates referrals, triages patient messages, broadcasts preventive reminders, and sends appointment reminders and lab results. The program is also able to determine the patient's insurance status and can submit claims to participating insurers.

Stanford University and the University of California–Berkeley performed a pilot study with RelayHealth®, Blue Shield of California, ConnectiCare, and several large self-insured employers affiliated with Pacific Business Group on Health (using Aetna as a third party administrator).[3] The pilot was designed to answer the following questions:

Eugenie M. Komives, MD, is the Senior Medical Director for Network Support at Blue Cross Blue Shield of North Carolina. She can be reached at eugenie.komives@bcbsnc.com or PO Box 2291, Durham, NC 27702-2291. Telephone: 919-765-2505.

- What is the impact of the availability of RelayHealth® webVisit® services on healthcare utilization and costs?
- How do patients respond to the opportunity to communicate with their clinicians online in this manner?
- How do clinicians respond to the opportunity to deliver non-urgent care online using these tools?

The program was conducted between April 2001 and May 2002. Physicians were reimbursed $25 per webVisit® (other communication was not reimbursed), and the patients had copayments of $0-$10 per webVisit® consultation. Two hundred eighty-two physicians and 3,688 patients agreed to participate in the study. A control group matched for baseline demographic characteristics, including access to the Internet, was selected. Analysis of available claims information found that office visit costs decreased by $1.92 per patient per month, and total medical costs decreased by $3.69 per patient per month. The cost of reimbursement for webVisits® averaged $0.31 per member per month, and the return on investment was greater than five-to-one for the insurers. Patients and physicians were very satisfied with the program, and most (75%) agreed to continue using the service after the pilot program ended. Physicians indicated that reimbursement was critical in motivating them to use the program.

Based on the findings of this program, Blue Shield of California expanded the program to all of their Preferred Provider Organization (PPO) and Health Maintenance Organization (HMO) physicians. The medical director of the University of California–Davis Health System, a participant in the pilot program, indicated that in-person clinical productivity per day and per visit went up significantly. He postulated that this was likely due to the movement of non-urgent medical issues to the webVisit® format, which frees time for more acute office visits. Also in response to these findings, Blue Cross and Blue Shield of Massachusetts announced a similar pilot program using RelayHealth® in March, 2003.[4] The American Medical Association (AMA) and the American College of Physicians have issued position papers urging the Center for Medicare and Medicaid Services (CMS) to begin reimbursing physicians for these types of services for Medicare patients as well.[5]

In their position paper on the issue of reimbursement for e-visits, the American College of Physicians listed examples of reimbursable and non-reimbursable e-mail services.[5] Non-reimbursable e-mail services typically require no more than two minutes of physician time and could often be delegated to non-physician staff after instruction. Examples include reporting normal test results, e-mail with other clinicians in reference to patients, and renewing prescriptions (services that are typically not reimbursed today). Reimbursable services involve such things as a new diagnosis with treatment that does not involve a subsequent office visit, follow-up of chronic diseases that involve changes in medication, treating relapses of previously diagnosed conditions that require significant physician judgment, reporting lab tests that require changes in management, extended family counseling, review of computer-transmitted patient medical data, and answering questions about preventive health or general health questions. Without the electronic format, such services would typically involve a face-to-face visit, and thus are reimbursable today.

General recommendations for the appropriate use of electronic communication with patients are available from the AMA.[6] and other organizations. These include the following (not a comprehensive list):

- Develop a patient-clinician agreement for informed consent in using e-mail; specify appropriate use of e-mail versus phone or office consultation; ensure security mechanisms are in place; and have hold-harmless understandings for technical failure of the system.
- Install general security measures (e.g., password-protected screen savers, rules against sharing e-mail addresses with family members or outside third parties, etc.). Many recommend encrypting messages and using authentication or password protection methods for clinicians and patients.
- Use e-mail to communicate with established patients only.
- Include copies of all messages in the patient chart.
- Establish turn-around time expectations; provide coverage when the primary clinician is out of the office; provide guidelines on the length of messages and what constitutes appropriate content; use auto-reply features to assure that messages are received; use the patient’s identification numbers in the body of e-mail messages; have standard block text at the end of the e-mail regarding unintentional disclosure, and signature, phone and address of the sender, etc.

Several vendors offer products that meet such requirements. Examples include Medem’s iHealthRecord™, which is free to clinicians who do not charge their patients for the service, HealthyEmail®, and MyDocOnline™.[7]

Summary

Clinicians are rapidly gaining experience with online clinician-patient consultation, and more tools are becoming available to support these efforts. In addition, we now have evidence that using electronic communication is cost-effective to payers and appealing to patients and providers. At present, there appear to be few barriers to the adoption of these solutions for practices that use other online services. Security concerns can easily be overcome by using programs described in this commentary. Larger and longer studies that evaluate the benefits and cost savings in more detail may help convince other payers and providers of the utility of the Web-based programs. More studies are needed to understand the effect of clinician-patient electronic communication on the costs of caring for chronic illness. When these solutions also include support tools, such as electronic prescribing, which could improve patient safety and quality of care, they should be encouraged.

In their article entitled, “Electrons in Flight–Email between Doctors and Patients,”[8] Delbanco and Sands postulate that the future of e-communication in medicine will be integrated with a patient-controlled health record and will include secure synchronous and asynchronous communication, video conferencing and messaging, instant transcription into the written record, full-patient access to the record, translation into different languages, connectivity to multiple data sources, incorporation of multi-media educational materials. It will also allow data from home-based diagnostic technology to be sent to clinicians. "Electronic communication will move medicine inexorably toward such transparency, enabling doctors and patients to share knowledge, responsibility, and decision-making more equally. We need to explore rapidly how this change will affect the quality of care for patients and the quality of life for doctors."

The widespread dependence on Internet-based electronic communication to support a variety of commercial, educational, and entertainment needs and interests offers us an opportunity to develop innovative approaches to some long-standing problems—assuring the accessibility of clinicians to their patients and the effectiveness and timeliness of communication between them. It is exciting that we now have well-documented examples of how these new technologies can be used to enhance the quality of primary care practice in both large and small practice organizations. **NCMedJ**

Innovations in the Practice of Primary Care:

Communicating with Patients through E-mail

Donald C. Spencer, MD, MBA

American medicine is used to technological change. We usually think of technologic advance in terms of the latest generation of magnetic resonance imaging (MRI) scanner or the newest composite material used for hip prostheses. Clinician-patient communication and the documentation of that communication have gone through technological change as well. In 1754 the managers of the Pennsylvania Hospital, including Benjamin Franklin, adopted new rules for its physicians and surgeons. Rule eight stated that "the practitioners shall keep a fair account (in a book provided for that purpose) of the several patients under their care, of the disorders they labor under, and shall enter in the said book the recipes or prescriptions they make each of them." The recording of medical information has gone through several technological changes over the past decades. I took over the practice of Dr. James Covington in Wadesboro, North Carolina in 1984, along with some meticulous records he had kept of the patients under his care. In the course of reviewing one patient's file, I noted that the doctor's handwritten notes in 1947 had been supplanted with notes Dr. Covington had personally typed on his typewriter. As I took over his practice, I was changing the technology of documentation once again by dictating my office notes, which were then transcribed by a paid technician. My current practice of entering parts of the patient's history directly into an electronic health record underscores the distance we have come from 1754. The technology of non-face-to-face patient communication is undergoing transition today as well. Alexander Graham Bell's invention of the telephone in 1876 is being increasingly supplanted by a patient preference for clinician-patient e-mail communication. Bell warned of the resistance to change by stating, "When one door closes another door opens; but we often look so long and so regretfully upon the closed door, that we do not see the ones which open for us."[1]

Given the controversies surrounding clinician-patient e-mail, I was asked by our medical school dean to chair the E-Health Committee in October 2002 at the University of North Carolina at Chapel Hill (UNC), where I serve as a clinical faculty member in family medicine. The primary charge of the committee during my leadership was to develop a pilot for clinician-patient e-mail that would explore the usefulness and the challenges of this new technology. The group consisted of four physicians, including the chief of the hospital staff and the chair of a clinical department, information technology experts, and a marketing professional. The committee performed a literature review of relevant communications on clinical e-mail and explored commercial options that might assist us in applying the technology effectively. The committee developed a pilot Web portal to test the concept of e-mail in two UNC clinics. We developed a survey of clinicians at UNC to explore their attitudes toward doctor-patient e-mail. Finally, we made recommendations to administration on how to proceed with system-wide implementation.

> *"'When one door closes another door opens; but we often look so long and so regretfully upon the closed door, that we do not see the ones which open for us.'"*[1]

In reviewing the work already done on clinical e-mail communication, acknowledgement of the "digital divide" is particularly important in a public hospital such as UNC. Not all patients have access to computer resources. The gap between digital "haves" and "have-nots" is real but narrowing. Twenty-four percent of Americans have no direct or indirect experience with the Internet. Americans more likely to be "wired" are younger,

Donald C. Spencer, MD, MBA, is Professor of Family Medicine and Director of Operations for the University of North Carolina (UNC) Department of Family Medicine. He is also the Medical Director for the UNC Family Practice Center. He can be reached at spencerd@med.unc.edu or CB 7595, Chapel Hill, NC 25799. Telephone: 919-966-6058.

well-to-do, white, well-educated, and living in non-rural areas. Southerners are the least likely to use the Internet. Only 38% of Americans with disabilities go "on-line" as compared with 63% of all Americans.[2]

Kane published a classic reference in the *Journal of the American Medical Informatics Association* that our committee relied on heavily. The article presented guidelines to facilitate effective clinician-patient interaction, while using principles that would increase patient safety and decrease lawsuits.[3] We followed suggested communication guidelines, such as establishing turnaround time standards, warning against e-mail use for urgent matters, informing patients about e-mail privacy issues, and establishing categories of e-mail transactions (prescription refills, scheduling, etc.).

More recent work on patient e-mail has been published since our committee's work. Liederman and Morefield published their experience at University of California–Davis with a commercial Web messaging system (RelayHealth®). They confirmed the high patient satisfaction of such systems with 85.8% of patients either "very satisfied" or "somewhat satisfied." Seventy-five percent of clinicians were either "very likely" or "somewhat likely" to continue using the system after the study period.[4] Waldren and Kibbe, writing for the Center for Health Information Technology of the American Academy of Family Physicians, endorse the inclusion of provider-patient e-mail in the electronic health record.[5] In a two-part series, Car and Sheikh review the progress to-date of e-mail consultations and advocate for the coordinated action of healthcare professional organizations, patient groups, policy makers, and the information technology industry to facilitate widespread use.[6]

Our E-Health Committee reviewed commercial vendors that could help us with our development. We had presentations from Medem™ (www.medem.com), Tumbleweed® (www.tumbleweed.com), MedFusion (www.medfusion.net), and RelayHealth® (www.relayhealth.com, formerly Healinx™). Medfusion has collaborated with the American Academy of Family Physicians to provide physician members with Web portals for doctor-patient communication. Additional commercial options for doctor-patient e-mail are referenced by Scherger in Family Practice Management.[7,8]

The Committee developed Web portals for patients to communicate with clinicians in the UNC Family Practice Center (FPC) and the UNC Diabetes Care Clinic. The Web portal approach was used because of the advantages it offered. The structured format of a Web site allowed for easy categorization of the type of message with routing of the message to appropriate triage personnel. Information such as medical record number and pharmacy name could be entered as data fields on a Web form. Such information is frequently forgotten by patients in unstructured e-mail messages. The Web portal approach allowed for future technical security options, such as encryption, that are more difficult to attain with standard e-mail messaging. During our committee work, we had to deal with the upcoming Health Insurance Portability and Accountability Act (HIPAA) regulations that changed the scope of our project. Warnings and privacy disclaimers were "required reading" before a message could be sent by a patient using the Web portal approach we developed. Usage growth was continual in the Family Practice Center since the project was begun in October 2001. The Webmail address was promoted on the telephone answering welcome message for the clinic, as well as posters and patient brochures throughout the Family Practice Center. At the onset of the project, just over 100 e-mails were received by the FPC each month. As of the summer of 2004, the clinic received just under 600 messages per month. For comparison, the clinic received an average of 9,623 phone calls per month during the period October 2003 through September 2004 (not all of which are answered because of the high volumes of calls). During fiscal 2004, the FPC saw 46,538 visits, or an average of 3,878 patients per month. This works out to be about 0.15 e-mails per visit compared with 2.5 phone calls per office visit. In a simpler time and a smaller practice, I described the nature of telephone calls in my own practice in the 1980s.[9] The phone call-to-office-visit ratio was one-to-32 at that time. While my small rural practice in the 1980s cannot be directly compared to a complex academic family practice center, patient communications appear to have gotten more complex over time. We are hopeful that the ratio of e-mails and phone calls to office visits is a moving target, and, with time, we can increase the e-mails while decreasing the incoming phone calls to a point that we answer a higher percentage of them promptly.

The categories of e-mail messages we received are instructive. Forty-one percent of e-mails received from the Web portal messaging system in the FPC were in the "Ask Your Doctor" category. The "Request Appointment" category accounted for 29%. Prescription refills were requested 16% of the time. During the period of use of the system, we requested patients to call their pharmacies for refills so this may have cut down on the number of e-mail requests for refills that we were getting. The remainder of the other catgories ("Cancel Appointment," "Change Appointment," "Referral Request," "Address Change," "Billing Question," and "Name Change") account for the remaining 14%. The important observation from these data is that less than half of e-mails require the direct attention of the physician. Our committee concluded that a triage system was essential for a functional clinician-patient e-mail system.

During the development phase of the e-mail pilot we conducted a survey of our physicians concerning their opinions about clinician-patient e-mail and our plans. The survey was conducted online during February 2002. The topic was received enthusiastically and we received responses from 195 clinicians. Attending physicians comprised the majority of the sample, with responses from 163 (or 84%) of the total. There were 19 non-physician practitioners and 13 resident physicians who answered the survey. Our first question asked, "Given a plan for dealing with privacy, security, and triage concerns, which statement best fits your feelings about getting e-mails from patients?" Seventy-five percent of respondents replied either that they would use clinician-patient e-mail for all or some of their patients or they would continue to use standard e-mail on their own. The remaining 25% stated that they would not use clinician-patient e-mail. There was strong physician agreement with several of our questions. Physicians would never want to answer e-mail from patients who have not had a face-to-face visit (77%). They thought that all e-mails and responses should be part of the medical record (71%). E-mail communication was felt to improve patient satisfaction (57%). There was physician concern that patient related e-mail might increase physician workload rather than allow for improved efficiency (63%), and there was worry that patients would use e-mail for messages more appropriately communicated on the telephone or in-person (55%). Clinicians were equally split over the question "I think that documentation of e-mails in the medical record will reduce my legal liability."

Clinicians could freely comment on the survey. The range of responses underlined the potential for division in the medical staff over the topic of e-mail. Examples of positive comments were:

- "Eliminates telephone tag."
- "Scheduling appointments would flow more smoothly. Routine questions could be answered easily."
- "Patient families 'comparison shop' at times … I think communication by e-mail is one of the things some sophisticated families are looking for when then do their 'shopping'."
- "Allows physicians to answer questions when most convenient, and allows for thoughtful and informed response."

Negative comments were of equal interest to our committee:

- "One problem is that one of my patients is a little nutty and sends me daily five-page e-mails."
- "I know of several patients that would want a long-term e-mail conversation rather than an occasional question."
- "In clinical care by e-mail, you miss the communication from being face-to-face or 'voice-to-voice'."
- "I think that this is a VERY BAD IDEA."
- "My patients are mostly poor; few have e-mail."
- "Patients WILL use e-mail inappropriately. As an example, yesterday, I received a request from a parent to be a reference for her for a health-care job on my home e-mail. Secondly, I care for adolescents, and it is most unnerving when an IM [Instant Message] comes through from SWARM124 or such saying, 'Dr. So-and-so, is that you?'"

Our committee made recommendations to the administration that included extending our pilot program to all clinics with an "opt out" for non-inclined physicians. We emphasized the importance of the triage function, privacy and security, and administrative support. We are currently working with a commercial vendor to assure encryption of messages through an enhanced Web portal and incorporation of the e-mails easily into our electronic medical record. We suspect much current e-mail activity between doctors and patients goes on "under the radar screen" in a HIPAA non-compliant fashion. By continuing to work collaboratively with our patients and our physicians, we hope to evolve a system that will adopt the new technology of clinician-patient e-mail to enhance health. Someday we may even get reimbursed for it. **NCMedJ**

Emerging Trends in Medical Education:

What Are They? And Why Are They Important?

David W. Musick, PhD

Introduction

Medical education is currently in a state of rapid evolution. The purpose of this paper is to consider some emerging trends in how our future physicians are trained during medical school. The initial four years after completion of the bachelor's degree, known as undergraduate medical education or UME, serve as the foundation of subsequent lifelong learning. Whether a given medical school has a strong primary care mission or primarily emphasizes the preparation of future academicians, the educational issues prominent today are basically the same: how can we best train the physicians who will likely care for us and our children? The importance of this educational mission and the need to ensure its continued prominence in our society cannot be over-emphasized.

There are many categories of educational trends that affect UME, but this paper will address only two. These trends may be classified into two broad categories as follows: *Educational Theory and Philosophy*; and *Medical Professionalism and Humanism*. I will speak briefly about each category.

Educational Theory and Philosophy

At first glance, one may be tempted to think that an emphasis on *educational theory and philosophy* is nothing different, so how can this be an emerging trend? After all, isn't education and related theories what a medical school is about?

Believe it or not, the answer is "yes and no." A seasoned medical educator once wrote a tongue-in-cheek editorial entitled "When Is a School Not a School? When It Is a Medical School."[1] Historically, much of what has passed for formal education in medical schools consisted of activities that appeared to have been given seemingly little advance thought. Part of the reason for this is the long-standing use of the apprenticeship model of education, where students simply followed physicians and learned by observation. Such learning, especially during the clinical years, is highly context-dependent; students learned about patient care based on the types of patients that happened to show up in the hospital or clinic during a given time frame. However, with major recent changes in the healthcare system itself (especially shorter lengths of stay for nearly all patients who are hospitalized), we are now challenged to incorporate as much "real world" training as possible into the medical curriculum. As a result, more and more training is moving out of teaching hospitals and into a variety of new settings. So part of this trend reflects the rapidly changing environment for training medical students and resident physicians.

We know from educational research that there are three things that correlate highly with student achievement, regardless of what field of study one is engaged in. Those three things are: clarity of purpose, organization, and understandability. In other words, if you, as a student, know what the *purpose* of a given course or clerkship is, in terms of educational objectives, if the course or clerkship is *organized* to maximize your chances of achieving the educational objectives, and if you have a clear *understanding* of what you are expected to know and do (and how to do it), then chances are you will learn what you are supposed to learn.

There is great variability in how medical schools go about planning and carrying out the educational experiences required of medical students. Most medical school faculty members have little, if any, formal training in educational methods. Partly because of this lack of training, educational activities are sometimes highly organized; but at other times, they aren't. There are many factors that have an impact on how well faculty organize and carry out the educational mission, most notably the increasing time pressures faced by many teaching physicians and the lack of a stable funding source for medical education that takes place outside of the teaching hospital itself. Nevertheless, as stated in a recent journal article on residency training (i.e., graduate medical education), the emerging trend today is to "put the E back in medical education."[2]

Specifically, a major emphasis that has surfaced in recent years is the "outcomes movement." This concept requires educators to pay increased attention to not only the *process* of education (i.e., how we teach), but also to the *outcomes* of the process (i.e., whether students actually learned what we claim to have taught them). An illustration might help here. There once was a small

David W. Musick, PhD, is Associate Dean of Medical Education at the Brody School of Medicine at East Carolina University. He can be reached at musickd@mail.ecu.edu or 600 Moye Blvd, Brody 2N-72D, Greenville, NC 27834. Telephone: 252-744-2132.

boy who told his friend, “I taught my dog Rover to whistle.” His friend leaned down in front of the dog and listened for a few moments, hearing nothing. He said to the dog’s owner, “I don’t hear him whistling.” His friend replied, “I said I taught him; I didn’t say he learned it.” Sadly, many in medical education seem to think almost exactly in those terms!

Emphasizing Competency

The new emphasis on outcomes is primarily a result of an educational paradigm called “the competency model” of education. National accreditation bodies for medical schools, as well as for residency and fellowship training programs, have adopted the competency model in earnest. Notable here, for example, is the new “Six General Competencies” model, a competency-based educational approach that has been adopted by both the Accreditation Council for Graduate Medical Education (ACGME) and by the American Board of Medical Specialties (ABMS). Medical students and faculty alike should become familiar with this terminology, because it will probably be with you for the rest of your professional lives. Residency programs are now expected to demonstrate clearly that graduating residents are competent in six categories and to certify that competence in a variety of ways. Physicians in practice will also be expected to maintain their specialty certification via a system of ongoing measurement of competency, or “maintenance of certification” (MOC). This process will also feature the “Six General Competencies” approach mentioned previously. And, predictably, this model has also begun to be emphasized within accreditation standards for medical schools. The competency model can be summarized generally by the following quote from the ACGME’s “Outcome Project” Web site:

> “[The] Outcome Project refers to educational outcomes which are ‘evidence showing the degree to which program purposes and objectives are or are not being attained, including achievement of appropriate skills and competencies by students’…Achievement of learning is the ultimate purpose of any well-structured educational activity.” [3]

Given the complex body of knowledge, skills, and attitudes that medical students are expected to achieve, the task of specifying, measuring, and documenting well-defined educational outcomes in each area has become very complex. Medical educators at all levels across the country are currently engaged in rigorous debates about this very task. Suffice it to say that the movement of medical education accreditation toward the competency model will result in many changes to the methods used to train future physicians and to the process of ensuring that physicians already in practice can maintain their specialty certifications.

Other issues are also emerging in regard to medical education philosophy. For example:

- *Technology in Education* will include how to incorporate computers and/or other information storage and retrieval devices into the teaching and learning process and into providing efficient patient care. This includes enhancing communication among members of the healthcare team, between health professionals and the patients they serve, and between physicians and those entities that pay for healthcare (e.g., insurance companies). Examples include the use of Palm® technology, electronic prescription services, and medical records; and taking full advantage of electronic resources available online that inform the provider about evidence-based medicine.
- *Quality of Care* will include how the traditional apprenticeship model of clinical education must be modified to include research findings about such things as human performance, quality assurance in medicine, and preventive care. Examples include an emphasis on patient safety, reporting and prevention of medical errors, duty hours for physicians in training, and community-oriented health intervention projects.
- *Alternative Assessment* will include how to measure learning based on a variety of methods that will give a complete picture of what the student knows, can demonstrate, and ultimately can do on a regular basis.[4] Gone are the days where we will rely solely on standardized multiple-choice exams (in the basic science years) and subjective ratings by faculty (in the clinical years) to tell us whether a medical student is ready to progress to the next stage of the learning process. Examples include documented personal observation of students in the clinical setting; testing students with standardized patients; learning procedural skills using computer-assisted human simulators; assessment of physicians by patients and/or other members of the healthcare team; and the use of educational portfolios to document a variety of educational accomplishments.

Some of these concepts and methods can seem intimidating to faculty, as they represent profoundly different approaches to teaching and evaluating student progress. Such methods require the active partnership and collaboration of one’s students, and this, in turn, requires viewing students in different ways than the more traditional approaches. It appears that the competency model will now be emphasized throughout medical training and well into the future clinical practices of our students.

Medical Professionalism and Humanism

The second major emerging trend that must be considered is *medical professionalism and humanism*. It must be acknowledged that this trend is certainly not completely new. After all, hasn’t the tradition of “medicine as a compassionate healing art” been with us from the very beginning of the profession? And haven’t physicians always been considered “professionals?” Yes, but there are some new developments worthy of attention.

One such development pertains to cultural diversity in medicine, including the issue of “spirituality in medicine.” This emphasis is a reflection of the increased diversity of the patient population in the United States. For example, at least two thirds of the medical schools in this country now offer formal courses of study that examine the role of patient spirituality in the healing process. Recent scholarly literature suggests that certain health outcomes may be heavily influenced by the patient's cultural background, spiritual practices, and/or native traditions. This is an emerging and important area of research inquiry at the national level.

Some people place this type of thing squarely in the category of complementary or alternative medicine. But it's more than that; much more. It is foundational to the practice of what is now called "holistic, patient-centered care." In order to practice such care, it is necessary to be familiar with the types of patients served and their cultural backgrounds. Included is the need to expand our horizons a bit to consider not only the health of the individual patient, but the entire community from which the patient comes. We must be willing to accept a greater level of community involvement as part of the educational process, including a willingness to contribute to regional and national discussions about the healthcare system itself.

Related to this is dialogue taking place nationally and within every medical discipline about what it means to be a "medical professional." The concept of professionalism, which is included as one of the "Six General Competencies" mentioned earlier, has been defined in a variety of ways. Perhaps most noteworthy is the definition offered by the American Board of Internal Medicine and the American College of Physicians in a 2002 document entitled "Medical Professionalism in the New Millennium: A Physician Charter."[5] This document contains three fundamental principles that help define professionalism: the primacy of patient welfare; patient autonomy; and social justice. These principles are to be worked out in everyday practice through adherence to a set of ten professional responsibilities. Both current and future physicians should obtain this document and think seriously about the implications it will have on their future careers as physicians. (see Table 1).

Another way to think about the professionalism trend has to do with the churning debate about healthcare in our country. Is healthcare a right or a privilege? Clearly, we haven't decided yet. Issues such as managed care, increasing numbers of patients without health insurance, and the malpractice insurance crisis are contributing to a re-examination of medicine as a career choice. Many practicing physicians are changing careers, choosing to opt out of the system entirely rather than continue facing the daily pressures of dealing with frustrated patients, cost-cutting measures that threaten basic care, complex billing systems, and payers who don't want to pay claims. Organizations have sprung up across the country to provide retreats and other types of interventions for physicians who are angry, exhausted, emotionally burnt out, and exceedingly frustrated with a system that they have little control over. One popular healthcare consultant has observed emphatically that "the soul of medicine is on trial."[6]

As part of this emerging trend that compels us to think about medical professionalism and why people should want to be physicians in the first place, it is critically important for us to focus on the related issue of *why* the process of educating new physicians is so important. To do that, I share a brief story. In December of 2002, a young man that I knew well visited our home. He was a 21-year-old college student. He had not felt well recently; he seemed unusually tired. He complained of several symptoms related to a significant pain in his right upper arm. In fact, this pain had been present, off and on, for over three years. He had been to see doctors in several different locations over the course of the previous three years and had received several different diagnoses—everything from "repetitive motion injury" to "carpal tunnel syndrome" to "muscle strain of unknown origin." He was given pain medication a time or two, but some of the physicians seemed suspicious about his asking for pain medicine, in spite of his experiencing such severe pain that he couldn't concentrate very well on his studies and often missed class due to feeling badly. He saw a total of 13 different physicians during that three-year period for this problem. He had numerous exams, tests, physical therapy sessions, blood work, needle sticks, and electrodiagnostic studies. And he spoke frequently about how harried and tired the physicians seemed to be.

Table 1.
Medical Professionalism in the New Millennium*+

Fundamental Principles	Set of Professional Responsibilities
Primacy of Patient Welfare	Professional Competence
	Honesty with Patients
	Patient Confidentiality
Patient Autonomy	Maintaining Appropriate Relations with Patients
	Improving Quality of Care
	Improving Access to Care
	Just Distribution of Finite Resources
Social Justice	Scientific Knowledge
	Maintaining Trust by Managing Conflicts of Interest
	Professional Responsibilities

**From Physician Charter on Medical Professionalism; Medical Professionalism Project (2002).*
+Jointly Adopted by: the American Board of Internal Medicine Foundation, American College of Physicians Foundation, and European Federation of Internal Medicine.

This young man was very discouraged about his interactions with the healthcare system. He felt that his problem had not been taken seriously and that some of his physicians had been dismissive of him. He was also frustrated because his problem seemed to be getting worse, but he wasn't quite sure what to do about it. At the time of our conversation, his arm appeared grossly swollen. A physician colleague was contacted the next day, and arrangements were made for the young man to be seen immediately; in fact, he had a biopsy under anesthesia on

Christmas Eve of 2002.

As it turned out, the young man was diagnosed with a soft tissue Ewing's Sarcoma, a fairly aggressive type of cancer. He spent the entire 2003 year in and out of the hospital. He was hospitalized 11 times that year. He had nine rounds of inpatient chemotherapy, along with surgical removal of his tumor. During the surgery, he lost the median nerve in his upper arm, his dominant arm, resulting in some permanent loss of function in his right hand. He also endured five weeks of outpatient radiation therapy. He had a very scary neutropenic episode. This was a tough year for this young man and his family. The rest of his story is better. He received excellent care after the correct diagnosis had finally been made. His surgery was successful, he has undergone follow-up exams every three months, and, as of today, he is cancer-free and feels well. He is also back in school on a full-time basis. What does his story say about medical professionalism? Does the structure of our modern healthcare system, which often frustrates physicians and patients alike, encourage or hinder the practice of medicine in its best sense?

In the fall of 2003, at the annual meeting of the Association of American Medical Colleges in Washington, DC there was a panel presentation concerning the future of medical education in this country. One of the speakers was the mother of two children who suffer from cystic fibrosis. This mother spoke eloquently about her dilemma as the parent of a sick child. She spoke of the uncertainties that her family has to face and live with every day. These uncertainties are about: her children's treatments and their future prognosis, how to deal with information overload about their disease, what that information might mean to them, how to negotiate their way through the maze that is our current healthcare system, and how to make medical decisions for her children (e.g., confronting frequent questions, such as, "Is this a lung infection or just a simple cold? Should I go to the emergency room tonight or wait and call the doctor in the morning?").

"the soul of medicine is on trial."

Interestingly, this mother also saw many similarities between the uncertainties that her family faced and the uncertainties that define medical practice itself. She told her audience that it is not only an uncertain time to be a patient, it is also an uncertain time to be a physician, given complex new scientific discoveries, clinical ethical dilemmas, and ever-increasing levels of knowledge needed by tomorrow's physicians. She suggested that her physicians faced many uncertainties of their own during their everyday practices with such questions as, "Will this patient trust me? Is this the right treatment approach? Will I have enough time to spend with this family? Will the insurance plan cover the tests this child needs?"

This brave woman went on to talk about the importance of what many now refer to as "collaborative medicine"—how patients and their physicians must learn to be partners in the medical care given and received. She was asked what she wanted today's medical students to know from her perspective as a mother of two children with chronic illness. Here is part of what she said:

> "I want every medical student to know that all of the science they are learning will bring physical healing, but I equally want them to know the power of words. I want them to know the impact a doctor has when they choose words that support human partnerships. Like being able to say to a patient, 'I want to know what is happening.' 'I understand how you are feeling.' 'I believe I can help.' I hope we can beat this.' What matters to patients and families is not just what the doctor says, but how he or she says it. The echoes of our doctors' words played on and on long after we learned the technical meaning of cystic fibrosis."

And then she closed her remarks by making a profoundly important statement:

> "I want the doctors of tomorrow to know that when all the formal teaching is over, and I walk into your office, my need is for medical care for my child; but my desperate hope is that you have the same stake in my child's health as I do."[7]

Powerful words! These remarks from the perspective of a consumer of modern healthcare are important, not only to physicians in training, but to those who teach them. They illustrate in a very personal way the need to pay close attention to the training process and to acknowledge how the non-technical "art of medicine" will always be vitally important.

This issue of professionalism is intensely personal for each of us. Do you remember the young man mentioned earlier in this article? He is my son. We live as a family with the uncertainties associated with his illness. It is never far from our thoughts, and it impacts our lives every day. And our experiences as a family with the healthcare system, both during his illness and since then, have had a profound impact on how I think about and contribute to the process of educating physicians.

Conversations about professionalism and humanistic medical practice, about being sensitive to cultural issues, and about providing holistic care are an important part of the physician training process. They should remind us of what medicine is truly all about: the patients. When tomorrow's physicians progress to the point of their training where they put on the white coat for the first time, and, subsequently, wear it to the wards and the clinics every day, they must always remember how important mere words can be to the patients receiving their care. This is the essence of professionalism, and our training process must not overlook it.

Conclusion

The uncertainties that tomorrow's physicians will face are, in fact, a reflection of the uncertainties we all face—as people. Modern medicine is indeed a partnership between the physician and the patient. Equally, in lieu of the emerging trends just discussed, medical education *must* become more of a partnership between students and faculty, between medical schools and the community physicians who sacrifice their own time in order to help teach our students, and between medical schools and the communities they should be dedicated to serving.

This article has briefly summarized two emerging trends in the process of educating tomorrow's physicians: an emphasis on educational theory and philosophy and a focus on professionalism and humanistic medical practice. Medical education is evolving rapidly with new methods; increased emphasis on lifelong learning; and new ways of assessing the knowledge, skills, and attitudes of our students. Medical education takes place in an elaborate cultural milieu, one that is uniquely hierarchical and tends to embrace change very slowly. Nevertheless, we must embrace these trends if we are to be successful in efforts to educate competent, humanistic physicians for the next generation. **NCMedJ**

Instructions for Authors

Manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All manuscripts submitted for review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

North Carolina
MEDICAL JOURNAL

Remembering Eben Alexander, Jr., MD

David L. Kelly, Jr., MD

Dr. Eben Alexander, Jr., died at his home in Winston-Salem, North Carolina, Thursday, November 4, 2004. Dr. Alexander was born in Knoxville, Tennessee on September 14, 1913, to Elizabeth McMath Alexander and Eben Alexander, MD, a prominent surgeon in Knoxville. He graduated from the McCallie School and then attended and graduated from the University of North Carolina at Chapel Hill where he was Phi Beta Kappa. He graduaged cum laude with a doctor of medicine (MD) from Harvard Medical School in 1939 and was elected to Alpha Omega Alpha, the honorary medical society. He was later made permanent president of his medical school class of 1939, which included many prominent physicians and surgeons.

He began his residency training in neurosurgery at the Peter Bent Brigham and Children's Hospital in Boston. His training, however, was interrupted when he joined the Air Force in 1942. He received training at the Walter Reed General Hospital prior to being transferred to the Pacific theater where he served in New Guinea and the Philippines. He was awarded the Bronze Star and was discharged with the rank of major in 1946. After the war, Eben returned to Boston and then to Toronto and New Haven, where he completed his formal neurosurgical training. In 1949, he joined the full-time faculty at the then Bowman Gray School of Medicine of Wake Forest College in 1949, being appointed assistant professor of surgery in charge of neurosurgery. In 1954, he was appointed professor of surgery (neurosurgery). From 1949 to 1978, he was professor and head of the department of neurosurgery. He built a superb clinical program in neurosurgery and participated in the training of 39 residents, as well as enriching the learning experience of numerous medical students, interns, and residents. A review of his writings (some 200 publications) reflects an unbelievably broad interest and grasp of professional and societal concerns.

He was chief of professional services at the Medical Center for 20 years, participating in a substantial way to both the hospital and the medical school's growth and development. He arguably was the most influential member of the faculty in the history of the Bowman Gray School of Medicine. Dr. Alexander was president of virtually every important neurosurgical society including the American Association of Neurological Surgeons (the Harvey Cushing Society), the Society of Neurological Surgeons, and the American Academy of Neurological Surgeons. He served many years on the editorial board of the *Journal of Neurosurgery* and was an assistant editor, and later editor, of Surgical Neurology. He also served on the *North Carolina Medical Journal*'s editorial board and was a major contributor to their efforts.

He served six years as a member, and later chairman, of the North Carolina Board of Medical Examiners and was founder and chairman of the committee on ethics for the Medical Center.

His honors and awards are much too numerous to list; however, they include the North Carolina Physician of the Year in 1969; the Medallion of Merit at Wake Forest University in 1989, which is the highest award that can be awarded to a member of the faculty; the Distinguished Service Award from the American Medical Association; and the Distinguished Service Award from the Society of Neurological Surgeons.

In 1983, he was appointed professor emeritus. At that time he stopped active clinical practice, but continued writing and editing and also performed as an unofficial ombudsman for many friends and patients in need of medical care.

His activities in the community were numerous. He was a loyal and faithful member of the Centenary United Methodist Church and a weekly attendee of the Rotary Club of Winston-Salem where he served as president in 1959-1960.

He possessed an excellent innovative spirit and energy. He was among the first to advocate seat belts. He was an advocate for people with disabilities and was instrumental in the movement to improve sidewalk and ramp access. He established a successful support group for paraplegics, as well as special clinics for them and children with spina bifida.

Dr. Alexander will always be remembered for his enthusiasm and proficiencies, his perseverance and attention to detail, his spirit of compassion, honesty and excellence in all that he did.

We at the Wake Forest University Baptist Medical Center have benefited greatly from his skills, his good works, and have been blessed to have witnessed a career of great breadth and success and a life of abundance.

Dr. Alexander is survived by his wife, Mrs. Betty Alexander, four children, and four grandchildren. **NCMedJ**

North Carolina Medical Journal

a look at

Dietary Quality in Long-Term Care

The North Carolina Institute of Medicine

Since January 2002,
Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

Running the Numbers

A Periodic Feature to Inform North Carolina Healthcare Professionals about Current Topics in Health Statistics

Contributed by Thomas C. Ricketts III, PhD, MPH, and Katie Gaul, MA
Cecil G. Sheps Center for Health Services Research

Primary Care Physician Supply in North Carolina

The first map shows changes in the ratio of physicians-to-population for the period 1994-1998, and there is a general trend toward improved ratios and better distribution of primary care physicians across most counties in the state. This trend slows in the next period, 1998-2003. There are smaller increases in the ratio of doctors-to-population, and we are beginning to see more areas where there are physician losses. The final map shows that some of these changes in ratio are due to population shifts. In some counties the population has grown faster than the doctor supply, and in others, the doctor supply has decreased along with the population. The latter category includes places where the economy has slowed and places that are at real risk for losing important human and professional resources. Counties where there is rapid population growth present other challenges for physician supply as the professionals have to meet the needs of more people.

The North Carolina Healthcare Safety Net

To the Editor

The North Carolina Healthcare Safety Net Edition (Volume 66, Number 2) is worthy of everyone's attention, for it shows how tenuous the safety net is and how easily it can be torn further.

On reading and rereading this volume, I have not found a reference to a valuable, but overlooked resource for low-cost and excellent patient care, the retired physicians who reside in almost all of our communities.

I have spent the past 14 years as a member of the Senior Physician Services Group Committee of the American Medical Association (AMA) and have learned that many of our retired colleagues all across the country would gladly help meet the need by volunteering their services. As physicians retire earlier to escape the rigors and changes associated with medical practice today, more are available to help in the volunteer arena. We have learned, too, that after a few months to years of retirement, these healthy, experienced, and, sometimes bored, retirees are more than ready to once again don their white coats part-time and care for patients. Often, the only reason they do not offer their talents is that they are not asked.

Hilton Head Island has a splendid free clinic, which is staffed largely by retired physicians. Visit them while you are there and see what can be done. They have a complete plan for an all volunteer clinic and seem pleased to share their expertise. Several of our North Carolina communities have utilized the retired physicians as well.

The two major impediments to volunteer care by retirees have been liability and licensure. However, if one stays in the same state and has not relinquished his or her license to practice, there is not a problem as long as continuing medical education (CME) credits are maintained. As to liability, there is a recently funded legislative mandate that volunteer physicians are to be treated as federal employees in the matter of liability and, thus, are covered. The North Carolina Medical Society would likely be the best source for exploring this avenue, as there are some other provisions to be considered. Another source of information is the Senior Physicians Group at AMA.

In addition, North Carolina Medical Mutual provides a very low-cost policy, which covers the purely volunteer retiree, subject to underwriting. This has the advantage of full-time coverage, not just while working in a clinic. Kudos to Med Mutual for offering this excellent policy, for not all mutual or commercial companies offer this kind of community service coverage.

The purpose of this letter is to encourage readers to volunteer and to encourage those who need physician volunteers to ask the retirees in their area to serve. There is a wealth of talent and experience withering on the vine, and some of it is just waiting for an opportunity to be a part of the North Carolina healthcare safety net. It deserves more attention than it has been given.

James H. Burrus, MD, FACOG
Shelby, NC

To the Editor

Access to and delivery of quality healthcare to ALL of our people should be the goal of any healthcare system. At present, ready access is limited to the insured (corporate and self-insured; Medicare and Medicaid; veterans; and government employees, including politicians) and much less to the uninsured (more than 45 million, including approximately nine million infants and children) and many underinsured. You briefly allude to this in your introduction to the North Carolina healthcare safety net and offer a solution: "…until healthcare insurance is universal, the uninsured will remain a health policy issue of concern."

There are 1,200+ for-profit health insurers in the United States with consequent duplication of administration (CEOs, directors, employees, and stockholders), forms, and procedures amounting to about one-third (about $500 billion per year) of the cost of our healthcare (about $1.6 trillion in 2003 and rising 7-8% per year).

A crisis begs for action. Access and much of those insurance costs could be addressed with universal, single-payer, tax-funded (like Medicare and Medicaid and the rest of the developed world) national insurance. The overwhelming majority of our people want it, but are not heard or represented. So far, special interest politics have prevented this with for-profit health insurers each, or collectively, vigorously opposing, if not lobbying against, any change (remember the Harry and Louise ads?). If we could ever get over this obstacle, many of the other problems with the delivery of healthcare could be more readily solved.

Another problem that immediately comes to mind is the myth of perfection in medicine and the unrealistic expectation of those we serve. Ours is the most litigious society in the world (300+ lawyers per 100,000 persons compared with 50 in the United Kingdom and five in Japan), and this has led to rising defensive medicine with many unnecessary and very expensive tests and procedures. Carefully organized mediation boards to evaluate the legitimacy of claims and awards might help. Are we driving potential students from careers in medicine with these problems?

I heartily agree with and endorse your comment regarding the need for universal health insurance. Until that is accomplished, we will continue to flounder in a sea of discontent and disservice to our people and our profession.

Robert McLelland, MD, FACR
Durham, NC

To the Editor

Thank you so much for your well timed and thoughtful discussion of the dissipation of the safety net for healthcare in North Carolina.

As President of the North Carolina College of Emergency Physicians, I can safely say that most emergency physicians will be surprised that there was not more emphasis on emergency departments (ED), other than an isolated comment that almost 700,000 uninsured received care in an ED in North Carolina last year. This volume might be greater than all of the other components of the safety net that you describe combined.

The ED is, in fact, the safety net to the safety net, as you describe it, which warrants additional discussion of its own. Emergency departments in the state are routinely used for non-emergent clinic problems by the uninsured who have no local clinic or are turned away from their clinic because of capacity issues. The ED is by far the most expensive place to treat these patients because the overhead of running an ED is so much higher than that of a clinic. It is naive to believe that the state and local governments do not ultimately pay for the increased cost of trying to provide this care in the most expensive environment available.

It is a profound disservice for the uninsured to try to treat many of these patients in an ED because proactive continuity of care and disease management is so badly needed to successfully manage many of their their ailments. This cannot be provided in an ED.

Most ED's in North Carolina are so backed up with non-emergent uninsured clinic patients, that it has a profound effect on the efficiency and safety, never mind the convenience, with which patients with true emergencies can be managed in our EDs. On most days, any given ED has patients with significantly urgent or emergent medical problems who wait unacceptably long periods for non-emergent patients to be screened and helped however possible.

Because of EMTALA,* emergency departments cannot turn away these patients based on the ability to pay. This well intentioned federal statute ensures that all unsured will have access to EDs for healthcare, but provides no funding to hospitals to provide this mandated care. The uninsured probably represent at least 25% of patients seen in EDs across the state, and much more in some areas. As you point out, these same hospitals and physicians remain vulnerable to the skyrocketing malpractice costs associated with caring for these patients, despite providing care that is more often than not unreimbursed.

I thought it was curious that the North Carolina College of Emergency Physicians was not asked to contribute to your otherwise outstanding task force, since our constituents provide the majority of the "safety net" care of the uninsured that you desribe. We would be happy to particpate in your discussions in the future, if you so see fit. Thank you.

Edward N. LaMay, MD
President, North Carolina College of Emergency Physicians
Durham, NC

To the Editor

I read the Issue Brief and Commentaries in the March-April 2005 issue of the *North Carolina Medical Journal*. These reports focused on providing healthcare to the uninsured and the North Carolina healthcare safety net.

I found the Issue Brief and Commentaries interesting. However, I was dismayed to learn that the Task Force, and Task Force Steering Committee, was without representation from North Carolina's emergency medicine specialists. More importantly, I was distressed that the critical and essential role that emergency medicine specialists play in the North Carolina healthcare safety net was not well-described, and that Task Force recommendations made no attempt to address the unique problems that care of the uninsured present to emergency medicine providers. My dismay and distress are all the more acute since using the numbers that the Task Force provided in its reports, emergency medicine specialists cared for more uninsured patients in 2003 than all other components of the healthcare safety net combined!

It is critical that North Carolina Institute of Medicine, North Carolina state legislators, and all North Carolina citizens be aware of the role emergency medicine specialists play in North Carolina's healthcare safety net. Emergency medicine specialists are the very fabric of the ultimate safety net. Providing this safety net 24 hours-a-day, seven days-a-week is part of the mission of emergency medicine. However, fulfilling this mission poses a unique set of problems that affects not only the uninsured, but every patient who needs or may need emergency care. It is absolutely essential that any discussion of the North Carolina healthcare safety net include emergency medicine specialists.

I am optimistic that as debate and discussion of the Task Force's reports and Commentaries ensue, it will be apparent that including representation from North Carolina's emergency medicine profession is an integral part of achieving better healthcare, not only for North Carolina's uninsured citizens, but for all North Carolinians.

C. Michael Sheppa, MD, FACEP
President Raleigh Emergency Medicine, Inc.
Raleigh, NC

Response from the Task Force Director

Drs. Lemay's and Sheppa's letters, published in this issue of the Journal, raise questions about the lack of representation of emergency physicians on the Task Force on the North Carolina Healthcare Safety Net, and in the commentaries on the special issue on the healthcare safety net published in the March-April issue. We appreciate the comments of Drs. LeMay and Sheppa, but want to assure them that the Task Force was acutely aware of the problems faced by the state's hospital emergency rooms in addressing the healthcare needs of the rising numbers of uninsured. The Task Force included several chief executives of urban and rural hospitals throughout the state, who raised these issues throughout the Task Force deliberations. While we feel that enormity of the contribution made by hospital emergency departments to the care of the uninsured in our state were appropriately dealt with in our discussions and in our final report, we agree with Drs. LeMay and Sheppa that it would have been better to have included representation from the physicians who actually provide this care. We have included representation of emergency medicine physicians in our new Task Force that is studying ways to expand health insurance coverage to the uninsured.

Alzheimer's Disease and Family Caregivers

To the Editor

The January/February 2005 issue of your Journal dealing with Alzheimer's disease was a truly valuable work relating to this condition. The broad range of Alzheimer's concerns from basic medical issues to socioeconomic ramifications was addressed admirably. This range of articles underscores the cruel irony that the burden of this disease is born by family, caregivers, and society at large.

Efforts to promote early recognition, diagnosis, and reasonable treatment interventions can only serve our state well into the future. Thank you for bringing this issue to publication.

Michael J. Kushner, MD
Wilson Orthopaedic Surgery and Neurology Center, PA
Wilson, NC

To the Editor

Please express appreciation to Myron Green for sharing his experience caring for his wife, Sadie, who has advanced dementia, in the January/February 2005 issue of the *North Carolina Medical Journal*. His capacity is remarkable, and it was a great privilege to read his description of coming to accept "… the way she is …" and then to give her all that she needs, day after day, with steady skill and amazing grace.

Thanks also to Dr. Donald Madison, who gave us the eyes and ears to see and listen to what it is like to do this. His essay told us what we must do without lectures, facts, figures, or predictions. It put a face on Alzheimer's disease and on the remainder of the issue, which then provided a larger context for this call to action.

We must act personally, regionally, and nationally to support Myron and Sadie, husbands and wives, neighbors, parents, and grandparents. Once we accept " … the way [it] is … ," maybe we will learn and teach and act together to do what we must do.

Upstate Medical University, State University of New York
Syracuse, NY

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

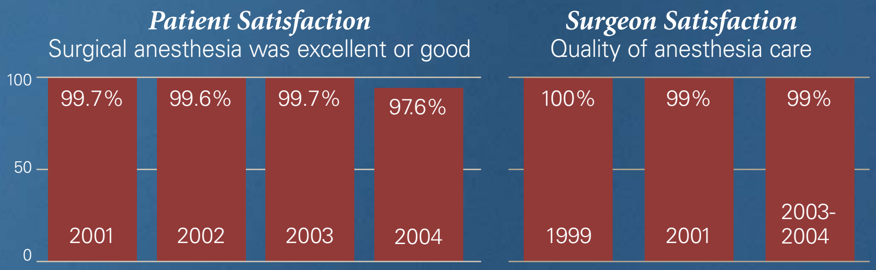
Transforming
Healthcare

We Measure Satisfaction
One Patient At A Time

Southeast Anesthesiology Consultants and Southeast Pain Care Are Dedicated To Patient and Surgeon Satisfaction.

One patient at a time. Everyone talks about exceeding expectations, but Southeast Anesthesiology Consultants and Southeast Pain Care do more than talk.

Through ongoing patient surveys, we measure the satisfaction levels of our 70,000 anesthesia and 30,000 chronic pain patients each year. In addition, we survey our surgical colleagues every other year for their assessment of our performance.



Patient and surgeon satisfaction results are audited by a third party and are statistically significant.

Patient and surgeon satisfaction surveys are crucial elements in our comprehensive Continuous Quality Improvement program, which also includes 50-point quality checklists on every patient we treat. It's all part of our dedication to Assuring Safety and Administering Comfort, one patient at a time.

Managing Chronic Health Conditions Through Member Health Partnerships

Diabetes, asthma, kidney disease, fibromyalgia, migraine or heart disease. When a patient receives the news that they have any one of these chronic conditions, chances are that they will want to learn everything they can about it.

At Blue Cross and Blue Shield of North Carolina, we want our members to learn how to better manage their chronic conditions, as well as get the facts on how they can live a healthier lifestyle. We want to help them sort through the information overload that they will likely encounter, and get them up-to-date information about their specific condition when they need it.

That's why we offer Member Health Partnerships℠. Designed to educate our members about their individual health concerns, these customized programs also help reduce the health risks that may develop with a chronic condition.

With educational resources, self-management tools, condition-specific quarterly newsletters and even financial incentives, members will benefit from the knowledge they can gain from these free, confidential programs. They can also speak with specially trained nurses, who can assist them in understanding their treatment options and help them get the most out of their office visits with you.

In addition to conditions such as asthma, diabetes or heart disease, we also offer a Member Health Partnerships program for expectant mothers with prenatal care issues.

If you have Blue Cross and Blue Shield of North Carolina patients who would benefit from any of our Member Health Partnerships programs, encourage them to call us at **1-800-218-5295** or visit us online at ***bcbsnc.com*** for more information.

For more than 71 years, our members and participating doctors have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's stable, reliable and largest health insurer.

Innovative health care designed around you.℠ | ***bcbsnc.com***

Southeastern Regional Medical Center becomes nursing classroom

UNCP four-year nursing program to be conducted at the Medical Center

LUMBERTON — Southeastern Regional Medical Center will provide a working environment for students enrolled at the University of North Carolina at Pembroke.

The program facilities will be located at the current SRMC Corporate Services Building and provide 7,000 square feet of clinical settings, classrooms, computer labs, and offices.

"UNCP's nursing program will assist our region by graduating top-quality nurses," Chancellor Allen Meadors said. "The nursing field is a noble, caring profession, and it is critical to help resolve the increasing nursing shortage in our region."

"We at SRMC are excited about the approval of the UNCP four-year nursing program," Chief Executive Officer and President Luckey Welsh said. "Our citizens will benefit for years to come because of this collaborative effort."

The nursing program is expected to add 100 BSN graduates annually to the Lumberton area.

Perceived Racial/Ethnic Bias in Healthcare in Durham County, North Carolina:

A Comparison of Community and National Samples

Joëlle Y. Friedman, MPA, Kevin J. Anstrom, PhD, Kevin P. Weinfurt, PhD, Mary McIntosh, PhD, Hayden B. Bosworth, PhD, Eugene Z. Oddone, MD, MHS, Cedric M. Bright, MD, and Kevin A. Schulman, MD

Abstract

Background: *We sought to compare findings of a national survey of perceptions of racial/ethnic discrimination in healthcare to those of a community survey, with emphasis on the perceptions of Latinos.*

Methods: *Responses from a national survey were compared to a telephone survey of residents of Durham County, North Carolina.*

Results: *Black respondents in the Durham sample were more likely than those in the national sample to feel that a healthcare provider had treated them with disrespect because of health insurance status (28% vs 14%; $P < 0.001$). Approximately one third of Durham Latinos and 14% of Latinos in the national sample felt they had been treated with disrespect because of their English-language ability ($P < 0.01$). Compared to a national sample of white participants, white respondents in Durham were more likely to believe that black persons are worse off in terms of receiving routine medical care (40% vs 27%; $P < 0.01$) and having health insurance (58% vs 43%; $P < 0.01$). As compared to their national counterparts, there was a similar trend for how white respondents in Durham perceived how Latinos fared ($P < 0.001$ for all comparisons).*

Conclusions: *Overall, the perception of bias in healthcare was greater among Durham residents, especially among newly immigrated Latinos, than among their national counterparts.*

Introduction

Over the past two decades, there has been growing interest in racial and ethnic disparities in the use of preventive health services and medical procedures for many conditions.[1,2] Differential use of appropriate medical therapies is a crucial flaw in the United States healthcare system, impeding our ability to achieve the goals of *Healthy People 2010*.[3] These goals include the elimination of disparities in care for cancer screening and management, cardiovascular diseases, diabetes mellitus, human immunodeficiency virus infection (HIV) and acquired immunodeficiency syndrome (AIDS), and child and maternal health.[3]

Attempts to develop interventions that rectify disparities in healthcare have had varying degrees of success. Interventions have included cultural competency programs,[4,8] screening and outreach services for minority populations,[9,12] and programs to enhance patient-provider communication.[13,14] Most reports of these programs do not describe a needs assessment component of the projects, although needs assessment is usually the first step in the development of an effective intervention, because it provides a comprehensive description of the problem and its origins.[15]

We set out to describe the local community of Durham County, North Carolina, regarding public perceptions of racial and ethnic discrimination in healthcare, with the goal of developing interventions designed to improve healthcare for minority patients. We were especially interested in exploring the healthcare experiences of newly immigrated Latino residents, a sizable and underexamined segment of the community. Durham County is a diverse community, having almost equal percentages of black and white residents[16] and a rapidly growing Latino population.

From 1990 to 2000, the Latino population in the Raleigh-Durham metropolitan area increased from 9,923 to 72,580, a 631% increase.[17]

The starting point of this study was the report of the Henry J. Kaiser Family Foundation (KFF) entitled *Race, Ethnicity & Medical Care: A Survey of Public Perceptions and Experiences.*[18] The report offered the first national description of the public's knowledge of and attitudes about racial and ethnic differences in health and healthcare. Among 3,884 adult respondents living in the continental United States, approximately three quarters of respondents viewed racism as a problem in healthcare.[18] However, it was not clear how we were to extrapolate the KFF findings to the local community. Any such extrapolation would be important in efforts to inform interventions that focus on local rather than national concerns and to encourage buy-in and endorsements by local governments and community organizations. Therefore, we sought to determine how applicable the findings of the national survey were to the local community, with special emphasis on exploring how members of the Latino community perceive their experiences with the healthcare system.

Methods

We compared responses to the KFF national survey and responses to a community-based survey. The KFF survey has been described elsewhere;[19] the community survey is described below. This study was approved by the institutional review board of Duke University Medical Center.

Sample Design

Eligible subjects were adults living in Durham County, North Carolina, in households with telephones. The sampling design targeted interviews with disproportionately large subsamples of black and Latino adults. The sample was designed to generalize to the Durham County adult population in telephone households and to allow separate analyses of responses by black, Latino, and white respondents.[20,21]

Two separate samples (Survey Sampling, Inc., Fairfield, Connecticut) were used to complete all interviews. The first was a disproportionately stratified sample drawn for telephone exchanges serving Durham County. The sample was drawn using standard, list-assisted, random-digit survey methodology. Active blocks of telephone numbers (area code + exchange + two-digit block number) that contained three or more residential directory listings were selected with probabilities in proportion to the number of listed phone numbers. After selection, two more digits were added randomly to complete the number. The resulting numbers were compared against business directories, and matching numbers were purged. Exchanges with higher than average density of black households were oversampled to increase the overall sample incidence of black respondents.

For the second sample, to achieve an oversampling of Latino respondents, participants were recruited by random-digit dialing from a list of households with Latino surnames. We selected this approach because Durham has few nonclustered Latino households.

Survey Development and Administration

The KFF survey was the foundation for our assessment.[18] We adapted additional survey items from the California Health Interview Survey (CHIS),[22] the El Centro Hispano/Proyecto LIFE survey,[23] and a review of the literature.[24,25] Specifically, we used the Health Belief Model to identify potential barriers to care. The Health Belief Model was developed to explain why people fail to engage in disease prevention or screening tests before the onset of symptoms.[26] The model proposes that the likelihood of one carrying out a particular health behavior (e.g., seeking healthcare) is a function of personal beliefs about perceived susceptibility, severity, benefits, and barriers.[27]

We augmented the candidate survey items with items derived from a provider survey. The brief, informal provider survey was administered by e-mail to PrimaHealth IPA Network providers (a provider network local to Durham County). The provider survey was used to identify perceptions of barriers regarding the provision of medical care for persons of different cultures. We also provided a draft of the survey to a convenience sample of community leaders (i.e., public health officials, public officials, community group leaders) for comment to ensure that we considered relevant factors that cause or contribute to local barriers to healthcare. Finally, we conducted a small pilot test by conducting cognitive interviews with black and Latino community members to assess content validity and to verify that many barriers to care were considered as pre-coded responses in the survey. For Latino participants, the final survey was translated into Spanish and back-translated for validation purposes.

Given the length of the survey, we split the survey instrument into three components—the core survey, additional items for split-half sample 1, and additional items for split-half sample 2. All subjects completed the core survey items and one of the split-half sets of questions.

Similar to the KFF survey, the survey was administered by telephone from October through December 2002 in either English or Spanish, according to the preference of the respondent, by Princeton Survey Research Associates (Washington, DC). At least 15 attempts were made to contact a respondent at every sampled telephone number. Calls were staggered over times of day and days of the week to maximize the chance of contacting potential respondents. Each household received at least one daytime call. In each contacted household, interviewers asked to speak with the youngest adult male currently at home. If no adult male was available, interviewers asked to speak with the oldest adult female at home. This systematic respondent selection technique is regularly used by the survey firm to produce samples that closely mirror the population in terms of age and gender. The proportion of working numbers where a request for interview was made was 77% (2,615/3,384). The proportion of contacted numbers where consent for interview was at least initially obtained was 54% (1,415/2,615). Eighty-three percent (1,175/1,415) of the contacted numbers were eligible for the study. (A household was considered ineligible if there was no adult in the household or if there was a language barrier). The proportion of initially cooperating and eligible interviews that were completed was 96% (1,131/1,175).

We developed survey weights to adjust for planned effects of the sample design and to compensate for patterns of nonresponse that might bias the results. Additional details on the weighted analysis are available from the authors upon request.

Measures

Since our survey was based on the KFF survey, our domains mirror themes described in the KFF report.[18] The final survey domains were as follows: demographic characteristics, knowledge of differences in health and healthcare access, personal experiences with being treated unfairly, and perceptions of the influence of race/ethnicity and racism. The coding scheme described below refers to response categories for both the national and Durham surveys, unless otherwise noted.

For all measures described below, except for demographic characteristics, we included "don't know" and "refused" in the "other" category, because we were interested in examining the probability of a participant responding in a certain manner compared to all other responses.

Demographic Characteristics

Demographic information included self-identified race/ethnicity, age, sex, country of origin, marital status, education level, income, home ownership, and health insurance status. Respondents were asked to indicate if they were Latino or of Latino descent and then to indicate their race (Asian, black, white, other). For purposes of this analysis, we excluded respondents who identified themselves as Asian or other. All respondents who reported that they were Latino or of Latino descent were coded as Latino, and the remaining sample was coded as black or white. Due to the relative homogeneity of country of origin among Latino respondents (69.4% reported Mexico as the country of origin), we recoded country of origin as a dichotomous variable (1 = United States, 0 = other). We also recoded marital status (1 = married, 0 = other), education level (1 = at least some college, 0 = other), and home ownership (1 = own home, 0 = other) as dichotomous variables. We created four sets of indicator variables for regression analysis. Two indicator variables were created to represent race, with white as the reference category. Three indicator variables (30 to 39, 40 to 49, ≥ 50) were created for age, with 18 to 29 serving as the reference group. We created three indicator variables for health insurance (i.e., Medicare, other, and no insurance), with private insurance as the reference group. Finally, financial status in the Durham survey was assessed using a single item with five response options, as follows: "you are having difficulty paying the bills, no matter what;" "enough money to pay for bills, but you have to cut back;" "enough money to pay bills, but little to spare for extras;" "bills are paid and still have enough for extras;" and "don't know" or refused to answer. Due to small cell sizes, we combined the first two categories of financial status, resulting in low income as the reference category.

By comparison, the KFF survey asked respondents to report income in terms of income distribution (e.g., \$25,000 to < \$30,000), and three indicator variables were used to represent low income (< \$25,000; referent category), middle income (\$25,000 to < \$40,000), high income (≥ \$40,000). Due to small cell sizes, we combined "don't know" and "refused to answer."

Knowledge of Differences in Health and Healthcare Access

We used two questions to assess knowledge of racial/ethnic differences in health and healthcare access. The first question asked respondents how they thought black persons fared, compared to the average white person, in receiving routine medical care when they needed it, having health insurance, and getting needed healthcare. The second question was identical, except that it asked respondents how they thought Latinos fared, compared to the average white person. Response options for both questions were "better off," "worse off," "just as well off," and "don't know/refused to answer." We dichotomized these variables as "worse off" and other.

Perceptions of the Influence of Race and Racism

We defined racism as being treated worse than others because of race or ethnicity. To give the perceived influence of race/ethnicity in healthcare a frame of reference, participants in both samples were asked about perceptions of the influence of race/ethnicity in major social institutions. Respondents were asked whether they thought racism was a major problem, a minor problem, or not a problem at all in education, the workplace, housing, and healthcare. We recoded the response options so that 1 indicates a major problem and 0 indicates other (including don't know/refused to answer).

Respondents were then asked if they thought black and Latino persons received the same quality of care, higher quality of care, or lower quality of care compared to most whites. We dichotomized the response options so that 1 indicates lower quality of care and 0 indicates other (including don't know/refused to answer).

Personal Experiences with Being Treated Unfairly

Respondents were asked to recall their experiences with healthcare in the past few years and whether they ever felt that healthcare providers or other staff members judged them unfairly or treated them with disrespect because of whether they had health insurance, how well they spoke English, or their racial/ethnic background. Responses included "yes," "no," and "don't know/refused to answer." We recoded the responses as 1 for yes and 0 for other.

Statistical Analysis

We used survey weights for all analyses to correct for the complex survey design and nonresponse bias. (A detailed report regarding the weighted analysis is available from the authors upon request.) Our first set of analyses compared responses between the two samples by race/ethnicity for 15 key questions. We used simple statistics to describe both samples, and we used normal approximations to compare the groups to calculate P values. Our large sample size afforded statistical power to detect very small differences. Thus, we considered a difference between the community and national samples practically significant only if there was an absolute difference of ≥ 10% and a P value ≤ 0.05.

For the second set of analyses, we attempted to determine how perceptions of racism in education, the workplace, housing, and healthcare (hereafter termed institutions) differed across race/ethnicity after adjusting for demographic characteristics. Using survey-weighted multiple logistic regression analysis, we developed eight models. The first four models analyzed perceptions of racism across institutions for Durham respondents, and the remaining four models analyzed perceptions for national respondents. We included the following demographic characteristics in the models: age, sex, income, education level, and marital and health insurance status—all factors related to access to care. (We did not include country of origin in the models because it was strongly correlated with Latino ethnicity.) We converted parameter estimates for each variable to approximate relative-risk ratios using the method described by Zhang & Yu.[28]

We performed all analyses using Stata version 8.0 (Stata Corporation, College Station, Tex).

Results

Table 1 shows the demographic characteristics of the Durham and national samples. The samples were similar across race/ethnicity with respect to marital status, and white and black respondents in Durham were similar to their national counterparts in terms of sex, country of origin, home ownership, and health insurance status. However, whereas 54% of white respondents and 41% of black respondents in the national sample had at least some college education, these figures were 72% for white respondents and 50% for black respondents in the Durham sample ($P < 0.001$; $P = 0.02$).

Durham Latinos differed from Latinos in the national sample in terms of age, sex, country of origin, education level, home ownership, and health insurance status. Durham Latinos were younger and were significantly less likely to report the United States as their country of origin, to have health insurance, to have at least some college education, and to own a home ($P < 0.001$ for all comparisons). A greater percentage of Latino respondents in the Durham sample were men, as compared to the national sample (64% vs 50%; $P = 0.01$).

Knowledge of Racial/Ethnic Differences in Health and Healthcare Access

As shown in Table 2, when asked if the average black person is worse off than the average white person across a variety of factors, responses of white respondents differed greatly in the Durham and national samples. For example, 40% of white respondents in Durham thought that blacks are worse off in terms of receiving routine medical care, compared to 27% in the national sample ($P < 0.01$). Fifty-eight percent of Durham whites believed that blacks are worse off than whites in terms of having health insurance, compared to 43% in the national sample ($P < 0.01$). In most cases, black participants' responses differed by less than 4% between the two samples.

There was an even greater difference between the white samples on questions of whether Latinos are worse off than the average white person, with white respondents in Durham more likely to perceive that Latinos are worse off ($P < 0.001$ for all comparisons). Despite being quite different demographically, there were only small response differences on these items between the two Latino samples. The only major difference among the Latino samples was that 70% of Durham Latinos reported that Latinos were worse off than whites with respect to having health insurance, as compared to 54% of national Latinos ($P < 0.01$).

Perceptions of the Influence of Race and Racism

There were small differences between the national and community samples with respect to whether blacks receive lower quality of care than whites. However, more whites in the Durham sample than in the national sample perceived that Latinos receive lower quality of care ($P < 0.001$).

Overall, black respondents in Durham were less likely than

Table 1.
Subject Characteristics

Variable	White		Black		Latino	
	Durham (n=392)	National (n=1,479)	Durham (n=338)	National (n=1,189)	Durham (n=332)	National (n=983)

Having health insurance	72[b]	48	60	60	70[b]	54
Getting needed healthcare	55[b]	35	53	51	51	47
Have you ever felt that a healthcare provider judged you unfairly or treated you with disrespect because of…?						
Whether or not you have health insurance	12	10	28[b]	14	20	21
How well you speak English	4	1	11	5	34[b]	14
Your race or ethnic background	2	1	20	12	22	15
Do you think most African Americans receive lower quality of healthcare than most whites?	23	23	56	64	22	43
Do you think most Latinos receive lower quality of healthcare than most whites?	53[b]	27	61	61	62	56
Do you think racism is a major problem in the following institutions?						
Education	22	27	40b	50	40	40
Workplace	13	21	40b	59	37	41
Healthcare	14	16	27	35	40[b]	30
Housing	20[b]	30	41[b]	59	35	41

[a] Values are expressed as weighted proportions that agree with the statement, unless otherwise indicated.

[b] Indicates a significant difference at $P \leq .05$ and a response difference of ≥ 10 percentage points in the comparison with race/ethnicity-matched respondents in the national sample.

their national counterparts to perceive racism as a major problem in education ($P < 0.01$), the workplace ($P < 0.001$), and housing ($P < 0.001$) (see Table 2). While there were small differences between the Latino samples with respect to education, the workplace, and housing, 40% of Durham Latinos thought that racism was a major problem in healthcare, compared to 30% of national Latino respondents ($P = 0.02$).

Personal Experiences with Being Treated Unfairly

Black respondents in the Durham sample were more likely than those in the national sample to feel that a healthcare provider had treated them with disrespect because of health insurance status (28% vs 14%; $P < 0.001$). Thirty-four percent of Durham Latinos and 14% of Latinos in the national sample felt they had been treated with disrespect because of their English-language ability ($P < 0.01$).

Multivariable Analysis

We performed multivariable analyses to determine whether racial/ethnic differences regarding perceptions of racism in the four social institutions held after adjusting for age, sex, income, education level, and marital and health insurance status. The magnitude of the adjusted differences in perceptions of racism was comparable to that found in the unadjusted analyses (see Tables 3 and 4).

Table 3.
Multivariable Analysis—Durham Sample: Racism as Major Problem in Social Institutions

Characteristic	Education RR (95% CI)	Workplace RR (95% CI)	Housing RR (95% CI)	Healthcare RR (95% CI)

Discussion

Our goal was to compare the findings of a national survey of perceptions of racial/ethnic discrimination in healthcare to those of a community survey, with a special emphasis on the healthcare experiences and perceptions of newly immigrated Latinos.

Although the demographic characteristics of the samples were quite different, perceptions of racial/ethnic bias among Latinos in the national and Durham samples were similar. However, we found substantial differences in attitudes about health insurance and English-language ability on one's ability to receive medical care. Durham Latinos were significantly more likely than Latinos in the national sample to report that Latinos were worse off than whites in terms of having health insurance, and Durham Latinos were more likely to feel they had been treated with disrespect by healthcare providers because of their English-language ability. Also, Durham Latinos were more likely to believe that racism was a major problem in healthcare.

One possible explanation for our findings is that a greater percentage of Latinos in Durham, compared to Latinos in the national sample, were born outside the United States (95% vs 49%). Research has shown that more acculturated Latinos have higher rates of insurance coverage and access to care.[29,34] The Durham Latino population may be less assimilated than Latinos in the national sample and may not be as fluent with the English language. Latinos who have lived in the United States for longer periods might speak English better than recent immigrants and may be more likely to have acquired health insurance. A decrease in language barriers and greater access to health insurance may alleviate some of the negative perceptions

Table 4.
Multivariable Analysis—National Sample: Racism as Major Problem in Social Institutions

that Latinos have of the healthcare system. Furthermore, the influx of Latino immigrants into Durham County is a recent phenomenon, and the local healthcare system may still be building up the infrastructure needed for this population. Nevertheless, Durham Latinos face considerable challenges in the healthcare system, and interventions to address their concerns should be developed.

Although black respondents in the Durham sample were less likely than those in the national sample to view racism as a major problem in education, the workplace, and housing, there was no difference between the national and community samples with respect to perceived racism in healthcare. One striking difference between national and community samples of black respondents concerns personal experiences with being treated unfairly. Compared to the national sample, twice as many blacks in the Durham sample felt that a healthcare provider had treated them with disrespect because of their health insurance status. This may be attributable to the sources of insurance in the two samples: Although equal proportions of black respondents in both samples reported having health insurance, 16% of Durham blacks reported Medicaid as their primary source of insurance, compared to 8% of blacks in the national sample. We conducted a post hoc analysis to address this finding and found that Durham blacks with Medicaid had similar complaints about disrespect as those who reported being uninsured. Respondents with Medicaid may face greater challenges in accessing healthcare than do respondents with other types of insurance.

Compared to the national sample, white respondents in Durham reported a greater understanding of the lower quality of care and poorer health outcomes experienced by blacks and Latinos. These results may confirm the presence of barriers or may reflect a greater awareness among whites living in the multiracial community of Durham County. Black residents of Durham County make up 39.5% of the population, compared to 12.3% nationwide.[16] As a result, Durham whites may be more attuned to racial/ethnic differences and perceptions than their national counterparts.

A strength of this study was our ability to partner with community groups. Specifically, we collaborated with a grassroots organization that provides services to Latino residents, a community organization dedicated to promoting effective approaches to removing barriers to healthcare, and researchers from a local historically black university. The involvement of these groups ensured that our assessment addressed problems of interest to the local community.

Our study has several limitations. First, our survey method excluded people who did not have telephones, so persons of very low socioeconomic status may not have been able to participate. Also, the phone numbers used in the survey did not include mobile phone numbers, perhaps further contributing to sample bias. The low response rate for both the Durham and national surveys increases the likelihood that those who responded differ from those who did not. While our survey weights attempt to correct for nonresponse bias, this correction was limited to key demographic variables. However, for both limitations, it is difficult to estimate the magnitude of the potential bias. Moreover, the KFF survey was conducted in 1999, whereas the Durham study was conducted in 2002. Given the age of the KFF data, there is the possibility of a temporal bias.

In summary, we found significant variation in the experiences and perceptions of racism in healthcare between national and community cohorts. These differences are especially important at the community level for setting public policy priorities and informing decision makers about issues of interest to the community. For example, according to Census 2000 data, 35% of black Durham County residents report having at least a college degree, compared to 17% statewide; and 23% of black Durham residents have annual incomes less than $20,000, compared to 30% statewide.[16,35] These data illustrate that there can be regional variation among state constituents and underscores the importance of conducting local needs assessments.

Furthermore, our findings regarding the perceptions of Durham Latinos could generalize to the experiences of other rapidly growing, newly immigrated Latino communities. Health concerns in these communities are understudied, and our findings provide preliminary data for researchers and community workers seeking to better understand this population. Finally, our findings show that racial/ethnic minorities perceive racism to be a major problem across four major social institutions after adjusting for several factors. Interventions that address the barriers to care identified in both the community and national surveys could be effective in reducing health disparities and improving the health of minority patients. **NCMedJ**

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

POLICY FORUM

Quality of Long-Term Care: Nutrition as a Critical Dimension

> *"Finding the balance between medical/nutritional need and resident preference is an on-going effort of nursing home staff that requires individualized attention, creative thinking, and shared decision-making between staff and residents and their family members."*

COMMENTARIES

INTRODUCTION

Policy Forum:
Quality of Long-Term Care: Nutrition as a Critical Dimension

Over the next decade or two, the American healthcare industry will experience a dramatic shift in focus as the nation's older adult population grows rapidly—especially the population beyond age 85. There will be unprecedented pressure on the long-term care field as more of our population living to these advanced ages is no longer able to live independently for reasons of physical or cognitive decline. This demographic transition, and the service demand likely to come with it, has created a growing concern that skilled nursing facilities may not be prepared for these mounting expectations.

In addition to our expectations for skilled nursing facilities to provide medical and nursing care of the highest technical level, these facilities are expected to make every effort to provide a residential environment that is safe, nurturing, stimulating, and, wherever possible, like "home." Unfortunately, no nursing home, regardless of the quality of care provided or the staff efforts to make the facility pleasing and comfortable, is ever "just like home."

An aspect of nursing home care most frequently mentioned by residents and families is the quality of the food and dining services. In this issue of the *North Carolina Medical Journal*, we have invited some of North Carolina's most knowledgeable individuals in long-term care to examine the challenges and opportunities for addressing food/fluid intake/dining issues in skilled nursing facilities. Polly Godwin Welsh, RN-C, Director of Regulatory Systems for the North Carolina Health Care Facilities Association (NCHCA), has written an Issue Brief outlining the many facets of this important dimension of long-term care quality. A number of Commentaries (by physicians, nurses, dietitians, regulators, and advocacy personnel) describe the complexities and difficulties of meeting the expectations and nutritional needs of nursing home residents follow the Issue Brief. The Commentaries were organized by members of the Quality Standards Work Group, a legislatively mandated, interdisciplinary group that has been working on a wide range of issues related to quality of care in North Carolina's nursing home industry for three years.

No one in our state, regardless of their economic situation, should think these issues have little relevance to their own future. Few of us will escape the necessity of dealing with the availability or quality of long-term care. As we face these matters in our own lives and in the lives of our loved ones, they seem of utmost importance. Yet, the discussion of quality of care definition and measurement in long-term care has received relatively little emphasis in health policy deliberations.

North Carolina is fortunate that NCHCFA, our state's nursing home trade association, has embarked on a monumental effort to make the nursing homes of North Carolina the "best in the nation." As part of this effort, NCHCFA is making food consumption and dining (and attention to fluid intake and hydration) key components of their expanded effort to change the total experience of long-term care residence.

We hope that by describing these issues, Journal readers will appreciate the challenges facing this healthcare sector. We also hope that this issue will prompt policy makers and other stakeholders to begin working together to prepare for a future long-term care delivery system that will have the capacity to provide high-quality care for the many who will need this level of service.

As always, we invite our readers to comment on these articles in future issues of the Journal.

Managing Editor

ISSUE BRIEF

Nutrition and the Dining Experience in Long-Term Care:

Critical Indicators of Nursing Home Quality of Care

Polly Godwin Welsh, RN-C

Long-term care facilities of all types, those providing skilled nursing care in particular, are at a crossroads. With the predicted growth of the older adult population, and the population of older adults who will require dementia-specific care, long-term care facilities face a probable and rapid increase in the need and demand for skilled nursing services. In fact, the number of adults over the age of 65 in nursing facilities* is predicted to double by 2020.[1] Currently, there are 16,032 nursing facilities in the United States with more than 1.4 million residents.[2] In North Carolina, there are 424 nursing facilities with capacity for 42,897 residents.[3] In the face of the changing demographics in our society, nursing facilities are re-engineering to embrace the future and successfully meet these challenges. Part of the re-engineering will involve modifications of the physical plant, new construction and innovations in technology and services to match the evolving needs of residents.

This issue of the *North Carolina Medical Journal* focuses on one of the most salient aspects of long-term care quality—food and the dining experience (as well as hydration and fluid intake). Nutrition is one of the major determinants of successful aging and, for most, eating is one of life's most pleasant daily experiences. In the long-term care setting, the medical-nutritional needs of nursing facility residents are often competing with the provision of "consumer-defined" quality of care. To begin with, nursing facility residents often have complex healthcare conditions that limit their function, depress their senses of taste and smell, require multiple medications, and necessitate therapeutic or mechanically altered diets. These treatments can limit independence, choice, and pleasure and, thus, have a negative effect on quality of life. In the interest of preserving both the health and happiness of their residents, long-term care facilities are trying to find a balance between the residents' required medical treatments and personal preferences. North Carolina's nursing facilities are finding ways to achieve this balance as they also juggle the logistic challenges of feeding large numbers people in a highly regulated industry. Many of these specific efforts are described in the commentary by Nadine Pfeiffer, BSN, RN, and her colleagues in this issue of the Journal.[4]

> *"Though nutrition, hydration, and the dining experience in general is but one indicator of overall quality of care, it is clearly among the most critical indicators of quality from a consumer's point of view."*

Those of us who have been asked to contribute to this discussion bring a variety of perspectives (viz., industry, regulatory, advocacy, clinical, administrative) and extensive periods of professional experience in dealing with the challenges of providing high-quality nutrition and fluid options to those served by North Carolina's nursing facilities. Though nutrition, hydration, and the dining experience in general is but one indicator of overall quality of care, it is clearly among the most critical indicators

---

* Skilled nursing facilities are "institution[s] (or a distinct part of an institution) which are primarily engaged in providing skilled nursing care and related services for residents who require medical or nursing care, or rehabilitation services for the rehabilitation of injured, disabled, or sick persons, and is not primarily for the care and treatment of mental diseases." § 1819(a) and 1919(a) of the Social Security Act.

Polly Godwin Welsh, RN-C, is the Director of Regulatory Systems for the North Carolina Health Care Facilities Association. She can be reached at pollyw@nchcfa.org or 5109 Bur Oak Circle, Raleigh, NC 27612. Telephone: 919-782-3827.

of quality from a consumer's point of view. We view the challenge of addressing these issues as one of our most important tasks.

The Social and Cultural Importance of Food and Dining to Long-Term Care Quality

Few would question the importance food plays in everyday life. From physiologic, social, and personal financial perspectives, food plays an enormous role in the human experience. Americans spend about 13% of their annual income on food, the third highest household expense, behind housing (33%) and transportation (19%).[5] The food industry markets to the young and old. Restaurants and grocery stores are multi-billion dollar industries, offering nearly unlimited choices to those who can afford them. Most Americans can eat anything they want, whenever they want, and often chose to eat too much. We have television channels, shows, and magazines dedicated to food preparation. Holidays are typically centered on food and dining. We don't think of Thanksgiving, Halloween, or a birthday without thinking of turkey, candy, and cake, respectively. Food is the center of celebration, pleasure, and entertainment throughout life in the United States, even in nursing facilities. For nursing home residents, mealtime may be the highlight of each day and is a key component of health and quality of daily living.

On any given day, approximately 40,000 North Carolinians reside in skilled nursing facilities due to catastrophic health events, disability, frailty, and/or declining health.[3] Each resident has a unique, but usually culturally-defined life history of nutrition, consumption, and food experience. As part of their effort to provide patient-centered care, nursing facilities strive to meet reach resident's nutritional needs, dietary preferences, and expected dining experiences at a time when many other personal choices and freedoms are being lost. These losses make preserving resident choice an even more critical component of quality care. The commentary by Beverly A. Speroff, RD, LDN, and her colleagues in this issue of the Journal provides a useful overview of the dining experience in nursing facilities and describes ways nursing facilities balance residents' nutritional needs and preferences.[6]

Medical Care and Quality of Life: Competing Issues

Long-term care facilities face two, sometimes seemingly competitive, goals with regard to nutrition: (1) maintaining optimal levels of health through dietary means, and (2) assuring the highest possible quality of life. In order to accomplish the first goal, nursing home staff must do a thorough and nutrition-focused assessment and develop an individualized plan for meeting the resident's medically-defined nutritional needs. To meet the second of these goals, it is essential that nursing home staff frequently assess and document each resident's dietary preferences so explicit arrangements can be made to assure that residents have as much choice and independence as possible. Facility staff try to reach both goals without compromising the health or happiness of the resident. Accomplishing this requires consultation with the resident (when possible), family members, and the resident's physician.

The notion of involving nursing home residents themselves in decisions about diet and fluid intake is consistent with the idea that, for many nursing home residents, living in such a facility is "home." With average length of stay in such facilities being approximately 2.5 years (901 days) for current residents and just over one year (388 days) for discharged residents,[7] it is logical that residents (when they are able, and family members or a guardian if they are not) should have such a decision-making role. Residents have the right to choose (or refuse) specific treatments and services provided by nursing facilities, once the facility has ensured that the patient (or his/her guardian) is fully informed about his/her functional status, medical, and/or rehabilitation needs.

Therapeutic and Mechanically Altered Diets

The majority of skilled nursing residents are likely to have a chronic disease or condition (e.g., diabetes or high blood pressure) that requires a prescribed diet. There are many different types of therapeutic* or mechanically altered** diets with varying degrees of restriction and complexity. Armed with the necessary dietetic knowledge, food service managers and dieticians must balance considerations of seasoning, nutrition, taste, texture, and variety to produce meals that residents will consume in quantities that provide adequate nutrition and satisfaction. In addition to preparing and serving special diets, staff members teach and reinforce the benefits, and necessities, of these special diets. At the same time, staff members try to honor the resident's choices.

In the past, nursing facilities have been criticized for using what is perceived to be a predominantly "medical model" approach to the organization and provision of care. Compared to patient-centered care, the medical model focuses more on treatment and is less likely to consider the resident's personal preferences. Because a therapeutic diet can negatively affect individual food consumption patterns and lead to unplanned weight loss, it is possible that a medically-recommended diet could have deleterious effects on both quality of life and physical health status. As Dorner, Niedert, and Welch[9] have pointed out:

> *A diet that is not palatable or acceptable to the individual can lead to poor food and fluid intake, which results in weight loss and undernutrition, followed by a spiral of negative health effects. Often, a more liberalized nutrition intervention that allows an older adult to participate in his or her diet-related decisions can provide for the person's nutrient*

---

* Therapeutic diets are used to help treat/manage certain chronic diseases (e.g., diabetes and hypertension).

** A mechanically altered diet includes foods that may be pureed or softened to help patients who have trouble chewing and/or swallowing.

needs and allow alterations contingent on medical conditions while simultaneously increasing the desire to eat and enjoyment of food. This ultimately decreases the risks of weight loss, undernutrition, and other potential negative effects of poor nutrition and hydration.

The American Dietetic Association recommends liberalizing therapeutic diets when possible,[8] but this remains challenging in some ways. Honoring resident choice, following prescribed therapeutic diets, maintaining resident health, and complying with state and federal regulations are individual variables that are not mutually exclusive. Nursing facilities have to take appropriate steps to assure that dietary restrictions considered medically necessary are followed. But within these boundaries, nursing facilities are challenged to identify multiple options that will allow the maximum degree of individual choice in food and beverage selections throughout the day.

Health Conditions Can Affect One's Ability/Desire to Eat

Catastrophic health events take a heavy toll on our ability to consume and enjoy food. While in the treatment phase of an acute illness, patients are more likely to be at risk for malnutrition and dehydration. They are also more likely to experience depression, which also can decrease appetite. Close attention must be paid to these factors as people who are ill or rehabilitating return to their homes or enter any long-term care setting.

"Long-term care facilities provide 'supportive social services for people who have functional limitations or chronic health conditions and who need ongoing healthcare or assistance with normal activities of daily living.'"[8,9] By definition, nursing facility residents have healthcare conditions that may impact their ability to feed themselves and/or consume enough calories or fluids to stay healthy. Some residents may have added difficulty due to their medications, age-related sensory losses, and/or decreased physical function or cognitive abilities.

Medications and Side Effects

Nursing facility residents take an average of eight prescription medications a day.[10] Medications from almost every category can have profound effects on one's ability to consume and enjoy food. Many medications may decrease appetite, sense of taste and smell, or cause gastrointestinal disturbances. It is difficult to find normal day-to-day pleasure in eating with these side effects. The commentary by Christopher M. Herman, MD, in this issue of the Journal addresses the medical aspects of dietary management among nursing home residents.[11]

Age-Related Loss of Senses

In addition to the side effects of certain medications, normal aging can affect our sense of taste and smell. As we grow older, our sense of taste and smell begins to diminish, and this worsens as we reach the age 70 and beyond.[12,13] Taste and smell greatly affect our desire and ability to nourish our bodies by telling our brains that it is time to eat and digest food. Without these signals, many residents do not consume enough nutrients.

For this reason, long-term care facilities often use flavor enhancers, primarily powdered odor enhancers mixed with soups, gravies, eggs, vegetables, grits or cereals, sauces, or pastas, such as macaroni. The work of Susan Schiffman[14-17] at the Duke University Medical Center has been an important stimulus for further experimentation with flavor enhancement as a way of assuring the desired nutritional intake of long-term care residents who have experienced sensory losses of taste and smell in their older years. In her work on these problems, Schiffman has shown that older persons living in long-term care facilities consume more food when flavor enhancement is used, and the increased consumption is associated with improved immune function and functional status related to nutrient intake.[15]

Functional Limitations, Tube Feeding, and Feeding Assistance

Most people who are admitted to a nursing facility are admitted after a surgery or a sudden illness. These health events can cause unique problems in relation to nutrition and fluid intake. For example, many persons who suffer strokes may have limited abilities to speak, swallow, and/or use their arms and hands. In this case, speech therapists, occupational therapists, nursing staff, and physical therapists in the skilled nursing facility work diligently to restore these abilities, but for some the loss is permanent.

According to federal data for North Carolina skilled nursing facilities, only 47% of nursing facility residents are able to eat independently. Twenty-eight percent eat with some assistance, and 25% are totally dependent on someone else to feed them.[2] About 10% of residents are tube-fed.[18] While all efforts are made to avoid feeding tubes, some severe circumstances make their use necessary, as described in the commentary by Timothy S. Carey, MD, in this issue of the Journal.[19]

For some residents who experience a loss in motor function that interferes with independent feeding, complete rehabilitation may be possible, while others may need specially trained nursing assistants to provide ongoing feeding assistance. This ongoing assistance can be frustrating to the resident because it is an additional loss of personal independence, may seem unnatural to be fed as an adult, and is time-consuming. According to the Commonwealth Fund study by Burger, Kayser-Jones, and Prince-Bell, a dependent resident requires a minimum of 20-30 minutes to assist him/her with eating and still make the experience satisfying to the resident.[20] The heavy staffing requirements of providing a highly personalized approach to eating for these populations is a constant challenge to all skilled nursing facilities and a potential source of dissatisfaction expressed by both residents, families, and guardians. In addition to knowing how to help residents eat, staff members must know how to ease resident frustration and offer support as being fed by someone else can be a difficult, but necessary, process to sustain life.

Dementia

Another medical condition that can present unique nutritional challenges is dementia. The resident with dementia may greatly decrease his/her consumption of food by simply being unable to remember to eat. For example, the resident may become distracted and leave the table without eating enough or at all. With advanced dementia, the resident may forget how to hold food in their mouth, how to chew, and how to swallow. This may become a part of an encompassing condition commonly referred to as "failure to thrive."

Trained nursing facility staff must employ special feeding techniques and cues to get residents who suffer from dementia to eat enough. Facilities also use snacks and activities to increase consumption. Staff may target residents who have dementia or reduced consumption with recreational opportunities that offer food and beverages as an integral part of these activities in an effort to increase nutritional and fluid intake. The commentary by Heidi K. White, MD, MHS, in this issue of the Journal provides a thorough discussion of nutrition issues related to the care of persons with advanced dementia.[21]

Logistical and Technical Aspects of Meeting the Nutritional Needs of Residents

Preparing food within the constraints of a congregate healthcare setting is one of the most challenging aspects of long-term care facility management. Operational budgets, the use of safe and sanitary equipment, and proper storage and access to the appropriate quantity and quality of food supplies are often under-estimated daily challenges of a food service department. Facilities must involve registered dieticians and food service managers, who are trained to interface with the operation of an institutional kitchen. The registered dietician and food service managers plan menus with many considerations, including seasonal food options and regional and cultural preferences. Facilities strive to prepare tasty, nutritionally-balanced meals in large quantities three times a day, 365 days a year. North Carolina's long-term care facilities serve an average of 32 food items to each resident every day.

Food choice does not present the challenge at one's home that it does in a nursing facility. In the average facility, about 90 people are served three meals a day along with periodic snacks.[2] Accommodating large numbers of special requests can easily overwhelm the dietary department. There is no realistic way to accommodate 90 or more menu changes at each meal. Upon admission and throughout their stay, residents and families hold discussions with care planners regarding food and beverage preferences. Many times these preferences are uncomplicated and easily accommodated. Finding the balance between medical/nutritional need and resident preference is an on-going effort of nursing home staff that requires individualized attention, creative thinking, and shared decision-making between staff and residents and their family members.

> *"Food choice does not present the challenge at one's home that it does in a nursing facility."*

Working within State and Federal Regulations

Maintaining the health and safety of each resident is the goal of each long-term care facility. As mentioned previously, meeting the individual resident needs and preferences, family expectations, and doctor's orders, while abiding by state and federal regulations, can be challenging. Long-term care is one of the most regulated segments of the United State healthcare system, and nursing facilities strictly adhere to rules and regulations. A commentary by Cindy H. DePorter, MSSW, in this issue of the Journal explains the regulations that pertain to nutrition and fluid intake among nursing home residents.[22]

Facility staff members counsel and educate the residents and family members about the risks of not following a prescribed therapeutic diet. For example, a resident at risk for choking may ask for food that is restricted according to his/her nutritional care plan. Nursing facility staff must explain the risks involved with eating such foods to the resident and/or family. The facility could be held legally responsible if the resident choked on the food that the resident's physician had restricted. While eating restricted food now and then may seem harmless, it could present a significant health risk to residents who are prescribed therapeutic or mechanical diets. In a nursing facility, the negotiation of risks, choice, and benefits are carried out on a minute-to-minute basis.

While mindful of the regulations, facilities try to creatively satisfy the needs, priorities, and preferences of residents and families. For example, many residents want their families to bring them food from home. Nursing facilities permit families to bring home-cooked meals to their loved one; however, the food should not be shared with other residents. Skilled nursing facilities cannot risk having other residents exposed to possible food-borne illnesses. Although it is unfortunate, in this example, it is impossible for the facility to guarantee the safety of food preparation that occurs in other locations. A number of long-term care facilities have created special occasions to help provide the residents a variety foods, such as hosting an oyster roast, ordering specialty take-out meals from area restaurants, etc. The commentary by H. Harvin Quidas, et al., in this issue of the Journal describes other ideas that nursing facilities have used to make food and/or the dining experience more interesting to residents.[23]

Conclusion

For all residents in a skilled nursing facility, regardless of medical condition, their life experiences from birth-to-present create needs far beyond the mechanical act of food consumption. Where, when, and how residents wish to dine; their food likes and dislikes; the role of the dining experience as socialization;

and their ability to exert choice and control affect the amount of satisfaction and pleasure they gain from the act of eating.

In these efforts, today's skilled nursing facilities face a number of substantial challenges, but all agree that finding ways to satisfy residents is one of the most important aspects in creating the nursing facility of the future—within which we would all be willing to reside ourselves, or have a loved one reside, were the need to arise. As our society's need and demand for skilled nursing care increases, the capacity of existing facilities will be stretched beyond present expectations. But, as these trends occur, careful attention to how food, nutrition, and hydration issues are managed will have much to do with the ultimate success of our efforts to make long-term care a pleasant and health-enhancing experience. **NCMedJ**

COMMENTARY

So, Who's Complaining about the Food?

Ombudsman Perspectives on "the Dining Experience" in North Carolina's Nursing Homes

H. Harvin Quidas, Twilla Chavis, Aimee D. Kepler, and Nancy Murphy

The Long Term Care Ombudsman Program was established and authorized by the federal Older Americans Act amendments in 1978 (and codified in North Carolina state law in 1989). This legislation mandated that every state establish a program of professional personnel having the responsibility of advocating for those who reside in long-term care facilities. The legislation charged the Long Term Care Ombudsman with protecting Resident Rights and helping to ensure resident safety and quality of care. In addition, ombudsmen should empower families of residents and the consumers of long-term care services by offering educational programs on long-term care issues and options.

The North Carolina Long Term Care Ombudsman Program is part of the Elder Rights and Special Initiatives Section of the Division of Aging and Adult Services within the North Carolina Department of Health and Human Services. There are 29 Regional Long Term Care Obdudsmen located in the 17 Area Agencies on Aging across the state, with each agency serving multiple counties. The efforts of these regional ombudsmen are extended through a network of over 1,100 "grassroots ombudsmen" who receive training and then volunteer their time in their respective communities as advocates for residents in long-term care facilities. They also work with facility staff and administrators in the interest of assuring a high quality of life for those who reside in these facilities.

One would think that complaints about food, the dining experience and the availability and consumption of fluids would be a major concern and frequent complaint of both residents and the families of residents of long-term care facilities. As Regional Long Term Care Ombudsmen, we receive fewer formal complaints from the residents of nursing homes* or their family members about either dining or hydration than one might expect. But, in any discussion with residents or family members, it is rare that these topics do not emerge in describing the totality of a loved one's experience in a given facility. Food (including regular meals and snacks/refreshments) and fluid intake are very important parts of the *context* within which the resident's total life experience takes place. Not only are meals (and the opportunity to consume snacks) important anchors in the daily routine of nursing home residents, but the quality (viz., taste, smell, appearance, texture) of food and beverages is an important indicator of life satisfaction among those residing in these facilities. Most residents of long-term care facilities, even those who are not ambulatory and have to be served their meals or are assisted with fluid intake, actually look forward to scheduled food- or beverage-related events throughout the day. But, residents differ (as we would expect among any other population) in the relative weight or importance they attribute to various aspects of food and dining. While many residents actually are excited to begin each day with the smells and anticipated tastes of breakfast foods, others are not "morning persons" and would instead focus their attention on lunchtime options or the dinner meal. In other words, much of the daily rhythm and pace of a typical day as a resident of a long-term care facility revolve around

---

* These formal complaints about both food/dining or hydration are more frequent from residents of adult care homes or their family members.

H. Harvin Quidas is a Regional Long Term Care Ombudsman at the Cape Fear Area Agency on Aging. She can be reached at hquidas@capefearcog.org or 1480 Harbour Drive, Wilmington, NC 28401. Telephone: 910-395-4553 Ext. 208.

Twilla Chavis is a Regional Long Term Care Ombudsman at the Lumber River Council of Governments. She can be reached at tc@mail.lrcog.dst.nc.us or 4721 Fayetteville Road, Lumberton, NC 28358. Telephone: 910-618-5533 Ext. 3036.

Aimee D. Kepler is a Regional Long Term Care Ombudsman at the Triangle J Council of Governments. She can be reached at akepler@tjcog.org or 4307 Emperor Blvd., Suite 110, Durham, NC 27703. Telephone: 919-558-2719.

Nancy Murphy is a Regional Long Term Care Ombudsman at the Triangle J Council of Governments. She can be reached at nmurphy@tjcog.org or 4307 Emperor Blvd., Suite 110, Durham, NC 27703. Telephone: 919-558-2719.

these opportunities for food and drink. The social interactions with other residents and staff associated with meal times or snack times often provide a positive and much-anticipated uplift to what might otherwise be a mundane and boring daily routine.

It, therefore, figures that if one wanted significantly to change how nursing home residents and families view nursing home care, making changes or improvements in the the residents' dining experience or their access to beverages and snacks throughout the day would be an important place to begin. Improvements in dining would ultimately change how the nursing home experience is viewed by persons who are neither residents or family members of residents, but only hear about these aspects of the experience from others.

What Are the Major Complaints about Either Food or Hydration?

Most of the (usually informal) complaints we Ombudsmen hear about food, food service, or hydration in North Carolina's nursing homes come from residents themselves. Most of these complaints are about matters that are beyond the ability of the Ombudsman to handle. For example, many of the negative comments are about the general taste (flavor) and consistency (manner of preparation) of typical food items. Many North Carolina nursing homes serve populations of older adults who have been raised in rural communities where families are accustomed to raising much of the food they consume. Many residents were used to preparing food using high-fat and sodium flavorings (e.g., ham or "fatback"). Institutional food service staff and dietitians are not likely to prepare food in the same ways, nor are they likely to use artificial flavorings to achieve a similar taste or the appearance of standard food items. The food just isn't what one would have been accustomed to at home. The ombudsman can open a formal complaint if the resident finds the food unsatisfactory, lacking in quantity/appeal/preference, or failing to meet medically indicated directions, etc., and long-term care facilities are generally receptive toward finding a resolution for the resident.

> *"...much of the daily rhythm and pace of a typical day as a resident of a long-term care facility revolve around these opportunities for food and drink..."*

Other complaints about food and the dining experience are highly variable among residents, but a few are frequent enough to seem routine. The presentation of food is extremely important. Many residents do not like several food items served in such a way that they "run together." Since residents do not typically serve themselves from a buffet table or in a family-style arrangement, food placed on a plate by a food service staff member may not look like food the resident would have chosen for him/herself, either in placement on the plate or in quantity of serving. To take another example, bread laying on top of vegetables or meat can become soggy and unappetizing. Sectional plates or trays also have a clear "institutional" food service appearance, and do not evoke feelings of a home-like environment.

With regard to food, one might conclude that *little things make a huge difference* in how a skilled nursing facility is viewed by those who reside there.

Most of the "formal" complaints in this area relate to hydration (or fluid intake). Often these are related to the way in which water pitchers, drinking straws, and cups are placed in resident rooms. Non-ambulatory residents often complain because water is not offered frequently throughout the day; the water pitchers, cups, etc. may be placed on top of a dresser across the room or placed in a window sill out of reach of the resident; milk is served as a beverage on every tray at every meal or just before bedtime, yet many older adults have never consumed milk with meals, or are lactose-intolerant and cannot consume this beverage; or iced tea (which many North Carolina residents have consumed regularly, in a sweetened form, and in substantial quantities throughout their lives) is served with little or no ice in short, round glasses, instead of tall glasses with lots of ice and lemon. Persons who have grown old living in a southern, rural environment are often accustomed to eating a heavier meal in the middle of the day, and a lighter one in the evening. Hence, "soup and sandwich" at noon may be boring and a heavier meal in the evening may not be an easily adapted pattern. Some residents are accustomed to having a bowl of cereal just before bedtime. Adding cereal to the options for pre-bedtime snacks could help assure these residents that living in a long-term care facility is not so radically different from what they experienced when living at home. These are the "cultural differences" that are the source of expectations and valuations of the way nursing homes serve their clientele. Often the steps taken to deal with these expectations are not costly, but require special, even personalized, effort, which can be a burden on already over-burdened staff of these facilities.

Family members have complained that sometimes the pitchers from which water is consumed are not washed and sterilized with any frequency, only refilled. These are standard procedures that should be addressed by any facility in a standardized way, and there are specific regulations pertaining to such matters.

What Are the "Lessons Learned" from Resident and Family Reactions?

It is important to recognize that those of us who have worked in long-term care for many years are seeing positive changes in a wide spectrum of areas related to food, nutrition, and hydration in nursing homes. These changes are welcomed by all stakeholders, especially residents and family members.

One of the most important lessons to be learned from the comments (and often the complaints) of long-term care residents and families is that the allowable (and recognizable) independence of living in these facilities is indicated by the feeling that one can choose from several options with regard to food/dining and beverage consumption. It is often not the number of options, but the fact that a *choice* is possible among types of food, beverage, or time and venue within which consumption of either occurs.

Second, it is important to realize that choices made now may not be the same choices tomorrow or next month. Individual preferences and functional abilities change over time, and it is important to give residents frequent opportunities to reconsider these choices. For example, as the ability to chew certain textures of food change, so do the residents' options for mealtime, and new options should be offered in consultation with nursing and medical professionals involved in the care of these patients.

This underscores the importance of periodic and frequent *assessment* so that facilities can have up-to-date information on the functional status, as well as the preferences, of each resident. For example, we have seen instances where a given resident is unable to feed him/herself using common tableware (fork, knife, or spoon), but the resident can eat using his/her hands. Hence, adapting to this situation by offering "finger food" options, once these functional limitations/abilities are noted, can have a tremendous influence on the nutritional status of the individual resident and contribute to overall life satisfaction. Periodic re-assessment of resident capacities and medical needs is essential to providing the optimal and most life quality-enhancing dining and hydration experience.

Long-term care residents are often treated by multiple healthcare providers, both within and external to the the facility. When one care provider suggests trying a different type of diet, the need for such a diet and the progress of the resident in adapting to it should be reassessed frequently. We have all seen instances where a resident's physician prescribed a temporary therapeutic or mechanically altered diet for a resident who ultimately lost weight because facility staff failed to reassess the resident's needs in an appropriate time frame. Some residents in this situation have remained on termporarily prescribed diets for months longer than they should have. Prescribed dietary plans need frequent reassessment to prevent such occurrences. Dramatic changes in dietary intervention plans can cause undue concern among family members, especially if their loved one does not adapt well to the changes introduced by the prescribed diet. When facility staff make hurried determinations that a resident has difficulty swallowing, or if staff confuse a slow eating pattern for such difficulty, this can often lead to the prescription of a therapeutic diet, which is unappetizing and, therefore, not consumed. Careful assessment of functional abilities, such as swallowing, can often determine the actual problem and lead to changes in the way food is served, not in the texture of the meal itself.

Long-term care facilities have been given high positive marks for efforts to incorporate fresh fruits and vegetables into the planning for meals and snacks served to residents. The acquisition and processing of these food items can be both time-consuming and expensive, but many facilities have made a serious effort to add these elements to their overall food and dining experience. Wherever these efforts have been made, there is widespread appreciation from both residents and family members.

It is our observation that long-term care facilities are constantly innovating and discovering new and better ways to address the food and dining preferences of their residents, often with little or no public acknowledgement of their efforts. There are literally hundreds of examples of facilities going out of their way to serve meals in an attractive and pleasant way, or scheduling special events (like periodic "order out" evenings when pizza and other food items can be ordered from area restaurants to be delivered for a particular meal, or scheduling a "tropical week" during which fruit slushies are served to encourage more fluid consumption in a festive atmosphere). We believe more should be done to recognize and compliment these facilities for these efforts.

Though the Long Term Care Ombudsman Program is often seen as conveying only the "bad news" associated with resident or family complaints, we feel it important to point out the number of times that we actually hear from residents and family members some very positive comments about the way our North Carolina nursing homes have been attempting to make food and the dining experience a positive and enjoyable aspect of everyday life in these settings. One recently discharged resident, who was in a North Carolina nursing home for a post-acute rehabilitation period, asked one of us if she could return to the nursing home on a daily basis and pay for lunch since she enjoyed dining at this facility so much.

Finally, it is our observation that nursing homes are faced with serving the long-term care needs of two very different populations. One of these populations is composed of residents who are cognitively functional and able to express their preferences, and many of these residents are mobile enough to partake in any and all activities related to dining. The other population is composed of residents with limited cognitive and physical functional abilities, for whom individual choices are difficult to express. Family members and residents in the first group are strong advocates for their dining and hydration choices, and staff are responsive. However, the second group of residents have very few advocates on their behalf. The data cards for these patients usually have blank spaces where dietary choices or preferences should be noted. When residents in this category are actually given choices in food/dining or beverage options, family members are pleased and often surprised.

The challenge for long-term care is going to be how to serve these two populations of residents and give some level of choice to both, while attempting to make the experience of living in such facilities feel safe, comfortable, and pleasant. Food and the dining experience are an important part of the totality of the long-term care experience, and we are fortunate in this state to have so many nursing facilities who care enough to address these issues as part of an overall effort to make long-term residence in a nursing home an experience of high quality. **NCMedJ**

COMMENTARY

What’s New in Long-Term Care Dining?

Nadine A. Pfeiffer, BSN, RN, Denise A. Rogers, Michelle R. Roseman, NHA, MBA, Leslie C. Jarema, NHA, Aimee Reimann, NHA, and Debbie Combs-Jones, MT, MHA

Throughout the years, nursing homes have traditionally been viewed as medically oriented with rigid schedules and limited choices, decorated with institutional-type furnishings and stark white painted walls. Visitors were few. In many cases these views were validated by actual practice. But in the early 1990s, the “medical model” nursing homes began to change as a few culture change philosophies emerged. Facilities started implementing innovative concepts, which are called “enhancements” in North Carolina, to make these facilities more home-like.

The term “culture change” has become synonymous with “environmental transformation” in the realm of culture-change enthusiasts. The concepts are now many, but they all have the same goal. They all implement an enhancement that transforms the medical model into a more home-like model, thus improving resident quality of life. Some opt to follow the named philosophies in their entirety, while others opt to base the changes on a particular model, altered to suit their facility’s individual needs or goals.

One of the original culture-change philosophies was the Eden Alternative,[1] started by Dr. William Thomas. This philosophy focuses on 10 principles to incorporate staff empowerment with team building and to then use plants, animals, and visits by children as the enhancements to complete the environmental transformation of the facility into a more natural and less “institutional” human habitat. This philosophy focuses on improving the quality of life and quality of care for residents and staff.

> *“The ability to choose your own food, socialize with friends, interact with attentive staff members, and enjoy a delicious and healthy meal provides a dignity unmatched by most other services.”*

The WellSpring Model[2,3] was started in 1994 and focuses on a collaborative effort between several nursing homes to cross-train and form a coalition. The homes in this coalition pay a licensing fee and monthly fee to the WellSpring Alliance, which supplies all training materials, clinical training experts, a data reporting system, and technical support during the implementation process. Spearheaded by a nurse practitioner, all staff are trained in eight quality of care modules, and they are managed in each home by a coordinator. Care resource teams, comprised of various staff members, are developed in each home to devise and implement culture-change strategies. The coalition-member homes share the costs of the program. There is continuous review of performance

data related to resident outcomes in a variety of areas. This model focuses on the quality of care aspect of culture change.

The Pioneer Network[4] is yet another model for culture change. It informally began in 1992 with educational sessions on culture change. The first organized meeting of the movement was held in 1997, and in 2000 the Pioneer Network was officially named and took on its general mission of being a network of people dedicated to facilitating deep-system culture change. This concept directs each nursing home to acknowledge that culture change is an on-going process, base their enhancements on a core set of values, establish a clear vision for change, and establish a mission statement. The implementation of best practices tailored to individual needs is also stressed.

The concept of Person-Centered Planning[5,6] was initiated by the husband and wife team of Eric and Margie Haider (administrator and Director of Nursing at Crestview Nursing Home in Missouri). In 1998, they began a pilot project adopting person-centered planning into the long-term care setting. This philosophy focuses on each individual and offers more freedom, choices, and independence. This model puts the person in the center and provides more individualized care that is in the best interest of the person.

There are six critical components of person-centered planning: (1) supporting personal satisfaction in the lives of residents; (2) creating individualized living spaces; (3) empowering staff as advocates for the residents; (4) respecting individual life patterns, preferences, and needs; (5) providing opportunity for personal growth, development, and contribution; and (6) fostering a connection to the greater community.

According to data from the 2005 North Carolina Nursing Home license renewal applications, 54% of the facilities across North Carolina have self-reported that they embrace these care philosophies, and 19% of those facilities (73) have reported implementing innovations in the dining experience. The following are some best practice dining enhancements that stem from a divergence from the medical model and signify a transformation into true culture change in long-term care.

Best Practice Dining Enhancements in Long-Term Care

Creating a positive mealtime is a balancing act secured through attention to detail, compassion for the residents, and culinary expertise. At Abernethy Laurels in Netwon, North Carolina, the dining experience involves delicious food served by attentive wait staff and is combined with an inviting atmosphere that allows social interaction. In September of 2004, the age-old tray style dining service was replaced by a more personal table side dining program. Residents enter into a remodeled dining room filled with warmth and friendliness, eager to partake in the fare offered by Executive Chef Eddie Williams and his staff. Residents are free to choose from a menu of entrees and side items based on their individual preferences. Meals are served by friendly staff members who engage each resident in informal conversation, while remaining attentive to the individual needs of the diners. This conversation promotes social interaction, as

May I Serve You, Please?

Ted W. Goins, Jr.

A growing number of healthcare professionals are climbing on the bandwagon of "culture change" in long-term care. Resident-centered care and services are replacing the old, institutional, assembly-line approach of the past. Residents get a voice and vote in how they live. A collaborative, team philosophy is replacing the autocratic model. Those who have embraced these changes have created a much better home in which people can live and work. Facilities who don't change will not thrive, and may not even survive.

Lutheran Home–Hickory residents, families, and staff are excited about buffet dining.

Some of the more notable innovations are occurring in food service. The old system is dying: a system characterized by meals served at 7:00 am, 12:00 pm, and 5:00 pm; residents receive the meal the dietician planned whether they like it or not (with few alternates); meals served from a central kitchen in institutional, dome-covered plates often with luke-warm "hot" food, and luke-warm "cold" food. Meals have been served in the worst traditions of institutionalization, encouraged, if not mandated by punitive federal regulations.

A new day is dawning. Resident-centered care is opening eyes and attitudes. Healthcare professionals, state regulators, and others have joined in asking, "Why can't we do this a new way?" The answer is now "why not!"

Lutheran Home–Hickory is a wonderful example. With support from a Long-Term Care Enhancement grant from the state of North Carolina, the Lutheran Home has transformed a once institutional dining room into a "restaurant." Gone are the institutional colors, observation windows from two halls and a nursing station, and trays delivered from a distant kitchen. All have been replaced with a warm décor, wooden blinds to soften the windows, and a restaurant-style buffet at wheelchair height. Depressing, dark, coffee mugs for all liquids have been replaced with clear cups so

continued on page 289

well as offers an insight into the condition and health of each resident. This daily interaction re-connects the staff member with the resident, allowing for specific requirements to be identified and met, while creating an atmosphere of compassion.

In specific instances where a pureed meal is required, the Pureed Food Enhancement Program (PFEP) offers visually appealing and delicious choices. In days gone by, pureed foods were prepared on-site with a blender. This method created a situation where caloric content, nutritional value, taste, color, and texture were compromised. The mechanical alteration resulted in a bland, shapeless, unappetizing meal being served to residents to fulfill the need for pureed food. Residents often will not eat a meal they cannot recognize. Therefore, residents did not meet their individual dietary requirements, sustenance needs, or morale buoyancy. The PFEP presents pureed meals with uncompromised taste, formed in the shapes and colors of the items being served, with measured calories and nutritional values necessary for the well-being of the resident. Imagine a pureed pork chop, in the shape and color of a pork chop that looks so close to its non-pureed counterpart that the resident uses her fork to cut around what appears to be a bone. Spirits can be uplifted through serving a meal containing identifiable items that possess an enticing and aromatic flavor like other tablemates enjoy.

Since instituting table-side dining services, Abernethy Laurels has experienced a phenomenal rise in resident satisfaction with the food quality and atmosphere. Weight loss has been reduced and malnutrition is non-existent. The ability to choose your own food, socialize with friends, interact with attentive staff members, and enjoy a delicious and healthy meal provides a dignity unmatched by most other services. The dining experience is one more example of Abernethy Laurels' mission to "…add life to years."

The Forest at Duke, a continuing care retirement community in Durham, North Carolina, recently completed an addition/renovation project. Thirty-four adult care apartments were added and integrated into the existing Health Care Center. The project created six neighborhoods connected to an interior street with shared common spaces in a virtual village environment. Each neighborhood serves residents with a different set of care needs.

The creation of the new and innovative Health and Wellness Center gave The Forest at Duke the opportunity to offer more normalization of the dining experience in a long-term care setting. Each "neighborhood" has its own "restaurant" with individualized themes and décor. The secured special care unit, *The Riviera*, has a Mediterranean style "outside" café, Niko's Bistro. The intermediate special care unit, *Regency Square*, serves its residents in the Italian themed, Denali's. The skilled residents in the *Olsen* neighborhood dine in The Metro, an American "restaurant." Residents in the *Biltmore*, who have both medical and cognitive challenges, eat in their own home, 1950s-styled kitchen. *Carlton* residents enjoy their meals in an art deco restaurant, The Gatsby. La Maison, a country French restaurant accommodates the *Holbrook* neighborhood.

Each restaurant has natural lighting and a garden view to

continued from page 288

people know what they're drinking. It's the little things that make the difference.

Residents are served their drink of choice and the soup of the day, while they await their meal. Residents then visit the buffet and order what they desire. If resident still has a lifelong aversion to broccoli and orders a double helping of mac 'n cheese—go for it! No one should mandate when and what an older adult should eat.

"No one should mandate when and what an older adult should eat."

The transition has not been easy. In its new approach to redesigning the dining experience, Lutheran Home–Hickory started with lunch, and plans to include breakfast and dinner. Staff members, and even some residents, have found it difficult to discard 43 years of tradition. Persistence pays off. Staff is working to take the same and other dining innovations to the smaller units, including two Alzheimer's-type units, in the 204-bed facility.

The best measure of success came when Administrator Amber McIntosh and the team responsible for the transformation were called to the dining room one day at lunch. The residents, who sought some assistance from activity staff, had prepared an entire meal for the team as a sign of their appreciation. A resident spokesperson reduced the entire team to tears as she thanked them for sharing dignity and a beautiful place to eat. The state of North Carolina can take a great measure of credit through the Long-Term Care Enhancement grant that made this possible.

Meal times are another issue being addressed at Hickory and in many other long-term care facilities. Meal times were set like clockwork, literally. How many of us like to sleep-in occasionally, or finish watching that movie before eating supper? In the nursing home of old you ate at 7:00 am, 12:00 pm, and 5:00 pm, period! Some facilities are finding ways to bend over backward to give residents what they want when they want it. Lutheran Home–Hickory even has a colorful snack cart that makes the rounds of the building. Care for a Moon Pie and a Coke? Now that's livin'!

Lutheran Home–Hickory has helped lead the change/charge for Lutheran Services for the Aging's five nursing facilities and two retirement communities. Each facility

continued on page 290

enhance the dining experience. Signage including the menu of the day is clearly visible for cueing and wayfinding. Elegant table settings are provided, as well as lounge areas that include stocked bars for pre-dining activities. Assistive device rooms are provided to promote the facility's policy of seating all residents in dining room chairs during mealtime. Color coordinated linen napkins and attractive décor are provided, as well as dinner music.

For residents who have been identified to have weight loss, aromatherapy is used to stimulate the appetite. Essential oils known to increase appetite are sprayed in the dining area prior to the meal being served. Research studies are demonstrating the effectiveness of aromatherapy in successfully increasing weight in residents with dementia.[8] The *Biltmore* residents are stimulated by the aroma of coffee, toast, and baked goods cooking in their own kitchen.

For those residents requiring a pureed diet, efforts are made to present them in an attractive way by the use of "food molds" that simulate the food item that has been pureed. To ensure the quality of the food served, they are taste-tested at each meal.

To further encourage independence, choice, socialization, and offer flexibility, any resident in the Health and Wellness Center may dine in any of the "restaurants." Additionally, they may invite family members or friends from outside to join them for meals.

At Rex Rehabilitation and Nursing Care Center in Raleigh, North Carolina, scenic wall murals in several areas have enhanced that facility.[7] Susan Watkins, a restorative nurse, started the transformation by painting her small windowless office with a view of an arched Mediterranean villa balcony over red-tiled roofs that are cascading down hills to a deep blue ocean. With resident input, a beach scene resembling the North Carolina Outer Banks was painted in the big dining room. This mural includes a lighthouse, seagulls, a fishing boat (a resident's request), and a couple seated on a beach. The industrial kitchen in one corner was transformed to look like a crab shack, which made the freezer fit nicely. One wall in a windowless room, which was once a big storage room, now has a huge painted window with a view of the mountains. This pleases the residents who were fond of the mountains. On another wall, a stone fireplace is painted that looks so real one can almost feel the warmth from the fire. The Rehab dining area was turned into a realistic looking French café, and another dining area was turned into a beautiful garden room with a painted gate, stone wall, fountain, and trellis. These murals have made a change in the atmosphere in which the residents gather and eat. They no longer are looking at white walls, but at color, at pleasing scenes, which conjure up memories of favorite pastimes and pleasant experiences.

When Moses Cone Extended Care Center in Greensboro North Carolina, began the Eden Alternative journey in 2002, the first thing they wanted to do was to bring the smell of grandmother's kitchen back to their residents. Since they weren't blessed with the money to re-design their kitchen, they resorted to use of a little ingenuity to achieve their goal and the

continued from page 289

is on their own culture change path, learning from each other and from other innovators. The small 20-bed assisted living residence at Trinity Oaks Retirement Community in Salisbury has installed a buffet serving table to replace another institutional system. Although the dining room is too small for at-the-table choices, residents tell the staff what they desire, and staff serves it from the buffet in the adjoining serving kitchen. This system provides a personalized restaurant-style service, which benefits the residents by adding choices and accommodating preferences. The aroma from the buffet can also help with residents' appetites. This system is an example of how elders and staff can overcome space and other limitations to create a much more enjoyable dining experience. Innovations can work in every nursing and assisted living facility.

Trinity Oaks' Assisted Living residents enjoy dining together.

Food and nutrition are important for every age. We all enjoy a tasty meal in a comfortable environment. No one has to give that up. The future of long-term care may depend on our ability to offer these important quality of life dimensions.

Ted W. Goins, Jr., is President and CEO of Lutheran Services for the Aging, Inc. He is an active advocate for North Carolina's elders and nursing homes. He can be reached at tgoins@lsanc.net or PO Box 947, Salisbury, NC 28145. Telephone: 704-637-2870.

Wall mural in the dining room at the Rex Rehabilitation and Nursing Care Center result was fantastic. They created a small buffet cart that can be placed directly in the dining room. The buffet brings the wonderful smells, which normally stay in the kitchen, out to the residents. The residents can look and smell the selections at each meal and decide what and how much they want to eat. The resident is then escorted to a seat where he/she receives waited service, enjoys the meal, visits with friends, and requests "seconds" if desired.

The buffet and its wonderful aromas have been extremely successful with residents, and they also netted three unexpected benefits. The aromas increased the residents' appetites, which resulted in a drop in weight loss and an increase in the desire of residents to socialize in the dining room. The third, and perhaps the best, benefit was actually an impact on their visitors. Visitors now regularly come to the Moses Cone Extended Care facility at mealtime, view the buffet, select a meal, and sit with the residents for the type of family gathering they used to experience in their younger days.

The Lutheran Home–Winston-Salem has had remarkable success using flavor enhancers to increase both the enjoyment and levels of food consumption. A large proportion of persons over the age of 65 have smell and/or taste losses sometimes caused by normal aging that can impair nutritional status. There are also many medical conditions that have been reported to cause smell and taste losses in the elderly. These conditions include cancer, Alzheimer's disease, Parkinson's disease, and viral infections. A reduced sense of smell and taste can sometimes be combated by adding flavor enhancers to foods.[9]

Flavor enhancer is defined as a substance that increases the pleasantness of the flavor of another substance. Enhancing food flavors can help our elders maintain appetite and food enjoyment. Long-term care facilities are using flavor enhancers during their cooking process to complement the food product. Some examples of how we are enhancing flavors of foods include using bullion cubes to make sauces and gravies meatier or by using fruit extracts to enhance gelatins or fruit-flavored desserts.

Summary

A number of long-term care facilities in North Carolina have adopted ways to improve the dining experience for long-term care residents. Wall murals and dining room themes help to create a pleasant atmosphere that also might stimulate resident imagination. Aroma therapies are also positive stimulants that increase the appetite and pleasure in eating. Flavor and food presentation are probably some of the most obvious modifications. We can all understand the desire to have our food taste and look good. There are probably even more ideas that could make eating in a nursing home more pleasant and home-like. Efforts like these are critical to stemming weight loss among residents and also to maintaining resident independence to the extent possible. We hope more facilities across the state will use and build on these ideas as they try to maximize their residents' quality of life. **NCMedJ**

COMMENTARY

The Dining Experience in Nursing Homes

Beverly A. Speroff, RD, LDN, Karen H. Davis, RD, LDN, Kristen L. Dehr, MS, RD, LDN, and Kate N. Larkins, MS, RD, LDN

According to the United States Bureau of the Census Current Population Survey dated March 2000, there were 32.6 million people living in the United States who were at least 65 years old.[1] In North Carolina, 12% of the state's population, or an estimated 1.04 million people, were in this age group. By 2030, this figure is expected to rise to 18% of the population. North Carolina currently has 424 licensed nursing homes with a bed capacity of 42,897 residents.[2] According to the North Carolina Department of Health and Human Services, 60% of people who live to age 65 will need long-term care sometime in their lives; 40% will need nursing home care.[3]

Many aspects of an older adult's life, such as degenerative diseases, functional limitations, medications, and social considerations can result in a decreased sense of independence. In addition to actual loss of independence, many residents in nursing homes experience "learned dependency" from excessive care given by those working in the nursing home setting.[4] These factors have the potential to result in weight loss, dehydration, pressure wounds, and other negative health outcomes. According to the Minimum Data Set (MDS)* information transmitted to the North Carolina Division of Facility Services from January to March 2005, 11.2% of residents had 5% or greater weight loss in the 30 days prior to their assessments.[5]

As mentioned, many factors may influence a long-term care resident's independence and, in turn, their weight. Less obvious among some of these factors may be their combined effect on the dining experience. A positive dining experience should foster independence, promote self-esteem, and make the resident as comfortable and safe as possible, while providing a nourishing, pleasant meal and minimizing negative health outcomes. Providing a positive dining experience to long-term care residents can be challenging. Functional limitations that range from an inability to walk to difficulty swallowing, along with chronic diseases that require therapeutic diets, make it difficult for facilities to provide the type of home-cooked meal each resident might prefer. An effort should be made to maintain each resident's dignity and minimize the possibility of excess dependency during the dining experience.

Rethinking the Dining Room

The American Dietetic Association's *Practical Interventions for the Caregivers of the Eating-Disabled Older Adult* discusses many aspects in which the dining experience can be optimized.[6] These ideas range from mobility issues in the dining room to food presentation. The dining room layout, for example, directly affects the ease of mobility to and from meals. Long-term care facilities should arrange tables and chairs to allow easy access by residents utilizing wheelchairs and walkers. Facilities should also ensure that dining room table height is at a level that will accommodate residents seated in wheelchairs. Even if the dining room is easily accessible by residents in wheelchairs, staff should be encouraged to transfer residents into dining room chairs when possible.

The dining experience can also be enhanced if care facilities present a home-like environment by using tablecloths, cloth napkins, and seasonal centerpieces. Vibrant contrasting colors can be used for tablecloths, placemats, tableware, and/or napkins to increase the nutritive intake of residents with dementia and other patients who may have vision impairments that make it

Karen H. Davis, RD, LDN, is the Director of Dietary Service, and **Kristen L. Dehr, MS, RD, LDN**, and **Kate N. Larkins, MS, RD, LDN**, are regional dietitians at Medical Facilities of North Carolina. They can be reached at KDavis@mfnc.to, DehrKL@mfnc.to, and Klarkins@mfnc.to or Medical Facilities of North Carolina, Inc., 1300 South Mint, Suite 201, Charlotte, NC 28203. Telephone: 704-338-5855.

difficult to distinguish food from table placements (i.e., plates, cups, etc.).[7] Cloth napkins also make a better protective barrier for clothing than paper napkins do.

The dining experience can also be improved by simply offering the residents beverages and pleasant conversation while they wait for their meal. Age-appropriate music, along with proper lighting and room temperature (per resident preference), are other easy ways to make the dining experience more comfortable and interesting.

Two other ideas that improve the dining experience by promoting independence and choice involve the way meals are presented to residents. Facilities should consider presenting meals in a buffet-style setting or using family-style dining, which also promotes a home-like atmosphere. Both of these options allow residents to have increased independence by allowing residents to create their own menus and determine their own portion size.

Eating with Sensory Loss and Chronic Disease

Residents in North Carolina nursing facilities are admitted with different diagnoses, singly and in combination, which can influence how well they enjoy their dining experience. Sensory losses associated with glaucoma, stroke, arthritis, and other conditions affect a person's ability to consume nutritionally-balanced meals and participate in the social aspects of dining. Many residents cannot see the food placed in front of them, manipulate the utensils very well, or hear conversations at the table. In addition to sensory impairments, chronic diseases and their treatments may contribute to loss of appetite, nausea, vomiting, early satiety, fatigue, lethargy, and decreased ability to feed oneself. In 2003, the North Carolina Long Term Care Ombudsman Program provided 441 training sessions for long-term care staff on sensitivity to sensory losses associated with aging.[8] Staff who received the sensitivity training did not enjoy their dining experience. Many of them wanted to retreat to a private location, felt embarrassment, or simply did not want to eat.

> *"A positive dining experience should foster independence, promote self-esteem, and make the resident as comfortable and safe as possible, while providing a nourishing, pleasant meal and minimizing negative health outcomes."*

In addition to functional challenges, many residents are also prescribed therapeutic diets.* The MDS 2005 data show that 47% of residents received a therapeutic diet, and 42% of nursing home residents received a mechanically-altered** diet.[5] A contributing factor to the high incidence of mechanically-altered diets is the fact that 40% of adults more than 65 years of age have no teeth, and only 2% of adults more than 65 years of age still have all of their natural teeth.[9] Therapeutic diet orders, such as 2gm sodium diets, calorie-controlled diabetic diets, or fat-restricted diets may be too restrictive for the nursing home population and may contribute to existing medical problems through complications, such as weight loss, decreased nutritional status, and diminished quality of life. Some facilities use diet types, such as no concentrated sweets and/or no added salt with recipes for large quantities that can serve most residents in a facility. As a result, these menus can be low in calories, bland in taste, and unappealing. Therapeutic diets may be beneficial for certain disease states in the nursing home setting, but they may result in a decreased calorie intake for those whose health needs do not require as much restriction.[10]

One approach used to combat the feeding challenges caused by chronic disease and functional decline is to provide a liberalized diet. Many nursing homes have embraced a liberalized diet plan, which allows all residents to have a regular diet, with minimal restrictions, such as elimination of a salt packet, altered sweet dessert, or other changes according to the resident's medical condition. In 2002, the American Dietetic Association established a position statement for the support of liberalized diets in nursing facilities.[11] The research demonstrated that therapeutic diets may not be warranted in lieu of the overall effects on a resident's quality of life. Many nursing facilities have adopted liberalized menu plans for their residents who have therapeutic needs secondary to diabetes and other disease states, such as hypertension.

A Team Approach

In addition to providing more liberalized diets, facilities can improve resident dining satisfaction and nutritional health through interdisciplinary care team coordination and communication. Members of the interdisciplinary team include the physician, registered dietitian, physical therapist, occupational therapist, speech therapist, pharmacist, social worker, nursing staff (including registered nurses, licensed practical nurses, and nurse aides), and the activity department. Family and resident involvement in the care planning process is also important. As an example of care team coordination, the registered dietitian

---

* Therapeutic diets are used to help treat/manage certain chronic diseases (e.g., diabetes and hypertension).

** A mechanically altered diet includes foods that may be pureed or softened to help patients who have trouble chewing and/or swallowing.

can monitor the consumption of meals for all residents or target those who have a higher risk for malnutrition, dehydration, and other nutrition-related outcomes.[12-13] The registered dietitian can determine if a resident's decreased intake is secondary to drug-nutrient interactions, changes in preferences, or changes in disease state. If drug-nutrient interactions occur, the dietitian may inform the pharmacist who can recommend medications and/or order appetite stimulants to counteract the possible negative outcomes produced by the interactions. Speech therapists can evaluate tolerance to current diet textures and fluid consistencies. As a result of this team approach, a meal can be presented that is individualized to the resident's needs and food preferences.

Dietary and activity team members can play a crucial role in making the dining experience personal for each resident. These departments can create theme/holiday meals, "meal-of-the-month" menus, and other special events. Residents also have the right to consult with the dietary department to design facility menus that express their religious, cultural, and preferred food choices. Facilities should use this information along with Dietary Guidelines for Americans,[14] My Food Pyramid,[15] and the Dietary Reference Intakes[16] to create a nutritious menu. To carry out the provision of nutritionally balanced menus, a facility may spend 7-10% of its total budgeted expenses on food service-related costs.[17]

Self- and Assisted-Feeding

Feeding difficulties occur in 87% of the elderly population.[18] It is the duty of the direct care staff to inform the rehabilitation department when someone is having trouble. Occupational therapists can evaluate a resident's need for adaptive equipment and individualized needs, such as proper positioning. Proper positioning (in a chair or bed) is one of the most useful ways to increased independence and, therefore, should be used during all dining experiences.[19] Improper positioning can increase difficulty in self-feeding or swallowing, increase frustration, fatigue, and decrease the resident's motivation to eat enough food. For residents with functional limitations, self-feeding is a challenge and may decrease socialization at mealtime. Adaptive equipment may minimize the energy required for self-feeding and, in turn, may improve the residents' ability to socialize.[19] An occupational therapist can develop a plan of care for positioning and train direct care staff.

Other feeding difficulties may be related to visual impairment and/or blindness. Residents with these deficits benefit from standardized placement of food, beverages, and service ware on their trays. The positional "clock system" can be used to inform the resident of the physical placement of specific foods in relation to their tray set-up.

Physical therapists can also be an asset by spearheading programs such as a "Walk to Dine" program. In this program, nurse aides and nurses work with physical therapists to assist residents with transfers from their wheelchairs into dining room chairs and work with occupational therapists on proper positioning of residents. Perry Gains, CNA, in Restorative Nursing at Charlotte Health Care Center, notes that minimizing chaos in the dining room by transferring residents into dining room chairs, and thus decreasing the number of wheelchairs and Geri chairs in the room, can help achieve a positive dining experience for everyone. This process decreases the risk of aspiration by allowing optimal positioning and provides an increase in resident dignity during dining. To further increase dignity during dining, residents with similar cognition and table manners or those affected by disease states such as dementia should be seated together. Thus, a resident can socialize with other residents who have similar habits and communication skills. Hearing-impaired residents may be reluctant to eat in noisy, crowded dining rooms because they are unable to hear mealtime conversation, which results in a feeling of isolation. Nursing facilities can limit unnecessary staff conversations, use sound-absorbing materials in the design and décor of the dining room, and ask residents for their individual suggestions on how to address noise reduction.

Improving the social aspect of dining is another way to achieve a positive dining experience. A program entitled "Dining with Dignity" was created to use socialization to increase the intake and independence of residents during meals.[20] The program is based on the enjoyment of meals with friends and families. It targets individuals at risk for malnutrition, dehydration, and pressure wounds and provides them with companionship at meals. Specifically, family members and "volunteer meal companions" are trained to appropriately assist residents during meals.[14] The program trains the volunteers on concepts such as cueing, "hand-over-hand" assistance, the "power of touch," and the importance of pleasant conversation. Residents who receive assistance from families or companions during meals consume a larger portion of their meals and decrease their risk of malnutrition, dehydration, and pressure wounds.[14] This supports the concept that nursing staff, families, and feeding companions should be an important part of the interdisciplinary team. One nursing home resident involved in the "Dining with Dignity" program summarized her reaction to the program in this way, "I socialize with different people and get to meet new people everyday. We have become a big circle of friends." This statement demonstrates how important the dining experience can be for a resident's total long-term residential care.

Summary

The dining experience is an opportunity for residents to experience the independence they once knew and still desire. Through appropriate meal consistencies an optimal dining room setting, and coordination of the total healthcare team, these desires can be reached. The resident benefits from this emphasis on the dining experience, while the interdisciplinary team members gain more insight into the individual needs of residents. The dining experience can be an important part of the clinical care of the resident by assuring appropriate nutritional and fluid intake, and it can help assure a desirable quality of life even while residing in a long-term care facility. **NCMedJ**

Fluid Intake and Hydration: Critical Indicators of Nursing Home Quality

Robert J. Sullivan, Jr., MD, MPH

After emerging from the primordial sea, humans evolved a sophisticated system for maintaining hydration in order to survive. Despite extremes of environmental stress, internal fluid and electrolyte balance remain remarkably stable. Compensatory mechanisms required to accomplish this feat begin with a sense of thirst, which stimulates fluid consumption.[1] With adequate fluid intake assured, the kidneys retain or discard fluids and electrolytes as appropriate. Under most circumstances, this remarkable mammalian adaptation to life on dry land requires no conscious intervention. In fact, the overwhelming majority of healthy children and adults pursue their daily affairs blissfully unaware of their hydration requirements, or their efforts to meet them.

Such is not the case for infirm elderly individuals. They experience a reduction in the ability to compensate for fluid excess and deficit due to a diminished sensation of thirst[2] coupled with a decline in kidney function. As a result of these changes, for the first time in their lives, older individuals and their caregivers must devote specific attention to fluid intake and elimination.[3] Since changes of aging are subtle, and often are ignored or pass unnoticed, it is not surprising that unrecognized chronic dehydration is a common finding among older adults presenting to emergency departments.[4]

Attention to fluid intake is particularly important for those living in nursing homes. Many of the reasons leading to nursing home placement are associated with significant hydration challenges. Residents with cerebral deterioration or injury may fail to respond to thirst stimuli or be unable to gain access to fluids. Renal function can be reduced by infection, diabetes, kidney stones, and urinary tract outflow obstruction. Medications administered to control illness can adversely influence bodily control systems. As a result of such challenges, mechanisms that maintain hydration may prove inadequate. In response, nursing facility management must establish systems of care to provide ongoing hydration support, and staff must be trained to assume an active role in promoting fluid intake.[5] Failure to manage hydration can be life-threatening and is a common reason for hospitalization.[5] Fortunately, excellent reviews and guidance are available in the medical literature to guide both novice and experienced caregivers.[6]

Initial Evaluation

Immediately upon arrival at a nursing facility, the staff should conduct a comprehensive assessment of the new resident's needs and capabilities. In regard to fluids and hydration, the assessment should document prior requirements for hydration assistance, physical limitations on swallowing, and underlying medical conditions and medications that could present problems. Direct observation during meals and throughout the first day will provide additional information regarding intake and elimination patterns and capabilities. An immediate plan of care must be established to address hydration whenever concerns or problems are documented. Virtually all information necessary to understand hydration requirements is addressed in the Minimum Data Set (MDS).* With this information available, a care plan can be created to assure ongoing stability.

When determining fluid intake requirements, all sources of fluid gain and loss need to be considered. Residents exhale moisture with each breath, and their skin constantly exudes moisture that evaporates from the surface. They lose additional moisture through bowel evacuation and the production of urine as they eliminate waste products of metabolism. They gain some fluid through metabolism of foods, but it does not

---

* "The Minimum Data Set (MDS) is part of the federally mandated process for clinical assessment of all residents in Medicare or Medicaid certified nursing homes. This process provides a comprehensive assessment of each resident's functional capabilities and helps nursing home staff identify health problems." equal losses. Thus, a daily intake of at least two or more liters is necessary to sustain equilibrium.

While most residents can successfully continue self-management of fluid intake as they have done throughout their entire lives, the admission assessment is designed to detect risk factors for dehydration. Generic risk factors discovered from research studies include female gender, age over 85, more than four medical conditions, more than four medications, bedridden, laxative use, and chronic infections.[8] Specific risk factors include fluid loss associated with kidney disease or diabetes. Diuretic medications prescribed to control heart failure and hypertension cause a steady loss of fluids. Fluid problems can be sudden and severe if nausea, vomiting, and diarrhea persist for any length of time. Fever will enhance the loss of fluids in the form of sweat. Intake is reduced for residents with swallowing problems associated with Parkinson's disease, strokes, or dementia. Depression, delirium, anxiety, and agitation cause a loss of interest in food and fluids. These, and many more problems, are commonly encountered in nursing home residents.

Top-quality nursing care organizations have a variety of pre-defined care plans established to deal with hydration issues detected in the MDS evaluation process. Plans provide a structure for ongoing resident support, periodic observation, documentation, and notification when problems arise. Nutritionists or dietitians will establish the plan for food and fluid type, volume, and frequency. Speech therapists assess swallowing skills and provide recommendations regarding fluid consistency and optimal feeding position. Occupational therapists address requirements imposed by physical disability and provide solutions, such as the use of straws, "sippy cups," vessel with large handles, or resilient grip materials. Once the degree of supervision and assessment for fluid intake is established, every member of the staff is expected to participate in plan implementation. While the focus of most hydration strategies involves improvement and maintenance of function, the nursing home must also have comprehensive plans available for managing nutrition and hydration for the terminally ill under hospice care.

Daily Monitoring

Success in maintaining hydration requires ongoing attention to the resident's environment and daily demeanor. Staff members should ensure the ready availability of refreshing fluids throughout the day and watch to be sure they are used (see Sidebar on page 298). Hydration is not limited to the dining experience. Residents in nursing facilities must have a wide variety of fluids available hour-by-hour, just as they did prior to entering the nursing home. Staff knowledge of preferences expressed by individuals can guide the choice of fluids offered. That includes juice with breakfast, milk with cereal, coffee or tea with meals, soft drinks and water throughout the day for refreshment, and perhaps wine or beer in the evening. For those capable of ambulation, a water cooler or drinking fountain offers a suitable source for refreshment. Bed-bound residents and those confined to chairs must have pitchers with fresh, cool water and cups within reach. Resident charts should include regular documentation regarding the amount of fluids and foods consumed at mealtime. Where fluids are readily available, most residents will take care of their needs without needing assistance. If staff members observe a decline in intake or function, an evaluation for dehydration should be promptly undertaken. Periodic weight checks are helpful, although changes may reflect problems with nutrition rather than hydration.

Residents with medical or emotional problems associated with dehydration will require more intensive monitoring of intake and urinary output. Intake volume is easy to estimate by measuring the fluids consumed from bedside pitchers and during meals. By contrast, monitoring kidney output is challenging for most ambulatory residents since collecting and measuring urine is neither easy nor pleasant. Demented patients may lack the mental capacity to cooperate. The frequency of visits to the bathroom provides a useful clue regarding the adequacy of renal function. For incontinent patients, experienced staff members often assess urinary concentration and volume when changing diapers. Although hardly quantitative, diaper evaluation does permit detection of major changes in output.

> *"Since the physical manifestations of dehydration are non-specific and often obscured by the aging process and/or illness, it is not surprising that this diagnosis is often overlooked."*

Assessing Suspected Dehydration

Dehydration can develop rapidly in older individuals due to illness and changes in medication or environment. If the air-conditioning should fail on a hot afternoon, all residents need to be encouraged to consume extra fluids. Should the nursing home staff become aware of changes in a resident's appearance in regard to either health or function, immediate evaluation is needed.

Since the physical manifestations of dehydration are non-specific and often obscured by the aging process and/or illness, it is not surprising that this diagnosis is often overlooked.[9] Symptoms of dry mouth, fatigue, weakness, restlessness, loss of appetite, nausea, and vomiting are commonly reported. However, signs of pale dry skin and poor skin turgor can reflect normal aging. A dry mouth is more likely to reflect mouth breathing than lack of fluid intake. Constipation and fecal impaction often occur with dehydration, but commonly occur without it. A drop in blood pressure and a rise in pulse when the resident sits or stands is one method used to detect intravascular volume deficits associated with dehydration.

While physical examination for signs of dehydration is helpful, the single most valuable indicator is a documented drop in urinary volume. The normal urine output exceeds 600cc/day for most adults. When the output falls below 400cc/day, an evaluation is needed. Most residents can successfully collect and submit a 24-hour urine specimen. However, if there is a serious question regarding dehydration, placement of a temporary urinary catheter to document output is worth doing. By having the resident to void prior to catheter placement, the presence of a possible bladder outflow obstruction can be simultaneously documented.

Laboratory tests can assist the evaluation of dehydration provided that baseline levels are available for comparison. A rise in hemoglobin and hematocrit are typical findings accompanied by a rise in the blood urea nitrogen (BUN) and creatinine levels. A normal BUN/creatinine ratio is 10:1. Due to increased urea reabsorption associated with dehydration, the ratio will shift to over 20:1. Finding a urine specific gravity over 1.015 in the absence of urinary glucose indicates the kidneys are working hard to conserve fluids. Checking a urine specimen for sodium concentration is particularly helpful. Documenting a concentration below 25 mEq/L in the absence of renal disease or diuretic therapy is a highly significant indication of a hydration problem. An even more accurate test involves calculating the urinary fractional excretion of sodium by comparing plasma and urine sodium and creatinine concentrations.

Rehydration

If physical findings and/or laboratory tests suggest dehydration, an immediate response is required. The resident's physician should promptly be notified and rehydration efforts initiated. If the resident can ingest fluids by mouth, drinking water, diluted juice, soft drinks, electrolyte solutions (e.g., Gatorade®), soups, coffee, or tea should be encouraged. Careful documentation of fluid intake and output must be maintained until the resident is stable. There is no formula available to estimate the volume of fluid needed. Instead, staff must rely upon clinical evidence of response using the same indicators used for diagnosing dehydration. An increase in arterial pressure, urine output, and urine sodium excretion are reliable signs. Look for a return to prior levels of mental performance and a resumption of typical daily functions as further indication of success.

Creative Hydration Programs

Lanaya Cunningham, RD

The staff at Universal Healthcare and Rehabilitation Center in Concord, North Carolina use a nourishment cart covered with a decorative canopy as part of their hydration program. The dietary staff stocks the cooler on the cart with various juices and milk, plus a variety of snacks including gelatin, ice cream, and pudding, which can also contribute to the total liquid intake of the residents. The cart is pushed from room to room, and beverages and snacks are offered at mid-morning, mid-afternoon, and in the late evening.

The afternoon hydration and nourishment pass at Taylor Extended Care Facility in Sealevel, North Carolina is part of the activity program. The cart is decorated with balloons and has music playing while the staff pushes it through the halls in the mid-afternoon. The staff offers snacks to the residents from the cart, which may consist of ice cream, soft drinks, or juices. The snacks and the music are often coordinated to coincide with the planned activity in the facility that day. The activity staff report that the residents often come into the hallway in the afternoon when they hear the music, and they look forward to receiving a beverage and snack.

Lanaya Cunningham, RD, is a Facility Survey Consultant in the North Carolina Division of Facility Services. She can be reached at: lanaya.cunningham@ncmail.net. Telephone: 919-733-7461

Feeding tubes

Residents who receive food and fluids via a naso-gastric or an enterostomy tube represent a special situation since all nutrition and hydration can be controlled by the nursing staff. Nutritionists will design the protocol for both food and fluid administration. If followed with care and attention, the protocol should ensure stability.

Summary

Hydration issues are important considerations for the elderly and infirm. What was previously taken for granted often becomes the focus of daily attention. Nursing homes must take a proactive stance in designing systems and training staff to deal with hydration. The minimum daily fluid requirements, and the steps necessary to investigate suspected dehydration, should be well known and understood by all members of the staff. **NCMedJ**

COMMENTARY

Regulating Food Service in North Carolina's Long-Term Care Facilities

Cindy H. DePorter, MSSW

> *Based on a resident's comprehensive assessment, the facility must ensure that a resident: maintains acceptable parameters of nutritional status, such as body weight and protein levels… The facility must [also] provide each resident with sufficient fluid intake to maintain proper hydration and health.*[1] — United States Code of Federal Regulations

The provision of food service to residents is among the many regulated services in long-term care facilities. Long-term care facilities face a challenging task in providing three tasty, nutritious meals a day to their nearly 43,000 residents, each with special needs and preferences. In order to ensure that North Carolina's long-term care facilities provide these meals appropriately, North Carolina's long-term care facilities are regulated by the federal Centers for Medicaid and Medicare Services (CMS) through special delegated authority to the North Carolina Division of Facilities Services (DFS).

To understand how long-term care food services are regulated, one must first understand how these facilities are regulated in general. As part of the Social Security Act, Congress included a minimum set of quality and performance standards to regulate all long-term care facilities certified to receive Medicaid and Medicare funding.[2] This legislation covers everything from resident assessments to survey and certification processes to dietary services.

The duty of enforcing this legislation falls under the Centers for Medicare and Medicaid Services (CMS). CMS is also charged with drafting the specific regulations and manuals needed to implement the law. Title 42 of United States Code of Federal Regulations[1] contains the specific regulations long-term care facilities must comply with in order to qualify for federal reimbursement under Medicaid and Medicare. CMS contracts with each state to inspect facilities, assess their regulatory compliance, and to oversee the licensure process. In North Carolina, the state Division of Facility Services (DFS) performs these functions.

Within the North Carolina DFS, the Licensure and Certification Section's primary responsibility is to ensure that citizens of North Carolina receive safe and adequate healthcare. The Section does this by conducting annual inspections of healthcare facilities, agencies, and clinical laboratories. Eighty percent of the Section's 150 employees are dedicated to performing these inspections, most of which take place in long-term care facilities.

This commentary provides an overview of federal (CMS) regulations pertaining to food service provision in nursing homes* and the criteria by which these services are evaluated. It also discusses how state regulatory processes address issues of food service and hydration in long-term care facilities, along with examples of how most facilities are dealing with common challenges in this area.

Understanding Federal and State Regulations

The federal regulations related to long-term care dining issues can be found in the United States Code of Federal Regulations, §483.15 (Quality of Life); §483.25 (Quality of Care); and §483.35 (Dietary Services).[1] To interpret the regulations, states use the CMS *State Operations Manual*, which includes detailed instructions to surveyors.[3]

---

* In this commentary, the term "nursing home" refers to an in-patient facility that provides skilled-nursing care 24 hours-per-day by licensed registered nurses.

Cindy H. DePorter, MSSW, is the Assistant Chief of the Licensure and Certification Section at the North Carolina Division of Facility Services. She can be reached at cindy.deporter@ncmail.net or 2711 Mail Service Center, Raleigh, NC 27699-2711. Telephone: 919-733-7461.

Preserving Resident Quality of Life

> *The facility must promote care for residents in a manner and in an environment that maintains or enhances each resident's dignity and respect in full recognition of his or her individuality.*[1]

Each resident of a long-term care facility has the right to be treated with dignity and respect. Preserving resident dignity involves activities that help residents maintain their self-esteem and self-worth (i.e., assisting with grooming and appearance, promoting independence in dining). CMS expects the dining environment to be pleasant and for residents to have a positive dining experience. The dining room should be clean, people at the same tables should all be served at the same time, and the staff providing dining service should be courteous and helpful (i.e., not yelling across the room for assistance). Residents should not have to wear "bibs," and facilities should not serve food on paper plates or use plastic forks on a regular basis.

"Each resident of a long-term care facility has the right to be treated with dignity and respect."

Tying in directly with the regulation to preserve dignity is a regulation to preserve resident food and beverage choice. Each resident has the right to make choices about his/her life and healthcare in the facility. Their choices include *where* they want to eat (e.g., in their room or in the dining room) and *what* they want to eat. The facility should educate residents about the risks of choosing not to follow a prescribed therapeutic diet. For example, diabetic residents often do not want to eat the 1,800-calorie American Dietetic Association diet. Most facilities have an NCS diet (No Concentrated Sweets) that is intended for diabetic residents. The NCS diet allows residents more food choices and freedom. Facilities also have the flexibility to change the types of foods offered at meals to accommodate the resident's choice.

The resident can choose to eat in his/her room versus in the dining room. If a resident would like to sleep late in the morning without skipping breakfast, this is their right. The facility should work with residents to honor this request and still have some type of breakfast available. It might not be the same breakfast that was served to the other residents at the scheduled mealtime, but as long as it meets the nutritional guidelines, it would be acceptable under federal and state regulations. Family members are also permitted to bring the resident food from home or restaurant. Family members are not permitted to bring food to be served to other long-term care residents.

Maintaining Quality Care

> *Each resident must receive, and the facility must provide, the necessary care and services to attain or maintain the highest practicable physical, mental, and psychosocial well-being, in accordance with the comprehensive assessment and plan of care.*[1]

With regard to dining, providing quality care is geared around the resident's ability to consume foods and fluids. Nursing homes are required to maintain acceptable parameters of nutrition, such as body weight and protein levels, based on the resident's clinical condition and risk status. This means that, if a resident experiences unplanned weight loss, the facility has to assess and implement strategies to ensure that the weight loss is not because of some avoidable issue, such as a resident having mouth pain while he/she eats. The facility has the responsibility of assuring that weight loss is clinically unavoidable. If the resident is losing weight because of a clinical condition, the facility still should assess and attempt interventions to maintain resident weight. Along with this comes the issue of the resident having the right to refuse food. In some instances the resident may have a terminal illness and may opt to refuse food. Regardless of the resident's condition, all residents have the right to refuse food. If this happens, the facility should discuss food refusal with the resident (when possible), the resident's family, and the resident's physician to make sure that the resident's wishes are being honored. The facility should document the discussion in the resident's record and support the decision that was reached.

Dehydration falls under the same regulatory requirements. The facility has to provide sufficient fluid intake to assure proper hydration and health. If residents with dementia cannot maintain their own hydration, facilities must offer fluids to these residents throughout the day, not just at meal times. If a resident decides to refuse liquids, he/she has the right to do so. Facilities should document the resident's desire to refuse liquids in his/her record. Facilities should also document that this choice has been discussed with the resident (when possible), the resident's family, and physician. The resident's wishes should be honored.

Dietary Services

> *The facility must provide each resident with a nourishing, palatable, well-balanced diet that meets the daily nutritional and special dietary needs of each resident.*[1]

Regulations specified under Dietary Services address the following areas of food service provision: staffing, menus and nutritional adequacy, food, therapeutic diets, frequency of meals, assistive devices, sanitary conditions, and feeding tubes.

Staffing

Regulations for dietary services are designed with the general intent for facilities to provide each resident with a nourishing, palatable, well-balanced diet, which also meets the individual daily nutritional and special dietary needs of each resident. CMS requires facilities to have a qualified dietitian as indicated by Dietetic Registration of the American Dietetic Association or have the basis of education, training, and experience to identify residents' dietary needs, appropriately assess and plan, and help implement the dietary program. A qualified dietitian is not required to be at the facility on a full-time basis. Facilities that do not employ a full-time dietitian, must designate a person to serve as the director of food services. The director of food services must receive frequent consultation from a qualified dietitian. The regulations do not specify how often a consultation should occur, but consultations usually occur on a monthly basis. The facility must also employ sufficient support personnel who are competent to carry out the functions of the dietary services. DFS judges whether a facility has sufficient dining staff based on their ability to prepare and provide meals in a timely (e.g., quickly enough to ensure the food is served warm) and in an appropriate manner (e.g., all residents at one table are served at the same time). Facilities determine what works for them in terms of sufficient staffing.

Menus and Nutritional Adequacy

Facilities are required to have menus that meet the nutritional needs of residents in accordance with the recommended dietary allowance of the Food and Nutrition Board of the National Research Council, National Academy of Sciences. In addition, all menus are to be prepared in advance and carefully followed.

Food

Each resident should receive food prepared by methods that conserve its nutritive values, flavor, and appearance. Food must be palatable, attractive, and served at the proper temperature. In other words, the facility has to cook the food in such a manner that it looks, tastes, and smells appetizing. To ensure that food is prepared and served in an appetizing manner, DFS depends, in large part, on the residents' and the residents' families' feedback to survey teams on how the resident and/or family perceives the food. How does the food taste? What does it look like? Does it smell good?

DFS surveyors find that food is a serious concern to residents. Mealtime is a social time and a time when residents interact with each other. DFS survey teams routinely ask resident's how they like the food. The question opens up an important dialog between surveyors and residents and helps establish credibility for surveyors. Meal times are a highlight of many residents' days, and it is important that residents are satisfied with this general category of service offered by the facility in which they live.

Therapeutic Diets

The food has to be prepared in a form designed to meet individual needs. Some residents, for example, have no teeth, and therefore must have their food chopped or pureed (mechanically altered). A physician, in conjunction with the nursing home staff, may prescribe a therapeutic or mechanically altered diet. The facility must have substitution foods of similar nutritive value available to residents who refuse to eat the foods routinely served in their prescribed diets. The staff should offer these substitutions to the resident whenever this occurs.

Frequency of Meals and Snacks

CMS regulations require long-term care facilities to provide three meals a day at regularly scheduled times, which are comparable to mealtimes in the community. There must be no more than 14 hours between a substantial evening meal and breakfast the following day. Each day a snack must be offered at bedtime. When a nourishing snack is provided at bedtime, then the facility may have 16 hours between the evening meal and breakfast the following day, if a resident group agrees to this meal span. Snacks vary from graham crackers and juice to fruit and milk to other types of healthy snacks. The facility must offer snacks to residents each night. Residents also may have their own snacks in the facility. Proper storage is an important consideration to lessen the chance of pests. The key idea related to both meals and snacks is choice. Facilities in North Carolina have gone to great lengths not to impose simple "one-size-fits-all" approaches with regard to both meals and snacks.

Assistive Devices

Assistive devices, or special eating equipment, may help residents who have functional limitations. The facility must provide special eating equipment and utensils for residents who need them. This would include items such as large-handled/easy grip forks and spoons, plate guards that help keep food on the plate, or postural supports that help residents with positioning.

Sanitary Conditions

In addition to federal laws, long-term care facilities must also follow state laws with regard to sanitation and safe food handling. The Departments of Environment and Natural Resources and the Division of Public Health work together to meet this public health need. County inspectors grade all the nursing home food service departments just like they do restaurants.

To comply with federal regulations, long-term care facilities must procure food from sources approved or considered satisfactory by federal, state, or local authorities. Food must be stored, prepared, distributed, and served under sanitary conditions. The facility must also properly dispose of garbage and refuse. Elderly people are often immuno-compromised and, therefore, are more susceptible to food-borne illnesses, so these stringent requirements are applied. However, this does not mean that families cannot bring food into the facility. Many families bring food to residents, and it is an acceptable practice. In addition, facilities may have fresh seasonable vegetables and other seasonal meals as long as they come from approved sources. There are no regulations that prohibit this practice. Facilities have great latitude in being able to provide meals that meet standard nutritional guidelines, but still meet the unique likes and dislikes of their specific resident populations.

Feeding Tubes

Residents who have feeding tubes or are at risk for weight loss or dehydration must also have special protections. Facilities are not to place and feed a resident by naso-gastric tube unless the resident's clinical condition makes it unavoidable, and if a resident requires this type of feeding over the long term, a gastrostomy tube would be considered. These regulations also make sure the facility is providing the correct treatment and services to maintain this form of feeding. This includes placement of the tubes, monitoring of intake for proper nutritive levels, and total management of the feeding tube functionality.

State Survey Teams

DFS survey teams visit each facility periodically (no less than once per year) to ensure that all facilities comply with the regulations pertaining to the operation of a nursing home. Federal survey teams may also visit these same nursing homes. While federal survey teams typically visit a facility only after a state survey team has noted deficiencies, federal survey teams may visit facilities at any time for any reason.

DFS surveys teams generally include four-to-five professionals—a combination of nurses, dietitians, social workers, and pharmacists. The annual surveys inspect the overall care in the nursing home, which includes using a variety of indicators, such as pressure sores, dehydration, abuse, and nutrition. Inspections typically take three days, and DFS conducts at least 15% of the inspections during weekends, evening, and/or early morning hours. Surveyors observe; review facility documentation; and interview residents, families, and staff to make their determinations. To determine if there is a "deficiency," the surveyors consider the outcome, what occurred, why it occurred, how often it occurs, the impact, whether the facility has resolved the problem, if they facility knew there was a problem, etc.

If the survey team finds that a nursing home is out of compliance with any regulation or standard (including patients' rights violations), DFS cites the facility for a violation. The facility must then submit a response/plan of correction to DFS for approval. DFS will conduct another survey to make sure the facility implemented corrective action. If a facility fails to implement corrective action, they may be subject to state and/or federal sanctions and fines. In worst case scenarios, facilities might be required to suspend new admissions, have a temporary manager appointed to operate the facility, or have their license revoked. Fines range from $50.00 to $10,000.00 a day. However, in most cases, the facility corrects the problem promptly and is not sanctioned or fined. Facilities also have the right to appeal any deficincy that they incur.

Summary

Other commentaries in this issue of the *North Carolina Medical Journal* describe innovative food and dining practices in some of our state's long-term care facilities.[4,5] Federal and state regulations do not prohibit these innovations, and DFS supports the concept of "enhancements" of the dining experience in these facilities. The Division of Facilities Services, therefore, encourages facilities to assess and operationalize various dining methods, allowing residents to select their foods, dining times, dining partners, and other preferences. The regulations allow facilities to utilize innovative dining approaches, such as buffet lines, or family-style serving options, which allow residents to order at the table as they would in a restaurant. The regulations do not dictate whether facilities should serve food to residents on trays, in buffet lines, or in a family style. While there are many regulations, they leave room for innovative new ideas as long as these ideas do not compromise resident health or safety.

Food consumption and the dining experience are an integral part of the resident's life in a nursing facility. It is important that resident preferences are being honored, and the dining experience is as pleasant and home-like as possible. The facility's responsibility is to provide adequate nutrition and hydration that assures the resident is at his/her highest level of functioning emotionally, functionally, and physically. Meeting the unique needs of each resident in a facility can be a daunting task, but one of immense importance to the quality long-term care. **NCMedJ**

COMMENTARY

A Physician's Perspective on the Dining Experience in Long-Term Care

Christopher M. Herman, MD, CMD

Nursing Homes have long been the location where services are provided to individuals who suffer from chronic functional and cognitive impairments. Hopes to "cure" these chronic conditions are unfortunately unrealistic. The goals of a nursing home can be best summarized as one in which the facility cares for its "residents in a manner and in an environment that promotes the maintenance or enhancement of each resident's quality of life."[1] Maintenance and enhancement of quality of life become the focus, not cure.

Since mealtimes are often the highlights of a patient's day, they can become a significant source of improved quality of life, or a source of frustration and complaint, for the patient, family, and facility. Although there are many specialized diets from which to choose, most of these diets are not appropriate for use in a nursing home setting. Often, a more liberalized diet that provides for the patient's nutritional needs while considering the resident's medical conditions can increase the desire to eat and the enjoyment of food. This ultimately decreases the risks of weight loss and undernutrition.[2]

Prescribing Therapeutic Diets

Diets in nursing homes are often chosen for the patients by the attending physician based on the patient's medical condition. These are called "therapeutic diets." Therapeutic diets are defined as diets that are provided to meet the specialized nutritional needs of the patient based on his/her medical condition. The assumption is that the diet will improve the patient's overall health and condition. There are likely hundreds of specialty diets that are available for a patient. Most of them are chosen based on two parameters: texture and nutritional modifications.

Alterations in texture are chosen in order to minimize the risks of complications. One obvious choice would be a pureed or thickened liquid diet. This diet might be chosen for a patient with a cerebrovascular accident that has resulted in some amount of dysphagia (difficulty in swallowing). Physicians prescribe these diets to minimize the risk for aspiration.

Nutritional modifications of the diet include such choices as increasing or decreasing calories or the addition of mineral or vitamin supplements. One example is to choose a cardiac prudent diet for a patient who suffers from coronary artery disease.

Initial orders for a patient's diet are usually contained within the FL-2 form* that the long-term care facility receives from the hospital. The hospital discharge summary may also serve as source of a dietary order that is either confirmed or changed by the patient's attending physician. Once a long-term care facility receives an order for a diet, there are several regulatory concerns. Long-term care facilities will create a written care plan that focuses on the specific needs of the patient. One of these needs will be the dietary restrictions that are set forth by the attending physician. "All diets… shall be ordered by the physician or other legally authorized person and served as ordered." The facility is also responsible to "ensure that each patient is provided with a palatable diet that meets his or her daily nutritional and specialized nutritional needs."[3]

Unfortunately, these types of "prudent" choices by a clinician may not always reach the intended goal of benefiting the patient in a long-term care facility. The use of therapeutic diets in long-term care is often unpalatable and, therefore, associated with weight loss. In fact, the American Dietetic Association recommends that, whenever possible, facilities offer a more liberalized diet to long-term care residents instead of strictly holding to therapeutic diets.[4] Most clinicians would easily come to the same conclusion, but they are often bound by their training and experience.

---

* Most facilities require a physician-completed FL-2 form upon admission. The FL-2 form includes the patient's level of care and medical diagnoses and conditions.

Christopher M. Herman, MD, CMD, is an internist and geriatrician who currently serves as the President of Physicians Eldercare and president of the North Carolina Medical Directors Association. He is also the medical director and attending physician for several local Nursing homes and assisted living facilities. Dr. Herman can be reached at cherman@peltc.com or or 3880 Vest Mill Road, Winston-Salem, NC 27103. Telephone: 336-245-5408.

The training of physicians in the dietary needs and options of patients is usually limited. Most of the training occurs in a controlled hospital setting during residency. Physicians are then expected to apply this training to other settings, such as the nursing home. Applying his/her training in a new setting often presents the physician with a challenge in understanding what is best for the patient, based on the medical diagnosis versus the patient's preference. Compliance with a therapeutic diet is often very difficult for those patients with the best of intentions. It is even more challenging for those patients who have spent decades establishing their eating patterns, likes, and dislikes.

Unplanned Weight Loss

Weight loss within long-term care facilities has important clinical and regulatory significance. The prevalence of protein energy malnutrition for residents in nursing home facilities ranges from 17% to 65%.[5] Malnutrition among elderly populations is associated with poor outcomes and is an indicator of risk for increased mortality.[6] Research has shown that most long-term care residents who have evidence of malnutrition are on restricted diets, which might discourage nutrient intake.[7]

Weight loss is a complex issue within nursing homes, but there are several problems that can be identified as contributors. One such problem is that many residents are already nutritionally compromised by the time they are admitted to the nursing home. Acute and chronic medical conditions have often laid waste to their caloric intake. Additionally, medications, smoking, and a decline in taste and smell can all decrease food intake.

It is well established that people consume smaller amounts of food as they age. There are a number of reasons for reduced food intake among elderly people, which range from decreased physical activity to disease conditions to earlier or more powerful signals of satiety. This is called anorexia of aging.

The body of literature that focuses on the systemic effects of illness and food intake has been growing. Many of these studies have focused on cytokines. Cytokines are small proteins that are released by the body in response to most illnesses, such as cancer, heart failure, and infections. These proteins then regulate activities, such as inflammation, blood production, and fighting infection. These studies have shown that cytokines, such as interleukin 1 and 6, tumor necrosis factor, and ciliary neurotrophic factor, tend to cause muscle wasting and can reduce albumin, pre-albumin, and cholesterol.[8] The effects of this anorexia are far reaching, producing systemic effects, such as anemia, immune dysfunction, increased infections, decreased cognition, decreased function, and orthostatic hypotension, to name a few.

When considering the management options for patients in long-term care facilities, it is important to understand that these patients are already at a disadvantage for the previously stated reasons. As a result, facilities should provide residents with adequate calories, eating and fluid intake assistance, along with focusing on treating their underlying medical illnesses.

One situation worth noting concerns the use of supplements to improve the nutritional status of patients. Many would argue that the supplements should be given during meals in order to avoid early satiety rather than giving them prior to a meal. One study sought to answer this question and showed that when nutritional supplements were given an hour before a meal, an older person consumed more calories than when the supplement was given during a meal.[9] It has been shown that glucose infused into the duodenum produces less satiety in older persons.[10] As a result, nutritional supplements that contain carbohydrates are less satiating than supplements that are high in protein.

Some additional suggestions to enhance the dining experience in older adults in nursing homes would include cooking for simplicity by focusing on flavor and appearance of food. Ideally, only a few simple diets would be offered. However such a restrictive focus would require the involvement of the administrative staff, nursing staff, and the medical director.

My experience has shown that most families do not expect a specialized diet to be provided in a nursing home. Many families realize their loved one is already experiencing nutritional decline. For this reason, family members often are happy if the patient can take in any food. However, families of assisted living facility residents have expressed greater concerns when they feel that an adequate therapeutic diet is not available. These concerns are likely based upon the family's perception that the patient's medical illness is not as advanced and, therefore, requires continued diet modification.

Most clinicians have treated patients whose medical conditions have required changing to a less-textured diet, which then resulted in the resident eating less due to the unpleasant sight or consistency of the meal. In order to maintain appropriate and adequate levels of oral intake, clinicians may decide to return the resident to a more "risky," liberally textured diet. This decision necessitates family involvement. Family and staff education are vital for a facility to successfully implement such changes.

Summary

Unfortunately, weight loss is frequently an expected part of a patient's normal nursing home residential trajectory. However, the clinical team should determine if the weight loss is reversible. The patient's clinical condition is often such that weight loss cannot be reversed or improved. Currently, life expectancy for a patient who has been admitted to a nursing home is approximately 2.2 years. These patients have been suffering from multiple medical conditions that have ravaged their body and mind and left them in a frail condition.

Food has many personal meanings to each resident that can improve the quality of a person's few remaining years. While many specialty diets are available to patients in a hospital, many of these diets may not be appropriate for patients who reside in a nursing home. Careful attention should be given to the prescription and preparation of meals in long-term care facilities. A focus on liberalizing diets in long-term care facilities can lead to improved quality of life for many patients. **NCMedJ**

COMMENTARY

Nutrition in Advanced Alzheimer's Disease

Heidi K. White, MD, MHS

Nursing facilities that care for patients with advanced dementia strive to provide high-quality nutritional care. The standards set forth in federal regulations state, "Based on a resident's comprehensive assessment, the facility must ensure that a resident maintains acceptable parameters of nutritional status, such as body weight and protein levels, unless the resident's clinical condition demonstrates that this is not possible."[1] Alzheimer's disease (AD) frequently involves weight loss,[2-7] which is a strong predictor of mortality.[8] Weight loss and subsequent malnutrition may be an unavoidable part of the natural history of end-stage AD and other dementias. Whether nutritional intervention can delay functional decline and morbidity is largely untested. However, observational data from subjects with AD indicates that weight gain is associated with a reduced risk of mortality.[8] Similar data in institutionalized subjects including those with dementia show that weight gain of even small amounts can improve morbidity and mortality.[9] An understanding of the nutritional consequences of Alzheimer's disease, along with appropriate assessment and a thoughtful approach to intervention, may help to avoid the complications associated with malnutrition, thus preserving a better quality of life until death.

> *"...nutritional intervention that seeks to enhance the hedonic reward during mealtime may significantly benefit AD patients who are at risk for nutritional decline."*

Factors Promoting Weight Loss

Taste and Smell Dysfunction

Taste and smell dysfunction occurs with normal aging and can be exacerbated by medications and disease.[10,11] Although some changes in taste perception have been reported,[12] multiple studies in subjects with mild to moderate Alzheimer's disease have demonstrated deficits in odor identification.[13,14] In addition, odor threshold may become progressively more abnormal as the disease progresses.[15] Olfactory dysfunction may not be specific to Alzheimer's disease; similar olfactory deficits have been noted in Parkinson's disease and vascular dementia.[16]

Inflammatory Mediators

Cytokines,* such as interleukin 6, are an integral part of anorexia-cachexia syndromes in other disease states, such as cancer and heart failure.[17,18] Cytokines, including interleukin 1 and 6, and tumor necrosis factor alpha, play an important role in the inflammatory process that accompanies the hallmark changes of amyloid plaques and neurofibrillary tangles that occur with AD.[19-22] In essence, these inflammatory mediators may produce important changes in the areas of the brain that control appetite.

Abnormal Eating Behavior

Abnormal eating behaviors contribute to weight loss. Typical behaviors include needing frequent verbal cues to complete the eating process, verbally refusing food, pocketing food in the cheeks without swallowing, clenching teeth, and spitting food.[23,24]Abnormal eating behavior may be more subtle, such as a fluctuations in appetite, delusions about food (e.g., believing food is poisoned), increased distractibility at mealtime, and

* Cytokines are regulatory proteins released by cells of the immune system. These proteins act as intercellular mediators in the production of an immune response.

Heidi K. White, MD, MHS, is Assistant Professor of Medicine at the Center for the Study of Aging and Human Development and Division of Geriatrics, Department of Medicine, Duke University School of Medicine, and Geriatric Research Education and Clinical Center, Durham Vetrans Affairs Medical Center. Dr. White can be reached at white031@mc.duke.edu or Box 3003, DUMC, Durham, NC 27710. Telephone 919-660-7516.

changes in food preferences.[25] Destruction of the hippocampus and surrounding cortical areas may explain certain behaviors. In late-stage AD, plaques and tangles have been described in the hypothalamus, the neurologic center of appetite regulation.[26,27]

Dysphagia is a common manifestation of late-stage AD.[28,29] Even in early stage AD, an increased duration of the oral and pharyngeal components of swallowing have been observed.[30]

Balancing Energy Intake and Expenditure

Although inadequate oral intake is likely the primary cause of weight loss in moderate-to-severe AD, increased energy expenditure could contribute to a mismatch between energy intake and energy expenditure that leads to weight loss. While it has been suggested that resting metabolic rate may be elevated in AD, several studies now confirm that there is no evidence to support this.[31,32] The idea that physical activity in the form of behavioral disturbances (e.g., pacing) may contribute to increased energy expenditure has not been supported either.[33] To date, there are no data on AD patients during the dynamic phase of weight loss. It is evident from our work, and that of others, that not all AD patients are losing weight all of the time.[8,34] There can be periods of acute weight loss, a slow gradual weight loss, and variations in weight, which may include periods of substantial weight gain.

It is possible that relatively subtle and, perhaps intermittent, changes in factors, such as a behavioral disturbance that influences both energy intake and energy expenditure, may tip the balance toward weight loss for patients with AD. This imbalance may be multifactorial and intermittent. Rather than one particular cause or abnormality leading to weight loss, AD may lead to a condition in which changes in energy intake and expenditure are not easily compensated. Preliminary data from institutionalized subjects with AD show that Body Mass Index (BMI)** is inversely correlated with a measure of behavioral symptoms, which indicates that lower BMI was associated with higher frequency and severity of behavioral problems.[35]

In summary, both primary and secondary factors may contribute to weight loss in advanced AD.[36] Primary factors, such as those discussed thus far, are attributable to the pathophysiology of Alzheimer's disease and may or may not be amenable to intervention. Secondary factors are not attributable to the pathophysiology of AD, but are commonly encountered conditions that may contribute to weight loss and are perhaps more amenable to intervention (see Figure 1).

Evaluating Weight Loss and Malnutrition

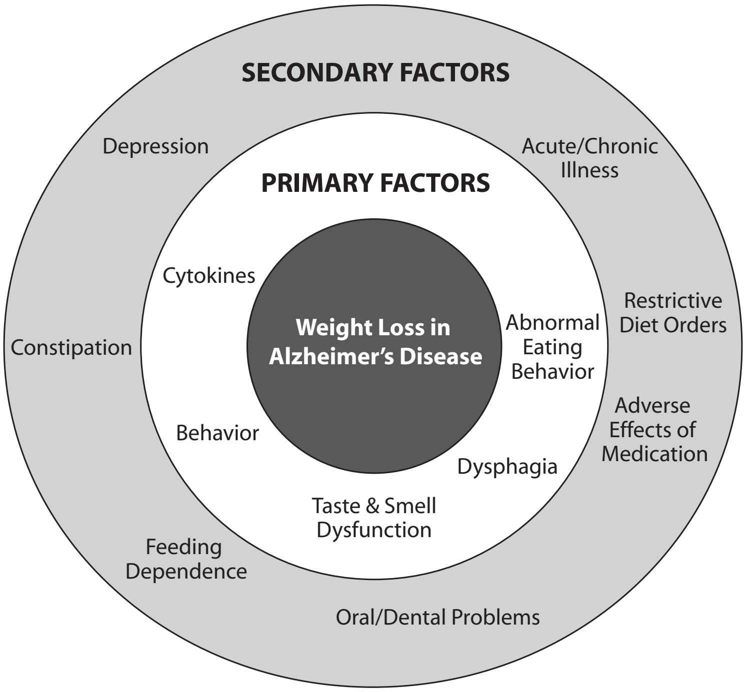
When to Evaluate

Periodic weight measurements are a primary resource for monitoring nutritional status and recognizing change. Most residents of nursing facilities are weighed monthly unless their condition would warrant weekly monitoring. According to parameters set for the Minimum Data Set, weight loss of 5% in one month or 10% in three months is considered of clinical importance and should entail further evaluation. Older adults with a BMI less than or equal to 21 are likely to be malnourished.[37] Conditions such as pressure ulcers that increase nutritional requirements should also prompt evaluation.

Other Illness

Common infections, such as pneumonia or urinary tract infections, will often produce anorexia. Cancer, thyroid dysfunction and other common causes of weight loss are part of the differential diagnosis. Constipation is a common condition in institutionalized individuals because of decreased fluid intake, decreased physical activity, and medication that promotes this condition. Chronic constipation can have a profound impact on appetite, yet be difficult to identify in patients with cognitive impairment. Chronic pain may also be difficult to identify, but

Figure 1.
Weight Loss in Alzheimer's Disease



Primary factors of weight loss are related to the pathophysiology of AD. Secondary factors are common occurrences that may be more amenable to interventions that promote nutritional well-being.

** BMI, weight in kilograms divided by height in meters squared, is a helpful measurement of nutritional status.

can cause anorexia. Depression is another common treatable cause of weight loss in older adults. Each patient should be specifically evaluated for depression and aggressively treated when it is suspected to be present. Depression is also common occurrence in early dementia, but may also be present in more advanced disease.

Medications

Medications should be reviewed. Commonly used drugs can cause many symptoms that potentially limit caloric intake (see Table 1). Acetylcholinesterase inhibitors, which are the primary treatment for the cognitive symptoms of AD, have several potential adverse effects including nausea, vomiting, and anorexia that may contribute to weight loss.[38,39] Additionally, galatamine, an acetylcholinesterase inhibitor, has been associated with an increased incidence of weight loss.[40] Patients with dementia may not be able to voice symptoms attributable to these drugs.

Table 1.
Medications and Induced Symptoms

Medication Type	→	Medication Induced Symptom
NSAIDs, alcohol, nicotine, cholinesterace inhibitors		Anorexia
Toxic levels of drugs (e.g., digoxin, theophylline), antibiotics, NSAIDs		Nausea
Anticholinergics, HIV drugs, antibiotics		Taste and smell dysfunction
Sedatives, opioids		Inattention
Antipsychotics		Movement disorders
Anticholinergics		Dry mouth
Bisphosphonates		Esophagitis
Phenothiazines, haloperidol		Dysphagia[62]
SSRI, antibiotics, laxatives		Diarrhea
Antipsychotics, atypical antipsychotics		Increased appetite

Physical Examination

A thorough physical examination is an important part of the assessment of weight loss and malnutrition. The mouth is a particularly important part of the examination that should not be overlooked. Dental abnormalities such as ill fitting dentures, tooth decay, and abscess formation may contribute to weight loss. Dry mouth and antibiotic use can lead to thrush, a yeast infection that can cause discomfort and unwillingness to eat.

Table 2.
Risk Factors for Aspiration Pneumonia

Risk Factors
Dysphagia
Feeding dependence
Oral Care dependence
Number of decayed teeth
Tube feeding
Multiple medical diagnoses
Number of medications

Dysphagia

Patients with advanced dementia often develop serious difficulties swallowing. They may resist food being placed in the mouth, fail to manage the food bolus once it is in the mouth, or aspirate when swallowing. Caregivers should be encouraged to report changes in eating behavior and signs of dysphagia. Coughing and choking during eating are common signs of aspiration. So called "silent aspiration" occurs when patients with advanced dementia suffer the consequences of aspiration without any identifiable signs. A swallowing evaluation by a speech therapist that includes visualization of the swallow either in a barium study or by fiberoptic techniques can be helpful in determining the presence and severity of swallowing dysfunction. Although this evaluation can be helpful, many patients experience the sequelae of aspiration, but do not demonstrate aspiration on such testing. On the other hand, many patients who clearly aspirate on testing do not seem to suffer obvious consequences of aspiration, such as weight loss or aspiration pneumonia. Risk factors that predispose patients with advanced dementia to aspiration pneumonia are listed in Table 2.[41]

Interventions for Weight Loss in AD

For the most part, getting patients with dementia to eat is a process of trial and error. It is important to make sure that food is available not just at mealtimes, but whenever the patient is inclined to eat. Many patients need supervision, constant reminders, and simple directions to complete a meal. Providing finger foods can be helpful for patients who are challenged by the use of utensils.[42] Appetite and alertness may be better early in the day so breakfast and lunch become more substantial meals. Providing preferred foods can also increase intake.[43] Simplifying the environment so that there are fewer distractions during mealtime may be helpful as well.

Researchers have demonstrated that improving the ambiance during mealtime in a nursing facility by manipulating social and environmental aspects improves food consumption and nutritional status.[44] Studies that have implemented soothing dinner music for dementia patients demonstrate that this intervention can improve mealtime agitation and food intake.[45,46] Taken together, these studies—although few in number and scope of intervention—suggest that a nutritional intervention that seeks to enhance the hedonic reward during mealtime may significantly benefit AD patients who are at risk for nutritional decline.

Feeding a patient, who can no longer feed himself/herself, can be very time consuming, and some patients may respond better to a particular caregiver. Techniques that are particularly effective in feeding a patient should be shared and mimicked by other caregivers. Research indicates that the quality of the relationship between the person being fed and the feeder is an important predictor of food intake.[47] Even severely demented patients respond best to caregivers who are personal, interested, involved, flexible, calm, cooperative, and more willing not to seek control in the relationship.

Maximize Taste and Smell

Dietary restrictions, such as low sodium and low cholesterol, that limit aroma, flavor, and calories should be avoided. Flavor enhancement has been shown to increase food intake and maintain weight in nursing home residents.[48] Facilities and caregivers should take advantage of aromatous foods, which stimulate the physiologic responses that prepare an individual for food intake and stimulate appetite. In addition to mealtimes, activities such as baking bread or popping popcorn can stimulate appetite and provide needed calories.

Nutrition Supplements

Oral liquid supplements should be given between meals to boost calorie consumption.[49] Liquid supplements should not replace food intake, as it could result in decreased calorie consumption.[50]

A routine vitamin/mineral supplement should be considered for all patients with moderate to advanced AD, because inadequacies in micronutrient intake are common among eating-dependent nursing home residents.[51] Like all older adults, most patients with AD will require calcium and vitamin D supplementation. Several studies indicate that even subtle deficits in nutritional status can impact cognitive performance in non-demented older adults.[52-54] Even if nutritional supplementation does not improve cognitive symptoms, nutritional interventions may help to maintain the muscle and bone mass necessary for continued independent physical function and, in more disabled patients, prevent challenging complications, such as pressure ulcers.

Appetite Stimulants

Orexigenic agents (appetite stimulants) are often considered in the treatment of end-stage dementia with nutritional decline. None have been studied for their effectiveness in patients with advanced Alzheimer's disease. Megestrol acetate (a hormone therapy often used to treat certain cancers and other diseases with anorexia cachexia) may be a reasonable choice due to limited data with nursing home patients, but may take several months to have an effect on appetite and weight status.[55,56] Studies of megestrol acetate in patients with cancer and AIDS have only found an increase in fat mass, but no significant increase in lean body mass. No survival advantage has been demonstrated. Side effects include adrenal suppression, fluid retention, deep vein thrombosis, confusion, and impotence. Other agents that have been used to stimulate appetite, but for which there are little or no data regarding their use in advanced dementia include cyproheptadine, dronabinol, testosterone, growth hormone, oxandrolone, and steroids.

When considering the use of an orexigenic agent the origin and causes of the weight loss and the goals of care need to be carefully defined. If dysphagia is the primary issue hindering caloric intake then appetite stimulation may only serve to make the patients condition more uncomfortable. However, if agitation and distractibility are hindering intake, a greater sense of appetite may help the patient to focus attention on eating. The goals of care are also important to consider when making this decision since the benefits of appetite stimulants may be even fewer in advanced dementia than in other disease processes.

Antidepressants

In the situation of otherwise unexplained weight loss, even when symptoms of depression have not been clearly identified, a trial of an anitdepressant may be reasonable. Although tricyclic antidepressants frequently result in weight gain for younger patients who consider this an unpleasant side effect, they may not produce this same effect in frail institutionalized patients. Side effects that include constipation, dry mouth, orthostatic hypotension, and urinary retention make these agents less desirable with the advent of selective seratonin reuptake inhibitors (SSRIs, e.g., sertraline, citalopram). Initial concern that SSRIs may produce weight loss in older adults has not been substantiated.[57] Mirtazapine, a multi-receptor agonist, has been associated with increased appetite and weight gain in younger patients in comparison to SSRIs. However, effectiveness of this agent in producing significant weight gain in frail older adults or patients with dementia is unknown.

Minimizing Aspiration Risk

Altering food and liquid consistency can minimize the risk of aspiration. Semi-solid consistencies are generally tolerated better than liquids. Potentially helpful techniques to minimize the risk of aspiration are upright positioning of the patient during meals and for 30 minutes after meals, tucking the chin during swallowing, swallowing multiple times with each bolus, and keeping the bolus less than one teaspoon. A speech therapist should participate in developing the treatment plan and provide staff education for implementation.

Good oral hygiene reduces the bacterial load in the mouth that can be aspirated and may decrease the risk of pneumonia. A growing number of studies indicate that angiotensive converting enzyme inhibitors may elevate substance P levels and, in so doing, stimulate cough and improve oral sensation, thus decreasing the risk of aspiration and pneumonia.[58]

Feeding Tubes

Even with diligent care, weight loss may continue, and malnutrition may ensue. Both physicians and patients' surrogate decision-makers tend to have high expectations for feeding tube placement to improve nutrition, functional status, and quality of life.[59] These high expectations for improved nutritional and health status are not supported by current research. There have been no randomized clinical trials comparing tube feeding with oral feeding in the severely demented. A review of existing literature by Finucane and colleagues found no evidence to support that tube feeding prevents aspiration pneumonia.[60] In fact, tube feeding does nothing to prevent the aspiration of oral secretions nor can it prevent aspiration from regurgitated gastric contents. Furthermore, Finucane found no evidence to support that tube feeding prevents other infections, the consequences of malnutrition, or pressure ulcers. There was no evidence to support a survival benefit, improved functional status, or greater patient comfort. Adverse events associated with feeding tubes includes aspiration pneumonia, tube occlusion, leakage, and local infection. Although the mortality during percutaneous endoscopic gastrostomy tube placement is low (0-2%), perioperative mortality ranges from 6-24%.

In circumstances where careful hand feeding has not provided adequate nutrition and has resulted in pneumonia or other complications of malnutrition, the possibility of providing food and liquid as tolerated, but allowing a natural death to occur should be considered. For the patient with severe dementia, the decision of whether or not to institute a feeding tube ultimately lies with the patient's family or guardian. However, families and physicians are often aided by advance directives that allow patients with dementia to convey their wishes regarding this issue either before or during the early stages of disease. It is important for healthcare providers to initiate conversation with the patient regarding care at the end of life when cognitive abilities will still allow a meaningful discussion. In most cases, given the current evidence, the decision for careful hand feeding without the use of a feeding tube is very appropriate. Federal regulations should not be seen as a barrier to this course of action as long as the eating problems are properly identified and assessed and reasonable efforts to hand feed are being made.[61] Careful documentation by the physician and other care providers should indicate that nutritional decline is not preventable because of the patient's advanced dementia diagnosis.

Summary Recommendations

A physician should evaluate the patient with advanced AD who is losing weight, has a low BMI, or unmet nutritional needs (e.g., pressure ulcers). A thorough medical history and physical examination should be done. The physician, nutritionist, speech therapist, nurse, direct care worker, and family should contribute to the process of evaluation and the implementation of the nutrition care plan. All of these individuals must work together to ensure that weight loss and malnutrition are recognized, evaluated, and treated. The effectiveness of each intervention must be evaluated. Maintaining nutritional health will not always be possible. All involved should understand the goals of care, which may range from expected improvement in nutritional status to supportive and palliative care in the face of an advanced and terminal condition. The goals of care are likely to evolve as assessments are made and as interventions are evaluated. The nursing home medical director and primary care physicians of individual patients must provide leadership in this process, especially when alternatives to oral feeding are considered. **NCMedJ**

COMMENTARY

Use of Feeding Tubes in the Care of Long-Term Care Residents

Timothy S. Carey, MD, MPH

One of the most difficult decisions faced by a family caring for a disabled elder is whether or not to place a gastric feeding tube. Recent high-profile media coverage of the Terry Schiavo case has brought this issue into the public arena. Prior to the early 1990s, placement of a feeding tube for direct delivery of nutrition into the stomach, or "enteral feeding," was a surgical procedure requiring general anesthesia and the operating room. During the 1990s, the procedure became simplified, using percutaneous techniques either performed in the endoscopy suite or by interventional radiology. These procedures could be performed using conscious sedation and local anesthesia. Feeding could be initiated within 24 hours. The ease of the procedure was greater, and the immediate complication rate was reduced. Patients who were too ill for the procedure now received enteral feeding. Previously, enteral feeding was often performed through long-term naso-gastric tubes. These tubes frequently clogged or fell out, and were associated with significant patient discomfort. Coincident with the greater ease of gastrostomy tube insertion, the number of tube insertions rose dramatically, almost doubling during the 1990s even after adjustment for the increasing age of the population. Use of feeding tubes was even greater in the southeast, and this rise has continued as increasing numbers of tubes are being placed on an outpatient basis.[1]

Indications for Feeding Tube Placement

Feeding tubes may be placed for a variety of reasons. Some are for acutely ill patients who are in an intensive care unit and are unable to take food by mouth, but who may otherwise have a reasonably good prognosis. This may be the case after trauma or a severe medical illness such as pancreatitis. Gastric feeding tubes are commonly used in head and neck malignancy patients as a 'bridge' around the time of surgery and radiation therapy. More controversial indications include placement of feeding tubes after a cerebrovascular accident (stroke). If the patient otherwise has a fairly good prognosis in terms of level of consciousness and residual functional status, many tubes inserted after strokes can be removed in the year following the event.[2] The most problematic situation in which feeding tubes are used is for elderly adults with neurodegenerative diseases, including cognitive impairment due to Alzheimer's disease and multi-infarct dementia. Unfortunately, these diseases are progressive, and the feeding tube is not part of a rehabilitation plan. There is extreme variability in the use of feeding tubes for this indication around the country. For unclear reasons, the use of feeding tubes is particularly common in the southeastern United States. According to data from the Medicare nursing home Minimum Data Set (MDS), North Carolina ranks sixth in the proportion of severely cognitively impaired elders in long-term care who receive gastric feeding tubes. In North Carolina, 40% of patients with cognitive impairment have feeding tubes, in Alabama the percentage is 47%, but in Maine, only 9%.[3]

> *"Given the substantial uncertainties regarding the benefits of gastric tube feeding, discussions with families should include assisted feeding as an option, as long as all concerned recognize that ongoing weight loss may continue to occur."*

Timothy S. Carey, MD, MPH, is Kenan Professor of Medicine and Director of the Cecil G Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill. He can be reached at tim_carey@unc.edu or at CB 7590, Chapel Hill, NC 27599-7590. Telephone: 919-966-7100.

Risks and Benefits

When wide variation occurs in the utilization of a diagnostic or therapeutic treatment, it's generally due to uncertainty regarding therapeutic benefit, variations in the supply of providers and technology, and varying preferences for treatment.[4] In the case of feeding tubes, providers are often uncertain regarding benefit, and families have variable preferences regarding the pros and cons of this treatment. Yet, over the past decade, moderate amounts of data have been collected and published regarding the utility of gastric feeding tubes in frail elderly with cognitive impairment. Rationales for insertion of these tubes include the prevention of aspiration pneumonia, prolongation of life, or improvement in quality of life. Unfortunately, the benefits of feeding tubes to prevent such complications appear to be quite limited. Alzheimer's disease and related dementing illnesses are conditions that affect the entire brain and the entire body, not just swallowing functions. Patients with gastric feeding tubes continue to have episodes of aspiration pneumonia after insertion.[5] The pneumonia is likely due to aspiration of saliva into the lungs when the patient is asleep, as well as possible aspiration of the very thin liquid that is placed in the stomach through the feeding tube. In addition, healing of decubitus ulcers (bedsores) and improvement in nutritional parameters, such as blood albumin levels, appears to occur for only a minority of patients who receive feeding tubes.[6] Overall, these frail patients have a mortality rate between 30 and 50% over six months, with some studies reporting even worse survival.[7] Some authors recommend that gastric feeding tubes be considered extraordinary treatment since the benefits are limited at best in demented patients.[8] Certainly, families should have a detailed and shared decision-making discussion regarding the very limited benefits of this technology, as well as its significant risks.

The risks of feeding tubes include some risks associated with tube insertion. While the risk of perforation of a structure such as the colon is rare, such complications are potentially catastrophic. Feeding tube removal in the days following insertion can also be extremely risky as peritonitis can result. When a feeding tube falls out or is pulled out (as by a confused patient) in the days following insertion, the patient needs to be emergently transported to the hospital for assessment for peritonitis and re-establishment of the feeding tube using a technique similar to the original endoscopy or a radiologic procedure. Patients may sometimes require arm restraints so that they do not manipulate the gastric feeding tube. These restraints lead to decreased quality of life. Finally, many of the other commentaries in this issue address the social significance of food in our society. When a feeding tube is inserted and oral feeding is ceased, the sensory experience of eating is denied. The social interaction that is so much a part of meals is also absent. While some facilities use tube feeding as a supplement to oral feeding rather than as a replacement, many place patients on a "nothing-by-mouth" status.

Shared Decision-Making and Alternatives to Tube Feeding

Assisted feeding to an amount as much as the elder is able to take is certainly an acceptable alternative to placement of a gastric feeding tube for patients who have some remaining ability to swallow. Given the substantial uncertainties regarding the benefits of gastric tube feeding, discussions with families should include assisted feeding as an option, as long as all concerned recognize that ongoing weight loss may continue to occur.

What are the drivers that have led to the common use of a procedure with such limited evidence of benefit? Assisted feeding takes significant amounts of staff time, much of it one-on-one with the patient. Personnel must be trained, attention to set-up of utensils and foods must be performed, and diets may need to be individualized. Although advantageous to the patient, these interventions are costly to facilities. In contrast, once a feeding tube is inserted, the time involved for a staff member to hang a bag of high calorie liquid takes only a few minutes. Reimbursement to the facility may be increased due to the apparent technical nature of the activity. Labor costs are therefore decreased, reimbursement increased, and the care providers may have the somewhat false illusion that "everything is being done." These cost and reimbursement issues may represent a perverse incentive, leading to increased feeding tube use.[9] Medicare's use of 10% weight loss as a nursing facility quality indicator is laudable, but is not intended to mandate use of tube feedings for patients with end-stage dementia. A palliative approach for such patients, appropriately documented, is certainly acceptable.

Policy interventions to assist families and providers in this extraordinarily difficult clinical situation should include financial incentives to facilities for provision of assisted feeding programs; development of shared-decision making modules for use by patients and providers as they grapple with these difficult decisions; and frank discussions of the limits of technology in its ability to preserve life or improve functional status for this important and frail population. **NCMedJ**

Why not hire Medical Billing experts?

It is easy to say something is wrong! It is quite another story to know and understand what's wrong. With changing regulations and requirements, processing insurance claims for your patients demands that you know the reason for denied claims and be ready ***immediately*** to challenge each one that comes back to you with a denial.

Unfortunately many practices ignore unpaid claims. We call this the Mercedes drawer. In reality, these claims, although time consuming, should get top priority.

CAYMM is committed to your Mercedes drawer. Established in 1993, CAYMM is an innovation Medical Billing Practice Management and Consulting Company as well as a Value Added Reseller for NDC MediSoft offering medical billing, practice solutions, support and training.

CAYMM's Quality, Service, and Performance are Unsurpassed!

The North Carolina Institute of Medicine

Since January 2002, Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

Patient Flow between Hospitals and Nursing Homes in North Carolina in 2003

The North Carolina Hospital Discharge Data Base consists of more than one million records each year for inpatients discharged from North Carolina hospitals. These records contain information on the source of admission and the discharge status for each patient. This information allows us to describe the volume and characteristics of hospital patients who are transferred directly from and to nursing homes.

During calendar year 2003, there were 1,037,913 inpatient discharges from North Carolina hospitals. Forty-two percent of these hospital patients had their admission source listed as "referral" and 38% had "emergency room" listed. Only 1,411 or 0.1% were identified as being transferred to the hospital directly from a nursing home (skilled nursing facility). Of these 1,411 patients, diseases of the respiratory and circulatory system were the most common principal diagnoses (25% and 18%, respectively), 80% were age 65 and older, 64% were females, and Medicare was the most common expected source of payment (89%).

Seventy-seven percent of all hospital patients in 2003 were discharged to home/self care (routine discharge). Seven percent were discharged to their home under the care of an organized home health services agency. About 7% were transferred to nursing homes: 6.4% or 66,307 to a skilled nursing facility and 0.5% or 4,753 to an intermediate care facility. Another 855 were transferred to "long-term care" and 299 were transferred to a "Medicaid-approved nursing facility."

The following table compares 2003 hospital patients with a routine discharge to those transferred to skilled and intermediate care nursing facilities, by selected patient characteristics.

Percent	**Routine Discharge**	**Discharged to Skilled Nursing Facility**	**Discharged to Intermediate Care Facility**
Age			
Under age 65	75.5	13.9	23.3
65-74	12.0	18.8	14.8
75-84	9.5	37.8	31.8
85+	3.0	29.5	30.1

North Carolina Institute of Medicine
Vice President

The North Carolina Institute of Medicine (NC IOM) with The Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill announces that the position of Vice President of the NC Institute of Medicine is available, on a part-time basis at 50% effort. The Vice President will assist the President of the NC IOM in the administration and oversight of the Institute. The position requires an ability to work with state policy makers, healthcare professionals and trade associations, business and community leaders, and advocacy organizations to involve them in the policy development process, as well as their support in the implementation of key recommendations on health and healthcare issues. Persons seeking this position should have an understanding of health and healthcare issues, extensive experience facilitating diverse groups, public speaking and writing ability, knowledge of the policy analysis process, and fundraising skills. It is desirable that the applicant has quantitative analytical skills necessary to conduct and present results from health policy analyses.

The applicant must have the following skill set:

1) Public policy analysis, including the ability to identify and evaluate different policy options.
2) Excellent public speaking ability, including the ability to convey complex health issues and policy options to large and diverse audiences.
3) Facilitation skills, leading large task force meetings with varied stakeholder groups including legislators, county commissioners, state and local agency staff, providers, business and community leaders, faith community, and consumers.
4) Excellent writing skills, including the ability to translate complex health policy, clinical and/or scientific concepts into information to be presented to policy makers, providers, and/or the general public.
5) Fundraising abilities.

An advanced degree (doctorate, medical, or equivalent) plus 5+ years experience in a health policy setting or equivalent experience is preferred. Salary for this position is commensurate with professional credentials and experience. The position is part-time, with the amount of time negotiable with the Board of Directors based on the nature of other commitments, but is assumed to be in range of 50 percent. The position may evolve into a full-time position in the future.

All staff of the NC IOM are employed by and through the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill. The position is at the North Carolina Institute of Medicine, located at the Woodcroft Professional Center in Durham, NC. The North Carolina Institute of Medicine, in collaboration with the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill, is an Equal Opportunity Employer.

Salary range is $35,000 - $65,000 (part-time), depending on experience and qualifications.

Coming in the September/ October 2005 issue of the North Carolina Medical Journal

a look at Preventing Child Abuse in NC

Caregivers Don't Need To Do This Alone!

- Significant increase in the number of persons providing care to a friend or family member age 60 or older from 2000 to 2003
- Over 25% of adult North Carolinians now provide care to an older friend or relative
- Almost half of those receiving care are reported to have memory loss or dementia

Many people need the support of others who are in similar situations or perhaps the support of a professional. They may need education on caregiving issues. Caregivers may need respite or a "time-out" from their caregiving duties. Seeking information on what services are available and assistance to help connect with these services can be an important first step.

Thinking about EHR?

The Carolinas Center for Medical Excellence Offers Free EHR Consulting!

Electronic health records (EHRs) can transform your practice. But success takes time, planning and strategy. CCME can help.

Doctor's Office Quality – Information Technology (DOQ-IT):
- Assists your practices with the transition to an EHR.
- Includes FREE consultation and on-site readiness assessment.
- Is web-based with over 30 convenient tools and resources for your practice.

You can sign up to participate today if you are a:
- North Carolina primary care practice serving a Medicare population.
- Practice that is seeking knowledge and guidance with practice assessment, planning, selection and implementation of an EHR.
- Practice that is interested in moving to an EHR within the next 18 months.

We'll help you every step of the way:
- We'll assist with the evaluation of your current systems and processes.
- We'll provide guidance with your EHR vendor selection and implementation.
- We'll offer direction using the EHR to improve your clinical outcomes.
- And, we'll provide access to tools, resources and individualized assistance to help your practices prepare for, select, implement and use an EHR.

Space is limited, apply today!

Our Healthy Lifestyle Choices initiative pays doctors to assess and treat obesity

We heard you.

And we're doing something about it.

Blue Cross and Blue Shield of North Carolina asked doctors across the state: How can we support you on the front lines in a battle against our epidemic of obesity?

Doctors in North Carolina told us they want to address excessive weight and obesity with their patients. But you also told us there simply isn't enough time to squeeze one more health condition into an office visit.

We heard you. Blue Cross and Blue Shield of North Carolina is now paying doctors to assess a members' weight and provide treatment if necessary. We will cover up to four visits a year for this purpose for members in participating plans.

It's part of our new obesity initiative called Healthy Lifestyle Choices.

Obesity shortens lives and increases health care costs. The first step toward a healthier, more active life can start in the doctor's office – where we are encouraging a hard look at how excess weight can impact people's health.

Healthy Lifestyle Choices is a broad program that extends from online support for members trying to maintain a healthy weight or lose a few pounds – to coverage of doctor visits and prescription weight-loss drugs when medically necessary – to establishing Bariatric Surgery Centers of Excellence to identify providers of superior results in obesity surgery.

For more information about the Healthy Lifestyle Choices program or to request educational materials for your patients, email your request to ***quality@bcbsnc.com***.

For more than 70 years, our members and doctors have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's stable, reliable and largest health insurer. Learn more at ***bcbsnc.com***

Attainment of Goals from National Guidelines among Persons with Type 2 Diabetes:

A Cohort Study in an Academic Family Medicine Setting

Julienne K. Kirk, PharmD, Kenneth R. Huber, MS, and C. Randall Clinch, DO, MS

Abstract

Background: *Cardiovascular disease is the leading cause of mortality in patients with diabetes, but goals for reduction of modifiable cardiovascular risk factors are difficult to achieve in primary care. We evaluated the change in risk factor control for a cohort of patients with diabetes and hyperlipidemia over a four-year period, as well as the change in proportion of patients meeting clinical practice guideline goals.*

Methods: *Medical records were reviewed from a cohort of 86 randomly selected persons with type 2 diabetes in an academic family medicine setting. Data were abstracted to assess the attainment of and change in five treatment goals related to glycemic, blood pressure, and lipid control from 1999-2003. Descriptive statistics were applied to demographic variables. Mean differences in outcomes were assessed with the paired t-test. The McNemar test was used to assess non-parametric variables, and the Wilcoxon signed ranks test was applied to differences achieved in mean goal scores for outcome variables.*

Results: *The mean numbers of treatment goals attained were 2.76 (SD = 0.92) in 1999 and 2.48 (SD = 1.1) in 2003. Significant improvements were noted in the mean values of HbA1c (0.4% decrease, $p = 0.03$), diastolic blood pressure (4.3mmHg decrease, $p < 0.001$), low-density lipoprotein cholesterol (LDL-C; 10.6 mg/dL decrease, $p < 0.01$), and high-density lipoprotein cholesterol (HDL-C; 8.3 mg/dL increase, $p < 0.001$) over the four-year study interval. No significant differences were noted in the percent at goal during the study for HDL-C or for HbA1c. A significant decrease was found in the percent at goal from 1999-2003 for LDL-C (from 79% to 40%, respectively). The decrease in the percent LDL-C at goal was explained by the more stringent practice guideline goals introduced in 2001 for diabetes (i.e., LDL-C < 100 mg/dL).*

Conclusion: *Despite significant improvement in mean values of modifiable risk factors, the percent of patients meeting 2003 guideline goals for HbA1c, systolic blood pressure, and LDL cholesterol did not improve. These findings suggest that patient-level improvements may not be adequate indicators of a practice's achievement of guideline recommendations. Percent attainment of guideline goals may be a useful performance measure of practice-level quality improvement initiatives.*

Key words: *Type 2 diabetes, blood pressure, HbA1c, hyperlipidemia, dyslipidemia, National Cholesterol Education Program (NCEP) Adult Treatment Panel guidelines, LDL cholesterol, body mass index, American Diabetes Association (ADA) Standards of Care, Primary Care*

Introduction

Diabetes has been diagnosed in approximately 13 million people in the United States, with an additional estimated 5.2 million cases remaining undiagnosed.[1] Cardiovascular disease (CVD) is responsible for approximately 65% of diabetes-related deaths, with a two- to four-fold higher CVD death rate noted among adults with diabetes versus those without diabetes.[1] As such, the prevention of CVD is a primary goal in the management of patients with diabetes.

The American Diabetes Association (ADA) has put forth guidelines annually for several of the modifiable risk factors of CVD, including control of glycemia, blood pressure, and blood lipid concentrations.[2] The National Heart, Lung, and Blood Institute (NHLBI) has established widely used clinical guidelines for the screening and treatment of blood lipids [National

Julienne K. Kirk, PharmD, CDE, BCPS, is Associate Professor in the Department of Family and Community Medicine, Wake Forest University School of Medicine. She can be reached at jkirk@wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157. Telephone: 336-716-9043.

Kenneth R. Huber, MS, is a medical student at Wake Forest University School of Medicine.

C. Randall Clinch, DO, MS, is an Assistant Professor in the Department of Family and Community Medicine.

Cholesterol Education Program (NCEP) Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults].[3,4] Consensus recommendations for blood pressure control have been established by the Joint National Committee (JNC) on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure.[5,6]

Many individuals with diabetes receive treatment in a primary care setting, and published literature indicates goals targeting CVD risk reduction among persons with type 2 diabetes are not being optimized.[7-9] The intent of the current study builds upon a previously published cross-sectional analysis,[7] which described the frequency with which ADA (hemoglobin A1c or HbA1c), NCEP (cholesterol), and JNC (blood pressure) goals were met in a family practice setting for persons with type 2 diabetes. Kirk et al,[7] revealed that overall blood pressure, low density lipoprotein cholesterol (LDL-C), and HbA1c values did not reach the goals for the guidelines in effect in 1999.[3,5,10] Evidence further demonstrating the benefits of achieving and maintaining blood pressure, LDL-C, and glycemic control has accrued since this initial publication.[11-15] Changes in the guidelines related to the control of blood lipids and blood pressure since our first study have led to recommendations for tighter control of these parameters (see Table 1).[2,4,6] The purpose of the current study was to conduct a follow-up analysis on the cohort of persons with diabetes from our previous study, focusing on the attainment of CVD-related guideline parameters (i.e., HbA1c, LDL-C, HDL-C, and blood pressure).

Table 1.
Guidelines for Persons with Diabetes

	Year	
Parmeter	**1999**	**2003**
HbA1c[*]	< 7%	< 7%
Systolic blood pressure[†]	< 130	< 130
Diastolic blood pressure[†]	< 85	< 80

[‡] Based on the National Cholesterol Education Program (NCEP) Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol

[§] LDL-C goals based on risk stratification per NCEP Adult Treatment Panel (ATP) II[3]

Methods

A cross-sectional analysis evaluating CVD risk factors and pharmacotherapy in a randomly selected sample of 124 persons with type 2 diabetes and hyperlipidemia was previously performed.[7] Data were obtained from an academic family medicine clinic in the southeast. Approximately 56,000 patient visits to this clinic are conducted annually, and the mix of insurance coverage includes Medicare (22%), Medicaid (12%), managed care (61%), and self-pay (5%). There are 30 medical residents in training along with three fellows, 15 faculty physicians, three physician assistants, two registered nutritionists, and one pharmacist diabetes educator. Resident physicians, physician assistants, and faculty physicians care for patients seen in this practice.

The methods of this prior study are reported elsewhere.[7] Briefly, medical records were randomly selected using ICD-9 codes for type 2 diabetes and hyperlipidemia. Demographic variables (i.e., patient age, gender, and race) as well as height, weight, personal and family coronary heart disease history, tobacco use, total cholesterol, LDL-C, HDL-C, triglycerides, HbA1c, and systolic and diastolic blood pressure values were abstracted from a structured review of the medical record. The study protocol was approved by the Institutional Review Board. For the current study, follow-up data were available on 86 patients. Seven of the original 124 patients were excluded because they were involved in a clinical trial where management of blood pressure, lipids, or HbA1c was dictated by a study protocol, and 31 of the original patients were lost to follow-up (i.e., patient changed healthcare provider or died).

Descriptive statistics were performed to compute means, standard deviations, frequencies, and percentages for the demographic variables and for the lipid, blood pressure, body mass index, and HbA1c variables. Simple means were calculated for the lipid, blood pressure, and HbA1c variables. Chart data were eligible for abstraction if an office visit was associated with the collection of laboratory data. No patient had more than four eligible office visits for either year studied; missing values were excluded from the analysis. The mean values for the lipid, blood pressure, and HbA1c values were then combined with the appropriate demographic variables to determine if a patient was meeting the goals recommended by the ADA or the NHLBI. The paired samples t-test was used to assess for a difference at the level of the patient in the means of the LDL-C, HDL-C, body mass index, HbA1c, and systolic and diastolic blood pressure values between the two study periods of 1999 and 2003 (two-sided alpha = 0.05). The non-parametric McNemar test was used to assess for a significant difference in the number of patients at the identified goal for LDL-C, HDL-C, HbA1c, and systolic and diastolic blood pressure values between 1999 and 2003 (alpha = 0.05). A "goal score" was computed for each year, 1999 and 2003, with a value of "5" representing a person who attained the recommended goal for each of the five variables under study (i.e., for LDL-C, HDL-C, HbA1c, and systolic and diastolic blood pressure) for that year; a value of "0" represented a patient who met none of the goals for the five variables under study for that year. A histogram was created to depict the distribution of the goal scores for the years 1999 and 2003. The Wilcoxon signed ranks test was used to test for a difference between the mean "goal scores" as well as between the five individual variables from 1999 and 2003 (two-sided alpha = 0.05). All statistical analyses were carried out using SPSS (Version 12.0).

Results

The mean age of our sample was 59.6 years (SD 12.6 years); 53.7% were women. Approximately 54% were African American, and 47% were white. Analyses of those patients from the baseline study lost to follow-up revealed no significant differences from those included in the current study, with the exception of higher mean total cholesterol and triglyceride measures (225 mg/dL versus 207 mg/dL, p = 0.03; 357 mg/dL versus 217 mg/dL, p = 0.03, respectively).

There was an overall low percentage of missing data in the current study. The systolic and diastolic blood pressure variables had no missing data; the HbA1c and HDL-C variables had 1.2% missing data; and the LDL-C variables had 5.8% missing data. Missing data were excluded from analyses.

At the patient level, significant differences were noted at the 2003 follow-up for HbA1c (a 0.4% decrease; p = 0.03), diastolic blood pressure (a 4.3 mmHg decrease; p < 0.001), LDL-C (a 10.6 mg/dL decrease; p < 0.01), and HDL-C (an 8.3 mg/dL increase; p < 0.001). There was a trend toward a significant decrease in systolic blood pressure (a 3.5 mmHg decrease; p = 0.09) (see Table 2). No difference was detected in the body mass index (p = 0.89).

The number and percent of persons with diabetes "at goal" for HbA1c, systolic blood pressure, diastolic blood pressure, LDL-C, and HDL-C are listed in Table 3. While mean LDL-C improved by 10.6mg/dL between 1999 and 2003, the percentage of patients at goal for LDL-C significantly worsened (from 79.1% at goal in 1999 to 39.5% at goal in 2003; p < 0.001). No significant differences were found among the other four variables, though there was a trend toward a significant improvement in the percent at goal for HDL-C (p = 0.09).

Overall, mean goal scores were lower in 2003 than 1999 (p = 0.035). The mean number of goals met in 1999 was 2.8 with a standard deviation (SD) of 0.92; only two patients met all five goals, while nine patients met only one goal (see Figure 1). In 2003, the mean number of goals met was 2.48 (SD 1.1). Similarly, only two patients met all five goals; however, three patients did not meet any of the goals that year. When considering the five individual quality indicator variables of HbA1c, systolic blood pressure, diastolic blood pressure, LDL-C, and HDL-C, the only significant difference noted in goal scores was a decrease in the LDL-C score (p < 0.001) from 1999-2003.

The 1999 NCEP ATP II LDL-C goals were then applied to our 2003 data. When applying these earlier criteria, no significant difference in the percentage of patients at goal for LDL-C was noted in the 2003 data: 83% (71/86) were at goal in 2003 vs. 79% (68/86) in 1999 (Chi-square 2-sided p = 0.19).

Table 2.
Change in Quality Indicators 1999-2003

Indicator	Mean (SD)	Mean (SD)	Difference	95% CI of the Difference
	1999	2003		(Lower, Upper)
HbA1c	8.6 (2.0)	8.2 (1.8)	-0.4	(-0.76, -0.05)
Systolic BP	137.6 (18.6)	134.1 (14.3)	-3.5	(-7.49, 0.55)
Diastolic BP	76.2 (9.3)	71.9 (9.2)	-4.3	(-6.38, -2.22)
LDL-C	125.5 (39.8)	114.9 (40.9)	-10.6	(-18.10, -3.09)
HDL-C	38.9 (11.2)	47.2 (12.1)	8.3	(8.55, 10.25)

SD (standard deviation), CI (Confidence Interval), BP (blood pressure), LDL-C (low-density lipoprotein cholesterol), HDL-C (high-density lipoprotein cholesterol)

Table 3.
Frequency "at Goal" for Quality Indicators 1999 vs. 2003

Indicator	1999 N (%)	2003 using 1999 standards N (%)	2003 using 2003 standards N (%)	Difference in number "at Goal"
	At Goal	At Goal	At Goal	P value[†]
HbA1c	12 (14.1)	*	16 (18.8)	0.33
Systolic BP	32 (37.2)	*	34 (39.5)	0.86
Diastolic BP	72 (83.7)	79 (91.9)	68 (79.1)	< 0.001[‡]
				0.48[§]
LDL-C	68 (79.1)	71 (82.6)	34 (39.5)	0.68[‡]
				< 0.001[§]
HDL-C	53 (61.6)	74 (86)	61 (71.8)	< 0.001[‡]
				0.09[§]

[*] No change in the 2003 standards occurred for this quality indicator, therefore the data are the same as those in the "2003 using 2003 standards" column,

[†] McNemar test

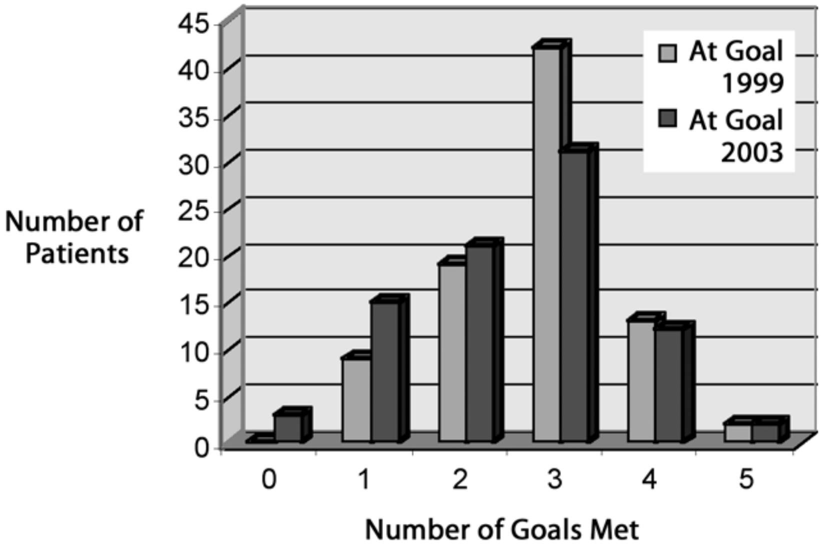
[‡] P value reflects the difference in number at goal for this quality indicator in "1999" vs. "2003 using 1999 standards"

[§] P value reflects the difference in number at goal for this quality indicator in "1999" vs. "2003 using 2003 standards", BP (blood pressure), LDL-C (low-density lipoprotein cholesterol), HDL-C (high-density lipoprotein cholesterol)

Discussion

While improvement with respect to decreased mean HbA1c, diastolic blood pressure, and LDL-C, and increases in the mean HDL-C were achieved over the four-year study interval, the overall number of patients at goal for LDL-C decreased by approximately 40% (see Tables 2 and 3). This paradoxical improvement in patients' mean LDL-C levels despite a decrease

Figure 1.
Number of Cardiovascular Disease-Related Guideline Goals Met (1999 vs. 2003)



in the number of patients at goal for LDL-C in 2003, are explained by the change in the NCEP ATP III guideline with the introduction in 2001 of type 2 diabetes as a coronary artery disease equivalent and the new LDL-C goal of less than 100 mg/dL.

Attainment of goals targeting metabolic endpoints related to cardiovascular disease risk reduction among persons with type 2 diabetes has been studied among primary care providers.[7-9] Some primary care practices have used computer-assisted interventions to improve diabetes care with limited improvement in metabolic outcomes.[16] Compliance with blood pressure or lipid guidelines in cross-sectional data are based primarily on surrogate markers, such as reports of awareness of guideline recommendations,[17] physicians' perceived implementation of guidelines,[18] or performance of recommended screening tests.[19] However, even high rates of risk factor testing (HbA1c, blood pressure, LDL-C) have been shown not to correlate with optimal metabolic control among persons with diabetes.[20] Grant et al., found that high annual testing rates corresponded to only 34% of patients at goal for HbA1c (< 7%), 33% at blood pressure goal (< 130/80), and 46.1% at goal for LDL-C (< 100 mg/dl).[20] Primary care providers are not alone in their difficulty achieving practice guideline goals. Aliyu et al., reported that 38% of cardiologists' patients with established coronary heart disease and no contraindications to statin therapy had sub-optimal management of their dyslipidemia when compared against the NCEP ATP III guidelines.[21]

A previous cross-sectional study assessing ADA-specific lipid treatment goals among adults with type 2 diabetes in a university primary care setting revealed 42% were at goal for HDL-C, and 47% were at goal for LDL-C.[8] In a comparison of national samples of white, African-American, and Mexican-American persons with type 2 diabetes, Harris reported the percent of those with LDL-C values less than 100 mg/dL were 15.4%, 19.6%, and 21.1%, respectively.[22] The percent at goal for HbA1c (i.e., < 7%) for all subjects was 44.6%.[23] In the current study, we found that 71.8% (61/85) of patients were at goal for HDL-C in 2003, while only 39.5% (34/86) were at goal for LDL-C. Only 18.8% (16/85) were at goal for HbA1c (see Table 3). Most patients were at goal for only two of the five variables under study in both 1999 and 2003 (see Figure 1).

A limitation of the current study is its small sample size. The fact that the study patients were from an academic family medicine practice also limits the external validity of the study. While the patients seen in this practice are representative of a mixed population, greater than half of the patients have a managed care plan. Additionally, this follow-up study included only persons with type 2 diabetes and a coexisting diagnosis of hyperlipidemia. It is possible that the percentage of those at goal for HbA1c may differ among persons with type 2 diabetes without hyperlipidemia. Another consideration is the potential confounding effect of the aging of our cohort; treatment goals may be more difficult to achieve with advancing age.

Summary

This longitudinal study, conducted among a sample of persons with type 2 diabetes in an academic family medicine setting, describes the attainment of goals related to metabolic control and CVD risk reduction. The current study highlights the impact that changes in guideline recommendations can have on a practice's achievement of metabolic goals despite improvements at the patient level. We found that patients achieved on average approximately half of the guideline-specific goals related to CVD risk reduction. These results echo those of other investigators in that practice guideline goals are difficult to attain in the primary care setting. Further research is needed to elucidate the barriers related to attaining guideline-specific goals for patients with diabetes in primary care, such as short, infrequent visits; lack of information technology support; and competing demands.[24] Our findings suggest that patient-level improvements may not be adequate indicators of a practice's achievement of guideline recommendations. Percent attainment of guideline goals may be a useful performance measure of practice-level quality improvement initiatives.

Trends in Up-to-Date Status in Colorectal Cancer Screening, North Carolina, 1998-2002

Jane A. Kim, MD, MPH, Deborah Porterfield, MD, MPH, and Ziya Gizlice, PhD

Abstract

Background: *Rates of colorectal cancer (CRC) screening are rising nationwide. Our purpose was to determine the proportion of North Carolina adults who were up-to-date with CRC screening in 1998-2002 and analyze trends by socio-demographic subgroups.*

Methods: *We examined data from the North Carolina Behavioral Risk Factor Surveillance System. For 1998, 1999, 2001, and 2002, we determined the proportion of respondents 50 years old and older who were up-to-date, defined as a home fecal occult blood test (FOBT) in the past 12 months and/or a sigmoidoscopy or colonoscopy in the past five years. We examined trends in up-to-date status in all respondents and in selected socio-demographic subgroups. We also examined the characteristics of respondents who were up-to-date in 2001-2002.*

Results: *From 1998-2002, the percentage of respondents 50 years old or older who were up-to-date with CRC screening increased from 46.1% to 54.0% (test for trend, $p < 0.0001$). The proportion who were up-to-date increased among those 50-74 years old, those with a high school or college education, and those with incomes less than \$25,000. Proportions that were up-to-date did not significantly increase among African Americans and respondents with less than a high school education. In 2001-2002, we found low percentages that were up-to-date among adults 50-54 years old, Hispanics, and the uninsured.*

Conclusions: *The proportion of North Carolina adults who are up-to-date with CRC screening is increasing, but not across all socio-demographic groups. These results indicate that there are subgroups that need to be reached with screening programs. Efforts to educate the public and providers about CRC screening should continue.*

Introduction

Colorectal cancer (CRC) is a leading cause of cancer in the United States and ranks only behind lung cancer as a cause of cancer death.[1] The American Cancer Society (ACS) estimates that 4,100 new cases and 1,590 deaths from colorectal cancer will occur in North Carolina in 2005.[1] Colorectal cancer screening reduces mortality[2-6] and is cost-effective.[7,8] The United States Preventive Services Task Force, the American Gastroenterological Association, the ACS, and others recommend screening for adults 50 years old or older.[9-11] Multiple modalities can be used for screening: a yearly fecal occult blood test (FOBT), flexible sigmoidoscopy or barium enema every five years, a combination of FOBT and sigmoidoscopy, or colonoscopy every ten years (see Table 1). Despite expert group recommendations and multiple screening modalities, national rates of CRC screening[12,13] remain far below rates for mammography, prostate-specific antigen screening, and Pap smear testing.[14-16]

Although CRC screening rates were low throughout the 1990s, recent data from the national Behavioral Risk Factor Surveillance System (BRFSS) show modest increases in screening rates. From 1999-2001, the percentage of adults 50 years old or older who reported FOBT screening within the past 12 months increased from approximately 19% to 24%, and the percentage reporting a sigmoidoscopy or colonoscopy within the past five years improved from 34% to 39%.[12,13] In 2001, approximately 53% of adults 50 years and older were up-to-date with screening, defined as an FOBT in the past 12 months or

Table 1.
Colorectal Cancer Screening Guidelines for Average Risk[§] Individuals 50 Years Old or Older[*][9-11]

Any one of the following:
1. Yearly fecal occult blood testing (FOBT)
2. Flexible sigmoidoscopy (FS) every five years
3. Combined yearly FOBT and FS every five years**
4. Colonoscopy every ten years
5. Double-contrast barium enema every five years

[§] Average risk: individuals without a family or personal history of colorectal cancer, personal history of adenomatous polyps, and the absence of an illness, such as inflammatory bowel disease that predisposes individuals to CRC

[*] Recommendations of the American Gastroenterological Association Consortium Panel, United States Preventive Services Task Force, and American Cancer Society (ACS)

[**] ACS recommends the combination of flexible sigmoidoscopy and FOBT over either test alone

a lower endoscopy (colonoscopy or sigmoidoscopy) in the last ten years.[13]

Recent trends in up-to-date status in North Carolina are of interest to the Cancer Prevention and Control Branch of the North Carolina Division of Public Health, which is responsible for surveillance and has implemented CRC screening programs for underserved populations in the past. These trends are also of interest to the Advisory Committee for Cancer Coordination and Control, which makes recommendations on cancer screening and control for North Carolina and is currently writing an updated state plan for cancer control. We were also interested in assessing recent trends in CRC screening to determine if various factors, such as insurance policy changes, state-based legislation, and public awareness campaigns might have resulted in an increased proportion of North Carolinians who were up-to-date with CRC screening. We examined the data from the North Carolina BRFSS for trends in CRC screening rates, including trends across selected socio-demographic subgroups from 1998-2002. We also evaluated the characteristics of those who were up-to-date in 2001-2002 in order to identify populations that might be in need of interventions to improve the performance of CRC screening.

Methods

The BRFSS is a multistage, random-digit-dialed, state-based telephone survey of noninstitutionalized adult United States residents ages 18 and older.[17] The BRFSS consists of a core set of questions with additional optional modules for topics, such as colorectal cancer screening. States have the option to add these additional modules based on the data needs of their state. Colorectal cancer screening questions were mandatory core items in the 1999, 2001, and 2002 BRFSS. The North Carolina Cancer Prevention and Control Branch paid to add questions to the 1998 BRFSS for enhanced surveillance of colorectal cancer screening behavior and needs assessment for public health programs.

During the study period, the North Carolina BRFSS conducted 17,764 interviews. Colorectal cancer screening questions were asked of the 7,642 respondents who were ages 50 years old or older at the time of the interview. Response rates of all eligible individuals with telephones in North Carolina ranged from 56% (2001) to 64% (1998) and were calculated via the CASRO method.[18] The CASRO method calculates the response rate by taking the percentage of complete and partial interviews out of an estimate of all eligible households.

Interviewers asked four questions about whether respondents had ever been screened with sigmoidoscopy/colonoscopy or a home FOBT and, if so, when they received screening (see Box 1). To reflect updated evidence regarding colonoscopy and proctoscopy, endoscopy questions changed in 1999 to ask about screening with "sigmoidoscopy/colonoscopy" instead of "sigmoidoscopy/proctoscopy." For this analysis we refer to both sets of terms as "endoscopy." In 2001, BRFSS changed endoscopy response choices to include endoscopy within the past ten years, the time frame recommended for colonoscopy screening. We defined up-to-date status for the analysis of trends from 1998-2002 as a home FOBT in the past 12 months and/or a sigmoidoscopy or colonoscopy in the past five years. We chose this definition in order to compare trends across years because the ten-year answer choice was not available before 2001.

For each year with data on CRC screening from 1998-2002, we determined the proportion of respondents who were up-to-date with screening for the total number of respondents as well as for the socio-demographic subgroups of gender, age, race, education, and household income. Those who responded "do not know/not sure" or "refused" were excluded. We used a test for trend to determine if there were significant trends in the proportions who were up-to-date with CRC screening. Trends were not calculated for subgroups with less than 100 respondents in a given year.

For 2001 and 2002, we also calculated the percentages who were up-to-date using an alternate definition: FOBT within the past 12 months and/or a sigmoidoscopy/colonoscopy within the past ten years. Given that the national BRFSS now uses the ten-year time interval to determine the percentage of individuals who were screened with lower endoscopy during recommended time intervals,[12] we used this updated definition of up-to-date in order to be consistent with the national definition. This definition of up-to-date includes respondents who were appropriately screened with colonoscopy within the past ten years, but also those who had a sigmoidoscopy five to ten years earlier and were no longer up-to-date with guidelines. To evaluate whether screening according to guidelines increased significantly between 2001 and 2002, we compared the difference in the proportions of respondents who were up-to-date using a t-test.

We combined data from 2001 and 2002, the most recent years for which we had data, and examined the characteristics of respondents who were up-to-date with screening. Combining data from 2001 and 2002 allowed us to determine the proportions who were up-to-date with screening in subgroups, such as the uninsured and Hispanics, groups with small numbers sampled in each individual year.

We used SUDAAN version 8 to calculate rates, averages, standard errors, and 95% confidence intervals.[19] Data from the sample were weighted to adjust for unequal probabilities of selection due to the disproportionate sampling method and due to people living in households with different numbers of telephones and different numbers of adults. The final sample data were also weighted to account for unequal non-response rates among different demographic groups. Two-sided p-values < 0.05 were considered statistically significant. Analyses using BRFSS data are exempt from Institutional Review Board approval because the BRFSS does not have any personal identifiers and is a public health surveillance system. These data were analyzed as part of the surveillance work of the North Carolina Division of Public Health.

Results

Trends in Up-to-Date Status in Colorectal Cancer Screening, 1998-2002

The percentage of respondents 50 years old or older who reported a home FOBT in the past 12 months or endoscopy in the past five years increased from 46.1% [95% confidence interval (CI), 42.2, 50.1] in 1998 to 54% (95% CI, 51.2, 56.7) in 2002 (test for trend, p < 0.0001, see Table 2). Table 2 shows the trend in the percentage of all respondents that were up-to-date from 1998-1999 and 2001-2002, the years in which North Carolina asked questions about CRC screening, and Table 3 presents trends in up-to-date status by socio-demographic subgroups. There were statistically significant positive trends in up-to-date status among males and females, those 50-74 years old, whites, those with a high school or some college education, and those with incomes less than $25,000 (see Table 3). There was a 24 percentage-point increase in up-to-date status among those with incomes less than $15,000 (33% to 57%) and a 13 percentage-point increase from 31% to 44% in the 50-54-year-old age group. In contrast, there were no significant trends in the percentages who were up-to-date among respondents with less than a high school education or a college degree or greater and those with incomes greater than $25,000. Respondents with higher levels of education and income already had high baseline percentages of individuals who were up-to-date in 1998; these groups experienced only small increases over the five-year period.

Box 1

Questions on colorectal cancer screening, 2002 BRFSS (Behavioral Risk Factor Surveillance System)

A blood stool test is a test that may use a special kit at home to determine whether the stool contains blood. Have you ever had this test using a home kit?

A Yes
B No
C Don't know/not sure
D Refused

How long has it been since you had your last blood stool test using a home kit?

A Within the past year
B Within the past two years
C Within the past five years
D Five or more years ago
E Don't know/not sure
F Never
G Refused

Sigmoidoscopy and colonoscopy are exams in which a tube is inserted in the rectum to view the bowel for signs of cancer or other health problems. Have you ever had either of these exams?

A Yes
B No
C Don't know/not sure
D Refused

How long has it been since you had your last sigmoidoscopy or colonoscopy?

A Within the past year
B Within the past two years
C Within the past five years
D Within the past ten years
E Ten or more years ago
F Don't know/not sure
G Refused

Table 2.
Number and Percentage of North Carolina Respondents 50 Years Old or Older Who Were Up-to-Date with Colorectal Cancer Screening,* 1998-2002

	Total Number of Respondents	Percent	95% Confidence Interval
1998	931	46.1	(42.2, 50.1)
1999	1,031	45.2	(41.8, 48.7)
2001	2,473	55.4	(52.5, 58.2)
2002	2,942	54.0	(51.2, 56.7)

Test for trend, 1998-2002: t-value = 4.47, p < 0.0001

* FOBT within past 12 months and/or sigmoidoscopy/colonoscopy within the past five years

Proportions and Characteristics of Up-to-Date Respondents, 2001-2002

For 2001-2002, using the updated definition of up-to-date, which was an FOBT in the past 12 months or sigmoidoscopy/colonoscopy in the past ten years, the percentage of respondents who were up-to-date

* FOBT within past 12 months and/or sigmoidoscopy/colonoscopy within past five years

with CRC screening was 57.4% in 2001 and 56.4% in 2002; this difference was not significant.

In the combined data from 2001 and 2002, approximately 58% of whites were up-to-date compared to 54% of African-Americans and 41% of other minorities, a category that included Asians, American Indians, and native Hawaiian or other Pacific Islanders (see Table 4). Fewer respondents of Hispanic origin were up-to-date with screening (49.9%) compared to those who were not Hispanic (57.0%). Only 45% of respondents 50-54 years old were up-to-date, compared to 59% of those 55-64 years old and 61% of those 65 years old or older. Forty-nine percent of respondents with less than a high school education were up-to-date versus 63% of those who had a college education or beyond. Approximately 59% of those with health insurance were up-to-date with screening, compared to only 34.8% of respondents without health insurance.

Discussion

From 1998-2002, the percentage of North Carolina adults 50 years old or older who were up-to-date with CRC screening increased, but remained low, and positive trends in up-to-date status were present in some, but not all socio-demographic subgroups. In 2001-2002, screening rates continued to improve, but more than 40% of respondents still had not been screened according to guidelines. There were notable disparities in the percentages that were up-to-date in 2001-2002 by race, age, and insurance status.

The proportions of those who were up-to-date in North Carolina are similar to those obtained from the national BRFSS. In the 1999 national BRFSS, 44% of adults 50 years old or older were up-to-date with screening, defined as an FOBT in the past year or a sigmoidoscopy in the past five years,[13] compared to 45.2% of North Carolina respondents. In the 2001 national BRFSS, 53.1% were up-to-date using the updated definition, an FOBT within the past 12 months or lower endoscopy within the past ten years.[20] In North Carolina, approximately 57% of respondents reported screening within these time intervals.

The increase in the percentages of North Carolina respondents who were up-to-date may be due to national and state efforts to promote CRC screening. The Centers for Disease Control and Prevention (CDC) launched multi-media campaigns in 1999 to educate the public and healthcare providers about CRC screening.[21-23] The American Cancer Society also implemented a colorectal cancer screening media campaign in March 1999 and 2000. Activities organized through North Carolina's Cancer Prevention and Control Branch of the North Carolina Division of Public Health included a media campaign to promote screening and regional training sessions for physicians. In addition, the North Carolina Advisory Committee on Cancer Coordination and Control funded a pilot project in 2000 to

Table 4.
Characteristics of North Carolina Respondents 50 Years Old or Older Who Reported FOBT within Past 12 months and/or Sigmoidoscopy/Colonoscopy within the Past Ten Years, 2001-2002

promote CRC screening in six local health departments.

Medicare and the North Carolina General Assembly implemented policy changes in 1998 and 2001 that may have contributed to the increasing proportion of North Carolina respondents who were up-to-date. In January 1998, Medicare began to cover screening FOBT, sigmoidoscopy, and barium enema for average-risk enrollees 50 years old and older. Medicare further broadened its coverage in 2001 to cover screening colonoscopy for average-risk enrollees 50 years old or older.[24] Also in 2001, the North Carolina General Assembly passed legislation mandating that state and private insurance plans cover CRC screening tests.[25] The 2002 North Carolina BRFSS, however, showed only a small increase in up-to-date status compared to previous years. It will be interesting to see whether rates of up-to-date status in subsequent surveys reflect these policy changes.

Although the percentage of North Carolina adults 50 years old and older reporting CRC screening within recommended time intervals is increasing, approximately 46% of adults are not up-to-date with screening. In addition, not all socio-demographic subgroups experienced improvements in up-to-date status. There were significant improvements in whites, those with incomes less than $25,000, and those with a high school or some college education. There was no significant increase in up-to-date status, however, among respondents with less than a high school education and those with incomes between $25,000-$50,000, indicating a possible need for interventions in these populations to help increase levels of screening. In addition, screening among all respondents 50-54 years old improved from 30% to 43% from 1998-2002, but the proportion who were up-to-date among this age group in 2002 was still low. It may be important to target individuals in this age group in order to help them start and continue with screening according to guidelines.

Prior research has found that increasing age, higher levels of education, having health insurance, and being of non-Hispanic background[26-32] are associated with higher rates of CRC screening. The findings from our study are consistent with results from these prior studies. In 2001-2002, North Carolina BRFSS respondents 50-54 years old had low rates of up-to-date screening compared to those of older age, and individuals with low educational attainment and low incomes had lesser rates of up-to-date screening compared to those with higher levels of education and income. Rates of up-to-date screening among the insured were almost twice as high as those among the uninsured. Fewer Hispanics were up-to-date compared to non-Hispanics. Current educational and awareness programs to promote screening may not be reaching the groups who had low percentages of individuals who were up-to-date; poor access to healthcare and lack of income to pay for tests are other possible reasons for these low rates.

African Americans have higher rates of colorectal cancer death and are diagnosed at a more advanced stage more often than whites.[1,33] These disparities may be due in part to low rates of CRC screening in African Americans.[34] In our current study, we found that rates of up-to-date screening among African-Americans did not increase significantly over time, but that the actual rates of up-to-date screening in 2001-2002 were comparable to whites. It is encouraging that African Americans had similar rates of up-to-date status in recent years compared to whites, and the lack of a significant trend may be due in part to sampling error due to small sample sizes in 1998-1999. Efforts to promote CRC screening among African-Americans should continue given their higher rates of mortality and diagnosis in advanced stages of disease.

There are a number of limitations to this study. First, the change in wording from "sigmoidoscopy/proctoscopy" in 1998 to "sigmoidoscopy/colonoscopy" in 1999 may have resulted in higher screening rates in 1999, 2001, and 2002 due to a previously unmeasured use of colonoscopy. The change from proctoscopy to colonoscopy may mean that the increasing trends are due in part to the change in question wording, which could have introduced measurement error and potential bias into our results. The extent to which this change may have affected the results is unclear. Defining up-to-date screening status for the analysis of trends as a sigmoidoscopy or colonoscopy within the past five years may underestimate the actual percentage of those who are up-to-date, since individuals who had colonoscopy between five and ten years ago are in compliance with current guidelines. The BRFSS questions on CRC screening did not distinguish between diagnostic and screening procedures, possibly resulting in overestimates of actual screening rates. Another limitation is that the percentages of up-to-date by socio-demographic characteristics in 2001-2002 are not adjusted for the other variables. Further investigation of these associations with a multivariate model might help define which characteristics are most strongly associated with up-to-date status. This was a telephone survey, so responses were limited to individuals who owned home telephones. The response rates were low, and respondents may have answered differently compared to those who chose not to participate. Another limitation is recall bias; responses were self-reported and may not accurately reflect the actual performance of screening tests. Comparisons of self-report and chart audits, however, have found fair-to-good agreement between patient self-report and medical records.[35-37] And finally, the small numbers of African Americans surveyed in the 1998 and 1999 BRFSS may have affected the accuracy of these estimates.

Conclusions

The percentage of North Carolina adults who are up-to-date with CRC screening is increasing, and state rates of up-to-date status parallel trends seen on the national level. Although this is an encouraging finding, many adults 50 years old or older are still not up-to-date with current guidelines, and some socio-demographic subgroups, such as the uninsured, Hispanics, and those 50-54 years of age, have particularly low rates of individuals who are up-to-date with screening. There is a need for educational programs and screening initiatives for the public and for healthcare providers, especially targeted toward populations who had low percentages of respondents who were up-to-date, in order to improve the performance of colorectal cancer screening in North Carolina.

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Thanks from the *North Carolina Medical Journal*

Without the voluntary assistance and carefully executed reviews of a number of anonymous reviewers, no journal can offer the kind of peer-review for submitted manuscripts that can assure its readers the highest quality of published articles. We are fortunate in having the service of a number of individuals who have given generously of their time and expertise in service to the *North Carolina Medical Journal* this past year, and we are pleased to have this annual opportunity to acknowledge their efforts.

INTRODUCTION

Policy Forum:
Access to Dental Care

Since 2002, when the North Carolina Institute of Medicine began publishing the *North Carolina Medical Journal* as a statewide journal of health policy analysis and debate for all the healthcare professions, key policy makers/shapers, and the interested lay public, we have wanted to highlight the problems of assuring access to primary dental care services in our state. This year, we are fortunate to have a new relationship with the North Carolina Dental Society as an organizational co-sponsor of the Journal. This relationship and the 2005 North Carolina Oral Health Summit, convened by the Oral Health Section of the North Carolina Department of Health and Human Services, were catalysts for the production of this Journal issue. In this issue of the Journal, we summarize the principal themes of these discussions concerning the state of oral health in North Carolina, along with a number of policy options for addressing the shortages of dental workforce supply.

North Carolina, like a number of other states, is facing a significant shortage of practicing dentists. Moreover, problems accessing primary dental care are even more severe in certain rural areas of the state, for those with low incomes or dependence on coverage from the state's Medicaid program, and for persons with special needs, such as persons with disabilities. Few disagree that the number of dentists in our state needs to increase rapidly, and concerted efforts should be made to attract additional dental practitioners to serve underserved areas and populations.

On a positive note, North Carolina is one of the nation's leading states with regard to preventive dental care programs for children, which are primarily offered through the public schools. In addition, community water fluoridation efforts statewide have extended access to this valuable preventive oral health technology to more than 80% of our state's population. Since the 1960s, the prevalence of dental caries in the permanent teeth of 12-17 year olds has declined by more than 80% for whites and 65% for African Americans. Despite these impressive 40-year trends, reported by Drs. Gary Rozier and Rebecca King, serious problems remain. As many as 20-30% of North Carolinians report that they have been unable to access basic dental care services when needed, and one out of three school-age children have untreated dental decay.

While this issue of the *North Carolina Medical Journal* provides an overview of the challenges many people in North Carolina face when trying to access dental care, there are a number of challenges that are not discussed in any detail. For example, we have not provided a detailed discussion of the national faculty shortages for dental schools or community colleges that are preparing needed dental professionals. In addition, we do not discuss some of the highly sensitive issues regarding the expanded use of dental hygienists, which are being utilized in other states. These are issues that may warrant attention, but were beyond the scope of this publication.

Like a number of the health and healthcare policy issues previously addressed in Journal, opinions differ about how best to meet the oral health needs of our population. Short-term and longer-term options are considered, each with costs and likely benefits. We hope that the articles presented here will help explain our state's oral health challenges as policies and programs are developed to meet these important health needs.

ISSUE BRIEF

Assuring the Accessibility of Basic Dental Care Services:
Issues of Workforce Supply, Organization of Care, and Education

Kristen L. Dubay, MPP, M. Alec Parker, DMD, and Gordon H. DeFriese, PhD

The most common form of dental disease is caries (tooth decay).[1,2] In fact, dental caries is the most common chronic disease among children—five times more common than asthma (59% versus 11%, respectively).[3] Nationally, more than half of all children have dental caries by the second grade.[2,4] In North Carolina, during state fiscal year 2004-2005, 22% of children were found to have untreated tooth decay in kindergarten.[5] Nationally, 30% of adults have untreated tooth decay. [2,6]

Many people do not understand the integral role that oral health plays in a person's general health. Studies are increasingly uncovering associations between chronic oral infections and other conditions, such as diabetes, heart and lung diseases, stroke, low birth weight, and premature births.[1,2] Untreated oral health problems cause unnecessary pain and suffering. They can also decrease the economic productivity of workers through lost work days or distraction, and have a similar negative effect on children's capacity to learn. Individuals with oral health problems may experience a loss of self-esteem, and in some extreme cases, death. Oral and pharyngeal cancers are also significant oral health problems that can lead to serious illness and disfigurement. Further, individuals that delay needed dental care often face higher treatment costs when they do receive care.[1,2]

Most people experience caries and/or periodontal (gum) disease at some point in their lives. Fortunately, most of these problems are preventable and treatable with a combination of self-care, professional care, and community-based initiatives. Community water fluoridation, for example, has significantly reduced the prevalence and severity of dental decay in North Carolina and the nation.[7] Professionally-applied dental sealants, varnishes, and gels, and the use of products containing fluoride, (e.g., toothpaste, mouth rinses, dietary fluoride supplements) effectively prevent dental decay. Self-care practices that include a diet with limited sugars and carbohydrates, regular tooth brushing and flossing, along with regular professional cleanings are also critical to maintaining oral health. Regrettably, many people either cannot access needed dental care, do not know how to access the care they need, or do not realize the importance of dental care to their overall health status.

> *"Studies are increasingly uncovering associations between chronic oral infections and other conditions, such as diabetes, heart and lung diseases, stroke, low birth weight, and premature births."*

Dental care services are one category of healthcare for which there is both the expectation of widespread, if not universal, availability, and yet low levels of consumer demand in comparison with conventional healthcare (i.e., medical) services. Dental care is a segment of overall healthcare where preventive services are of unquestionable primary importance to both the maintenance of health status and the minimization of future costs of treatment. But oral health within communities requires attention to both individual health-promotive behaviors as well

as collective interventions, such as the assurance of dental care access and the fluoridation of public water supplies.

Patterns of Dental Disease in North Carolina

North Carolina has benefited from more than 30 years of detailed and on-going epidemiological studies documenting the extent and the patterns of dental disease in this state. In addition, the preventive dentistry programs targeted to children in this state set it apart from most others. As a result, it is possible to describe the distribution of dental disease (in terms of need) as well as the success of various programs to address the prevalence of dental disease among North Carolina's children in a way that has made North Carolina the envy of many other states. Drs. Gary Rozier and Rebecca King provide an overview of the history of dental disease trends in North Carolina in a commentary in this issue of the *North Carolina Medical Journal*.[8]

These accomplishments have been realized through an effective and long-term collaboration between the state's Oral Health Section of the North Carolina Department of Health and Human Services (DHHS) and the University of North Carolina at Chapel Hill (UNC-Chapel Hill) School of Public Health. In the 1960s, Drs. John Fulton and John Hughes of the UNC-Chapel Hill School of Public Health worked with state epidemiologists and oral health personnel to develop the first statewide oral health survey.[9] This landmark study demonstrated widespread patterns of untreated dental decay, endentulism, and periodontal disease and served as the stimulus for legislative action to create a major new initiative in dental public health with a particular focus on the oral health of North Carolina's children. The 1960-1963 Fulton-Hughes study was followed 13 years later (in 1976-1977) by a second statewide epidemiological survey conducted by Dr. John Hughes and Dr. Gary Rozier, which enabled the calculation of oral health rates of change in North Carolina.[10] More recently, in 1986-1987 and 2003-2004, Rozier and his colleagues[11,12] at the Oral Health Section of the North Carolina DHHS conducted clinical examinations and questionnaire surveys of 80% of North Carolina school children in kindergarten through 12th grade, which included open-mouth dental screenings by dental professionals. Few states have such a resource to track the accomplishments of dental healthcare and preventive services.

Poverty and Access to Dental Care

Oral health status, like general health status, varies according to sociodemographic factors. For example, people who are low-income, minorities, and/or are less well educated tend to have poorer dental health than others. Low-income children are more likely to experience tooth decay, have a severe experience with tooth decay, and have untreated decay.[3,13]

Between 1999 and 2002, children ages two through 11 with family incomes below 100% of the federal poverty guideline (FPG)* were found to be nearly two times as likely to experience tooth decay as children in families with incomes at or above 200% FPG.[14] Adults and children in poverty were more than twice as likely as their higher-income peers to have untreated tooth decay.[14] Likewise, Latino and African-American children experienced higher rates of tooth decay (treated and untreated) than white children. Poor and minority children are also less likely to receive preventive treatments, such as dental sealants (3% versus 23%, respectively). Similarly, African-American adults are less likely to survive oral and pharyngeal cancers than whites (five-year survival rates are 34% versus 56%, respectively).[1,15]

Education also plays a key role in dental health. Less educated adults are less likely to have a regular oral cancer examination,[17] more likely to experience destructive periodontal disease, and more likely to eventually lose all of their teeth. For example, more than 13% of individuals without a high school diploma have lost all of their teeth, compared to less than 4% of individuals with more than a high school diploma.[1]

Special Analyses of Dental Health Issues in North Carolina

All of these socio-demographic differences in dental health have been addressed at the state-level through a series of meetings/conferences with North Carolina dental health professionals and other interested individuals. In 1989, the North Carolina DHHS was asked by the General Assembly to consider the problem of access to primary dental care by low-income persons in our state, particularly those covered by the state's Medicaid program. Subsequently, the Secretary of the Department, Dr. H. David Bruton, asked the North Carolina Institute of Medicine (IOM) to organize a statewide task force that would examine these issues and make recommendations to address the significant problems low-income individuals and those living in rural and other underserved areas have accessing dental care. The North Carolina IOM Task Force began work in 1998 and completed its report to the North Carolina DHHS and the North Carolina General Assembly in April 1999.[16] The work of the Task Force was generously supported by grants from the Kate B. Reynolds Charitable Trust and The Duke Endowment. The 1999 North Carolina IOM report offered 23 specific recommendations for addressing dental care access issues facing low-income persons in the state. Subsequently, the North Carolina IOM followed-up the work of the Task Force with two meetings, in 2001 and 2003, to discuss the steps that had been taken to fulfill the recommendations from the 1999 report. In April of 2005, the Oral Health Section of the North Carolina DHHS evaluated these issues at the North Carolina Oral Health Summit. The recommendations of the 2005 Summit are highlighted herein where appropriate.

---

* According to the federal poverty guidelines in 2000, 100% of FPG for a family of four was an income of $18,000.

Policy Approaches to the Problem of Dental Care Access

Since the mid-1990s, it has become clear that an insufficient number of dentists and dental hygienists have been entering practice in North Carolina. Too few dentists are willing to serve low-income populations, particularly those covered by the state's Medicaid program. A number of possible avenues have been suggested for meeting these challenges. While there is general agreement that dental healthcare is a critical aspect of overall population health and making these services available is fundamental to overall health policy in our state, many of these proposed solutions are controversial.

In North Carolina, as in many other states, there is a growing sense that professional dental care is becoming less and less available, particularly as a number of dental schools across the nation have closed, and as the total number of newly licensed dentists has decreased nationally. The Kate B. Reynolds Charitable Trust, one of the state's leading health-oriented private philanthropies, has made access to dental care for low-income populations a high priority for more than a decade. Some of their programs are described by John Frank, Director of the Trust's Health Care Division, in this issue if the *North Carolina Medical Journal*.[18] Dental care in the United States is clearly among the best in the world for those who can afford it and for those who have regular access to professional care. Unfortunately this is not the case for a sizable proportion of our state's population.

Four basic strategies to improve access have been considered over the previous decade: (1) increasing the dental provider participation in the North Carolina Medicaid program, (2) increasing the supply of dentists, (3) increasing dental care availability for special needs populations, and (4) increasing public awareness of the importance of oral healthcare.

Strategy One: Low-Income Access to Dental Care

Of North Carolina's more than 8.5 million population, approximately 18% are Medicaid recipients—881,356 of whom are less than 21 years old.[19] North Carolina provides dental coverage for all eligible Medicaid recipients (adults and children). Unfortunately, use of these services is low. On average, only 27% of Medicaid recipients visited the dentist in state fiscal year 2004, a percentage that varies by geographic location. In 2005, the percentage of Medicaid recipients who visited a dentist ranged from a low of 17% in Swain County to a high of 36% in Wilkes County.[19] Low-income, uninsured individuals face other barriers to access because the entire financial burden for services is theirs. These individuals often look for free or reduced-cost services and safety net clinics.

Medicaid Payment Rates for Participating Dentists. One of the primary factors responsible for low dental service utilization among Medicaid beneficiaries is the limited participation of dentists in the Medicaid program. In 2004, only 25% of the private practice dentists (855 of 3,446) in North Carolina were considered "active participants" in the program, meaning they billed Medicaid for more than $10,000 in a single year. This is a 33% increase from 2000, but still too few to serve the needs of the Medicaid population, which grew approximately 11% over the same period. The total number of dentists that served at least one Medicaid patient in 2005 is 1,771. Therefore, the current ratio of private dentists participating in the Medicaid program per Medicaid recipient is 1:885.[19] Given this relatively small number of dental professionals practicing in North Carolina, many Medicaid recipients have difficulty finding a dentist who will treat them.

In an effort to prevent dental caries and reduce the need for dental care treatment within the Medicaid population, a program called *Into the Mouths of Babes* (IMB) was developed by the Oral Health Section and introduced across the state. The IMB program provides dental preventive service packages to health departments and physicians' offices serving Medicaid-eligible children. The packages include targeted oral health education for caregivers and a dental screening and fluoride varnish application for high-risk children from birth to age three. Collaboration is also underway with the Early Head Start program to develop educational materials for use with their clientele, to help their clientele access dental preventive services within the medical community, and to help them to find a dental home. Although this program has been effective in preventing dental caries, it is unable to address the low dental care utilization rates among this population.

To address utilization, it is important to understand why dental health professionals may not serve Medicaid patients. One of the main reasons given for low dental provider participation in the North Carolina Medicaid program is low Medicaid reimbursement rates. The North Carolina Medicaid program pays dentists 73% of the UNC-Chapel Hill Dental Faculty Practice's "usual, customary and reasonable" (UCR) charges for a selected list of dental procedures commonly provided to children. These rates were increased in 2003, from 62%. The increase came as a result of a settled lawsuit. The National Health Law Program filed the lawsuit, Antrican v. Bruton, against the North Carolina DHHS on behalf of low-income children, challenging the adequacy of North Carolina's Medicaid dental reimbursement rates. Data indicate that, between 2003 and 2005, the percentage of Medicaid-eligible children ages birth through 21 years with a Medicaid dental visit increased from 29% to 32%, and it is believed that higher Medicaid reimbursement rates may have contributed to this increase. Dr. Mahyar Mofidi offers a review of the North Carolina experience with dentist participation in Medicaid in this issue of the Journal.[20]

Despite the 2003 increase in Medicaid reimbursement rates, there is still a feeling among dentists that rates should increase further and move toward a market-based fee schedule. The UNC-Chapel Hill School of Dentistry fee schedule was initially adopted because it was one generally supported by both dental providers and the Division of Medical Assistance. However, more recently, both groups have begun to discuss the potential benefits of a market-based fee schedule. Dr. Mofidi provides a more detailed explanation of this issue on page 457 of this Journal.[20]

Participants at the 2005 North Carolina Oral Health Summit recommended that moving toward a Medicaid reimbursement rate reflecting the 75th percentile of market-based fees in North Carolina would significantly reduce barriers to access for the Medicaid population. Such a target would indicate that reimbursement rates would be equal to or greater than the rates charged by 75% of dentists in the state. Recently, the North Carolina General Assembly has taken positive steps toward increasing the Medicaid dental reimbursement rates. In the 2005 session, the North Carolina General Assembly appropriated two million dollars in each year of the 2005-2007 biennium to increase Medicaid dental rates. This translates into an approximate increase of $6.4 million/year after factoring in the federal and county shares of Medicaid costs.

Increasing Volunteer Efforts of Dental Professionals in the Care of the Underserved. Beyond the needs of just the Medicaid population, there are important and impressive voluntary efforts on the part of some dental professionals (both dentists and hygienists) to meet the most urgent needs of all those without adequate access to primary dental care. Some of these efforts are in conjunction with clinics operated by federally qualified health centers (FQHCs), while others are through programs offered by "free clinics" in various communities across the state. In this issue of the Journal, Dr. Steve Slott offers a description of some of these voluntary efforts, but with a clear message that more of this type of volunteer effort would be both welcome and likely to have a sizeable impact among our state's population who are most in need of routine dental care.[21]

Strategy Two: Increasing the Supply of Dental Professionals

In addition to the challenges related to low dentist participation in the Medicaid program, dental care access is problematic for many because of the limited supply of dental professionals. In 2004, there were 3,628 licensed, active dentists in North Carolina.[22] This represents a dentist-to-population ratio of 4.2 dentists per 10,000 population—a rate that is well below the national average of 5.7 dentists per 10,000 population. The need for dentists is particularly acute in four eastern, rural counties (Camden, Hyde, Jones and Tyrell) where there is no practicing dentist. In addition, there are three other counties in North Carolina that have only one dentist each (Gates, Graham, and Northampton).[22] Only eight counties have a dentist-to-population ratio equal to or greater than the national average. Seventy-nine counties qualify as federally designated dental health professional shortage areas, meaning that they have a full-time-equivalent dentist-to-population ratio of at least 1:5,000, or between 1:4,000 and 1:5,000, with unusually high needs for dental services or insufficient capacity of existing dental providers.[23]

The number of dental hygienists in North Carolina poses less of a challenge to access. In 2004, there were 4,324 active, licensed dental hygienists in North Carolina, which represents an increase of 18% from state fiscal year 2000 to 2004.[22] In 2004, North Carolina had 5.1 dental hygienists per 10,000 population, a level greater than the national average of 4.4 per 10,000 population. Unfortunately, dental hygienist shortages remain a problem in certain areas of the state. For example, three North Carolina counties (Currituck, Jones, and Northampton) have only one dental hygienist, and in four counties, there is no active dental hygienist (Bertie, Gates, Hyde and Tyrrell).[22]

There are several potential strategies for responding to the shortage of dental health professionals, and they can be divided into short- and long-term strategies. The short-term strategies include making it possible for more out-of-state dentists to enter practice in North Carolina and expanding the role of public health dental hygienists in the provision of educational and preventive dental care services in additional safety net organizations. The long-term strategies include increasing the class size at UNC-Chapel Hill School of Dentistry, developing a new school of dentistry at East Carolina University, and expanding the number of residency training programs and graduates in the specialty of pediatric dentistry.

Attracting Dentists and Hygienists from Out-of-State. In the short run, one strategy for increasing the number of dentists in the state is to make it possible for more out-of-state dentists to practice in North Carolina. Presently, about 40% of all dentists practicing in North Carolina are graduates of dental schools outside of North Carolina.[23] Therefore, dentists educated in other states play a significant role in serving North Carolina residents. It has always been possible for any graduate of an accredited United States dental school to apply for a license to practice in North Carolina. However, prior to 2003, applicants were required to take the North Carolina clinical examinations. These examinations were barriers to out-of-state dentists because they were complicated to schedule and involved extensive logistical and financial commitments of the examinees. As a result, in August 2002, Senate Bill 861 was signed into law (SL2002-37) allowing licensure by credentials for dentists and dental hygienists who have practiced in another state for at least five years without any disciplinary actions. Since that time, 162 dentists (with eight denials) and 182 hygienists (with four denials) have received a North Carolina license by credentials.[23]

The North Carolina State Board of Dental Examiners is further pursuing participation in a Southeast Regional Examination procedure through which dental graduates (dentists and hygienists) who take the clinical examination in any participating state in the region can also apply for a license in North Carolina by reciprocity. The Board of Dental Examiners is also actively pursuing participation in a forthcoming national credentialing examination. Participants at the 2005 North Carolina Oral Health Summit supported all three of these initiatives and felt these were important efforts to improve the state's ability to attract dentists trained in other states.

Expanding the Role of Public Health Dental Hygienists. Another short-term strategy for increasing the capacity dental health professionals in North Carolina is to expand the role of public health dental hygienists to provide educational and preventive dental care services in safety net organizations other than public health department clinics serving low-income populations. In this issue of the Journal, Dr. Rebecca King, Chief of the Oral

Health Section of the North Carolina DHHS, offers a detailed description of dental public health programs in North Carolina.[24] In 1999, the North Carolina General Assembly passed legislation to revise the North Carolina Dental Practice Act to permit specially trained public health dental hygienists to perform preventive clinical services outside the public school setting under the direction of a licensed public health dentist (Sec. 11.65 of HB 168).

Under the North Carolina Dental Practice Act, 32 dental hygienists working in local health departments and one working in a safety net special care clinic, had been specially trained to provide services under the direction of a public health dentist by June 2005. In addition, the North Carolina Oral Health Section was able to use the increased capacity of its qualified state public health dental hygienists (36 people) to expand the reach of its sealant program. In the 2004-2005 school year, the majority of the 6,459 sealants provided to 1,911 children by the North Carolina Oral Health Section were placed by hygienists under the direction of a public health dentist. The successes experienced within the state and local public health programs could also be extended to other safety net providers, such as federally-funded community or migrant health centers, state-funded healthcare clinics, or not-for-profit clinics. These programs serve predominantly Medicaid, low-income, or uninsured populations. Allowing hygienists to provide educational and preventative dental care under the general supervision of a dentist employed at such safety net organizations may extend the safety net organizations' capacities to provide preventive care to underserved populations. Participants at the 2005 North Carolina Oral Health Summit requested that the North Carolina State Board of Dental Examiners reconsider the feasibility of allowing these types of arrangements.

Increasing the Productivity of Dental Education Programs. In the long-run, more significant steps need to be taken to increase the number of dental care providers, particularly dentists, in North Carolina. As North Carolina's population continues to grow, the shortage of dental providers will become even more acute. Currently, the UNC-Chapel Hill School of Dentistry is the only dentistry program in North Carolina, and it accepts 80 students each year. Adding seats to each class at the UNC-Chapel Hill School of Dentistry could positively impact the number of dentists in the state. However, there are a number of challenges to increasing the school's class size. Additional laboratory facilities for the teaching of basic clinical sciences, clinical training facilities, and faculty would be necessary. Such changes would require further funding, which is not readily available.

Increasing the Class Size at UNC-Chapel Hill. In this issue of the *North Carolina Medical Journal*, two commentaries address the complex issues associated with increasing the production of dentists from the UNC-Chapel Hill School of Dentistry. Dr. John Stamm, former Dean of the School of Dentistry at UNC-Chapel Hill, summarizes the current dental workforce situation in the state and recent appropriations by the North Carolina General Assembly to support planning for increasing dental school enrollment in North Carolina. In addition, the new dean of the UNC-Chapel Hill School of Dentistry, Dr. John Williams, describes the complexities of dental workforce issues that bear on the issue of dental class size. His commentary advocates support for an existing plan to expand enrollment at the UNC-Chapel Hill School of Dentistry by 50% (from 80 to 120 students per class).[25]

Developing a New School of Dentistry at East Carolina University. Another option for increasing the production of dentists in the state is to develop a new, second dental school. A commentary in this issue of the Journal, authored by Dr. Michael Lewis, Vice Chancellor for Health Sciences at East Carolina University (ECU) in Greenville, makes the case for a new, "community-oriented" school of dentistry at ECU.[26] The ECU proposal is to develop a school of dentistry that will attract individuals who would like to practice professionally in North Carolina communities that need high-level dental care, and have inadequate dental care access. As exemplified by the Brody School of Medicine and the ECU School of Nursing, ECU has a history and culture of exposing health sciences graduates to strategies for serving underserved populations. Moreover, a sizeable proportion of these graduates are motivated to stay in North Carolina and choose primary care as a career path. Therefore, this strategy could be used to reduce workforce shortages in underserved communities, which would improve access to care for underserved populations. Participants at the 2005 North Carolina Oral Health Summit agreed that there is a need to produce more dentists in this state, and they supported further examination of this issue to determine which of these strategies would be most appropriate and feasible.

Increasing the Number of Fellowship-Trained Pediatric Dentists. Finally, beyond the general dentist under-supply problem, there is a need for more fellowship-trained pediatric dentists in North Carolina. Pediatric dentists are very important because, according to the American Academy of Pediatric Dentistry, they provide a disproportionately higher amount of oral healthcare for underserved children and children receiving Medicaid. A 2000 Task Force report from the American Academy of Pediatric Dentistry found that between 1990 and 1998, the number of trained pediatric dentists in the United States declined from 3,900 to 3,600. This decline was attributed to a lack of pediatric training programs rather than a lack of interest in pediatric dentistry training.[27] The only graduate program for this specialty in North Carolina is at the UNC-Chapel Hill School of Dentistry. In this issue of the Journal, Drs. Michael Roberts and William Vann, Jr., offer an extensive discussion of issues related to the pediatric dental workforce and efforts to increase the supply of pediatric dentists.[28]

As a response to a perceived shortage of pediatric dentists, the Department of Pediatric Dentistry at UNC-Chapel Hill increased enrollment in the early 1990s from two residents per year to three using insecure funding sources. The success of this recent increase in pediatric residency programs has been very valuable, and it is important that it continues. The pediatric workforce is aging, and its future supply is projected to decrease. Additionally, pediatric dentists are still largely concentrated in urban areas and are unavailable in many communities. The 2005 Oral Health Summit participants supported strategies for continuing to increase the supply of pediatric dentists through continual support for increasing the number of pediatric dental residents at The UNC-Chapel Hill School of Dentistry and developing at least one additional pediatric residency program in North Carolina.

Clearly, there is a significant need to increase the number of both general and specialty dentists in North Carolina. However, doing so will require significant financial support. In addition, some of these strategies are controversial, and it will be important to evaluate each option closely before undertaking any of the initiatives.

Strategy Three: Increasing Dental Care Availability for Special Needs Populations

Many special needs patients have unique and more extensive barriers to accessing dental care than other demographic groups. Special needs patients often have cognitive and/or physical disabilities that require special care. Many of these patients live in nursing homes, assisted living facilities, or group homes. Even those living independently or with families in the broader community may have trouble accessing care for reasons such as transportation challenges or finding a provider willing to serve them. Dental professionals face a unique challenge when treating special needs patients because each patient is different. Some patients can be served in a traditional private practice environment, needing no additional time or services, while others must be served at their residence, require specific facility capabilities, and/or take significantly longer to serve than traditional patients.

Barriers to accessing dental health services arise from a variety of factors within the special needs community. For some, oral health is simply overlooked due to the patient's inability to provide self-care or a caregiver's lack of knowledge or training. Most dentists are not trained to deal with the needs of this population. Others find it too onerous, since most of the special needs patients are Medicaid recipients and, thus, services are reimbursed at low rates. Even dentists who treat special needs patients may refuse to treat severely uncooperative or disruptive patients because they lack the expertise or resources needed to care for these patients.[29]

Strategies for better serving the special needs populations were discussed at the 2005 Oral Health Summit. Recommended strategies included developing a data system for gathering information on the amount of training oral health students receive about serving special needs patients; teaching dental professionals techniques that would help practices integrate special needs patients into a more traditional patient base; establishing concentrated special needs clinics with appropriate facility and equipment needs in which dentists could be encouraged to provide part-time services; and developing additional Medicaid reimbursement codes for services to disabled/special needs populations. The commentary in this special issue of the *North Carolina Medical Journal* by Dr. William Milner[30] summarizes the complex issues surrounding the organization and provision of dental care to special needs populations and offers a number of concrete suggestions for how this care might be better managed.

Strategy Four: Increasing Public Awareness of the Importance of Oral Healthcare

Given the low rates of participation in the North Carolina Medicaid dental program by beneficiaries (only 27% of eligible beneficiaries in 2004 had at least one dental visit; the percentage for Medicaid beneficiaries 21 years of age or younger was 31%),[22] there has been a concern that the importance of dental care and good oral health practices needs further emphasis, especially among younger populations covered by this program. This is a problem of widespread significance within the general public. Even among those with dental care insurance, rates of utilization are far less than for conventional medical care. For this reason, it is considered important to continue to emphasize school-based educational programs in health education, which include units on oral health, prevention, and self-care.

Summary: Policy Options for Dental Care Access in North Carolina

As we move into the 21st Century, it is important that North Carolina can assure access to basic (primary) dental healthcare services for all populations. A focal point of this effort is centered around having sufficient numbers of dental healthcare professionals to provide needed services, and that these professionals will be willing to serve those with only a modest ability to pay for their care, especially when these individuals and families are covered by programs like Medicaid.

In this regard, six strategies warrant further consideration and debate as policy options for the future:

- Increasing the numbers of graduating dentists and dental hygienists entering practice in North Carolina, and especially those electing to practice in rural and underserved communities.
- Increasing the numbers of graduate-trained practitioners in general dentistry and pediatric dentistry.
- Allowing public health dental hygienists to perform dental preventive services in clinical settings outside of public health departments in order to extend the reach of these services to those most in need.
- Subsidizing the care provision taking place in remote rural areas or inner cities where those most in need are provided access to basic dental care.
- Training more dentists and hygienists and organizing care delivery programs to meet the needs of special care patients.
- Encouraging a greater level of voluntarism among dental care professionals to serve the needs of low-income populations in special clinical care programs, and through active participation in the North Carolina Medicaid program.

Defining the Need for Dental Care in North Carolina:
Contributions of Public Health Surveillance of Dental Diseases and Conditions

R. Gary Rozier, DDS, MPH, and Rebecca S. King, DDS, MPH

A long-standing principle held by epidemiologists who study the health status of human populations is that any disease can demonstrate important variation among people with different characteristics, across different geographic locations, and over time. Substantial fluctuations in the amount of disease can occur as the relative importance of diseases rises and falls, usually in response to scientific breakthroughs and widespread application of effective interventions, but often for unknown reasons.

The prevalence of dental diseases and their consequences are particularly prone to change because of the complex and interacting nature of their many biological, environmental, and social determinants. Dental diseases were at record highs during the first half of the 20th Century.[1] Few people went unaffected, and most could expect to loose some of their teeth by middle age. In the early 1960s, almost 3,000 students graduated from high school in North Carolina having lost all their teeth to the ravages of dental disease.[2] In the mid-1970s, the number of missing teeth among those in their sixth decade of life was two and one-half times greater than the number of filled or decayed teeth.[3]

National trends through the 1990s demonstrated several significant advances in oral health status during the last half of the 20th Century.[1,4] Primary among these changes were substantial declines in dental caries (tooth decay) in permanent teeth beginning in childhood and extending through young adulthood, modest reductions in destructive periodontal (gum) disease, and improvements in tooth loss and oral cancer mortality. Even with these improvements, however, dental disease still is recognized as a silent epidemic, with dental caries and periodontal diseases being among the most common of all diseases. Particularly hard hit are the poor, minorities, those living in remote geographic areas and those with special healthcare needs, creating large disparities in disease and in access to preventive and treatment services.

Important changes in public health practice, the field of dentistry, and the North Carolina population have occurred during the last few decades that should substantially affect the oral health of North Carolina residents. In this commentary, we briefly review the current status of dental diseases and trends that have direct relevance to issues involving access to dental care. Available data require us to focus primarily on children. We will use both clinically determined disease status as well as indicators self-reported in questionnaire surveys of the North Carolina population.

> *"After decades of remarkable improvements in the prevalence of tooth decay, the trend line seems to be leveling off or possibly increasing for primary tooth decay."*

North Carolina Oral Health Assessment Systems

A core function of dental public health is to monitor the burden of oral diseases and the availability of preventive and treatment services. The Institute of Medicine (IOM) of the National Academy of Sciences recommends that public health "…regularly and systematically collect, assemble, analyze, and make available information on the health of the community, including studies on health status, community health needs,

and epidemiological and other studies of health problems."[5] The oral health surveillance system for North Carolina is one of the more comprehensive in the nation and is responsive to this IOM recommendation and historical precedents for public health practice.

The surveillance for oral health in North Carolina consists of several major elements. Periodically, a scientific sample representative of the entire state or subgroups of its population are selected to participate in dental examinations and interviews. Four of these surveys have been conducted, all with large samples and good response rates. The first two of the four surveys provided estimates for dental disease for the North Carolina population of all ages in 1960-1963[6] and 1976-1977.[3] The second two provide comparable estimates for school children in kindergarten through 12th grade in 1986-1987[7] and 2003-2004.[8] The North Carolina Oral Health Section also conducts annual surveillance of dental caries and its treatment in kindergarten and fifth grade. Assessments began in the 1996-1997 school year and continue with open-mouth dental screenings by trained dental professionals of about 80% of all children in these grades in almost all of North Carolina's counties.[9]

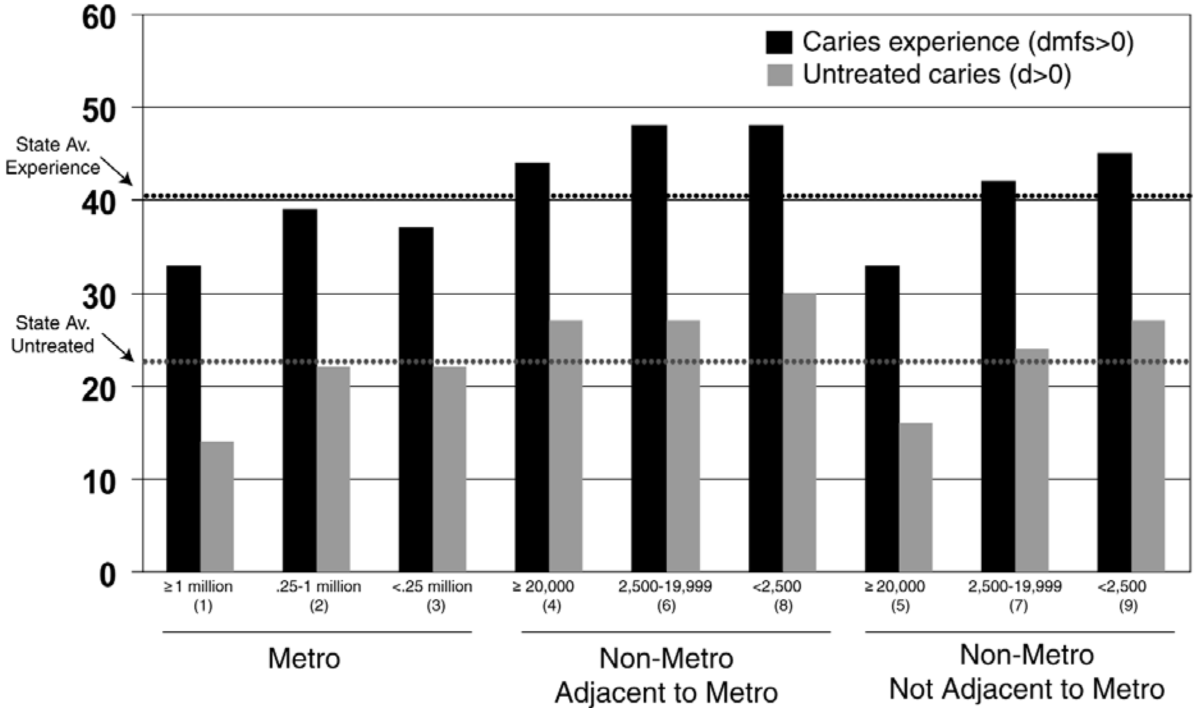
North Carolina participates in the Behavioral Risk Factor Surveillance System (BRFSS), a random telephone survey of the state's residents 18 years of age and older.[10] This survey, done in all states, provides information on dental use and outcomes in North Carolina that is collected in a routine, standardized manner at the state level and for a few larger counties. This system was expanded in January 2005 by the Child Health Assessment and Monitoring Program (CHAMP) survey.[11,12] CHAMP is the first telephone survey of its kind in North Carolina to measure access to dental care, dental utilization, and outcomes of children from birth to 17 years of age, thus providing a seamless account of dental care access and outcomes for the entire state from birth into adulthood.

Other components of the oral health surveillance system for North Carolina include detailed information about water fluoridation and oral cancer incidence and mortality, but information from these elements of the system is not included in this commentary.

Oral Health Status of North Carolina's Population

Key indicators for the oral health of North Carolinians are presented in Table 1 (see page 440), most of which are taken from the 2003-2004 survey of school children. Several findings are evident from these data. First, a large percentage of children

Figure 1.
Percent with Caries Experience and Untreated Caries by North Carolina County Rural-Urban Continuum Codes, Kindergarten Students, 2003-2004



(1) Anson, Cabarrus, Gaston, Mecklenburg; (2) Alexander, Brunswick, Buncombe, Burke, Caldwell, Catawba, Chatham, Cumberland, Davie, Forsyth, Franklin, Haywood, Henderson, Hoke, Johnston, Madison, New Hanover, Orange, Pender, Person, Randolph, Rockingham, Stokes, Yadkin; (3) Alamance, Edgecombe, Greene, Nash, Pitt, Wayne, Onslow; (4) Carteret, Cleveland, Davidson, Halifax, Harnett, Iredell, Lee, Lenoir, Lincoln, Moore, Richmond, Robeson, Rowan, Rutherford, Surry, Vance, Wilson; (5) Craven, Dare; (6) Beauford, Bladen, Columbus, Duplin, Granville, Jackson, Martin, McDowell, Montgomery, Sampson, Scotland, Stanley, Transylvania, Watauga, Wilkes; (7) Hertford, Macon, Washington; (8) Avery, Caswell, Gates, Jones, Polk, Swain, Yancey, Warren; (9) Alleghany, Ashe, Bertie, Cherokee, Clay, Graham, Hyde, Mitchell, Northampton, Pamlico, Tyrrell.

are affected by tooth decay, and the severity, as measured by the mean number of decayed, missing, and filled surfaces per child (dfs or DMFS), among those affected is high. Second, a large percentage of parents report that they believe that their children need dental treatment, such as fillings, teeth pulled, or cleanings. This self-reported need is supported by actual clinically determined need through the oral health survey in 2003-2004. About 31% of North Carolina children have untreated decay in primary

Table 1.
Oral Health Status Indicators for North Carolina, 2003-2005

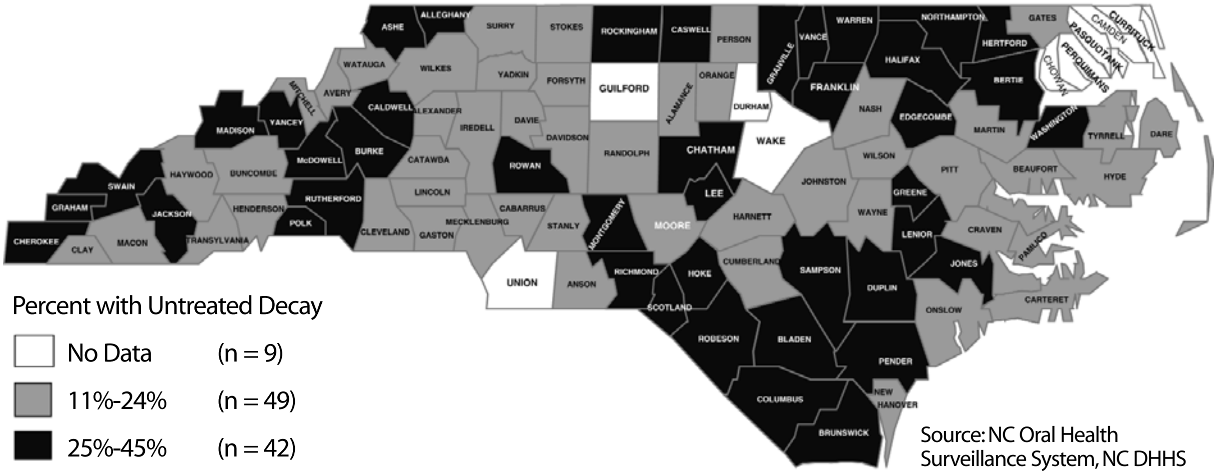
Condition	Overall[†]	Non-Hispanic White	Non-Hispanic African American	Hispanic
Disease Experience				
% any caries in primary teeth (5-9 year olds)	53.7	49.8	55.1	65.0
Mean dfs per child with any caries (5-9 year olds)	8.8	8.5	8.1	11.0
% any caries in permanent teeth (6-17 year olds)	37.5	35.7	41.6	35.7
Mean DMFS per child with any caries (6-17 year olds)	4.4	4.1	5.1	3.9
% any caries in either tooth type (5-17 year olds)	55.8	53.2	58.2	61.3
% clinical evidence of incisor trauma (6-17 year olds)	11.8	10.6	14.1	8.6
% parent reporting serious trauma (5-17 year olds)	10.7	11.5	9.3	8.6
Untreated Disease				
% with 90% of untreated primary tooth decay (5-9 year olds)	19.7	16.9	22.1	28.8
% with any untreated primary tooth decay (5-9 year olds)	30.8	25.7	37.0	41.4
Mean decayed primary tooth surfaces per child among those with any decay (5-9 year olds)	5.1	4.6	5.3	5.8
% with 90% of untreated permanent tooth decay (6-17 year olds)	10.0	9.1	11.4	10.7
% with any untreated permanent tooth decay (6-17 year olds)	13.4	10.6	18.2	16.5
Mean decayed permanent surfaces per child among those with any decay (6-17 year olds)	2.6	2.2	2.9	2.8
Demand				
% parents reporting child needs treatment (5-17 year olds)	51.5	42.4	67.5	60.3
% parent reporting wanted care, but did not get it (5-17 year olds)	60.1	65.8	49.6	72.2
% children ever experienced dental pain in lifetime (kindergarten-third grade)	23.5	19.1	28.2	32.2
% children experienced dental pain at least once in last 3 mos. (grades 4-12)	31.0	28.8	36.4	26.5
Outcomes				
% children's health rated fair or poor by parent 1-4 year olds	6.6	‡	‡	‡
5-17 year olds	16.4	10.9	22.5	36.3
% adults with tooth loss (18 years and older)				
Some tooth loss because of tooth decay or gum disease, but not all	44.7	41.6	58.0	25.2
Complete tooth loss because of tooth decay or gum disease	9.3	9.5	11.0	3.9

[†] Denominator includes all race and ethnic groups.

[‡] Preliminary estimates from CHAMP, 2005. Sample sizes do not permit estimates by race or ethnicity.

Notes: All estimates are from the 2003-2004 oral health survey of schoolchildren except parents' perceptions of oral health of children one to four years of age and tooth loss, which are from the CHAMP[11] and BRFSS,[10] respectively.

Figure 2.
Percent of Kindergarten Students with Untreated Dental Caries by County, 2003-2004



Source: NC Oral Health Surveillance System, NC DHHS

(baby) teeth; 13% in permanent teeth. A third interpretation from data presented in Table 1 is that untreated tooth decay is highly concentrated in a small percentage of children. With regard to outcomes, a large percentage of adults overall lose teeth because of dental disease, and this is highly age-dependent, probably reflecting inadequate access to dental care and values held years ago. Finally, disparities by race and ethnicity exist for most of the indicators, with Hispanics being much worse than whites on many important indicators. African Americans have indicators that usually fell between those of the other two groups.

Surveillance data on caries experience and untreated dental caries in kindergarten students are presented in Figure 1 according to a scheme used by the federal government to classify United States counties according to their rurality.[13] Each county in North Carolina has been classified according to the population size of its metropolitan (metro) area if it has one, and nonmetropolitan (nonmetro) area according to its degree of urbanization and adjacency to a metro area. A nonmetro county is defined as adjacent to a metro county if it physically adjoins one of the state's metro areas and has a least 2% of its employed labor force commuting to central metro counties. Both dental caries experience and untreated tooth decay differ by population size of the county and its adjacency to a metro area. Children in nonmetro counties that are adjacent to a metro county have more caries experience and untreated decay than children in other types of counties, regardless of population size. Between 40% and 50% of children in these nonmetro counties of all three size categories show obvious signs of tooth decay, and close to 30% have some untreated decay. Within each of the three metro and nonmetro classifications, caries experience and untreated decay generally increase as the population size decreases, particularly in those counties not adjacent to metro areas.

A county-specific geographic distribution of untreated decay in kindergarten students is displayed in Figure 2. As many as one out of every four kindergarten students in 42 counties begin school with untreated decay. This number is as high as one out of every three students in a dozen of these counties. Most of the counties with students who experience large amounts of caries and receive a small amount of treatment are located in northeastern, southeastern, or western counties.

Trends in Dental Diseases in North Carolina

Remarkable improvements in dental caries have occurred in the permanent dentition of school-aged children in North Carolina over the last 40 years. Trends in 12-17-year-old children are presented as an example of these improvements (see Figure 3). Lifetime caries experience is presented as the mean of the person-level count of decayed, missing, and filled teeth (i.e., the DMFT index, a standard epidemiologic tool designed for these

Figure 3.
Trends in Dental Caries (DMFT) in 12-17-Year-Old Children, North Carolina

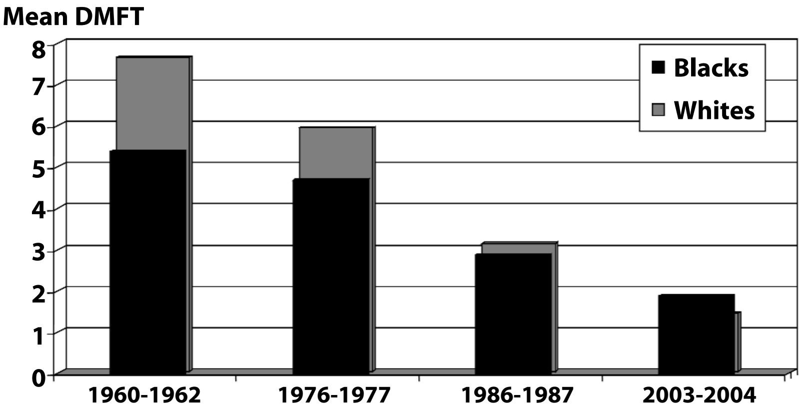


Figure 4.
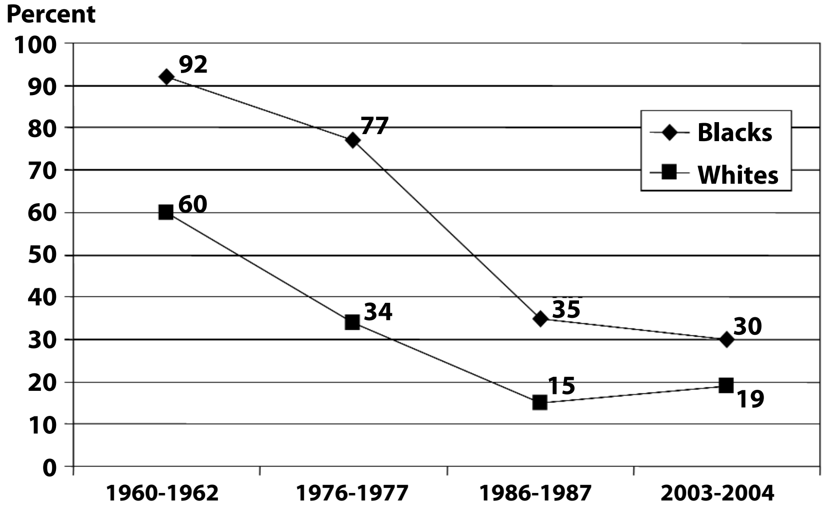
Trends in Untreated Decay (%DT/DMFT), in 5-17-Year-Old Children, North Carolina



purposes). The mean DMFT score per person declined by 82% in white adolescents between 1960-1962 and 2003-2004 from 7.6 per person to a low of 1.4. A reduction of 65% occurred in black adolescents. The decrease in mean DMFT per person from 5.4 to 1.9 is likewise impressive. Along with the decline in the occurrence of tooth decay, the proportion that is untreated also has declined, and by a substantial amount (see Figure 4). Most of this change occurred, however, between 1960-1962 and 1986-1987. The amount of untreated decay did not change much between 1986-1987 and 2003-2004 (see Figure 4).

Trends in primary tooth decay are not as favorable as for permanent teeth. After years of decline, trendlines in the prevalence of caries in primary teeth have leveled off or appear to have even increased in some groups of children between 1986-1987 and 2003-2004 (see Figure 5). The increase is particularly striking for children whose caregivers have less than a high school education. Surveillance data suggest that most of this increase probably occurred in children born in the mid- to late-1990s and, thus, entered kindergarten in the early 2000s and thereafter.

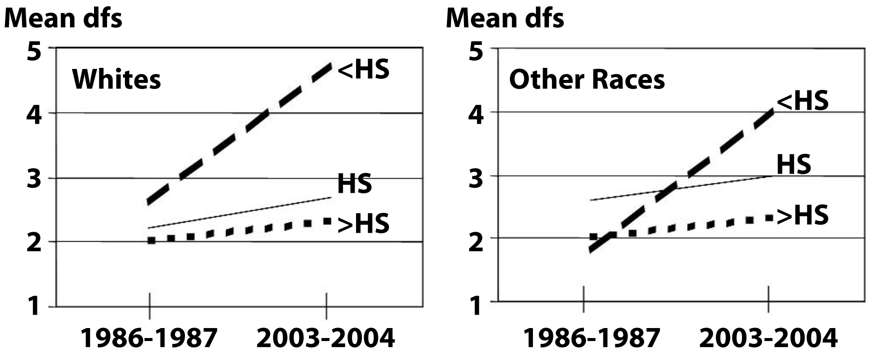
Discussion of Key Findings from Oral Health Surveillance

The key indicators reviewed in this commentary suggest that substantial improvements in the prevalence and severity of tooth decay, the major dental disease affecting children and young adults in North Carolina, have occurred over the last 40 years. Multiple factors are likely to have contributed to these changes in disease status. A comparison of a few of the possible dental experiences of adolescents born in the 1950s with those born in the 1990s, roughly the cohorts being compared in 1960-1963 and 2003-2004 as 12-17 year olds in Figure 3, reveals major differences.

Of significance is the increase in preventive programs. In the 1950s, only 15% of the North Carolina population was drinking fluoridated water, while other public health preventive programs, such as school water fluoridation and fluoride mouthrinse programs in schools were nonexistent. Fluorides were rarely a part of preventive services provided in private dental offices, and less than 20% of children used fluoridated toothpaste. By the 1990s, more than 80% of the population served by municipal drinking water systems was drinking fluoridated water. A significant portion of the remaining child population was exposed to systemic fluorides through the school water fluoridation program, to topical fluorides in public health mouthrinse programs, or applications in dental office settings. A major contribution to the downward trend in tooth decay has been the increase in use of fluoridated toothpaste. By the 1990s, almost everyone who brushed their teeth was using fluoridated toothpaste. Although not presented, our survey results also show that in 2003-2004, close to 60% of adolescents had one or more dental sealants, surpassing the national goal of 50% set for 2010.

The availability of dental services also increased during this 40-year period. In the 1950s, only one dentist for every 4,000 people practiced in the state.[14] They employed fewer than 100 dental hygienists. By the 1990s, the ratio had improved to one dentist for every 2,500 people.[15] Public health workforce supply also increased rather dramatically during this period. In the 1950s, only about

Figure 5.
Trends in Caries (dfs) in 5-9-Year-Old Children, by Parent Education Level, North Carolina



Note: HS = high school

30 public health dentists worked for the state in school-based programs, and the state employed no public health dental hygienists. Only a few local health departments had dental clinics. By the 1990s, a network of more than 100 public health dentists and dental hygienists was providing services in almost every county.

Demand for dental services also likely grew rather dramatically after the 1950s because of changing norms about dental health. The significant increase in dental insurance coverage, which was not available to the earlier cohort of adolescents, but had grown to be more than 50% when the later cohort was growing up, also was likely to be a contributing factor to the increase in demand for care.[16]

These changes in tooth decay mirror trends in dental disease nationwide. Between 1988-1994 and 1999-2002, the two most recent national surveys, a reduction in the prevalence of caries in permanent teeth of up to 10% was observed among persons six to 19 years of age and up to 6% among dentate adults 20 years of age and older.[4] While we do not have recent information about dental caries or periodontal diseases for the adult population of North Carolina, national information suggests that destructive periodontal disease should have improved as well.[17] The North Carolina BRFSS indicates improved tooth retention in adults, an important outcome measure of oral health status. The growing number of people with more teeth can increase the need for dental care, although this need can be counterbalanced by a shift in types of dental procedures from treatment to diagnostic and preventive. While not addressed in this commentary, publications from the North Carolina State Center for Health Statistics suggest declines in oral cancer incidence during the 1990s in most population groups.[18]

This review of surveillance information available for North Carolina also suggests that in the face of these improvements, a large percentage of the population continues to have unmet need and suffer its consequences on oral health-related quality of life. The public's demand for dental services is much more difficult to measure than unmet clinical need or even self-reported need for care. However, responses to the one question asked of parents in the most recent school survey most directly related to demand for dental care suggests that excess demand does exist, ranging from about 21% to 36% depending on race and ethnicity. The extent to which these children and adolescents are able to get dental care in North Carolina depends on a number of factors, many of which present significant barriers to realizing their desire for dental care.

Large disparities in oral health status and access to dental services continue to exist in the state. We chose to present disparities by race and ethnicity, rurality and geographic location, but clear disparities also are apparent by other characteristics of individuals, such as their age and poverty status. The analysis of untreated dental caries found that statewide roughly one out of five children have untreated decay in primary teeth when they start school, but many counties have as many as one of four young children in this condition, 24 counties with one out of three. These counties clearly cluster in sections of the state known to have other health and social disadvantages. Untreated disease also clusters in a small number of people. The ubiquitous distribution of tooth decay among children has shifted so that most are not affected in their permanent teeth at any time during their childhood, and only 10% to 20% of those who are affected have almost all of the untreated disease.

Statistics for dental caries presented in this commentary are for obvious carious lesions. We did not include non-cavitated lesions, nor were radiographs used for any determinations of caries status. The true amount of tooth decay in the North Carolina population is underestimated, probably by about 35% to 40% based on the exclusion of noncavitated lesions alone. Noncavitated lesions are responsive to fluoride therapy and other preventive interventions, which implies the need to continue programs that emphasize preventive strategies that will prevent noncavitated lesions from progressing to the stage that they need restorative intervention.

Implications for Public Health Action

Several conclusions with important implications for public health can be drawn from this review. After decades of remarkable improvements in the prevalence of tooth decay, the trend line seems to be leveling off or possibly increasing for primary tooth decay. Smaller reductions in decay prevalence are evident in the permanent teeth of today's young children than in those in the past. So far, this effect seems to be most pronounced in children born during or after the mid-1990s. These trends are consistent with national trends through 2001, providing some support for the conclusion that these observations in North Carolina reflect actual trends.[4] These emerging trends need to be monitored closely so that we can determine if they represent statistical fluctuations around what are historic low levels of decay, or if we are observing the early signs of a trend toward more disease.

Nevertheless, investigations need to be undertaken into the possible reasons for what appear to be unfavorable trends in dental disease. We may be seeing the early indications of increased disease—the consequence of a reduced availability of preventive dental services, particularly school-based services. The rapid growth of the North Carolina population overall and, more specifically, the number of people at elevated risk for disease, may be straining the capacity of the dental care system to respond to public needs and demands. Key factors related to the demand for dental services, such as the importance the public places on oral health, may also be a contributing factor. A better understanding about why these trends are occurring would help guide public policy.

Progress has been made since the early 1960s in reducing disparities in dental disease and access to care between whites and African Americans living in North Carolina. The growing Hispanic population, who have more disease than its non-Hispanic counterparts, may be eroding the gains made in reducing these disparities. Programs that can help eliminate disparities in dental disease and access to dental care are needed. Approaches will require implementation of innovative strategies, such as: the current *Into the Mouths of Babes* program that encourages physicians to provide preventive dental services for very young, low-income children; expanding existing community-based programs; or restoring discontinued community-based programs that helped us achieve the observed major reductions in dental disease during the 1960s, 1980s, and parts of the 1990s.

Wide concern has been expressed about the lack of access to dental care in North Carolina and nationally, particularly for children from low-income families and for preschool-aged children overall. This concern is bolstered by information abstracted from surveillance systems in North Carolina. Many young, school-aged children have untreated decay, but the overall amount of untreated decay is highly concentrated in a small segment of the population. Untreated decay in older, school-aged children, although less prevalent, is even more concentrated in a small number of children. Addressing the dental needs of these very high-risk children will require intense and concentrated efforts involving multiple strategies.

Finally, the ability to examine trends in dental disease in some detail for North Carolina demonstrates the value of the oral health surveillance system in North Carolina. The surveillance system has matured over the years, but still has limited ability to monitor adult oral health status in general and the oral health status of some minorities, such as American Indians or Asians, who are a small proportion of the state's population, at the level of detail possible with other population groups. The oral health status of adults needs to be brought under surveillance so that the oral health conditions of children being born today can be monitored as they grow into adulthood.

Acknowledgements: The 1960-1962 survey was supported in part by a grant from the Public Health Service Grant No. DH 00003 from the Health Resources Administration. The 1976-1977 survey was supported in part by a grant from the W.K. Kellogg Foundation. The Kate B. Reynolds Charitable Trust provided partial support for conducting the 1986-1987 survey. The Centers for Disease Control and Prevention provided funds through Grant No. U48/CCU415769 to help support the 2003-2004 study.

Special recognition is given to the dozens of state and local public dentists and dental hygienists working in dental public health over the last 40 years who helped collect data on which this commentary is based. **NCMedJ**

COMMENTARY

The Dentist Workforce in North Carolina 2005:
A Commentary

John W. Stamm, DDS

This commentary, delivered at the North Carolina Oral Health Summit 2005, presents a basic assessment of the currently active dentist workforce situation in North Carolina. The assessment suggests that North Carolina's dentist workforce supply, while qualitatively excellent, is quantitatively insufficient, ranking North Carolina 47th out of 50 states. In addition, like many states, North Carolina is experiencing significant maldistribution in its supply of dentists. Moreover, the massive projected population growth, changing demographics, disease trends, alterations in demand for care, and potentially significant changes in dental practice styles all further reinforce the view that North Carolina urgently needs to develop substantially increased capacity for enrolling and graduating high quality dentists.

Within acknowledged limitations, the present analysis offers a number of conclusions: *One*, there is an urgent need for dentist workforce expansion in North Carolina based upon the existing dentist shortage, the current maldistribution of dentists, and the very strong North Carolina population growth projected out to 2030 by the United States Census Bureau. *Two*, North Carolina's goal should be to position its dentist-to-population ratio to rank somewhere near the national median of 6.0 dentists per 10,000 population. *Three*, to achieve its need for more dentists, North Carolina should rapidly pursue significant dental student enrollment expansion. *Four*, dental student enrollment growth should be linked with North Carolina Area Health Education Center programs to encourage training in appropriate rural and underserved community settings. *Five*, expansion in dental and dental hygiene enrollment should provide admission priority to academically qualified candidates from rural North Carolina. *Six*, expansion should be considered for General Dental Practice Residency programs and Pediatric Dentistry Specialty programs.

Introduction

The opportunity to examine the status of North Carolina's dental workforce comes at a critical time. On one hand, caries rates among school children and adolescents continue to decline, relatively fewer extractions are being performed, fewer adults are becoming edentulous, and a majority of North Carolina citizens are receiving excellent oral healthcare services. Nevertheless, as one looks forward, the state faces increasingly serious dental, oral, and craniofacial healthcare challenges. For North Carolina's oral healthcare system, whether in the private or public sectors, the current and growing challenge is to provide the population with adequate access to professional dental care in all counties of the state, but especially for rural and economically disadvantaged populations, regardless of where they live. The dental care access problem in North Carolina is acute and getting worse.

"[A] severe shortage of dentists... has emerged in North Carolina. ...North Carolina currently ranks 47th of the 50 states in terms of the dentist-to-population ratio."

Contrast this with the situation nearly 30 years ago, when data from the 1976 North Carolina Dental Disease Prevalence Survey, and the National Health and Nutrition Examination Survey (NHANES), permitted Schonfeld and Warren-Hicks to write, "The dental care system in North Carolina is considerably underutilized in each of the six Health Service Areas due to the low level of demand for dental care. It is expected that this underutilization will result in a drop in productivity in future years due to the four percent annual net increase in dental manpower. The

North Carolina population has been increasing at an annual rate of one percent."[1] Surveying the North Carolina dental manpower growth between 1972 and 1979, Konrad and DeFriese wrote, "These data show a steady growth in the number of licensed dentists over the period 1972 to 1979. Since the year 1972, the average annual net growth in the supply of dentists in the state has varied between 3.1 and 4.9% per year, with an average net growth rate of about four percent."[2] In contrast, and from the perspective of 2005, it is very clear that North Carolina has changed dramatically since the mid-1970s, and for many persons in the state, gaining access to needed and adequate dental, oral, and craniofacial healthcare has become a more difficult and/or unaffordable proposition.

While acknowledging some over-simplification, the current and likely future access to dental care challenge faced in North Carolina appears to arise from a confluence of four distinct elements or trends:

- *Deterioration of Dental Medicaid.* North Carolina's Medicaid dental reimbursement rates deteriorated during the 1980s and 1990s. Not only that, significant coverage restrictions were also imposed in the early 2000s.
- *Shortage of Dentists.* A severe shortage of dentists has emerged in North Carolina. In the United States, North Carolina currently ranks 47th of the 50 states in terms of the dentist-to-population ratio.
- *Mal-distribution of Dentists.* In North Carolina, as in most other states, and as is true for many other service professions, the distribution of dentists has continued to evolve to the disadvantage of the state's rural populations.
- *Massive Population Growth.* The United States Census Bureau projects that among the states, North Carolina will jump from being the tenth to the seventh largest in population in 25 years. The Census Bureau estimates the 2000-2030 relative population growth will be 29.2% for the United States, but 51.9% for North Carolina.

In consideration of these factors, in 1998, the North Carolina General Assembly charged the North Carolina Department of Health and Human Services (DHHS) with exploring the dental care access issue and recommending strategies for improving the situation. Specifically, the legislature asked the North Carolina DHHS to develop strategies for:

- Assisting dentists in increasing the number of Medicaid patients they treat;
- Increasing Medicaid patients' access to quality dental services;
- Teaching dental professionals how to better integrate Medicaid and other low-income patients into their practices; and
- Expanding the capacity of local health departments and community health centers to provide properly diagnosed and supervised preventive services, such as sealants, fluoride, and basic dental hygiene treatments to low-income patients.

The legislature's charge to the North Carolina DHHS deserves closer attention. Three of the four concerns to be studied, and strategies to be developed, focused on North Carolina Medicaid issues as they related to dentistry. The fourth area of focus was on local health departments and community health centers and their capacity to offer preventive dental services. In the legislature's charge itself, no direct reference was made to the supply of the privately practicing dental workforce in North Carolina. Yet, privately practicing dentists constitute over 95% of the dentist workforce in the state.

On receiving its charge, the North Carolina DHHS contracted out the task of evaluating the four issues identified and recommending appropriate corrective strategies to the North Carolina Institute of Medicine (IOM). The North Carolina IOM formed a high-level, blue-ribbon Task Force on Dental Care Access that undertook the study and released its report in May 1999.[3] The report included 23 recommendations.

Since that time, a good deal has been accomplished in implementing most of these recommendations, or parts thereof. Implementation efforts have included: (1) significant new legislation, (2) changes to dentist licensing procedures by the North Carolina State Board of Dental Examiners, (3) generous funding from the Kate B. Reynolds Charitable Trust for new and expanded community dental clinics, (4) changes in legally permitted duties for dental hygienists in public health clinics, (5) refinement in contract terms for dentists qualifying for support through the state's Office of Research, Demonstrations and Rural Health Program Development, and (6) some additional funds for children's dental care through North Carolina Medicaid. The North Carolina IOM has provided a particularly useful service by issuing follow-up reports in 2001, 2003, and 2005, which tracks the progress made on the original 1999 recommendations.[4,5]

The North Carolina IOM Recommendations on Dental Workforce

In spite of the fact that no direct reference to North Carolina's dental workforce supply appeared in the legislature's original charge to North Carolina DHHS, the North Carolina IOM study recognized that dental workforce supply concerns existed and needed attention. In its 1999 Report, the North Carolina IOM Task Force on Dental Care Access offered nine recommendations for "increasing the supply of dentists and dental hygienists in the state with particular focus on recruiting dental professionals to practice in underserved areas and to treat underserved populations."[3] These appeared as recommendations 4-12 in the report and will not be reproduced here.

Importantly, however, the nine dental workforce recommendations emphasized issues related to, or for the most part restricted themselves to, the Medicaid and the local/community health centers' components of the legislature's original charge to the North Carolina DHHS. Two important exceptions were the recommendation that the North Carolina State Board of Dental Examiners (SBDE) establish a licensure-by-credentials pathway, and that the SBDE also consider whether existing regional (i.e., multi-state) dental examining boards could form yet another pathway to dental licensure in North Carolina. The first of those two pathways has been implemented.[6] The second of these two pathways appears on track for future implementation. But, the North Carolina IOM was not charged to undertake a comprehensive dental workforce study, and it did not do so. As a result, several large-scale dental workforce issues, with important public policy implications for North Carolina, were not addressed in the North Carolina IOM Report.

The North Carolina Legislature Begins to Address Concerns over Dental Workforce Supply

The legislature's major response to the 1999 North Carolina IOM Report was the 2001 introduction and passage of Senate Bill 861, which, among other achievements, set into motion a study to evaluate the feasibility of increasing North Carolina's capacity to train dentists.[6] Specifically, the legislature charged the University of North Carolina Board of Governors to evaluate alternative approaches for enrolling, training, and graduating more dental students in North Carolina. The Board recruited a team of external consultants to conduct the study and generate a report with recommendations for the Board.[7] The Board of Governors received, whetted, and formally approved the report and delivered it to the legislature in July 2002.

The consultants' recommendations contained in the Board of Governors report called for a significant and rapid enrollment increase, from 80 to 105 dental students, at the University of North Carolina at Chapel Hill (UNC-Chapel Hill). There has been concrete follow-up on this recommendation, and UNC-Chapel Hill has submitted an enrollment expansion plan, through the Board of Trustees and the Board of Governors, to the North Carolina legislature. The legislature has, in turn, authorized planning funds for this initiative, which has now been expanded to increase enrollment by 50 students per class, specifically by going from 80 to 130 admitted dental students per year.

The Board of Governors' study for the legislature also recommended that the General Dentistry Residency Program at East Carolina University (ECU) be significantly expanded, and that ECU consider the establishment of a pediatric dental residency program. The Board's report further recommended that ECU evaluate the feasibility of establishing a dental hygiene program. Subsequently, ECU submitted a request for planning funds to expand their General Dental Practice Residency Program, but the legislature did not appropriate funds for their request. To date, it appears that ECU has not acted to implement the other recommendations related to training programs in pediatric dentistry and dental hygiene.

Dental Workforce in North Carolina 2005: A Brief Overview

On January 1, 2004, North Carolina had 3,483 active in-state dentists and 4,052 in-state licensed dental hygienists.[10] In that same year, North Carolina's dentists practiced in 96 of the state's 100 counties. Still referencing the start of 2004, North Carolina's dentist-to-population ratio stood at 4.1 dentists per 10,000 people, compared to the national figure of 6.0 dentists per 10,000 people. An examination of dentist-to-population ratios in all 50 states in 2004 revealed that North Carolina's dentist-to-population ratio ranked 47th out of 50 states.[11] Table 1 provides some basic information for placing the state's dental workforce concerns into a relevant context.

Table 1.
Dental Workforce Context, North Carolina, 2004

North Carolina population in 2003—8.4 million

Population Growth 1990-2000:
North Carolina—21.4%
United States—13.1%

Annual North Carolina dental expenditures $1.65 billion

3,483 active in-state dentists (81% generalists)

Distribution (96 counties have one or more dentists)

North Carolina has 4.1 dentists per 10,000 population
(National figure is 6.0 per 10,000)

North Carolina's dentist-to-population ratio ranks 47th among 50 states

4,052 in-state licensed dental hygienists

Table 2 provides more detailed information about the rate of growth in the dentist workforce in both North Carolina and the United States between 1976 and 2003. These data indicate North Carolina's dentist-to-population ratio has been virtually flat since 1987. Moreover, the national dentist-to-population ratio has been consistently 40-50% higher than North Carolina's.

Turning to the stock of dental hygienists in North Carolina, Table 3 shows that the number of active dental hygienists has grown from 1,368 dental hygienists in 1979 to 4,052 in January

Table 2.
Dentist Workforce, United Sates and North Carolina, 1976-2003

	United States			North Carolina		
Year	**Population** *(millions)*	**Active Dentists**	**Dentist-to-Population Ratio** *(per 10,000 population)*	**Population** *(millions)*	**Active Dentists**	**Dentist-to-Population Ratio** *(per 10,000 population)*
1976	217.6	110,300	5.1	5.6	1,900	3.4
1987	242.3	137,800	5.7	6.4	2,600	4.1
1992	254.9	152,900	6.0	6.6	2,700	4.1
1995	264.6	158,600	6.0	7.2	2,900	4.0
2000	281.5	166,000	5.9	7.8	3,100	4.0
2003	290.3	173,600	6.0	8.5	3,500	4.1

Table 3.
Active Dental Hygienists per 10,000 Persons in North Carolina, 1979-2003

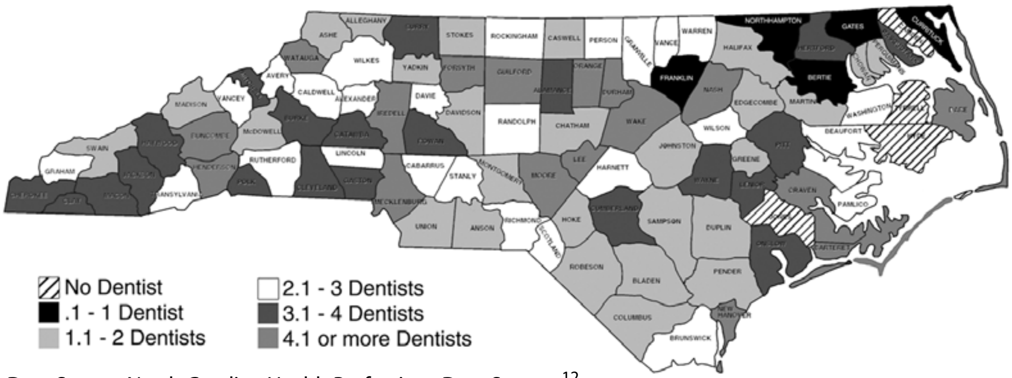
Year	Licensed Dentists per 10,000 Population	Active Dental Hygienists per 10,000 Population	Active Hygienists	Dental Hygienists-Dentist Ratio
1979	3.8	2.4	1,368	0.62
1989	4.1	3.3	2,190	0.82
1998	4.0	4.5	3,395	1.12
2003	4.1	4.8	4,052	1.18
Change Percentage (1979-2003)	7.9%	100%	199.3%	

2004, a 199.3% increase. In terms of the ratio of dental hygienists per 10,000 population, this too has grown from 2.4 in 1979 to 4.8 in 2004, a 100% increase in the ratio. In contrast, the dentist-to-population ratio grew by only 7.9% over the same period. These two disparate growth rates account for the improvement in the ratio of dental hygienists-to-dentists. In 1979, there were 0.62 dental hygienists for every licensed in-state dentist. By January 2004, the ratio had changed, indicating 1.17 dental hygienists for every North Carolina active, in-state dentist.

The Distribution of Dentists in North Carolina

Beyond concerns about the adequacy in the overall supply of dentists in North Carolina, the dental care access problem is significantly compounded by the uneven distribution (hence, the availability) of dentists across the state's 100 counties. Figure 1 indicates the number of dentists per 10,000 people in each of the state's counties, as reported for 2003.[12] Most revealing is that only eight North Carolina counties have a dentist-to-population ratio that approaches or exceeds the United Sates average of 6.0 dentists per 10,000 people. This explains, in large measure, why 79 North Carolina counties are federally designated dental shortage areas.[13] In North Carolina, 28 counties are served by two dentists or fewer per 10,000 population. These workforce distribution concerns need to be evaluated against the continuing high population growth in North Carolina, and the expected impact of that population growth in terms of the future availability of professional dental services in both urban and rural counties.

Figure 1.
Number of North Carolina Dentists per 10,000 Population, by County, 2003



Data Source: North Carolina Health Professions Data System.[12]

Productivity and Quality Increases by Dentists and the Dental Team

Almost all good economic analyses of dental workforce supply recognize that it is the supply of dental services, not simply the supply of dentists, dental hygienists, dental assistants, and dental technicians, that is critical to the population. This is a valid and important distinction. In recent decades, the dental team has demonstrated continuing increases in service productivity (and quality) per unit of time. In acknowledging the significance of productivity and quality increases, these have their weakest impact where the stock of dentists is low and/or where the available dentists are aging and may be past their most productive years. While it is only speculation, it does appear that older dentists close to retirement constitute a substantial proportion of the supply of dentists in rural North Carolina counties.

Access to Dental Care in the Face of North Carolina's Population Growth

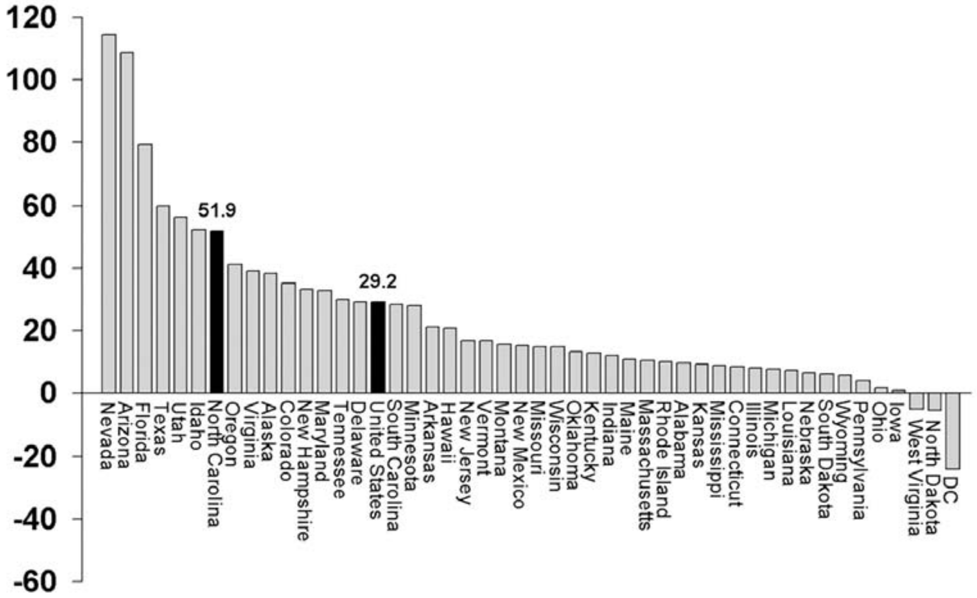
Beyond the dentist workforce shortage and dental care access concerns in 2005, the projected population growth in the state will greatly magnify the problems that currently exist. The challenge of providing future dental care services for North Carolina's population will, therefore, become more formidable with each passing year. North Carolina is currently the tenth largest state, on top of which it is also one of the fastest growing states.[8] Already during the 1990-2000 decade, United States Census Bureau data show that North Carolina's population grew by 21.4%, compared to the United Sates population that grew by only 13.1% for the same period.[9]

Looking ahead, the continuing population changes for North Carolina are even more dramatic. Figure 2, adapted from recent United States Census Bureau estimates, illustrates that in terms of absolute population growth during 2000-2030, North Carolina will experience the 5th largest population increase among the 50 states.[15] Based on these estimates, North Carolina's population is projected to be 4.2 million larger in 2030 than in 2000. It is remarkable that, for the period 2000-2030, the total United Sates population is expected to grow by 29.2%, while over the same period North Carolina's population is projected to grow by 51.9%.[15]

Assuming that the United States Census Bureau provides the most reliable population projections available, the preliminary implications for the dental workforce needed by North Carolinians in 2030 are staggering. Two scenarios may be considered. Under the first scenario, North Carolina will continue to rank 47th out of 50 states and maintain its dentist-to-population ratio of 4.1 per 10,000 population. Just 25 years from now, to maintain the current ratio, North Carolina will require approximately 5,500 active dentists, in contrast to the 3,606 active as of January 1, 2005.[16] Under the second scenario, in which the national dentist-to-population ratio norm is adopted for North Carolina, the state will need 6,320 active dentists in 2030.

The impact of dentists retiring from active practice deserves more explicit consideration when considering future dentist workforce needs. Assuming a typical 35-year career span for dentists and a rectangular age distribution, it becomes apparent that approximately 3.0% of active dentists retire or otherwise leave dental practice each year. In North Carolina, this suggests that approximately 95-105 dentists each year leave active practice, with that number going up as the workforce slowly expands. To place the impact of dentists retiring from practice into perspective, the UNC-Chapel Hill School of Dentistry currently graduates 75-80 dentists per year, not enough to replace those leaving practice. This situation has existed for some time. These and other issues cited above deserve careful and intensive attention as North Carolina considers its need for more dental education capacity.

Figure 2.
Absolute Population Growth (in thousands) by State: 2000-2030



Adapted from US Census Bureau, Population Division Interim State Population Projections, 2005. Internet Release Date: April 21, 2005.

Discussion

In calling for an increase of the dentist workforce in North Carolina, together with incentive measures to promote enhanced access to dental services for rural and underserved populations, the rise of contrary perspectives can be expected. In part, this may arise because workforce and population projections are imperfect, by definition. In a similar vein, some may suggest that dentists' productivity increases have not been sufficiently considered. That is true; though the current access-to-care concerns have arisen even while dentists' productivity, nationally, grew 1.12% per year during the 1990-2002 period.[17] (One assumes North Carolina dentists exhibited similar productivity growth during that period.) Moreover, as was indicated previously, productivity increases have less impact where there is a significant dentist shortage involved. Others may point out that career/practice styles may be changing, in part by the continuing influx of women in the dental profession. Some may question why in-migration of dentists has not been separately considered in the current overview. Also not accounted for are the state's large African American, Hispanic and retired elderly populations, all of whom appear likely to be underserved and may be assumed to exhibit above-average dental needs. In short, while a formally constructed dental workforce analysis would be more illuminating, the following points appear to be a fair and robust reflection of the current dentist workforce concerns facing North Carolina.

- North Carolina ranks 47th out of 50 states in terms of the dentist-to-population ratio.
- The United States has 6.0 dentists per 10,000 persons; North Carolina has 4.1 dentists per 10,000 people. The

national ratio is close to 46% better than North Carolina's.

- North Carolina has only eight counties whose dentist-to-population ratio approaches or exceeds the national average of 6.0 per 10,000.
- 79 North Carolina counties are 'federally designated dental shortage areas'.
- The North Carolina dental hygiene workforce has expanded progressively during the past 25 years, considerably exceeding the growth rate of the North Carolina dentist supply.
- The United Sates Census Bureau projects North Carolina as the nation's fifth fastest growing state, becoming the seventh most populous state by 2030, implying significant future growth in dental service needs.

It is apparent that the North Carolina General Assembly continues to be sensitive to the public policy dimensions of the dentist workforce shortage in North Carolina. Specifically, the legislature has gone beyond its initiatives in 1998 and 2001 (encompassed in Senate Bill 861), and has appropriated $2.0 million in fiscal year 2005-2006 planning funds with the goal of rapidly and cost-effectively expanding dental school enrollment in North Carolina.

The legislature also continues to rely on the North Carolina Area Health Education Centers system to help ensure that dental student practitioners gain rural and community-based dental care experiences. These student rotations are typically focused on North Carolina rural health clinics, but also on state mental health centers, on Indian Health Service facilities, military and coast guard installations, as well as Veterans Affairs (VA) hospitals.

Aside from the powerful and appropriate influence of market forces, the size of the future dental workforce needed in North Carolina will be largely defined by two additional considerations. The first of these is that North Carolina's current position as 47th out of 50 states with respect to dentist-to-population ratios must be rectified. A preferred ranking would see North Carolina positioned around the middle of the range, say 25th out of the 50 states. The second consideration, as already shown, is the state's projected population growth, which significantly exceeds the national growth rate, and thus may push North Carolina into becoming the seventh most populous state in just 25 years. With a 2030 estimated population of 12.2 million, this alone will account for 4.2 million more people than in North Carolina's 2000 census. Essentially, the current dental workforce shortage, overlayered with a North Carolina population estimated to be 51.9% higher than in 2000, dramatizes the need for a substantially larger and responsive oral healthcare workforce.

North Carolina has considerable dental education capacity. In 2005, the state operated 12 dental hygiene programs, 11 of which are based in the Community College System. In addition, there are 15 dental assistant education programs, 14 of which are community college-based, and there is one community college-based dental technology program. The state's dental school is based at UNC-Chapel Hill, where the maximum current annual enrollment is 80 dental students. Interestingly, it would appear that all of these programs function at a sub-optimal size. A recent economics study by the American Dental Association determined that the economies of scale in university-based dental education were such that the lowest per-student costs were approached as a dental school's total enrollments entered the 800-1,300 DDSE* range.[14] The DDSE estimated for the UNC-Chapel Hill School of Dentistry at the time this paper is published is approximately 526.

This commentary on North Carolina's dentist workforce status has focused largely on the availability and distribution of general dentists, because that is where the dental care access problem is the most acute. It is recognized, however, that dental assistants, dental hygienists and dental technicians are also key members of the dental team, and all contribute to the quality and productivity of dental care services delivered. For that reason this commentary has offered a relatively brief glimpse at the growth of North Carolina's dental hygiene work force, relative to that of dentists.

In the same vein, and with respect to advanced dental education, North Carolina currently has four general dental practice residency programs, located in Charlotte, Winston-Salem, Greenville, and Chapel Hill. A fifth general dental practice residency program is being considered for the Asheville area. The University of North Carolina also trains specialists for all dental specialties recognized by the American Dental Association. At the current time, there appears to be a need in the state for more pediatric dentists, as well as for dentists trained to serve the special needs of the ever growing elderly population, a significant proportion of whom are medically compromised and/or dependent on extensive pharmaceutical regimens. Access to dental care for institutionalized seniors is marginal at best. The supply and distribution of dental specialists in North Carolina may well deserve a future workforce study.

Conclusions

This commentary has presented a basic analysis of the current dentist workforce situation in North Carolina. The assessment offered does not represent a formal, fully specified and nuanced workforce study. Taking into account this limitation, the analysis suggests that North Carolina's dentist workforce supply, while qualitatively excellent, is quantitatively insufficient, ranking North Carolina nearly last out of 50 states. Such a position is generally perceived as undesirable with respect to healthcare policy norms.

Moreover, the massive projected population growth, changing demographics, disease trends, alterations in demand for care, and potentially significant changes in dental practice styles all

---

* DDSE is the DDS Undergraduate Equivalent. It is obtained by weighting each category of students by a teaching intensity factor, and summing the resultant weighted components. E.g., DDSE = (1.0 x undergraduate DDS enrollment) + (1.7 x dental specialty enrollment) + (1.7 x non-clinical graduate student enrollment) + (0.6 x allied dental enrollment) + (1.2 x non-specialty advanced dental education enrollment).

further reinforce the view that North Carolina urgently needs to develop substantially increased capacity for enrolling and graduating high-quality dentists. Committing to an enrollment increase program, together with increased community-based training experiences, would directly improve dental care access for people in North Carolina, would also contribute to greater economic development in the state, and would lead to positive distributional benefits.

Within acknowledged limitations, the current assessment of the dentist workforce status in North Carolina permits the following conclusions:

- Significant dental workforce expansion in North Carolina is justified by the existing dentist shortage, the current maldistribution of dentists, and the very strong population growth projected out to 2030 for North Carolina by the United States Census Bureau.
- In terms of dentist supply, North Carolina's goal should be to climb from its current 47th position to rank near 25th out of the 50 states with respect to the dentist-to-population ratio.
- Significant dental student enrollment expansion in North Carolina is necessary and should seek to capitalize on the acknowledged economies of scale achievable by encouraging institutions to enroll students up into the 800-1,300 DDSE range.
- Dental and dental hygiene student enrollment expansion must include additional linkages with North Carolina AHEC to help facilitate increased training capacity and to encourage dental training in appropriate rural and community settings.
- Dental and dental hygiene student enrollment expansion should make it possible to provide admission priority to academically qualified candidates from rural North Carolina.
- Expansion of general dental practice residency programs and pediatric dentistry specialty programs should be strongly encouraged.

Editorial Note: Dr. Stamm uses figures from the North Carolina State Board of Dental Examiners, which report the numbers of dentists active as of January each year. The Issue Brief in this issue of the Journal uses figures from the NC Health Professions Data System provided by the Cecil G. Sheps Center for Health Services Research, which reports active dentists through October of each year. Because the numbers are collected and reported ten months apart, the numbers of dentists and dental hygienists reported in this commentary may differ from those in other papers in this issue of the *North Carolina Medical Journal*. These differences are not considered to have significant implications for the policy analyses or conclusions drawn from their use in any case.

COMMENTARY

Access to Dental Care for Young Children in North Carolina:

History and Current Status of Workforce Issues

Michael W. Roberts, DDS, MScD, and William F. Vann, Jr., DMD, MS, PhD

Dental caries is considered the most prevalent childhood illness with a prevalence of over 44%, surpassing asthma (11%). Among preschool children, dental caries is considered a major health problem, and this issue has recently come under scrutiny by policy makers, physicians, investigators, and public health officials. This played a central role in the fact that the year 2000 Surgeon General's Workshop and Conference was dedicated to children's oral health issues.

The access to dental care for children in North Carolina mirrors the national picture or is worse. The circumstances in North Carolina are complicated by workforce issues as well as the fact that a substantial number of children are eligible for Medicaid or are uninsured. The purpose of this commentary is to review factors impacting access to dental care for children with a special emphasis on young, preschool children. We also review recent efforts to address the issues and point out several challenges on the horizon.

The Third National Health and Nutrition Examination Survey (1988-1991) found that nearly 80% of two-to-five-year-old children below the poverty level have experienced caries.[1,2] The United States Surgeon General's Conference in 2000 underscored the scope of the nationwide problem of access to dental care for children, especially low-income and minority families, and those with special healthcare needs. Reasons cited include the lack of dental professionals trained to see special populations and/or accepting Medicaid clients. Children lose an estimated 52 million hours a year from school due to dental pain and related care.[3]

In response to a perceived developing national workforce concern, the American Academy of Pediatric Dentistry (AAPD) formed a "Task Force on Work Force Issues" in 1998 that published a white paper summarizing its deliberations.[4] The Task Force noted that since the late 1980s, there has been a growing shortage of pediatric dentists in many geographic locations of the United States. These concerns were substantiated with data; by 1998, the number of trained pediatric dentists in private practice, public institutions, and dental education had declined to 3,600 from approximately 3,900 in 1990. The Task Force concluded that the root cause of the shortage was because the number of pediatric dentistry training positions and graduates was not adequate to offset deaths and retirements.

The dearth of training positions in the specialty was the subject of an American Dental Education Association's (ADEA) request to Congress and is described in their "Primary Care in General and Pediatric Dentistry Programs FY 2000 Appropriations Request" to increase the funds to support additional Title VII grants. This request noted that "the United States is not training enough pediatric dental healthcare providers to meet the increasing need for pediatric oral health services."[5]

While accurate projections of workforce issues in a dynamic society are difficult, Waldman[6] projected a need for an additional 3,000 pediatric dentists to meet the dental care needs of the children in the United States by the year 2020. A National Symposium of Pediatric Dental Educators and AAPD leaders examined the specialty workforce issues in 1998 and set a goal to increase training positions by ten per year from 2000-2010. To accomplish this goal, the AAPD urged existing residency programs to look for creative ways to increase their training numbers. The AAPD also focused its advocacy efforts toward increasing Title VII funding for program expansion and new program start-ups and encouraging hospitals and dental schools to apply for these grants. These efforts have been successful: the number of first-year trainee positions grew from 181 in 1997 to 278 in 2005.[7] This increase of over 30% was achieved through the establishment of seven new residency programs and wide-spread program expansion across the United States.

While national workforce data have made a dramatic swing since 1998, some concerns remain. The AAPD estimates that approximately one-third of dental care to children is provided by pediatric dentists, noting that specialists deliver a disproportion-

ately higher amount of oral healthcare for Medicaid and medically compromised children. Currently the number of children in the United States is increasing, and the ratio of dentists-to-population is decreasing, a circumstance that has potential to further overload the demand on pediatric specialists.

Access Issues for Children in North Carolina

Improved access to dental care for children in North Carolina was the top priority of the North Carolina Academy of Pediatric Dentistry throughout the decade of the 1990s. Their efforts were focused on improving dentists' participation in Medicaid by attempting to increase procedure reimbursement rates. In 1999 the North Carolina Institute of Medicine (IOM) Task Force on Dental Care Access issued a report to the North Carolina General Assembly and to the Secretary of the North Carolina Department of Health and Human Services identifying inadequate access to dental care as being commonplace among children of families living in poverty.[8] This problem is especially notable among children birth through five years of age. Approximately 25% of all children entering kindergarten each year in North Carolina have untreated dental decay.[7,8] And, among parents who feel that their children have unmet healthcare needs, 57% report the unmet need is for dental care, a percentage almost two-times greater than that reported for medical care.[8]

Many would argue that North Carolina has a statewide dental workforce shortage, magnified by a workforce misdistribution. The fact is North Carolina ranks 47th nationally in the supply of dentists.[9] Four of its 100 counties have no dentists in practice, and 79 counties qualify as federally recognized dental professional shortage areas.[10]

> *"Currently the number of children in the United States is increasing, and the ratio of dentists-to-population is decreasing..."*

The dental access problem for young children in North Carolina is compounded by two factors; (1) low dentist participation in the Medicaid program and (2) the paucity of practicing dentists. In 1998, there were only 47 actively practicing pediatric dentists in North Carolina.

North Carolina IOM's Recommendation Aimed at the Specialist Workforce

Recommendation #13 in the North Carolina IOM Report addressed the issue of training more specialists. It recommended that the number of training positions in the pediatric dentistry residency program at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) School of Dentistry be increased and also recommended that consideration be given to the establishment of additional pediatric dentistry residency programs at other sites.[8]

What about the Addition of New Residency Training Programs?

Following the publication of its report, the North Carolina IOM hosted a meeting of dental directors from East Carolina University, Wake Forest University School of Medicine and the Carolinas Healthcare System [Carolinas Medical Center (CMC)]. Wake Forest University considered initiating a program, but did not go forward. Recently CMC has expressed an intention to develop a program.

The Residency Training Program at UNC-Chapel Hill

The UNC-Chapel Hill School of Dentistry Department of Pediatric Dentistry has been the only residency program in pediatric dentistry in North Carolina since 1955. From 1955-1985, the program was 24 months in length. During this time frame, up to three students/year (a program total of six trainees) were accepted annually, depending on department resources. By 1986, the program had 66 alumni, two-thirds of whom were practicing in North Carolina.

The program length was extended to 36 months in 1986, but the class size was reduced to two residents per year (a program total of six trainees) because resources could not be stretched to support more than a total of six residents. In 1992, the program was awarded a five-year grant from the federal Maternal and Child Health Bureau and recognized as one of three Centers for Excellence in Pediatric Dentistry in the United States. Prior to this time the program never had stable funding, but was supported by a hodge-podge of creative financing mechanisms with reliance on the UNC-Chapel Hill School of Dentistry, the UNC Hospitals, and private resources, which could only sustain very low resident stipends.

The Maternal and Child Health Bureau support has served as a recruitment magnet for exceptional residents. Since 1992, many of these individuals have had the background and sophistication to support their training using a variety of governmental grants. This permitted program expansion of one additional resident per year in most years since 1992 and under this scenario, an extra 11 residents have been trained. Since the advent of the 36-month program, the retention of graduates in North Carolina has been 75%, and this does not include several who left the state for academic appointments.

In 2003, the UNC-Chapel Hill School of Dentistry Department of Pediatric Dentistry was awarded a competitive three-year non-renewable Title VII grant from the federal Heath Resources and Services Administration (HRSA), Bureau of Health Professions to increase the number of pediatric dentistry residency positions by one per year for 2003-2006. As noted previously, these grants are intended to be seed money to initiate new residency programs or increase the number or positions in existing programs.

To summarize, at present there are nine residents (three per year) in training at the UNC-Chapel Hill School of Dentistry, but this number will dwindle to six (two per year) in 2008 unless additional funding is identified and secured to sustain the increase.

Another strategy put in place at the UNC-Chapel Hill School of Dentistry has been to strongly encourage and assist their dental students to complete pediatric residency training outside North Carolina and urge them to return to the state to practice. This strategy has also seen success in the past decade.

As a result of recent cumulative efforts to increase the number of pediatric specialists practicing in the state, the number of private practitioners increased from 47 in 1998 to 92 in 2004, a 96% increase. Notably, five of the pediatric dentists are engaged in community dental clinics within health departments or in Medicaid clinics.[11] While the number of pediatric dentists practicing in North Carolina and the number being trained may be sufficient at present, there is continued concern about the aging of the pediatric workforce and the future increase in the number of children in the state. These trends could have a negative impact on access to dental care.

The North Carolina Dental Medicaid Challenge

Many factors influence the low use of dental services among North Carolina Medicaid recipients. Low dentist participation in the Medicaid program remains an issue. North Carolina has one of the lowest rates of actively participating dentists in the country. Recommendations #1, 2 and 3 of the North Carolina IOM Report addressed issues that would encourage increased dentist participation.[8]

In 2000, a class action law suit (Antrican vs. Burton) was brought by a group of parents against the North Carolina Medicaid Program alleging inadequate access to dental care for their Medicaid-covered children. Settled in 2003, this litigation resulted in reimbursement rate increases for 27 selected dental procedures. This action led to additional dentists agreeing to become Medicaid participants (see Table 1).

Unfortunately, however, the settlement did not include an inflation adjustment clause. Most experts agree that reimbursement levels should reflect the 75th percentile of market-based fees (fees equal to or grater than those of 75% of dentists in the state) to encourage dentist participation.

Although the absolute number of dentists participating in Medicaid increased 4% from 2001 to 2004, the percentage of practicing private dentists who participate in Medicaid remained constant or declined slightly over the same period (49% to 47%).[11]

What Does the Future Hold for Our State?

American Dental Association President-Elect, Robert M. Brandjord, has noted that access to care is the umbrella for the major issues facing dentistry. He stated also that the challenge to dentistry was to motivate the political will of state legislatures and Congress to properly fund access to dental care.[12] A lack of political will in our state would appear to be demonstrated in two recent illustrations:

- Acting on the recommendation of the North Carolina IOM Task Force, during the 1999 General Assembly session, Senators Howard Lee and Beverly Purdue introduced North Carolina Senate Bill 752 to appropriate funds to add three UNC-Chapel Hill School of Dentisty pediatric dentistry residents (one per year) at a sustained state funding level of $100,000 per year. This bill was not passed, and securing funding to support an increased number of training positions in pediatric dentistry at UNC-Chapel Hill remains elusive. Considering its current heavy dependency on federal support through the Maternal and Child Health Bureau

Table 1.
Number and Percentage of Private Dentists Participating in the Medicaid Program

	2001	2002	2003	2004
Total number of private dentists who practice in NC (not including public health dentists)*	3,280	3,381	3,414	3,621
Number of private dentists who "actively" treat Medicaid enrollees**	644	670	712	855
Population of North Carolina***	8,198,173	8,311,778	8,421,050	8,541,263
Number of Medicaid enrolled children under 21 years of age*	536,795	580,990	616,874	643,922
Dentist-to-Medicaid ratio	1:833	1:867	1:846	1:753

** Source: Data provided by North Carolina Division of Medical Assistance. The 1999 IOM Task Force on Dental Care Access Report defined "active participation" in the Medicaid program as those dentists who received more than $10,000 in Medicaid reimbursements in a fiscal year.

*** North Carolina State Demographics online at: http: //demog.state.nc.us/

grant, the program is at high risk of being forced to reduce the number of training positions to even lower levels as federal funding sources evaporate, a prospect with a high likelihood in the future.

- Recently, the General Assembly (Session Law 2005-276) passed a budget that puts all children five years of age or younger covered by North Carolina Health Choice program into the Medicaid program effective January 1, 2006.[13] Medicaid reimbursements for dental procedures are significantly less than North Carolina Health Choice. Younger children have had the most difficulty in establishing a dental home in the past. This legislation has the potential to aggravate the access to dental care issue for affected children.

Summary

The 2000 North Carolina IOM report contained 23 recommendations. To date 16 have been fully or partially implemented. This represents progress, but accomplishing full compliance remains a goal. Absent new training programs in our state, as current federal training grants phase-out, identifying financial support to continue training an adequate number of pediatric dentists for North Carolina will be a challenge. **NCMedJ**

COMMENTARY

Dentist Participation in Medicaid:
Key to Assuring Access for North Carolina's Most Underserved

Mahyar Mofidi, DMD, MPH

Dental care is essential to overall health.[1] Despite improvements in prevention and oral health status, millions of people still experience preventable dental disease.[1,2] There are glaring and persistent socioeconomic disparities in the distribution of oral health problems with persons from low-income families and minority backgrounds being affected to a much larger extent than their counterparts.[1,2]

Research has documented many factors, both complex and inter-related, that contribute to the persistence of oral health disparities.[1] Inadequate access to regular dental care represents a chronic, significant problem to achieving oral health.[1,2] Even though Medicaid has the potential to markedly improve access to dental care for millions of economically disadvantaged persons, this federal-state program has unfortunately not lived up to its potential. Less than one in every five children enrolled in Medicaid uses preventive services in a given year.[1,2]

> *"Less than one in every five children enrolled in Medicaid uses preventive services in a given year."*

Among the primary reasons for poor utilization of dental services by Medicaid enrollees is scarcity of available dentists.[2] Numerous studies on access to dental care have been completed, including those of dentists who consistently cite three major issues for their lack of participation in the Medicaid program: (1) inadequate reimbursement rates; (2) broken appointments and patient non-compliance; and (3) burdensome paper work associated with Medicaid.[2] Of these, insufficient reimbursement rates, which are often less than what it costs to operate a dental practice, constitute the principal reason for keeping many dentists away from treating Medicaid enrollees.[2-4] In North Carolina, the 1999 North Carolina Institute of Medicine Task Force on Dental Care Access identified a significant increase in reimbursement rates as its number one recommendation for improving access to dental care.[5] It noted that more dentists would be willing to see more Medicaid patients if reimbursement rates were increased.

Increasing Medicaid Reimbursement Rates

Over the past several years, a number of states have developed comprehensive approaches to increase dentist participation in the Medicaid program.[4] Establishing competitive, market-based reimbursement rates has been a central strategy.[4] These efforts appear to have improved both the dentist participation rate in Medicaid and access to dental care for beneficiaries.

What has the experience in North Carolina been? There have been several rate changes since 1999. These payment rates, however, are still below dentists' fees charged to non-Medicaid patients and are not consistent with a market-based approach. Nonetheless, by April 1, 2003, as a result of a dental care law suit settlement, there was a significant reimbursement rate change for many dental procedures benefiting children.[6] The majority of targeted dental services affected by the reimbursement rate change also happen to be available to the adult Medicaid recipients. These services include, but are not limited to, comprehensive exams, radiographic x-rays, fillings, and extractions. Common adult procedures, however, such as scaling and root planning (i.e., deep cleanings) and dentures were not affected by the rate change.

How have increased reimbursement rates impacted dentists' participation in the Medicaid program and, more importantly, the beneficiaries' utilization of dental services? This question is a difficult one to answer as causality sequencing cannot be established with available data. Preliminary evaluations suggest that increased rates have indeed coincided with improved participation and utilization levels.[7] Following is a brief summary of results:

Mahyar Mofidi, DMD, PhD, is an Adjunct Associate Professor with the UNC-Chapel Hill School of Dentistry and a Research Scientist for the UNC-Chapel Hill Institute on Aging. He can be reached at Mahyarm@email.unc.edu.

Dentists' participation

- During 2001 and 2004, there was a 33% increase in the number of dentists "actively participating" in the Medicaid program (from 644 to 855, respectively). The 1999 North Carolina Institute of Medicine Task Force defined "active participation" in the Medicaid program as those dentists who received more than $10,000 in Medicaid reimbursements in a fiscal year.
- Between 2003 and 2004, 143 new dentists began actively participating in the Medicaid program bringing the overall active dentist participation rate to 24%.

Utilization

- The percentage of Medicaid enrollees receiving dental services increased from 20% in 1998 to 27% in 2004.
- From 2001 to 2004, utilization of dental services among children jumped from 28% to 31%, while utilization among adults aged 21-64, went from 24% to 25%.
- Utilization rates for older adults aged 65 and older remained relatively stable, going from 16% in 2001 to 17% in 2004.

Challenges and Concerns Associated with Reimbursement Rates

Notwithstanding the progress in dentist participation and dental access for the enrollees, a number of challenges and concerns associated with increasing reimbursement rates must be mentioned.[7]

- Increase in access to dental care is primarily attributable to those dentists who were participating in the Medicaid program, but who began to serve more patients after the reimbursement changes. While the number of these dentists is on the rise, it is important to note that among all providers who billed for Medicaid procedures in 2004, only half can be considered as "active" providers in the Medicaid program. In addition, over the past several years, the number of all dentists participating in the Medicaid program has remained relatively flat and may be decreasing as a proportion of all dentists in the state.[7]
- Despite an increase in the dental utilization rate for children, the 31% rate for 2004 still lags below utilization levels of children in the general population. For example, children between 200% to less than 400% of the federal poverty guideline (FPG) and children equal to and greater than 400% FPG have 49.4% and 65.2% dental utilization rates, respectively.[4] In addition, among children whose families can afford private dental insurance, 55.8% were reported to have at least one dental visit during the past year.[8] A more reasonable benchmark against which to compare the progress of the North Carolina Medicaid dental program for children may be the Healthy People 2010 goal that at least 57% of children from low-income families receive a preventive dental visit each year.[9]
- There has been little change in older adults' utilization levels. In fact, dental utilization rates for older adults in the Medicaid program falls far behind those of their counterparts in the general population. In a national study, among older adults with private insurance coverage, 65% reported at least one dental visit during the past year, while among those without private dental coverage, 33.9% had at least one visit.[8]
- The reimbursement rates for certain frequently used and needed services for Medicaid-eligible adults, such as deep cleaning and dentures are low.[7] For example, Medicaid pays $78.11 for a quadrant scaling and root planning, while the standard fee at University of North Carolina at Chapel Hill (UNC-Chapel Hill) dental faculty practice for the same procedure is $196. Medicaid also pays $309 for a complete denture, whereas the fee charged by UNC-Chapel Hill is $903. Such low reimbursement rates may discourage dentists from treating Medicaid-eligible adults who, in turn, without adequate access will be vulnerable to experiencing oral health problems.
- Although the state has taken action to address reimbursement concerns, stakeholders agree that a more comprehensive approach that strives to mirror market-based fees and regularly accounts for inflation is needed.[7] States such as Alabama, Michigan, and Tennessee have established competitive Medicaid reimbursement rates to significantly improve access to dental care.[4] For example, dentists in Tennessee are reimbursed at the 75th percentile of the East South Central region's fees, as determined by the American Dental Association's Survey of Dental Fees. The 75th percentile fee level for a particular region indicates that 75% of dentists in that market are charging that amount or less for a particular service, and 25% of dentists are charging more than that amount for that particular service. States that come close to the 75th percentile fee have experienced positive outcomes. For example, the number of Medicaid-participating dentists in Tennessee increased from about 380 before the rate change to approximately 700 participating dentists after the rate change. Access to dental care rose from 24% to 47%, approaching a range that is seen in the private sector in Tennessee.

At the 2005 North Carolina Oral Health Summit, it was generally agreed that, as an ultimate goal, Medicaid rates should reflect the 75th percentile of market-based fees in North Carolina.[10] Subsequent to the Oral Health Summit, the North Carolina General Assembly appropriated $2.0 million in each year of the biennium to increase Medicaid dental rates.[10] It remains to be seen whether Medicaid payments that approximate private sector markets will result in increased dentist participation in Medicaid and increased access above and beyond current levels.

Nonfinancial Factors in Dentists' Participation in Medicaid

Raising dental reimbursement rates is necessary, though not sufficient, in getting more dentists to treat Medicaid patients. As stated, dentists cite a number of nonfinancial barriers to treating Medicaid patients. Often cited are administrative burdens, including complex provider enrollment procedures, burdensome patient eligibility processes, and prior authorization requirements. Several states have reported that administrative fixes in Medicaid operations combined with funding improvements have led to increased dentist participation.

North Carolina is illustrative. Medicaid now accepts both electronic and paper claims submissions.[11] Prompt payment mechanisms have been implemented, such that dentists are paid in 17 days and 35 days, respectively. To improve dentist participation and reduce Medicaid claim problems, the North Carolina Division of Medical Assistance (DMA) provides information and education to dental offices on how to file Medicaid claims.

A high "no-show" rate among Medicaid enrollees and patient noncompliance also explain dentists' reluctance to participate in Medicaid. These problems have often been attributed to lack of consumer awareness about the importance of oral health and lack of care coordination within the Medicaid program.[12] Two of the North Carolina Institute of Medicine Task Force's recommendations focused on these issues.[5]

No statewide action has been taken with respect to educational activities for Medicaid consumers.[6] North Carolina would be well advised to look at the oral health promotion programs of other states. In Michigan, for example, the state, collaborating with the Michigan Dental Association, developed an educational publication, *Don't Wait Until it Hurts*, to encourage enrolled beneficiaries to seek preventive dental care.[12] Other states have used a more targeted approach, focusing on populations that are at greater risk.[12] In Maine and Michigan, caregivers of children who have not had a dental visit in the previous year receive periodic reminder mailings to encourage them to schedule a dental exam for their children.

As for care coordination, case management services are needed to help some Medicaid beneficiaries access dental care services and adhere to treatment plans and oral hygiene protocols. The North Carolina DMA has pilot-tested dental care coordination models in some counties.[10] It has found that there are currently insufficient numbers of care coordinators to provide adequate dental care coordination for all Medicaid recipients. Again, our state would be well advised to learn from the experiences of other states. Medicaid agencies in some states have established innovative strategies to enhance care coordination, which include targeting preschool children in Head Start and Early Head Start programs and their families.[12] In Alabama, to improve patient attendance, a "Rights and Responsibilities" packet, which describes the patient's responsibilities and sanctions if the patient misses an appointment, has been developed for use by dentists.[12]

Among the suggestions offered at the 2005 North Carolina Oral Health Summit regarding dental care coordination, was to extend care coordination to beneficiaries with an enhanced risk for dental caries or for complications from dental disease.[10] Studies will be needed to assess whether more intense and organized assistance to beneficiaries will result in increased access to dental care.

Success in increasing dentist participation in the Medicaid program also hinges on successful outreach efforts targeting dentists.[4] Over the past several years, the North Carolina Dental Society, whose membership includes approximately 86% of private dentists in the state, has been at the forefront of encouraging private dentists to treat patients on Medicaid.[7] Through newsletters and statewide and regional meetings, the Dental Society has been actively promoting changes, financial (e.g., rate changes) and administrative (e.g., enhanced claim filing systems), which have been implemented within the Medicaid dental program.[7] In a joint effort with the DMA, a Frequently Asked Questions (FAQ) document, which addresses common provider questions and concerns, was developed and subsequently promoted within the membership. Similarly, seminars and workshops have been conducted not only to respond to provider inquiries and address misconceptions about Medicaid, but also to share the positive relationship that exists between the Dental Society and DMA. These and other outreach activities need to continue in an effort to increase dentist participation in Medicaid and improve access to dental care.

Provider Attitudes and Behaviors

An important aspect of dental care access, which has received little attention, is the reportedly negative attitudes and behaviors of some dentists and their staff toward patients who are insured by Medicaid.[13] Stigma associated with those on a public assistance program may keep some dentists away from treating Medicaid clients. It is not known if these dentists would see Medicaid patients even after addressing the financial and nonfinancial factors presented above.

In a North Carolina study, a diverse group of Medicaid beneficiaries explained that, after negotiating one barrier after another (e.g., finding a provider, obtaining convenient appointment times, securing transportation, etc.) to get a dental appointment, they faced what they perceived as judgmental, disrespectful, and discriminatory attitudes and behaviors from dentists and their staff because of either their race and/or public assistance status.[13] For some beneficiaries, such perceived treatment discouraged their efforts to pursue dental care. Quality patient care requires that health professionals be aware of and respond to individual differences among patients, evaluate information about them in an objective, unbiased manner, and develop relationships that promote open and trusting communication. The current proposals aimed at improving access to dental care for Medicaid enrollees (e.g., increased reimbursements, patient education) fall short of addressing the more vexing obstacles to dental care that beneficiaries face. Thus, strategies to improve dental care access for Medicaid enrollees should also focus on cultivation among dentists of more "patient-centered care" that is culturally respectful and responsive to patients' values and needs.

North Carolina Health Choice for Children

In October 1998, North Carolina implemented its State Children's Health Insurance Program (SCHIP), entitled North Carolina Health Choice for Children (NCHC). NCHC offers healthcare coverage to uninsured children who come from working families with incomes that are too high to qualify for Medicaid, but too low to afford private insurance. NCHC provides comprehensive health insurance coverage, including dental, vision, and hearing services. A major feature of NCHC has been reimbursing dentists generally at 90 to 95% of usual, customary, and reasonable fees.[14]

NCHC has greatly improved access to dental care.[14,15] These children have experienced much better access to dental care when compared to children enrolled in Medicaid. Evidence shows that participation in NCHC is associated not only with increased dental utilization and regular dental care, but also reduced unmet dental needs. Improvement in access to dental services for low-income children in North Carolina is consistent with the results that other states have witnessed under SCHIP.[16] The success of state SCHIP programs in increasing access to dental care has been attributed to a variety of factors. Central among these has been paying dentists' fees close or equal to their usual private practice charges.

Despite these reported gains, because of budgetary constraints, the North Carolina General Assembly has recently enacted legislation to transfer coverage of children aged birth to five from NCHC to Medicaid.[10] The General Assembly also passed legislation to reduce all of the NCHC provider payments from the current reimbursement rates to the Medicaid rates for children aged 6-18 by July 1, 2006.[10]

Such actions prompt a number of questions and concerns. For example, how will the new changes impact access to dental care for the affected children? What type of effect will these changes have on dentists? Will affected children lose their usual source of dental care? It would seem that an important first step toward ensuring that low-income children have access to dental care is for the state to adopt the kind of Medicaid fees that will attract sufficient numbers of providers. Without such a commitment, we may well lose the important gains made by NCHC toward reducing the dental access gap for low-income children.

Conclusion

Issues surrounding participation of dentists in the Medicaid program are complex. Accordingly, increasing such participation requires a multifaceted strategy. Stakeholders in North Carolina have taken significant steps toward improving dentist participation in Medicaid. Notable among these has been a consistent increase in Medicaid reimbursement rates, which has been associated with improved participation and access to dental care. But, challenges remain with respect to attracting more dentists. Adequately addressing these and other challenges should significantly improve access to dental care for underserved populations and reduce oral health disparities. **NCMedJ**

COMMENTARY

Special Care Dentistry Delivers a Formula for Change:
A Model Has Been Developed but Must Be Implemented Statewide

William E. Milner, DDS, MPH

The Reality of Now

Not-so-pretty scenarios are being played out daily in our communities:

- The benefit of a lifetime of dental care rapidly disappears for patients who cannot access a local dentist's office. Longtime dental patients are frequently turned away from practices because of complicating medical conditions, limited mobility, or change in financial status. Lack of on-site care in skilled nursing facilities, group homes, or home health programs forces them to receive only emergency care at best. A lifelong routine of regular checkups and preventive and restorative care is forced to come to an end.
- Unable to clean their own mouths, these compromised residents depend on the facilities or home caretakers for daily preventive care. Almost universally, caretakers shy away from cleaning mouths; they will take care of every other part of the body, but avoid the mouth out of fear that they will hurt the resident or that they will be bitten. What results is a filthy mouth with rapidly progressing root decay and gum disease. It gets worse for the typical dementia, head trauma, or non-communicative stroke patient who cannot say he or she hurts.
- After a few months of little or no oral healthcare, residents are in a constant state of oral infection, a dangerous condition with spin-off effects. Oral bacteria and debris can be aspirated into the lungs, which causes aspiration pneumonia and necessitates costly treatment and trips to the hospital. Diabetics have trouble controlling their disease because of this constant source of infection. Oral bacteria can also enter the blood stream, landing on heart valves and causing infection.
- Families are frustrated with the lack of availability of basic dental care. Caretakers are willing to drive anywhere for help, but help doesn't exist. Those with autism, cerebral palsy, muscular dystrophy, and a dizzying variety of syndromes are left without the hope of care.

Talk to a facility director of nursing, a health coordinator for group homes, or any family member providing care for a home health patient, and you will hear the same scenarios confirmed. Fragile, disabled, dependent North Carolinians deserve better. Luckily a solution is at hand. North Carolina has a tested and proven model of care, the established networks to create a statewide system, and the political will to provide quality, consistent care to its most vulnerable populations.

Four major areas must be considered from a public policy perspective to change this situation.

Table 1.
North Carolina's Rapidly Growing Senior Population

NC ranks 10th among states in the number of persons age 65+.
By 2020, the population 65+ will have grown 71% from the 2000 baseline.
By 2030, there will be 2.2 million 65+ (17.8% of the population).
In 2000, 219,068 persons with disabilities received Medicaid.
Total Nursing Home Residents – 47,336 in over 400 facilities.
Total Group Home Residents (mental/physical disabilities) – 4,520.
Total Home Based Residents (mental/physical disabilities) – 5,364.

A Different Dental Practice and a Provider with a Mission

A new type of dental practice is emerging because of the huge growth in numbers of the older population. To accommodate this demographic and health status shift in the population, the North Carolina Dental Society has initiated a new service area—Special Care Dentistry.

What is it? Special Care Dentistry serves those living in nursing homes, assisted living facilities, group homes, or the community at-large—patients who have intellectual and/or physical disabilities and are medically compromised. There are a few special care practices in the state. This infant area of expertise needs the support of North Carolina's dental care proponents and special care interest organizations in order to expand to serve the state's entire special care population.

William E. Milner, DDS, MPH, is President of Access Dental Care. He can be reached at bmilner@accessdentalcare.org or 2275 Vanstory Street, Suite 102, Greensboro, NC 27403. Telephone: 336-292-5029.

There are two major similarities between a traditional dental practice and a practice dedicated to special care.

- The treatment philosophy is the same. No matter what the disability, all patients deserve the same quality of care that any of us within the community receives.
- The other similarity involves how care is provided. Special Care Dentistry involves the complete dental team—dentist, dental hygienist, dental assistant, and office support staff.

But to be successful, the practice of Special Care Dentistry, whether on a full-time or part-time basis, requires a completely different practice organization.

- For instance, it requires an expanded practice location. Although Special Care Dentistry can be delivered in the fixed-office setting, most special care patients either cannot be easily moved to an office or exhibit behaviors that cannot be managed in a waiting room. Because of this, most patient care takes place at a facility, community center, or in the hospital operating room. Local private practitioners working in a limited number of facilities can provide emergency care and some clinical services, but they cannot provide comprehensive services for the entire special care community.
- It requires different equipment. Equipment needs to be mobile because it needs to go into a variety of settings, such as a long-term care facility, community center, or home. Residents who are sick or who have trache tubes or cumbersome geri-chairs cannot be transported outside to a "Winnebago style" van for care, especially in the middle of winter.
- It requires different reimbursement rates. Because 80% of special care patients depend on Medicaid to pay for their dental care, and Medicaid reimburses at approximately 62% of cost, a special care practice cannot serve the entire community with comprehensive, quality care, and be fiscally sustainable based solely on fee-for-service reimbursement.
- It requires a different legal structure. The most workable structure to emerge is the nonprofit practice. Nonprofit status allows the funding of start-up costs through grants and provides tax deductibility for contributions that help offset the cost of providing care to most patients at Medicaid rates.

Beyond the changes in practice organization and reimbursement, it requires a provider with a specific set of dental and interpersonal skills.

- It requires a different mindset. Direct patient care for special care patients requires more time per patient. It requires special training, flexibility, creativity, and a dedication to serve these difficult patients. In addition, this type of practice is more physically demanding than the traditional practice, both because of moving portable equipment into and out of facilities on a daily basis and treating patients who may be combative.
- It requires extensive communication about care because more individuals are involved in treating or approving treatment plans for the patient. The dental provider in a nursing home works with facility and hospital administrators, physicians, directors of nursing, charge nurses, social workers, other ancillary providers, a variety of responsible parties, those responsible for the daily oral hygiene of the patient, state facility surveyors, and the patient. Communication with these team members adds extra time to the process.
- It requires attention to detail. The nursing home chart is huge compared to the typical dental chart. Twenty percent of special care patients require conscious sedation for treatment. Conscious sedation monitoring by nurses and the dental team greatly extends treatment time. The long list of drugs these patients are taking requires a specialized knowledge of pharmacology. Treatment forms include a variety of permission requirements for guardian, power of attorney, and healthcare power of attorney.

Formula for Change: Expand the Number of Comprehensive, On-Site Programs

Making excuses for intermittent, less than comprehensive care is unacceptable and degrading to special care patients. To serve the special needs populations, dentistry must expand the recruitment efforts and the number of training opportunities for special care dental providers who will serve all patients, no matter their reimbursement source, location, type of dental care needed, or disability.

The nonprofit practice is the most workable model to date. It is a model that can be expanded to accept special needs patient referrals from local practitioners; serve the rapid influx of retirees to North Carolina; relieve the gap in service to those deinstitutionalized by North Carolina's mental health hospital system; and support special care patients, families, local healthcare providers, and organizations representing the special needs patients.

Access Dental Care mobile equipment and truck.

Changes Require a New Breed of Community Practitioner

The growth of this special needs population requires a dental team with special training. Until recently, the few practitioners providing comprehensive special care worked at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) School of Dentistry, in a limited number of hospital dentistry programs, in the state mental retardation hospital system, or in a local private pediatric practice. A few private practice dentists go to a limited number of nursing facilities on their "day off;" most work with few dental staff and carry basic portable equipment. Unfortunately, none of these is sufficient for today's special care dental treatment needs.

Special Care Dental Programs

North Carolina's Special Care Dentistry programs emerged in the late 1990s and have created a sample framework for a statewide system.

- In the mid-1980s, The North Carolina Dental Society created a special care committee to address the treatment needs of patients and education needs of providers.
- In 1997, this committee supported the development of Carolinas Mobile Dentistry (CMD) at Carolinas HealthCare System, Charlotte. It began service to nursing homes in the Charlotte area. CMD covers 1,800 beds.
- In 2000, the North Carolina Dental Society initiated Access Dental Care. This Greensboro non-profit assisted Wake Forest University Baptist Medical Center (WFUBMC) in creating their Special Needs/Portable Dentistry program in 2002. It also teamed with Healthy Cabarrus, Kannapolis to start a branch of Access Dental Care in a four-county region around Concord/ Kannapolis. Access Dental Care has now absorbed the WFUBMC program to serve 4,000 beds and plans an expansion of service to the Triangle region.
- By 2006, the Carolinas Mobile Dentistry and Access Dental Care programs will cover over 7,000 beds.

Table 2.
Access Dental Care Five-Year Summary

Totals from August, 2000 – July, 2005*
Clinical
• 3702 Total Patients in the Practice
• 19,505 Total Patient Visits
• 32,116 Patient Services Provided
Financial
• $2,815,966 billed with an average gross of $98 per patient.
• $1,908,824 paid to date
• Over $903,000 in uncompensated care provided. This amounts to almost two years of net revenue. (80% of our patients are Medicaid beneficiaries)
• 162 Operating Room Patients (MR/DD patients-Medicaid) with an average gross of $1350 per patient.

*Figures do not include the newly acquired WFUMBC program.

The UNC-Chapel Hill School of Dentistry is, first and foremost, a teaching center, not an access to care facility. Its staff's expertise has made it the default special care referral source over the years for local practitioners. The special care population has grown so rapidly and is so difficult to transport that the school cannot continue to provide statewide access to care. To complicate matters, the School of Dentistry has experienced decreases in public funding, limiting its ability to start new teaching programs targeting special care populations. This means that neither dental school students nor faculty members have the opportunity to learn how to treat special needs populations in the community setting. If dental students are not introduced early in the education process to delivering care in community on-site programs, we lose the opportunity to put future practitioners into the special care professional pipeline.

State mental hospital dental staff experience on-the-job training because they handle North Carolina's toughest cognitively disabled patients daily. But, a few years ago, North Carolina decided to initiate a program of de-institutionalization, placing many of these severely and profoundly handicapped residents back into community group homes. Now group home programs are desperately seeking local dental care for these residents, arguably the most difficult to treat in dentistry. Communities without special care providers have no resources to call on.

Some larger hospitals have dentists on staff and/or graduate training programs that care for special care residents, primarily in the operating room setting. These dental teams are also responsible for in-house physician referrals, preparing patients for surgery, and providing oral care to support cancer therapy. To this point, they are at capacity providing in-house care and have not been able to expand to on-site community programs.

There are some dentists providing limited care to long-term care residents. Because of the extreme shortage of comprehensive special care programs, facilities contract with these providers knowing that many of their residents will not get the care they need. Mass examinations are followed by some extractions and denture work. Treatment plans for the remaining residents are provided, and the facility is required to find a dentist willing to provide care. This is a dead-end referral because most local dentists are not trained to deal with these patients.

Some local dentists will continue to treat some special care patients. Pediatric dentists still care for children with disabilities, but their practice volumes have forced them to restrict the number of older special care patients they see. General practitioners have an important role in caring for early dementia patients and the manageable chronically ill.

Formula for Change: Special Care Professional Education

A new model of care requires a new program of education for dental providers. At this point, North Carolina does not have a program that trains special care providers. Short student rotations and courses at the UNC-Chapel Hill School of Dentistry provide exposure to the special care patient, but do not provide the formal training necessary to enter an active practice. A post-graduate residency would allow dentists and hygienists to gain across-the-board dental skills provided in fixed, mobile, and hospital settings. Education for current local practitioners interested in Special Care Dentistry can be supplied by mini-residencies, regular continuing education, and on-site practical experiences.

Residents and their families are asking legitimate questions about the lack of daily oral care. Facility administrators and directors of nursing must finally make oral health and daily oral hygiene a priority. When this happens, special care dental staff can train the facilities' admitting nurses and education coordinators, who can, in turn, maintain a consistent teaching and monitoring process of direct care staff. Charge nurses and nursing aides must understand the ramifications of not providing daily oral hygiene and be held accountable. Failure to do this will, at some time in the future, put the facility at risk (e.g., families will take legal action).

There are a few existing education programs that need to continue. North Carolina Division of Facility Services surveyors, those in charge of ensuring that federal and state Medicaid funds are spent wisely, receive regular training. This training should to be expanded to include other long-term care advocacy groups. Future facility administrators are provided oral health programming information during the North Carolina School of Public Health Administrator in Training course. Every future administrator knows what a comprehensive dental program looks like. University interdisciplinary training should continue giving various future healthcare providers an understanding of oral health issues.

Funding that Matches the Practice

As it is currently structured, Medicaid reimbursement does not address the unique practice nature of special care dental services. Many services required by these patients are not even deemed eligible for reimbursement. Right now, 75-80% of skilled nursing home residents and almost all group home residents depend on Medicaid to reimburse their medical and dental providers.

To correct this inequity and to draw more practitioners into special care practice, higher reimbursement rates must be implemented, taking the following factors into account for special care patients.

- Special care patients take longer to treat. Their behavior must be handled before their dental needs can be treated. All of this requires working with the gamut of care givers and responsible parties. This takes more time that is not reimbursed and allows fewer patients to be treated in a day. (Access Dental Care currently averages 15 patients per day) For example, the autistic patient requires a special treatment regime and environment. It takes many appointments to gain the patient's trust, none of which are reimbursable. The treatment setting must be quiet, consistent, and supportive of parents.
- Patients with special care needs require more expertise to treat. Each new employee, dentist, or auxiliary must spend six months to one year learning to care for these individuals. None of this training experience is reimbursable to organizations.
- On-site programs require travel time and expenses, none of which is reimbursed. Access Dental Care fuel costs have doubled in the past five years. Each team spends approximately two hours each day going to a facility, setting up the dental equipment, breaking down the dental equipment, and returning to the administrative office.
- Communication with responsible parties takes time and is not reimbursed.

Public funding of dental services for the truly needy and vulnerable populations continues to be a problem. Historically dentistry has received 1-2% of total Medicaid funding, and now, in North Carolina, Dental Medicaid rates reimburse at 62 cents on the 2001 dollar. A lawsuit several years ago increased Medicaid rates by 12%, but inflation has now neutralized these gains with no sign of significant increases in the future. Although the overall population is increasing dramatically, the relative numbers of the special needs population are small, and what might seem to be a large increase in reimbursement rates would actually result in a relatively small increase in overall expenditures.

Formula for Change: Innovative Funding of Special Care Dentistry

Existing special care programs have been created through "grassroots" community efforts, with initial funding from grant support. Generous seed money from several North Carolina foundations is the reason for Special Care Dentistry's successful programming to date. Medicaid's inclusion of adult services has given providers the chance to deliver comprehensive care. There is ample financial data to craft an expanded list of reimbursable services for Special Care Dentistry. It should include funding for education priorities, public policy initiatives, program development, and fair fee-for-service reimbursement.

Public Policy Initiatives

Starting a new field of service delivery involves creating a new structure of practice. Old rules must be reviewed, present practices changed to improve service, and future programs created to deal with a changing population. Special care providers are currently treating patients five to six days a week plus trying to develop awareness of special needs in education, research, local program building, and public policy development. It is an overwhelming task. This core of individuals has the expertise to manage this change process, but they need the time. Unfortunately, the present organizations operate on such a thin profit margin, any time spent not treating patients puts them at financial risk. The following action areas need to be implemented.

- Provide support for long-term care provider organizations to establish consistent, quality Special Care Dentistry services.
- Work with communities wanting their own special care dental program. Several North Carolina communities are requesting help, but there is no time available to help them develop a program.
- Create health services research projects that support the development of community programs and ensure the quality of care provided.
- Review North Carolina's existing dental practice laws to allow for the more efficient practice of Special Care Dentistry.

Formula for Change: A Special Care Dentistry Center

Fund a North Carolina Special Care Dentistry Center to coordinate the activities mentioned in this commentary. A part-time dentist, a hygienist, and an office assistant can bring together the necessary parties to do the job right. Funding must be sustainable, giving this group the chance to work on the necessary issues and not spend all their time raising money.

Our Next Step

Many North Carolina foundations, the North Carolina Dental Society, long-term care organizations, individual nursing/group homes, and responsible parties of the mentally and physically disabled have "put their money where their mouths are." North Carolina's long-term care organizations understand the need for change and are asking special care dental providers what they can do to help create a statewide system. Dentistry has developed a successful model for providing care, but now needs the support of other organizations that will benefit from these changes. It is time to agree on a workable business/policy plan and make sure that specific changes are made. North Carolina's future long-term care residents deserve a better quality of life—one that puts the mouth back into the body. **NCMedJ**

COMMENTARY

Public Health Dentistry and Dental Education Services:
Meeting the Needs of the Underserved through Community and School-Based Programs

Rebecca S. King, DDS, MPH

One essential role of public health is to reduce the prevalence of disease in populations through proven preventive measures, thereby reducing the need for treatment services. The ongoing problems of the lack of access to quality oral healthcare, along with the difficulty of establishing a "dental home" for all North Carolina citizens, and especially for its children, continues to challenge dental care provider resources in North Carolina. Dentists in private practice deliver the majority of direct patient care services to all segments of the population. However, an increasing amount of care is now being rendered by numerous public health safety net dental clinics. Collaborations of publicly and privately-funded services have directed resources to augment the care provided by dentists in private practice. The collaborations are various combinations of state, local, and federal levels of government, non-profit agencies, faith-based community organizations, and volunteer efforts by concerned citizens. The result is that disadvantaged citizens who previously could not access a dental care provider can now more easily receive dental treatment and preventive services.

Perhaps the overarching description of the efforts of all dental public health and safety net providers is stated in the North Carolina Oral Health Section's mission "to promote conditions in which all North Carolinians can achieve oral health as part of overall health."[1]

With a focus on the three principles of public health—assessment, policy development, and assurance—the North Carolina Oral Health Section and other dental public health agencies have developed strategies to address both the *supply* of available care and the *need* and *demand* for care. Efforts concentrate on:

- Oral health monitoring—assessment and surveillance of treatment and need,
- Dental disease prevention—policy development to reduce need,
- Dental health education and health promotion—assurance to reduce need while increasing demand, and
- Access to dental care—assurance to increase supply.

State Level Strategies: North Carolina Oral Health Section

The North Carolina Oral Health Section is the only public program in the nation that provides statewide dental health prevention and education services specifically for children. The Oral Health Section is in the Division of Public Health, Department of Health and Human Services. Its function is mandated by the North Carolina General Assembly under the statutory authority of G.S. 130A-366, with services delivered at the county level. The majority of staff is funded by 77% state appropriations and 23% Federal Financial Participation. In addition, one county funds four public health dental hygienist positions with county and Smart Start funds, and one county funds a hygienist position with Maternal and Child Health Block Grant funds.

> *"The youngest North Carolina children at risk for tooth decay lack access to preventive oral care, as well as to dental treatment services."*

Too many citizens, particularly children, experience preventable oral diseases. Prevention is the key to improved oral health. No matter how many treatment resources are established in the state, the treatment of dental disease cannot solve the problem.

Rebecca S. King, DDS, MPH, is Section Chief of the Oral Health Section, Division of Public Health, North Carolina Department of Health and Human Services. She can be reached at rebecca.king@ncmail.net or 1910 Mail Service Center, Raleigh, NC 27699-1910. Telephone: 919-707-5487.

The vision is for North Carolina children to be cavity-free forever. The goal of the North Carolina Oral Health Section is to *prevent* dental disease, especially in children. To achieve this goal, the Section's programs are organized into five broad components: (1) Dental Disease Prevention Services, (2) Oral Health Monitoring Systems, (3) Dental Health Education/Health Promotion, (4) Access to Dental Care, and (5) Dental Public Health Residency Program. Section services are based on best practices as defined by the Centers for Disease Control and Prevention (CDC). Because of the limited number of staff, the Section primarily serves elementary school children, in order to have the greatest and longest-lasting impact. Since the 'patient' of dental public health is the community, the majority of the programs are geared toward the general public, including healthcare providers, with specific activities targeted to high-risk elementary and preschool school children. Eighty-three percent of the Section's staff—54 public health dental hygienists and two public health dentists—reside in the counties they serve and provide direct services in cooperation with local health departments. The Section serves over 288,000 children annually.

Programmatic Components of the North Carolina Oral Health Section

Dental Disease Prevention Services

The citizens of North Carolina continue to suffer from several oral diseases, including tooth decay, periodontal disease, and oral cancer. Tooth decay is the most prevalent childhood disease with more than 60% of North Carolina's schoolchildren still experiencing this disease. Several Section activities focus on decay prevention through the use of fluorides and protective dental sealants.

Community water fluoridation. Fluoridation of community water supplies continues to be the most effective evidence-based strategy for preventing dental decay. The CDC promotes community fluoridation as one of the two most effective public health measures to reduce dental decay, the other being school-based dental sealant programs. CDC's Water Fluoridation Reporting System (WFRS) database shows that 85% of North Carolina citizens served by municipal water supplies now receive fluoridated water. The Section provides technical assistance and uses federal Preventive Health and Health Services Block Grant funds to provide financial assistance to water systems wanting to fluoridate or to update older fluoridated water systems. These Block Grant funds have been reduced significantly over the last few years and are currently at risk for elimination by Congress. If that happens, other resources will have to be identified to support fluoridation and other proven dental preventive efforts.

The water systems that are not currently fluoridated are small and/or have structural or logistical problems that make it difficult to fluoridate. Systems that fluoridate often require hiring a water plant operator with a higher level certification than would be required if the system did not fluoridate. The higher level certification commands a higher salary, which is a burden on a small system. If their water comes from multiple sites, these systems can require additional fluoridation equipment, placing an additional financial burden on a small system. Each site of the water systems that add fluoride must be checked at least daily. For example, a water system with six well heads, each requiring its own fluoridation equipment, must have a properly certified operator check each injection point daily. Most future growth in the proportion of the population served by community water fluoridation will be in response to (1) increased population in the fluoridated areas as the state becomes more urban, (2) fluoridated water systems extending into rural areas, and (3) small water systems merging with larger fluoridated systems.

Into the Mouths of Babes (IMB). The youngest North Carolina children at risk for tooth decay lack access to preventive oral care, as well as to dental treatment services. Except for that provided by the relatively few pediatric dentists in North Carolina, dental care for this group is practically nonexistent. A partnership of six North Carolina agencies addressed the issue by developing a medical model for the provision of preventive dental services to Medicaid-covered children under age three. This model, called *Into the Mouths of Babes*, trains physicians and other medical providers to perform an oral screening and refer children for dental treatment if necessary, counsel parents on taking care of their child's teeth, and apply fluoride varnish. Medicaid reimburses the medical provider for these preventive oral procedures up to six times per child before the third birthday.

IMB is part of the Section and continues to partner with the North Carolina Division of Medical Assistance (Medicaid), the North Carolina Pediatric Society, the North Carolina Academy of Family Physicians, and the University of North Carolina at Chapel Hill Schools of Dentistry and Public Health. Representatives from each of these agencies form the IMB Advisory Committee, which partners with the North Carolina Dental Society. IMB trainings occur through collaboration among the Oral Health Section trainer, the North Carolina Academy of Family Physicians, and North Carolina Pediatric Society.

As of June 2005, approximately 400 physician offices, residency programs, and health departments were providing the IMB preventive oral procedures, with approximately 40% of Medicaid-eligible children receiving the services. Section staff are working with Early Head Start to develop new training materials for teachers and educational materials for parents to emphasize the importance of preventing disease in the primary teeth and to seek early dental preventive services.

Because North Carolina data show that dental decay is on the increase in the preschool population, the Section is examining ways to effectively address the dental needs of this vulnerable group of children. Medicaid requires at least 90 days between IMB oral preventive procedures. Eliminating this requirement would allow more scheduling flexibility. In addition, children qualify for the oral preventive services only up to their third birthday. Extending the eligibility to allow children to receive the procedure at the three-year well-child checkup would increase the opportunity to receive all six encounters, resulting in an increased preventive benefit.

Preliminary North Carolina data analysis shows that children having four, five, or six of these fluoride varnish procedures before their third birthday need less treatment for tooth decay. The analysis shows a dose-related response, with some benefit seen even in children having fewer encounters. The proportion of children with repeat visits for IMB oral preventive services has increased, and we hope to see this trend continue. The dissemination of the data demonstrating the effectiveness of these early preventive procedures should encourage more physicians to participate in IMB and more parents of high-risk children to request these services.

Dental Sealant Initiative. The expanded use of protective dental sealants has great potential for reducing the rate of tooth decay, especially in areas of the teeth not as affected by fluorides. The CDC recommends school-based dental sealant programs as one of the two most effective public health measures to reduce dental decay. The Section's sealant initiative has two parts:

- School-based sealant projects are targeted to children in the elementary school setting. The projects are conducted by teams of the Section's public health dentists and dental hygienists, who set up a temporary "Dental Office" in the school. Patient examinations and treatment plans are provided for eligible children by the dentists and public health dental hygienists place sealants for these at-risk children at no cost to the participants.

  This model received a recent boost by one of the recommendations of the 1999 North Carolina Institute of Medicine Task Force on Dental Care Access.[2] The recommendation led to a change in the North Carolina Dental Practice Act,[3] which now allows public health dental hygienists, trained by the Section, to place dental sealants when the public health dentist, who is providing the legally required direction of this activity, is not on-site during the sealant project. Approximately 15,000 sealants are provided annually for children at high risk for tooth decay. While the projects deliver direct preventive services to children who are at high risk for decay, they are also designed to educate children, parents, and others in the community about the need for sealants and to encourage them to ask their private dentists about sealants.
- Sealant promotions that occur in offices of private dentists are a public/private partnership where privately practicing dentists use their facilities to place sealants for eligible children at no cost. Another public/private partnership model uses a private office facility or other site, such as a community college dental clinic, where sealants are placed by both private and public health practitioners working side by side.

Such sealant initiatives illustrate the Section's focus on prevention, coupled with dental health education/promotion and services.

Oral Health Monitoring Systems

The Oral Health Section has always used evidence-based monitoring systems to guide programmatic strategies.

Statewide Oral Epidemiological Surveys. North Carolina is the only state with a series of statewide oral epidemiological surveys dating back to the early 1960s. The Section conducts these surveys about every ten-to-15 years. The most recent survey was conducted in 2003-2004. These surveys assess the oral health needs of the citizens of the state, and the data are used to plan and evaluate the state's dental public health program. They also evaluate the effectiveness of specific public health efforts, such as community fluoridation, dental sealants, and fluoride mouthrinse.

Dental Health Assessment. State dental public health professionals assess more than 134,000 elementary school children each year for oral disease. Their calibrated assessment is useful for identifying and referring those children who need dental care, as well as conducting disease surveillance and tracking disease patterns. This surveillance technique is used annually for kindergarten and fifth grade children in North Carolina. Children who are in need of dental care are identified and, with the help of school nurses, are referred to local providers. The assessment collects data on cavities, past restorative treatment, and sealant prevalence. The collected data allow for the evaluation of goals established as part of overall community health-based objectives.

Dental Health Education/Health Promotion

Statewide school-based education programs include classroom education, videos and other audiovisual tools, educational materials, and interactive exhibits. Portable educational/promotional dental exhibits, educational videos and slides, and media promotion campaigns are used statewide.

Education for professionals includes programs, educational information and materials, and in-service training for teachers and allied health professionals. Other training and instructional materials are provided to healthcare professionals through local organizations, the university system and dental and medical publications. A comprehensive dental health curriculum, *Framework for Dental Health Education*, and innovative on-line educational materials are available to elementary school teachers.

Children's Services. In 2004-2005, almost 151,000 children were provided instruction on topics, such as dental care, sealants, nutrition, oral conditions, fluoride, plaque control, tobacco use, and injury prevention. Section field staff also emphasize teacher training and support so that classroom instruction on dental health will be an ongoing process during the school year.

Adult Services. More than 13,000 adults are provided educational services each year in keeping with the Section's emphasis on preventive dental education and promotion to parents and teachers.

Professional Services. Section staff provide a number of services to health professionals. These services include educational/informational programs for local and state healthcare professional meetings and state and local dental societies, training programs for health department staff and other health professionals, and consultation with healthcare professionals across the state and nation. Section staff work with dental programs in community colleges as part of their public health curriculum. The Section mentors students and residents from the University of North Carolina at Chapel Hill Schools of Public Health and Dentistry.

Consultation Services. Educational consultation is provided by the health educators, upon request, to dental public health staff in addition to teachers and other healthcare providers.

Educational Materials. Approximately 500,000 pieces of educational materials are printed and distributed statewide each year, primarily to schools and health departments.

Educational Exhibits. Almost 5,000 people annually attend and receive information through point-of-contact dental health education exhibits used in various sites. With 11 different topics, the exhibits are used by individuals including Section staff, county staff, Department of Health and Human Services employees, community college staff, and related healthcare professionals.

Access to Dental Care

Access to dental care includes two aspects. These are (1) referral and follow-up for those persons in need of dental care and (2) improved access by the indigent population to dental care funded by third-party reimbursement. One measure of access to dental care in a population is the level of untreated dental cavities. According to the 2003-2004 North Carolina School Oral Health Survey, 19% of white, 30% of black and 38% of other (predominantly Hispanic) North Carolina children had untreated dental cavities. The Section's 2004-2005 kindergarten and fifth grade (K-5) statewide assessment data indicate that 22% of kindergarten children have untreated cavities in primary (baby) teeth, and 5% of fifth grade children have untreated cavities in permanent teeth.

In 2004-2005, almost 8,600 children received needed dental care as a result of follow-up by Section staff. Lack of access to appropriate dental prevention and treatment for the medically indigent is a major and worsening problem. Current access obstacles need to be reduced to improve participation from the private sector. Participation in Medicaid by privately practicing dentists has improved somewhat in the last few years as reimbursement has been increased, and paperwork has been streamlined.

The IMB program has increased access to oral preventive services and referrals for dental treatment for North Carolina's very youngest children. North Carolina 2003 Medicaid data show an eight-fold increase in the number of Medicaid-covered children under age three who received oral preventive services in a *medical* (i.e., physician's) office, with many referred for dental treatment.

The Section's successful collaboration with the North Carolina Dental Society continues with the North Carolina Dental Society-sponsored *Give Kids a Smile!* program. Statewide, dentists participate in and open their private offices to at-risk children for restorative care and sealant delivery. The 2005 *Give Kids a Smile!* Program provided 10,887 sealants for children. A variety of restorative services were provided, including 1,556 fillings. The approximate value of all of the services provided for the children was $1,170,000. The total number of patients treated was 4,832. Approximately 3,000 volunteers gave their time to provide these needed services. Collaborative projects enable public and private partners to work together to have an impact on access to dental care.

The American Academy of Periodontology states that periodontal (gum) disease is a risk factor for preterm and low birth weight babies. Medicaid pays for dental treatment for eligible pregnant women. However, many dental practitioners are reluctant to treat pregnant women. As part of professional education, the Oral Health Section needs to work more closely with the North Carolina Dental Society, UNC-Chapel Hill School of Dentistry, UNC-Chapel Hill School of Public Health, and North Carolina Area Health Education Centers to educate dental practitioners about the importance of addressing the oral health needs of pregnant women. These efforts would help expectant mothers decrease their risk of having low birth weight babies and reduce the transmission of decay-causing bacteria to their newborns.

In 1998, the North Carolina General Assembly charged the North Carolina Department of Health and Human Services to evaluate and recommend strategies to improve access to dental care for the Medicaid population and to improve the Medicaid program's provision of preventive services for their clients. The Secretary of the Department of Health and Human Services asked the North Carolina Institute of Medicine to convene a group to make recommendations to be reported back to the Legislature in April 1999. The resulting 23 recommendations have been reviewed every two years to document progress. The most recent review occurred in an Access to Dental Care Summit sponsored by the Section in April 2005. The Summit gathered community and dental care leaders to discuss potential strategies for improving dental care access, whether by further implementation of the original 1999 recommendations or through new strategies to improve access. The Summit report was published by the North Carolina Institute of Medicine in December 2005 as the "2005 NC Oral Health Summit Proceedings and Proposed Action Plan." If implemented, the updated action plan will help ensure access to dental care for more underserved North Carolinians across the state.

Dental Public Health Residency

The purpose of the North Carolina Dental Public Health Residency program is to allow dental practitioners with formal academic dental public health training, such as a Master's in Public Health (MPH), to gain valuable practical experience in the field of dental public health and to prepare candidates to become board certified in the American Dental Association accredited specialty of Dental Public Health. Dental public health residents participate in the planning, administration, and evaluation of programs that seek to reduce oral disease incidence and to improve the oral health of the community. The Section offers one of only two such residencies in the United States based in a state or local dental public health program. Chapter 130A-11 of the North Carolina Public Health Laws mandates the creation of a state public health residency, while the Residency Advisory Committee is an official committee within the Department of Health and Human Services. The Section's residency program is accredited by the American Dental Association's Committee on Dental Accreditation and as such, adheres to the Association's *Standards for Advanced Specialty Education Programs in Dental Public Health.*

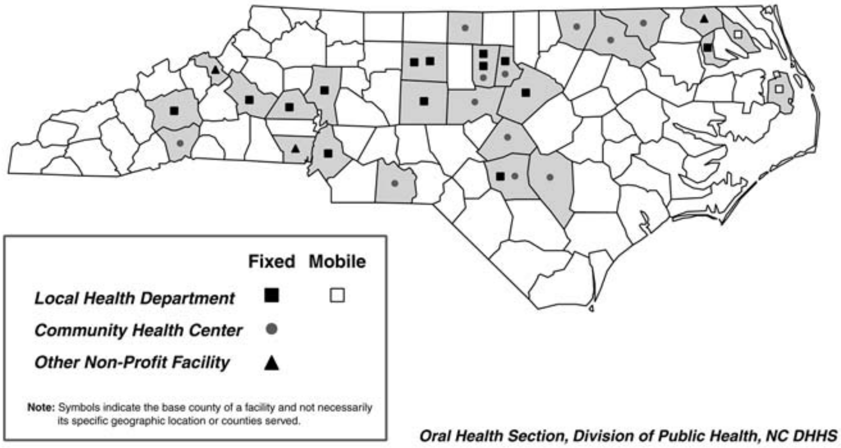
Local Government Strategies

Ninety-four of the 100 counties in the state have established some type of safety net dental care access facility or program, with many programs established within the past ten years.[4]

Most of these programs are operated by local health departments. Many of these programs combine mobile and fixed clinical facilities. They mostly serve children and adults with emergent care needs. Funding for these programs comes from local county budgets, grants, and reimbursement from third-party payers—mainly Medicaid and North Carolina Health Choice (S-CHIP). Recent increases in Medicaid fee-for-service reimbursements help these programs maintain viability. Many of these local programs were planned and implemented with technical assistance from representatives of the Section. Annual data from the community's kindergarten and fifth grade students that is collected by the Section demonstrates the need for these treatment resources and their funding. By providing assessments, referrals, case-management, school-based sealant projects, and education, public health dental hygienists employed by the Section or by county health departments contribute to a comprehensive community-based dental public health program.

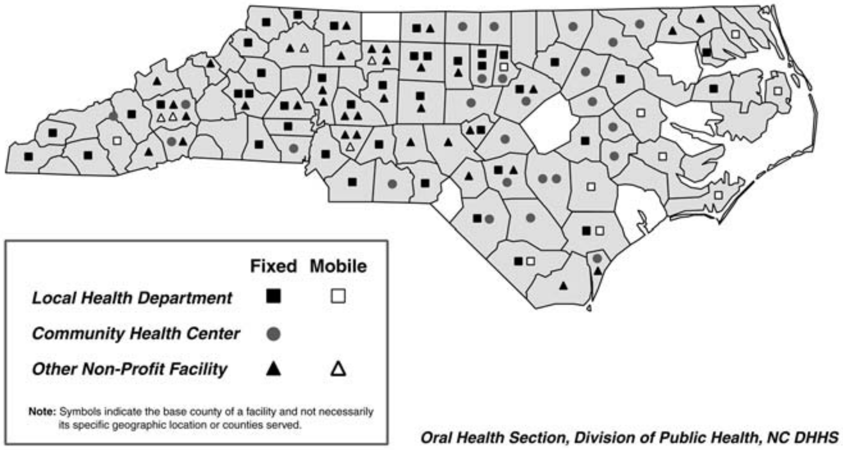
As previously described, one of the recommendations of the 1999 North Carolina Institute of Medicine Task Force on Dental Care Access[3] resulted in recent changes in the North Carolina Dental Practice Act.[4] These changes allow public health dental hygienists employed or contracted by county health departments to provide sealants and other specific preventive and therapeutic services for established patients already treatment-planned by the county's public health dentist, but without the on-site presence of that dentist.

Figure 1.
Dental Care Safety Net Facilites Prior to 1996



Oral Health Section, Division of Public Health, NC DHHS

Figure 2.
Dental Care Safety Net Facilites—October 2005



Oral Health Section, Division of Public Health, NC DHHS

Since 2000, the Section has certified 49 public health dental hygienists employed by local health departments to provide services without the on-site presence of a dentist. Thirty-three of these hygienists still work in dental public health programs. Of these, 17 provide clinical services to patients, and 31 provide community-based services, such as screenings for preschool and school age children.

Federal Funding for Dental Care Programs

Twenty-three federally qualified/community/rural health centers operate dental clinics in North Carolina. These clinics treat citizens in need, especially children, under guidelines established by the Health Resources Services Administration (HRSA). In Dental Health Provider Shortage Areas (DHPSAs), private and public health dentists are eligible to receive professional student loan repayments as an incentive to serve in geographic areas where the lack of access to dental care is documented. Coordinated by the North Carolina Office of Research, Demonstrations, and Rural Health Development, many DHPSAs have attracted and employed dentists to serve their residents. New federal guidelines require the construction of all new centers to include dental clinics.

Nonprofit Agencies and Volunteer Initiatives

Several communities rely on the dental services provided by local nonprofit agencies. Often these agencies collaborate with health departments to widen the scope of local resources. Also meaningful are open-door or "free" clinics staffed by volunteer dentists from the community. Most of these clinics are operated part-time, mostly in the evenings, and use either their own facility or another facility.

State Staffing Limitations

All of these activities are contingent on having qualified dental public health staff. Oral Health Section data indicate that improvements in dental health for permanent teeth have leveled off or are decreasing. Tooth decay in the preschool population is increasing. Additional staff (public health dentists, dental hygienists, health educators, and support staff) are needed to provide the preventive and educational services needed to reverse these trends. Yet, over the last 15 years, the Oral Health Section has lost almost 20% of its staff due to budget cuts. In addition, one-third of Section staff will be eligible for retirement in the next five years. The Office of State Personnel has acknowledged repeatedly since 1996 that salaries for Section dentists and dental hygienists are not competitive with private practice or local health departments, yet funding has not been identified to address these inequities. There are serious concerns about how the Oral Health Section will attract good staff to replace the retiring career dental public health practitioners as they leave the workforce.

Conclusions

Great strides have been made in reducing dental disease in the North Carolina population, particularly for our children. As described above, needed action steps include:

- Assuring adequate funding to support community water fluoridation and other dental preventive best practices.
- Increasing the proportion of young children at high risk for dental decay who receive the optimal number of IMB dental preventive services.
- Developing collaborations to educate dental practitioners about the importance of addressing the oral health needs of pregnant women to decrease the risk of low birth weight babies and to reduce the transmission of decay causing bacteria to their newborns.
- Supporting the action steps in the "2005 NC Oral Health Summit Proceedings and Proposed Action Plan," released by the North Carolina Institute of Medicine in December 2005.
- Maintaining and strengthening state public health resources and services to assure access to needed oral health services and programs for those most in need.

It is critical that adequate resources be directed toward prevention so that all North Carolinians can achieve oral health as part of their overall health. **NCMedJ**

The Role of Free Dental Programs in Care Provision for the Underserved

Steven D. Slott, DDS

Of the approximately 4,000 licensed dentists in North Carolina, only 24% accept Medicaid reimbursement for dental services to any appreciable degree. Therefore, for the 1.5 million citizens of the state currently enrolled in the Medicaid program,[2] there are less than 1,000 dentists statewide from whom they may seek treatment. This translates into one dentist per 1,500 Medicaid recipients. Factoring in those who do not qualify for Medicaid, yet are unable to afford dental treatment, it may be noted that the number of available dentists to treat the underserved population, in private practice, is inadequate. Additionally, other factors, such as (mal)distribution of dentists, and location of clinics, add to the difficulties for the underserved, further reducing their ability to access needed dental care. Anecdotal information from dental Medicaid providers frequently includes reports of patients traveling long distances in order to find a provider who will accept Medicaid reimbursement. Given the inadequacy of the existing dental care delivery system, the value and necessity of safety net programs becomes clearly evident.

According to the Oral Health Section of the North Carolina Division of Health and Human Services, currently within North Carolina, there are more than 75 dental clinics dedicated to serving low-income patients who have limited access to dental care. These safety net clinics include public health, community health centers, and free clinics.[3] Although it is somewhat difficult to ascertain the exact number of free dental clinics or programs with a free dental component, of the 63 members of the North Carolina Association of Free Clinics, 21 list dental care as a component of their overall program.[4]

Table 1 shows the number of free dental components among 58 out of 63 members of the North Carolina Association of Free Clinics (NCAFC). Although these figures represent only those clinics who are members of NCAFC, they do offer some perspective on the amount of time, services, and equivalent dollar amounts donated toward dental needs, which comprise only 3.6% of overall visits to the free clinics.

Program Hurdles for Free Clinics: Funding and Personnel

Focusing on the free dental clinics, there are two main hurdles with which these programs must deal in order to be successful. As would be expected, these are funding and personnel. In addressing funding issues, it should be realized that there are many available sources for viable dental nonprofits, including,

Steven D. Slott, DDS, is the founder and President of the Open Door Dental Clinic of Alamance County. He can be reached at Sslott1027@aol.com or PO Box 1744 Burlington, NC 27216. Telephone: 336-226-5349.

but not limited to, governmental organizations/grants, charitable trusts, local organizations, and private donations. Additionally, there are dental supply dealers and other organizations with programs providing free or low-cost supplies to qualified free dental clinics. The problem in funding often resides not in the lack of available resources, but in the lack of awareness of these resources by volunteers or paid personnel who are inexperienced in searching them out, inexperienced in grant writing, or lack an understanding of the various funding or resource entities' requirements. Table 2 provides examples of some sources of funding, in-kind donations, or other support. Each source has its own restrictions, but the long-term success and sustainability of the dental programs will depend to a large part on their ability to seek out these resources, match their needs to the needs and desires of the sources, and on their ability to keep expenses to a minimum while still providing necessary services for their targeted population.

Table 2.
Examples of Available Resources for Free Dental Care Programs

Source	Type of Resource
Charitable Foundations	
Kate B. Reynolds Charitable Trust	Grant/Monetary
The Duke Endowment	Grant/Monetary
Canon Foundation	Grant/Monetary
Governmental	
NC Office of Rural Health Department of Health and Human Services	Monetary
Private	
NC Dental Society	Monetary
NC Association of Free Clinics	Monetary (available to members only)

World Dental Relief	Supplies (reduced cost)
3M ESPE Dental Products	Supplies
Local	
Civic Organizations	Monetary/other
Local Foundations	Monetary
Local Benefactors	Monetary
Local Businesses	Monetary/in-kind/other
Local Hospitals	Monetary/in-kind
Local Dental Societies	Monetary/in-kind/other
Churches	Monetary/in-kind/other
Local Government	Monetary/in-kind/other

The second main hurdle is that of personnel. The recruitment, retaining, and scheduling of volunteer workers is crucial to the viability of any nonprofit organization, free dental clinics being no exception. Whether or not there are paid personnel within the organization, this aspect of the program certainly requires constant oversight and effort. Additionally, as these clinics are a part of the healthcare field in which licensure, liability, competence, confidentiality, political, worker safety, and other complicated issues abound, the task of recruiting and maintaining an adequate workforce is even more challenging. Without strict strategies and policies in place with which to handle these issues, the chance of long-term success of a free clinic decreases dramatically.

Summary

Due to the shortcomings of the existing healthcare delivery system in general, and the dental field in particular, safety net programs are not simply optional; they are mandatory to help meet the overwhelming healthcare needs of the underserved. Free dental clinics are a vital part of this system, and indeed, millions of actual dollars,

"Given that most dental professionals have limited contact with the underserved, the free clinics offer the opportunity to bring in volunteer dentists, hygienists, and dental assistants who may then gain first-hand knowledge of the access crisis and work directly with North Carolina's growing population in greatest need of dental care."

The Open Door Dental Clinic of Alamance County

The Open Door Dental Clinic of Alamance County originated in October of 1998 operating one night per week in the newly opened Alamance County Health Department Dental Clinic facility. Although the focus of the health department clinic was to be on children, the Health Director and the Dental Advisory Committee desired to provide some dental services for the adult population as well. Thus, arose the idea of a free adult clinic to meet one or more nights per week. Dr. Steven Slott, a local dentist, and member of the Alamance County Board of Health, agreed to undertake the project, and the Open Door Dental Clinic was born.

Portable dental care in action—hundreds receive dental care at Burlington Missions of Mercy, October 2005

The clinic operated on Tuesday nights for extractions only. The list of volunteers included ten dentists from the local dental society, ten dental assistants, one dental hygienist, four front desk personnel, and dental assisting students from the Alamance Community College dental assisting program. Due to the overwhelming need, a second night of clinic was initiated for extractions only. In 2002, with funding from the Kate B. Reynolds Charitable Trust, in cooperation with the Alamance Regional Medical Center, a third night was initiated for restorative needs. An integral part of the restorative night was the involvement of dental students from the University of North Carolina at Chapel Hill (UNC-Chapel Hill) School of Dentistry. Through a cooperative effort between UNC-Chapel Hill, the health department, and the Open Door Dental Clinic, dental students were allowed to provide clinical services to the patients in the clinic.

In 2004, planning for a new program operating under the Open Door Dental Clinic was undertaken. A portable dental program modeled after the Virginia Dental Association's Missions of Mercy program was the desired goal, which would help the underserved not only in Alamance County, but in many different dental care shortage areas of the state as well. This program includes utilization of portable dental chairs, units, lights, and all necessary peripheral equipment to set up large portable dental clinics in which volunteer providers would render free dental treatment to hundreds of financially qualified individuals during two- or three-day weekend events. Once again, through the generous support of the Kate B. Reynolds Charitable Trust, in cooperation with the Alamance Regional Medical Center, along with funding assistance from other local and state organizations, enough portable equipment was purchased to have a 30-chair portable clinic, complete with full sterilization, x-ray, all necessary instruments and supplies, and a large truck in which to store and transport the equipment. Utilizing this equipment, as many as six or seven free clinic weekend events will be held in different areas of the state each year.

During 2005, in addition to the fixed-site clinics in Burlington, five portable clinics have been held, in the west, east, and central areas of the state. In each clinic, 250-350 needy patients received dental treatment consisting of extractions, fillings, cleanings, and other services. Volunteers for each event included ten-20 dentists; ten-30 dental students; two to eight hygienists, dental assistants, and assisting students from community college programs; and scores of general volunteers. Tentative plans for 2006 include portable clinics in Murphy, Boone, Washington (NC), Burlington, and Wilmington. Treatment for 500 or more patients per weekend event will be the targeted goal for 2006, with increases each succeeding year. For 2005, it is estimated that the dollar value of donated dental services from the Open Door Dental Clinic of Alamance County will be in excess of $350,000, with increases to be seen in each succeeding year. Patient visits for 2005 for both fixed-site and portable clinics will be estimated to be between 2,500 and 3,000. Estimated visits for 2006 will be 3,500-4,000.

Needy patients waiting for treatment in Burlington, October 2005

Funding for the Open Door clinic has come from many different sources. As previously stated, two grants have been received from the Kate B. Reynolds Charitable Trust, the first in the amount of $41,000 to fund the start up of the restorative night and, most recently, $140,000 to fund the portable initiative. In addition, funds have been received from local Alamance County foundations, the Alamance-Caswell Dental Society, civic organizations, the Alamance Regional Medical Center, and other private donors. In-kind donations of dental equipment, facilities, and supplies have also been donated by the Alamance County Health Department, the Henry Schein Cares program, and from numerous dentists in the area.

millions of dollars worth of services and thousands of hours of professional manpower are donated each year to provide free dental services for the needy. The short-term benefits of these clinics are obvious, the rendering of dental care to tens of thousands of individuals per year who would otherwise go without. The long-term advantages may be somewhat less than obvious, however. Given that most dental professionals have limited contact with the underserved, the free clinics offer the opportunity to bring in volunteer dentists, hygienists, and dental assistants who may then gain first-hand knowledge of the access crisis and work directly with North Carolina's growing population in greatest need of dental care. Additionally, the free clinics often offer the same benefit for dental students from the University of North Carolina at Chapel Hill, as well as for undergraduate pre-dental students. This is a key aspect, as for every one of these students who may eventually enter the dental profession with a willingness to provide for the underserved population, tens of thousands of individuals in need could potentially receive dental treatment over the span of a dental career.

The challenges of beginning and maintaining a free dental program over the long term are daunting. However, for those willing to invest the time and effort, the resources are available for long-term success with a resultant significant, positive impact on the dental care access crisis now in existence. As stated by Dr. Franklin M. Boyar in describing his free dental program in Florida, "Project: Dentists Care is simply an organization that brings together unmet health needs of indigent populations within our communities with the desire of individual dentists to help their fellow man, along with the responsibility of a profession to deliver needed care to the underserved."[5] Inherent in consideration of itself as a profession is the understanding by the component members of dentistry that it is indeed a responsibility, not simply an option, to deliver needed dental care to all citizens, regardless of their ability to pay. At the heart of any successful resolution of the dental care access crisis is the ability of dental providers to accept this responsibility, significantly increase Medicaid acceptance, willingly participate in access initiatives, and provide the care for which they have been granted licensure by the citizens of North Carolina. **NCMedJ**

COMMENTARY

Improving Access to Dental Care Remains a Priority of One of North Carolina's Largest Philanthropies

John H. Frank

For more than a decade, improving access to dental care has been a priority for the Health Care Division of the Kate B. Reynolds Charitable Trust. Since 1995, the Trust has awarded more than 130 grants totaling $21.2 million in support of programs addressing multiple facets of the issue. Yet, in meetings, workshops, and consultations, front-line professionals in every corner of the state continue to list dental access as one of the top three healthcare concerns facing their communities.

With funding provided by the Kate B. Reynolds Charitable Trust and The Duke Endowment, the North Carolina Institute of Medicine Task Force on Dental Care Access began a study of the issue in 1998. Results of the study, which were released in 1999, showed that North Carolina ranked 47th in the supply of dentists to serve state residents, with only 3.8 dentists per 10,000 population—far below the national rate of 6.0 dentists per 10,000. Uneven geographical distribution of practicing dentists intensified the shortages, particularly in rural areas. At that time, four counties had no dental practice; another 36 counties had no dental practice that offered services to Medicaid patients. Although a significant number of private dentists regularly volunteer their time at free clinics and community or rural health centers, the number of Medicaid- and uninsured- or underinsured-patients exceeds the number that can be served by available providers. Following the study, the task force issued 23 recommendations intended to lay the foundation for delivering adequate preventive and curative dental care to all residents across the state.

> *"Although a significant number of private dentists regularly volunteer their time at free clinics and community or rural health centers, the number of Medicaid- and uninsured- or underinsured-patients exceeds the number that can be served by available providers."*

Even before the dental access study was undertaken, the Health Care Division of the Trust had begun funding programs to establish and expand existing dental services around the state, and that emphasis continues today. The programs funded by these grants typically rely on cooperative programming among existing organizations and generally fit one of four structural categories: hospital-based, health department-based, community or rural health center-based, and free-clinic-based.

Many of the expansion programs target children and other special needs groups, in which dental disease often remains untreated. At the time of the Task Force report, 25% of all of North Carolina's kindergarten children exhibited untreated dental disease, and a large number of those were from low-income populations living in rural areas. In an effort to extend dental care to these children, the Trust has awarded several grants for providing mobile dental services. An example is a 1996 grant to Mission St. Joseph's Hospital in Asheville for a dental van, called the ToothBus. Although it began as a stand-alone unit, a second ToothBus was soon

John H. Frank is Director of the Health Care Division of the Kate B. Reynolds Charitable Trust, one of the state's largest private foundations with assets of more than $500 million. The Trust was established solely for the benefit of the people of North Carolina. The Health Care Division, which awards three fourths of the Trust's funding each year, supports healthcare programs directed to the financially needy in communities across the state. Mr. Frank can be reached at john@kbr.org or 128 Reynolda Village in Winston-Salem, NC 27106. Telephone: 336-723-1456.

The ToothBus is a 40-foot dental office on wheels that serves children who have no other access to dental care. It is a program of the Billy Graham Children's Health Center at Mission St. Joseph's Hospital in Asheville.

added, and within four years, ToothBus vans were delivering services to 46 elementary schools in ten counties. The ToothBus and numerous other mobile clinics around the state reach thousands of children each year.

Table 1.
Grantees by Region

	Grants	Amount*
Western	35	$5.5
Eastern	32	$5.2
Northern Piedmont	23	$3.6
South Piedmont	21	$3.7
North Central	12	$1.9
South Central	11	$1.3
TOTAL	134	$21.2

* Grant in millions.

Another area of emphasis for the Trust is manpower development. Grants awarded in support of manpower development are intended to increase the overall number of dental professionals in the state, with particular focus on reducing shortages in underserved areas. A majority of these education grants have been awarded to community colleges for expanded training programs for dental hygienists and dental assistants. Grants have also been made to the University of North Carolina at Chapel Hill (UNC-Chapel Hill) School of Dentistry to support student internships served in rural North Carolina counties.

As part of our commitment to improving dental access, the Trust hosted a Promising Practices Meeting in September 2003 in Winston-Salem for representatives from public and private agencies across the state. During the day-long meeting, the North Carolina Institute of Medicine presented a progress report on the implementation of its Task Force recommendations. The Trust also selected panelists from successful dental programs to discuss features of their programs with attendees. The event was intended to disseminate information while encouraging innovation and collaboration in addressing dental access at the community level.

Although significant dollars have been invested since 1995, the Trust continues to include improving dental access for the financially needy among its priorities. In reviewing grant requests, the Trust is particularly receptive to applications that address the following issues:

- A plan for ensuring adequate staffing,
- A back-up plan for dealing with "no shows,"
- Evidence of support for the program from dentists practicing in the community, and
- A financial plan that includes Medicaid reimbursement numbers adequate to sustain the program over the long term.

Please visit our Web site (www.kbr.org) to learn more about the types of programming that fall within Trust grantmaking guidelines and the procedures for submitting an application. **NCMedJ**

COMMENTARY

Access to Primary Dental Care:

A Commentary on the Economics of Dental Practice and Thoughts on Solutions to Improve Access to Primary Dental Care

John N. Williams, DMD, MBA

Imagine a world in which there were no self-induced health problems. A world in which there were no obesity, no hypertension, no motor vehicle accidents, and no oral health problems. Realistically however, we realize that all of these conditions exist because accidents happen, individuals ignore information that contributes to healthful lifestyles, and most people are not motivated to change their unhealthful habits to healthful ones, and sometimes healthcare services are not available to provide care for those in need. In addition to accidents, knowledge, and motivation, economics play a major role in the availability of healthcare services.

A current topic of discussion in dentistry and medicine is lack of access to services to prevent and manage unhealthful conditions. It has been observed that many people living in the 100 counties of North Carolina, particularly those in counties with a lower-economic vitality, lack access to dental care. An uneven distribution of dentists practicing within the state exists in that only eight counties have a dentist-to-population ratio at or above the national average of 5.8 dentists per 10,000. These eight counties contain the large population centers in the state. Another 78 counties have fewer than the national average numbers of dentists and, thus, are designated by the federal government as dental shortage areas. Four counties of North Carolina have no dentists.[1] Much of the dental workforce literature uses a simple calculation of dentist-to-population ratio to determine shortage or surplus numbers of dentists relative to national averages without much consideration of today's dental practice economic influences on access.

> *"Much of the dental workforce literature uses a simple calculation of dentist-to-population ratio to determine shortage or surplus numbers of dentists relative to national averages without much consideration of today's dental practice economic influences on access."*

Access is a complex concept with a strong economic influence. Having adequate access, requires certain behaviors on the part of both the providers of health services and the receivers of health services. The United States healthcare system operates in a free market, capitalist economy where producers and consumers have a variety of alternatives upon which to base healthcare purchasing decisions. As with any free market, those with more financial resources have more choices. An important distinction is that *medical* care costs function differently than *dental* care costs when medical insurance is available. Most consumers with medical insurance are oblivious to the costs of services in advance of receiving them, and prior to the consumer seeing the final costs, much discounting of the full fees charged occurs through third-party contracting and negotiated prices. In contrast, dental costs, with or without insurance, are usually known in advance of receiving treatment, and the consumer can make an informed economic decision.

Another significant difference between medical and dental

John N. Williams, DMD, MBA, is Professor and Dean of the University of North Carolina at Chapel Hill School of Dentistry. He can be reached at john_williams@dentistry.unc.edu or CB# 7450, Chapel Hill, NC 27599. Telephone: 919-966-2731.

market costs is the extent to which third-party payers (insurance companies) are present. In North Carolina, fewer persons are covered by some form of third-party payment mechanism for dental care than for medical care, which has approximately 87% of the population covered by an employer, individual, or government-sponsored programs.[2] Dentistry has avoided much of the market influence of third-party payers, who can establish what they will pay through a schedule of benefit payments or determine payments based on regional usual, customary, and reasonable (UCR) fees. In economic terms, dentists, for the most part, are price makers, which gives them freedom to set fees for professional services, while our medical colleagues have become price takers—receiving whatever a third party decides to pay regardless what fee a physician may charge. This difference is significant because it has a major influence on the way dental care and, ultimately, dental care access is made available.

The supply of providers (physicians and dentists) also has an impact on the free market system. In the mid-1980s, there was a national concern over the existing number of dentists graduating from dental schools, which in some parts of the United States was perceived as an "over-supply" of dentists. Between 1983 and 2001, six private dental schools closed, and the national number of dental graduates fell from 5,756 in 1983 to 3,778 by 1993, a decline of 34%. In recent years, three new dental schools have been established, but enrollments have only increased to approximately 4,300 dental students nationally.[3] The reduction in the national supply of dental graduates by over 30% gives the dentist of today a huge market advantage when determining what fees to charge, where and when to practice, and what type of payment source (i.e., private pay, insurance, or Medicaid) to accept. Therefore, from a purely economic standpoint, dentists operating in the free market can optimize their economic benefit and avoid less financially beneficial payment arrangements. In practical terms, this explains why dentists locate in urban areas (generally more vital economic environments relative to rural areas) and avoid participation in poorly funded, third-party payment programs like Medicaid. The financial alternatives are simply too compelling.

This is not to suggest that dentists aren't concerned about access and don't participate individually or as part of various programs to reduce the access problem by providing free dental care. Many dentists do these altruistic things. From a purely economic perspective, however, this market phenomenon explains how and why dental care is delivered in the United States today, and why many states, including North Carolina, have an uneven distribution of dentists and access problems.

In contrast, enrollments in medical schools during this same 22-year time span remained unchanged despite a national call in the mid-1990s to reduce the entering medical school class size by 20-25% by 2005.[4] This reduction did not occur. While the numbers of primary care physicians in North Carolina are also a concern, relative to dentists, there are large numbers of physicians in the healthcare economic market.* This has limited physician influence over what fees to charge, where and when to practice, and what type of patients to see due to heightened competition. Third-party payers can more easily dictate the economic terms within a more competitive healthcare market.

At this point, one might ask what all this discussion of healthcare economics has to do with dental care access. I assert that our current economic climate is the basis for understanding this extremely complex topic of access and will add to one's understanding of what solutions might or might not work to improve access for the underserved populations in North Carolina.

Access to care is not only complex, but a relative concept as well. I draw on my personal knowledge of access to dental care problems in Kentucky. Kentucky is a state not very different from North Carolina in demographic and economic characteristics, but with less than half the population of North Carolina and enrolling twice as many dental students in two dental schools. Comparisons of oral health status and behavior reported by the Centers for Disease Control and Prevention (CDC) as part of the Oral Health Surveillance Program make it possible to study some dental behaviors and outcomes nationwide. Findings related to North Carolina and Kentucky indicate that, relative to the United States as a whole, Kentucky and North Carolina are doing a comparable job of providing some dental care access for the public. Compared to Kentucky, in percentage terms, in 1999 about the same percentage of people in North Carolina visited dentists annually (67.2% vs. 67.6%), and about the same percentage of the population received a tooth cleaning (68.2%), while fewer people in North Carolina had lost their natural teeth (24.4% vs. 44.3%).[5]

In 1999, these North Carolina dental health outcomes were achieved in a state with one dental school enrolling 75 doctor of dental surgery (DDS) students per year and with a statewide DDS-to-population ratio (4.3 DDS per 10,000) below the national average (6.4 DDS per 10,000).[6]

At this point, I'll summarize my commentary on today's economic market on the access question as follows: (1) access is a complex topic; (2) the free market of economics in dental care delivery has a significant influence over dentists in terms of where, when, type of practice dentists choose, and the extent of their participation in Medicaid programs; and (3) determining whether a problem with access to dental care exists is relative to the desired dental care outcomes.

With this economic context in mind, and having a major influence over the current dental delivery model, we can do better for the citizens of North Carolina. There are compelling reasons to work harder to improve the dental health outcomes of the state. As the old economies of tobacco, textiles, and

---

* In 2004, there were 7,401 primary care physicians and 3,628 dentists practicing in North Carolina. That same year, the physician-to-population ratio was 8.6 per 10,000, and the dentist-population ratio was 4.2 per 10,000 population. Cecil G. Sheps Center for Health Services Research. University of North Carolina at Chapel Hill. Health Professions Database. Available at: http://www.shepscenter.unc.edu/hp/prof04.htm. Accessed November 2005.

furniture have gone away, new economic opportunities will depend even more on a healthy workforce, which includes a population with good dental health. I suggest four strategies to consider as alternatives to improve access and, ultimately, the quality of oral health for our state's population.

Expand DDS Educational Capacity at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) School of Dentistry

Given the projected 52% growth in the North Carolina population (more than 12 million individuals) over the next 25 years and making some cursory assumptions about the state's current dental workforce demographics (retirements, etc.), it is prudent to increase the capacity for enrolling a larger DDS class size at UNC-Chapel Hill for a period of time.[7] University planning for this event started two years ago. We need to expand the dental education enrollment capacity by 50% (to an enrollment capacity of 120 per class) and be sensitive to ever-present market forces such that we can adjust enrollments either up or down in response to the demand for dental services. The rationale for expanding the UNC-Chapel Hill program is: (1) economy of scale, (2) availability of dental faculty, and (3) a 50-year history of graduating dentists as primary care general practitioners.

First, the American Dental Association monograph on the Economics of Dental Education reports that economies of scale are provided by expanding an existing dental school's enrollment (lower marginal cost per student) rather than incurring higher educational costs per dental student enrolled in a small (less than 50-member class) dental school.[8] Over time, adding 20-to-40 more dental students to the existing class size of 81 could be done in an incremental fashion. An upgrade in facilities would be needed to handle the maximum capacity of up to 120 dental students per class, and planning is already underway.

Second, at the national level, there is a concern about the availability of dental faculty to teach. The American Dental Education Association (ADEA) states that in 2003-2004, there were more than 240 vacant, but funded dental faculty positions existing at the 56 United States dental schools.[9] While this number has declined over the past five years, it has remained above 200, with most vacancies occurring in the clinical sciences. An established dental school with an existing faculty can more readily handle faculty shortages by reallocating faculty responsibilities in the short run.

Finally, most dental school graduates, and certainly those at UNC-Chapel Hill, enter primary care general practice. Since 1954 when the first DDS graduated from UNC, over 75% of the students have entered primary care general practice and have located throughout the state.[10]

Enhance the Integration of the Dental Care Delivery System

North Carolina is fortunate to have an existing Community College network of educational programs for educating dental hygienists and dental assistants. Better integration of the dental team during their education programs can improve productivity once in practice. There are dental care delivery systems in other states that make use of expanded-duty dental assistants and have expanded duties for dental hygienists. These arrangements can add to dental office productivity and, hence, expand access. It has been suggested that dentists should enhance their productivity through new workforce models, and North Carolina should be active in these discussions.[11,12]

Institute a Required, One-Year Post-DDS General Dental Residency Program for All Newly Licensed North Carolina Dentists

Utilizing the emerging network of dental clinics in low-access areas, the existing Federally Qualified Health Centers (FQHCs), contemporary instructional technologies and in partnership with the state Area Health Education Centers (AHEC) system, it is feasible to deploy dental graduates into a one-year general dental residency program. This could be a requirement for all graduates who attend UNC-Chapel Hill. This concept has been discussed as a realistic way to better prepare dentists for the future and can improve access.[12,13] The advantage of using dental graduates over the reliance on third- or fourth-year dental students to provide care is the graduate's better understanding and application of comprehensive care. They are more efficient and can expand their knowledge, skills, and values by serving the state in one of several selected low-access areas. In this way and through existing partners, the state could establish a network of facilities with an annual revolving dental workforce. Given the economic attractiveness of private dental practice today, it is unrealistic to expect past models of loan forgiveness to provide any long-term solution to expanding access. These facilities could establish the continuity of place, but the workforce would revolve annually. It would be hoped that some dental participants may elect to establish themselves in practice within the underserved geographic area and help to address the access issues over the longer term.

Improve Medicaid Reimbursement Rates for Dental Care

With a better understanding of the economics of today's dental practice, an immediate way to improve access to dental care for the state of North Carolina is to increase reimbursement rates paid to dentists to at least the 75th percentile of North Carolina private practice market rates in 2005. This would provide an economic incentive to dentists and increase the number of dentists accepting Medicaid patients. This was a major recommendation from the North Carolina Institute of Medicine Task Force on Dental Care Access in 1999.[14] Today, dentists operate in a free market and will respond favorably to these raised rates for treating Medicaid patients. The numerous practice opportunities available to dentists will require this type of program to create a broad enough Medicaid network across the state to meet the dental care access challenge.

Conclusion

In conclusion, I have provided a brief commentary on the economics of dental practice today, and how it influences the dental care access dilemma and current dental care delivery model in the state. There are compelling reasons to work harder to improve the dental health outcomes of the state. I suggested four strategies to consider as alternatives to improve access and, ultimately, the quality of oral health for our state's population. Working in partnership throughout the state with other educational programs, the AHEC program, the North Carolina Dental Society, state government, and others, we can and will do innovative things to engage the public and improve access to dental services for the citizens of North Carolina. It is my hope that one day we will be able to live in a world in which all citizens may enjoy optimal oral health. **NCMedJ**

Improving Oral Health in North Carolina:
Exploring the Potential of a New School of Dentistry at East Carolina University

Michael J. Lewis, MD, PhD, D. Gregory Chadwick, DDS, MS, and F. Terri Workman, JD

Dental care is an essential component of healthcare. Inadequate attention to dental health issues can have deleterious effects on the health of our population at every age level and especially among school-age children and the adult workforce. North Carolina faces enormous challenges, as do other states, in both the recruitment and retention of dentists serving rural and low-income areas. While it is clear that dental care technologies and modes of clinical practice have made it easier, more efficient, and, often, less costly to serve larger numbers of patients' dental care needs with the same number of dental care providers, there are demographic challenges. In our rural and smaller counties, there is a serious shortage of dentists, and a number of these dentists are nearing the age of retirement. The opportunity for dentists in rural and smaller counties to implement these technological efficiencies is not likely to be in place for many more years.

Since the publication of the North Carolina Institute of Medicine Task Force Report on Access to Dental Care for Low-Income Persons,[1] there has been a growing consensus that the state faces a shortage of dentists, and that the supply is not likely to meet demand in the near-term, given current levels of productivity from the existing School of Dentistry at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) or the recruitment of dentists from other states and schools of dentistry.

The Current Dental Workforce and North Carolina Demographics

In North Carolina, the dental workforce is growing older; in order to keep current ratios of dentists-to-population, we will need to replace at least one third of the 3,628 dentists in the current professional workforce in the next ten-20 years. As important, the number of dentists of African-American or other minority-group status is only 10% compared with a state population that is 34% nonwhite. There are as many as 40 North Carolina counties where no dentists provide services to persons covered by Medicaid. Four counties (in eastern North Carolina) have no dentists. There are too few pediatric dentists in North Carolina (a total of 108 as of 2004, representing 3% of the total North Carolina dental workforce), and there are many counties, particularly in the eastern part of the state, where residents would have to drive at least two hours to find an emergency care facility that would be able to treat the dental care needs of a child. It is estimated that North Carolina needs an additional 1,209 dentists to enter practice over the coming ten-20 years—without considering the impact of deaths and relocations of North Carolina dentists out-of-state—to meet the anticipated needs represented by current demand.

North Carolina was the 11th largest state as of 2000 in terms of total population (8.0 million), and it is one of the seven fastest growing states. With a population of 8.4 million in 2003, North Carolina is predicted to become the seventh largest state by 2030 (with a population of 12.2 million) and absorb the seventh largest population increase among the 50 states.[2] North Carolina has the second largest number of rural residents; only Pennsylvania has more.

Nationally, there are 5.7 dentists per 10,000 population. As of 2004, North Carolina had 4.2 dentists per 10,000, representing a slight increase since 2003. The ratio of dentists-to-population is quite different in metropolitan and rural areas of the state. Urban areas have a ratio of 4.8 dentists per 10,000 population, while rural areas have only 3.1 dentists per 10,000 population in rural areas. Despite the rapid increases in our state's population, the dentist-to-population ratios for North Carolina have remained relatively unchanged since 1987, and North Carolina's ratios are consistently low by national standards. It is significant that only eight out of 100 North Carolina counties have dentist-to-population ratios that either meet or exceed the national level of 5.7

Michael J. Lewis, MD, PhD, is Vice Chancellor for Health Sciences at East Carolina University. He can be reached at lewismi@mail.ecu.edu or AD-48 Brody Medical Sciences Building, Greenville, NC 27834.

D. Gregory Chadwick, DDS, MS, is Associate Vice Chancellor for Oral Health at East Carolina University.

F. Terri Workman, JD, is Associate Vice Chancellor for Health Sciences at East Carolina University.

dentists per 10,000 population, while as many as 28 counties have only two dentists or fewer serving 10,000 or more people.

To bring the state as a whole up to the *national* level of 5.7 dentists-per-10,000 population, would require the addition of 1,251 dentists. If an effort were made to raise the ratio of dentists-to-population statewide to the *current state rate for urban areas* (i.e., 4.8 dentists per 10,000 population), an additional 480 dentists would be required. Since retirements, deaths, and relocations further increase the number of needed dentists, it is clear that current state efforts to produce more dentists cannot meet either of these goals.

The East Carolina University Response: A New School of Dentistry in Eastern North Carolina

It is against this background of need and demand for dental care in North Carolina that the Chancellor and Trustees of East Carolina University (ECU) propose to initiate the planning process leading to the development of a four-year school of dentistry in Greenville. ECU offers an appropriate location and academic venue for such a school. The University is located in and serves a geographic region of the state with a clear need for additional dental care and resources. Moreover, the professional dental community in Greenville and surrounding counties of eastern North Carolina has given strong support and encouragement to the idea of a new school of dentistry located in Greenville.

> *"...the new school of dentistry at ECU will give emphasis and exposure to the variety and excitement of practice in communities throughout North Carolina where dental care is presently in short supply."*

There is no question that the oral healthcare needs of North Carolina's underserved populations will require multiple, not single, strategies. Moreover, the persistent and urgent need for additional dentists, particularly in the largely rural areas of eastern North Carolina and the western-most counties of the state, validates the need for multiple initiatives if the oral health of North Carolina's population is to improve. But, a critical factor in all of these policy deliberations is the adequacy of professional dental workforce supply, as well as the geographic maldistribution of these professionals within the state.

Eastern North Carolina Demographics

Eastern North Carolina is a region characterized by both small and socio-economically disadvantaged populations. An examination of the data shows that a large proportion of the populations in several counties of eastern North Carolina have incomes that place them below federal poverty guidelines (FPG). Although the percentage of their populations living in poverty since 1980 has declined, 31 out of the 41 counties have as many as 20% of their children living in poverty. Further, median household income in North Carolina statewide was a modest $38,194 in 2002, but in only four of these 41 counties does median household income rise above this statewide average. Families in these lower-income areas have less disposable income and healthcare purchasing power as well as limited access to public health and other subsidized sources of dental or other healthcare.

ECU is in the fortunate position of having existing land sufficient to accommodate the footprint of any physical plant for a new school of dentistry that might be designed. Moreover, the utilities infrastructure within the Health Sciences campus is already in place and will not require significant upfitting to facilitate such construction. The implications of adding a school of dentistry to the Health Sciences Division have been carefully considered, and the faculty and administration at ECU and, in particular, at the Brody School of Medicine, are well aware of the demands of adding yet another healthcare professional school at ECU.

ECU is proposing to develop a dental school with a mission similar to the one embraced by the Brody School of Medicine at the time of its inception. With this history and the current need as guideposts, it is our intent to develop a "community-oriented" school of dentistry. By this terminology we specifically refer to our intent to develop a school of dentistry whose primary mission will be to attract into the profession individuals of high intellectual capacity who have a desire to practice dentistry in this state, and who are oriented toward a professional lifetime career of service to communities in need of high-level dental care. Moreover, the new school of dentistry at ECU will give emphasis and exposure to the variety and excitement of practice in communities throughout North Carolina where dental care is presently in short supply.

Many of the students admitted to the Brody School of Medicine are from rural and underserved counties, are identified as having a passion for primary care and are given intensive exposure to the day-to-day challenges of serving populations with either socio-economic or other barriers limiting access to care. Students are also enabled to visit and learn about constructive and effective healthcare organizations within the region that have made substantial efforts to meet the needs of these traditionally underserved populations. This same approach to be integrated with the overall plan for an ECU school of dentistry will be developed in partnership with local public health and dental professionals in private practice throughout the region.

> *“Our intent is to develop a school of dentistry whose primary mission will be to attract into the profession individuals of high intellectual capacity who have a desire to practice dentistry in this state, and who are oriented toward a professional lifetime career of service to communities in need of high-level dental care.”*

ECU embraces a global commitment to the community-based practice of dentistry, whether among those now in practice who will become involved as adjunct clinical faculty assisting our students in understanding the challenges of practice in the local settings where these practitioners now reside, or whether it is in our programs that help graduating students select a practice location where their services will be most needed and where they can satisfy both professional and personal goals.

Feasibility of a New School of Dentistry at East Carolina University

As the proposal for a new school of medicine at ECU was taking shape in the 1970’s, it was the intent that this institution would address what was widely viewed as a shortage of primary care physicians in the state, particularly those serving in rural and underserved counties. Although the goals of the new school of medicine at ECU were widely shared as highly salient policy objectives, there was anxiety over how a second publicly-supported medical school would impact the existing four-year school of medicine at the University of North Carolina at Chapel Hill. In the 24 years since the graduation of its first four-year class, the Brody School of Medicine has clearly delivered on its mission. The school has (1) improved access to care; (2) graduated classes of physicians with a high proportion choosing to practice in North Carolina after finishing their clinical residencies, one of the highest percentages of in-state practice locations among United States medical schools; and, (3) graduated one of the nation’s highest percentage of graduates who have chosen to practice in primary care fields. In addition, the Brody School of Medicine often has one of the highest percentages of minority population graduates of all the United States medical schools. In fact, last year, the school was number one in the United States (with the exception of the three historically African American schools of medicine). Given the low percentage of minority dentists (10%) in North Carolina contrasted with the growing need for minority providers, this would be a great advantage.

Moreover, the claims or the fears that the existence of a medical school at ECU would threaten the programs and strengths of the medical school at UNC-Chapel Hill have not been borne out. While the two institutions are different in so many ways, having different overall philosophies and programs, each serves the state in distinctive ways. The schools enjoy a collaborative relationship in both educational and research ventures. A new school of dentistry would continue with this same level of collaboration to benefit of the people of North Carolina.

Conclusion

This proposal is offered by *East Carolina University* for it is now clear, and has been clearly demonstrated through our very successful Brody School of Medicine, that we know how to do this, and have done it successfully. This proposal is offered because *the people of North Carolina deserve no less.* **NCMedJ**

DENTISTS 2004

TRENDS IN PROFESSIONAL SUPPLY

Did you know ...

In 2004 there was a 15% increase in the number of dentists indicating that their primary specialty was dental public health.

STATE TOTAL

There were 3,628 licensed, active, in-state dentists in North Carolina in 2004.

- Between 2003 and 2004, North Carolina experienced a 4.8% (+167) increase in its supply of dentists.
- Twelve counties lost dentists between 2003 and 2004, thirty-seven counties had no change in supply and fifty-one counties had an increase in the number of dentists.
- Gates, Graham and Northampton each have only one dentist and Camden, Hyde, Jones and Tyrell have not had a dentist indicating a primary practice location in those counties since 1995.

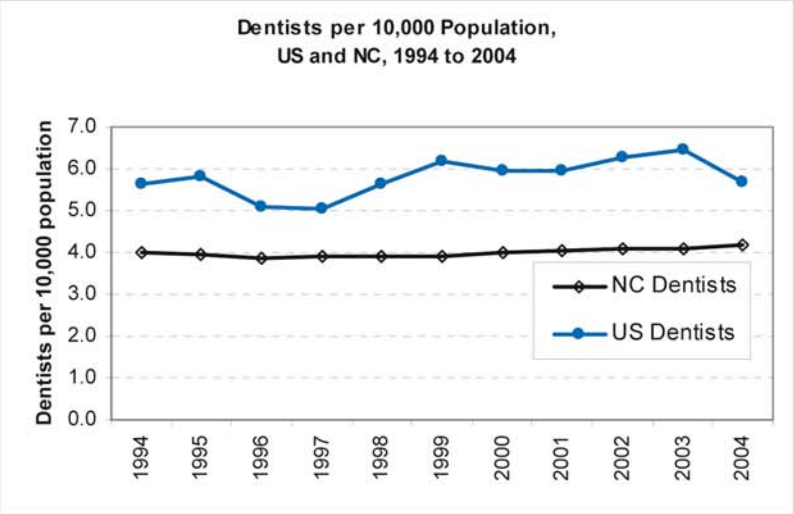
DENTISTS PER 10,000 POPULATION



Dentists per 10,000 Population, US and NC, 1994 to 2004

North Carolina had 4.2 dentists per 10,000 population in 2004—a very slight increase from 2003. There were 4.8 dentists per 10,000 population in metropolitan areas and 3.1 dentists per 10,000 population in non-metropolitan areas.

Nationally, the ratio was 5.7 dentists per 10,000 population in 2004.

DENTAL HYGIENISTS 2004

STATE TOTAL

In 2004 there were 4,324 licensed, active, in-state dental hygienists in North Carolina and 99% (4,291) were female.

DID YOU KNOW ...

In 19 states, dental hygienists can initiate treatment and provide dental hygiene services without the specific authorization of a dentist.

Source: ADHA, May 2005

TRENDS IN PROFESSIONAL SUPPLY

- In 2004, there was a 5.6% (+229) rise in the number of dental hygienists registered with the Board of Dental Examiners. This is a return to moderate growth rates seen in 2002 (4.9%, +192) and 2001 (5.4%, +197) after the drop in growth seen in 2003 (0.9%, +37).
- Sixty counties showed growth in 2004 while 19 counties decreased their supply of hygienists. There were twenty-one counties that had no change in their number of hygienists.
- Three counties had only one hygienist with a primary practice location (Currituck, Jones, Northampton) and 4 counties did not possess any (Bertie, Gates, Hyde and Tyrrell).

DENTAL HYGIENISTS PER 10,000 POPULATION

State of North Carolina: North Carolina has 5.1 dental hygienists per 10,000 population—slightly more than the 4.8 per 10,000 population ratio in 2003.

Metropolitan and non-metropolitan counties: In 2004 there were 5.5 dental hygienists per 10,000 population in metropolitan counties, and 4.2 dental hygienists per 10,000 population in non-metropolitan counties.

National ratios: National statistics show a ratio of 4.4 dental hygienists per 10,000 population in 2004, a slight increase from 4.3 per 10,000 population the previous year.

AGE

< 31	24%

Readers' Forum

To the Editor:

I read the issue of the *North Carolina Medical Journal*, "Preventing Child Abuse and Neglect," with interest. I note, however, that even scientists do not face up to the real issues when faced with the tenets of religion, no matter how illogical those beliefs may be.

To discuss child abuse without even mentioning that at least half of all children are unwanted and born into dysfunctional families who cannot care for them, reveals the fear and reluctance of society to disagree with religious teachings. It is well known that crime and child abuse decrease as the number of unwanted children decreases.

There is a big difference if a functional family unit has an unplanned pregnancy as compared to a single woman without family support who is forced to continue her pregnancy on the basis that a god doesn't like contraceptives or abortions.

Until we face the necessity of family planning, we are "spitting in the ocean" and will just be throwing money at another welfare program. Until we can rationally discuss the necessity of family planning, contraceptives, day-after pills—yes, even abortions—we are only fooling ourselves about the prevention of child abuse.

John A. Henderson, MD
Asheville, NC

Editorial note: The full report of the North Carolina Institute of Medicine Task Force on Child Abuse Prevention includes a recommendation to expand the Medicaid family planning waiver to provide family planning services to more people more quickly. For complete details on the report, please visit the North Carolina Institute of Medicine's Web site at http://www.nciom.org/projects/childabuse/childabusereport.html.

The North Carolina Institute of Medicine

Since January 2002, Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

Before you purchase equipment check the leasing advantages!

- Leasing is 100% financing. You acquire equipment without a large cash outlay.
- Leasing does not affect your other credit lines.
- Leasing eliminates investing in obsolescence, with easy upgrades and trade-ins.
- Leasing generally covers the "Soft Costs."
- Lease payments can be fully deductible, pre-tax expenses.
- Leasing is fixed rate financing that will not change your payment during the lease term.
- Lease financing can be done over the phone with no financial statements (up to $75,000 for medical).
- Leasing can be flexible in providing terms to fit your needs.

Regal Finance has specialized in providing equipment lease financing for healthcare providers nationwide since 1987. We understand the unique issues related to financing healthcare practitioners.

It's like wearing your comfy shoes at work.

That's what people say who have worked with us at CCME to improve the quality of care for their patients and clients.

We're sedate and not very flashy, but we always can be counted on for a dependable experience—just like wearing your sneakers to work.

When we need to be, though, we can be your lace-ups—firm, precise, exact.

That's because we have more than 20 years of successful experience providing quality improvement services throughout the Carolinas.

So, next time you look at the shoes in your closet, think of CCME and how working with us can be a comfortable, reliable experience. Just like wearing your favorite shoes!

CCME delivers.

A partnership that brings Gamma Knife technology within reach

New hope is now within reach for many North Carolina patients who need brain surgery. A new Leksell Gamma Knife®, only the second to be placed in service in our state, is now available at Pitt County Memorial Hospital in Greenville. Gamma Knife radiosurgery is a powerful tool for treating brain tumors and other neurological conditions. Patients who undergo radiosurgery for brain lesions typically recover quickly and have few side effects. Our Gamma Knife team brings an extraordinary level of experience and expertise to the application of this leading-edge therapy.

Gamma Knife services are provided through the collaborative efforts of Pitt County Memorial Hospital, the Leo W. Jenkins Cancer Center, the Brody School of Medicine Department of Radiation Oncology, Eastern Neurosurgical and Spine Associates and Carolina Radiation Medicine.

For more information, www.gamma.pcmh.com or call 1-877-847-1201 or 252-UHS-GAMMA (847-4266).

North Carolina Institute of Medicine

The Duke Endowment

Russell M. Robinson, II
Chairman

In 1940, the North Carolina Medical Society began re-publishing the *North Carolina Medical Journal*, which was founded by the Society in 1849. In its 20th century reincarnation, the Journal intended to promote communications among physicians. It was a noble cause then and remains so today. In 2002, the North Carolina Institute of Medicine assumed responsibility for publishing the Journal, expanding both its scope and its readership to include all the healthcare professions.

The Duke Endowment recognized the importance of the Journal, not only to the physicians of North Carolina, but also to the medical and health communities in general, and so an association was formed between The Endowment and the Institute of Medicine to financially support the Journal. That relationship was solidified further in 2005 when The Endowment became co-publishers with the Institute of Medicine to produce the Journal on a bi-monthly basis.

The Endowment recognizes the historical significance of the Journal and hopes to build on that base by expanding its audience and contents. Today, each Journal features a particular healthcare theme, and includes articles featuring ideas and programs addressing those issues. The topics are designed to be relevant to physicians, physician assistants, nurses, dentists, pharmacists, public health officials, hospital administrators, healthcare decision makers, policy makers, and philanthropists.

The Endowment's goal in this partnership is to improve and provide a literary journal that will aid communications among the healthcare providers and to assist them in understanding health and policy issues as well as learning of successful programs being funded by this and other foundations. We invite others to join us in this venture through subscriptions to and/or advertisements in the *North Carolina Medical Journal*.

{How many healthcare needs can you spot in this picture?}

Jim Bernstein, it seemed, could see them all. Across every rolling hill in North Carolina, he knew that someone — a mother, a grandfather, a newborn — needed access to high-quality, cost-effective care.

Today, with your help, a new generation of health professionals will carry forward that vision and help rural and undeserved communities receive the very best that medicine has to offer. Contribute to the Jim Bernstein Health Leadership Fund and you'll help develop future leaders, strengthen networks among physicians throughout the state and provide financial aid to college-bound children of rural health center employees. And you'll be part of a nationally recognized legacy of care that will continue to better the lives of thousands of North Carolinians for decades to come.

To learn how you can contribute, just contact Judy Howell at the North Carolina Foundation for Advanced Health Programs at (919) 821-0485 or judy.howell@ncrrbiz.com.

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

CAPRELA (Cancer Prevention for Latinas):
Findings of a Pilot Study in Winston-Salem, Forsyth County

Alejandra E. Koval, MA, MPH, Alicia Alemán Riganti, MD, and Kristie Long Foley, PhD

Abstract

Objective: *To evaluate knowledge and attitudes that affect cervical and breast cancer screening among uninsured Hispanic women.*

Study Design: *Cross-sectional, descriptive study of uninsured Latino women in Forsyth County, North Carolina.*

Data Sources/Study Setting: *A convenience sample of Hispanic women who immigrated to the United States within the last ten years, primarily from Mexico (N = 70).*

Data Collection Methods: *Two trained lay health advisors (promotoras) administered in-person, structured surveys to 70 women in the community. All interviews were conducted in Spanish. Additionally, two focus groups were conducted in Spanish to elucidate cultural beliefs and barriers to cancer screening not otherwise captured in the standardized surveys. Quantitative data were analyzed using logistic regression analysis. Qualitative data were transcribed and analyzed using a multi-step framework approach to identify and validate themes.*

Principal Findings: *Of 70 women, 42 (60%) reported a Pap smear within the last year; 26 (37%) reported two exams within the past three years. Among women aged 40 and older, 10 of 18 (56%) reported ever having a mammogram. Being married (OR=4.05, CI 1.07-15.25) and having the same healthcare provider (OR 5.64, CI 1.04-30.56) predicted better Pap smear screening in multivariate analyses. Limited knowledge about breast cancer and needing an interpreter to communicate reduced the likelihood that women received a mammogram. Qualitative results indicated that women had poor prior experiences with Pap smears, held several misconceptions about cancer etiology and risk factors, and expressed distinct gender roles for Latina women and men that may affect healthcare utilization.*

Conclusions: *Screening rates for cervical and breast cancer are low among uninsured Latina women. Therefore, community and clinic-based interventions are needed to improve underutilization of and satisfaction with cancer screening practices among uninsured Latina women.*

Introduction

Cancer is the leading cause of death for women between 40 and 79 years of age and the second leading cause of mortality in American women of all ages. Even with reduced incidence rates, there remain significant disparities in the incidence and mortality rates of cervical cancer among women of color, when compared to rates among white women. The incidence of cervical cancer among Hispanic women is 16 cases per 100,000, compared with nine cases among white women.[1,2] Breast cancer incidence is low among Hispanic women compared with non-Hispanic white women, but a greater proportion of Hispanic breast cancer patients experience a longer duration of symptoms and are more likely to die from the disease.[3,4] Having both a longer duration of symptoms and excess mortality point to the lack of adequate care received for breast cancer in this population. It may be expected that breast cancer incidence rates among the Hispanic population will increase due to changing exposures associated with increased acculturation.[5]

Disparities in breast and cervical cancer screening are at least partially to blame for the excess morbidity and mortality experienced by Hispanic women. Only 67% of Hispanic females

Alejandra E. Koval, MA, MPH, is Regional Manager of the Triad Baby Love Plus Program for the North Carolina Department of Health and Human Services. At the time of the study, she served as a Research Associate for Wake Forest University Health Sciences, Department of Surgical Sciences, The Hypertension and Vascular Disease Center. She can be reached at alejandra.koval@ncmail.net or, NC DHHS, 4265 Brownsboro Road, Suite 115, Winston-Salem, NC 27106. Telephone: 336-896-7944, ext. 254.

Alicia Alemán Riganti, MD, is an Assistant Professor in the Department of Preventive Medicine at the School of Medicine, Universidad de la Republica, Montevideo, Uruguay. At the time of the study, she was an Assistant Professor for the Latin American Center for Perinatology and Human Development (CLAP) in Uruguay.

Kristie Long Foley, PhD, is an Assistant Professor of Social Sciences and Health Policy in the Department of Public Health Sciences, Wake Forest University Health Sciences. She can be reached at kmlong@wfubmc.edu.

(over age 40) report having had a mammogram within the past two years, which is 4.7 percentage points lower than non-Hispanic whites. Differences in screening rates appear to be declining. There is a 9.7 percentage-point decrease in today's rates from those ten years ago.[6] Low income, lower levels of formal education, race, ethnicity, culture, insurance status, and age all contribute to underutilization of breast cancer screening.[7] Similarly, although Pap smear screening rates are rising for ethnic minorities, Hispanic women consistently report lower rates of cervical cancer screening than non-Hispanic women or African American women. Twenty-five percent of Hispanic women have never had a Pap smear, compared with 9% of non-Hispanic women. Fifty-one percent of Hispanic women 40 years and older and 43% of Hispanic women between 18 and 40 years of age reported not having a Pap smear during the previous year.[8]

While Hispanics are generally treated as a homogenous group, there is great variability in screening patterns among various Hispanic/Latino subgroups. In a comparison of three cancer screening practices (Pap smear, mammogram, and clinical breast exam) among five subgroups of Hispanic women, Zambrana et al[9] determined that Mexican women were the least likely to be screened with any procedure. Additionally, using data from 1990-1992 National Health Interview Survey (NHIS), Peek[6] reported mammography rates of 35% among Mexicans, 43% among Puerto Ricans, 41% among Cubans, and 47% among other Hispanics. Further, regional variations exist: 45% of Mexican Americans in Texas had been screened for breast cancer compared to 60% of Mexican Americans in California.[6]

This study evaluates breast and cervical cancer screening patterns among uninsured Hispanic/Latino women living in North Carolina, primarily of Mexican origin. Our goal was to evaluate screening practices and barriers to early detection among women who had recently immigrated to the United States and who had limited financial resources, yet had access to free mammography and Pap smear services through a local free clinic.

Methods

Setting

This study was conducted in Forsyth County, North Carolina. This county was home to 19,577 Latinos as of 2000. New arrivals are mainly from the rural areas of Mexico, such as the states of Guerrero and Oaxaca, where access to healthcare services is limited. The average level of education among Hispanics/Latinos who immigrate to the United States is fifth grade, a lower attainment level than for Hispanics at the national level. More than one quarter of North Carolina Latinos live in poverty (27.4%).[10,11] The study targeted an apartment complex with 260 occupied units, where 90% of the residents are of Hispanic origin.

Data Collection

Upon Institutional Review Board (IRB) approval, the study team identified, contacted, and established a rapport with two *promotoras* (lay health advisors). The selected *promotoras* were of Mexican origin to reflect the majority of Latina immigrants in the Forsyth community. They act as a bridge between researchers and the target population and are able to develop a sense of trust in the participants of a community program. They are often the best recruiters, not only of participants, but also of other community health workers.[12,13,14]

The *promotoras* were paid to attend two training sessions, which entailed how to: inform the women about the purpose of the study and the target populations and instruct them about confidentiality issues and consent procedures. Training also familiarized *promotoras* with the questionnaire and provided a mock interview session. In addition, *promotoras* received an operations manual. Because the survey included the use of color-coded cue cards, we taught *promotoras* how to manipulate the cards as they were reading the questions.

Promotoras recruited women who met the following criteria: (a) an adult (at least 18 years of age); (b) uninsured; and (c) a resident of the United States for less than ten years. *Promotoras* maintained a roster where they indicated the number of attempts they made until they were able to reach the participant, as well as contact information for them and intent to participate in a focus group. The average number of attempts was 1.34 (± 0.90), range 1-5.

Sample

The *promotoras* conducted 70 in-person, structured, Spanish interviews within eight weeks during the Spring 2004. The average time to complete the survey was 30 minutes. Surveys were conducted either in homes (95%) or at the workplace (5%). Participants received a gift card to a grocery store when they completed the survey.

The principal investigator (PI) and a co-PI also facilitated two focus groups with seven and eight women, respectively. For the first focus group, women between 20 and 40 years of age were recruited. The goal of the second focus group was to include women 40 years old and older, but the research team experienced difficulty locating and recruiting older women to participate. Only two women over age 40 participated in the focus group.

We used a model apartment that was made available by the management of the property. Food and childcare in a nearby location were provided. Although the initial goal was to stratify the women by age group, we were not able to recruit enough women age 40 and over for the second session, so we invited women who were younger in order to meet the minimum necessary for a fruitful focus group experience.

Focus group questions addressed knowledge, beliefs, myths, barriers to screening practices, *familismo*[a] and *machismo*,[b] and probed into the women's interest in participating in an educational intervention. The goal of the focus groups was to provide greater insight into the cultural impact of cancer knowledge and screening behavior. The discussions were taped, transcribed, and then translated into English. Women received a gift card to a grocery store for their participation in the discussion.

Measures

We selected the survey constructs based on a review of the literature and previously established surveys[15,16] used among low-income women. We also modified them to be culturally relevant to Hispanic women, based on input from our two Hispanic study team members, the co-PI, and a nurse practitioner who works in the Hispanic community.

Cancer Screening Practices. The dependent measures in this study included Pap smear screening behavior and mammography screening behavior. Pap smear screening behavior was divided into the following categories: ever had a Pap smear, having had a Pap smear within the last year (since 2003), and whether they had received at least two Pap smears within the last three years (since 2001). This latter measure was calculated to establish whether the women had adopted regular Pap smear screening behavior.

Mammography screening behavior was measured among women 40 years old and older and included: ever had a mammogram, having had a mammogram within the last year (since 2003), and whether they had received at least two mammograms within the last three years (since 2001). Similar to Pap smear screening, our goal was to establish whether regular screening behavior occurred.

Demographics included age (less than 24 years, 25-32 years, 33-39 years, and greater than or equal to 40 years), place of origin, and length of residence in the United States (less than or equal to three years, three and one half to six years, greater than or equal to seven years). For marital status, we categorized all responses into: married/living together, and residing without a partner (single, divorced/separated, widowed, and never married). We also determined the total number of children in the home, but dichotomized the variable into (any children vs. no children.). We stratified educational attainment as sixth grade or less, seventh through 11th grade, and high school graduate or more. We measured employment status as follows: housewife, volunteer (no job), part-time job, full-time job, unemployed (job hunting), unemployed (not seeking job), retired, can't work (disabled), and other. We computed the total number of people in the household (continuous measure). Women were asked if they typically see the same provider when they go for healthcare (yes/no). We asked women to determine how well they spoke English (very little and need interpreter, enough to manage without an interpreter, and fluently). Because no one responded that they spoke English fluently, the item was dichotomized.

Knowledge of cervical cancer was a summary measure of six items. For each correct response, respondents received a score of 1. A total score of 6 was possible on the cervical cancer knowledge scale. They were asked whether they agree or disagree with the following statements: (1) "Cervical cancer runs in the family;" (2) "Hispanic women have a higher cervical cancer risk than other women;" (3) "Young women are at higher risk of developing cancer than older ones;" (4) "Women smokers are at higher risk of developing cancer;" (5) "Having sex without a condom increases the risk of cervical cancer;" and (6) "If the Pap test is positive, they will have to remove my uterus." A maximum score achieved among the women was 5 out of 6. We totaled and divided the scores into low knowledge (0-1), moderate knowledge, (2-3) and high knowledge (4-5) for analytical purposes."

Knowledge regarding Pap smear screening was a summary measure of seven items, with each correct item scored as 1. A higher score on the total scale indicated greater knowledge. The women were asked (1) "Do you know whether there is a test for cervical cancer?" Women who said yes and could either name or describe the procedure were coded as 1. We also asked (2) "How often do you think a healthy woman should have a Pap test?" Women who responded that they should have a Pap smear at least once per year were considered correct and assigned a value of 1. Women were also asked to indicate whether they agreed or disagreed with the following statements: (3) "I feel ok; I don't need a Pap;" (4) "If a woman no longer has menstrual periods, she doesn't need to have a Pap any more;" (5) "After a few negative Paps you don't need a Pap any more;" (6) "Women who have had their uterus removed don't need a Pap;" and (7) "Only women who have had several sex partners need a Pap." Women who correctly responded to these questions were scored a 1. Again, we totaled and categorized the scores into low knowledge (less than or equal to 3), moderate knowledge (4-5), and high knowledge (6-7).

Barriers to Pap smear participation included three items: (1) "Getting a Pap can hurt;" (2) "No cure for cancer, so why bother getting a Pap;" and (3) "I don't have time to get a Pap." The scores were then dichotomized into having at least one or more barriers (1,0).

Knowledge of breast cancer was a summary measure of five yes/no items. Women were asked whether they agreed or disagreed with the following: (1) "Hispanic women are at greater risk for breast cancer than others," (2) "Older women are at higher risk for breast cancer than younger women," (3) "The only treatment for breast cancer is surgery that removes the breast,"(4) "Women

---

[a] The concept of *familismo* (familism) is used to describe a high degree of interpersonal bonding within the Latino family, resulting in greater identification with the group and dependence on the family.

[b] *Machismo* (as opposed to Marianismo, which defines the role of the ideal woman modeled after the Virgin Mary, as based on chastity, abnegation, and sacredness, while reinforcing obedience and virginity) characterizes the male gender role in Latino society. It stresses virility, independence, physical strength, and sexual prowess. *Machismo* is socially constructed, and promotes and reinforces a particular set of behaviors. The influence of *machismo* and *marianismo* on sexuality and gender roles leads to the exaltation of penetrative sexual behavior and to women's ignorance about their bodies and about sexuality.

who have never had children are at lower risk for breast cancer," and (5) "Breast cancer runs in the family." The possible range of scores was 0 to 5. Scores were categorized into low knowledge (0-1), moderate knowledge (2-3), and high knowledge (4-5).

Knowledge about mammography screening was a summary measure of five items, with each correct item scored a 1, and a maximum possible score of 5. A higher score on the total scale indicated greater knowledge. The women were asked, (1) "Do you know whether there is a test for breast cancer?" and (2) "How often do you think a woman your age should have a mammogram?" They were also asked whether they agreed or disagreed with the following statements: (3) "A woman over 40 who feels well does not need a mammogram;" (4) "mammography radiation can cause cancer;" (5) "After a few mammograms that show everything is ok, you don't need to continue having them." We categorized scores into low knowledge (0-1), moderate knowledge (2-3), and high knowledge (4-5).

In order to explore *barriers to mammography screening*, we asked women whether they agreed or disagreed with the following statements: (1) "It's difficult for me to get an appointment for a mammogram," (2) "The technician does not treat me with respect," (3) "It is too complicated to go somewhere else for a mammogram," (4) "I have no money for a mammogram," (5) "I don't know where to go for a mammogram," (6) "I'm embarrassed to have a mammogram done," and "(7) It hurts to get a mammogram." Scores assigned were yes = 1 and no = 0. We ranked barriers into low (0-3), moderate (4-5), and high (6-7).

Data Analysis

Quantitative. We computed descriptive statistics for all variables in the study. Measures of central tendency (e.g., mean, standard deviation) were obtained for continuous variables and frequencies for nominal and ordinal data. We conducted bivariate analyses using chi-square tests to evaluate the correlations between all independent and dependent variables (screening behavior). Multivariate analyses using logistic regression were conducted to evaluate the effect of knowledge of cervical cancer and barriers to Pap smear on Pap smear screening behavior within the last year. Due to a limited sample size of women age 40 and older, mammography screening behavior could not be evaluated using logistic regression techniques. All quantitative analyses were conducted using Stata 7.0.[17]

Qualitative. Transcripts of focus groups were analyzed using a multi-step framework approach.[18] The first step involved familiarization and immersion in the raw data. Two investigators who were present during the focus groups independently read the transcribed interviews and extracted key comments associated with how individuals ascribed meaning to the cancer experience. The second step was identification of a thematic framework. The investigators met to discuss the abstracted information and identified themes that emerged. This process was also reviewed by a third and independent reviewer. Third, the thematic framework, including all themes, was applied to all data.[18]

Results

Descriptive Statistics

Seventy-eight women were approached, 70 (90%) completed the survey. Table 1 describes the demographic characteristics of the survey. Women were, on average, 32 years of age (± 9.2; range 19-52). They had eight years of formal education (ranging zero to 15), which is slightly higher than the average for new immigrants into the state,[11] yet lower than the national average of high school attainment.[10] Most women were married or living together (72%) and less than half were employed outside the home (46%). The mean number of years of residence in the United States was 5.2 (range 0.5 to 9.5). The sample was predominately of Mexican origin (97%) and Catholic (79%), with limited knowledge of English. Almost everyone (93%) responded that they need an interpreter during a medical visit. Most of the women typically received healthcare at a local free clinic (62%) or a local university-owned community clinic

a Only includes women who were at least 41 at the time of the interview to ensure that they had at least one year since their 40th birthday.

b At least two within last three years and not in same year. For mammography, the women had to be at least 43 years of age to be included in the calculation.

c Pap smear scores were categorized as follows: low (0-3), moderate (4-5), and high (6-7). Mammogram scores were categorized as follows: low (0-1), moderate (2-3), and high (4-5).

(17%). Approximately one-in-four women (25.7%) reported that they typically see the same healthcare provider for care.

The majority of the sample reported that they had at least one Pap smear, but only 60% were examined within the last year (see Table 2). Only 37% had regular screenings (at least two consecutive Pap smears within the last three years and not in the same year). Among the 18 women age 40 and older, ten (56%) had a mammogram once, six (33%) had a mammogram within the past year, and only two (11%) reported at least two mammograms during a three-year time frame.

Respondents answered an average of two and one half (± 1.1) out of five questions correctly on the cervical cancer knowledge scale and five (± 1.6) out of seven questions correctly on the Pap smear knowledge scale. Approximately one half of the sample (49.5%) experienced at least one barrier to Pap smear screening. The most commonly cited barrier to Pap smear was pain associated with the screening test (38%). An additional 19% indicated that they don't have the time to get screened. Of the possible three barriers, the average number of barriers reported was 0.6 (± 0.8).

Women were able to correctly answer an average of two (± 1.2) out of five questions related to breast cancer knowledge and four (± 1.0) out of five questions related to mammography knowledge. On average, women reported 1.9 (± 1.5) barriers to mammography. The most common barriers were: no money for a mammogram (61%), too complicated to go to a different place (28%), and too embarrassed to have a mammogram (22%).

Bivariate analyses revealed significant associations between greater Pap smear knowledge (p = 0.03), having children (p = 0.02), being married (p = 0.007), and being seen by the same provider (p = 0.02) with Pap smear screening behavior. Using these variables, we conducted a multivariate analysis. We utilized this simplified model due to the limited sample size and reduced statistical power to include many covariates. Greater knowledge about Pap smear (OR 4.3, 95% CI 0.8-22.9) and having any children (OR 5.0, 95% CI 0.9-27.9) showed a non-statistically significant association with recent Pap smear completion when controlling for marital status and having the same healthcare provider. Married women (OR 4.05, 95%CI 1.07-15.25) and those who had typically seen by the same healthcare provider (OR 5.64, 95% CI 1.04-30.56) were more likely to have had a Pap exam within the past year (see Table 3).

Bivariate analyses also demonstrated that women who stated that were able to communicate with a healthcare provider without an interpreter were significantly more likely to have received a mammogram within the past year (X2 4.57, p = 0.05). Higher knowledge scores were also marginally associated with having a recent mammogram (X2 24.57, p = 0.10). No multivariate analyses were conducted regarding mammography due to small sample size.

Table 3.
Adjusted Odds of Having Had a Pap Smear within the Last Year

Indicator	OR	95% CI
Pap Knowledge		
Low	—	
Moderate	0.83	0.15-4.56
High	4.33	0.82-22.87
Married	4.05	1.07-15.25
Any Children	5.04	0.91-27.87
Same provider	5.64	1.04-30.56

Note: Odds ratios from the multivariate logistic regression equation, adjusting for Pap knowledge, marital status, children, and receiving care from the same provider.

Focus Group Results

Several themes emerged from the transcribed focus groups. These include themes specifically related to the Pap smear experience, knowledge about cervical and breast cancer etiology and risk, and the importance of gender roles on healthcare utilization.

Focus groups revealed that the primary reason women sought a Pap smear was for contraception or pregnancy-related planning or care. This provides some explanation as to the higher rates of Pap smear among married women and women with children in this sample. Some women reported that they found the providers who performed the Pap smear to be impersonal and uninformative. Women reporting impersonal or uninformative providers had very little understanding as to the purpose of having the Pap smear; they were simply complying with the provider's request. One study participant said:

> She didn't tell me anything. That is, she only told me that … they had to see … to see that each month the cells got better … or worse…. I tell her [her friend] "maybe the doctor is waiting until I get the illness pretty bad…. I don't know. Because I … I mean, she didn't give me any medication or anything. She didn't tell me this … nothing, nothing, nothing … that's why … I don't know what causes cancer, nor anything of that sort. And they haven't … told me anything….

Some women complained that they never receive results of the Pap test, which led them to worry unnecessarily and to avoid going for Pap smears in the future. "*Si estás bien … olvídate. Ni una llamada ni nada. Si te hablamos es que tú estás mal. Pero como nunca hablan….*" (If you're ok … forget about it; not even a call, nothing. If we call you, it means you're unwell. But since they never call….")

Women had very little knowledge about breast cancer etiology and risk factors. Some misconceptions revealed during the focus groups were that milk clots may form during breast feeding, which can lead to breast cancer. Some women also thought that eating nuts or seeds and using antiperspirant deodorant could lead to breast cancer. In regard to cervical cancer, some of the women said that certain birth control methods can produce cysts which, in turn, can become cancerous. Although they identified a few accurate risk factors and behaviors, women never identified age as a risk factor. There was no understanding that uterine, vaginal, and cervical cancers are different. Some of the barriers to seeking a Pap smear or mammogram included procrastination, lack of information or recommendation from the healthcare provider, lack of time, cost, and language/communication barriers with their healthcare provider. Fatalism was also described as a barrier to cancer screening. "*…de todos modos, cuando Dios dice: 'Te toca' … es porque te toca.*" ("When God says, 'It's your turn,' it means it is your turn)" and "*Para mí el cáncer es la muerte….*" (For me … cancer is death.").

We also inquired about gender roles and *machismo* as a barrier for cancer screening. Some women stated that many husbands do not want their wives to be examined by a male doctor, which could be a major barrier to screening, especially when women have little control over who provides their healthcare. Other participants stated that their husbands care about the health of their family, but do not play an active role in it. Being screened or taking the children to the doctor is the wife's duty; "À la Mexican," they commented.

Discussion

This study provides preliminary evidence that uninsured women of Hispanic origin have low rates of regular cancer screening and healthcare utilization. This has serious public health implications for Hispanics, the fastest growing population in the United States, as well as the healthcare system that serves this population.

The structured survey and focus group data suggest that barriers to both breast and cervical cancer screening reported in this study are consistent with results observed in previous research among Hispanic women.[1,10,19,20] These women are likely to receive an initial Pap smear to obtain birth control. They are not likely to have regular Pap smears, however, which may be due to their considerable dissatisfaction with the Pap smear experience and the lack of follow-up regarding their results. This may be one explanation for the very low rates of maintenance Pap smear behavior.

Women who regularly see the same healthcare provider were 5.5 times more likely to have repeat Pap smear exams. Together, these results suggest that seeing the same provider may help build rapport and trust and improve communication surrounding the Pap smear experience. Free clinics could greatly improve the care that they deliver to the uninsured population by identifying a core group of healthcare providers who regularly conduct Pap smears for their patients. Focus group data also suggest that female healthcare providers may be more desirable among this population.

Focus group data also reinforce previous literature, which has demonstrated that Latinos hold negative conceptions of cancer as being a death sentence, something to avoid talking about, and a form of punishment from God, and they believe that there is little one can do to prevent it.[21] Because of their fatalistic view and fear associated with the disease, many Hispanics are reluctant to find out information about cancer or to get screened for the disease. In this regard, Burgess Wells et al. observed that there is a high correlation between purpose-in-life and breast health behavior. Purpose-in-life is significantly related to self-efficacy (having the knowledge and ability to care for oneself),[22] which may explain why Latinas delay seeking healthcare. This has significant implications for intervention development and should be incorporated into strategies to promote Pap and breast cancer screening among Latina women.

Although this study had a very limited sample of women ages 40 and older (18), the results suggest very low breast cancer screening rates for uninsured Hispanic women. This may be due to limited knowledge about breast cancer and poor communication with the healthcare provider. Women who did require an interpreter were significantly less likely to receive a mammogram. Myths about breast cancer also pervade (e.g., eating nuts may cause breast cancer), which also need to be debunked in order for women to have adequate breast health and screening behavior.

The results of this study should be interpreted with caution, as they were derived from a small, convenience sample of uninsured Hispanic women. *Promotoras* were able to recruit only 18 women ages 40 and older, thus limiting the interpretation of data regarding mammography utilization. Older women were also difficult to recruit for the focus groups, which limits the generalizability of the findings to a younger population of recent Latina immigrants. Additionally, the presence of an academic institution and a free medical clinic in the community from which these women were recruited may have influenced access to cancer screening services. Although the results could be safely generalized to low-income, Hispanic women in Forsyth County who have recently immigrated to the United States, they may not be generalizable to other counties in North Carolina.

Conclusion

Despite these limitations, this study is an important preliminary evaluation of breast and cervical cancer screening patterns among uninsured Hispanic women and the factors that contribute to poor regular screening behavior in this population. Interventions should be targeted not only to educating women about cancer and early detection, but also to the healthcare providers likely to provide care to these women. Cultural beliefs that underlie their screening behavior (e.g., lack of 'prevention' concept, machismo) need special attention when designing Hispanic-friendly interventions. Additional research is necessary to replicate these findings in larger populations of uninsured, Hispanic women, with more attention given to the healthcare delivery system and its contribution to poor screening behavior. **NCMedJ**

Racial Disparities in Birth Outcomes Increase with Maternal Age: Recent Data from North Carolina

Paul A. Buescher, PhD, and Manjoo Mittal, PhD

Abstract

Background: *Racial disparities in birth outcomes persist in North Carolina and the United States. We examined patterns of birth outcomes and women's health measures in North Carolina by race and age to portray the largest disparities. We wanted to see if our data were consistent with the "weathering hypothesis," which holds that the health of African American women may begin to deteriorate in early adulthood, with negative effects on birth outcomes.*

Methods: *We conducted a descriptive analysis of 1999-2003 North Carolina live birth and infant death records and 2001-2003 Behavioral Risk Factor Surveillance System survey data. Birth outcome measures examined were low birth weight, very low birth weight, infant mortality, neonatal mortality, and postneonatal mortality. Women's health measures examined were obesity, self-reported health status, high blood pressure, high cholesterol, current smoking, and smoking during pregnancy. Rates for whites and African Americans were compared for each of three age groups.*

Results: *Racial disparities in birth outcomes increase with increasing maternal age. African American teens often experience better birth outcomes than older African American women. Racial disparities in measures of women's health also increase with increasing age.*

Conclusions: *Health problems among older African American women of reproductive age may contribute substantially to racial disparities in birth outcomes. Improving the health of older African American women may be an effective strategy to reduce the overall racial disparities in birth outcomes.*

Introduction

There are longstanding disparities in birth outcomes between whites and African Americans in North Carolina and the United States. For infant mortality and low birth weight, African Americans have rates at least two times those for whites, and the gap has been increasing over time. Arline Geronimus has proposed a "weathering hypothesis" to help explain this pattern.[1,2] The weathering hypothesis proposes that the health of African American women may begin to deteriorate in early adulthood as a physical consequence of cumulative socioeconomic disadvantage. As a result, the racial differential in infant mortality, for example, is larger at older maternal ages than at younger ages. A conclusion from this is that improvements in health among adult African American women would help reduce their infant mortality rate. This report examines recent North Carolina data to see if these data are consistent with this hypothesis.

Many studies suggest that women's preconceptional health is an important determinant of birth outcomes. Chronic health conditions, substance abuse, and other health problems cannot all be fixed after a woman becomes pregnant. In this study, we look at patterns of women's health measures and birth outcome measures by maternal race and age. Since we present only parallel, descriptive data, this study cannot demonstrate that women's health problems cause poor birth outcomes. However, a number of previous studies suggest that this is the case. For example, other researchers have found that maternal chronic hypertension,[3,4] obesity,[5,6,7] smoking,[8,9,10] and high cholesterol[11] are associated with subsequent adverse birth outcomes. One study suggests that the excess incidence of maternal chronic hypertension among African American women, including hypertension preceding pregnancy, contributes to the racial disparity in pregnancy outcomes.[3] Since smoking cessation interventions during pregnancy have had limited success,[9] efforts should be made to reduce smoking among all women of reproductive age as a

Manjoo Mittal, PhD, is a Statistician with the State Center for Health Statistics within the North Carolina Division of Public Health. He can be reached at manjoo.mittal@ncmail.net or 1908 Mail Service Center, Raleigh, NC 27699-1908. Telephone: 919-715-4477.

strategy for improving birth outcomes. Postpartum maternal smoking strongly increases the risk of Sudden Infant Death Syndrome (SIDS) and is associated with other infant health problems.[12]

Methods

We examine several 1999-2003 birth outcome measures for non-Hispanic African Americans and whites for the maternal age groups 15-19, 20-34, and 35 years and older: percentage low birth weight (less than 2,500 grams), percentage very low birth weight (less than 1,500 grams), infant deaths (first year of life) per 1,000 live births, neonatal deaths (first 27 days) per 1,000 live births, and postneonatal deaths (28-364 days of age) per 1,000 live births. These measures pertain to the entire five years of birth and infant death data combined, 1999 through 2003 inclusive. The percentage low birth weight and the infant mortality rate are standard overall measures of birth outcome, though the causes of low-weight births and infant deaths are heterogeneous. The vast majority of very low-birth-weight births and neonatal deaths are preterm deliveries, while more than half of postneonatal deaths result from SIDS, birth defects, and injuries/accidents.

We also present selected 2001-2003 health indicators from the North Carolina Behavioral Risk Factor Surveillance System (BRFSS) for non-Hispanic African American and white women for ages 18-24, 25-34, and 35-44: obesity, self-reported health status, high blood pressure (2001, 2003 only), high cholesterol (2001, 2003 only), and smoking. These measures pertain to the entire three years of BRFSS data combined, except those for blood pressure and cholesterol, which are for two years of data combined (these two questions were not asked on the 2002 BRFSS survey). Previous studies have shown these measures to be associated with adverse birth outcomes. The BRFSS is an ongoing random telephone health survey of adults in North Carolina.

The 15-19 year-old age group was used for the birth and infant death data because this is an age category commonly used for analysis of teen birth statistics; there are very few births to girls under age 15. The BRFSS survey interviews only persons ages 18 and older, and so the 18-24 year-old age group was used to define young adult females.

Several years of vital records and BRFSS data were aggregated to yield large enough numbers for meaningful analyses by race and age. All numerators of the race-age specific birth outcome measures are greater than 30, and most are much larger than 100. All numerators of the race-age specific BRFSS measures for females except one (African American women ages 18-24 with high cholesterol) are 20 or greater. African American/white ratios of the birth outcome and women's health measures were computed for each of the three age groups. Statistical significance of the racial differences was assessed using the chi square test. For the BRFSS measures, statistical significance was calculated using the SUDAAN software, which accounts for the complex sample design of the BRFSS when computing the errors of the estimates. A p value of less than 0.05 indicates a statistically significant difference at the 95% confidence level.

Birth weight is reported very accurately on birth certificates in North Carolina, and maternal smoking during pregnancy is reported fairly accurately.[13] An infant death was ascertained by an infant death certificate that matched to the live birth certificate. These matched records are needed because maternal race and age are recorded only on the birth certificate. Less than 1% of the 1999-2003 birth records were missing information on maternal race, age, or smoking or on birth weight.

The BRFSS data are self-reported by the respondents over the telephone and, thus, are subject to some bias. However, if the degree of bias does not differ much by race and age, the basic results here will not be affected. Overall in North Carolina, approximately 5% of households do not have a telephone. A higher percentage of African Americans than whites live in poverty; therefore, it is likely that a higher percentage of African Americans do not have a telephone. A result of this would be that health problems among African American women, as measured here, are more understated than for white women, since the poorest women (without telephones) have the most health problems. Therefore the racial differentials in the BRFSS measures in this study may be somewhat understated. Less than 1% of the 2001-2003 BRFSS records for females ages 18-44 were missing information on age, race, health status, blood pressure, or cholesterol. Approximately 10% were missing information on Body Mass Index (BMI), which was used to measure obesity.

On the birth certificate, mother's race and ethnicity are self-reported by the mother around the time of delivery, usually while in the hospital. In the BRFSS, race and ethnicity are self-reported over the telephone by the adult survey respondent. Self-report is the preferred method of collecting data on race and ethnicity.[14] The race reported by the mother on the birth certificate is sometimes reclassified to a standard category according the coding rules of the National Center for Health Statistics.[14] However, this will have little impact on the results of the present study since the data here are limited to non-Hispanic whites and African Americans.

Results

Table 1 shows the distribution of live births in North Carolina during the period 1999-2003 for non-Hispanic African Americans and whites, by maternal age. Twenty-eight percent of all live births shown in Table 1 were to African Americans, while 44% of the teen births (ages 15-19) were to African Americans. Table 1 reveals that teens comprised 18.7% of African American births, compared to 9.2% of white births.

Table 2 shows differences in selected birth outcomes by maternal race and age. The general pattern is that the percentages and rates of adverse birth outcomes for African Americans increase with increasing maternal age, and the racial disparities increase with increasing maternal age. Most of the racial differences shown in Table 2 are statistically significant at $p < 0.0001$. The two measures that are most associated with preterm delivery, the percentage very low birth weight and the neonatal death rate, have the largest racial disparities at the older ages. The teen postneonatal death rates are the same for African Americans and whites (3.8), but for mothers ages 20 and older, the rates for African Americans are more than two times the rates for whites.

Table 3 shows differences in selected women's health indicators by maternal race and age. We include several chronic disease indicators and two measures of smoking, a behavioral risk. The general pattern here is similar to that for the birth outcomes: the measures for African American women increase with increasing age, and the racial disparities in these indicators increase with increasing age. All of the racial differences at age 35-44 except one are statistically significant at $p < 0.05$. For four of the measures—percent with fair or poor health, percent with high cholesterol, percent who currently smoke, and percent of mothers who smoked during pregnancy—African American 18-24 year-olds have lower rates than white 18-24 year-olds (two of these are statistically significant). But the African American rates increase substantially with age, so that by ages 35-44 African American women have higher rates than white women for all but one of these four measures.

Discussion

A much higher percentage of births occur to teens among African Americans than among whites (19% vs. 9%). Also, African American teens often experience better birth outcomes than older African American women. Though perhaps controversial, Geronimus raises the question of whether African American communities adjust their fertility-timing norms and expectations to emphasize childbearing at the ages when women are the healthiest or may have the greatest social support available.[1]

The BRFSS data presented here show that selected health indicators for African American women worsen substantially with age, and racial disparities in measures of women's health increase with age. Geronimus found sharp increases with age in the African American/white ratios of hypertension and high blood lead level prevalence among women.[1] These results suggest the

importance of targeting health interventions to African American women in their 20s and 30s as a means of reducing the overall racial disparity in low birth weight and infant mortality. This is consistent with the overarching Healthy People 2010 goal of reducing health disparities.

A limitation of this study is that it presents only descriptive statistics, without other control variables. Therefore the differences that are attributed here to race and age could be due substantially to other factors (such as education, income, social support, or medical conditions) that are associated with race and age. Also, the similarity in the race/age patterns in the data on women's health and birth outcomes does not prove that women's health problems cause adverse birth outcomes.

The observation that racial disparities in neonatal mortality widen with maternal age is consistent with the view of aging as a "weathering" process, which may involve life circumstances that undermine women's health in ways that can affect reproduction.[1] Racism, poverty, crime, and environmental problems disproportionately take their toll on the health of African American women,[15] leading to increasing health disparities as age increases. A recent North Carolina study suggests that unequal treatment based on race has negative effects on adult health, and African Americans are much more likely than whites to experience unequal treatment based on their race.[16] Eighteen percent of African American adults reported having emotional upset and/or physical symptoms due to treatment based on race, compared to 4% of white adults; 7% of African Americans reported experiences worse than other races when seeking healthcare, compared to one percent of whites.[16] There is evidence that prolonged, active coping with social injustice may exact a physical price.[1] High levels of stress may have negative effects on health, and stress can affect maternal behaviors such as smoking, nutrition, and substance use.[17] Strategies to improve the health of older women of reproductive age should include measures to provide protective resources for women at earlier ages to prevent health problems when they become older.

As Geronimus states: "While most Americans take for granted their good health during their young and middle adulthood—indeed these ages are referred to as the 'prime' of life and the 20s as the 'prime childbearing ages'—our findings suggest that among African American women in poverty, health deterioration may begin on an accelerated course in the mid-20s, and reproductive disadvantage may intensify."[1]

In conclusion, an effective strategy to prevent infant deaths and reduce racial disparities in birth outcomes must include measures to improve women's health before they become mothers and to sustain their health throughout the reproductive years.[18] Future research on racial disparities in birth outcomes should examine differential exposures to risk and protective factors not only during pregnancy, but over the life course of women.[19] **NCMedJ**

POLICY FORUM

Contemporary Issues in Rural Healthcare, In Honor of James D. Bernstein (1942-2005)

> *"State government could not merely issue edicts or dangle money; it had to engage in meaningful partnerships, be prepared to make long-term investments in communities and nurture the leadership needed to deliver the desired improvements."*
> *— Jim Bernstein*

COMMENTARIES

INTRODUCTION

Policy Forum:
Contemporary Issues in Rural Healthcare
In Honor of James D. Bernstein (1942-2005)

To a state like North Carolina, there are few topics as central to the concerns of those responsible for the development of health and healthcare policies as rural health. But even in North Carolina, where a number of innovative approaches to the delivery of personal healthcare services and the education of healthcare professionals have been developed, special arrangements have been necessary to ensure rural residents could access care and that adequate numbers of professional healthcare providers were available.

Most of the nation sees North Carolina as a state that has embraced the challenges of rural healthcare and made substantial progress in addressing the most pressing problems in rendering services to the state's rural populations. Many other states have looked admiringly at the accomplishments of North Carolina's four medical schools in training a generation of physicians who have chosen careers in primary care and to practice in North Carolina. Many of our state's graduates locate in smaller, non-metropolitan communities. Likewise, the state's Area Health Education Centers Program has become the national model for how to organize regional systems to: provide continuing education for healthcare professionals, bring the benefits of specialty consultation to smaller communities, and educate students from multiple disciplines in community-based settings to help attract newly educated healthcare practitioners to become permanent community members and participants in local healthcare delivery systems. But, perhaps the single reason North Carolina is so highly respected for its accomplishments in the arena of rural health and healthcare derives from the efforts led by James D. Bernstein (1942-2005) and the program he began in the early 1970s, then known as the Governor's Rural Health Program (and the North Carolina Office of Rural Health).

In contemplating a special issue of the *North Carolina Medical Journal* in which we would take stock of lessons learned over the past three decades or more about the problems of assuring access to quality healthcare for rural communities, and reflecting on current issues and problems in relation to rural health still needing attention, the Editors of the Journal decided to dedicate this installment of the Journal in honor of Jim Bernstein, our beloved colleague, friend, mentor, and national leader. Jim set the pace and defined the direction of much of what we would consider the nation's rural health agenda for the 21st Century. Jim's untimely death this past year brought to Chapel Hill hundreds of individuals who wanted to visit with Jim one last time, to share his wisdom and good humor, to share stories of battles won (and lost), and efforts made in behalf of rural communities in North Carolina and elsewhere. Several hundred of his friends and admirers attended the memorial service in his honor. For all of this, Jim would have been (and was) very grateful. But, he would be most pleased to know that we took this opportunity to reflect on what has been learned from our years of concentrated effort, to analyze current issues still needing attention, and to re-dedicate our individual and collective efforts to keeping these issues in the forefront of national, state, and local health policy deliberations for the decades ahead. It is our hope that this issue of the Journal will be an additional step in that direction.

A Personal Reflection on Jim Bernstein

I hope that our readers will allow me this brief opportunity to print a few words about a close friend and colleague, who has been a constant source of inspiration and intellectual stimulation throughout my 35 years in North Carolina.

When Jim arrived in North Carolina near the beginning of the 1970s, there was no way that he could have known what a tremendous influence he would have in this state, in the nation, and among his colleagues at the University of North Carolina at Chapel Hill (UNC-Chapel Hill). Although he knew he wanted to work on the special problems in rural healthcare, he could not have known what serendipitous events would give him the opportunity to launch *the single most extensive and effective program in rural health anywhere*. Nor could he have known what great personal influence he would have on the people served by the program he spawned or among the colleagues he assembled to make these things happen.

Jim did not begin the program in rural health in North Carolina by writing on a "blank slate." There was a rich history of efforts to develop the resources and capacities of several communities and prominent healthcare facilities in this state, which he and his colleagues were able to bring into closer working relationships with one another. Moreover, there were a number of outstanding health professionals with whom Jim established personal relationships, and together, they forged an effective alliance that worked well for many years. Thomas Ricketts, himself a national figure in rural health research at the Cecil G. Sheps Center for Health Services Research at UNC-Chapel Hill, offers a detailed overview[1] of this history and the pillars of personality and professional esteem on whose shoulders Jim was able to stand in building the program for which he is so well known.

Jim Bernstein managed to make the task we were all engaged in, and the process of getting the job done, both stimulating and fun. There are few people like Jim Bernstein we will meet in this life, and we are fortunate to have been some of the many who have known him well. He will always be a part of our lives and careers, despite how much we will miss him every day, and for that, we must be very thankful.

Jim was always an unselfish person—willing to share (or *give*) the credit for almost everything he did to some other member of his colleague group. Even as he "retired" from some of the roles he previously played in North Carolina state government, he had a hard time taking credit for many of the things he caused to happen. He only wanted to talk about his colleagues and the pride he had in assembling such an effective team.

Jim was one of the two or three people I met and got to know well when I arrived in North Carolina in 1971. A year or so after my arrival here, Jim "decided" (and then *gently* told me) that now that I had a PhD *degree*, what I needed was a "real education" because I knew "next-to-nothing about contemporary healthcare policy and program development." He proceeded to help me acquire the understanding clearly missing from my previous degree program and my brief professional experience in medical sociology. He set up a series of luncheon discussions for the two of us with Glenn Wilson, then the Associate Dean of the UNC School of Medicine. The *quid pro quo* in all of this was that Jim and I would get a chance to ask questions of one of the most knowledgeable people in American healthcare, and Glenn would get lunch prepared by the two of us. It was a wonderful education for us, but Jim was ahead of me in that he had come to know Glenn in Cleveland when Glenn was Vice President of Kaiser, and he had experienced a couple of years of service with the Indian Health Service before coming to Chapel Hill. He had far more information and background than did I, so I learned from the *two of them* … something I have continued to this day. In a very real sense (and this is something I said to him, but to few others until now), were it not for Jim Bernstein, I think I would have spent my career very differently. One can never repay that level of influence.

Over the years, as I have tried to make my way in the field of health services research, Jim and I teamed up on many levels to obtain grant funding, to lend technical assistance to various organizations, to address policy issues at the state and county levels, or just to share our interest in several areas of our work.

I only regret that I did not help get him appointed to more boards and committees where I had a role. Few people could enrich a discussion, a meeting, or a complex organizational task like Jim Bernstein.

INTRODUCTION—continued on page 24

As Editor of this Journal, I am very grateful to Jim's good friend and colleague, Donald Madison, for writing in this issue an overview[2] of Jim's remarkable career and a description of how North Carolina's rural health program took shape and continues to have great influence in the field of rural health at a national level.

Contemporary Issues in Rural Healthcare

In our attempt to identify and clarify some of the more complex and demanding issues in rural health and healthcare with this issue of the Journal, we hope to honor Jim Bernstein in a way he would consider useful. It is our hope that publications like this one can help keep the initiatives he and others started in forward motion and help raise their visibility as public policy issues of our time.

Those who have examined the differential health indicators for both rural and urban communities in the United States have come to the conclusion that, when the effects of age, gender, and other covariates are "controlled" through statistical adjustments, the once clear disadvantage of rural areas in terms of both mortality and morbidity is no longer apparent.[3] Disease and mortality differences between metropolitan and non-metropolitan areas in this country are more likely associated with racial and ethnic or socio-economic characteristics of populations than with the size or remote location of place. Yet, the accessibility of healthcare services for those with virtually any disease or disability is far less certain in rural areas of the United States. Moreover, rural residents consistently are more likely to describe their health as "poor" or "fair" than are residents of more urban areas.[3] These observations, coupled with the urbanization of the population as a whole and the "aging" of United States rural populations in general, will make the task of assuring the availability and accessibility of quality healthcare services for rural populations an even greater challenge for future healthcare policy and program development.

Despite these seemingly paradoxical findings of non-differential urban-rural differences in critical health indicators (when other factors are taken into account) and the lack of access to basic healthcare services in rural areas, wide variations in health status indicators of the nation's rural areas exist. Geographic areas characterized by low socio-economic status or minority racial, and ethnic group concentrations are likely to have far worse health status indicators, as well as more restricted access to healthcare services.

These wide variations and the implications of limited access to basic healthcare services have caused most states to give special attention to these issues. In North Carolina, since the early 1970s, this effort has revolved around the work of the Office of Rural Health, or what is now known as the Office of Research, Demonstrations, and Rural Health Development, within the North Carolina Department of Health and Human Services. In this issue of the Journal, it is our intent to give special focus to a number of the key issues confronting this state and others in the first decade of the 21st century. For some of these issues, it will seem as though little or no progress has been made. For others, considerable forward movement has taken place.

One observation worth noting is that rural health policy, after several decades, is now a matter of significance in national health policy. Jeanne Lambrew, one of President Clinton's chief health policy advisors, describes the current political landscape and illustrates evidence of the how rural health constituencies have been influential in recent national policy development.[4]

In a broad brush examination of contemporary rural health issues, there are several issues that still seem to be the defining issues of the field. The first of these relates to the healthcare professional workforce and its distribution. Concerns regarding an adequate supply of healthcare professionals are perhaps as important now as they were three decades ago, especially with regard to certain professions (e.g., dentistry), and yet, these issues have become intertwined with others, such as reimbursement (payment) policies, practice act limitations on non-physician providers, and practice organization arrangements. There are still significant issues related to how we recruit and retain healthcare professionals in small and remote communities. Examples include considerations of how newly trained physicians, dentists, nurses, pharmacists, and others are incentivized to consider practice locations in rural communities through educational loan repayment programs, scholarships, and other financial inducements. Donald Pathman[5] offers a detailed discussion of ways in which these programs have had an impact and how lessons learned from past decades of experimentation with financial and obligated service placements can be used to further refine programs. Robert Seligson and Pam Highsmith[6] of the North Carolina Medical Society Foundation provide a description of the Community Practitioner Program, which was developed under the Foundation with support from the Kate B. Reynolds Charitable Trust and the Society's own membership. The Program's purpose is to help rural communities acquire the medical personnel needed to sustain primary care services when recruitment and retention have proven to be a problem. This is an initiative that has worked "hand-in-glove" with the activities of the state Office of Rural Health and helps to explain why so many North Carolina communities, formerly without primary care services, have achieved success in starting and maintaining such programs in recent years.

A second major dimension of efforts to address the nation's rural health problems involves a complex set of factors that determine which rural communities will be able to address these issues most successfully. The North Carolina Office of Rural Health, under Jim Bernstein's leadership, put the majority of its emphasis on facilitating communities who had the leadership capacity to organize viable local efforts in response to these problems. As a result of decades of intense collaboration with local communities across North Carolina, there is now a body of knowledge and experience that has proven to be useful in assuring the success of local health services planning efforts. Torlen Wade and his colleagues[7] provide an overview of the basic approach to the establishment of local community and state governmental partnerships in rural health program development that has characterized the modus operandi of the Office of Rural Health since its inception. Rita Salain,[8] a person who has worked both in North Carolina and now in Georgia, adds to this discussion by illustrating in greater detail the various components of community development that have been shown to be essential and effective in making organized approaches to rural health issues possible.

In the discussion of the program development aspects of rural healthcare, practicing physicians play a critical role, both as direct providers of care and as leaders through the restructuring or development of local healthcare services to ensure greater effectiveness and long-term organizational and financial viability. Steve Crane[9] provids a useful discussion of the potential role physicians may play as these discussions take place, building on the experience in three of the western-most counties of our state. Leadership of rural community development efforts and the skills involved in identifying appropriate and effective leaders for such efforts were among the most important aspects that many have identified as a central feature of the way Jim Bernstein and the Office of Rural Health were able to facilitate the development of so many separate rural health programs across our state. In this issue of the Journal, we are pleased that one of Jim's many colleagues, Tim Size[10] from Wisconsin, offers a perspective on the importance of leadership and its development based on his many years of developing rural community-hospital networks in southern Wisconsin.

In every effort to bring greater coherence and organizational effectiveness to rural health services, a vital function is associated with local or regional hospitals. Jeff Spade, Executive Director of the North Carolina Hospital Association's Rural Health Center, and Serge Dihoff, Assistant Director for the North Carolina Office of Research, Demonstrations and Rural Health,[11] provide an overview of the way in which North Carolina hospitals have become closely involved with small rural communities in the effort to facilitate these developments.

A discussion of rural healthcare programs and priorities would not be complete without consideration of the difficulties these communities face in meeting the challenges of mental health and substance abuse services. Given the enormous impact of efforts to restructure mental health services in our state, there are many opportunities for persons with serious and persistent mental health problems to fall through the cracks and to have their needs go unmet. In this issue of the Journal, John Gale and David

Lambert[12] of the University of Southern Maine provide a discussion of the problems associated with assuring access to such services in rural communities. In addition, a sidebar illustration of a successful program offering mental health and substance abuse services in North Carolina has been contributed by Denise Levis.[13] Levis describes how mental health and substance abuse services have been integrated with the Community Care of North Carolina (CCNC) Program, a set of networks across the state through which the care of Medicaid enrollees is managed in an effort to achieve both quality of care and cost-containment objectives.

The area of major concern to all who have focused their work in the rural health arena that is absent in any detail from these pages is the matter of financing rural healthcare services and programs. However, these issues are raised parenthetically throughout these discussions. It is clear that the patchwork of federal and state programs to cover the cost of particular rural health programs and needs does not reflect a comprehensive approach to meeting these national health challenges. It has, more often than not, been possible to address rural health needs through public financing only when specific rural-urban comparisons are made visible and raised to a level of importance that justifies specific targeting of new funds. Today, more funds are available to meet the broad spectrum of rural healthcare needs than were three decades ago. However, much work remains to be done to help rural residents benefit equally from the modern healthcare capacities that residents of more urban areas have.

We hope that these papers will be of interest and encouragement to those who have worked long and hard to address the fundamental problems of rural health. We also hope that our readers will find stimulation among these papers for further efforts toward the goals embraced by these authors and enunciated on so many occasions by Jim Bernstein, to whose memory this issue of the Journal is respectfully dedicated.

Gordon H. DeFriese, PhD

The Work of James D. Bernstein of North Carolina

Donald L. Madison, MD

It is fairly common that someone's extraordinary service to the state be commemorated with a named building—commonly a dormitory on a state university campus—a park, a street, a stretch of interstate, even sometimes with a new, man-made lake. But such commemoratives are reserved ordinarily for governors, senators, or other long serving elected politicians. Their service to the state is doubtless deserving of such recognition; but so, often, is that of certain bureaucrats who over an extended period managed to change the face of North Carolina in some significant way—not by votes collected or bills signed, but simply by their vision, creativity, and long, hard work.

That North Carolina has led the nation in production of bright-leaf tobacco for many years is widely known. And the names of some of those responsible for the manufacture of tobacco products—Hill, Duke, Reynolds, Gray—are also well-known, if not by the nation as a whole, then at least by North Carolinians. The same can be said for textiles and furniture and banking, where this state has also been in the lead or threatens to place or show. But rural healthcare, which is neither a product, a highly marketed service, nor even a recognized "field" of labor or keen academic interest, is yet vitally important to the well being of this still predominantly rural state. And it is also linked to North Carolina in the minds of all those who know of it. For North Carolina leads the nation in rural healthcare and has for a good while—at least since the late 1970s.

There are several reasons, but the indisputable main one is the work of the late James D. Bernstein (1942-2005) and that of the superb staff he assembled. For his labors on behalf of the people of North Carolina, Jim Bernstein deserves to have a dam or a bridge named after him, at least a byway that branches off from some blue highway and leads to one of the approximately 85 rural community health centers for which his North Carolina Office of Rural Health is responsible for helping groups of local citizens establish. In addition, that Office collaborated with or followed some other agency—federal, state or philanthropic—or one of the universities in the state, in building, repairing, or helping stabilize several other community health programs. We should also recognize Jim Bernstein's work on the national level, for leading change in both the Medicaid and Medicare legislation to permit more equitable reimbursement for rural health centers and hospitals, and his leadership of national organizations devoted to the interests of rural health. Finally, and as important, historically, is the example that the North Carolina Office of Rural Health set for other states, that example activated by a national grants program of the Robert Wood Johnson Foundation with Bernstein at its helm. These efforts and more are his legacy to the state of North Carolina and the nation, and all were done from a home base in state government in Raleigh.

He was not a native North Carolinian. In fact, Jim Bernstein came to Chapel Hill temporarily; that, at least, was the plan. He had been an officer in the United States Public Health Service in Santa Fe, New Mexico, where he served as administrator of the Santa Fe Indian Hospital and Director of the Indian Health Service for Northern New Mexico.

Jim grew up in Westchester County, just outside New York City. His paternal grandfather was treasurer of Loews, the nation's oldest theater chain, which for a time, before the Justice Department intervened, also owned the lion's share of Metro-Goldwyn-Mayer (the pun is acknowledged and accurate). Jim's father manufactured advertising clocks, including those with the image of a certain grocery chain store pig with the "Piggly Wiggly" legend on the face. His mother, Jacqueline, was the family intellectual as well as the main attraction for most visitors to the Bernstein household—visitors who often included celebrities, especially artists and actors. Once people visited the Bernstein home, says Sue Bernstein, they were glad to return. And that was mainly because of Jackie Bernstein, who during the week regularly drove her Chevy Nova, alone, into northern Manhattan to work with needy children. As a youth, Jim was an athlete: swimmer, football player, hockey player—and later a hockey coach—first a playing "head coach" for the Johns Hopkins club team—"Fightin' Jim Bernstein," the college newspaper called him. Later in North Carolina, not a traditional hotbed of hockey, he served as a coach to youngsters.

After graduating from John Hopkins with a degree in political economy—and where he volunteered some of his time as a teacher of prison inmates—Jim applied for and was accepted

---

Donald L. Madison, MD, is Professor of Social Medicine in the UNC School of Medicine and Contributing Editor for the *North Carolina Medical Journal*. He can be reached at donmad@med.unc.edu or at the Department of Social Medicine, UNC School of Medicine, CB# 7240, Chapel Hill, NC 27500-7240. Telephone: 919-962-1140.

into the third class of Peace Corps volunteers. The core training for his assignment, at Princeton University, was followed by a brief French language immersion in Quebec. A group of volunteers then headed for their two-year terms in Morocco, where Jim would become an English teacher, and also as it turned out, the physical education instructor for boys at the Lycee Ben Barra, a high school in Taza. Not his top choice, Taza was only about 280 miles from Tangier and the Mediterranean coast. Jim preferred going to the far south of Morocco, to the desert. But the need was in Taza. Lycee Ben Barra was a state-run boarding high school for young people who lived in the sparsely populated countryside, in places that were too rural to have a local high school. Several Peace Corps volunteers were assigned to Taza, but only one other—Susan Dill, a native of the San Francisco Bay Area—was a teacher; and like Jim, she taught English and physical education (for girls) at the Lycee Ben Barra. As the two Americans at the school, Jim and Susan became friends; and when Jim ignored the Peace Corps' warning to avoid Moroccan French pastry and came down with a severe bout of gastrointestinal inflammation, Sue prepared soup and other light fare until his digestive tract had healed. Upon recuperating from his illness, Jim built up an appetite so voracious that, says Sue, he soon "looked like a butterball."

Those bacteria-induced events led to an even closer friendship between the English teachers Bernstein and Dill, and during the latter half of their term in Taza, they were married. As it does virtually everywhere, marriage in Morocco involves certain articles of written certification, but in Taza, Jim was taken aback to learn while filling out the requisite form that he would be permitted to take up to three additional wives. He was, however, obliged to certify with his witnessed signature that he would not exceed this limit.

After Morocco, Jim applied to graduate programs in hospital administration and attended the School of Public Health at Ann Arbor. From there he went to Cleveland for a yearlong administrative residency at Mt. Sinai Hospital. After that he entered the Public Health Service, requesting an Indian Health Service assignment. His two preferences were Anchorage, Alaska, and Santa Fe, New Mexico. When she learned that Jim had marked Alaska first on his preference list, Sue responded, "We need to talk." He learned the next day that it was still not too late to change his first choice to New Mexico, and soon the Bernsteins were on the road to Santa Fe.

In 1969, along with nearly two-dozen other young PHS officers with ambitions to be leaders in the broad field of public health, Jim was awarded a fellowship in "Global Community Health." The Public Health Service described what it had in mind for these Fellows:

> *The Global Community Health Fellows are bridging the gaps of our time by respecting tradition but refusing to be bound by it. These men and women from all parts of the United States have been making special contributions to federal, state, local agencies, and private organizations in the United States and developing nations. Each brings to his or her fellowship assignment a sensitivity and commitment to*

(Above) The burka-clad Susan Dill. (Below) Newlyweds posing by the wedding cake, a traditional French croquembouche, which consists mainly of a decorative "tree" made of creampuffs held together by caramel syrup.

alleviate the health problems of the community. During their concentrated exposure to the mosaic of health, its interlacing problems on all levels, and academic pursuits, the Fellows gain invaluable practical knowledge for the transmutation of the health system.

Looking past the rococo metaphors, this is in fact an accurate representation of what Jim did during his three fellowship years and the work he continued beyond that time.

The fellowship allowed these young PHS officers to follow their muses wherever they might lead. They could arrange to study some aspect of community health virtually anywhere in the world. The fellowship usually included an advanced degree program in something, perhaps one of the fields of public health or public policy or administration. Slightly more than half of the fellows in Jim's group were physicians; the others were administrators, environmental engineers, dentists, and nurses. Administrator Bernstein, who had already spent two years in Morocco, and who had a master's degree in hospital administration, wished to pursue an advanced degree in public health and study the problems of rural health in America.

From looking at some basic statistics from the census, Bernstein learned that Texas, Pennsylvania, and North Carolina had the most rural towns (those with 2,500 population or less) of any of the states. And so he considered these three first. Texas, he said, interested him; but although it had many, many small towns, it also had several large cities. Pennsylvania had Philadelphia and Pittsburgh. North Carolina, on the other hand, had no large city. (In the early 1970s Charlotte was not yet considered large, not at least by the rest of the nation.)

The doctorate Jim was seeking would perhaps be in administration or possibly in epidemiology. According to Glenn Wilson, whose friendship with Bernstein began in Cleveland while Jim was doing his hospital administrative residency there (and where Glenn was Vice President of the Kaiser Health Plan, in charge of the Ohio region), Jim called Glenn from Santa Fe to tell him that he was thinking of enrolling in a doctoral program in epidemiology at the University of Texas School of Public Health in Houston.

Glenn says that he told Jim: "Well, It's alright for you to go to Houston, but Sue and the baby can't go with you." (The first of Jim's three children, Lori, was born in Santa Fe; Eric, two years younger, and Donna, six years younger than Eric, were both Tar Heels born.)

I asked Glenn why he would say that about Houston?

"Have you been there?"

I had; but I'd also lived in the Los Angeles basin in the 1950s, and so my impression of the air pollution in Houston was considerably less graphic than Wilson's. Jim, however, apparently took Glenn's point.

"You need to come to Chapel Hill and talk to Cecil Sheps," Wilson told him.

At the time Glenn was still in Cleveland but was completing negotiations to relocate to Chapel Hill to become Associate Dean of the School of Medicine for Community Affairs, where he would later launch the North Carolina Area Health Education Centers (AHEC) program.

Bernstein in his summer USPHS uniform, Santa Fe, New Mexico.

Bernstein had first entered the Public Health Service, as had many of his generation of healthcare professionals, because of the Vietnam War. He went to Santa Fe in 1966, which was the year when the draft accompanying the Vietnam buildup accelerated sharply, the year when virtually every medical graduate of the class of 1965 (my class), having just completed internship, would be drafted (unless they were deferred for residency training). Wilson says, "The only good thing I can say about the Vietnam War is that it diverted Jim. He was going to be a hospital administrator … in civilian life … somewhere. But the specter of the draft stood in the way. And with some assistance from me, but more from Congressman Charles Vanik [of Cleveland], he ended up in the Indian Health Service."

While Jim was in Santa Fe, he had become interested in an idea that Professor Bob Oseasohn, an epidemiologist and chair of Family and Community Medicine at the University of New Mexico in Albuquerque, had launched as an experiment and for which he asked Jim to serve on the planning committee. The experiment called for a nurse to deliver primary care for a small town—Estancia—backed up on the telephone, mainly, by physicians in Albuquerque, 62 miles to the northwest. Oseasohn later left New Mexico to become Associate Dean of the University of Texas School of Public Health in Houston. And when Jim became a Global Community Health Fellow, Dr. Oseasohn tried to recruit him as a doctoral student, thus, Jim's interest in Houston.

Why, I asked Wilson, did he want to get a PhD?

"All I remember was what he told me as he was getting out of the PHS. He had finished his two-year term, and this opportunity (the fellowship) had come along, and he had decided he wanted to get a PhD and become a teacher. I think that the experience in the Indian Health Service persuaded him that he didn't want to be a hospital director, nor, as best as I recall, a line bureaucrat in the federal government. He wanted something different than that. So that may have been part of the motivation to do something else. It was not very well defined."

But, pollution aside, why did you bad-mouth Houston to him?

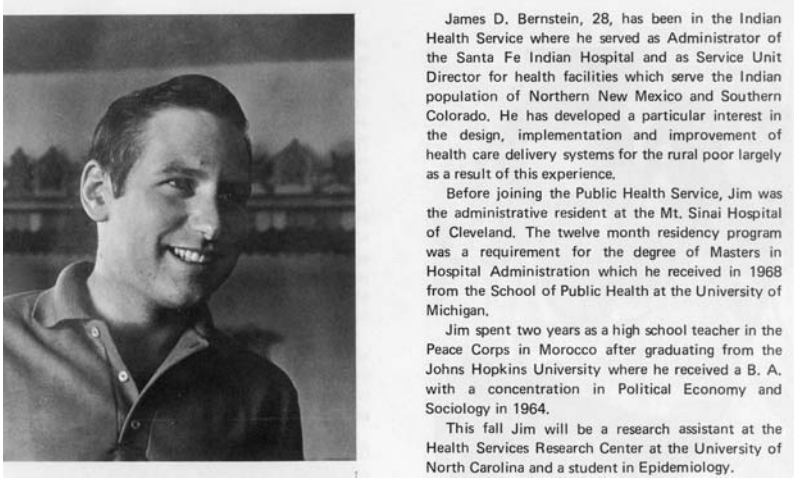
"Well," Glenn said, "I have the highest respect for Bob

Oseasohn. As you know, I tried to recruit him here later. But I really doubted that Jim would be happy in Houston, and I wanted him to talk to Cecil, which he did. Now why he wanted to do the PhD, I still don't know."

Jim's own version of his visit to Chapel Hill is worth quoting. This is from the remarks he made at the memorial service for Cecil Sheps in May of 2004.*

> "[Taking Glenn Wilson's advice], I called Cecil Sheps, and he said, "You need to come to Chapel Hill to see me." Don Madison picked me up at the airport and took me to Cecil's office, which was in the South Building. After a brief introduction, Cecil handed me an agenda, which included interviews with Don, Conrad Seipp (Deputy Director of the Health Services Research Center), a professor in Health Policy and Administration, and John Cassell (Chair of Epidemiology). He said that after I was through with all that we would meet at his house. My plan was to combine academic coursework with a rural practicum at the Health Services Research Center. My first interview at Health Policy and Administration was not encouraging. The professor I spoke with only wanted to tell me that my grades would probably not meet the high admissions standards of the program.… Next I went to see John Cassell in Epidemiology. It was graduation day and Cassell was putting on his cap and gown to go to the ceremony. Cecil had obviously put in a good word for me. Dr. Cassell asked me to walk with him to the graduation ceremonies so we could talk. By the time we reached Memorial Hall he said that he wanted me in his department if I wanted to come. Later that afternoon, I met Cecil at his house, where he said, 'Let's take a swim in the pool.' Within 20 minutes, he had laid out my next three years as a part-time student in epidemiology and a Research Associate at the Health Services Research Center."

I recall that Jim seemed to enjoy his coursework and classmates and appeared to be a well-motivated, serious public health student.



James D. Bernstein, 28, has been in the Indian Health Service where he served as Administrator of the Santa Fe Indian Hospital and as Service Unit Director for health facilities which serve the Indian population of Northern New Mexico and Southern Colorado. He has developed a particular interest in the design, implementation and improvement of health care delivery systems for the rural poor largely as a result of this experience.

Before joining the Public Health Service, Jim was the administrative resident at the Mt. Sinai Hospital of Cleveland. The twelve month residency program was a requirement for the degree of Masters in Hospital Administration which he received in 1968 from the School of Public Health at the University of Michigan.

Jim spent two years as a high school teacher in the Peace Corps in Morocco after graduating from the Johns Hopkins University where he received a B. A. with a concentration in Political Economy and Sociology in 1964.

This fall Jim will be a research assistant at the Health Services Research Center at the University of North Carolina and a student in Epidemiology.

The Public Health Sevice published a booklet introducing its class of Global Community Health Fellows, devoting half a page to each. This is the entry for Jim Bernstein.

Glenn Wilson remembers, however, that he "…didn't want to settle down and write a dissertation. He never did write very much, as a matter of fact…. He and I and Gordon [DeFriese, then an Assistant Professor of Sociology and a Research Associate in the Health Services Research Center] used to have lunch about once a week when my office was in MacNider. That dissertation project fell apart to some extent. I'm not sure he would ever have finished it anyway, because he wanted to do something practical and they wanted some theoretical paper. That's how it was described to me. And as the weeks went by I could see it unraveling. And then when Cecil came by and said: 'Walstonburg,' away Jim went."

That is probably an accurate reading of Jim's motivation, although it is incorrect chronologically, because according to Jim, the Walstonburg project began almost immediately upon his arrival in North Carolina: "When I arrived in Chapel Hill, in July, I went to see Cecil, and he informed me that I was to be in Wilson, NC, the next day to meet Dr. Edgar Beddingfield, and that night to be in Greene County to meet with a group of citizens who wanted to build a health center."

Walstonburg, a small town without a doctor, was representative of hundreds of others in North Carolina, and perhaps thousands throughout the south and midwest by the late 1960s and early 1970s. But it had something special going for it: It was less than 20 miles from Wilson, where Dr. Edgar Beddingfield was affiliated with the Wilson Clinic. Beddingfield was a past-president of the North Carolina Medical Society, but his influence in the state went well beyond medical society office-holding and even medical affairs. He was widely respected as a statesman. Early in his career he had gone to Stantonsburg, a small town between Wilson and Walstonburg, had entered general practice, and was still practicing there, albeit on a part-time basis (the rest of the time he was doing occupational health work through the Wilson Clinic).

Beddingfield had long been interested in the problems of the small town without a doctor, and he was intrigued by the possibility of relief offered by the physician assistant (which had more or less been invented by Dr. Eugene Stead, the legendary chair of medicine at Duke) or the family nurse practitioner, which was just then being advanced by the nursing school at Chapel Hill and its Dean, Lucy Conant, with the strong backing of Dr. Sheps, Director of the University of North Carolina at Chapel Hill (UNC-Chapel Hill) Health Services Research Center, or some other type of trained "intermediate level" practitioner supervised by a physician, such as the Medex program, at the University of Washington and Dartmouth, where ex-military corpsmen, Vietnam veterans, were trained to perform essentially the same duties.

---

* The remarks at the Sheps memorial are published in James D. Bernstein, "Cecil Sheps Was My Mentor," in Donald L. Madison (editor), *Cecil G. Sheps Memorial Volume*. Chapel Hill: Cecil G. Sheps Center for Health Services Research, The University of North Carolina at Chapel Hill, 2005. All other quotes by Bernstein that appear in this article are taken from a long interview recorded by Nan Rideout in 2004 and transcribed by the author.

All of these “intermediate’ level practitioners required some defined clinical protocols, plus telephone and occasional personal clinical support and backup by a reasonably nearby physician, and, of course, intensive training. And in the case of Walstonburg, Beddingfield, who believed strongly in the concept, but who himself had no personal experience with it, was interested in providing the necessary medical backup. He also knew something about small rural communities and how to approach them. Bernstein credited Beddingfield as the “real father” of the North Carolina Office of Rural Health largely because of his support and critical political interventions. But Jim already knew, or at least had the instincts that told him, much of what he would have to do.

Walstonburg became Jim’s “field work,” supervised by Cecil Sheps. I told Wilson my take on this experience, as I remembered it, and then asked him to respond: If you look up Greene County in the Atlas of North Carolina, the 1967 version published by the UNC Press, you would find, I told him, that it was not the poorest county in the state, although it did rank toward the lower end and it was one of eight counties in the state with a majority African American population. Jim was going down there all the time, probably not every other day, but it seemed like it. He had this plan of educating the population, and so he goes over to North Carolina State to the School of Design to find students who could create a sort of cartoon book that would explain the health center and what a nurse practitioner would do. He was just a bundle of energy and ideas (some of which I thought were just short of wacky). But how, I asked Wilson, do you explain all that?

“Well,” he replied, “I think it was several things: One, Walstonburg was a clean slate; there’s nothing there. So there’s a chance to do something, and he got caught up in that. And then there was another kind of challenge, and that was to show the doubters—there were a couple of them in that general area, who quietly scoffed at this Jew from New York and what he was attempting to do; and he took that as a challenge. And so he started. And he was accepted. This was the beginning of his rare talent of sitting down with people, all kinds of people, and listening to them, and putting factions together. Now, not in the sense that he would always do what they wanted. He would bring in others to lead them away from some stupid mistake they were about to make. But Walstonburg is where he learned that. And he came back every week just full of himself, at what they, the community, could do. I told him it was crazy to take these design students to Walstonburg, but he didn’t always listen to me. And then we had a long conversation about what could be done for those people, and I reminded him of my friend Henry Daniels’ statement [Daniels was a career labor union executive with the health program of the United Mineworkers of America] that when you try and do something for people, you usually end up doing it *to* people. You’ve got to do it *with* them. And they’ve got to buy into it, and they’ve got to put up some money. So we had a long discussion about getting them to put up some money. I think I learned that with the Mineworkers clinics, in Canada [with the Steelworkers], and in Cleveland [in organizing the Community Health Foundation]. And Jim became an evangelist of that notion. And most importantly—this is another important trait of his—he never took the credit. And that’s one reason that the Office of Rural Health under his leadership worked so well.”

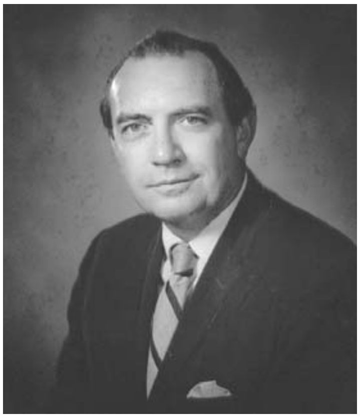
Did you go out to Walstonburg?

“Yes, a few times. And as you said, there wasn’t anything there, except a few poor people, mostly black, who had a magical relationship with a guy named Bernstein. Remember, this was 1971 or 1972. It wasn’t that far removed from the days of segregation.”

I asked Glenn what he could tell me of the relationship between the blacks and whites on the board that had to be formed—or I guess it had already been formed when Jim got there?

“You know, I think that was the first Bernstein magic. Because at that time, there was Klan activity, at least there were Klan signs up and down that road, to my certain knowledge, because I was traveling through that area, including Greene County, frequently—I didn’t have any business in Greene County, but I traveled through there to visit hospitals in the east, to learn the state (we were beginning the AHEC effort then), and I was mostly wandering around on my own, usually taking the long way to Wilmington. But the Walstonburg board members got along with great civility. I must have gone to maybe half a dozen meetings in that community.

“This was the same time,” Wilson continued, “that a community hospital in the east and another in the piedmont wanted to see pictures of the medical students we were going to send them—for obvious reasons. And we refused. So it wasn’t yet the era of enlightenment across the state. We finally told them that we weren’t going to do business with them on those terms. We would send them qualified students, who might be female or black. But those meetings in Walstonburg were far more congenial than anything I saw in my work with the community hospitals. And I never asked Jim how he put it together. So I don’t know. But that same pattern ensued in all of the rural health centers. Remember, though, you had not only black and white, but also rich and poor, who often don’t speak to each other—in civil terms. How did he do it? I don’t know, but he did. And as far as I’m concerned that’s the reason the Office of Rural Health was such a smashing success.”



Dr. Edgar Beddingfield

So Jim had Greene County, which was essentially a medical vacuum. He had a community board. He had Dr. Beddingfield to back up the nurse practitioner. But he didn't have a nurse. As Bernstein explained: "The idea for the program was that we would ask the boards in these communities to locate a nurse that they thought highly of. The kind of person they'd go to at night when people were sick. And then we would send that person to school, pay for them to go back to Chapel Hill or, later, to Greenville or Asheville. And they would then come back to the community where they lived and their family lived, and they then would stay there. They wouldn't leave. That was a really good concept. But in Walstonburg, it didn't turn out that way. So we had to search for somebody from the outside. And we finally found a nurse practitioner in Colorado. And she came here. Donna Shafer was her name. She did a really nice job. Donna was just a good one to be there—she was very unassuming, not aggressive. Which was what we needed at the time. So they just couldn't get mad at Donna. It worked very well."

Entrace to Walstonburg, NC

In fact, Donna, who later married an Englishman and moved to the United Kingdom, became a close personal friend of the Bernsteins, who named their youngest daughter after her.

I asked Torlen (Tork) Wade, who now directs the Office of Rural Health, how, in fact, the staff found the nurses who would be trained as practitioners in the early days.

"It was a combination," said Tork. "Some were hospital nurses, but most were nurses in doctors' offices. That made it a lot easier to sell the model because they would be backed up by that same doctor. Those were the ones who really worked well —taking a nurse out of the practice, sending her to Chapel Hill, and having her come back to work with that doctor. It was a very good model. But, it's funny; today it doesn't work nearly as well. You know, the level of education is much higher now. Most of them have master's degrees. But it's much harder to get them out into the community. And there isn't that confidence on the part of the doctors, because they haven't worked with them over a long time already. They're just hired. Maybe they're better trained, but having a local person be the provider was critical in the early days. Betty Queen in Black River was the first nurse practitioner there. Everybody knew her in the whole county. They loved her. They didn't really care if she was a nurse practitioner or even what that was; what they knew was that she could help them."

I knew that Glenn Wilson would remember how the Office of Rural Health came about.

"Well, it was Cecil. The committee of the legislature came to me, because we were preparing to reapply to the federal government for renewal of the AHEC support, and I said, 'How about making this statewide?' And they agreed to that (with state money). Meanwhile, Cecil had gone to Governor Holshouser and put this rural program in as part of the AHEC program. Chris [Fordham, then Dean of the UNC School of Medicine] and I went over there to see the Governor and told him, 'You really can't do that.' (Because medical schools don't do these kinds of things very well anyway, and we'll be seen as being in competition with the local doctors, and it will all blow up.) 'You need to set up something separate for this.' Holshouser said, 'But there isn't time.' And so at about 11:00 that night, it landed in the Governor's Office. And then the question, who would run it? It was very clear—that fellow from Walstonburg. It was settled that night, in my presence. And the Governor called Bernstein."

Jim's own account is not inconsistent with Wilson's, but it leaves out the organizational questions and the University's concern about combining it with AHEC.

"James Holshouser had just been elected Governor of North Carolina…. Cecil, in his unique fashion, calls up the Governor-elect to tell him that he has this terrific health program that is going to help solve the health access problems of rural North Carolina. He then asks the Governor-elect when he should come see him. Later, Cecil describes to the Governor his concept of a rural heath program built around community-operated health centers staffed by family nurse practitioners and physician assistants. When the Governor asks how he is supposed to make this happen, Cecil tells him that will be no problem—just leave it to him. Cecil then calls me into his office to tell me that he has figured out what I need to do next with my career. I am going to Raleigh to set up this new health program."

The program was announced publicly by the Governor and the Secretary of Human Resources, David Flaherty, who introduced the 30-year-old Bernstein at a news conference on Monday, June 19, 1973. Earlier the Legislature had appropriated $456,000 for the program—for the first five clinics. But the Governor's announced goal was to have 15 new clinics established within 26 months. Obviously, this goal anticipated further appropriations.

Soon after the announcement, Jim went to see Flaherty to negotiate his job. The conversation went well, although, as Jim said: "We didn't come to any resolution in his office, but it looked like we would come to some kind of understanding. And then he surprises me, and says, 'Oh, by the way, before you leave I want you to talk to this group.' Well, what he had done, when the notice had gone out from the Governor about the program, and it was in all the newspapers and on television, he had gotten all these letters of protest, most of them from physicians. And so they had invited all the people who had questions or who were mad to meet in this auditorium in one of the state buildings in Raleigh. I've forgotten which one. So he marches me on the stage, and there must have been 150 or 200 people in that room—lots of Board of Medical Examiners people and all these types. And he gets up there and says: 'Now I've invited all you people here who have criticisms or questions about our program, and here's the guy who can answer all your questions, he's the new director of the program.' So I took question by question by question. And you know something? When you're younger, in a lot of ways it's easy. You think you know more than you know. And it was such a new kind of thing, they didn't know if I was wrong or right. So when I said there is evidence around that the doctor can be in a different spot than the nurse or nurse practitioner, seeing patients with protocols, and it's worked in other places—I'd seen it in New Mexico and other places, but they'd never had any experience with it. So it was difficult for them to tear it down. I went through question by question by question for about an hour and a half until everybody wore down and went home."

That opposition was one obstacle. A second one was getting a law passed that would permit nurse practitioners and physician assistants to practice in these clinics at the level for which they were trained to practice. Bernstein explained: "Dr. Beddingfield was doing this in Walstonburg without a law to back him up. So we had to get a law through, and that was the next big fight. And I was sort of the floor manager, since I was the only one there who knew much about it. So I was hooked up with key legislators that Senator Royal and some of the others had put together. And we had our battle. And if it weren't for people like Dr. Beddingfield we wouldn't have won that battle. He was key to the whole thing. Anyway, at the end, when the bill was going through, and I was watching from the top, looking down, some legislator, I won't say where he was from, made a motion to fire Jim Bernstein. And the Speaker of the House said he was out of order. Because the legislature doesn't have the authority to fire a named person. They have the authority to get rid of a job, but not a named person. So I survived."

Having escaped that episode of parliamentary chicanery, Bernstein had to organize a statewide program. It was one thing to work, as he had done day and night, on the Walstonburg project. But now he was committed to be a wholesaler.

In this story, there are three Jims—Bernstein, Holshouser, and, later, Hunt. The young Bernstein, just beginning his work in Raleigh, once told me about a phone call he'd received at home the night before. It came from Atlanta, as best I remember, but it could have been from someplace else where a national governors' conference was then being held. The conversation left Bernstein in mild shock, which lasted at least until the next day when he told me about it. From this phone call, he learned that he had made the big time. The dialogue began like this: "Hello." "Jim?" "Yes." "This is Jim." (silence—then): "Jim who?" "Jim Holshouser."

Glenn Wilson notes one crisis Jim's Office was about to face: "I should remind you that the office was up and running and Jim was scrambling around the state. I know that while Jim was scrambling around the state, it wasn't that long before we had a change in administration. And he and I had concluded that Jim Hunt would not continue that program on which his Republican opponent had campaigned. And Sarah Morrow, who was Secretary of Human Resources under new Governor Hunt, thought this was something the local health departments should be doing. And so Jim Bernstein went to see Jim Hunt. He was accompanied by Mrs. Warren of Prospect Hill, who was a friend of Jim Hunt's—I think Glenn Pickard may have called her. Anyway, she called Jim Hunt and got him to come up there and see the Prospect Hill Clinic. I think Jim Bernstein went with him. And he had some support in some communities, not a lot at that point because it was still getting off the ground, but some, enough so the Democratic Administration was persuaded that it was a good idea. What Governor Hunt saw at Walstonburg and Prospect Hill and Snow Camp and one or two other places was some real community support and, potentially, a powerful political force, and he wasn't about to put it in the health departments or do anything to Jim Bernstein."

Along with Governor Hunt, Dr. Morrow would also become one of the program's most ardent supporters.

But, Glenn added, "…as for the overall operation. At the beginning, I wouldn't have given you a nickel for the chances of that succeeding. High visibility programs like that, programs that are cooked up by administrations usually don't survive when there's a change, I don't think. But here was an exception to that rule."

Bernstein needed a staff. First to join was Terry Alford, an architect recently graduated from North Carolina State University. Terry was a North Carolina native who had helped on Walstonburg as a student. He stayed on Jim's staff for a couple of years before going out on his own, although he continued working on rural health clinics in North Carolina and all over the nation. The Office of Rural Health helped build new buildings, but renovations were generally less expensive, and Jim's principle that the local community be required to come up with part of the money (a small part—the state put up the majority share on a five-to-one match) suggested a need for economy. So most of the earliest buildings were renovations, and, as Tork Wade remembers, "Terry Alford would put those blue awnings on some otherwise ugly building and make it look spectacular." In fact, Terry quickly became famous among those of us who knew his work because of those blue awnings. They became his motif.

But Jim also needed field staff, people who would do essentially the same job he himself had done in Walstonburg—attend board meetings, decide what technical assistance was needed and find it, help procure a nurse to be trained as a practitioner, arrange for physician back-up, and any number of other tasks that went into organizing a community health center. These people had to be self-starters with a talent for community organization, but also have a practical working knowledge of primary healthcare—not the clinical skills, but a knowledge of the things clinicians needed to perform their craft and a feel for how the relations among clinicians and the other staff and between the staff and the board and the community of patients should work.

First, Bernstein found Fred Hege, who had been director of the local Office of Economic Opportunity (OEO) Community

Action Agency (the basic local building block for President Johnson's War on Poverty) for Vance, Warren, and Franklin Counties. The Community Action Agencies were then being slowly dismantled (along with most of the other parts of the War on Poverty) by the Nixon Administration, under the leadership of OEO Director Donald Rumsfeld and his special assistant Dick Cheney. From this job, Fred had acquired the requisite community organizing experience, but he was also a former Moravian minister—a "missionary" in a sense, who by nature was an organizer of people and their efforts. Fred also had experience in state government. Soon afterward, Jim found Tork Wade and Burnie Patterson. Like Jim, Tork had been a Peace Corps volunteer (in Malaysia and on the Island of Borneo). He was just completing his master's degree in public health at Chapel Hill and for his fieldwork, had assisted Jim with the Walstonburg Clinic. Burnie was a social worker from Dare County, who met Jim while he was organizing a clinic on Nags Head. Burnie had earned his master's degree in social work at UNC-Chapel Hill. At about this time (1973-1974), I was teaching, through the School of Public Health, a reading seminar on rural health services, which I continued for about five years. It met once a week for two hours, and the assignments were formidable, since I included nearly all of both the recent and historical literature on rural healthcare in America. Jim sent Terry, Tork, and Burnie to take the course.

Other members of Jim's staff, who joined a year or two later, included the third ex-Peace Corps member, Roger Hagler, who had been an original volunteer—one of the group that had been sent off by President Kennedy with a ceremony in the Rose Garden. Roger, in fact, had been Tork's supervisor in Malaysia. There was also a second "missionary"—Gail Kelly, an ex-Maryknoll nun in Bolivia and Ecuador, where she had been a "do everything" healthcare provider—the general practitioner for an entire community; and Nan Rideout, who came from the western part of North Carolina and whose background was in teaching and hotel management (with a master's degree in the former, a bachelor's in the latter, and work experience in both).

Fred Hege was considerably older than Jim and provided a complimentary set of skills and experience. Nan Rideout had this to say about them: "The synergy that worked with Fred and Jim was amazing. I remember saying to them, 'I wish I could think the way you guys do.' And Fred said, 'you forget, there's two of us working at it, not just one.' There were so many things to deal with in terms of politics in local communities, politics in the General Assembly, as well as moving ahead with our goals for developing health services, and then the medical society also. Fred, I remember as being invaluable in that way, while Jim was completely involved in moving these projects ahead. Fred was also very instrumental in training those of us who came in later. I think Fred's background as a pastor and his ability to deal with people, understand people, was also invaluable. He used it well, because none of us ever saw him as a preacher, but he had those skills, which he used very adroitly. With many of the early office staff, it was a push-pull relationship, because Fred was very demanding, but he was very instrumental in shaping the office and those of us who came in."

Other early staff members, included Joan Peacock, who stayed on as Jim's assistant until she retired, and Judy Howell, who remains on the staff.

"You know," Nan continued, "I think that one of the most significant things about Jim was his ability to hire people. Regardless of their backgrounds or anything else, he hired really good people, and he wasn't afraid to take a risk if he thought someone, at a gut level, was right for the Office. He, in fact, eschewed those people with a background that would seem to fit because he wanted to take a new approach. He didn't want people to come in with preconceived ideas."

So people with degrees in health services administration?

"That was a definite negative. You'd have to prove to him that you could think outside the box."

Although later on, he did take people with those backgrounds, from the UNC School of Public Health and a few from the policy school at Duke. Tork says that the Office had a steady stream from there for a time and that they still have a couple, but that "the bread and butter came out of the School of Public Health."

"In addition to Jim's hiring good people," Nan says, "he was able to instill in us a sense of mission. We were focused on what we were doing. We didn't think of ourselves as part of state government. Jim was wonderful in isolating the office and letting it develop and percolate on its own. He was a wonderful buffer. And I have examples of times he really stood up for us. You could count on him when the chips were really down. And he also kept us stimulated and gave us enough independence in those early days. All of the original core field staff stayed with him at least 20 years, until we retired. There was virtually no turnover. I think that he hired people who were devoted to the mission and not to achieving status. And while we may have had some desires for the responsibility of running an Office, the greater desire was to see if we could accomplish something and achieve change. And that's why those of us in the early days never thought about leaving. It was a little frustrating to him because of that, maybe."

You mean he wanted you to go?

"Well, we all had other opportunities, and when we'd talk to him about them, he'd say, 'Go.' But nowhere else could one envision having the combination of responsibility for achieving a product like a health center and seeing the effect on a community, and

I think we were much more motivated by that than by the status of running a program. Jim was self-confident, but I didn't feel that he had any vanity or arrogance at all. He respected people for what they offered. And once I looked around the office, and I said to myself, 'My God, do you see how many tall women Jim has here?' (And tall men, too.) But it's unusual to find a person of short stature who's entirely comfortable surrounding himself with people who are quite tall. But I don't think he thought about that for a minute. It never occurred to him."

Well, he married a tall wife.

"I guess that was a good sign."

But there were those who didn't stay. Jim set down a set of principles. And many of them concerned the work of the field staff:

He started by saying: "We weren't going to run anything.… They, the community, would be primarily responsible, and we would provide the pieces that they couldn't put together themselves, as well as the know-how to make it work. Nor were we going to push ourselves or come out from Raleigh saying, 'We've got this new idea for your community and this is what you should do: You should have a health center; you should have a nurse practitioner; it should be run by the community.…' We acted only where we had a request. We might get a call saying, 'We haven't had a doctor in a long time and we're interested in just talking to you.' Then we'd send a staff person out. So that was another principle: Don't tell the community what they need. If they don't want what we have, that's fine. The next thing was to be able to put together all the pieces that were needed to do the job. So if a community wanted to do it, we had the ability to make it happen. And the most important part of that was our field staff … the people who interfaced with community folks. Our philosophy was, we go to them. So our field people were on the road all the time, meeting at whatever hour the community group could get together, whether it was Sunday afternoon or Monday night. And most of those meetings were at night. So we were going to be an agency that went to the community; very rarely did a community person ever have to come to Raleigh. And the staff person had to be able to deliver the goods. So if the community group wanted to explore this idea and then develop it, the staff person had to put together all the pieces. If a building was needed the staff person had to have access to an architect, which is why we had our own architect—and our own media person to back up our staff people. It was important that the community didn't see the staff person as someone who had—we didn't have much—a little bit of money to sprinkle around, but rather as someone who could actually help them get healthcare in that community. So the field staff had to learn about erecting buildings, they had to learn about medical records, and most important, they had to learn to work with communities and had to have community organizational skills, which are something, I've come to conclude, that you can't teach very easily. They are somethings you either have or you don't have."

Bernstein continued: "People—potential staff—who came by mistake to this office (versus another office), who were looking for a cookie cutter kind of job, something they could do every day, didn't make it in our Office. It just didn't work. And in the beginning, it was really hard on those people who would say, 'What's my job? What do I do?' Well, you've got to get on your feet out there. But there's a lot of support from the staff back home; you know, myself and the other staff people would kick around with you about how you're going to deal with your problems in that particular community—because always there were problems. None of it was easy. But if you were looking for someone who used a workbook and went out to a community and said, 'This is how we're going to do step one,' just like that, it wasn't going to work. You had to be a person who could think on your feet and make decisions and move forward on your own. Most of the people who could adapt to that kind of style, who liked it, stayed for years. Others, who didn't fit, didn't last long. They just left. Because they were uncomfortable in that kind of a role."

During the first year, Tork Wade remembers, the field staff identified five communities to work on: East End, Bakersville, Bladenboro, Newton Grove, and Westfield. Tork described, in general terms, the method that the field staff followed: "We'd kind of have these steps we'd follow. It might start with a call that said our doctor is retiring. They didn't want a nurse practitioner, per se, they just wanted a doc. But we'd go out and meet with them—and we didn't really have a physician recruitment program yet at that point—so we'd tell them what we had, what the requirements were, and they might not be interested. So it was, 'Thank you, and who else can we call?' There were a number of those. But once there was interest, where they would say your program does look like it might fit our needs, then we would do a market study and compile all kinds of preliminary statistics—you know, to decide whether there would be enough demand to make it work. And once we went through that and decided there would be demand and that the market was OK, it generally went through. It might have taken a while, but I just can't think of any that failed after it went that far. There might be delays, for example, to get the physician support. I remember places where the docs would object to the program simply because it was from government. You know, that was usually the biggest barrier—getting the back-up physician lined up. But they would usually come around in time. You might have to move on to another doctor. But they would come around, finally. And there would often be pressure from the community for them to respond."

"We might say, 'Well, Dr. Pickard would be glad to come in and talk with you.' Physician-to-physician, you know, and that would often turn them. Glenn Pickard [internal medicine at Chapel Hill] was the primary one who did that. Terry Kane [family medicine at Duke] went out some. And Zell Hoole [internal medicine at Chapel Hill], I think, once or twice. And Rob Sullivan [internal medicine at Chapel Hill and then at Duke]. And Larry Cutchin [internal medicine and pediatrics at the Tarboro Clinic] did some, too. But the major share of it was Pickard. He would go anywhere we needed him to go. He connected so well with the docs, and he was from North Carolina. Plus, he was the pioneer on all of that—along with Betty Compton [family nurse practitioner at Prospect Hill]. And then on the legal issues, Dave Warren [Duke Law] would go to assure them they weren't taking on a huge liability. We had wonderful support out of Chapel Hill. And then Jim had that connection with Beddingfield on Walstonburg. And that was huge. Because he was a big shot who all the docs respected. He was from the country, and a former president of the state medical society. And he was not an academic. But he carried a tremendous amount of weight. He didn't go around and speak, but he would pick up the telephone and talk at association meetings. But those were contributions without which the program wouldn't have gotten off the ground. A lot of that Jim pulled together. But some of those people came on their own initiative, because they believed in it. But Jim never had any problem asking, either. He knew it was important."

Over the 30-odd years of its existence under Jim Bernstein's direction, the Office of Rural Health established more than 80 health centers. But there were some additional programs where the Office did not take the lead, at least not initially (another agency—a foundation, the federal government, or perhaps another state agency—began the program or provided the initial funding and technical assistance), but the North Carolina Office of Rural Health usually either worked alongside or followed up later when there were problems. A good example is the Hot Springs Health Program in Madison County, started by Linda Mashburn (nee Ocker), a nurse with experience throughout Appalachia and in India; and Jerry Plemmons, former head of the local rural electric cooperative, who did the initial community organizing; and with assistance from the Health Services Research Center at Chapel Hill and major funding from the Appalachian Regional Commission (ARC). After a modest beginning, some early success; several crises; three decades of growth and change; assistance along the way from the UNC School of Medicine, the Mountain AHEC, the Office of Rural Health, several foundations, and an influential local politician, the Hot Springs Health Program is now a countywide primary care program (in a county with no hospital) that has more than filled the gaps left when the aging private physicians in the county could not replace themselves as they retired or died. It may be unique in the nation in this respect or at least one of a very few.

The Bernstein Family: Donna, Eric, Lori, Sue, and Jim

In its early days, the program got off to a good start, but then got into trouble—political, administrative, clinical, and fiscal. Jerry Plemmons is now chair of the board. I asked him what Jim Bernstein's role in all this was.

"He was the fixer."

And, indeed, when the Hot Springs Health Program seemed on the verge of "going down the toilet" (Linda Mashburn's description), Jim sent Gail Kelly from the Office of Rural Health staff, who practically lived in Madison County for the better part of four months. Linda, who by this time was no longer the executive director, but was still employed by the program as a home health nurse, says that she talked with "all the board—over the phone and in person, behind the scenes, and then I called Jim and said, 'Help, help, help!' And Gail Kelly, when she came up to do her work, stayed at our house. She came on the heels of this airlift of medical personnel [from Chapel Hill, because the program was, by then, without a doctor], and it was obvious that we could not survive long doing that. The airlift was a short-term thing, and we needed a long-term plan, and so Gail was there to work that out."

Jerry Plemmons added, "She made many of the decisions that an executive director would have made. She served in that role without being in that role. She put together … a plan to include an expansion to Marshall and the development of a Marshall clinic.… A part of that, as I recall it, was that the five-year ARC funding cycle was due to expire. And the program could not sustain itself without some outside support."

Linda explained why: "Because it had too small a service area, and it was operating in the poorest area of the county. Also, the major thing that had changed by the time Gail was there was that one of the two elderly physicians in Marshall had completely retired, and the other one was only half time and was looking to retire within the year. When I started the program in Hot Springs, Marshall did have medical services, but by this time those services were gone or going."

"What happened," Jerry said, "was that the board and the community supported expansion of the program into the Marshall area, which was Gail's recommendation. There was already a clinic in Walnut, which is maybe eight miles from Marshall, and that clinic was to be moved in the direction of Marshall. It ended up being about half way between the two communities, which then expanded the program's service area to include Marshall. And then, of course, the docs in Mars Hill were still active and were still opposed to…."

"But they were coming around a little bit," added Linda. "Because during the time I ran the home health agency for Hot Springs, and it was a county-wide home health agency, so I had many of the patients of the physicians in Mars Hill that I visited and had to deal with them for orders and such, and at least they saw some value in all of that. They were less hostile, let me put it that way."

Plemmons said, "That did do a lot to at least cool them down a little bit, but it certainly didn't change their attitude toward socialized medicine, which the Hot Springs Health Program was in their minds."

Did they use that term? I asked.

"Oh, my yes! Very definitely."

"Within a period of four months," Jerry said, "we were having an organizing meeting in Marshall—of community people. And it was at that kind of meeting that you [Linda] and I got elected to the board. When they changed the bylaws to include Marshall, then you and I went onto the board together; and we were on the fund-raising, planning committee for the new Marshall facility. The Office of Rural Health provided architectural services. Taylor Barnhill from Jim's staff—that was his entry into Madison County, and he did the architectural work. We had done a business plan, believe it or not, which said we could pay for the building in seven years. This would have been Gail's doing. None of us would have paid any attention to something like that."

"The next thing," added Linda, "was that I organized a door-to-door volunteer fund-raising campaign and got the volunteers to do it so that every single resident in the whole Marshall area was visited by a volunteer and told about the new facility and asked to pledge or donate to it. We raised about $25,000 that way, maybe a third or almost of the total cost."

Jerry remembers that the total renovation of the building, "…so that we could start the down payment of it and so on, was around $80,000. But what we learned early on from that fund-raising was … and we did that in order to have some match for some foundation monies. But we learned that by giving the community an opportunity to donate, they felt a greater sense of ownership and were more likely to use it if they felt it was theirs…. We maintained that philosophy throughout the years.

"But then Liston got us a state grant." Liston Ramsey was from Marshall and represented Madison County in the state legislature. He was, at the time, Chairman of the House Appropriations Committee and, later, for six years, Speaker of the House. He is a political legend, not only in his former district, but statewide.

I would be interested, I told Jerry (who is the consummate storyteller) in hearing how that happened.

"Well, one morning one of the fund-raising committee members ran into Liston down on the street in Marshall. And Liston said, 'I see where you fellas are trying to raise some money for a new clinic.' And he said 'yeah.' And Liston said, 'Well, do you'uns need a little state help?' And he said 'Well, yeah, I guess we could use a little state help, if the state has any money to give us.' And it just so happened that we were having a meeting of that committee that night—at my house. So he invited him to come, and he did come. We talked for maybe 45 minutes or an hour, just general conversation. And he thanked us. And we said, 'Well, do you need a proposal from us?' And he said, 'No, but them people in Raleigh, they like to see them articles of incorporation and bylaws. If you'll send that to me, that should be enough.' And we said, 'What do you think we might get from the state?' And he said, 'I really don't have any idea,' he said, 'Normally, them fellas don't cut me any more than half of my request.' He said, 'If I ask for 40, I might get 20.' So we were operating on the assumption that the state was going to kick in about $20,000. And the articles of incorporation and bylaws were sent to Raleigh. Didn't hear another word from Liston. Didn't see nothing in the paper about the Hot Springs Heath Program getting any money. The legislative session was over. Still nothing. And Liston's pattern then was that every Monday morning, he'd go by the post office at Marshall, pick up his mail, and go to Raleigh. Even when the Legislature wasn't in session, he would be in Raleigh most of the week. And one Monday morning one of the committee members ran into Liston, and he said, 'Well, I guess you fellas heard that we was able to get you fellas a little money.' He said, 'No, hadn't heard that.' Liston said, 'Well, we'll get you a check in a while.' He said, 'It takes the state a little while to write them things, but we'll get 'em to ye.' And so, the next Monday morning, I was in the post office at nine o'clock, when Liston came in for his mail. Liston said, 'Did you hear?' And I said, 'Yeah, Liston, I heard that you'd been successful, but didn't hear how much.' He said, 'Oh, I was pretty fortunate this time.' He said, 'I asked for $80,000 and got all of it.' And so with that our building was completely paid for. We had gotten so excited about that. And we had found out that when we switched from ARC funding to Public Health Service 330 monies, that we were then eligible for bricks and mortar from ARC, and we said, 'That's great. Let's see how we can use some of that money.' So, the original facility at Laurel was a 100-year-old farmhouse that had no insulation in the walls, and we had to put a radio in every exam room so the doctor could turn the radio up while he was interviewing his patient so that the confidential information didn't flow around and feed into the grapevine. And we decided that it was time to replace that facility. So we went to ARC and went to the community, and we got…. We opened the new Laurel facility and the new Hot Springs facility both in 1984. And not only did we get ARC money, but Liston, who by this time was Speaker of the House, helped too. He'd say, 'Well, a lot of people call it pork, and they's welcome to do that, but Madison County don't have any large state university or no large state employers or any state buildings, and if I can bring some state money back to help my people help themselves, then I'm proud to do it.' That was his line, and it was a good one. Because ours was a poor county, the poorest or second poorest in the western part of the state. And for many years it was the poorest in the Appalachian Regional Commission area."

"The new Hot Springs facility, which included a dental program, opened in '84, and then in '86 in Mars Hill, there was the community clinic staffed by three private physicians. There was also a solo practitioner across town. And by '86, one of the physicians in the clinic had moved to Florida to practice, another had died, and the third wanted to retire. And what ended up happening was—he wouldn't sell his facility directly to the Hot Springs Health Program…, so in '86 the Program bought the Mars Hill Medical Center through a convoluted deal with Mars Hill College. He'd given the facility to the College with the understanding that the College would sell it to us. And one of the significant things that happened was that MAHEC (Mountain Area Health Education Center) began graduating family physicians in '79, and we got a person out of their first graduating class—Chipper Jones."

That's before he went off to play baseball?

"Yeah. He only does that in the summer.* But recruiting physicians became easier. We can recruit physicians a hell of a lot easier than we can recruit dentists, that's for sure. And about as easy as we can recruit nurses. When we opened up the Mars Hill facility, that meant that we were the only primary care provider in the county. There were no private practice doctors. And that's still the case. I will say that the first two years we were in the Mars Hill facility, we did rent space to Dr. Whitson, who wasn't fully ready to retire. But that helped, because he retired gracefully, and he was not anti-Hot Springs Health Program."

Linda remembers the first time Jim Bernstein came to Hot Springs. "In the very early days, even before we got the grant from the Appalachian Regional Commission, this would have been in 1972, probably. You brought a whole planeload of folks out from Chapel Hill to Hot Springs, including Cecil Sheps, and I think Jim was on that trip. I know there was someone from Public Health Nursing along, too. This would have been in the first six or seven months I was there."

I remember that trip, I told her. The money from the ARC looked certain by then, and I wanted to see what kind of help might be available from Chapel Hill, which I had more or less assured the people at the ARC would be forthcoming. Jim would no doubt have been along because he was our "fellow" in rural health. So I took him with me everywhere I went—Wise and Clinton, Virginia; Harlan, Kentucky; Logan, Man, and Buffalo Creek, West Virginia, I remember. And to a conference in Davis, California, on rural health that I had helped organize for The Robert Wood Johnson Foundation. (Linda was at that conference, too.) And when I started the Rural Practice Project for The Robert Johnson Foundation—by this time Jim had begun the Office of Rural Health—I insisted that he be on the board. The Foundation officers objected because none of them had heard of him, but they gave in. I told them I needed someone local whom I could rely on for advice and feedback, and I trusted both Jim's experience and candor.

Jerry added to Linda's comment about Jim earliest visit to Hot Springs, speaking about that program's later years: "Every groundbreaking, every dedication, anything of that significance, Jim Bernstein was always there. You didn't have to beg Jim to come. He wanted to be there. He wanted to take part. And he was very generous in his comments at those events. I don't have a lot of stories about Jim that I could tell, other than to say that. But in later years I became amazed thinking back over those times.... I became chair of the Hot Springs Health Program, I think in '79. In those early years, I had gotten to know Jim, but not too well. But I felt comfortable in calling him anytime there was a question or an issue. No matter how elementary or simple it was. Jim would take all the time in the world to talk me through it and give me advice, and if someone else should be involved, he made sure that they were involved too, and were well informed. And I must admit, before I got involved in some other things, that I thought Jim had a really plush job, that all he did was sit down there in Raleigh and wait for me to call him. Because if I called, and he was on the other line or out of town or in a meeting, it didn't matter what, within 30 minutes to an hour, I could expect Jim to return the call. And later on I realized, of course, that he had a fantastic ability to keep a lot of balls in the air at one time. I'm glad I didn't know all of the things Jim was involved in because I wouldn't have called him. And I would have been the lesser for it. But he never made me think that I was taking his time or that he had other things to do. I'm sure that many times he had to rearrange his schedule to come up for our groundbreakings and dedications and things of that nature. But I never knew that. He never indicated that."

Another example, perhaps the best one, of joint programming was with the North Carolina Medical Society Foundation and its first Director, Harvey Estes, who took that position upon his retirement from the Duke University medical faculty in 1989. As Harvey remembers, "I was sitting there with four and a half million bucks in the bank from Kate B. Reynolds and with a mandate to do precisely what Jim had been mandated to do all along. And as I sat around thinking of my task, it became plain as the nose on your face that it made no sense to compete with a program that is already out there and successful. Well, we began to have weekly meetings at the Office of Rural Health, which became, I think, the most productive piece of my program and maybe of Jim's as well, because we began to sit around and think of what we could do together, me with my pot of money, he with his pot of money, to jointly tackle problems that neither of us could solve by ourselves."

Because of the limitations of the two pots?

"Yes, but mainly his. Ours had few limitations. We could spend it for most anything we wished. So we put together an advisory committee, which was a widely divergent group of practitioners and policy makers. It was a good group. And Jim, of course, already had lots of advisors, with the state and the University and the Sheps Center [previously referred to as the UNC Health Services Research Center], that he called on regularly. So we began to work together—not just occasionally, but every day, there would be something that the two of us talked about, a circumstance, some problem, something. And in our working relationship, we quickly became integral to each other.

"But I will say that I have never seen an office of any type that ran with more noses to the grindstone that they're supposed to be getting polished with than Jim's. Everybody on that staff was attuned to what they were doing, not to who's in charge, or the money. The money was important, but that was Jim's job. Their job was to go to Jim and say, 'Jim, I've got to have so many more thousand dollars because we've got to have it to do this thing that needs doing.' And then Jim would scratch his head

---

* For the uninitiated and those who will find this reference confusing, Dr. Chipper Jones, who must have heard and responded to this joking reference hundreds of times (and for which I apologize for my inability to resist repeating it yet again) does not play baseball for the Atlanta Braves.

and worry about where that money was going to come from, whether it came out of this pot or that pot. He knew his sources and he knew—he had this Foundation by then, and he could operate that mechanism. But he played all those things like a well-tuned orchestra. And our piece of money became another major instrument in the orchestra. And that was fine, because what we were really doing was for Bertie County or Hoke County and not for Jim or his Foundation or ours or anybody else. And never once was I under the impression that we were being courted for being a funding source.

"Jim was the most unselfish program leader I have ever worked with. There was nothing that interfered with his interest in the result at the other end. And he believed, vehemently, and he taught me, that you'd never get it to work unless those people are involved in what happens to their own community. And that gets to the fund raising. The amount may be inconsequential in terms of the total that is required, but it is very consequential in terms of getting the loyalty and involvement of people. They have to be involved. And he knew people. This was the thing that was most impressive to me. Here is this guy who sits in Raleigh, and you talk about some county—X County—and he would say, 'Let's go talk to (this guy) because he knows everybody in that county; and he can tell us what the political structure is and who you've got to get involved in order to make it fly.' And we would go to the strangest places. I remember once we flew down to Hatteras Island and landed on the island to talk to one of his old buddies…."

Not the lighthouse keeper?

"No, but it was an amazing experience. And we would go to Troy to meet with one of his old buddies. And we'd talk about his problem over dinner or after dinner. We'd have a cup of coffee, and then we'd drive back to Chapel Hill. Or I would go out with one of his seasoned crew. These were people who lived in the Raleigh area and had as their responsibility a covey of community boards. And they were responsible for the relationship between the Office of Rural Health and that community board. And they would go to the community board meetings, that were always at night. They would travel huge distances and spend the night and go to a board meeting, and meet with the staff, and then they would come home. And we would go with them on these trips, and we would do our business, jointly. Jim would go with us to these meetings. He knew all of these people, and he would meet others. When we came back, Jim's architect would draw up the preliminary drawings. It was a very wonderful and productive relationship, and a happy one. I just had all the admiration in the world for him and his crew and what they were doing. There was not a mean bone in his body, not a bit of selfishness. He just gave all of his effort and time. How his family put up with it I don't know."

So you had a first hand look at the problems of rural medical practice, rural hospitals, that whole scene, I told Harvey. I call it a "first hand look" to contrast it with the kind of look you'd had as an academic leader at Duke—just as important, surely, but different. Plus, you chaired a panel of the National Institute of Medicine on the topic of primary care. But counting all those academic activities, as well as your work with the Foundation and with Jim's Office, you've spent a long time looking at this whole body of problems, enough so that I can ask you as a real expert this question: How have those problems changed? Which ones have been solved or have disappeared?

"I don't think we have solved any of them."

But some have become less important, perhaps?

"Well, they've changed their order of magnitude, but they are still there. We have shifted from one set of problems to another. Manpower is still a major problem, but different than it used to be. Let me refer back to Ed Beddingfield, who quickly immersed himself in a very busy practice in Stantonsburg, doing a lot of OB (obstetrics), doing a lot a primary care, and living upstairs over his clinic. Well, the demand quickly ran away with him. And back then when the practice would overrun a doctor, that doctor would look for a partner, and they would split the work 50/50. I'm on call; you're on call. But that only works if your expectation is that I will work every day, and I will work every other night. Today's crowd is quite different from that. Half of those who aspire to go into primary care are women, or men with young kids, and to them that's not the way it is. You really aspire to work eight hours and to be off 18, or at least 12. Well, primary care does not lend itself to that kind of day for its practitioners. So today it's not the same as it was when Ed Beddingfield was in Stantonsburg, but in some ways it is the same, and we are having difficulty recruiting young men and women into it, because of the demands of the practice and the fact that the practice has to be thought about 24 hours a day. Somebody's got to worry about it. Because people call on the practice 24 hours a day. But the young doctor doesn't want to do that, so you've got to set up some administrative mechanism, some organizational entity, that will take that load, and then you've got to get the clinical load divvied up in eight-hour shifts. So in a way the problem is more complex now, because the demands on the practitioner—or on the practice—are more complex. The practitioner now doesn't have anything to do with business. That's somebody else's job. If the practitioner was handling it all, it would be intolerably complex now. Because he would worry about the business, the schedules, the new partners, who's working where, what the equipment is in that place. If the practitioner were to embrace all that into his activity, he couldn't do it. So we must learn how to do that. Our large medical centers are failing miserably. Because they don't know how to do it.

President Clinton hears about the problems confronting rural hospitals. To Bernstein's left is Montgomery County Hospital Administrator Kerry Hensley.

"Now Jim knew that. His passing is a tremendous loss because people trusted Jim, that he knew what he was talking about. Jim understood the problems I'm relating. But very few others do. Deans think they know. They may think they've got a good primary care service, because it takes care of the poor in their community. But does it take care of the well-to-do in the community? Let's ask that question. Because it doesn't take care of them either; it doesn't answer their basic question, which is 'Who am I going to go to at 12 o'clock at night?' And that's their basic responsibility if they take over primary care.

"Jim did not necessarily come across as a person with great strength. Meeting him the first time, you wouldn't figure that Jim had fiber that was not visible. His staff knew it. And his staff knew that you didn't rile Jim. You got Jim mad and you caught hell. He would lay in to people, read them the riot act. They all understood that it was not a pleasant experience. I never saw it, but they told me. See, I would get in the car with one of his senior staff people, and we would go to some community for two days, drive there and back in the car, and during that time, a lot of things would come up. Or you're there eating dinner and having a beer after dinner, so things come up."

You were one of his senior staff in a sense.

"Exactly."

Going out and doing the legwork?

"Not that Jim was unwilling to go, and he did go if he was needed."

Besides directing the Office of Rural Health, Jim became President of the Foundation for Alternative Health Programs in 1982. It was a non-profit, non-governmental body that could accept grants from private foundations, and its first task was to bring health maintenance organizations and other managed care schemes to North Carolina. In the late 1970s and early 1980s, the overriding concern in North Carolina and around the country was control of healthcare costs, and HMOs were seen as an effective solution. The Foundation was successful in bringing in the Kaiser Health Plan, although after 15 years Kaiser folded it's North Carolina tent and left the state. Later on, the Foundation changed its name to the Foundation for Advanced Health Programs. "Alternative" had, in the interim, taken on an entirely different meaning in terms of healthcare; but the program of the Foundation had also morphed over the years from a focus on managed care programs toward more general issues in medical care. Two of the Foundation's board members are Jerry Plemmons and Don Patterson. I asked Jerry, who has been on the board since sometime in the late 1980s, what the business at hand was when he became a member.

"Access, I think, and Medicaid. But the interesting thing about those meetings was seeing how Jim's mind got around whatever issue came up and thinking about it differently. It was always interesting for me to watch and listen to him, because he was not one to be put off by barriers. He would always see them as a challenge and an opportunity to figure out a different way."

Well, then, I asked him, what was the nature of the interaction between Jim and the board in those meetings? Was he using the board to learn or was he trying to convince the board.

"I think it was an equal kind of thing. It was an open brainstorming time, when an issue would be thrown out and anybody who had any thoughts or ideas or had seen anything similar or had run into anything that might be a problem with it, they would share that, and Jim would absorb it, of course, and then come back at the next meeting and say, 'Now here's what I've done.'

"I remember another thing that Jim got me into in 1993. The Clinton Administration was having a national conference in Little Rock on the Clinton health plan. And the Jackson Hole Group was there. And each state had two representatives. This was focused on rural healthcare. Dr. [Tom] Ricketts from Chapel Hill was there, too."

Jerry, you and Linda seem to agree from your own observations of the Hot Springs Health Program and its history that five years is about the time for a program administrator before burn-out sets in. But I want to remind you that Jim Bernstein was in that position for 30 years. And you, Jerry, made the point about how often he returned your phone calls in 30 or 45 minutes and was at every groundbreaking and so on. I guess my question for you is how do you explain that he didn't burn-out in five or even 15 years?

"I think he was a missionary," said Plemmons. "I think he realized that this was his calling. That's the only way I can explain it. Also, he had developed a heck of a support network. I mean, he knew people everywhere doing everything. And he wasn't at all shy about calling on them. Also, I think that Jim's survival under so many administrations speaks to his professionalism."

Don Patterson, a retired IBM executive and another member of the Foundation board, met Jim after IBM "loaned" him for a year to work for Governor Hunt. During this time he managed personnel administration, which included benefits, and other matters. It was also during Don's year in state government that the legislature started the Foundation, which at the beginning had a board that was appointed by various office-holders, including the Governor. And Governor Hunt appointed Don Patterson to the Foundation board in 1983. Patterson was also a neighbor of the Bernsteins in Chapel Hill, so their relationship became social and personal as well as professional.

"You know," said Patterson, "Jim didn't say a whole lot in those meetings, but when he said something, it was kind of like that old ad you'd see on TV for that stockbroker: When so-and-so spoke, everybody listened. E.F. Hutton, wasn't it? And that's the way Jim was. When he spoke, you knew that what he was saying was the way it would come out; that's what would happen. He didn't want to take a lot of chances. He wanted to make sure that everything was honestly done, and that's why I say he was one of the most ethical persons I ever knew. He did not want to have to report back to one of the foundations that we blew some of their money. It's just marvelous what he's done for this state when you stop and think about it. And not only this state. You go around the country to some of the rural areas … and see how they've patterned themselves after what Jim started here. We'd go to meetings. I remember one time we were down in Boca Raton … the meeting was about rural health, and they knew I was from North Carolina, and I bet you that nearly everybody said, 'Well, do you know Jim Bernstein?' 'Yes, he's here with us, at this meeting.' 'Oh, I've got to meet him,' they'd say. 'I've never seen so much that he's had a part in starting up.' And I'd say, 'Well come on, I'll introduce you.' You'd think they were meeting the President of the United States or something. That's just the kind of guy he was. He wanted to do everything right. He was willing to take chances, but he wasn't the kind of person who would take risks. He wanted to be sure it was right. It was, 'I don't know if this is going to work, and if it doesn't work we've wasted a lot of money that really isn't ours.' You know, we're up to almost $5 million in our budget now. That's what we distribute out through the state programs now, working with Tork Wade and the Office of Rural Health.

"When I think about Jim, the more I worked with him and saw what he was doing, he just had a knack for picking good people. Really good people. He wasn't a very formal guy. You know, he didn't know a lot about their resume or anything, but he could work with them for a little bit and know that they were going to be a good person and a good worker. He has surrounded himself with a lot of good people. Tork Wade is a good example, and Burnie Patterson. A bunch of those folks, are just good people. And another thing: Jim had no ego. As much as he'd done for this state, he could probably have developed an ego, but he just didn't. He'd say, 'It's part of the job. This is what they hired me to do.' And you never heard him brag about anything. But when you looked carefully at what had been done, you saw that he was the leader, he was the catalyst. But it was never an ego thing. That's what I admired about him."

Tork Wade also reflected on the Bernstein style: "As we got bigger Jim became more Raleigh-based, and it changed the amount that he was engaged with the rest of us on a day-to-day basis. And he delegated to either Burnie or myself a lot of the key operations. He'd do his own thing. He'd take a special interest in hospitals or something like that. And while he was doing hospitals, we were doing health centers. I had a special relationship with Jim, personal, too; it wasn't just work; and Burnie did, as well. So during all that time, we'd have a regular interaction every day during the day. And even at the end, after Jim left here to become Assistant Secretary, he and I talked several times every day. And we got together every day. I think that just the way we had worked for 30 years continued. It was fun. He was so engaging, and full of ideas, and enthusiasm, and laughter. It got so that I knew what he was going to say even before he said it. And the same with me. I didn't have to ask Jim how should we start, because I knew what he would say."

Nan Rideout says, "Jim was the one person we always thought would be there. Part of the esprit in the staff was the feeling of family that he was responsible for. We could always count on him being there for our personal problems and our family problems. And as a result, we thought he always would be there. He was always sensitive to his friends and needs of people in his sphere, but he was equally sensitive in terms of values to the disadvantaged. That was his primary focus, and that communicated a lot.

"Jim would talk with all of us on the staff, but in different ways. Once he told me, 'Burnie is the only one I can tell what I really think.' I think he also valued Tork a lot, because he was always steady, calm. And the women, Gail and I, were the ones who argued with him. He didn't like it, but we knew him and loved him and trusted him enough so that we could get away with it. It was successful so we kept doing it. But we always felt tremendous loyalty to him."

What about office intrigue? I asked Tork. As the staff grew, there must have been some tension.

"You know, we were so busy we didn't have time for any office intrigue, worrying about who was getting ahead of the next person. There were a few people who didn't fit in well. If you were someone who needed a lot of direction, you were up the creek. If you were young and you tagged along with someone that would be fine. But if you came in and were expected to carry your own weight and yet expected to get a lot of feedback … Jim wasn't a person who gave feedback very readily. You'd know if he was mad. But if you were doing a great job you'd hear that from someone else. It would be rare for Jim to say anything. And if he did, it was usually because he had another motive. The people that needed a pat on the back would be unhappy."

I asked Glenn Wilson why he thought Jim took the job as Assistant Secretary.

"Well, he thought for several weeks that he wanted to be Secretary. And we talked about that. I called Bill Friday to intervene on his behalf. The interview, according to Jim, went poorly. He answered all the questions directly. He came back and said, 'I blew it.' And he quickly realized that he didn't want the job."

Well, I don't see Jim as a politician, and when you get that high, you're a politician.

"No, and that's what he understood from the interview."

Why do you think he wanted to be Secretary?

"He wanted to fix things. Now Jim's naiveté was part of his charm."

He did, however, become Assistant Secretary.

"The reason Jim took that job, I think," said Tork Wade "is that Carmen [Hooker Odom] is very, very persuasive, and Jim liked Carmen. She convinced Jim to take the job. While Jim loved working with Carmen, assuming responsibility for large chunks of the health bureaucracy wasn't a great fit for what Jim did best. What Jim liked best and what he did better than anyone else I've known, was working with community and health leaders designing and implementing innovative solutions to difficult health issues. As Assistant Secretary for Health, too much of his time was spent dealing with the demands of a large bureaucracy. I think that was one reason that he elected to retire when he did."

But Carmen has had a hard time, with the budget cuts and all.

"And it was good that she was Secretary during that time because she has no problem making hard decisions."

When she had to make cuts, do you think she cut the right things?

"That's where Jim was particularly helpful. Because of the breadth of his knowledge about so many programs, he could help her make the best decisions. I have a lot of respect for the job she did during very difficult times."

Was Jim working harder in that job than when he was here?

"No … Jim always worked hard. But he didn't have the passion. He was doing stuff that we were doing out of here—like Medicaid. He still kept his finger in that, and that was fun. But a lot of it wasn't. You know, maybe I need help getting this job through personnel, that kind of stuff. And he'd help Leah Devlin, or he'd help me and other groups. And then he'd have to go give speeches for Carmen. So he'd have to go talk to a group that he had no idea about and had no interest in. He didn't have any problem relating to them because he could always relate to anyone, but it was something that was painful. I was happy when he retired. Happy for him."

After he retired, when did you notice that he was sick?

"Even before he retired he was complaining of stomach problems. And trouble swallowing."

So he never really had a retirement that was a peaceful one?

"I think he felt alright in the fall, but that was really the last time."

"We're going to miss him," says Don Patterson. "He's done so many things, and I hope we can keep his name on the forefront for a long time. We need to help people remember who he was, because I don't want anybody to forget about him. He was too super a person—a great asset to this state—and a great friend, to tell the truth."

You put your finger on something right then, Don. Because in addition to what Jim did in his work and how he worked and chose his staff and the other things you've been talking about, one of his outstanding attributes was as a friend. And we mustn't say that lightly. He would be as concerned about your personal life. And it wasn't like a good boss asking, "How's your family?" It went way beyond that. I've never, ever seen anything like it.

"Well, that's right. My first wife died in '79. She had a brain tumor. And then my present wife had ovarian cancer in '98. And Jim called me about every other day, wanted to know how things were going. Said, "What can I do for you?" I mean he was very concerned all the time. That's just the kind of person he was, concerned for other people, never put himself ahead of anybody. He was a true friend, the kind you needed. And he's raised a beautiful family. Those kids are super kids. And when he decided, look, I'm going to die and there is nothing they can do for me—I think his mother went through a lot with cancer. Anyway, I asked him, 'Jim, are you going to do any more treatment?' And he said, 'No, the kids are going to come home every other weekend to see me.' Because he would rather have a good quality of life with them. And except for his physical limitations because of his disease, I'd say he had a pretty good quality of life up until the day he died, almost.

"And at our board meetings I sometimes catch myself saying 'Now wait a minute, how would Jim solve this one.' Because I had so much respect for his ability to lead the Foundation and do the right things, and I feel obligated to keep doing it the way he would do it. That's out of respect for him and our friendship." **NCMedJ**

ISSUE BRIEF

State and Local Partnerships for Meeting the Healthcare Needs of Small and Often Remote Rural Communities

Thomas C. Ricketts III, MPH, PhD

American healthcare has been described as a "non-system," but there have been persistent efforts to coordinate and rationalize how we provide medical care in the United States. These efforts have resulted in what may be called informal systems of care. A perfect example of one of those systems is in North Carolina, a system created for the people of the state's smaller and poorer communities, communities that are most often rural and more often inhabited by racial and ethnic minority citizens.

Almost all of North Carolina could have been called rural at the end of World War II. The 1940 Census classified 72.7% of the state's population as rural or living in communities with fewer than 2,500 residents. A few cities—Charlotte, Durham, Greensboro, Asheville, Raleigh—had modestly large populations, but no city in the state had a population greater than 110,000. The state's economy was strongly linked to agriculture, and the prevailing perception of North Carolina was of a sleepy, rural, somewhat backward state.

World War II created an economic stimulus for the state when military installations were located in North Carolina—shipyards were established in Wilmington to build liberty ships, and facilities were developed to house prisoners of war in the central and the mountain regions of the state. But the war left another legacy beyond economic benefit: the state had experienced the highest medical rejection rate for its draftees of any state in the Union. The causes for rejection were usually chronic problems related to nutrition and poor or unavailable basic medical care and health advice. This embarrassing fact is often cited as the driver of the statewide "Good Health Campaign" promoted in 1949 by prominent North Carolinians, including Kay Kyser, who recruited radio personalities and Hollywood stars to help raise money and direct attention to the healthcare needs of the state. That public effort had a significant impact, but it built on prior efforts to expand health resources. For years, politicians had been debating whether to assist one or both of the private medical schools in the state (Duke University and Bowman Gray) or whether to create a large medical center by expanding the two-year medical school at the state university in Chapel Hill. Governor Melville Broughton appointed a Medical Care Commission in 1944 to study the health and medical needs of the state. That commission recommended the creation of a new, state-supported, four-year medical school in Chapel Hill that would share space with the existing School of Public Health and occupy space adjacent to a new, comprehensive teaching hospital. After years of consideration, the General Assembly supplied construction funds that were combined with money from the Hospital Planning and Construction Act of 1947, the Hill-Burton Act, to build Memorial Hospital in Chapel Hill and to create the teaching hospital. The Hill-Burton program also supported the construction of many North Carolina hospitals and public health facilities in rural communities.

As late as the 1950s, healthcare services in rural North Carolina were considered inadequate. An unflattering review of the quality of general practice in the state was published in the *Journal of Medical Education* in 1956.[1] However, there were examples of excellent medical care in some communities and effective public health structures had long existed in others. The nation's first local health department was established in Guilford County in 1911. Robeson County set up the first professionally managed rural health department in 1912 when county commissioners appointed a full-time county health director charged with the task of creating an administrative unit of county government to ensure the health of the county's citizens. The state's growing appropriations to the state Board of Health soon allowed other counties to organize their own essentially independent public health units.

Walter Hines Page and the Country Life Commission, a national organization committed to "uplift rural folk," helped to bring the problem of hookworm disease in North Carolina and the rural south to the attention of the Rockefeller Sanitary Commission for the Eradication of Hookworm Disease, which in

Sheps Center for Health Services Research and Professor of Health Policy and Administration in the School of Public Health at the University of North Carolina at Chapel Hill. He is also an Associate Editor of the *North Carolina Medical Journal*. He can be reached at ricketts@schsr.unc.edu or CB# 7590, UNC-Chapel Hill, NC 27599-7590. Telephone: 919-966-7120.

1909, began taking steps to eliminate this debilitating infection as one step toward improving the economy of the south. Because state officials considered the direct involvement of the Rockefeller group to be too intrusive on a population distrustful of wealthy northerners, the state Board of Health set up a cooperative Bureau for Hookworm Control to sponsor the campaign in North Carolina. The combined efforts eliminated the hookworm scourge and, in the process, created a lasting focus on public health at the county level. Rutherford County physician, Dr. Benjamin Washburn, who had worked in Wilson County during the hookworm campaign, began forming additional county departments modeled on the Wilson experiment.

A Division of Public Health in the two-year University of North Carolina (UNC) Medical School was created in 1936 with funds from Title VI of the Social Security Act. That Division, under the leadership of Milton Rosenau, continued the tradition of community-based programs and projects, and that orientation became part of the tradition of the independent school of public health that emerged in 1940. This commitment set the tone for the next generation of public health and rural health leaders, both academic- and practice-based, who assumed their positions in the 1940s, 1950s, and 1960s and who viewed the role and mission of state institutions as one of service outside their walls.

Milton Rosenau died unexpectedly in April 1946, soon after being elected President of the American Public Health Association. The University's President Frank Porter Graham, who was largely responsible for the service orientation of the University, followed the recommendation of the School of Public Health's acting directors and named Edward McGavran to become the new dean in April 1947. McGavran—a graduate of Harvard Medical School, a former county health director, director of a Kellogg Foundation public health training program, and a professor of Preventive Medicine at the University of Kansas—firmly fit the mold of the "outsiders" who came to North Carolina to encourage creativity in healthcare delivery and public health.

An addition to the School of Public Health faculty ensured a focus on rural and community-based health services in the state. In 1947, Cecil G. Sheps joined the faculty as an associate professor of public health administration. Sheps, a native of Winnipeg, Canada, and his wife Mindel, a professor of biostatistics, had been involved in the development of the Saskatchewan health insurance system that became the model for the universal, province-based system of healthcare financing in Canada. In a 1953 report to the Medical Society of North Carolina, Sheps maintained that a key ingredient in solving the state's healthcare delivery problems rested on "the development of a program of an extension of services from the University Health System to the state at large … in concert with other similar institutions of the state so far as medical and nursing schools are concerned." That commitment was later to result in discussions that created the Area Health Education Centers (AHEC) concept.

Building AHEC: Bringing Clinical Training to the Community

In 1965, Dr. Reece Berryhill, former dean of the UNC School of Medicine, became director of the new Division of Education and Research in Community Medical Care, created jointly by the UNC Schools of Medicine and Public Health to work in local communities that were forming working relationships with private practitioners. Dr. Berryhill was succeeded in 1967 by Robert Smith, MD, a general practice physician formerly of Guys Hospital in London. In 1967, the Division began an affiliation with Moses Cone Hospital in Greensboro, with financial support from Moses Cone Hospital, to give physicians from UNC-Chapel Hill another local practice option as part of their training in internal medicine and pediatrics. Later, through the Health Councils of Eastern Appalachia, the Division received a grant from the North Carolina Regional Medical Program in 1968 to support additional community-based training and to send clinical specialists to smaller hospitals for teaching and consultation assistance. In 1969, Glenn Wilson, the Vice President of Kaiser Cleveland Health Foundation, was recruited to UNC-Chapel Hill as Associate Dean for Community Health Sciences and as the new Director of the Division of Education and Research in Community Medical Care.

The North Carolina General Assembly appropriated $395,000 for a community-based training program for physicians at UNC in 1969 and again in 1971. These funds were used to support fourth-year medical school clerkships in affiliated community hospitals in Wilmington, Charlotte, Raleigh, Rocky Mount, and Tarboro.

The Carnegie Commission on Higher Education, with University of North Carolina President William Friday as a member, issued its report *Higher Education and the Nation's Health* in 1970. This report called for medical schools to devote more of their clinical training time to community settings using a new kind of entity, the Area Health Education Center. The United States Congress responded by authorizing the development of a limited number of community-based health professional educational partnerships under the Comprehensive Health Manpower Training Act of 1971 (P.L. 92-157). That legislation, which surprisingly did not include the term "Area Health Education Center," but used this term only in the conference report that followed enactment, made available federal funds for demonstration projects that would link academic health centers and community-based hospitals in networks focused on the training of multiple health professions as well as the stimulation of professional continuing education of those already in practice. As this new legislation was enacted, Glenn Wilson at the UNC School of Medicine assembled an interdisciplinary team to begin aggressive efforts to work out affiliation agreements with several additional hospitals and medical centers throughout the state for the purpose of applying to be designated as one of the first federally funded Area Health Education Centers Programs. The initial grant to the UNC School of Medicine to develop the AHEC Program in North Carolina was more than $8 million. The North Carolina AHEC Program would eventually involve collaborative relationships with the four schools of medicine (UNC-Chapel Hill, Duke University, Bowman Gray School of Medicine of Wake Forest University,* and East Carolina University's Brody School of Medicine).

A key element of the AHEC structure was the creation of regional centers that were closer to rural communities throughout the state. There was one completely rural AHEC, termed "Area L AHEC" after the multipurpose regional planning designation for the counties surrounding Rocky Mount and Tarboro. The decision to encourage distributed medical education recognized the state's demographics and gave the medical schools incentives to work with essentially rural hospitals. That initial AHEC focus on rural communities set a pattern for later development and orientation and closely followed the traditions of the University and the state's politics.

For the 1974/1976 biennium, the North Carolina General Assembly appropriated $23,500,000 for capital costs to build regional AHEC centers, $4,548,720 for operating expenses, $1,125,000 for residency grants, and $250,000 for Community Practitioner Stipends. The General Assembly also set targets for training in the AHECs, committing the program to develop 300 new primary care residency positions by 1980. Simultaneous with the establishment of the AHEC program, the state also began funding family medicine training programs. UNC established its Family Medicine Department in 1969 with Dr. Robert Smith as its first chairman, and the Bowman Gray School of Medicine in Winston-Salem opened its department in 1974. Duke University Medical Center added a division of family practice to its Department of Community Medicine in 1972. The General Assembly has continued its support of these programs with direct appropriations and capitated student and resident support.

By 1975, the federal AHEC program had funded programs in 11 states, including North Carolina, where the concept had already received legislative, professional, and public acceptance. There is general consensus that the North Carolina Area Health Education Centers Program was, at its inception, and remains today, the model for the nation, and that is due to the willingness of many partners to cooperate in its development and operations.

North Carolina's Health Services Research Center

Another key element of the rural policy structure fell into place with the founding of the Health Services Research Center at the University of North Carolina at Chapel Hill in 1968. The goal of the proposed center was to help develop more effective ways to "deliver personal health services in community settings" by exploring "new roles for professionals" and productive means to change organizational features of healthcare practice.[2] The Health Services Research Center fit snugly into the rural health policy network because the community-based system it intended to examine was largely devoted to increasing access for rural residents. As sites for its study of experimental comprehensive health centers, the Research Center selected the rural parts of Orange County and all of Caswell County, a 100% rural county. These areas formed the service area for a United States Office of Economic Opportunity (OEO) Neighborhood Health Center that used nurse practitioners. The Research Center soon worked out cooperative research and technical assistance agreements with other clinics being established in Walstonburg, Tarboro, and Hot Springs—all of which were located in very rural sites in the eastern and western parts of the state.

In 1970, three young United States Public Health Service (USPHS) officers (James Bernstein, Ted Parrish, and Michael Samuels) were selected as fellows in the USPHS Program in Global Community Health and were given the opportunity to enroll in graduate programs in the UNC School of Public Health. Each of these young Public Health Service scholars focused their work on problems related to rural primary care and the supply of rural healthcare professionals. All three men were full-time employees of the United States Public Health Service. All three men meshed well with the activities accompanying the development of the Health Services Research Center, with Samuels concentrating on problems of professional recruitment, Parrish on community-based health education, and Bernstein on the appropriate community structure for viable rural health services. Samuels graduated in 1975 and went on to a career in the Public Health Service, during which he served as deputy administrator of the National Health Services Corps and the Health Services and Resources Administration and as deputy to the United States Surgeon General. He later held faculty positions at the Universities of South Carolina and Kentucky. Parrish became active in local North Carolina health program development and is Chair of the Department of Health Education at North Carolina Central University.

James Bernstein took advantage of the commitment to rural communities, which was the focus of the UNC-Chapel Hill Health Services Research Center, where he was mentored by Cecil G. Sheps, the Center's director, and Glenn Wilson, the Associate Dean of the UNC School of Medicine. When James Holshouser became the first Republican governor of North Carolina in the 20th century, he began exploring ways in which he could bring the influence of the governor's office to bear on the extreme shortages of primary medical care in North Carolina's rural communities. He asked Dr. Cecil Sheps, then the acting vice chancellor for health affairs at UNC as well as the director of the Health Services Research Center, to discuss this matter with his colleagues and propose some concrete ways in which the state might address these problems during his four-year term of office. Sheps suggested to the new governor the idea of community-based primary care clinics staffed by advanced practice nurses specially trained to meet the everyday medical care needs of residents, who would be backed up in

---

* The Bowman Gray School of Medicine is now the Wake Forest University School of Medicine.

their clinical work by local physicians. The governor asked Sheps to elaborate on this idea and present a detailed proposal for how such an initiative might be taken. Dr. Sheps turned to Jim Bernstein to develop the formal proposal document. Once the governor studied the proposal, he concluded that it outlined a viable program, and he gave it his full support. He translated that support into an executive order that became part of his legislative agenda. Subsequently, the proposal drew wide support from politicians of both parties, including the Democratic lieutenant governor, James B. Hunt. Convinced that such a program would greatly benefit the state, the General Assembly created the Office of Rural Health with an appropriation of $456,000 in 1973.

North Carolina Office of Rural Health

A key element in the early success of the Office of Rural Health and its clinics was the support of the North Carolina Medical Society for the use of nurse practitioners. Two prominent physicians, Drs. Glen Pickard (of Chapel Hill) and Edward Beddingfield (of Wilson), convinced the Society to support a nurse practitioner practice act acceptable to the physician community. That support helped build the legal structure that allowed advanced practice nurses (called family nurse practitioners) to be trained, first at UNC-Chapel Hill and later at other institutions, and the new clinics to open. Even with this broad backing, gaining acceptance of the Office within state government remained a struggle.

Professionals in the Department of Human Resources, recently created during a general government reorganization to include the traditional public health functions as well as new and old programs related to health services, did not believe the Office would survive beyond the Holshouser Administration. After its initial placement in the Governer's Office, the legislature placed the Office of Rural Health within the Division of Facility Services, an agency previously responsible for administering the Hill-Burton Program and licensing hospitals. However, Governor Holshouser firmly insisted that the Office was attached to the Division only for administrative purposes and that any policy decisions were to involve consultation with the Governor's office. Prior to passage of the authorizing legislation and subsequent appropriations, the governor and the principal proponents of the program struck an agreement expressly delineating the direct route of accountability to the governor—a surprising agreement since it bucked the current trend toward greater consolidation of government into cabinet departments. This element of policy independence from other agencies in government, consequently, provided the key to the success of the Office and has remained one of its defining characteristics to the present.

The appropriation for the Office of Rural Health almost tripled in its second year to $1,200,000 and jumped to $1,611,000 in the third year. Funding grew much more slowly afterward as the Office gained recognition as a focused programmatic agency with a bounded set of goals. The Office established strong political stability in large part because Governor Hunt, elected to succeed Governor Holshouser, became a strong supporter of the Office and its concepts and because the Office carefully avoided using its policy independence to compete for resources directed to other agencies. The Office continued its independent role during a reorganization of health agencies under the administration of Hunt's Republican successor, Governor James Martin, during which time it was briefly aligned with the state's health planning functions. It became the Office of Rural Health and Resource Development, placed administratively within the Department of Human Resources, after Jim Hunt was elected for an historically unprecedented third four-year term in 1992. The reorganization that resulted in the Department of Health and Human Services (DHHS), under H. David Bruton, who served as Secretary of the newly named Department. At that time, the Office was renamed the Office of Research, Demonstrations, and Rural Health Development (ORDRHD, more often called the Office of Rural Health), to emphasize its role in fostering innovative approaches to healthcare delivery and financing. In 2000, when Michael Easley was elected Governor, he appointed Carmen Hooker Odom as DHHS Secretary, and she brought Bernstein into the position of Assistant Secretary for Health. Following Bernstein's retirement from state government in the fall of 2004, Torlen Wade became Director of the Office, and it retains a key place in the structure of the Department.

The accomplishments of the Office include the development of more than 80 rural health clinics; the placement and support of more than 2,500 physicians, nurse practitioners, physician assistants, and dentists; and the creation of the Community Care of North Carolina (CCNC, formerly Access II-III) networks that provide capitated care management for Medicaid eligibles. The office also supports a Migrant Health Program that awards small grants yearly on a competitive basis to local health departments and non-profit agencies for primary care services to farmworkers in high-need areas. This work is coordinated with the North Carolina Association of Community Health Centers, which operates an active regional technical assistance system for the Mid-Atlantic Region, as well as supporting the migrant health centers in the state

The Office of Rural Health may serve as the focus of policy relating to rural health issues, but it does not exercise formal administrative responsibility for oversight or even coordination of programs in other state agencies that serve rural communities or affect rural healthcare delivery. Instead, in part through support from private foundations, combined with the ability to create special programs from time-limited special appropriations, the Office serves as a resource and brokering agency that stimulates coordination among program directors and exerts its capacity to add value to programs and projects with funding flexibility. Consequently, few programs or initiatives in primary or community-based healthcare delivery fail to receive some input from the Office, as much because of its experience in working with almost every aspect of the delivery system as for its policy role and its close political ties to the General Assembly and the Governor's Office.

The North Carolina Foundation for Advanced Health Programs

The North Carolina Foundation for Advanced Health Programs, Inc., (NCFAHP) is a statewide non-profit organization charged with the mission of increasing the availability and affordability of healthcare for North Carolina residents. The Foundation, established in 1982 on the recommendation of a special legislative commission studying the issue of healthcare costs in the state, serves as a catalyst for programs that improve the quality of and access to healthcare while controlling costs. It works with business, medical, and civic leaders throughout North Carolina to explore solutions to healthcare problems and to develop specific approaches that meet community needs.

In the early 1980s, the first major initiative by the Foundation helped to expand the quality and number of competing alternative health plans available to North Carolina residents in a program to improve the healthcare marketplace. As part of that effort, the Foundation worked to bring health maintenance organizations (HMOs) to North Carolina for the first time. The Foundation was also instrumental in establishing Preferred Provider Organizations (PPOs) in the state and has encouraged the formation of locally-formed alternative health plans.

Through the hospital-based Rural Health Project, funded by the Robert Wood Johnson Foundation from 1986-1992, the Foundation helped to organize three hospital alliances, which assisted small rural hospitals in developing more cost-effective methods of maintaining and expanding appropriate medical services. The primary objectives of this program were to improve the financial stability of participating hospitals through the development of programs to improve market share, to enhance reimbursement options, and to increase the quality of, access to, and cost-efficiency of health services for rural residents. As an outgrowth of this project, the Foundation has also developed a model to assist small rural hospitals in their transition from acute care medical centers to primary care and specialty care providers. Our Community Hospital in Scotland Neck converted its 20-bed acute care unit into a 100-bed medical services center offering nursing home care and specialty care for senior citizens as well as emergency care and augmented primary care services for the general population.

The Foundation developed a program to improve the care of Medicaid recipients starting in 1986 with a single county demonstration program, the Wilson County Health Plan. That effort, jointly supported by the Kate B. Reynolds Charitable Trust promoted the concept of a "medical home" for Medicaid recipients in this largely rural county. From that demonstration, the Carolina ACCESS program evolved. This was a collaboration with the North Carolina Division of Medical Assistance to implement a federal waiver to demonstrate regionally the effectiveness of the "medical home" concept using a care manager supported with a per-enrollee fee. The program was successfully implemented in 12 counties with the Foundation providing leadership and management. With the approval of the General Assembly, the program was transferred to the Division of Medical Assistance and implemented on a statewide basis and now operates in 99 counties as Community Care of North Carolina (CCNC).

The Foundation also supports and manages projects intended to improve care for the uninsured poor, including a community-based primary care program that has provided the impetus for the development of new start-up community health centers in Wilmington, Kinston, and Wilson County. The Foundation also coordinated the "Covering Kids" demonstration to increase enrollment of children in Health Check/North Carolina Health Choice. Other projects included efforts to improve the management of health services, for example, supporting the implementation of the Baby Love program in 22 primary care centers to improve prenatal care; support of pharmacy access projects, including the 340-B program in the state; and developing networks among rural hospitals to assist in compliance with quality standards.

The NCFAHP is also the recipient of other grants to supplement the work of the Community Care of North Carolina program in its primary care management systems in rural parts of the state. The NCFAHP is the coordinator for one of five national demonstrations to improve the care of the elderly by improving working conditions for caregivers in the Better Jobs Better Care Program sponsored by the Robert Wood Johnson Foundation. The Foundation also managed the National Program Office for the Practice Sights program. That work supported the development of model recruitment and retention systems in other states using the successful methods and approaches of the North Carolina Office of Rural Health.

The East Carolina University Medical School

An important addition to the rural healthcare delivery structure in the state was the East Carolina University's Brody School of Medicine, in Greenville, North Carolina. Predominately rural, with an economy based on tobacco-dominated agriculture, eastern North Carolina has long projected an image as the state's poorest region and has lagged behind the rest of the state in industrial development. National commissions studying methods to expand the supply of physicians had identified North Carolina as a potential candidate for a new medical school. Politicians appreciated an opportunity to develop a stable economic engine for the east as well as to raise the prestige of the regional state university. However, the decision to create the medical school was a contentious one.

The battle to develop the East Carolina School of Medicine began in 1964 when Dr. Ernest Furguson, a general practitioner from Plymouth, North Carolina, and East Carolina College president Dr. Leo Jenkins agreed that East Carolina College (ECC), as it was then known, should build a medical school. Dr. Jenkins asked local physician Dr. Ed Monroe and ECC Professor Robert Williams to conduct a needs assessment, following which, Jenkins began an arduous campaign to locate a medical school on his campus.

The initial proposal from the needs assessment called for the creation of a two-year medical school that would send students to the UNC School of Medicine for the remainder of their education, an idea strongly opposed by the three other Schools of Medicine. Jenkins then went to the North Carolina General Assembly, which authorized and appropriated funds in 1965 to plan a two-year medical school at ECC if accreditation could be obtained, ignoring a recommendation from a panel of consultants who preferred to expand the existing ECC allied health programs. When ECC requested, in 1967, that the General Assembly grant it independent status as East Carolina University (ECU), the legislature rejected that proposal and instead made it one of the constituent universities of the consolidated University of North Carolina system, but it also authorized the creation of a Health Sciences Institute at ECU (which became the School of Allied Health and Social Professions.)

The need for more physicians in the state at that time was evident in statistics. North Carolina ranked 43rd of the 50 states in the ratio of physicians to population and 46th in the ratio of medical students to population. Mortality figures identified the state as one of the least healthy regions in the nation. In 1969, a Committee on Physician Shortage in Rural North Carolina appointed by the Legislative Research Commission acknowledged the need for better access to medical care and as a solution, recommended the expansion of the UNC School of Medicine from 75 to 200 graduates a year and the provision of subsidies to Duke University School of Medicine and the Wake Forest University School of Medicine to train North Carolina residents.

Popular support for a medical school at ECU continued, however, and in 1970, the General Assembly appropriated funds to develop a two-year medical curriculum at ECU, which then admitted 20 students to a one-year program.

Leaders in North Carolina's other three medical schools had heavily invested in training specialists, and they argued that if a crisis in access to primary care existed in North Carolina, it could best be addressed by training physician assistants and nurse practitioners. They also claimed that the problem was not a deficiency of medical students, but the lack of capacity for residency training.

In 1972, the UNC Board of Governors appointed a five-member committee headed by Lt. Governor Robert Jordan to advise it on health manpower needs. The committee subsequently recommended paying the Duke University and Wake Forest University Schools of Medicine a per-student stipend to train North Carolina medical students ($5,000 in 1975; $6,000 in 1976), continuing to enroll 20 degree candidates in the one-year ECU program, and commissioning a team of national consultants for a feasibility study.

The most significant body to study the issue of manpower and the possible need for a second, publicly-supported medical school was the so-called "Bennett Commission," which rendered its report in September 1973. That report indicated that the proposal to build a four-year school of medicine in Greenville was "premature" and that the only hope of success was to expand the school of medicine at Chapel Hill. The North Carolina General Assembly, in the end, did not accept the key recommendation of this report and appropriated funds for the development of what is now the Brody School of Medicine at ECU.

The 1974 General Assembly appropriated funds to expand the ECU school, adding a second year emphasizing family medicine and encouraging the recruitment of minorities. In November 1974, President William Friday proposed to the UNC Board of Governors that the ECU School of Medicine become a full, four-year medical school, and the 1975 General Assembly appropriated funds to make his proposal a reality. Enrolling its first class as four-year medical school in 1977, the school set as its central task the training of primary care doctors for rural and eastern areas of the state, with the intention of alleviating apparent shortages of physicians. The school was renamed the Brody School of Medicine in 1999 in recognition of the Brody family, prominent in business in the eastern part of the state.

The ECU Brody School of Medicine has been active in the training of primary care physicians with the support of the Robert Wood Johnson Foundation's Generalist Physician Initiative, the development of rural community-based residency sites, and participation in the Rural Scholars Program, where medical students from ECU and UNC receive focused clinical skills training in rural settings.

The North Carolina Student Rural Health Coalition

The North Carolina Student Rural Health Coalition emerged as an outgrowth of the success of the Tennessee Student Health Coalition that began at Vanderbilt University in 1969 and developed into a family of effective student activist organizations, which included the Appalachian Student Health Coalition and the West Tennessee Student Health Coalition. While he was a fourth-year medical student at Vanderbilt, Grady Stumbo, directed a related, but more professionally-oriented project sponsored by the Student American Medical Association (SAMA) to assist Appalachian communities. Those projects were the result of a general sense of dissatisfaction among medical students with the relationship between organized medicine and formal medical education and the needs of communities. The contrast between the theoretical component of a medical education at Vanderbilt or the University of Tennessee and the reality of the lives led by Appalachian residents in the late 1960s was too stark to be overlooked by concerned students in a period when social activism was the prevailing ethic. Richard Couto describes the origins and development of those Tennessee projects in *Streams of Idealism*,[3] a title drawn from commentary by Robert Coles,[4] who also figured in the development of social activism among healthcare professionals at the University of North Carolina and Duke University and who remains active in both universities working with medical students and faculty. Donald Madison, a medical school faculty physician at UNC-Chapel Hill and one of the staff recruited by Cecil Sheps to begin the UNC-Chapel Hill Health Services Research Center (now named for Sheps) played a substantial role in the development of the North Carolina Rural Health Center movement. Not only did he take a lead role in writing the proposal to fund the Lincoln Community Health Center in Durham and Durham County, but he played an active role with the development of the Hot

Springs Health Center in rural Madison County in the North Carolina mountains. In the mid-1970s, Madison was asked by the Robert Wood Johnson Foundation to lead the Rural Practice Project, a national program in which multi-disciplinary teams of healthcare professionals and administrative personnel were assembled to begin primary care clinical practices in communities having severe access to care problems in several states.[5,6]

In the early 1980s, students from a mix of health sciences schools organized the North Carolina Student Rural Health Coalition in the Durham-Chapel Hill area, with activity centered at Duke University and UNC-Chapel Hill. The Coalition subsequently sponsored health fairs in rural communities, helped place students and professionals in underserved towns and villages, supported public health awareness in rural communities, and agitated for more attentiveness to the rural healthcare and community development needs of rural North Carolina. Eventually, students from the ECU Brody School of Medicine and North Carolina Central University combined to create the current structure of the coalition, which also includes students from the UNC-Chapel Hill School of Public Health and the UNC-Chapel Hill and Duke University Schools of Nursing.

Students have been active in creating or supporting so-called “People’s Clinics.” Medical students from ECU, UNC, and Duke University and nursing students from North Carolina Central University offer free medical check-ups and other medical services in five community-managed clinics in eastern North Carolina: Fremont in Wayne County; Shiloh in Wake County; Garysburg in Northampton County; Bloomer Hill, which straddles the Nash-Edgecombe county lines; and Tillery in Halifax County. All five clinics are in rural, deprived, predominately minority communities, with few, if any, medical care resources, very high infant mortality rates, and severe economic problems.

Community Practitioner Program

The North Carolina Medical Society Foundation developed the Community Practitioner Program in 1989 with initial support coming from the Kate B. Reynolds Charitable Trust in the form of a $4.5 million grant. The program functions as a coordinating center for the recruitment and support of physicians, physician assistants, and family nurse practitioners who provide primary care in underserved areas in North Carolina. The funds go for loan repayment as well as for practice development. Practitioners receive support in return for five years of service in a qualified community, and they also agree to accept Medicaid and Medicare patients. To date, the Community Practitioner Program (CPP) has assisted 336 primary care physicians, physician assistants, and family nurse practitioners in 126 communities located in 76 economically distressed or medically underserved counties. In 2005, more than 400,000 patients were seen by CPP providers. Of the practitioners who were with the program for the five-year service period, 64% remain in the target communities; 73% continue to practice in rural or economically distressed counties, and 85% remain in North Carolina. In 2006, the program will add a management support capacity, Project Sustain, to continue to assist the community-based practices.

The program has been able to leverage the original Kate B. Reynolds funds to a total of $12 million over the 15-year period. That investment has allowed CCP-supported practitioners to provide approximately $225 million in care to uninsured patients. The CPP is the only non-governmental program of its kind in the nation and other states and medical societies have looked to it as a model for their own efforts.

The North Carolina Hospital Association

The North Carolina Hospital Association created the North Carolina Rural Center in 1996 to help its rural member hospitals cope with the special pressures they face. Initial support from the Center came from the Association’s membership and a grant from the Kate B. Reynolds Charitable Trust. Under the leadership of Jeff Spade, the Center musters the resources of current Association members, private consultants, state government agencies, and university faculty to provide support and advice to rural hospitals and communities. Its initial work focused on the support of networks to bring resources to rural communities through links between larger hospitals and smaller rural hospitals. The Rural Center sponsors an annual small and rural hospitals conference that brings together individuals from all sectors of healthcare and community development. The support goes beyond networking to practical technical assistance in quality assurance and information technology, two areas that are at the forefront of the Center’s agenda for the 21st century.

The Duke Endowment

One of the largest private foundations in the United States, with $2.5 billion in assets at the close of 2004, The Duke Endowment devotes part of its primary focus to the support of hospitals and healthcare in North and South Carolina. It provided over $39 million in health grants in 2004 and supported almost every rural hospital in North Carolina with funds to cover indigent care and special projects, including grants to renovate the obstetrics department in Ashe County in the rural mountains and to develop an injury prevention center in Kinston in eastern North Carolina. In recent grants, The Endowment has emphasized children’s health, with multiple grants to support school-based services. In 2005, its grants were focused on developing access to care for indigent populations with an emphasis on prevention. The Endowment looks to foster cooperation among agencies and organizations to leverage funds for greater impact. For example, specific to rural health, The Endowment, provided core funding for a family practice residency program in Hendersonville, North Carolina. This project involved the joint efforts of the Central and Mountain AHECs, the North Carolina Medical Society, the state’s four medical schools, other tertiary care hospitals in the region, and the North Carolina Hospital Association. The Endowment is targeting Health Information Technology in its 2006 health program along with its traditional focus on access to care. For rural North Carolina, the Endowment supports projects in economic and social development through its "Program for the Rural Carolinas" that recognizes healthcare as an integral part of rural communities.

The Kate B. Reynolds Charitable Trust

The Kate B. Reynolds Charitable Trust was created in 1947 by the will of Mrs. William Neal Reynolds of Winston-Salem and is one of the largest foundations in North Carolina, with assets of more than $500 million. Three-fourths of the Trust's grants are designated for health-related programs and services across North Carolina, and this amounted to $18.2 million in grants in 2004. Many grants have helped support healthcare innovation and service delivery in rural North Carolina as the Trust sought to achieve its primary goal of increasing the availability of health services to underserved groups. The Trust has an explicit emphasis on funding rural areas. A sample of recent grants illustrates this: funds to the Bertie County Rural Health Association and the Tyrell County Rural Health Association for capital projects to support access-oriented facilities; to Blue Ridge Hospital Systems to help improve access in a rural mountain area; to the Pender County Health Department to expand dental hygiene services for low-income children. The Trust works with other funders and agencies to coordinate its work to enhance the impact of its giving; this is facilitated by the participation on its advisory board of leaders in the North Carolina AHEC, the North Carolina Medical Society, North Carolina Hospital Association, and regional civic leaders from across the State.

Bringing It All Together

This brief review has only touched on some of the more prominent of the many people and programs that have helped the people of rural North Carolina receive the healthcare they need. The number and range of programs described here points to a single characteristic of the North Carolina approach to improving rural health: leaders in North Carolina healthcare and public policy have recognized that no one agency, organization or institution could really improve access to care alone—all of the fundamental elements of healthcare delivery had to be involved to truly have an impact. However, to make that happen, there needed to be some focus, some entity that, though it did not "command and control," helped various groups convene and collaborate. That entity was the Office of Research, Demonstrations, and Rural Health Development which, in turn, was supported by a network of connections and relationships that spanned government, the professions, and the institutions involved in healthcare delivery and finance.

The momentum for change was in place before the Office was founded—there were proposals for networks and changes in professional roles when the Office opened. But to make those things work in communities with the effective support of agencies and institutions required some central organization to work out the details at the local level, negotiate with the powers that affected all aspects of healthcare delivery, and, in the end, allow the credit for the small and large victories to be shared. This comprehensive approach was not so much a formal process of consensus, but rather a shared recognition that all stakeholders were invited to join in the work and that these efforts ought to focus at the community level. While large bureaucracies and interest groups might be able to stand apart at the state level, it is in the local community that the dangers and negative effects of isolation and and separation are readily seen. **NCMedJ**

ISSUE BRIEF

Building Local and State Partnerships in North Carolina:
Lessons Learned

Torlen L. Wade, MSPH, Andrea D. Radford, DrPH, MHA, and John W. Price, MPA

The first state office of rural health was established in 1973 in North Carolina, and over the years, it has evolved into one of the largest of such offices in the nation. Along the way, many lessons have been learned from both successes and failures in the Office's efforts to build local and state partnerships to meet the health needs of rural and underserved communities. This article touches on a few of the key lessons learned.

Guiding Principles

Jim Bernstein, the founding director of the North Carolina Office of Research, Demonstrations, and Rural Health Development, summed up the core belief guiding the Office since its inception as, "If improvement in [health] care or service is the goal, then those who are responsible for making it happen must have ownership of the improvement process." This core belief is put into practice through a state/local partnership approach to projects and a focus on community investment as the cornerstone of all improvement strategies. Jim established five key principles that for more than 30 years have shaped the Office's partnership initiatives and continue to shape them today:

- Ownership is vested with community participants;
- Roles and responsibilities of all participants, both community and governmental, are clearly defined;
- In-depth technical assistance is provided on a continuous basis;
- Accountability is clear and measured; and
- Meeting patient and community needs remains the focus of all activities.

These guiding principles were originally applied, tested, and refined in the work that brought the Office into existence in 1973—the Rural Health Centers Program. Under the Rural Health Centers Program, the Office provided financial and technical assistance to rural communities in developing community-owned and operated primary care centers. In providing this support, the goals were to foster the development of independent community organizations with the leadership, knowledge, skills, and tools to create and manage a community medical center. Unlike the financial assistance provided by the Office, which was viewed as short-term (three to five years) help to communities during the start-up period, the Office's technical assistance was always seen as a long-term commitment. Not only would technical assistance be available to help community boards prepare for their oversight and policy role and to help health center staff carry out their clinical, practice, and financial management responsibilities, it would also remain a key component of the ongoing operation of the center. The principle behind this commitment to long-term technical assistance was that the Office would be more than just a traditional funding

> *"In rural communities, where local resources are limited and where the loss of a clinician can close a health center's doors, being able to turn to the Office ... for help ... has been an essential part of the state/local partnership."*

Torlen L. Wade, MSPH, is the Director of the North Carolina Office of Research, Demonstrations, and Rural Health Development. He can be reached at torlen.wade@ncmail.net or 2009 Mail Service Center, Raleigh, NC 27699-2009. Telephone: 919-733-2040.

Andrea D. Radford, DrPH, MHA, is a Research Associate at the Cecil G. Sheps Center for Health Services Research. She can be reached at aradford@schsr.unc.edu or CB# 7590, Chapel Hill, NC 27599-7590. Telephone: 919-966-7922.

John W. Price, MPA, is the Associate Director of the North Carolina Office of Research, Demonstrations, and Rural Health Development. He can be reached at john.price@ncmail.net or 2009 Mail Service Center, Raleigh, NC 27699-2009. Telephone: 919-733-2040.

agency. It would be a partner with the community. While this commitment to partnership began during the feasibility and start-up phases of a new health center, it would continue well after a health center became operational. Office field staff still work with health centers that opened their doors more than 30 years ago. In rural communities, where local resources are limited and where the loss of a clinician can close a health center's doors, being able to turn to the Office for recruitment or emergency fill-in help or for help addressing financial and other crises has been an essential part of the state/local partnership. Each of the 85 health centers developed by the Office as part of the Rural Health Centers Program, is unique. Designed by individual communities to meet their particular needs, the health centers range from single practitioners in remote rural areas to multi-site, multi-provider operations serving several counties.

Throughout the 33-year history of North Carolina's Rural Health Centers Program, there were no major changes in the guiding principles, only refinements. The one significant refinement was an evolving definition of community. In the early 1970s, when there was a critical shortage of primary care providers throughout rural North Carolina, the focus was on securing care for all residents. As the supply of primary care physicians, nurse practitioners, and physicians became more plentiful, the office shifted its attention in the 1980s to providing access to care for low-income and underserved populations. Today, 80% of Rural Health Center Program funds support the direct provision of primary care to low-income and uninsured persons.

Although the principles were originally adopted to guide the Rural Health Centers Program effort, they are now used to guide other community-based initiatives and services within the Office, which are designed to improve the care of underserved and medically vulnerable populations, including the:

- *Medical and Dental Placement Program*, which recruits physicians, nurse practitioners, physician assistants, and dentists to serve in rural and underserved communities. In the last 30 years, more than 2,000 medical and dental providers have been placed in 96 of the state's 100 counties.
- *Farmworker Healthcare Program*, which targets the unique healthcare needs of seasonal and migrant farmworkers across the state by building up local delivery and outreach systems in high-impact areas.
- *Critical Access Hospital Program*, which assists small rural hospitals in securing Critical Access designation and, most importantly, promotes the formation of hospital networks that can improve the quality of services and financial stability. The program also assists partner hospitals with long-range planning, data analysis, grant-writing, and architectural and design assistance;
- *Prescription Assistance Program*, which provides prescription assistance software and technical assistance to community practices that help low-income residents obtain prescription drugs; and
- *Community Care of North Carolina*, which manages the care of Medicaid recipients through community health networks that are organized and operated by local physicians, hospitals, health departments, and departments of social services. Fifteen Community Care networks serve more than 650,000 Medicaid recipients and are creating the management systems needed to achieve long-term improvement in quality, cost, and health outcomes.

Over the Office's history, the importance of the five principles listed above has not changed and perhaps are the most important lessons that can be drawn from the Office's experiences. However, additional lessons have been learned along the way. These lessons can be divided into those that stemmed from work with local partnerships and those learned from work with other state-level partners.

Lessons Learned from Partnerships with Communities

Respect the Community's Perception of Their Needs

While academicians or state officials may have identified a need in a particular community, until the community acknowledges the problem, any attempts toward resolution will have mixed results. Education and outreach may be the necessary first steps in engaging a community to address their healthcare needs. Alternatively, the correct decision may be to step back and wait, but be prepared to step in when the community is ready.

Find and Nurture Local Leaders

Local leaders and champions are critical to developing sustainable healthcare initiatives in communities. Early on, Jim Bernstein recognized that community leadership was the critical component in the success of any community-based initiative. When dedicated leadership was absent, there were almost no prospects for successful community development. On the other hand, strong community leadership can offset other weaknesses in the development process. Leadership was so important that Jim made a concerted effort throughout his career to identify and nurture potential leaders at the community level.

Serve as a Resource

Over time, the Office has developed skill sets in a variety of areas to provide technical assistance to communities. Through this cadre of specialized technical expertise, the Office is able to assist communities in establishing non-profit corporations, organizing fund-raising and community-awareness campaigns, designing and building facilities, recruiting and hiring providers and staff, and overseeing medical operations. Because of the growing complexity of healthcare finance and reimbursement, the Office provides extensive technical support to health centers in all aspects of financial management. Rural health centers, such as Black River Health Services and Saluda Medical Center, developed 30 years ago, still retain a close working relationship with the Office. The Office also serves as a resource to other North Carolina agencies and to staff from other states.

Lessons Learned from Partnerships with State-Level Partners

Find and Create Flexibility within a Traditional Bureaucracy

State governments traditionally do not have a reputation for being the most flexible of institutions with which to work. The Office has balanced the need for reporting and accountability with the need for fast and straight-forward processes. While many policies cannot be changed, the Office has always tried to view rules and requirements from the perspective of those most affected by it. Therefore, whenever possible systems are designed to minimize the impact of bureaucracy while assuring that all state requirements are met.

Learn from Failures as Well as Successes

Not every good idea translates into a successful project. The Office has had opportunities to become involved in healthcare projects that were not tied to its long-term focus on building and supporting community-based systems designed to improve access to care. Although some of these non-core projects went well and made a contribution, other ventures were a struggle because they were not aligned with the Office's core values and skill sets. Non-core projects must be selected carefully to ensure they do not detract from what matters most.

Address Problems at the Appropriate Level, Whether It's Local, State, or Federal

While the Office emphasizes empowering local communities to address their own healthcare issues, there are often regulatory and legislative issues that impact communities, which can only be addressed at the state or national level. The Office has weighed-in on both state and national policy issues. In the mid-1970s, Jim Bernstein was active in developing the Rural Health Clinic Services Act (P.L. 95-210) legislation, which created reimbursement mechanisms for services provided by nurse practitioners and physician assistants in underserved rural communities. More recently, the Office, through the Community Care of North Carolina program, has worked with the North Carolina Department of Medical Assistance to create new provider delivery and reimbursement models that emphasize case management and continuity of care.

Build Bi-partisan Support

Rural health issues when seen from a local perspective are neither Republican nor Democratic issues, they are community issues. By focusing on supporting community-solutions to community problems, the Office has been able to build a broad base of support for its work during both Republican and Democratic state administrations.

Collaborate and Build Partnerships

Much of the Office's work has been accomplished through collaborations and partnerships at both the community and state level. Since its inception, the Office has viewed partnerships and collaborations as an essential part of its mission. Community Care of North Carolina is one example of the importance of collaboration. Its success is dependent on the collaboration and commitment of both state and local organizations. This program has achieved notable improvements in care quality and cost-effectiveness for Medicaid recipients by fostering community-wide collaboration around improved systems of care and by employing disease and case management strategies to improve care. The Office also tries to promote partnerships at the community level among different providers and agencies. In Bertie County, the Office helped to facilitate a closer working relationship between the local hospital, county health department, federally-funded community health center, and regional health system. As a result of this partnership, a multi-agency health campus has been constructed in this rural county allowing residents easy access to several providers and services in one location.

The need for collaborations and partnerships will continue as the Office works with others to address the current and future challenges in providing access to quality healthcare for rural and underserved populations.

Challenges Facing Rural Healthcare

There are several challenges facing rural healthcare. Some have been faced before, while others are new.

Increasing Number of Uninsured

As the traditional employment base of manufacturing and textiles leaves and as increasing numbers of immigrants settle in rural communities, the number of uninsured places additional stress on fragile safety net systems of care.

Aging Infrastructure and Physical Plants

Many of the health centers established by the Office are celebrating 25 or more years of service to their communities. Unfortunately, the physical facilities are beginning to show their age. In addition, the need for up-to-date and reliable computer networks to handle the routine business of healthcare has also increased. Finding significant levels of funding for capital and information technology infrastructure will continue to be a challenge.

Access to Mental Heath Services

Accessing affordable mental health services in rural communities is a growing challenge. Primary care practices and emergency departments often become the providers of last-resort for mental health issues in their communities. There is a growing need to both improve the ability of primary care providers to care for patients with behavioral health needs and to improve the ability of local systems to integrate and coordinate behavioral health services and primary care.

Access to Pharmaceuticals

Even with the implementation of Medicare Part D, many rural residents with limited incomes face challenges obtaining necessary medications. Rural health providers often find themselves cobbling together solutions from sample medications and pharmaceutical company donation programs to meet their patients' prescription medication needs.

Workforce and Staffing Issues

Rural healthcare faced a physician shortage in the 1970s due to the retirement of large numbers of general practice physicians. This shortage was dealt with in part through enhanced recruitment and retention efforts and by the widespread introduction of nurse practitioners and physician assistants into rural areas. Now rural health is facing another projected shortfall in primary care and key medical specialties, and once again, creative and collaborative solutions will have to be found.

Conclusion

More than 30 years ago, Jim Bernstein shared his vision for what a state office of rural health could be and what it could do. His philosophy of nurturing community-based solutions to community healthcare programs has contributed to the development of more than 80 rural health clinics across North Carolina and the implementation of other initiatives targeted at providing care to the underserved in North Carolina. The lessons learned have come from putting his philosophy and vision into practice. **NCMedJ**

COMMENTARY

The Heartland's Heartstrings:

The Power, Challenges, and Opportunities of Rural Health Advocacy in Washington

Jeanne M. Lambrew, PhD

The political power of rural health is legendary in Washington, DC. In September 2003, it caused a breakdown in deliberations over the highly-anticipated Medicare drug benefit. Senator Grassley (R-IA) walked out of negotiations with Representative Bill Thomas (R-CA) because rural Medicare provisions were not high enough on the agenda of items to address. The $25 billion, ten-year rural health package almost derailed the ultimate passage of the $400 billion drug benefit.[1] More recently, rural health funding cut-backs contributed to the surprising defeat of the conference agreement on the Department of Health and Human Services appropriations bill. At least seven Republicans voted against the final bill—more than the margin of loss—that, unlike either the House or Senate versions, zeroed out several rural health programs.[2] The $90 million in funding was ultimately restored to the $601.7 billion bill, but not without a major political embarrassment to Republicans who generally have such disagreements behind closed doors.

> *"North Carolina has also inspired federal policy. Its creation of the first office of rural health and innovative rural workforce policies has had a major effect on national health policy."*

These stories are dramatic pages in a long history of significant successes in rural health policy. In the post-Depression period, the Farm Security Administration created systems in 41 states to provide accessible care—serving as a model for subsequent national reform plans. In the 1950s and 1960s, health planning took hold, offering a rational model and funding for rural facility development. The federal focus on rural health outreach, training, and delivery system demonstrations accelerated in the 1980s. In the 1990s, culminating in a major investment in 2003, Medicare adopted policies that created special payment categories and rates for an array of rural providers.

In 2006, the power of rural health in Washington is still strong, but changing. Shifts in demographics, economics, and politics pose new challenges to rural health advocacy. In addition, health trends, such as consolidation of insurers and erosion of coverage will likely exacerbate problems facing rural health systems. This commentary reviews why rural health has a strong hold on federal policy, upcoming challenges, and the opportunities that rural advocates have to fundamentally change the United States healthcare system.

Rural Health's Hold on Federal Policy

There is a factual explanation for the power of rural health in federal policy. About 54 million Americans live in rural areas—a number that exceeds the number of seniors nationwide. Generally, rural people face larger and more difficult-to-solve health problems. They tend to be older, poorer, and sicker. They face barriers in accessing needed healthcare. Travel times to providers are generally longer in rural than in suburban or urban areas, and attracting and retaining providers is a perennial challenge. Sustaining hospitals, nursing homes, and other services for people with high needs poses a financial as well as a logistical problem.

The ability of these problems to merit increased federal

Jeanne M. Lambrew, PhD, is an Associate Professor of health policy at the George Washington University School of Public Health and Health Services and a Senior Fellow at the Center for American Progress. She can be reached at jlambrew@gwu.edu or 2021 K Street, NW, Suite 800, Washington, DC 20006. Telephone: 202-416-0479.

attention is enhanced by examples of success. Members of Congress are proud of the innovation and adaptation of their local rural health systems. Many of the payment policies in Medicare for rural hospitals originated to expand on models in states like Montana, North Dakota, and Iowa, homes to powerful Senators like Baucus (D-MT), Conrad (D-ND), and Grassley (R-IA). North Carolina has also inspired federal policy. Its creation of the first Office of Rural Health and innovative rural workforce policies has had a major effect on national health policy.

In addition to the facts and success that propel rural health policy, there is an element of mythology. Many Americans still view rural America as emblematic of bucolic life. We envision family-owned businesses, farms, and the values of small-town life: honesty, decency, and simplicity. This is somewhat disconnected from reality; for example, most rural work is in manufacturing or the service industry, and many farmers are immigrants. Nonetheless, these images are evoked with surprising frequency in the halls of Congress as justification of subsidies for rural health.

And, clearly, our democracy is structured to give rural residents a political edge. The Senate, with two representatives from each state irrespective of their size, gives rural populations a clear advantage. For example, California's population is nearly 73 times higher than that of Wyoming, giving each person in Wyoming a much greater ability to influence Senate policy. And, about half of all Americans live in 10 states, making coalition building relatively easy among the 40 other states that have higher proportions of rural residents.

Because of these facts, myths, and structural advantages, rural health advocates may rank among the most cost-effective lobbies in Washington. There is neither a large rural health political action committee nor a largess in rural communities that gives it an edge in the cut-throat world of Washington. Instead, there is a currency to the facts and stories about rural Americans and the health providers who care for them that has created a strong and relatively unique power base.

Challenges Ahead

The advantages of rural health in federal policy may be needed more—and strained more—in the future. The globalization of our economy has taken a heavier toll on rural America. Job growth has been depressed in rural areas more than in others. The lack of job opportunities has contributed to out-migration of young people and the more rapid "graying" of rural America. This overlays persistent poverty in many rural areas, especially in the south.

These economic and demographic trends have affected rural health systems. Demand is up, given the older and sicker population. The nature of the demand is also shifting as rural areas increasingly become recreation areas; accidents and trauma are rising. This combination has meant that healthcare has grown as an important element of rural economies.

There are also two major trends in the health system that could particularly affect rural areas: consolidation and contraction. *Consolidation* refers to the increasing dominance of large segments of the supply of healthcare in the United States. A handful of major private insurers now dominate coverage in the United States. Hospitals and nursing homes are increasingly part of large chains. Even doctors have tended to join larger groups. While this could offer support for some rural providers, it could mean less focus on local needs as regional needs prevail.

Contraction refers to the continued erosion of private coverage. There was a 13% reduction in the proportion of small business workers covered by their employers between 2000 and 2005. At the same time, large establishments that have often crowded out local, small businesses are less likely to offer insurance than they were in the past. This has led to a surge in the number of Americans who lack health insurance—or whose insurance is still leaving them vulnerable to catastrophic costs. Most economists suspect that these trends will continue.

Both supply-side consolidation and contraction of coverage are being accelerated by federal policy. Medicare's new focus on large regions has meant that more rural beneficiaries have access to private plans. Yet, it remains to be seen how rural providers and the people they serve will fare in plans that cover large areas, often multiple states. And, in Medicaid, the budget reconciliation legislation will, according to the Congressional Budget Office, reduce Medicaid coverage through a set of policies that tighten eligibility rules, raise premiums, and make applying more difficult. Rural people rely more on Medicaid than those in urban areas, and thus could be disproportionately affected.

This contraction extends to federal appropriations as well. While the initial conservative approach to policy was to encourage privatization of government functions at all costs, a backlash from fiscal conservatives has emerged that has led to intense pressure to reduce the size (i.e., spending) of government. This generally has been focused on small programs. These programs historically escaped the budget knife by having local champions. But, as Washington roils in investigations of special interest influence, protecting local funding is called "earmarking" and is subject to intense review and criticism. This is exacerbated by a break-down in bipartisanship. The exclusion of Democrats from the conferences on major legislation has meant a loss of numerous rural voices in the crafting of legislation. Moreover, the concentration of power in party leadership could subvert local and regional differences to a larger set of politics.

Opportunities

Despite these challenges, the elements that have empowered rural health policy in the past are intact. There is still a fact-based claim for different treatment. Arguably, the case is stronger given increased need and the economic importance of rural health systems. Evidence also will accumulate on the limitations of blanket solutions at the top of the policy agenda. The challenges of rural healthcare delivery will not be solved by information technology alone. Pay-for-performance may not work to improve value in small rural hospitals as it could in large urban facilities. And, the idea that empowering consumers with information and accounts to shop for healthcare simply cannot work in most rural health delivery systems. Awareness of this "square peg in a round hole" problem will strengthen the case for separate consideration of rural health needs in public policy.

There is also a new and potentially stronger mythology emerging about rural America. Globalization can allow for new types of economic growth in rural areas. Some areas have focused on regional planning, recasting higher education to train for emerging industries, and taking advantage of the information revolution to remove geographic barriers. If technology has enabled outsourcing to India, why not to rural Indiana, some argue. In addition, as the focus increases on our natural resources, rural Americans may be seen as stewards of our unique national and natural assets. This new set of images fosters an advocacy based on strength rather than weakness and emphasizes what has always been true in rural health: local delivery innovation works.

But, it will also require a more sophisticated advocacy. In an overall system that suffers from poor outcomes, high costs, and access problems unknown in other wealthy nations, advocacy based on equality is a challenge. When our urban health systems face serious problems themselves, does equality make sense? Instead, it may be time to move away from politics of comparisons and toward ideals. Rural health policy advocacy could be based on simple principles to which the whole system should aspire, such as affordable access for all, fair financing of efficient care, and focus on health promotion and prevention. This could justify the continuation of successful Medicare payment policies, increases in funding for training, and new programs to improve access. Embracing the idea that we could do more for less—but this may require an upfront investment—could appeal to the fiscal conservatives. By moving away from arguments based on victimhood or unfair treatment, it rejects the implicit assumption that this is an allocation problem, and rural funding must come at the expense of others.

Finally, many challenges in rural health delivery stem from larger, systemic problems of high costs, coverage gaps, inadequate and unfair financing, and sporadic quality. The next debate on fundamentally changing the United States health system may come soon, as business leaders engage in it as a matter of survival. It could be that the best use of the incredible capital of rural health advocacy may not be in supporting small policies that effectively put a finger in the dyke. Rather, rural health leaders should consider that the best hope for achieving their goals is to advocate for real reform of the system. This may not only precipitate change, but ensure that the unique needs of rural delivery systems are met within the context of a larger redesign of the system.

In closing, the idea of adhering to a large vision even when making local change was something I learned from Jim Bernstein, among others. In my graduate studies at University of North Carolina at Chapel Hill, I had the privilege of working in the Rural Health Research Program and with him. Federal health policy was improved by his actions and example. I hope his legacy will live on through progress in improving the health of rural, and all, Americans. **NCMedJ**

Forging Local Level Partnerships to Make Health Programs Possible

Rita C. Salain

Over the past several decades, a tremendous reservoir of experience and expertise has developed with regard to the role and importance of community planning and partnership development through which concerted actions to improve the health of rural residents can take place. In this commentary, I attempt to summarize some of this accumulated knowledge and experience and identify some of the critical steps toward meaningful community health action to improve the health of rural people, rural access to healthcare, and rural health program development.

In rural communities, if a primary care physician decides to re-locate to another town or close his/her practice, the community's healthcare options may become drastically limited over night. The same is true if a rural hospital closes or limits needed services because of financial distress. Both of these scenarios place an increased strain on public health providers in the area as well as the other private health providers. In communities with limited resources, one provider making a change impacts all the other providers, families, and individuals. Rural healthcare systems are fragile. Events that affect the ability of rural communities to provide quality healthcare vary, but most rural communities face a similar set of access to care barriers, which include financial, geographic, educational, cultural, and language.

> *"...communities with a demonstrated track record of working well together typically receive more attention and help than communities without a history of collaboration."*

In many rural communities, however, high-quality health services are available and thriving. The difference between a strong, high-quality primary care system and a system that fails in rural communities is often based on whether or not the community has local leadership dedicated to understanding and preserving healthcare that is appropriate and meets most of its citizens' needs. The success of most healthcare systems in rural communities hinges on community leaders who are willing to work together to identify needs, find resources, and invest their time and talent in solving healthcare access problems. Often rural health leadership includes working with adjoining communities to plan and deliver health services.

Creating a successful healthcare system in a rural community goes beyond the leadership of one person. Success depends on rural stakeholder collaboration and commitment. The events that prompt the formation of a partnership among stakeholders vary, as do the methods by which rural communities take action. A small community health planning group could be formed and charged with investigating and defining the problems. The group could be self-appointed or appointed by county or municipal government leaders, community physicians, the hospital, the board of health, etc. A coalition of local leaders or an appointed task force or partnership might be charged with finding outside help or consultation.

Regardless of how the group comes together to develop and maintain the most effective community health planning group, communities will need to identify appropriate constituents as stakeholders, agree on a governance structure that will make diverse participation possible, and explore ways individuals can work together to sustain rural health initiatives over time.

Importance of Stakeholder Support

Several years ago, a colleague from south Georgia asked me why some communities attract all kinds of resources while others

---

Rita C. Salain is a consultant in private practice and former Director of the Georgia Office of Rural Health and Primary Care. She lives in Decatur, GA, and Franklin, NC, and can be reached at ritasalain@bellsouth.net. Telephone: 404-373-8109 and 404-323-0572.

—with as much need—do not. My response was that communities with a demonstrated track record of working well together typically receive more attention and help than communities without a history of collaboration. Since all resources are finite, governments, corporations, and foundations prefer to invest funds where a successful outcome is more certain. For this reason, opportunities are limited for communities without a community health partnership, health and civic leadership, or a history of rural health development, including networks or other rural health collaborations. The rationalization for this thinking is that there will always be more communities with "need" than resources to meet those needs, and thus, assistance should be invested in areas where there is need *and* the probability of success. Technical support and resources should be invested when a legitimate community-based group asks for help, but the onus belongs to the rural community leaders to ensure that investments will be prudent and useful. Fundamentally, the responsibility for change rests on the shoulders of community leaders and stakeholders who are willing to invest their time, talent, and resources in work to improve health status in their community.

Stakeholders can be defined as "a person or group with a direct interest, involvement, or investment in something, e.g. the employees, stockholders, and customers of a business concern."[1] Not only does having stakeholder support make a community health planning group more attractive to funding agencies, but stakeholder support also helps ensure plans and proposals are relevant, appropriate, and acceptable. Having various stakeholders participating is important in reducing potential duplication and ensuring that problems and solutions are fully defined. In addition, stakeholders should provide accountability and broaden community support.

Across rural communities, the particular stakeholders needed to define and solve problems will vary based on the specific health problem being addressed, the proposed solution(s), etc. At times, a broad-based community group comprised of civic leaders, citizens, physicians, nurses, other business leaders, and elected or appointed officials will be appropriate. Often, input from disadvantaged groups (e.g., the uninsured; poor, minority populations) is crucial to understanding the nuances of the problem and for developing appropriate solutions.

In many cases, the formation of stakeholder groups is guided, in part, by program requirements for funding. For example, if a rural community is applying for a primary care operational subsidy from the federal government [e.g., to become a Federally Qualified Health Center (FQHC)], federal regulations specify that the majority of the organization's governing board members must be users of the service. That is a condition for receiving such a grant.

Many public and philanthropic grant programs have specific requirements. Often, these requirements involve defining and engaging stakeholders. For some, positions on governing boards will be required, while others might suggest the type of local guiding group necessary to become successful applicants. Some local health programs, such as county boards of health, specify who appoints board members, how many can be appointed, the length of their terms, and the professional background or credentials board members must have. This is an important area of local policy, and rural citizens should be sure they understand it.

Contact the Office of Rural Health

To begin, groups formed to address health access problems should request assistance from their respective state Office of Rural Health. These offices, now in every state, are great places to ask for help, and some have resources to plan and solve health status or health system problems. State ORHs are supported in part by federal resources matched with state funds. A list of ORH directors and phone numbers is available on the federal Office of Rural Health Policy (ORHP) Web page (http://ruralhealth.hrsa.gov/funding/50sorh.htm) or by calling 301-443-0835.

Other helpful groups might include hospital associations, medical or family practice associations, universities, associations representing county commissioners, public health officials, foundations as well as other specific health interest groups. The ORH staff should have relationships with many of these groups and be able to connect you with others who can help. Most ORHs work to be a one-stop resource and will help find and broker technical assistance and consultation from a variety of state, federal, association, and foundation groups. Your ORH can connect rural leaders with resources, ideas, people, and tools.

Constituent Identification: Who Should Be Included as Part of the Stakeholder Group?

Depending on the situation or health system problem, a full spectrum of rural health providers, users of health services, civic leaders, representatives of groups experiencing disparate health access or health outcomes, faith leaders, business leaders, and social service providers might initially be convened to address specific health system problems. There are diverse opinions on how to identify the constituents necessary to develop a rural health service program and when to invite these participants, Opinions about who to invite range from issuing an open invitation to selecting a handful of opinion leaders whose influence will be required to make change.

Issuing an open invitation to interested parties works best when a clear statement of the need exists along with specific working parameters, the time commitment required, and the projected timeline. Including specific expectations in the open invitation helps stakeholders determine if they will participate. Clear expectations of involvement, group direction, and a planned way to use stakeholder input are crucial components of successfully developing and maintaining health programs and health assets, as well as being important in keeping a broad-based group engaged.

Depending on the program to be developed, there are times when smaller groups might work better initially. For example, a group of physicians and staff might form as physicians recognize they are providing care to a growing portion of uninsured people. The physicians might notice they have fewer privately insured clients. They might identify that they need help managing coding, billing, and collections from public insurers (Medicaid and Medicare). They may ask for help in assuring that any patient eligible for a program is made aware of it and helped to enroll. They may first coalesce as a small, invited group to clearly define the problem. Later they might seek assistance in defining the problem more broadly—how the growing number of uninsured is impacting the hospital, emergency medical services (EMS), public health, etc. They could then form a larger group to research and quantify the problem, craft potential solutions, and/or develop additional resources. They might ask for help from their Office of Rural Health (ORH). The physicians might seek assistance with improving practice management or developing a Rural Health Clinic.

This example can also be viewed as a potential problem to retaining primary care physicians in a community. As the problems are identified more fully, it becomes clear that the growing number of uninsured is a community-wide problem (as well as a national one). The initial group might broaden to include—in addition to the original physician group—nurses, a hospital administrator, public health leaders, hospital board members, mental health providers (if any), EMS providers, pharmacists, and other concerned stakeholders. As this group grows, it will be important to include the voices of the people who are the major users of services or those who are most in need, (i.e., those who have no insurance, those eligible for but not enrolled in programs, and those with limited income, etc.).

The importance of group diversity may not always be apparent. For example, several years ago while working with a large group of medical providers, hospital administrators; cancer survivors; and public health, business, civic, and faith leaders in a rural region formed a coalition to improve cancer screening, detection, diagnosis, and appropriate treatment. After months of coalition meetings, one of the medical leaders asked why the faith community was at the table. One minister retorted, “Who do you think people call as soon as they get the diagnosis that they or a family member has cancer?” The faith leaders in that coalition made key contributions to the work and opened doors for screening where the need was great.

Representatives of disadvantaged groups almost always need to be at the health service development table, regardless of the eventual governance structure adopted by the group. Disadvantaged people might not be included at an entrepreneurial health table or with a group convened to improve the technical components of managing an efficient, effective primary care practice, for example. If, however, the issues to be solved deal with improving access to health services, full community participation can significantly benefit the planning process.

The *timing* of invitations is also important. It typically does not work to invite representatives of the uninsured, poor, or the underinsured *after* key decisions have been made. Too often, groups make the mistake of waiting until key decisions have been made to invite other representatives to the table. A serious consequence of delayed inclusion is that the newly invited individuals will not have the historical perspective of the group’s planning and thinking, nor will they have the ease of association and rapport, all of which have been building since the group was formed. Ground rules how the group functions are formed early in the process, thus making it harder for new members to understand the group’s informal rules. Delayed inclusion can also cause new members to be hesitant in offering opinions, which in turn, might lead to false conclusions about the new member’s willingness to actively participate.

Including as many stakeholders as possible from the beginning reduces the likelihood of criticism that key decisions were made without sufficient input from key groups who will use the planned health services. If a group finds they need to add members later in the process, they should provide a comprehensive orientation to new members, including where the group is in their thinking, planning, and studying of options.

Deciding Which Corporate Structure Will Make Diverse Stakeholder Participation Possible

Each community health planning group will need to agree on a governance structure for themselves. When considering an appropriate corporate structure for the group, form should follow function and necessity. Several corporate structures might work well. Sometimes groups form an informal board, task force, or coalition. Over time, the group might decide to form a 501(c)(3) or another corporate model. Other times, groups form and decide the work can be handled without formal incorporation. That same group might decide that by-laws and operating procedures will be useful and that appointing an organization to serve as the fiscal agent is prudent. Some groups might attach to existing organizations, such as hospitals.

The group should adopt a structure that facilitates collaboration and productivity. Even when the corporate structure is prescribed by a funding partner, the execution of that structure is largely in the hands of the community leaders. A good way to ensure a full spectrum of stakeholder participation is to specify diversity in the corporate structure (i.e., prescribe a ‘balanced’ group with all viewpoints represented) and to be vigorous in assuring diverse opinions, experience, and expertise are invited and respected.

Sustaining Health Service Initiatives

Being able to sustain a program or a new service once it is up and running is often a challenge. In addition to developing a program that provides high-quality health services and has a system for referring patients to accepting specialists when necessary, the group must make sure the new program or service exhibits efficient management, can demonstrate effectiveness, can be sustained, has broad community acceptance, and is seen as an important economic component in the community.

Ensuring Efficient Management

One of the first steps toward sustainability for a primary care or programmatic service is to ensure managerial efficiency. For example, if the health services to be provided are covered by insurance (i.e., Medicaid, Medicare, or private insurance), the providers must be properly enrolled as a provider. Staff must know how to code, file, and collect payment for services delivered. This is not easy in the rapidly changing health insurance market. Efficient practice and program management is essential.

The North Carolina Office of Rural Health pioneered the development of publicly supported practice management technical assistance to improve retention of primary care providers. Several states in the southeast (Alabama, Arkansas, Georgia, Louisiana, South Carolina, and Texas) now provide or broker primary care practice management services developed as a part of the Robert Wood Johnson Foundation's (RWJF) Southern Rural Access Program. The practice management component of that Program was modeled after the successful work of the RWJF *Practice Sights* initiative of the early 1990s, incorporating lessons learned from that project. The RWJF National Program Office for that initiative was directed by Jim Bernstein and his colleagues in Raleigh. The Southern Rural Access Program is phasing out now, but several states intend to continue offering practice management support. The Office of Rural Health in most states can advise if free or low-cost rural practice management assistance is available.

Evidence of Effectiveness

Another key component of sustainability is assuring that the service developed is effective and efficient and, thus, warrants being sustained. To make this case, a program evaluation is required. Armed with key information on effectiveness, cost, and utility, the next step is to find a long-term funding partner. This is more easily accomplished with unbiased, supportive data, and a clear description of what was done, for whom, by whom, at what cost, and to what end or outcome. Not every effort will require a funding partner, but many will.

Securing Financial Support

Sustaining health services in many rural communities still requires securing long-term funding. Because of the disproportionate percent of rural people who are uninsured or under insured, often additional resource support must be found. Funding might be found by securing a direct federal grant (generally not a long-term strategy), foundation gifts or grants, private donations, state funding, or local support for services. Many counties or parishes support the hospital, EMS, the public health department, public mental health services, and some invest in the retention and recruitment of primary care providers. Working with like-minded organizations in adjacent and or nearby communities is also a very effective way to support services by spreading costs and sharing resources.

Action Steps

The following steps, or similar ones, are generally thought of as community health system development, community encouragement, etc. There are a variety of approaches, both formal and informal, that can be used to develop a rural health action plan. Rural community groups are not alike, so steps, catalysts for change, and resources will vary.

- A rural community leader, clinician, or health administrator becomes aware of a health problem that needs to be addressed.
- A small group (or groups) is (are) formed to investigate the problem.
- Problem(s) are researched, information is shared and the group begins to investigate solutions.
- The group, based on the information gathered (i.e., specific data), decides that the health status or system problem is one they have the will to address, and they then begin to develop a plan for how to deal with the problem.
- Clinical leadership is brought together (if not already present) to participate in planning and solution development.
- The local group, including clinicians and other health providers, asks for information, support, data, technical assistance, facilitation expertise, etc., from the ORH, other technical assistance providers or other associations, foundations, or corporations—to help define the most significant problems and search for resources.
- The group forms a larger, multi-disciplinary, planning group charged with developing a strategic plan for health. The plan will ideally include short- (one-to-three year) and long- (five- to-ten year) term goals and specific measurable objectives. The plan can include working with other organizations in adjacent counties or parishes, and, at times, a regional initiative will form.
- The group either forms a specific governance structure or works with an existing structure (i.e., rural hospital, not-for-profit) to develop and implement the plan and provide frequent feedback to the community.
- The plan is put into action.
- The group collects specific data, evaluates the results and resources invested, and shares that data.
- The group continues to work the plan, make necessary changes, engages in strategic planning, forms additional partnerships, and continues the quest to secure and find resources to improve health status.

Broad Community Use of Services

Important to sustaining health services is for all the community to use local health services. The civic, business, faith community, and other opinion leaders must use health services in the community. Citizen leaders should not by-pass local health services. Rural providers must have a strong mix of insured clients to help carry the disproportionate load of self-pay, Medicaid, and Medicare patients they serve. Medicaid and Medicare often require deep fee discounts (sometimes below the cost of providing services). As a reassurance to all—healthcare providers should make it clear that they are formally linked with other regional providers and have referral agreements with other facilities and specialists when required.

Healthcare and the Economy as a Sustaining Factor

Another key to sustainability is for rural civic and government leaders to understand that health services are one of the most useful, sustainable economic engines in a rural community. Healthcare is big business. According to the National Coalition on Health Care in 2003, "the United States spent 15.3% of its Gross Domestic Product (GDP) on healthcare."[2]

Health services bring money into the community from the state and federal government (Medicaid and Medicare). Rural health dollars "roll over" about 1.5 times in the community. In many rural communities, the healthcare sector accounts for ten to 20% of all jobs in the community,[3] and health sector jobs often pay well and are sustainable jobs. Many times the healthcare sector is the largest employer in the county or parish.

The federal Office of Rural Health Policy (ORHP) invested in helping community leaders understand the economic impact of the healthcare sector through funding support for the *Rural Health Works Program*,[4] managed and pioneered by the University of Oklahoma. The *Rural Health Works Program* is especially useful because standard employment data, gathered through the Census, is used to calculate the economic impact of the healthcare sector on the rural economy. The database (IMPLAN) is used to calculate the payroll of businesses engaged in health services, including public organizations and then calculate the economic impact of those jobs and dollars spent in the community. Other models are available to measure the economic impact of healthcare in the local economy. Some calculate the dollar value to the community of each primary care physician. Many hospitals can quantify their economic impact on the community.

Business leaders, civic leaders, economic development staff, and elected officials are more likely to help sustain, attract, and grow programs and encourage health businesses if health services are viewed as a part of the economic vitality of the community. In addition to the direct economic impact of health services, the significant difference health makes in family life (i.e., affecting one's ability to earn a living, decreasing morbidity, and helping people enjoy a higher quality of life) is universally understood.

Summary

The quintessential difference between most successful rural health programs and unsuccessful ones is local leadership. The ways in which a community invites, values, develops, nurtures, and supports the involvement of diverse stakeholder groups form an important part of the base for local rural health program success. Successful programs are initiated by local stakeholder groups who are committed to collaboration, have a working governance structure, a good understanding of their health and healthcare challenges, and a plan for sustainability. A key first step for rural community health planning is to contact one's local state Office of Rural Health. Most ORHs will provide information, guidance, and technical assistance. There are many challenges in rural health, but there are also great successes. North Carolina communities fare better than many because the North Carolina Office of Rural Health has demonstrated how effective state and local leadership work together to directly benefit rural communities and rural people. **NCMedJ**

COMMENTARY

Rural Physicians and Community Leadership:
Skills for Building Health Infrastructure in Rural Communities

Steven D. Crane, MD

Few physicians at the beginning stage of their careers are so audacious as to describe themselves as "community health leaders." Nevertheless, nearly every physician who finds him/herself practicing in a rural community will often be inexorably drawn into discussions about greater health-related needs in the broader community. Once a healthcare professional is able to step back and take a panoramic view of the "health" of the community in which his/her practice is located, he/she often realizes that there are many health needs and barriers to care, and he/she quickly learns that it takes more than individual effort to meet these needs. Whether through the initiative of practicing physicians or others, community-wide initiatives to define existing problems, to plan a range of options for meeting these needs, and the effort to fund and then administer these emerging programs will usually require physician involvement … and even leadership. This commentary addresses some reasons why rural physicians need to become involved in solving some of these rural health problems, and how they can effectively provide needed clinical leadership even if they haven't previously thought of themselves in such a role.

> *"Physician leadership is a critical factor in developing community programs."*

The status of rural healthcare in North Carolina can be described as precarious at best. Many rural communities continue to be plagued by shortages of resources to serve the growing needs of a rural population that is increasingly aged and uninsured. The shortage of physicians in rural communities remains a chronic problem.[1] Despite some progress in the last decade in dealing with this maldistribution, significant disparities persist between metropolitan and rural areas.[2] Although most counties in North Carolina from 1998 to 2003 experienced an increase in the ratio of primary care physicians to 10,000 population, 38 of the state's 100 counties lost ground. Of the counties with increasing primary care shortages, about half were due to loss of physicians, and about half were due to rapid population growth that outpaced the supply of physicians.[3] Furthermore, in 2003, nearly 20% or 1.4 million North Carolinians under age 65 lacked health insurance coverage, with more than 300,000 having joined the ranks of the uninsured since 2000.[4] The combination of primary care provider shortages and declining health insurance coverage continues to threaten the healthcare safety net, particularly in rural communities.

The March/April 2005 edition of the *North Carolina Medical Journal* provided a comprehensive view of the various components of this safety net, which includes federally qualified health centers (FQHCs), Area Health Education Center (AHEC) teaching clinics, free clinics, public health departments, rural health centers (RHCs), hospital emergency departments, and efforts to integrate multiple service providers in service to the poor and uninsured.[5] As rural communities struggle to serve the health needs of their citizens, various combinations of these programs have been developed to address local health concerns. In all of these programs, physician involvement and leadership are critical components of developing successful safety net services in rural communities, but there are important barriers that prevent effective physician involvement and, perhaps, the successful implementation of vital programs.

The Western Carolina Experience

Henderson, Polk, and Transylvania counties are rural counties in the western, mountain region of North Carolina. The efforts by healthcare providers in these counties to improve access and quality of care for low-income, uninsured patients in their communities have significantly strengthened the local healthcare safety net. These efforts have included:

- The development of one of the first migrant health centers (Blue Ridge Community Health Services, Inc.) funded by

---

Steven D. Crane, MD, is the Program Director for the Hendersonville Family Practice Residency Program. He can be reached at Steve.crane@pardeehospital.org or 741 6th Avenue West, Hendersonville, NC 29739.Telephone: 828-696-1255.

the Health Resources and Services Administration (HRSA) as a federally-qualified health center (FQHC).

- An AHEC teaching clinic (the Mountain AHEC Rural Track Family Practice Residency Program).
- A free clinic staffed by family practice residents and private practice physicians in Henderson county.
- An expanded array of primary care and preventive health services by the Henderson County Department of Public Health with AHEC and private physician backup.
- Two additional rural health centers (the George Bond Health Center in Bat Cave and the Saluda Medical Center in Polk county).
- Expanded Community Care Network for managing the chronic illness [asthma, diabetes, depression, and attention deficit hyperacticity disorder (ADHD)] needs of Medicaid patients in the three counties with broad support from the private medical community in the three counties.

Collaboration has helped bring additional resources into the area to deal with the growing challenges, and spreading the risk and burden of uncompensated care has helped individual care providers while offering clients additional choice. Although in retrospect, each of these safety net initiatives has achieved a level of success, none of them would have been undertaken without vision, communication, cooperation, some measure of good fortune, and the intimate involvement of rural physicians. There are many ways physicians may impact the development of a particular program. In general, most involve some combination of advocacy of patients' interests, providing specific health or medical expertise, or serving as the arbitrator between agencies. This arbitration role often flows directly from the physician's role as patient advocate and medical expert, helping agencies set aside what can be competing interests for the common good of patients and the community. These programs also did not appear overnight. Where the region is today can be traced back to efforts that began more than 15 years ago and have progressed with one small step or success at a time.

Although program development in smaller communities can at times be more difficult due to fewer available resources, small size can also work to a community's advantage, as there may be fewer players involved, and problems, if they occur at all, may happen on a smaller scale. Personal relationships between agency representatives are often very important in any setting, but are particularly valuable in rural communities where individuals may serve multiple roles in different organizations.

Importance of Physician Leadership

Physician leadership is a critical factor in developing community programs. Physicians frequently bring unique clinical credibility to a project, knowledge and experience about health matters, access to key decision-makers in healthcare, and are granted the widest scope of practice within healthcare to establish direct patient care programs. Although outside consulting physicians can lend important advice and guidance, involving local physician leaders in health services planning is absolutely necessary for successful community health projects. A serendipitous effect of local physician involvement is the simultaneous nurturing of their community health leadership skills, which may be an important factor in retaining physicians in rural practice. Evidence supports that both community leadership preparation and having a sense of "belonging" to a community are determinants of whether physicians stay in or leave rural communities.[6] Others have also found evidence that underscores the importance of a "sense of place" in rural physician retention.[7,8] It is likely that physician involvement in these efforts, and the enthusiasm that can come from it, will be infectious and can lead to significant community health action.

Barriers to Physician Leadership: Time and Training

As important as it is for local physicians to be involved in community health leadership, time and lack of training in basic leadership skills can be significant barriers. Most physicians in rural practice have considerable patient care demands that often preclude involvement in planning activities during usual business hours. To include valuable physician input, planning groups may need to meet very early in the morning or after clinic hours, or they may need to structure meeting agendas to include physician partners in key discussions where the physicians' special perspectives are necessary and leave more administrative details to other meeting times. Group practices might be able to help cover a physician leader's clinic time so he/she can participate in an important community health project. Rural hospitals can also help fund physician time as a needed consultant to a developing program. Many rural communities have employed physicians, (e.g., those in academic, community health, or public health agencies), who have some built-in administrative time, which could be re-programmed to assist in developing community health programs. Finally, part-time or semi-retired physicians can be important sources of physician involvement in program development.

Although many physicians will be pushed into leadership roles at some level, most will have no formal instruction in management skills. Many have a limited understanding of how other disciplines, groups, or agencies impact healthcare, or they may have limited contact with other community leaders outside of healthcare. Basic tasks, such as organizing and chairing meetings, understanding general accounting practices, developing business plans, or writing grant proposals are important skills that nearly every community health project needs, but are often in short supply. It is not sufficient to recognize a health need and have an idea that could address it; ideas must be communicated to others. All stakeholders need to be included in planning and implementing a project. Most projects will require monitoring to assure that they are having the desired outcome, and any worthy project will need to be sustained.

For physicians to be effective leaders in their rural communities, there should be ways they can receive these skills either in residency training or as they find themselves in rural practice. Our Rural Track Residency Program includes an explicit curriculum in community leadership that includes a module in public health evaluation and planning, a direct longitudinal experience providing direct patient care to an underserved population, mentorship with faculty actively engaged in community health activities, and a required hands-on community project that allows residents to put these skills to practical use. Similar curricula could be added to other residency training programs for those planning careers in rural areas.

For practicing physicians, distance learning opportunities or rural leadership training programs could be an important way those interested rural physicians could acquire the skills and contacts that could quickly enhance their ability to serve as a community health leaders. The University of North Carolina School of Public Health runs a certificate program in Health Care Management, which is a 14-credit-hour program offered primarily on-line that is designed to give course participants basic healthcare management skills.[9] The North Carolina Office of Research, Demonstrations, and Rural Health Development could develop a program to identify interested rural physician leaders and support their involvement in this certificate program. The Office could also create networking opportunities for rural physician leaders, who are trying to increase their communities' capacity to address local healthcare needs and develop new programs. **NCMedJ**

Mental Healthcare in Rural Communities:
The Once and Future Role of Primary Care

John A. Gale, MS, and David Lambert, PhD

The provision of mental healthcare in rural communities has been a vexing challenge for clinicians and patients for many years. There is a chronic shortage of specialty mental health providers, particularly psychiatrists and psychologists, which has shifted much of the burden of care to primary care. Primary care clinicians have historically lacked the training and time within their busy practices to feel comfortable providing mental healthcare, particularly since the shortage of specialty mental health clinicians deprives them of consultation and referral sources. People who live in rural areas must often overcome significant travel distances, stigma, and lack of insurance and other resources to access the scarce mental health services that do exist.[1]

Despite this difficult picture, rural primary care and specialty mental health clinicians have persevered to provide some level of mental healthcare to people in rural areas. Over the last decade, improvements in clinical screening tools, treatment protocols and guidelines, and information technology have significantly enhanced the potential to increase access to and improve the quality of mental health services in rural communities, particularly to underserved populations. Recent policy initiatives hold much promise to provide the structural and financial support necessary to help rural communities realize these improvements.

> *"...60% of rural residents live in mental health professional shortage areas ... [and] ... 65% receive treatment for mental health problems from their primary care providers...."*

In this commentary, we first present a general discussion of the issues related to the delivery of mental health services in the United States with particular attention to how these issues complicate the delivery of services in rural areas. Next we describe the renewed call for integrating primary care and mental health in rural areas (hence "the once and future role of primary care" in our title) and related clinical and policy support to do so. We close by briefly describing the policy interventions and resources needed to further these integration efforts and to improve access to services for rural underserved populations.

Our Fragmented Mental Health Delivery System

The mental health delivery system in the United States is characterized by a fragmentation of services, separation of funding streams and delivery systems, poor reimbursement, inadequate access to specialty mental health providers, and the mal-distribution of existing resources. These issues greatly complicate the delivery of services in rural areas.

The United States mental health system is not a coordinated system of specialty mental health services but, rather, a fragmented collection of services and providers that has come to be known as the *de facto* mental health "system."[2,3] The term "system" is used to convey an understanding of where persons receive services, rather than to suggest a coherent whole that has developed according to a set of organizing principles.[4] Regier and colleagues identified four sectors where individuals may seek assistance for their mental health needs: (1) *specialty mental health*, (2) *general medical/primary care*, (3) *human services*, and (4) *voluntary support networks*. Our discussion will focus on the first two sectors, which make up the formal treatment system in most communities.

The *specialty mental health sector* is made up of psychiatrists,

David Lambert, PhD, is an Associate Professor at the Maine Rural Health Research Center, Muskie School of Public Service, University of Southern Maine. He can be reached at dlambert@usm.maine.edu or PO Box 9300, Portland, ME 04104-9300. Telephone: 207-780-4502.

psychologists, psychiatric nurses, and social workers practicing in various public and private inpatient, outpatient, residential, and community agency settings and is the sector that comes to mind when people think about mental healthcare. The *general medical/primary care sector* is made up of general and family physicians, pediatricians, internists, nurse practitioners, and physician assistants providing a range of healthcare services, including, but not limited to, mental health services.

Contributing to this fragmentation of services has been the historical separation of funding streams and governmental responsibility for oversight of service delivery. Mental health and substance abuse services have traditionally been viewed as separate and apart from the general medical system. These services have typically been reimbursed at lower levels than general health services and often through separate pots of money. The separation of funding streams continues through the use of carve-out programs by many state Medicaid programs and commercial insurance companies in which a behavioral managed care organization is responsible for the management and approval of mental health services. Responsibility for the oversight of the delivery of mental health and substance abuse services at the state level is typically housed in a separate state mental health agency. Some states further fragment these services by assigning responsibility for the oversight of substance abuse services to a separate substance abuse agency.

Populations Served

The delivery of mental health services has historically been based on the specialty care model in which mental health specialists treat mental health problems and primary care providers assess and refer patients to these specialists as necessary. The use of this specialty care model fails to explicitly acknowledge the reality that most people seeking mental healthcare fall into one of two broad populations.[5] The first is the special population of adults with serious and persistent mental illness and children with serious emotional disturbances. The second population is the general population of individuals who frequently have more modest and episodic mental health needs (in comparison to the special population).

Members of the special population, who are often covered by Medicaid as a result of their mental health diagnosis and/or disability, are best served by the specialty care system and often require specialized services, such as congregate housing, vocational services, and crisis services. Members of the general population, whose needs may often be appropriately met within the primary care system, are often "encouraged" to seek services through the specialty mental health system due to reimbursement and/or health plan coverage issues. Given the separation of services and delivery systems, poor reimbursement rates, the reliance on the use of the specialty model by third party carriers, and the growing demand for services within the general population, the supply and distribution of specialty mental health providers and services are inadequate to meet existing needs, particularly in inner cities and rural areas.

The Special Challenges of Delivering Mental Healthcare in Rural Areas

Rural residents, like their urban peers, experience a wide range of mental health and substance abuse problems. National mental health epidemiological studies show little or no differences in the prevalence of mental health problems among adults across rural and urban areas.[6,7] While the prevalence of mental health disorders is similar, the composition and context of mental healthcare is profoundly different in rural and urban areas.[4] The New Freedom Commission on Mental Health (2004) suggested the following framework in which to consider these differences:

- *Accessibility.* Rural residents travel further to receive services than urban residents; are less likely to have insurance benefits for mental healthcare; are less likely to recognize mental illnesses and understand their care options; and enter care later, sicker, and with a higher level of cost.[8,9]
- *Availability.* Rural areas have chronic shortages of mental health professionals (60% of rural residents live in mental health professional shortage areas); few comprehensive services; and providers that are physically isolated from each other and their patients.[10,11] Rural residents rely more heavily on informal supports and indigenous healers than do urban residents and are more likely to be treated in a primary care setting (65% receive treatment for mental health problems from their primary care providers).
- *Acceptability.* Even when scarce services are available and accessible in rural communities, they may not be acceptable to people living in a rural area because of stigma, which is particularly intense in rural areas where anonymity is difficult to maintain; cultural issues; and limited or non-existent choice of providers.[12,8]

In many ways, mental health providers in rural mental health systems are even more "de facto" than those in urban areas.[13] Rural mental health practice is characterized by a lack of available services, scarcity of resources, severe shortages of specialized mental health practitioners and providers, the under-utilization of services, the impracticality of specialization, and a recognition that clients must be supported beyond the narrow range of medically necessary specialized mental health services.[14]

At present, more than 90% of all psychiatrists and psychologists and 80% of master's-level social workers work exclusively in metropolitan areas, a workforce distribution that has remained remarkably constant over the years. This maldistribution has persisted for more than 30 years despite repeated efforts to overcome existing market forces and encourage more mental health providers to practice in rural areas. The failure of these efforts can be traced to the challenges faced by mental health clinicians who chose to practice rural areas. They are often called upon to treat patients outside of their fields of expertise, reach complex decisions without the advice of other professionals, interact with patients in a variety of nonclinical roles, and are

Piloting Mental Health Integration in the Community Care of North Carolina Program

The Community Care of North Carolina (CCNC) Program is a statewide initiative comprised of 15 networks serving more than 660,000 Medicaid enrollees in approximately 1,000 participating practices. In these networks, providers are expected to take responsibility for managing the care of their enrolled Medicaid population. Each network designates clinical and administrative leadership to work in partnership with the state to design and develop clinical improvement and cost containment initiatives. In recent years, networks in the CCNC program began to see an increasing number of Medicaid enrollees at primary care provider practices with both behavioral and physical healthcare needs. As a result of efforts in mental health reform and changes in the local service delivery infrastructure, four CCNC networks working in concert with their local management entities (LMEs) began piloting (in July 2005) a collaborative approach to managing the Medicaid enrollees with both behavioral and physical health needs and to serve them in the most appropriate setting. This mental health integration pilot is a state-level collaboration between the Division of Mental Health; the Division of Medical Assistance; the Office of Research, Demonstrations, and Rural Health Development (CCNC Program Office); and the North Carolina Foundation for Advanced Health Programs, Inc.

In the mental health integration pilots, the networks aim to do the following: increase the comfort level of primary care providers (PCPs) in identifying and treating people with depression who present in their offices; improve communication between the PCP and behavioral healthcare providers; implement psychiatric telephonic consultations; ensure, through improved coordination, that patients are able to access care at a point in the system where their health and behavioral health needs can be optimally met; and, adopt uniform process and outcome measurements for program evaluation. These pilot projects are targeting both the adult and pediatric populations (cohorts broken out by age, birth to five years and five years and older) using the "Four Quadrant Clinical Integration Model"[1] as the foundation for communication, collaboration, assessment, referral, and clinical management of care. As described by Barbara Mauer, the four quadrant model serves as a conceptual framework for collaborative planning in local healthcare delivery systems—using the framework to decide which providers will do what and how coordination for each person served will be assured.[1] The four quadrant model categorizes individuals based on the degree of clinical complexity, health risk, and functional status. For example, quadrant IV is indicative of those with both high behavioral health and physical health needs.

Data collection will be comparable across projects since common forms and tools have been developed and adopted, including a telephonic consultation form, behavioral health assessment form, case consultation request form, and provider surveys. In addition, based upon the patient's age, a common set of primary screening tools were chosen: the Ages and Stages Questionnaire (ASQ),[2] Parents' Evaluation of Developmental Status (PEDS),[3] Pediatric Symptom Checklist (PSC),[4] and Patient Health Questionnaire (PHQ-9).[5] All four pilot networks are implementing a universal screening tool and a clinical pathway for depression. Evaluation efforts by individual pilots are examining the following: impact of incentives to PCPs for completion of behavioral risk screening; value of different population management strategies; identification of primary care provider screening tools that work best for anxiety, bipolar, and attention deficit disorder; value of co-location models with a behavioral specialist in the PCP practice; impact of integrating with the school system; impact of ongoing educational sessions and "collaborative rounds" to improve communication and collaboration between PCPs and mental health providers; and, use of dedicated case managers.

North Carolina has invested in the development and implementation of the CCNC network infrastructure, which provides an ideal testing ground for innovative models and strategies. The foresight to invest in the development of community-based networks able to partner with the state in managing our most vulnerable citizens is a result of dedicated and visionary leaders at both the community and state level. The lessons learned in the mental health integration pilots will be used to guide the formation of Medicaid mental health policy and assist in forming targeted statewide training and technical assistance. The strategies and plan design models developed and implemented in the pilots will support the replication and expansion efforts in other networks and communities. A model that is able to integrate behavioral and physical healthcare needs will demonstrate the value of a chronic care management model that is patient-centric and able to identify and meet all the needs of an individual.

NOTES

1 Mauer, BJ. Behavioral Health/Primary Care Integration–the Four Quadrant Model and Evidence-Based Practices, Winter 2004, National Council for Community Behavioral Health Care, 2002.

2 Ages and Stages Questionnaire (ASQ) is a parent completed questionnaire. The questionnaire is age specific for children from four to 60 months of age. Questions are in five areas: communication, gross motor, fine motor, problem solving, and personal/social. Sensitivity is 72%, and specificity is 86%.

3 Parents' Evaluation of Developmental Status (PEDS) is a parent-completed questionnaire. The same ten questions are used for all children from birth to eight years of age. Sensitivity is 74-80%, and specificity is 74-80%.

4 Pediatric Symptom Checklist (PSC) is a questionnaire with 35 short statements of problem behaviors to include both externalizing and internalizing. The questionnaire is used for children ages four to 18 years. Sensitivity is 80-95% (all studies except one showed this level of sensitivity), and specificity is 68-100% (scattered across studies).

5 Patient Health Questionnaire (PHQ-9) is a symptom checklist for depression screening. Responses range from "not at all" to "nearly every day." Based on the response, a score is assigned.

Denise Levis, RN, BSN, MSPH, is the Quality Improvement Director for the Community Care of North Carolina Program. She can be reached at denise.levis@ncmail.net or PO Box 10245, Raleigh, NC 27605. Telephone: 919-715-1088.

subject to professional isolation and a high potential for burnout.[15,16] Rather than wishing for resources that we don't have and that history tells us that we may not achieve, we need to develop a national rural mental health plan that rationalizes our current system and capitalizes on our existing strengths and resources.

The end result is that many rural Americans rely heavily on the primary care system as their source of mental healthcare.[17] In fact, many rural residents express a preference for receiving mental health services through their primary care providers, given the issues of stigma and the perceived lack of confidentiality due to the small town environment (in which everyone knows your business). In many ways, these pressures are positioning rural communities to lead the way in developing rationalized systems of care in which primary care providers are an integral part of the mental health delivery team.

Renewed Calls for the Integration of Mental Health and Primary Care

Although discussions of the integration of primary care and mental health in rural areas date back to the early 1970s, a number of national reports and studies have signaled a renewed interest in and policy support for efforts to strengthen integration efforts among rural providers. The Surgeon General's Report on Mental Health acknowledged the crucial role of primary care in providing mental healthcare.[1] The President's New Freedom Commission on Mental Health (2003)[18] promoted integration of primary care and mental health to help address access problems in rural areas. The National Advisory Committee on Rural Health and Human Services' Report to the Secretary (2004) and the national Institute of Medicine's Quality Through Collaboration: The Future of Rural Health Report (2005)[19] call for integrating mental health with rural primary care. Mental health expansion and new access points grants, created under the President's New Access Initiative, provide funding for Community Health Centers (CHCs) to deliver behavioral health services.[20]

Resources Needed to Enhance the Integration of Mental Health and Primary Care Services in Rural Areas

Over the past decade substantial progress has been made in developing tools and resources to support the integration of mental health and primary care services. These tools and resources include a variety of screening tools, evidence-based practices, and best practice models. Legislative changes provide cost-based reimbursement for Rural Health Clinics employing doctoral-level psychologists and clinical social workers. The Bureau of Primary Health Care provides grant funding to support the development or expansion of mental health services by CHCs. The Bureau also supports the development of Health Disparities Collaboratives by CHCs using Ed Wagner's chronic care model to treat patients with chronic conditions including depression.[21]

It is no longer a question for a rural practice of how to get started but, rather, how to sustain these activities over time in a day-to-day practice setting.[22] The delivery and coordination of mental health services in a primary care practice require a balance between the provision of integrative services (e.g., coordination with primary care providers in the practice as well as external specialty care providers, engaging patients in the treatment process, educating clinicians and staff, etc.), which are frequently not reimbursable and more traditional assessment and counseling services which are.[22]

Additional tools and policy interventions are needed to further the expansion of these efforts. These include: (1) the development and implementation of electronic medical records to support clinical integration and communication; (2) continued provision of mental health expansion and new start grants by the Bureau of Primary Health Care; (3) the development of federal and state policies to compensate for the limited access to specialty mental health services; (4) support for the expanded use of telemedicine technology to provide access to psychiatric consultative support in rural communities; and (5) the provision of third party reimbursement and support for the delivery of mental health activities in rural practices, including reimbursement for integrative activities and the inclusion of these primary care practices in Medicaid and commercial behavioral managed care plans.

The integration of mental health and primary care services is a policy goal whose time has come. Due to long-standing resource constraints, rural communities and practices have led the way in developing integrated models of care, often in the face of limited financial and administrative support. For further progress to be made, we must acknowledge the challenges related to the integration of these services and develop policy interventions, training tools, and technical assistance to overcome them. **NCMedJ**

Leadership Development for Rural Health

Tim Size

Rural health has come a long way, but has a long way to go. With hindsight, some might minimize Jim Bernstein's leadership, now unaware that much of what he did for rural health was initially just an idea, a hope. It is this midwifing of a vision into reality that is the very essence of leadership. Henry David Thoreau described Jim's caliber of leadership when he wrote the oft repeated lines, "If a man does not keep pace with his companions, perhaps it is because he hears a different drummer. Let him step to the music which he hears, however measured or far away."[1] Jim Bernstein leaves a legacy that continues to challenge all of us to care and to achieve more than we first thought possible, whomever our drummer, whatever our position.

On July 15th, 2005, the National Advisory Committee on Rural Health and Human Services advisory to the Secretary of the United States Department of Health and Human Services, adopted a Special Resolution to honor James Bernstein, which concluded with the following: "The Committee believes that the best way to honor Jim is to consciously work to help develop the next generation of rural health leaders. Jim was a master of creating change by working within the existing policy framework and helping others to build sustainable programs that addressed long-standing problems. The Department should play a lead role by developing a program that identifies emerging leaders from and for rural communities and provides them with the training and resources to play a lead role in ensuring access to quality healthcare in their states and communities. This program warrants long-term support by the Department, and it should focus on rural needs within the larger policy context that affects us all. The Committee urges the Secretary to take the lead on this initiative, which will serve as a reminder of all of Jim Bernstein's fine work."[2]

While I can see/hear Jim wincing at the focused personal attention, I know he would put up with it to help further develop rural health, a process that must include understanding our past. I believe he would also be the first to remind us of the many people who are called to exercise leadership in both large and small ways.

> *"Leaders recognize that none of us are called to always lead, that sharing or conceding leadership to others is also a key role."*

This commentary is a personal statement without presuming to be writing the definitive word on what we need to know to further develop rural health leadership. My intent is to express belief as belief and not individual belief as universal truth, a convention too common today in our national "dialogue." The reader is invited to engage with what he or she reads here, taking what might be useful, and hesitating a moment to think through what might be useful, but doesn't immediately seem so. This is a "conversation," not a lecture.

What Is Leadership Development and Why Do We Need It?

The weekend I received the opportunity to write this commentary, our church was celebrating those living or dead who made a contribution to our faith and various communities. That service brought forth the image that individuals who exercise leadership are like a river's current—a part past where we now stand, a part yet to come. We have an ongoing need to remember and to look toward the next "generation." Rural leaders will arrive without the assistance of any of us, but deliberative leadership development will foster more effective and diverse leadership. A key responsibility of those here now is to mentor and to create structures for mentoring, in order to maximize the flow and effectiveness of tomorrow's leaders.

Leadership is the capacity to help transform a vision of the future into reality. This commentary focuses on *leadership* development more than *leader* development to emphasize that throughout our organizations and communities, we have and need individuals who may not be formally designated as leaders, but who can and do exercise leadership. Leaders recognize that none of us are called

Tim Size, is the Executive Director of the Rural Wisconsin Health Cooperative. He can be reached at timsize@rwhc.com or PO Box 490, Sauk City, WI 53583. Telephone: 608-643-2343.

to always lead, that sharing or conceding leadership to others is also a key role. None of us are called to lead on every issue; all are called to interact and support the vision and ideas brought by others.

We need to recognize that in addition to individuals having the potential to exercise leadership, the potential of leadership also exists "corporately," in groups of individuals, whether they are teams, organizations, or communities. Individually and collectively, at all levels, we are called to lead in one place or another and are "born" with traits that can both enable and interfere with that opportunity and responsibility. Wherever the individual or group starts, learning and growth are possible. We need to structure leadership development for groups and communities as well as individual leaders.

Leadership development, formal or informal, is not just for the chronologically young. I have a friend who for many years has been a newspaper reporter and columnist as well as the chaplain for a mission that works with our city's poor and addicted people. He has arrived at "retirement" age, but many of his readers are now seeing a columnist who speaks with a profoundly clearer voice. Some of the paper's readers who disagree with him would undoubtedly welcome the news of his retirement; so be it, leadership necessarily brings out in good measure both supporters and detractors.

Leadership comes in many contexts. Jim Bernstein and I talked more than once about the similarities and differences in our vocational situations. We held in common that we were born and raised "elsewhere," but became deeply rooted in our adopted home states. I work with mid-western rural communities facing relatively more racial homogeneity and less extreme poverty. These communities have a strong tradition of agricultural cooperatives that enabled our development of a cooperative of community hospitals—hospitals that work with and challenge both our state and our universities. Jim worked with southern rural communities facing more racial diversity and often extreme, community-wide poverty. He was able to be innovative from a position inside of government. Jim was notable in the respect and understanding he offered those working in a variety of circumstances.

A friend recently shared with me a few of the leadership challenges she faces, which are unique to her role as the chief executive officer of a hospital in a rural community. This commentary will not catalog such challenges, but her comments serve as a reminder for the "in the trenches" reality that rural health leadership development initiatives must address. "It is easy to become isolated, I am the only person doing what I do in our community. We are much smaller than most of our urban counterparts, so I need to juggle the crunch of many required 'to dos' without the luxury of additional staff who can take the ball from start to finish. And when first arriving, it was not unusual to have a 'new gal/guy in our community trying to tell us what to do' type greeting. 'She or he will be gone and never give us another thought.' "

The Role of Nature and Nurture

At one time, people tended to believe that leaders were born, not made. Now we tend to see leadership as a set of traits that can be nurtured. But what about nature, the traits we are born with? A while back, I was asked when I became an advocate. The answer was that we all receive some traits at birth, or shortly thereafter. "One of my most vivid memories of home in the late 1950s is the endless kitchen argument with my devout Baptist mother on the theory of evolution. Her particular tenacity on this issue may be traced to her childhood memories of her guardian's friend, William Jennings Bryan, the famed attorney on the then winning side of the 'Scopes Monkey Trial.' But like many women of her generation raised in the shadow of the old south, she had a finely tuned nature of smiling and cajoling while not giving an inch."[3] On the way to the rest of my life, I realized that what we did have in common was an innate passion to talk, and to never concede. Yes, nature matters, but it need not be determinative. Subsequently, with the help of a very well-financed Kellogg leadership program, others were able to teach me not to use a rhetorical cannon when a rifle was sufficient, and that once in a while, a concession wouldn't kill me.

America has a complex heritage when it comes to how it thinks about leaders—accepting contradictory leadership styles. We call the strong, individualistic characters, such as played by John Wayne, classic American leaders. Democrats and Republicans honor Jimmy Carter's leadership, whose less autocratic emphasis on partnership makes him a contender for "the country's most successful ex-President." We understand that leadership is not limited to the classically cinema-charismatic or those holding formal power, as Rosa Park's "simple" act of saying "no" will forever testify.

How our culture holds these apparent contradictions is not well understood. Robert Frost's poem "Mending Wall" set on a New England farm is most famous for the line "Good fences make good neighbors," a frequent citation of American individualism. But it is a better example of not reading a whole poem. Frost goes on to say, "I let my neighbor know beyond the hill, and on a day we meet to walk the line and set the wall between us once again…." Even this icon to self-sufficiency is expressed within the cultural context of selective cooperation.[4]

To develop as a leader, we must understand how leadership has unfolded in our own lives. A key initial transition is to recognize and accept "for better, for worse" what characteristics one has "hard wired" and then begin to see how one can develop further. This is also a precondition for those intending to take on the role of leader recruiter or mentor.

In my own development, a key step forward happened in my mid-20s while working as an "assistant superintendent" at a university hospital. As quickly as a light switch is turned on, I was lucky one day to realize that maximizing program successes was not the same as minimizing program failures. This eventually led to a transition from state government, which I experienced as being risk adverse, to an organization in the non-profit sector, which has allowed calculated risk taking. The operative word is

"I experienced." Jim Bernstein is the obvious counter example, having taken many risks and had many successes from a base within state government.

Risk taking requires comfort with failure, one of life's most powerful teachers. A while ago, I was asked to address how I maintain energy in the face of so many failures. I was taken off guard because I didn't think of myself as having had that many failures. Upon reflection, I was able to easily come up with a list of ten failures, many of which in less charitable circumstances would have involuntarily led me to "pursue a new career opportunity." I just hadn't been keeping a tally, and I still don't.

For us to have integrity as leaders, we have to continue to work to know who we are as we relate to our work. A timeless illustration is found in Chinese philosopher Chuang Tzu's "Woodcarver," written about 2,300 years ago:

> Khing, the master carver, made a bell stand
> Of precious wood. When it was finished,
> All who saw it were astounded. They said it must be
> The work of spirits.
> The Prince of Lu said to the master carver:
> "What is your secret?"
>
> Khing replied: …
> "What happened?
> My own collected thought
> Encountered the hidden potential in the wood;
> From this live encounter came the work
> Which you ascribe to the spirits."

The best explanation of this poem I know is in Parker Palmer's renowned work on vocation, an *Active Life*:[5]

> …we both act and are acted upon, and reality as we know it is the outcome of an infinitely complex encounter between ourselves and our environment. In this encounter we do some shaping, to be sure, but we are also shaped by the relational reality of which we are a part. We are part, and only part, of the great community of creation. If we can act in ways that embrace this fact, ways that honor the gifts we receive through our membership in this community, we can move beyond the despair that comes when we believe that our act is the only act in town…. When authentic action replaces unconscious reaction, the active life becomes not (in the words of Chuang Tzu) 'a pity' but a vital and creative power.

As noted by Parker Palmer, how we choose to frame or understand our relationship with others and our environment is critical to our growth as leaders. My best example occurred in graduate school, or more specifically in the dormitory elevator in graduate school. It was Chicago's oldest and slowest Otis elevator—it took an "eternity" to go the 12 stories to my room. One day it hit me that my frustration wasn't the result of the elevator, but my unrealistic expectation of its behavior. Subsequently, I still thought it was slow, but I didn't worry about it. So how do we frame rural health leadership? What kind of elevator is it? If we make the right investments, what kind of elevator can it become?

Servant Leadership and Rural Health

The concept of "servant leadership" is a perspective held by many throughout the rural health community, and I believe is a major frame for understanding the attributes of leadership we need in rural health. Robert Greenleaf, the man who coined the phrase servant-leadership described it as "the servant-leader is servant first…. It begins with the natural feeling that one wants to serve, to serve first. Then conscious choice brings one to aspire to lead."[6] I don't believe he is saying "natural" as in the sense "natural athlete," but that at some point in life, the feeling arises to serve, which in turn leads to a decision to exercise leadership. What are the attributes of servant leadership; what characteristics or skills must we look for when we recruit a leader or should we look for when we learn, teach, and reinforce? For me, a good start to that question is to compare the attributes of "servant" and "traditional" leaders. Cooper McGee and Duane Trammell do just this in "Hero as Leader to Servant as Leader."[7]

Examples of Traditional Leadership Skills

- Highly competitive; independent mindset; seeking personal credit.
- Understands internal politics and uses them to win personally.
- Focuses on fast action.
- Controls information in order to maintain power.
- Accountability is more often about who is to blame.
- Uses humor to control others.

Examples of Servant Leadership Skills

- Highly cooperative, interdependent; gives credit to others generously.
- Sensitive to what motivates others to win with shared goals and vision.
- Focuses on gaining understanding, input, buy-in from all parties.
- Shares big-picture information generously.
- Most likely listens first, values others' input.
- Accountability is about making it safe to learn from mistakes.
- Uses humor to lift others up.

Our Health Needs Collaborative Leaders

I had the opportunity to serve on the national Institute of Medicine's (IOM) Committee on the Future of Rural Health Care. For me, the major breakthrough in the Committee's work as documented in the report, *Quality Through Collaboration: the Future of Rural Health*,[8] was that the IOM's Six Quality Aims (originally constructed for the healthcare of the individual) apply equally well to a population health perspective, or said another way, "the community as patient."

This perspective that we need to "balance and integrate personal healthcare with broader communitywide initiatives that target the entire population,"[9] developed after the committee applied the IOM report, *Fostering Rapid Advances in Health Care: Learning from System Demonstrations*,[9] to rural health. Examples of applying the IOM's Six Quality Aims for a population health perspective include:

- *Safety*: Road construction designed to reduce auto accidents.
- *Effectiveness*: Public schools act to reduce risk of obesity/diabetes.
- *Community-centered*: Regional provider networks respect community preferences.
- *Timeliness*: Timely identification of epidemics.
- *Efficiency*: Public reporting of population-based measures of health status.
- *Equity*: Developing, maintaining rural jobs.

The Committee on the Future of Rural Health Care synthesis was that "rural communities must build a population health focus into decision-making within the healthcare sector, as well as in other key areas that influence population health. Most important, rural communities must reorient their quality improvement strategies from an exclusively patient- and provider-centric approach to one that also addresses the problems and needs of rural communities and populations."[8] This vision constitutes a major opportunity for rural health leaders to lead the health of our country, all of it. The "central thesis" of the recently published compendium *Reinventing Public Health, Policies and Practices for a Healthy Nation* makes the same point "to effectively improve population health and reduce health disparities, policy making in a variety of domains must take into account policies that address the fundamental social, economic, and ecological determinants of health."[10]

As an example, in Wisconsin, a voluntary coalition has developed a Strong Rural Communities Initiative (SRCI) to support the state's health plan by implementing sustainable rural models for medical, public health, and business collaboration to enhance preventive health services in rural Wisconsin. In *Wisconsin County Health Rankings 2005*,[11] a report by the Wisconsin Public Health and Health Policy Institute at the University of Wisconsin-Madison, 52% of metro counties in Wisconsin are in the top (best) quartile for Health Outcomes compared to only 11% of non-metro counties; 30% of non-metro counties are in the bottom (worst) quartile compared to 16% of metro counties. The specific purpose of SRCI is to improve health indicators for selected rural communities in Wisconsin and significantly accelerate establishing collaboration for prevention as the norm, not the exception, in rural Wisconsin.

The complexity of creating a healthy state requires a higher level of cooperation than any of us have yet experienced. This requires a significant expansion in our commitment and ability to develop collaborative leadership. Again, from *Quality Through Collaboration: the Future of Rural Health*:[8]

> Strong leadership will be needed to achieve significant improvements in health and healthcare in rural communities. Comprehensive community-based efforts will require extensive collaboration, both between stakeholders within the healthcare sector, and between healthcare and other sectors. It will be necessary to mobilize all types of institutions (e.g., healthcare, educational, social, and faith-based) to both augment and support the contributions of health professionals. Rural communities engaged in health system redesign would likely benefit from leadership training programs.[8]

Principles of Collaborative Leadership

The significant challenges we face today in healthcare require a form of leadership that is less authoritative and more collaborative. Ronald Heifitz and colleagues at the Stanford Graduate School of Business say it very well. These "problems require innovation and learning among the interested parties, and, even when a solution is discovered, no single entity has the authority to impose it on the others. The stakeholders themselves must create and put the solution into effect since the problem is rooted in *their* attitudes, priorities, or behavior. And until the stakeholders change their outlook, a solution cannot emerge."[12] It is important to not confuse being collaborative with endless stanzas of singing "Kum By Ya;" collaboration frequently requires strong external catalytic action.

Max DePree, in *Leadership Is an Art*,[13] offers a model for employer-to-employee relationships based on his experience that productivity is maximized by designing work to meet basic employee needs. His vision of the art of corporate leadership brought employees into the decision-making process. DePree's experience is primarily within the world of the Fortune 500, but many have found him to offer a useful framework for non-profit and public sectors.

While DePree was a successful leader of a Fortune 500 Company, some may describe him as impractical, a common descriptor thrown by the "pragmatists" at "collaborators." Robert Greenleaf offers a suggestion that may be helpful in thinking through this dilemma: "For optimal performance, a large institution needs administration for order and consistency, and leadership so as to mitigate the effects of administration on initiative and creativity and to build team effort to give these qualities extraordinary encouragement."[14]

As the executive director of a cooperative of rural hospitals for more than 25 years, it is easier for me than for many to see rural health through the lenses of collaboration, the opportunities it creates, and the threats it endures as a model for organization and community work. We have adopted and adapted DePree's eight leadership principles as a guide for both our internal and external relationships. To illustrate these leadership principles, the following is as described in the article "Managing Partnerships: The Perspective of a Rural Hospital Cooperative."[15]

There Is Mutual Trust—Develop relationships based primarily on mutual trust so that the cooperative go beyond the minimum performance inherent in written agreements. "While responding to a rapidly changing market in 1984, the implementation in six months, 'from scratch,' of a rural-based health insurance company in Wisconsin was only possible due to the prior existence of a basic level of trust among the key actors."

Commitment Makes Sense—Participants may join a cooperative to explore its potential; they remain only if they perceive that they are receiving a good return on their investment of time and money. "RWHC offers a broad array of shared services from which hospitals pick and choose according to their individual needs; commitments are made because they have been structured in a way that attempts to maximize the 'fit' for each individual participant."

Participants Needed—Each organization must know that it is needed for the success of the cooperative. "It is a major mistake to ever take for granted the participation or commitment of any member. The RWHC communication budget is ample testimony to the importance of early and frequent communication and consultation."

All Involved in Planning—The planning is interactive, with the plan for the Cooperative being the result of, and feeding into, the plans of the individual participants. "One theatrical but powerful example of ignoring the need for local input and preferences involved the Cooperative within months of its incorporation in 1979. Two regional health planners were practically driven from the bare wood stage of Wisconsin's historic Al Ringling Theater after their presentation of a unilaterally developed plan for local consolidations and closures. The plan was not implemented and did not contribute to further discussion of how rural healthcare in southern Wisconsin could be improved."

Big Picture Understood—Participants need to know where the organization is headed and where they are going within the organization. "RWHC has a motto: 'say it early and keep saying it.' A number of RWHC's more significant initiatives, such as improving rural hospital access to capital, various quality improvement projects, and advocacy for major education reform within the University of Wisconsin's health professional schools has been multiyear if not indefinitely long efforts."

Participants Affect Their Own Future—The desire for local autonomy needs to be made to work for the Cooperative through the promotion of collaborative solutions that enhance self-interest. "When RWHC began operations, many observers were highly skeptical about whether or not it would last, let alone make any real contribution—that rural hospitals' traditional need for autonomy would prevent any meaningful joint activity. Some shared services have been undersubscribed as hospitals have chosen local options when, at least from the perspective of RWHC staff, a cooperative approach offers a better service at a lower cost."

Accountability Up Front—Participants must always know up front what the rules are and what is expected of them. "Discussions at RWHC board meetings are frequently comparable to customer focus groups and equally valuable. Participation in all Cooperative shared services requires a signed contract, not so much as to permit legal enforcement, but to ensure that all parties in the partnership have thought through upfront the expectations of all the participants."

Decisions Can Be Appealed—A clear non-threatening appeal mechanism is needed to ensure individual rights against arbitrary actions. "The use of the cooperative strength of RWHC hospitals has been used to enforce an appeals process in a variety of circumstances, including a potential breach of contract by a large health insurer; individually, few could have justified the necessary prolonged legal challenge to enforce the contract but through concerted joint inquiry into the legal options available, further legal action became unnecessary."

Recruiting Rural Health Leaders

When recruiting organizational leaders, the recruitment and interview process must seek individuals who in addition to technical competence, also have demonstrated leadership in their prior work and activities. John Gardner, in his classic work, *On Leadership*,[16] notes six characteristics common to individuals who exercise organizational leadership. These characteristics are exhibited in many roles, for example, as the head of an organization, as a manager, or in a volunteer position:

- They think longer term—beyond the day's crises, beyond the current fiscal year.
- In thinking about the program or organization they are heading, they grasp its relationship to the larger organization or community—conditions external to the organization.
- They reach and influence constituents beyond their immediate area of responsibility.
- They emphasize the intangibles of vision, values, and motivation and understand intuitively the non-rational and unconscious elements in their relationship with their constituents.
- They have the political skills to cope with the conflicting requirements of multiple constituents and expectations.
- They think in terms of renewal. The leader or leader/manager seeks procedural and structural change consistent with an ever-changing reality.

In addition, as argued throughout this commentary, collaboration needs to be a core competency for leadership of those organizations claiming to work in or with rural communities. The following are a few examples of principles relevant to collaboration to keep in mind or discuss when recruiting or developing a leader.

Collaborative Leadership Isn't Always Traditional—If leadership is serious about maintaining and developing collaborative relationships, the following must be kept in mind:

- Management practices necessary for successful collaboration are not commonly seen in traditional, vertically organized institutions.
- Most administrators have had little experience, and even less training, regarding leadership within the context of collaborative models.
- The "natural" administrative response will frequently come out of traditions that may be inconsistent with the actions needed to support networking.

- The development of collaborative relationships has a different timescale than those based on authority—more time on the front end paid off later with less participant resistance.

Personal Attributes of a Collaborative Leader—A partial list of the personal attributes relevant to seeking or developing a collaborative leader include:

- Experience/potential for leading collaborative enterprises or networks, cultural competence across diverse communities and populations.
- When looking at alternative investments: the objectivity of an academic, the pragmatism of a businessman or woman, and the creativity of an artist.
- Appreciation for the dualities inherent in American culture—individualism and community, competition and collaboration; a realistic understanding of the health system challenges we face balanced by an "irrational" optimism and faith that we each can make a difference.
- A vision that leadership needs to be simultaneously top down and bottom up within organizations, as addressed by Max DePree.

Collaborative Leadership Skills and Experience—Below are a set of general questions intended to stimulate conversation regarding an individual's collaborative leadership skills and experience.

- What is the role of "trust" in your work with colleagues or partners? What examples can you offer of your ability developing trust in these "partnerships"? How did you do it? How was the relationship affected?
- How have you been able to make your collaborative partners feel useful?
- How have community partners been invited into your organization? What did you see as benefits and challenges in these instances? How would you do it differently today?
- In what ways have you worked to promote collaborative solutions that have enhanced the self-interest of both internal and external partners?

Summary

Leadership is the capacity to help transform a vision of the future into reality. Individuals who can and will exercise leadership are like a river's current—a part past where we now stand, a part yet to come. We have an ongoing need to remember and to look toward the next "generation." A key responsibility of those here now, is to mentor and to create structures for mentoring, in order to maximize the flow and effectiveness of tomorrow's leaders. When recruiting organizational leaders, the recruitment and interview process must seek individuals who in addition to technical competence, also have demonstrated leadership in their prior work and activities.

To exercise effective leadership, we must work to know who we are, how we relate to others, and the environment around us. "Servant leadership" is a perspective held by many throughout the rural health community and offers a key set attributes of leadership useful to rural health. To implement the Institute of Medicine's recommendations in *Through Collaboration: the Future of Rural Health*, we must develop leaders skilled in collaboration, both internal to their organization and across organizations.

The National Advisory Committee on Rural Health and Human Services had it right when they said to the Secretary and to the rest of us, "the best way to honor Jim is to consciously work to help develop the next generation of rural health leaders." There are, of course, a multitude of leadership institutes, programs, and courses throughout America; this is not a call for yet another separate entity. But it is a call to each of us in rural health to assure that we are deliberate in how we identify "emerging leaders from and for rural communities and provide them with the training and resources to play a lead role in ensuring access to quality healthcare in their states and communities."[17] Let's get started. **NCMedJ**

COMMENTARY

What Outcomes Should We Expect from Programs that Pay Physicians' Training Expenses in Exchange for Service?

Donald E. Pathman, MD, MPH

Training to become a physician is expensive, as the four out of five medical students who graduate in debt will confirm.[1] Young physicians' educational debt averages over $109,000 and increases by more than $4,000 each year.[2]

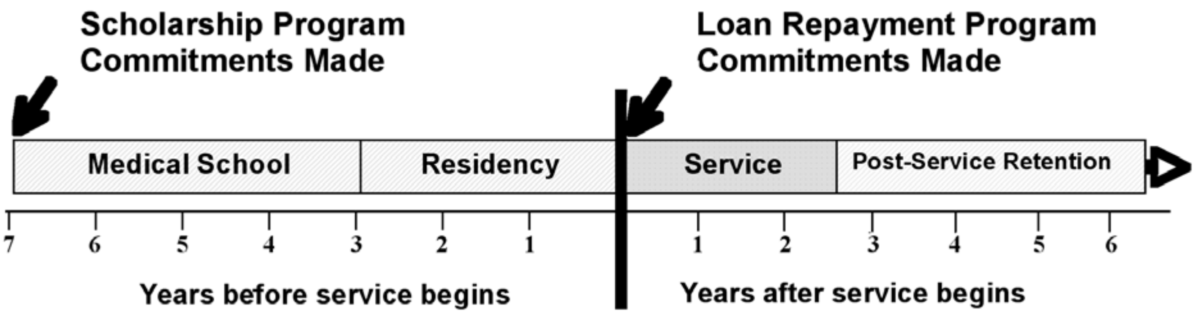
On the bright side, rising educational costs and students' fears of acquiring six-figure debts have created a market for government programs that link support for medical training costs to a period of obligated clinical work in physician shortage areas. One of the two most common types of such programs are service-requiring scholarships, which pay tuition and other costs for medical students while obligating them to a period of service that will begin when they complete residency five-to-seven years later (see Figure 1). The other common program type is loan repayment. Loan repayment programs recruit physicians as they complete residency and are ready to begin service in exchange for paying off the traditional education loans they acquired years earlier. Programs of both types typically require one year of service for each year of training cost support they provide.

These training support-for-service programs are a seemingly natural solution to both students' and the public's needs. They have grown in popularity over the past 25 years in tandem with rising tuition costs, with both federal and state agencies making ready use of them. The National Health Service Corps (NHSC)[3] currently fields an obligated physician workforce of about 1,700 scholars and loan repayers, and the Indian Health Service (IHS)[4] and Bureau of Primary Health Care[5] offer similar, but far smaller programs for physicians to work in Native American and Native Hawaiian communities. Most states also sponsor their own physician training support-for-service programs. There were a total of 69 state programs in 1996 with an estimated workforce of 1,300 practicing physicians.[6] These state programs doubled in number from 1990 to 1996 and very likely have grown further since.[6]

After 25 years of growth in these programs, the healthcare workforce advocates who lobby for them and legislators who create and fund them are not completely clear about some of their important aspects, including what outcomes can be expected. Without clear expectations, programs cannot evaluate themselves appropriately or be externally monitored, leaving program failings sometimes unrecognized and opportunities for strengthening programs unrealized.

This commentary takes the occasion of this special issue of the *North Carolina Medical Journal* dedicated to the life and work of Jim Bernstein to review what available research says

Figure 1.
Timeline of physicians' training years, signing of commitments with service-requiring scholarship and loan repayment programs, service periods (typically two-to-four years) and post-service retention.



Donald Pathman, MD, MPH, is Co-Director of the Progam on Health Professions and Primary Care at the Cecil G. Sheps Center for Health Services Research and a Professor and Research Director in the Department of Family Medicine, University of North Carolina at Chapel Hill. He can be reached at don_pathman@unc.edu or CB# 7590, Chapel Hill, NC 27599. Telephone: 919-966-4270.

about the outcomes possible from physician training support-for-service programs. Under Jim's 30-year leadership, the North Carolina Office of Rural Health became a nationally recognized leader in recruiting physicians to needy practice settings, in large part by perfecting programs of this type. Sixteen years ago, Jim guided and encouraged me and my colleagues at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) as we undertook our first evaluations of these programs, and the Office's ongoing councel has been invaluable.

> *"The key to long retention within service communities is to allow physicians to serve in well-run practices in communities that fit their needs, where they and their families can be happy and professionally fulfilled."*

The information and conclusions of this commentary are based on the findings of the most methodologically sound descriptive and outcome studies of the past 20 years, which are primarily cohort and cross sectional designs with appropriate comparison groups. Studies that were unable to control for statistical confounding, evaluations designed to find only positive outcomes (typically undertaken for program advocacy purposes), and testimonials were not used. The NHSC's Scholarship and Loan Repayment programs, the two largest programs in the United States, have been studied far more than other programs and, therefore, receive more attention in this discussion.

The Overarching Program Goal and Intermediate Measurable Outcomes

The fundamental public goal of support-for-service programs is to improve physician staffing in shortage area communities. To date, no studies have assessed whether communities that rely on service-obligated physicians indeed enjoy greater workforce growth in the long run than if they had relied only on traditional non-obligated physicians on the open market. Aside from the programs' overarching goal, there has been no general agreement on the measurable outcomes that legislators and the public should expect of these programs and, therefore, no agreement on the criteria by which programs should be evaluated. The outcomes most often discussed and studied reflect the intermediate accomplishments presumed to be necessary if programs are to achieve their long-term goal of improving physician staffing in shortage areas. These intermediate outcomes have included whether programs:

- fill all of their funded positions,
- select suitable physicians into the program and match them to individually appropriate communities,
- have their physicians serve in genuinely underserved communities,
- have high proportions of their physicians complete their service obligations, and
- have high proportions of their physicians remain many years in their service communities following their obligations.

These intermediate outcomes are considered, in turn, below.

Program position fill rates. Some programs, including the NHSC, have many more applicants than their funds can support and regularly fill all funded positions; other programs have many unfilled positions for lack of applicants.[7] Fill rate information for some programs is not reported or publicly available. Because many programs are able to fill all available positions year after year, any program that repeatedly fails to do so should assume that physician interest is being harmed in some way. Common ways programs reduce physician interest include offering unfavorable contract terms (e.g., financial benefits too small; penalties or service requirements too great), offering too few service site options from which physicians may choose, having poor program marketing, and/or having poor management. Mississippi's Family Medicine Education Loan/Scholarship program, for example, with its unprecedented ten-year service obligation, signed-up a total of only seven students from 2001 to 2004 despite having funding for 20 new students each year.[7] The legislature appropriately lowered the program's service requirement, but only to six years, which may still prove too lengthy to interest students.

Selecting appropriate physicians and matching them to individually appropriate sites. Appropriate physician selection criteria—the right demographics, backgrounds, motivations, and career interests—get much attention from some programs,[8] but available data suggest that they are generally not important to achieving program outcomes. Studies repeatedly find that the demographics and backgrounds of obligated and non-obligated physicians are generally not related to how satisfied they are in rural and underserved area practices nor how long they remain there.[9-11,a] Further, no studies have demonstrated that obligated physicians with certain demographics or motivations provide better care to patients in underserved practice settings. The quest for perfect

---

[a] Background characteristics *are* very important to who will freely choose to practice in rural and underserved areas (i.e., important to recruitment), but this is irrelevant when selecting among applicants to support-for-service programs. Recruitment factors are not the issue with physicians asking to work in these areas; only retention factors, and individual characteristics are not relevant to retention.

selection criteria sometimes reflects programs' unwillingness to accept responsibility for their shortcomings, shifting blame instead to their allegedly ill-prepared or overly self-centered workforces ("deadbeats").

Rather than particular physician characteristics, data suggest that only concordance between the needs and interests of obligated physicians and the practice site opportunities available through their service programs are key to the success of their physicians in underserved areas—physicians' satisfaction, communities' satisfaction, and physicians' retention. Whether a physician is male or female, was raised in a rural or urban area, graduated from a public or private school, or trained in family medicine or pediatrics are criteria that are generally irrelevant to program outcomes. No type of background or training will bring physicians meaningful contentment, enthusiasm for work, and long retention when the work and community settings don't fit them. Success for obligated physicians does often depend, however, on whether their program offers practice opportunities that meet their preferences, for example, to work in a community health center that provides hospital care for its patients and to live in a town large enough to support their spouse's law practice.[10,12] Physicians will usually succeed in practices that meet their career and family needs.

Matching participants to truly needy communities. Programs differ in the types of communities and practices where physicians are allowed to serve their obligations, in the number of specific sites they may choose from, and in how the match occurs. State programs, as a group, give greater latitude in the number and type of practices available, some allowing physicians to work in any practice in any rural county of their state.[6] For these programs, no listing of practice choices is created; physicians find their own sites from across eligible geographic areas. The most restrictive programs are the federal and a few state programs that have adopted a secondary program goal to support the physician staffing needs of publicly sponsored practices, like federally qualified health centers (FQHCs), Indian Health Service clinics, and prison health centers. Participants in these more restrictive programs must choose a practice site from a short list of limited options. Some programs go through elaborate steps to identify the few "most needy" sites eligible for physician placements—most notably the NHSC, which has designated health professional shortage areas (HPSAs), priority ranking of HPSAs, and annual restrictive Health Professionals Opportunity List (HPOL) of specific eligible sites from among priority HPSAs.

Using set criteria to rank need would seem to be a reasonable approach to limiting physician placements to the neediest communities. In practice, however, devising criteria of need and carrying out the designation and physician-to-community matching processes have proven problematic and contentious. The process by which HPSAs are designated, for example, has been criticized as politically influenced and evaluations have failed to find that communities with more critical HPSA ratings have worse physician shortages.[13,14] Site eligibility lists are notoriously out-of-date, which frustrates physicians who are trying to locate an appropriate service site. Using explicit NHSC site designation criteria serves principally to mollify practices (and their Congressional supporters) that aren't deemed eligible for physician placements and to justify the policy of using support-for-service programs as a staffing mechanism for publicly supported clinics. Using short service-site availability lists to serve these political ends and to meet the immediate staffing needs of subsidized practices may or may not be worth the greater likelihood that communities will receive ill-fitting physicians who are dissatisfied with their site assignments and more likely to leave as soon as their obligations are fulfilled.

Service completion rates. The proportion of physicians who complete their obligations with service is often the most sacredly held of outcomes for programs, but perhaps shouldn't be. The common view is that physicians owe society for the medical training and bright future afforded by program dollars, and they have a responsibility to needy communities to provide service as promised when they accepted program funding. Support-for-service programs obviously cannot improve medical staffing in underserved communities if participating physicians opt not to fulfill their obligations with service.

When many early NHSC scholarship participants of the late 1970s paid off their program obligations monetarily instead of providing service,[15] Congress quickly increased penalties for buying out contracts to three times the dollar amount physicians had received plus interest. Buy-out rates plummeted, and service completion rates have been around 90% ever since. Today, with these penalty rates, buying out a contract with the NHSC Scholarship Program or with the few state programs that charge similarly high penalties,[6] will often cost physicians a prohibitive $250,000 to $700,000. With these high penalties and the courts upholding the government's right to levy and enforce them, service completion rates can nearly always be made to look good.

Forcing service with harsh penalties, however, comes at a cost to programs and communities. Requiring disinclined physicians to work in needy communities increases the costs of monitoring physicians to make certain that they abide by their contracts and increases the costs of defending against litigation brought by unhappy participants.[16] A less happy and potentially disgruntled workforce is quicker to leave their service sites as soon as their obligation periods are over.[10,11,17] Among state scholarship programs, any buy-out penalties beyond simply repaying principal plus low interest are associated with lower participant satisfaction levels and shorter retention, which perpetuates physician shortages and the need for ongoing staffing assistance for repeatedly abandoned service sites.[18] Compelling service completion with financial penalties is not a perfect solution.

Loan repayment programs show some of their advantages over scholarship programs in their high obligation completion rates despite low buy-out penalties. Loan repayment participants sign program contracts when they are older and much better informed of their career options (see Figure 1). They sign up at the time they are ready to begin serving their obligations and can know their and their family's needs and know exactly where they will serve and if the site fits their needs. Very few loan repayment programs, accordingly, have found a need to set any buy-out penalties; as a group, their service completion rates average 93% without them.[18] It is the physician-program-community fit and the financial attractiveness of the program that prompts physicians to complete their obligations with service (the "carrot"), not financial and legal threats (the "stick").

High penalties are a common aspect of programs that establish post-educational service commitments for young students, especially scholarship programs (there are other types of programs that commit students and not all use penalties). It is reasonable to question the wisdom, and even the justice, of compelling students who commit to scholarship programs as 22-year olds, but realize seven years later, through natural maturation, that the program no longer fits their more mature career and family needs. An alternative is a third type of program, the *service-option loan*, which also recruits medical students, but achieves better outcomes by holding service as an *option* to repaying program dollars at low, affordable traditional education loan rates.[6] While only 45% of states' service-option loan participants opt to provide service, those who do demonstrate excellent satisfaction and retention in their service communities.[18] The 55% who pay off their program contracts are no different and require no greater public expense than the vast majority of all medical students; that is, they fund their education with what amounts to a publicly sponsored loan. If a 45% service completion rate for a given program leaves too few physicians available for needy communities, the program can offer more contracts up front in anticipation that not all will serve.

Retention. Beyond merely completing obligations with service, there has long been the hope that obligated physicians will remain in their service communities for years afterwards. Program impact becomes much greater if two or four years of obligated service in a needy community is lengthened through post-obligation retention to ten or more years of work there. Unfortunately, there is a common misperception that serving an obligation is a financially necessary, but undesirable, career step for many physicians, and retention in service communities after obligations are fulfilled, therefore, often cannot be expected. In fact, data show that physicians participating in state-run support-for-service programs remain in their service sites as long on average as other young physicians remain in practices of all types nationwide. Physicians obligated to state-run loan repayment programs remain substantially *longer* than other young physicians.[18]

When particular programs experience poor retention, it is sometimes rationalized that high turnover is inevitable in needy communities, which are allegedly too unattractive to retain physicians and their families. However, available studies find that retention for both obligated and non-obligated physicians is generally unrelated to community characteristics,[17,19] and retention is no shorter in underserved areas than in non-underserved areas.[9,19]

The key to long retention within service communities is to allow physicians to serve in well-run practices in communities that fit their needs, where they and their families can be happy and professionally fulfilled. When service programs are operated as a short-term solution for chronically under-staffed practices—placing physicians in sites without adequate regard to fit and allowing them to be paid poorly, without benefits and treated as temporary, replaceable workers—physicians can be expected to leave promptly after fulfilling their obligations.[10-12]

Influencing the practice location choices of program alumni. For most observers, the retention of program alumni within service sites is a sign of program effectiveness. For its first 20 years the NHSC saw service-site retention as a key program outcome[15,20,b] and touted that half to two thirds of its physicians remained in their service sites beyond their service obligations.[20,21] In the early 1990s, however, longitudinal studies showed that most of those who remained in their service sites did so for only a few weeks or months.[17] A large, recent evaluation found that only 20.7% of NHSC Scholarship program alumni remained more than one month past their obligations.[22] The NHSC of the mid-1990s began speaking of the importance of NHSC alumni remaining in underserved area practices anywhere and stated that retention in service sites was not really the objective. Several studies[23,24] confirm that NHSC alumni are indeed more likely to be practicing in underserved areas than other physicians, but it is not known whether this is due to their NHSC participation or to their pre-existing career plans, which attracted them to the NHSC in the first place. The important unanswered empirical question is whether retaining obligated physicians within service sites as apposed to within any underserved area will better solve physician shortages in the long run.

Secondary Goals

Improving staffing in publicly sponsored clinics. Support-for-service programs, as discussed earlier, are sometimes used as staffing mechanisms for publicly-supported clinics, which can either help or harm their primary goal of correcting physician shortages in service communities. If lists of eligible service sites are limited to a few publicly supported clinics, which tend to be those that are chronically understaffed (the "most needy") and less well managed,[25,26] then retention following service obligations will be poor. These same clinics will need another obligated physician every two-to-four years, perpetuating a "revolving door" staffing pattern and leaving the communities vulnerable whenever no new replacement physician is available. Alternatively, physicians can be given an ample number of

---

[b] "Retention of Corps providers has been seen as integral to that self-sufficiency [of local healthcare delivery systems]. Indeed, as one measure of its success, the new program looked to the number of Corps members who chose to remain in their communities at the end of their NHSC service."[20]

sponsored clinics in a variety of settings from which to select a service site. A wider selection leads to better community-physician matches and fosters competition for physicians among clinics, promoting more favorable employment contracts and better management. In the long run, this yields better retention and more stable physician staffing for publicly supported practices and their communities.

Correcting the demographic composition of the physician workforce. Another secondary goal for some programs, particularly the various federal scholarship programs, has been to minimize the debt incurred for a medical education for students from minority, poor, and rural backgrounds.[27,28] The hope has been that a financing avenue that requires less debt will encourage more students from disadvantaged backgrounds to undertake medical training. Whether the availability of service-requiring scholarships and service-option loans is instrumental in the career decisions of minority and poor students is unknown; it has not been formally studied.

With the goal of correcting the demographic imbalance of the United States workforce, the NHSC Scholarship program supports a disproportionately high number of African American physicians. As a group, however, African Americans in rural NHSC settings have proven less satisfied in their service practices and no better retained than other NHSC physicians.[29] This appears to be due to a mismatch between the urban orientation of most African American physicians[30] and the NHSC's practice of assuring that most of its physicians serve in rural settings.[29] Support-for-service programs that target a special demographic group must anticipate the unique needs of those individuals and adjust their operations accordingly, like tailoring their lists of eligible service sites or offering part-time work options. Secondary goals of any kind taken on by programs can affect their ability to achieve their primary goals in unanticipated ways.

Recommendations

Based on the literature, the following recommendations are offered to strengthen the outcomes and impact of physician training support-for-service programs.

- Legislators should be clear about the long-term goals of the support-for-service programs they create and fund. They should provide guidance to programs on how to balance the goals of improving physician availability in underserved areas in the long term with any other goals they set, such as to provide staffing for publicly supported clinics.
- Programs should be clear on the goals and specific outcomes they are pursuing and should be certain that the outcomes are appropriate to the goals. High buy-out penalties, for example, generally will not support a goal of stable, long-term staffing in underserved communities.
- Programs should regularly monitor and publicly report their outcomes. Several types of outcome data should be used:
    - Community and patient demographic data for the communities and patients where obligated physicians serve;
    - Program data on position fill rates, service completion versus financial buy-out versus default rates, and three-, 12-, and 36-month post-obligation retention rates;
    - Data from obligated physicians addressing their satisfaction, their perceptions of their fit with the community, their perceptions of the service program and service practices, and their suggestions for improving each of these. These data should be obtained through annual surveys of participants, exit interviews, and tallies of grievances.
    - Data from service practices addressing perceptions of their assigned physicians' volume and quality of practice and their physicians' fit with the community and the service program.
- In the interests of underserved communities, programs should be willing to accept outcome data and change their operations to improve outcomes.
- Programs should not tolerate poor management of their obligated physicians by practice, and legislators should not fund programs that tolerate mismanagement of this valuable public resource.

Conclusions

Twenty-five years of program evaluations have clarified many of the outcomes possible from physician training support-for-service programs. Studies have demonstrated that loan repayment programs, as a whole, have better outcomes than scholarship programs. The central importance of good community-physician matching clearly has been shown.

Information from formal research and programs' self evaluations has sometimes influenced today's programs. For example, studies demonstrating the strengths of loan repayment programs prompted Congress recently to allow the NHSC to make more loan repayment and fewer scholarship awards and led some states to expand their loan repayment programs.[6]

Other evaluation information remains generally unheeded. Despite the demonstrated importance of physician-community matches, very few programs offer site match or contract assistance to physicians and communities. Some programs have yet to make key strategic choices, like the desired balance between meeting the short-term staffing needs of publicly-supported practices and the long-term staffing needs of underserved areas. Many programs, even those with the best of intentions, tend to cling to traditional modes of operation, despite evidence showing more effective approaches.

Excellent outcomes are quite achievable from physician training support-for-service programs. In the interests of medically underserved communities, programs should have explicit outcome objectives, regularly monitor their outcomes, openly acknowledge weaknesses, and embrace change when needed. **NCMedJ**

COMMENTARY

North Carolina Medical Society Foundation's Community Practitioner Program

Robert W. Seligson, MBA, and Pamela P. Highsmith, MEd

Introduction

Thanks to the vision, wisdom, and passion of many dedicated North Carolinians, there exists today a largely unheralded 15-year-old program responsible for providing primary care to thousands of patients in underserved communities—patients who otherwise may have gone without medical services. Each year, physicians, physician assistants, and family nurse practitioners assisted by the North Carolina Medical Society Foundation's Community Practitioner Program (CPP) provide more than 400,000 visits to patients largely on the margin of today's healthcare system. More than half of all patients seen by CPP participants are uninsured or are Medicaid or Medicare eligible, and yet these patients are able to receive quality, continuous primary care by a provider who knows them in a community-based office setting.

> *"CPP works by enabling providers who are willing—indeed eager—to work in rural, economically distressed and medically underserved communities across North Carolina."*

CPP Beginnings

In 1989, the Kate B. Reynolds Charitable Trust granted $4.5 million to the North Carolina Medial Society Foundation to help medically underserved communities in North Carolina attract and retain needed medical practitioners. It was determined early on that collaboration with other healthcare stakeholders was key, thus an Advisory Board consisting of representatives of the Family Medicine Departments of each of North Carolina's four medical schools, Area Health Education Centers (AHEC), the North Carolina Office of Research, Demonstrations, and Rural Health Development (ORDRHD), the North Carolina Hospital Association's Rural Health Center (RHC), the North Carolina Department of Commerce, the Kate B. Reynolds Charitable Trust (KBRCT), the North Carolina Medical Society (NCMS), and rural practitioners was established. Close collaborative relationships, particularly with ORDRHD, AHEC, and RHC, created synergy and complimentary roles while avoiding duplication of efforts. These relationships exist today. The Advisory Board and the program's first director, E. Harvey Estes, MD, Emeritus Professor of Community and Family Medicine at Duke University, determined that the program's primary means of assistance should be educational loan repayment. On occasion, the program has also awarded moving expenses, support for continued educational training, or direct payment for a needed piece of major equipment. The program has also provided consultative services to improve the management skills of medical office staff and has worked collaboratively with chronically underserved communities, assisting local leaders in conceiving and developing a viable local healthcare infrastructure capable of sustaining healthcare providers over the long term.

During its 15-year history, the program has assisted 128 rural, economically distressed and/or medically underserved communities in 76 of North Carolina's 100 counties (see Figure 1). It has provided support to 347 physicians, physician assistants, family nurse practitioners, and medical practices. Of the estimated 400,000 patient visits provided annually, by these

Robert W. Seligson, MBA, is the Executive Vice President and CEO of the North Carolina Medical Society. He can be reached at rseligson@ncmedsoc.org or PO Box 27167 Raleigh, NC 27611. Telephone: 919-833-3836.

Pamela P. Highsmith, MEd, is the Associate Executive Director of the North Carolina Medical Society Foundation. She can be reached at phighsmith@ncmedsoc.org or PO Box 27167 Raleigh, NC 27611. Telephone: 919-833-3836.

practitioners, 34% are Medicaid recipients, 26% are Medicare recipients, 18% are uninsured, 41% are minority, and 55% suffer from chronic diseases. Since the program's inception, CPP providers have contributed an estimated $226 million in free or discounted healthcare services.

The Community Practitioner Program

CPP has three primary goals

- Improve access to healthcare for uninsured and underinsured populations in rural, economically distressed, and medically underserved communities across North Carolina, prioritizing federally designated Tier I, II, and II counties and whole or partial Health Professional Shortage Areas (HPSA).
- Provide cost-effective quality healthcare to underserved communities by helping the assisted CPP providers succeed and remain in their communities, operating financially viable practices despite low-Medicaid and Medicare reimbursement rates, a high number of uninsured patients, and often less sophisticated business operations.
- Develop and support a fellowship of primary care providers skilled in treating low-income, uninsured, and underinsured populations.

CPP works by enabling providers who are willing—indeed eager—to work in rural, economically distressed and medically underserved communities across North Carolina. The program provides financial assistance to participants in the form of educational debt relief in return for a commitment of five years in a target community. By paying up to half of their educational debt ($100,000 on average), CPP allows healthcare professionals to practice primary care medicine in areas of the state that need them most rather than choose more lucrative practices in urban areas to pay off medical school loans.

Because CPP is a private program, funded with non-public dollars, it is able to be more flexible than similar governmental programs. As a result, it has a remarkably successful retention rate. Sixty-four percent of CPP participants remain in their high-need communities beyond their initial five-year commitment, 73% continue to practice in rural or economically distressed communities, and 85% remain in North Carolina.

Due to the previously mentioned collaborative relationships, CPP operates with almost no physician recruiting expenses. Providers are referred by collaborating organizations including the ORDRHD, RHC, the state Department of Health and Human Services and its Division of Public Health. In addition, referrals are received from in-state medical schools for residents who are ready to begin practice and who express an interest in a rural or low-income community setting.

CPP Today

CPP is managed by the North Carolina Medical Society Foundation under the day-to-day supervision of Pamela P. Highsmith, Associate Executive Director of the North Carolina

CPP Snapshot

- 128 rural, economically distressed and medically underserved communities in 76 counties
- 347 physicians, physician assistants, family nurse practitioners, and medical practices supported
- $12 million spent on program costs to date
- An estimated 400,000+ patient encounters annually:
  - 34% Medicaid
  - 26% Medicare
  - 18% Uninsured
  - 41% Minority
  - 55% Chronic diseases
- An estimated $226 million in healthcare to the uninsured
- Retention rates for CPP medical providers:
  - 64% remain beyond initial five-year commitment
  - 73% continue to practice in rural or low-income communities
  - 85% remain in state

Quotes from Providers

"CPP support allowed me to start a rural health practice in a severe shortage area that couldn't afford to hire another physician. I have added two employees, allowing me to see more patients. By next year I will be hiring another physician to increase our patient load, as there are still many residents without a primary care doctor."

Kelly Rothe, DO
Burnsville

"CPP has allowed us to work with uninsured patients, Hispanic immigrants, and Medicaid patients and still maintain a viable practice. This is important because our community does not have a public clinic to provide a safety net for these high-risk populations."

Kit Helm, MD, and Sondra Wolf, MD
Franklin

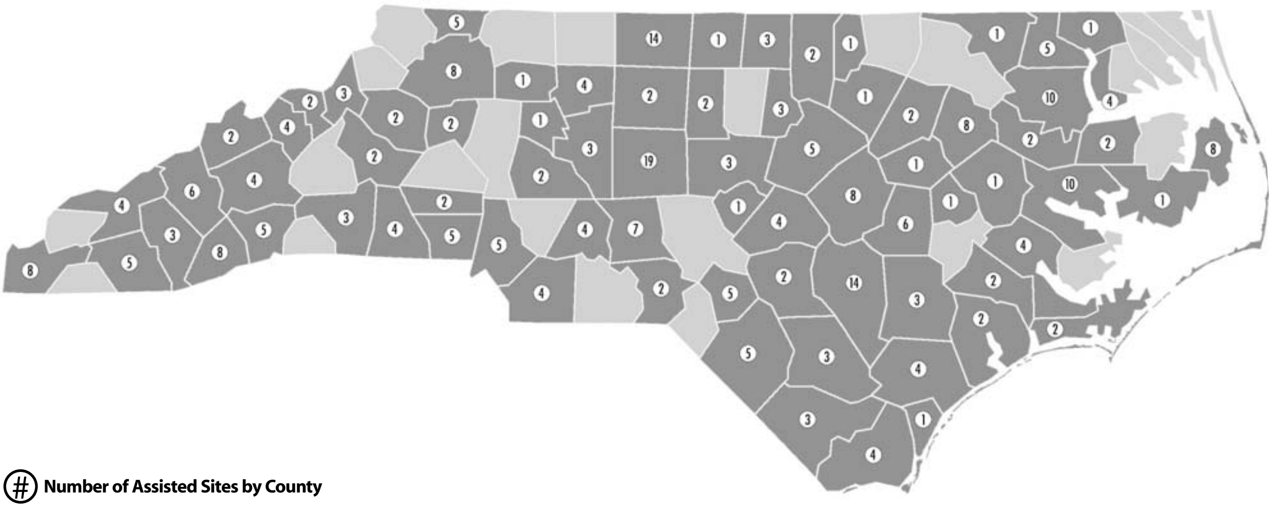
"Because of a longstanding family physician shortage, when my husband and I opened our family practice in Asheboro with CPP support, we acquired many patients who had not seen a doctor in over 20 years!"

Beth Hodges, MD
Asheboro

"CPP allowed me to practice in a rural site that, although underserved, does not meet the federal assistance guidelines. Without this help, I would have likely chosen another area. Since I have been here, I have made a tremendous impact on the needs of the Hispanic community because I am one of only two Spanish-speaking practitioners in the county."

Daniel Frayne, MD
Linville

Figure 1.
Community Practicioner Program Assisted Site—2005



(#) **Number of Assisted Sites by County**

Medical Society Foundation. Oversight is provided by the North Carolina Medical Society Foundation's 15-person Board of Trustees, chaired by Justine Strand, MPH, PA-C, Associate Clinical Professor and Chief, Physician Assistant Division, Department of Community and Family Medicine, Duke University. The program currently has an Interim Director, Cathy Wright, who will serve in this capacity until a full-time Project Director is identified.

CPP aims to support a minimum of 100 providers—primary care physicians, physician assistants and family nurse practitioners—in practice across the state at all times. At current funding levels, approximately 20 providers are added to the program each year as participants fulfill and complete their five-year commitments.

With a solid track record as a base, the North Carolina Medical Society Foundation has committed itself to continuing the program and to enhancing the support provided to recipients, as they attempt to survive in a reduced payment environment. This commitment is strengthened by projections of growing shortages of primary care providers, particularly in rural areas. A campaign is underway to secure needed funding and to build an endowment for its continued operations for the foreseeable future. **NCMedJ**

COMMENTARY

The Special Role for Rural Hospitals in Meeting the Needs of Their Communities

Serge Dihoff and Jeffrey S. Spade, CHE

North Carolina's rural hospitals occupy a special and significant role in the fabric and soul of rural communities. Rural residents traditionally relate to their community according to a handful of common "identifiers." Chief among these identifiers are community churches, high schools and their sports teams, volunteer fire departments and rescue squads, social clubs, and local hospitals. These common identifiers validate for the rural resident the community as their own, are a source of pride, and, in many instances, a point of friendly competition between communities. These community identifiers form the heart of the rural community infrastructure. At the most basic level, the rural hospital as a community identifier exists, from the perspective of rural residents, apart from the relative importance of the hospital's services, the quality of care of the hospital, or the economic support the hospital offers the community.

North Carolina's rural healthcare system was initially organized around the concept of a hospital serving its home county. Passage of the Hospital Survey and Construction Act of 1946, better known as the Hill-Burton Act, began a proliferation of hospital construction in the poor, rural communities of America—places where no hospitals would have been possible before. As a consequence, many rural communities throughout the country built their own local hospital. Community hospitals were founded in 72 of North Carolina's 100 counties, thus establishing the leadership role that rural hospitals fulfill within their communities today.

North Carolina's 61 rural counties are served by nearly 60 rural hospitals. Rural hospitals are usually smaller than the average North Carolina hospital, with rural hospitals caring for an average daily census of 77 acute care patients in 2004 versus an average of 135 patients for all North Carolina hospitals (see Table 1). In 2004, North Carolina rural hospitals cared for 227,612 inpatients, approximately 3.28 million outpatients, and an estimated 1.05 million emergency patients. The numbers speak for themselves—millions of visits for care and hundreds of thousands of hospitalized patients. North Carolina's rural residents depend heavily on their local hospital for valuable, timely, and necessary inpatient, outpatient, and emergency care services.

Rural Healthcare Networks

North Carolina's version of a *network* is a patient-focused system of care consisting of private and public organizations that provide an array of medical and social services to the community.

Table 1.
Averages for North Carolina Hospitals, 2004

	Average Rural North Carolina Hospital	Average North Carolina Hospital
Average Daily Census (Acute)	77	135
Annual Discharges	5,055	9,133
Annual Outpatient Visits	75,983	141,217
Annual Outpatient Surgeries	2,926	5,684
Annual Emergency Visits	21,867	30,859
Total Employees	590	1,343
Percent Net Revenue from Medicare/Medicaid	51%	49%
Patient Operating Margin	-2.3%	-0.2%
Uncompensated Care as a Percent of Gross Revenue	7.9%	7.2%
Average Age of Plant	10.1 years	9.5 years

Serge Dihoff is an assistant director for the North Carolina Office of Research, Demonstrations and Rural Health Projects. He can be reached at serge.dihoff@ncmail.net or 2009 Mail Service Center, Raleigh, NC 27699. Telephone: 919-733-2040.

Jeffrey S. Spade, CHE, is the Executive Director of the North Carolina Rural Health Center and Vice President of the North Carolina Hospital Association. He can be reached at jspade@ncha.org or at PO Box 4449, Cary, NC 27519-4449. Telephone: 919-677-4223.

A successful rural network should include the local rural hospital, along with its tertiary care referral center, in a highly-integrated collaborative, coordinated with community-based organizations such as public health, primary care, dental health, emergency medical services, social services, transportation, mental healthcare, and long-term care. The composition of a rural health network varies by community, but in communities across North Carolina, rural health networks consistently deliver efficient, effective, and coordinated quality health services to rural residents.

Jim Bernstein's design for successful rural hospital and health networks can be summarized in four basic concepts:

- To build community systems of care that assure access to healthcare services focused on meeting the health needs of rural residents.
- To provide the planning, implementation, and operational support required by rural hospital networks to achieve higher levels of integration while continuing to meet patient needs.
- To integrate national and local initiatives that complement state priorities and programs in order to improve the access, quality, and cost-effectiveness of patient care for Medicaid, low-income, and uninsured patients.
- To focus on patients, not the provider, as the key denominator in rural health network development.

Critical Aspects of Rural Hospitals

What are the critical aspects of rural hospitals in relation to the communities they serve? First, rural hospitals are central to the healthcare and social service networks that undergird every rural county and community. The healthcare "quilt" of a rural community is comprised of a broad spectrum of healthcare organizations, community agencies and services, government-sponsored health services and providers, and a vast array of human service organizations that provide essential health-related benefits to the residents of rural communities. Rural hospitals touch every component of this community support system, from public health departments, Medicaid, and social services to Healthy Carolinians projects, community health centers, and free clinics. In addition to their healthcare mission, rural hospitals offer the community knowledgeable health professionals, leadership, desperately needed resources and space, in-kind support, and the basis for collaboration and coordination. The rural hospital is an invaluable resource and lifeline that ensures the viability of rural communities and their associated healthcare networks.

Another crucial aspect of rural hospitals is their role as catalysts for the development of local access points for healthcare. Both primary care and specialty care physicians are dependent on the local hospital for a range of healthcare services from outpatient and emergency care to complex inpatient care. Many rural communities would lack access to even basic healthcare services without the support of their local, rural hospital.

> *"...rural hospitals contribute billions of dollars in local and regional economic value and bring tens of thousands of jobs to rural North Carolina economies and communities year after year."*

Today, rural hospitals are highly involved in the recruitment and retention of vital healthcare providers, such as physicians and nurses. In 2005, 36 rural North Carolina counties were designated by the federal government as whole or partial healthcare professional shortage areas (HPSAs). Since many rural North Carolina counties are considered HPSAs, the contribution of rural hospitals as the regional anchor for trained health professionals is paramount. More than 3,665 physicians practice in rural North Carolina counties. Many physician practices would not be viable without the ability to diagnose, treat, and care for patients at a local hospital. Furthermore, more than 19,100 registered nurses, 6,211 licensed practical nurses, and 1,826 pharmacists practice in rural North Carolina. The healthcare services provided by these valuable, highly skilled health professionals are directly tied to the services supported by rural hospitals.

Financial Vulnerability

Vulnerable is the most distinctive description of the status of rural North Carolina hospitals. Vulnerability is a concern for rural hospitals in many respects: fiscal, operational, service development, availability and affordability of physicians and clinical professionals, medical technology, reimbursement, physical plant and facilities, and community support. Rural hospitals are like rare, protected birds that face near extinction due to the fragility of their environment. Rural hospital boards and executives, along with their caregivers and medical leaders, work tirelessly to ensure their local rural hospital survives to meet the healthcare needs of their communities. However, this constant struggle with vulnerability is a battle that many rural hospitals will not weather without considerable assistance and attention.

One important measure of vulnerability, fiscal vitality, is the greatest threat to the survival of rural hospitals. Operating a rural hospital is often a budget-year-to-budget-year exercise of hoping limited and constrained revenues will cover increasing expenses. Line item costs, such as staff salaries and benefits, drug purchases, the cost of medical supplies, malpractice insurance premiums, and utility charges rise yearly, often increasing faster than general price indices and at rates beyond the hospital's control. On the revenue side, state and federal hospital payments are constrained to pre-determined rates of increase, squeezing the ability of rural hospitals to ensure that revenues meet expenses. Federal payment policies, which automatically pay rural hospitals less revenue per unit of service than urban hospitals, also contribute to the poor financial stability of rural hospitals. Continually walking the "financial tight rope" without a strong fiscal safety net defines the day-to-day existence of many rural hospitals in North Carolina.

The lack of fiscal stability and a weak revenue base hurts rural hospitals in many fundamental aspects. Due to advances in medical treatments and therapies; the aging population and the continued rise of chronic disease; and the revolutionary pace of change in information technology, hospitals that are responsive to the health needs of their communities should be continually investing in the development of new services, advancing their medical technologies and capabilities, and upgrading their facilities. To stay current with these necessary advances, hospitals must have access to capital funding. Unfortunately, the tenuous financing of rural hospitals renders them risky investments for Wall Street financiers, meaning access to badly needed capital is severely restricted, especially among small rural hospitals. As a case in point, of the 88 outstanding hospital bond issues currently underwritten by the North Carolina Medical Care Commission, only 32 (or 36% of active issues) were financed for rural hospitals. Only five of the hospital bond issues supported rural hospitals with fewer than 100 beds.

Dependence on Primary Care-Oriented Therapies

One vulnerability of rural hospitals that is not well documented or understood is their dependence on primary care-oriented therapies, treatments, procedures and diagnostic services to generate revenues. For most rural hospitals, 60% or more of revenues are attributable to outpatient services, such as radiological exams, laboratory tests, physical therapy, outpatient surgery, diagnostic cardiology, and various examinations involving fiber optic procedures. The availability of these primary care diagnostic services and procedures in a local setting is crucial to the health of a community. For rural hospitals, these services form the basis of the hospital's revenue infrastructure, supporting more significant, but costly, medical and emergency care services, and community services, such as intensive care units with highly trained professionals, emergency departments with trauma physicians, and obstetrical care with newborn nurseries and specialized labor rooms. These expensive, yet critical, emergency health services are usually the first to be trimmed or closed when hospital revenues fail.

Competition for primary-level outpatient services, by full-service medical practices, outpatient diagnostic center entrepreneurs, and outpatient surgery centers, can irreversibly harm the service and revenue base of rural hospitals. Several North Carolina communities have already faced the terrible prospect of closing their local hospital due to the drastic loss of primary outpatient services and revenues. When a rural hospital is near closing, the first question the community asks is "How can we continue to have local access to emergency medical care?" Competition among rural hospitals and other providers for primary-level medical, diagnostic, and surgical services is not necessarily a detrimental strategy on its own accord. However, great care must be taken in planning and developing these services in competition with rural hospitals, especially in smaller, isolated communities, in order to protect and preserve the community's long-term investment in critical and emergency health services. Rural communities that have faced this disastrous prospect often find that they are at a point of crisis—both their community health and economic viability will erode.

Dependence on Government Payments

A summary of rural hospital traits and characteristics would not be complete without emphasizing their dependence on government payments as a constant concern for North Carolina's rural hospitals. By virtue of their location, rural hospitals serve proportionately more elderly, poor, uninsured, and disadvantaged patients than their urban counterparts. As a consequence, rural hospitals are highly dependent upon Medicare and Medicaid for sources of revenue (51% of rural hospital revenues). Some rural North Carolina hospitals depend on government payers for more than 70% of their revenues. This dependence presents serious difficulties because government payers only reimburse hospitals at the financial break-even point, or less. In addition, government payment sources can be unpredictable due to federal and state budget constraints, leading to budget freezes, or even worse, budget cuts. Rural hospitals also have a substantial uncompensated care burden (7.9% of gross charges in 2004). As a result, in 2004, the average rural North Carolina hospital received 2.3% less revenue than it actually cost to provide patient care services —a situation that is untenable in the long run.

One development in rural hospital financing is worthy of special mention, namely the Critical Access Hospital (CAH) program. A CAH is a small, rural hospital with 25 acute beds or less. North Carolina has 21 CAHs. The CAH program is designed to help small, rural hospitals manage the detrimental impact of fixed-payment government reimbursements on their hospital finances. In North Carolina, CAHs are reimbursed for their inpatient and outpatient costs for serving Medicare and Medicaid beneficiaries. The CAH program has had a stabilizing effect on small, rural hospital finances. However, CAH reimbursement does not address the fiscal burdens of caring for uninsured patients, nor does it provide an adequate level of reimbursement for investments in renovations and upgrades to buildings, capital equipment, and medical technology, or to establish new healthcare services. As a consequence, the financial picture for North Carolina's CAHs has improved, but many small, rural hospitals, including CAHs, still face the perils of substantial operational losses and fiscal vulnerability.

Workforce Vulnerability

In addition to the instability of financial resources, human resources are another basis of vulnerability for rural hospitals. For obvious reasons, hospitals are extremely dependent on highly trained, knowledgeable, and caring staff to deliver exceptional and beneficial health services. However, the demand for primary care physicians and specialists (like general surgeons), registered nurses, mental health professionals, therapists, radiology technicians, pharmacists and pharmacy technicians, laboratory technologists, emergency medical service professionals, medical record coders, insurance billing experts, and hundreds of other skilled hospital professionals is placing an incredible burden on training programs and hospital recruitment and retention efforts. Across North Carolina, nearly every professional category experiences regular cycles of workforce shortage or adequacy. Demand and supply of various healthcare professionals change rapidly based on local market conditions. While all hospitals are equally susceptible to workforce shortages, rural hospitals are particularly vulnerable. The inability of rural hospitals to recruit or staff a few nursing positions alone can place routine medical services at risk of being limited or curtailed, reducing local access to essential healthcare. Furthermore, the expenses associated with recruiting, hiring, training, and retaining skilled healthcare workers are continually rising. Finding health and hospital professionals that desire to live and work in rural North Carolina is also challenging.

Rural Hospitals and the Local Economy

Looking beyond healthcare, rural hospitals are vital to the economic health of the community as well. Rural economic development and the viability and sustainability of rural hospitals are closely linked. Employers in rural communities frequently cite the availability of local healthcare services as a determining factor in business development. Less well known, however, is the contribution of rural hospitals to the economic vitality of their communities. North Carolina categorizes all counties into one of five economic development tiers. The economically challenged counties are in Tier 1 with the economically advantaged counties in Tiers 4 and 5. Of the 36 counties in the two lowest economic categories (Tier 1 and Tier 2), 33 of the counties are rural. Furthermore, these 33 economically disadvantaged rural counties are served by 28 rural hospitals. The importance of rural hospitals as an economic engine is best understood by examining some revealing statistics from 2001. North Carolina's rural hospitals accounted for an estimated $2.96 billion in direct economic output and $1.23 billion in direct salaries and benefits paid to an estimated 29,467 rural hospital employees in 2001 (see Table 2). When induced and indirect economic impacts are added to the direct economic benefits, rural hospitals generated an estimated $6.44 billion in economic output and $2.2 billion in salaries and benefits paid to an estimated 61,265 rural workers. The evidence is simple and straightforward; rural hospitals contribute billions of dollars in local and regional economic value and bring tens of thousands of jobs to rural North Carolina economies and communities year after year.

Table 2.
Economic Benefit of Rural North Carolina Hospitals, 2001

	Direct Impact	Indirect and Induced Impacts	Total Economic Impact
Economic Output	$2.96 billion	$3.48 billion	$6.44 billion
Labor Income	$1.23 billion	$0.97 billion	$2.20 billion
Employment	29,467	31,798	61,265

Summary

Rural North Carolina hospitals are a treasure to be valued, nurtured, understood, and embraced. Just as Jim Bernstein understood and envisioned many decades ago, rural hospitals and health networks are vital components of the rural communities they serve. Attention must be given to the value of preserving, enhancing, and investing in rural hospital and healthcare networks in order to ensure that effective, quality healthcare services remain consistently available and accessible for North Carolina's rural residents and communities. **NCMedJ**

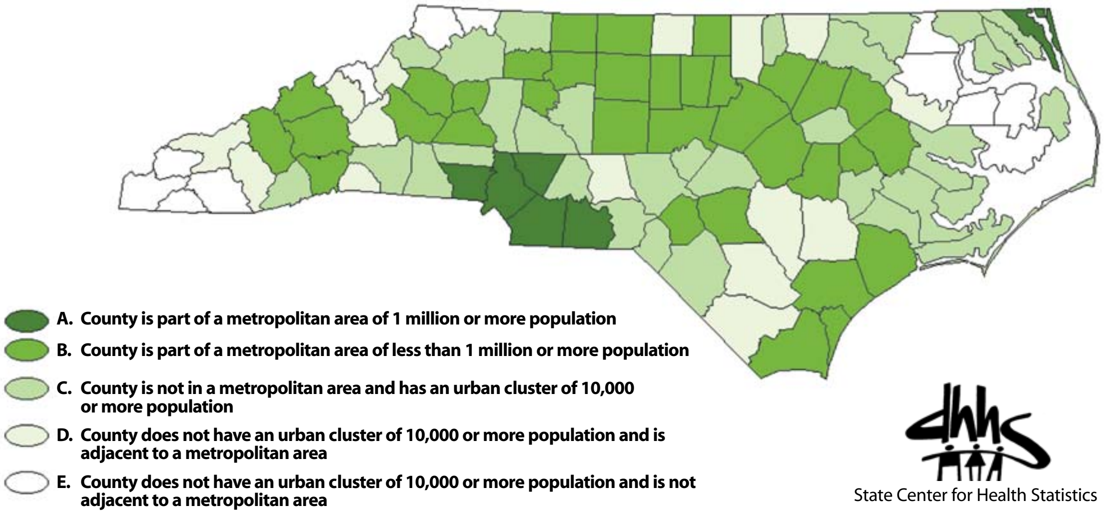
North Carolina Death Rates by a Rural-Urban Gradient

Death rates in North Carolina vary substantially across demographic categories, such as age and gender, and also by geographic area. For example, the death rates for many causes of death are highest in the older age groups, and counties in eastern North Carolina often have the highest death rates in the state. One important dimension of variation in health measures is the rural-urban continuum.

Urbanization in an area is an important characteristic affecting access to health services. Also, communities at different urbanization levels vary in their demographic, environmental, economic, and social characteristics. These characteristics strongly influence the magnitude and types of health problems that communities face. In this short report, we show death rates for selected causes of death by five levels of urbanization. This presentation is descriptive only. The causes of the health differentials by degree of urbanization are numerous and varied.

Figure 1.
North Carolina—Urban/Rural Catagories, 2003



We divided the 100 counties in North Carolina into five groups, from most to least urbanized (see map). This classification system is based on the United States Department of Agriculture's (USDA) 2003 Urban Influence Codes. These groups are roughly defined as: A. county is part of a metropolitan area of 1 one million or more population (six counties); B. county is part of a metropolitan area of less than 1 one million population (34 counties); C. county is not in a metropolitan area and has an urban cluster of 10,000 or more population (32 counties); D. county does not have an urban cluster of 10,000 or more population and is adjacent to a metropolitan area (15 counties); and E. county does not have an urban cluster of 10,000 or more population and is not adjacent to a metropolitan area (13 counties).

We present age-adjusted death rates for selected major causes of death for the combined 2000-2004 period. Age adjustment removes the effect of differing age distributions on the death rates. In general, rural counties have an older population and would tend to have higher unadjusted death rates for most chronic diseases just due to the age of the population. In 2004, the percentage of North Carolina's population that was age 65 and older was 11.9%. This percentage increases steadily from 9.4% in the most urban counties (category A) to 18.7% in the least urban counties (category E).

In 2004, the percentages of North Carolina's population of 8,541,000 residing in each of the five standard USDA urban/rural categories were: 15.3% in category A, 53.7% in category B, 22.8% in category C, 5.8% in category D, and 2.4% in category E. The table below shows age-adjusted death rates for each of these county groups and the state total, for selected causes of death.

Table 1.
2000-2004 North Carolina Age-adjusted Death Rates (Deaths per 100,000 Population) by Selected Causes of Death and Urban/Rural Category

		Most Urban				**Most Rural**
	NC Total	**Categ. A**	**Categ. B**	**Categ. C**	**Categ. D**	**Categ. E**
All Causes	897.6	889.1	874.9	936.5	961.2	906.0
Heart Disease	233.9	224.1	222.2	257.2	257.7	229.0
Cancer	197.4	192.3	196.1	202.5	201.3	197.3
Stroke	67.5	63.7	67.0	69.1	73.4	63.9
Diabetes	27.5	24.9	26.0	29.2	35.5	30.3
Chronic Obstructive Lung Disease	46.0	45.3	45.5	46.4	48.0	51.1
Alzheimer's Disease	25.5	35.0	24.8	23.9	22.5	21.9
Motor Vehicle Injuries	19.6	15.1	17.5	24.6	29.1	27.2
Other Unintentional Injuries	24.8	22.3	24.2	26.6	27.7	31.0
Suicide	11.7	10.7	11.2	12.8	12.6	13.5
Homicide	7.3	7.7	6.5	8.6	9.0	6.9

For deaths from all causes, heart disease, cancer, stroke, and diabetes, the age-adjusted death rates tend to be higher in the more rural counties, with the exception of category E (the most rural counties), where the death rates are lower than for category D. In looking at the unadjusted death rates for these causes of death (not shown in table), the category E counties have by far the highest death rates, reflecting their much higher percentage of the population that is age 65 and older.

For chronic lung disease, the most rural counties have the highest age-adjusted death rates. For Alzheimer's disease, the highest age-adjusted rate occurs in the most urban counties, with decreasing rates for the more rural counties (though the highest unadjusted Alzheimer's death rate occurs in the category E counties). For motor vehicle injuries, other unintentional injuries, and suicide, the most rural counties have the highest death rates. For homicide, the category C and D counties have substantially higher death rates.

The somewhat lower age-adjusted death rates observed in the Category E counties for many of the causes of death is consistent with the findings of other studies and may, in part, reflect the fact that these counties contain places where healthy people go to retire or retreat. The rural/urban differences in death rates observed here are purely descriptive, and we have not tested any of these differences for statistical significance. However, given that five years of data were used, all of the death rates shown in the table are fairly stable and based on at least 200 deaths in the numerator, with the exception of suicide (149 deaths) and homicide in the category E counties (66 deaths). Many factors account for the patterns shown here, including rural/urban variations in socioeconomic status and access to healthcare.

Readers' Forum

An Update From:

King LP, Siminoff LA, Meyer DM, Yancy CW, Ring WS, Mayo TW, Drazner MH. Health insurance and cardiac transplantation: A call for reform. J Am Coll Cardiol. 2005 May 3;45(9):1388-1391.

A Heartfelt Story for the Rich

One in four donated hearts in the United States comes from the ranks of the uninsured, according to a study in the *Journal of American College of Cardiology*. Socioeconomics has always been a factor in organ donations because of the expense of long-term care for a new organ. Nevertheless, the doctors and ethicists who did the study say the finding is a glaring inequity in a national organ donation system that strives for fairness.

You should not ask a group of people, in this case nearly one-quarter of heart donors, to contribute to a pool of resources not available to them," says Tom Mayo, director of Southern Methodist University's (SMU) Maguire Center for Ethics and Public Responsibility and an author of the study "Health Insurance and Cardiac Transplantation: A Call for Reform." "A system that derives such a substantial benefit from people who, if the tables were turned, would not qualify for a transplant for financial reasons raises serious questions of justice and the equitable allocation of life-saving medical resources."

By studying a database of nearly 300 organ donors, researchers from University of Texas (UT) Southwestern Medical Center, SMU, and Case Western Reserve University found approximately 25% of the donors had no health insurance. Half of those uninsured donors are between the ages of 45 to 64 years, the most common age group to receive a heart transplant. The estimated cost of a heart transplant is $391,000. Read more about this story and the study by going to http://smu.edu/experts/ or call SMU Office of News and Communications at 214-768-7650.

To The Editor:

The November/December 2005 issue of the Journal featuring access to dental care provided a balanced and sobering assessment of dental care access and treatment in North Carolina. In spite, of the efforts on the part of many people, advocates, clinicians, and policy makers alike, dental care for too many of our citizens is unattainable. Like obesity and the use of tobacco, the health consequences of diseased mouths are well known and the cost in misery and dollars well documented.

As noted in the variety of articles, the problem of access to dental care for all is complex and not likely to be solved by any one effort alone. However, that does not prevent the need to do so. All involved—providers of dental care, those who pay the bills, patients, community leaders, and those who make the laws—must come to a common understanding of the importance of affordable, equitable, and accessible dental care as a basic necessity. When such agreement is reached, the power to improve this area of our people's health will exert itself. Until then, I fear that we will still search for solutions in isolation and struggle to make them effective.

Thank you for an excellent issue.

Southeastern Regional Medical Center committed to improving health of community.

LUMBERTON — Southeastern Regional Medical Center (SRMC) is the lead agency in a partnership with the Robeson County Health Department and other health and human service agencies in the county. "The mission of the partnership is to coordinate and implement countywide health initiatives in an effort to create an environment that supports good health among the citizens of Robeson County," said Luckey Welsh, SRMC President and CEO. "We are proud to take a lead role in these grassroots programs toward better healthcare."

Examples of the partnership include free health screens for the early detection of diabetes, heart disease, and cancer, as well as the Community Health Education Center, SRMC's health library located in Lumberton's prime shopping mall. The library offers pamphlets, Internet access and a staffed help desk to answer questions regarding health issues.

Of recent note is the implementation of Project HEALTH, an acronym for Healthy Eating and Active Lifestyles for Tomorrow's Health. Project Health addresses rising concerns of childhood obesity in targeted Robeson and Columbus County schools. A three-year commitment has been guaranteed through a $450,000 start-up grant by the N.C. Health and Wellness Trust Fund Commission. After the three years, the program will be sustained by SRMC and the partnership.

Also included in the partnership effort is the SRMC Diabetes Community Center. The center offers a comprehensive Diabetes Self Management Program that is nationally recognized by the American Diabetes Association.

ePRxESCRIBE℠

Make the connection

Electronic prescribing saves time, improves patient safety and leads to better overall care management.

The future of prescribing is here today; initiated by Blue Cross and Blue Shield of North Carolina with a program we're calling ePrescribe. We're the first health insurer in North Carolina to put electronic prescribing tools into the hands of physicians who need them most.

More informed. More efficient.

Physician's PDA is loaded with patient information. Physician selects a medication and submits to RxHub.

RxHub checks drug histories, interactions, allergies, health plan formulary. Provides alerts to physician.

Based on results and alerts from RxHub, physician and patient discuss medication options.

Secure electronic prescription is sent to patient's pharmacy of choice.

Pharmacist receives legible prescription, reducing callbacks to physician to clarify.

Patient receives safe, medically effective and cost-effective medication.

Our vision for health care starts with efficiency and ends with safety. ePrescribe is part of that vision – to streamline processes, to eliminate errors and to lower overall health care costs.

For more information on the ePrescribe Program,

We've joined forces to care for those close to our hearts.

In North Carolina, there are few goals more important than achieving cardiac health for our citizens.

Today, North Carolinians suffer from heart disease at one of the highest rates in the U.S. One in four experience cardiovascular disease, and it is the cause of 34 percent of all deaths in our state.

That's why East Carolina University and University Health Systems Pitt County Memorial Hospital, along with private practice physicians, are joining forces. Together, we'll offer the best of scientific research and expert clinical medicine for the highest quality patient care experience. Our recent groundbreaking was the first step in expanding both leading-edge facilities to meet this serious national healthcare need.

Working as one, we proudly announce the future of cardiac care, the East Carolina Heart Institute.

Under the leadership of Dr. W. Randolph Chitwood, Jr., internationally recognized surgeon and robotic surgery pioneer, our partnership and two facilities will create a world-class cardiovascular destination.

The citizens of North Carolina will be among the first to benefit from our innovations to treat and prevent heart disease. But cardiac patients from around the world will soon appreciate the quality of care delivered by our skilled cardiovascular physicians.

Creating the East Carolina Heart Institute is just one way that we'll work together to care for people close to our hearts. Visit www.eastcarolinaheartinstitute.com.

EAST CAROLINA
HEART INSTITUTE

The Carolinas Center for Medical Excellence. We deliver.

Data driven

Quality improvement focused

Research-based

Patient-centered

After more than 20 years in the case review and quality improvement business primarily in hospitals, CCME is breaking new ground. That's why we have changed our name.

The Carolinas Center for Medical Excellence—CCME—better characterizes our work in quality improvement across the healthcare spectrum. Our logo with the archway represents our long history of improving quality of care while symbolizing our multiple strengths in the varied professional services we provide.

Hospitals. Nursing Homes.
Home Health Agencies. Physician Offices.
These are the people we serve.

A professional staff to help you deliver the right care for every person every time. A long history of quality improvement in healthcare.

CCME delivers.

Publishers of the *North Carolina Medical Journal*

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

Tarheel Footprints in Healthcare

Recognizing unusual and often unsung contributions of individual citizens who have made healthcare for North Carolinians more accessible and of higher quality

Recognizing Ann Probst, CNA, North Carolina's "Nurse Aide of the Year"

Anyone familiar with long-term care knows that the job of being a nursing assistant in a busy nursing home is both hard and demanding. Every facet of a resident's life in a skilled nursing facility is affected by the quality of care and compassion and skill of these direct care workers, who often have responsibility for as many as 20 residents at a time.

Ann Probst, CNA (left), from the Lutheran Home–Albemarle, since 1980, pictured here with one of her residents, Ms. Daisy Curlee

The North Carolina Health Care Facilities Association, the trade association for nursing homes in our state, has recognized the importance of direct care workers in the effort to provide quality health and life care to their residents. For this reason, six years ago the Association began its "Fabulous 50" program to honor ten nursing assistants in each of its five districts each year. An honoree in each district is singled out for special recognization, with one being selected statewide as the "North Carolina Nurse Aide of the Year." This year, the Association has chosen to honor Ann Probst, a 25-year veteran of nursing assistance serving the residents of Lutheran Home–Albemarle.

Many of her colleague CNAs, nurses, and family members joined together in nominating Ann Probst for this distinguished award. She has been described by those who work with her as a "transformational leader" because of the example she sets for others and for the way in which she instills the very highest level of concern for resident welfare in her everyday practice. One of the things for which she has been known is her unfailing commitment to the idea that each long-term care resident is an individual with unique gifts, if only those who serve them day-to-day can find the time and the means of unlocking those qualities of the person that define them as personalities. Her effort to know her patients as individuals have led her to use her own personal resources to decorate resident rooms for the holidays; to make her own special clothing to reflect the seasonal themes at different times of the year; to arrange for certain residents to attend church services in the facility or special crafts activities (and to arrange for their return to their rooms when these activities are over); to remind staff on different shifts to make it possible for certain residents to enjoy a televised sporting event of particular interest, to continue a hobby (e.g., coin collections or sewing), to acquire special apparel (like a jogging suit) when residents are experiencing difficulty dressing; to have activities like coloring books and games on hand for the visiting grandchildren of residents; or to be certain that patients are observed for critical signs of health and function of importance to nursing supervisors, who may not be in a position to make such detailed observations on a daily basis. It has been discovered that she anonymously paid the cable television bill of a resident whose family no longer could afford this luxury because the resident so enjoyed the experience of watching television at certain points in the day.

For Ann Probst, and the 49 other "Fabulous 50" nurse aides who have been honored this year, being a nursing assistant is a life's work offering the opportunity to serve dozens of persons at a point when they need both high quality, skilled nursing services, as well as the personal care of one who is dedicated to assuring a quality life experience when one is most vulnerable. Ann Probst's legacy is assured as both her daughter and her granddaughter have chosen to follow in her very large Tar Heel footsteps, choosing to become CNAs as well. For all these years of dedicated service to the people of this state in such a demanding role, the *North Carolina Medical Journal* is pleased to salute Ms. Ann Probst, CNA.

ARTICLE

Medical Homes for Children with Special Healthcare Needs in North Carolina

Savithri Nageswaran, MD, MPH, Marcia S. Roth, MPH, Catherine E. Kluttz-Hile, BSN, MA, and Anita Farel, DrPH

Abstract

Background: *The American Academy of Pediatrics defines a medical home as medical care for children that is accessible, continuous, comprehensive, family-centered, coordinated, and compassionate. North Carolina uses the medical home concept as a model for providing high quality care to children with special healthcare needs (CSHCN). However, until recently, information on medical homes for CSHCN in North Carolina has not been available.*

Methods: *Using North Carolina data from the National Survey of Children with Special Health Care Needs (2000-2002), we describe the characteristics of children having a special healthcare need. We conducted bivariate analysis of socio-demographic factors with medical home and its five components (family-centered care, effective care coordination, personal doctor or nurse, usual source of care, and referrals for specialty care) and multivariate analysis to identify the predictors of having a medical home.*

Results: *Fifty-six percent of CSHCN in North Carolina have a medical home. White CSHCN are 1.7 times more likely to have a medical home compared to non-white CSHCN. CSHCN with no functional limitations are 1.6 times more likely to have a medical home compared to children with some or severe limitations of their functional status.*

Conclusions: *Current, population-based information about CSHCN and their families is essential for assessing needs and evaluating pediatric initiatives at the state level. Disparities among CSHCN due to race and functional status should be considered in organizing services for CSHCN in North Carolina.*

Background

Children with special healthcare needs (CSHCN) are those who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional conditions and who also require health and related services of a type or amount beyond that required by children generally.[1] Using this definition, an estimated 9.3 million children in the United States have special healthcare needs, accounting for 13% of all children.[2]

In order to improve the quality of care for CSHCN, the Maternal and Child Health Bureau (MCHB) has adopted the "medical home" concept as a model of care for CSHCN. Increasing the proportion of children with special healthcare needs who have access to a medical home is one of the national health objectives.[3] The American Academy of Pediatrics defines medical home as medical care of infants, children, and adolescents that is accessible, continuous, comprehensive, family-centered, coordinated, compassionate, culturally effective, and delivered or directed by well-trained physicians who provide primary care and help to manage essentially all aspects of pediatric care.[4]

---

[a] The federal Maternal and Child Health Block Grant is designed to help states ensure the health of mothers and children, with a special focus on the most vulnerable populations (e.g., those who are hard-to-reach, low-income, children with special healthcare needs, and/or racial and ethnic minority populations).

Savithri Nageswaran, MD, MPH, is an Instructor in the Department of Pediatrics, Wake Forest University School of Medicine. Dr. Nageswaran can be reached at snageswa@wfubmc.edu or Medical Center Blvd, Winston-Salem, NC 27517. Telephone: 336-716-6508.

Marcia S. Roth, MPH, is the Director of Planning and Development in the Department of Maternal and Child Health, University of North Carolina at Chapel Hill, NC.

Catherine E. Kluttz-Hile, BSN, MA, is an Assistant Director of Programming for Health Services in the Division of Mental Health, Developmental Disabilities, and Substance Abuse Services, Department of Health and Human Services.

Anita Farel, DrPH, is a Clinical Professor in the Department of Maternal and Child Health, School of Public Health University of North Carolina at Chapel Hill.

There is wide variation among states in the way that services and systems of care for CSHCN are developed and implemented. Federal support through the MCHB Title V Program[a] provides an important foundation and is further shaped by state appropriations, third-party reimbursement, specific characteristics of delivery systems, and the population of CSHCN within each state. In North Carolina, services for CSHCN are organized through the Specialized Services Unit of the Children and Youth Branch in the Women and Children's Health Section of the Division of Public Health. The Medical Home Initiative for Children with Special Health Care Needs was designed by the Division of Public Health to provide a comprehensive approach to the development of medical homes for children, particularly CSHCN.[5] The Division of Public Health collaborates with the North Carolina Pediatric Society, private pediatric practices, healthcare demonstration projects (e.g., the Community Care Networks), the state Medicaid Program, parent advocacy organizations, (e.g., the Family Support Network of North Carolina, the Exceptional Children's Advocacy Center), medical schools, and specialty clinics linked to tertiary medical centers in planning and implementing programs for CSHCN.

Information on the characteristics of CSHCN and the presence of medical homes among CSHCN in North Carolina is essential for designing and implementing programs tailored to the needs of CSHCN in North Carolina. This information can also serve as a baseline for future evaluation of the state's performance. Until recently, state-level data on CSHCN and on the presence of medical homes were not available. The National Survey of Children with Special Health Care Needs provides an opportunity to obtain state-level prevalence estimates, to describe the needs of this population of children, and to identify areas that need improvement in the systems of care for CSHCN.[6]

The objectives of our study are: (1) to describe the characteristics of CSHCN in North Carolina, (2) to analyze information about the implementation of the medical home and its component parts (family-centered care, effective care coordination, personal doctor or nurse, usual source of care and referrals for specialty care) among CSHCN in North Carolina, and (3) to identify the socio-demographic factors associated with having a medical home presence in this population.

Methods

Data Source

The National Survey of Children with Special Health Care Needs was sponsored by the MCHB and conducted by the National Center for Health Statistics (NCHS) between October 2000 and April 2002. A random-digit-dial sample of households with children younger than 18 years was selected from each of the 50 states and the District of Columbia. The respondent for the survey was the parent or guardian who was most knowledgeable about the child's health. The methodology of the survey has been described elsewhere.[7] All survey data are publicly available at the NCHS website.[8] This study analyzed data about North Carolina's children with special healthcare needs collected by the National Survey. The weighted response rate for North Carolina was 63.1%.[7]

Variable Description

A child was identified as having a special healthcare need if he or she met any one of the five screening criteria listed in Table 1. Of the 5,548 children screened in North Carolina, 884 (14%) were identified as CSHCN. The CSHCN screener is a validated tool used to identify children with special healthcare needs.

The medical home is a composite outcome and a dichotomous variable (yes/no) derived from 12 questions on the survey to capture the five components of the medical home concept—namely, receipt of family-centered care and effective care coordination, presence of a personal doctor or nurse, access to a usual source of care, and absence of problems in obtaining referrals to specialists. The components, family-centered care, effective care coordination, and usual source of care were, in turn, derived from five, three, and two questions, respectively (see Table 2). If a child did not meet all of the five component

Table 1.
Proportion of Children in North Carolina with Special Healthcare Needs Identified through the CSHCN Screener Questionnaire (N = 5,548)

Screening Questionnaire Item*	Proportion of all children (%)
Child needs or uses more medical care, mental health services, or educational services than is usual for most children of the same age because of a medical, behavioral, or health condition that is expected to last 12 months or longer	7
Child needs or uses prescription medication because of a medical, behavioral, or health condition that is expected to last 12 months or longer	11
Child has a limitation in abilities to do the things that most children of the same age can do because of a medical, behavioral, or health condition that is expected to last 12 months or longer	3
Child needs or gets special therapy, such as physical, occupational, or speech therapy because of a medical, behavioral, or health condition that is expected to last 12 months or longer	2
Child has an emotional, developmental, or behavioral problem that is expected to last or has lasted for 12 months or longer for which he or she needs treatment or counseling	3

* Items not mutually exclusive

Table 2.
Criteria Used to Define a Medical Home in the National Survey of Children with Special Health Care Needs[*†]

Presence of a usual source of care	
	The child has a usual source for sick care
	The child has a usual source for preventive care
The child has a personal physician or nurse	
Experiences no difficulties in obtaining referrals to specialists when needed	
Receives effective care coordination when needed	
	The child has professional care coordination when needed
	Physicians communicate well with each other
	Physicians communicate well with other programs
Receives family-centered care	
	Physicians spend enough time with the child
	Physicians listen carefully to the family
	Physicians are sensitive to family's values and customs
	Physicians provide needed information
	Physicians make the family feel like a partner

* Based on respondents' report

† For actual questions, please refer to the Program and Collections Procedure manual of the National Survey of Children with Special Health Care Needs[7]

criteria, then he or she was considered not to have met the criteria for having a medical home. This strategy of deriving the medical home variable was based on the method reported previously.[9,10] The questions from the survey used to derive the medical home variable are supported in the literature.[11]

Age, gender, race, functional status of the child, metropolitan status of residence, income level of the household, mother's education, and adequacy of insurance were the independent, categorical variables of interest. Income level of the household was categorized as income less than 200% of Federal Poverty Guidelines (FPG) and more than or equal to 200% FPG, because, at 200% FPG, all children in North Carolina are either eligible for Medicaid (Health Check) or the State Children's Health Insurance Plan (Health Choice).

Functional status of the child was derived from two questions and categorized into "no limitation of activities due to the child's condition" and "some or severe limitation of activities." Adequacy of insurance was derived from five variables. To be considered to have adequate health insurance, a child needed to have: (a) public or private insurance at the time of the interview, (b) no gaps in insurance coverage in the year prior to the interview, (c) insurance coverage that usually or always meets the child's needs, (d) costs not covered by insurance that are usually or always reasonable, and (e) insurance coverage that usually or always permits the child to see needed providers. If the child did not meet any one of the criteria mentioned above, insurance was considered inadequate.

Statistical Methods

Following univariate analysis, bivariate analyses were conducted to determine the association between each one of the independent variables and having a medical home and its five components. The Pearson chi-square test was used to examine the association between categorical variables. Independent variables that were statistically significant for the presence of a medical home in bivariate analysis were included in multivariate analysis. We used a logistic regression model for multivariate analysis. Some cells in these data had a small number of observations. Since estimates derived from a small number of observations are not valid population estimates, the NCHS recommends using the relative standard error (RSE) to measure an estimate's reliability. Accordingly, if an estimate had an RSE [(standard error/ estimate) x 100] of greater than or equal to 30, then the result was considered inaccurate and, hence, was not used for further analyses. In order to obtain population-level estimates, appropriate survey weights were used in the analysis. Since the study is exploratory, we did not correct for multiple comparison and considered a p value of less than 0.05 to be statistically significant. Stata Intercooled version 8.2 was used for statistical analysis. The Office of Human Research Ethics at the University of North Carolina at Chapel Hill approved this study.

Results

There are an estimated 280,770 children with special healthcare needs in North Carolina, representing 14% of all children less than 18 years of age. The proportion of children meeting the criteria for special healthcare needs is presented in Table 1.

Most of North Carolina's CSHCN are boys (61%), white (71%), and live in a metropolitan area (70%). Only 57% have adequate insurance. Forty percent live in households with incomes less than 200% FPG. Fifty-eight percent of CSHCN have some or severe functional limitations. Fifty-six percent of the mothers of CSHCN have graduated from high school. A majority of CSHCN (81%) were older than five years of age at the time of the survey.

Among CSHCN, 91% have a usual source of care, 86% have a personal doctor or nurse, 78% receive family-centered care, 48% receive effective care coordination, and 81% report no difficulty obtaining referrals. Fifty-six percent of the children have met all five components of the medical home in North Carolina, and an additional 29% have met four of the five components. Of the 29% who met four components of the medical home, more than half lacked family-centered care.

Results of bivariate analysis of the independent variables with a medical home and its five components are presented in Table 3. A higher percentage of white CSHCN (60%) compared to non-white CSHCN (45%) have a medical home ($p = 0.007$). Access to a medical home is lower among CSHCN with functional limitations compared to those who do not have functional limitations (51% versus 62%, p = 0.02). While 60% of CSHCN with adequate insurance have a medical home, only 49% of CSHCN without adequate insurance have a medical home (p = 0.02). Age, gender, metropolitan residence, mother's education, and income status were not significantly associated with having a medical home based on bivariate analysis.

Differences were identified in the association of socio-demographic factors and the five components of the medical home (see Table 3). Family-centered care is associated with race, functional status, and adequacy of insurance. CSHCN who are non-white, lack adequate insurance, and have some or severe functional limitations receive family-centered care less often than their counterparts. While 11% of CSHCN with no functional limitations have difficulties obtaining referral to specialists, 24% of those with some or severe limitations have referral problems (p = 0.02). Access to a usual source of care was associated with mother's educational status: CSHCN whose mothers have a high school education or more have greater access to a usual source of care compared to CSHCN whose mothers did not have a high school education (95% versus 86%, p = 0.001). Race and household income were associated with access to a personal doctor/nurse.

Race, functional status, and adequacy of insurance were the

independent variables used in the logistic regression model to evaluate the association of socio-demographic factors with the presence of a medical home. None of the other variables (age, gender, residence, income status, and mother's education) confounded the relationship of the three independent variables with having a medical home.

The results of the multivariate analysis are presented in Table 4. In North Carolina, white CSHCN are 1.7 times more likely to have a medical home compared to non-white children, adjusted for functional status and adequacy of insurance. Children with no functional status limitation have 1.6 times the odds of having a medical home compared to children who have some or severe functional status limitation. After adjusting for race and functional status, adequacy of insurance was not associated with having a medical home.

Discussion

Fifty-six percent of CSHCN in North Carolina meet the operational definition of having a medical home. Children who are not white and children with functional limitations are significantly less likely to have a medical home compared to their counterparts.

Compared to national data,[10] a higher percentage of CSHCN in North Carolina have a medical home (56% versus 53%), receive family-centered care (71% versus 67%) and have effective care coordination (48% versus40%), and have no difficulty obtaining referrals (81% versus 78%). While the percentage of CSHCN in North Carolina with a usual source of care is similar to national averages, only 86% of CSHCN in North Carolina have a personal physician or nurse compared to 89% nationally. However, these differences in results between North Carolina and national data are small.

Race is an important correlate for not having a medical home in North Carolina. Previous studies have shown racial and ethnic disparities among children with special healthcare needs in access to healthcare, health-services utilization, and impact of a chronic health condition on families of CSHCN.[10,12,13] Our study provides further evidence of racial disparities in access to healthcare among children with special healthcare needs. This current information about racial disparities should be examined further.

Similar to CSHCN across the United States, severity of functional limitations was another independent predictor of not having a medical home. Disparities in healthcare of CSHCN associated with their functional status have been reported by other states.[14,15] Future studies are necessary to understand these variations in functional limitations and the causes for these disparities among children with special needs.

Although adequacy of insurance was associated with having a medical home in the bivariate analysis, the association was not significant after adjusting for functional status and race in a multivariate model. There is substantial evidence to show that being insured positively influences the healthcare experiences of CSHCN.[6,16-18] A significant difference may have emerged if insurance status were dichotomized as uninsured versus insured and the type of insurance as private versus public. Unfortunately, the sample size was too small to evaluate the association of having a medical home with insurance status or type, and we had to use adequacy of insurance as a proxy for insurance status.

The association between poverty and limited access to medical care of CSHCN is well documented in the literature.[6,10,13,17] The impact of having a child with special needs on the family is more pronounced in low-income families.[6,10,18] Although there was not an association between income and having a medical home in our study, it would be premature to conclude that level of income is not associated with access to a medical home in North Carolina. Income status was categorized into less than 200% FPG and greater than or equal to 200% FPG. The resulting smaller sample sizes did not permit analysis of multiple categories of income status in the logistic regression model. In fact, CSHCN from households with incomes less than 100% FPG had lower odds (unadjusted) of access to a medical home compared with those from households with incomes less than 400% FPG in bivariate analysis (data are not presented, but are available from the authors).

Table 4.
Adjusted Odds Ratios of Socio-Demographic Factors with Medical Homes in a Logistic Regression Model[*,†]

[†] Population-level estimates

Data Source: Centers for Disease Control and Prevention, National Center for Health Statistics, State and Local Area Integrated Telephone Survey, National Survey of Children with Special Health Care Needs, 2001.

Although the results for North Carolina are better than for the nation as a whole (40%),[10] more than half of CSHCN do not receive effective care coordination in North Carolina.

The American Academy of Pediatrics recognizes the importance of care coordination in the care of CSHCN and provides recommendations for care coordination for this population.[19] Policy development and program planning for CSHCN should emphasize improving care coordination for CSHCN in North Carolina. Family-centered care is another feature of access to services where North Carolina's performance should be improved. Similar to observations at the national level,[2,10] we found disparities associated with race/ethnicity and functional status of CSHCN in the receipt of family-centered care. It is possible that cultural or language differences accounted for the differences in family-centered care among racial/ethnic groups. The caregivers of CSHCN with functional status limitations report greater problems with referral to specialists. One could speculate that the referral needs of CSHCN with severe functional status limitations are much higher and likely result in problems in obtaining referrals to specialists. The association of functional status with referral problems and family-centered care needs further exploration.

It is important to note that there are differences in the association of socio-demographic factors and the five components of a medical home. For example, mother's education is an important factor in access to a source of care and not important for the other components of a medical home. Individual components of the medical home should be examined separately. The relationship between socio-demographic factors and having a medical home must be understood in order to monitor and evaluate their implementation.

Limitations

Although the National Survey of CSHCN was designed to make it possible to conduct state-level analyses, in-depth analysis could not be performed because the sample size for North Carolina was small. For this reason, specific categories among the socio-demographic factors could not be examined. Another important limitation involves the measure of having a medical home in this study. The National Survey contains information that can be used to measure the medical home concept. However, it does not fully operationalize all of its characteristics. If a different set of items were used to measure having a medical home, the results may be different. Hence, the results of this study can be compared only with other studies that use the same items to measure the medical home concept. This point is important when comparing studies across the United States and studies across different points in time. The lower response rate for the survey could have resulted in non-response bias. Since this study is exploratory in nature, multiple comparisons were made without correction, among socio-demographic factors and the components of the medical home. This could have resulted in a Type I error and in spurious associations. Hence, the associations between socio-demographic factors and the components of the medical home warrant further evaluation. Finally, because of the cross-sectional nature of this study, a causal relationship between the socio-demographic factors and the presence of medical home cannot be established.

Conclusions

Our study provides comprehensive information about the characteristics of CSHCN in North Carolina and the experience of these children and their families with a medical home. This information will be useful for North Carolina Title V needs assessment reports to the MCHB. Children with special healthcare needs belonging to specific minority groups and CSHCN whose conditions cause some or severe limitation of their activities were identified as at-risk for problems accessing a medical home. Disparities in access to a medical home should be considered in setting goals and in planning programs for CSHCN using the medical home model. The data in this study can be used to compare the health access situation for CSHCN in North Carolina with other states and to evaluate state performance in the future.

Each component of the medical home model must continue to be investigated. Since the lack of effective care coordination is the most common problem identified by families of CSHCN in North Carolina, strategies to improve performance in this area should be pursued. While efforts are made to provide certain components of a medical home, such as a usual source of care, there is a need to work toward increasing the effectiveness of care coordination and family-centered care to achieve the *Healthy People 2010* objective of providing a medical home to all CSHCN in North Carolina. **NCMedJ**

Implantable Left Ventricular Assist Devices:

New Hope for Patients with End-Stage Heart Failure

Carmelo A. Milano, MD, Andrew J. Lodge, MD, Laura J. Blue, RN, Peter K. Smith, MD, G. Michael Felker, MD, Adrian F. Hernandez, MD, Paul B. Rosenberg, MD, and Joseph G. Rogers, MD

Abstract

Introduction: *Recently, the Food and Drug Administration approved implantable left ventricular assist devices (LVAD) as destination therapy (DT) for end-stage heart failure patients who are ineligible for cardiac transplantation.*

Objective and Study Design: *This is a case series that describes the early results with DT LVAD at Duke University Medical Center (DUMC). An additional objective is to provide general information to a broad group of caregivers on this LVAD therapy, which is a new and developing treatment option.*

Data Source/Collection Methods: *Pretreatment clinical condition and outcomes data were collected retrospectively on this cohort of patients through chart review. Outcomes in our patients are compared to data from prior studies and established databases.*

Principal Findings: *Since approval of this therapy two years ago, 18 patients have been treated with implantable LVAD as DT at DUMC. The primary reason for ineligibility for transplant was advanced age (median age was 66). Nearly all of the patients (89%) were confined to the hospital requiring continuous inotropic infusions or temporary mechanical support (e.g., intra-aortic balloon pump) prior to LVAD. The 30-day survival following LVAD implantation was 94.5%; one-year survival was 60%. Eighty-nine percent of patients were successfully discharged to independent living. Operative mortality is similar to that of other cardiac surgery procedures performed on patients with advanced heart failure, while duration of intensive care stay and hospitalization remain considerably longer.*

Principal Limitations: *The principal limitation of this review is the absence of a control group of patients with end-stage heart failure who received conventional therapies. For this reason, the DT LVAD outcomes are compared to prior studies and database results.*

Conclusion: *Implantable LVAD therapy provides new hope for end-stage heart failure patients who do not qualify for cardiac transplantation.*

Introduction

Heart failure (HF) remains a major public health problem in developed nations. It is estimated that five million individuals in the United States suffer from HF with over 550,000 new cases diagnosed annually.[1] Roughly 100,000 patients have end-stage HF, which is characterized by the presence of symptoms at rest, refractory to standard oral medical therapies.[2] Treatment options for these patients remain limited and include inotropic infusions and cardiac transplantation.[2] Treatment with inotropes is associated with transient improvement in symptoms, but reduced survival. In a study of patients with end-stage HF treated with continuous outpatient inotropic infusions (COSI trial), one-year survival was only 6%.[3] Heart transplant represents an effective treatment, but only about 2,000 transplants are performed annually in this country; this number does not appear to be increasing despite efforts to use marginal donor organs. Thus, while heart transplant provides tremendous rewards for a select group, it remains epidemiologically insignificant.

Given the limited options for these end-stage patients, mechanical pumps have been in development for more than three decades to replace the function of the failing heart. The total artificial heart has been the most publicized mechanical option. Unfortunately, the total artificial heart (TAH), which requires removal of the native organ and provides replacement

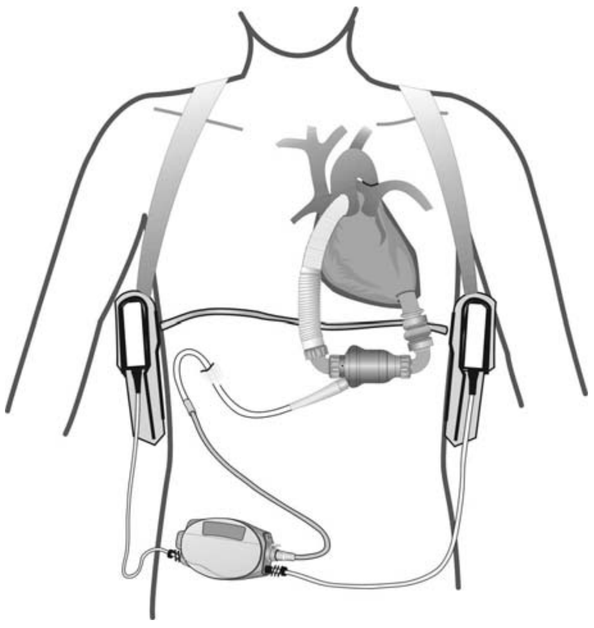
of both the right and left heart, has achieved limited application. Approximately 200 patients have been supported in investigational studies with these devices. There are two currently utilized TAH products: the CardioWest™ device has been Food and Drug Administration (FDA)-approved as a bridge to support patients who have deterioration of native heart function and are awaiting heart transplantation. Patients with this device are tethered to a large external driver that operates the pump, making discharge from the hospital difficult. The other TAH is the AbioCor® device (ABIOMED, Inc.), which recently failed to achieve FDA panel approval.[4] Major limitations for these products have consisted of thromboembolic complication and infection.

A more positive experience has occurred with implantable LVADs. Relative to the TAH, these devices attach more simply to the native heart; the left ventricular apex is cannulated for drainage of blood to the pump, and blood is pumped into an outflow graft, attached to the ascending aorta (see Figure 1). Development and testing of implantable LVADs has been ongoing for several decades. More than 10,000 patients have been supported with LVAD devices predominately as a bridge to transplantation. Extensive experience with patients who have been bridged to transplant suggested that these devices can restore normal hemodynamics even in the setting of biventricular failure. Home discharge and even return to employment has been possible for patients with implantable LVADs.[5] This positive experience led to the Randomized Evaluation of Mechanical Assistance for the Treatment of Congestive Heart Failure (REMATCH) trial in which end-stage HF patients who were not candidates for transplantation were randomized to optimal medical management versus implantable LVAD.[6] The Heartmate® I device (Thoratec, Inc.) was utilized exclusively in this trial. Patient's treated with LVADs experienced significant improvement in one- and two-year survival as well as improved quality of life relative to optimal medical management.[6] This trial led to FDA approval of the Heartmate® I as a destination therapy for patients with end-stage HF who fail to meet criteria for transplantation. Destination therapy refers to utilization of these devices as primary and final therapy rather than as a bridge therapy to support patients until transplantation is possible. Subsequently, the Centers for Medicare and Medicaid Services (CMS) have approved designated destination therapy (DT) LVAD centers. Duke University Medical Center has been designated as a CMS-approved DT LVAD center. In this paper we review, our early experience with implantable LVAD as primary treatment for end-stage HF.

Figure 1.
Implantable Ventricular Assist Devices



The Heartmate® II LVAD system is shown. The pump drains from the left ventricle via an apical cannula. Blood is pumped into the ascending aorta via an outflow graft. The Heartmate® II provides an axial flow with an Archimedes screw design. It is valveless and currently being tested as a DT LVAD.

Methods

From July 2003 to July 2005, 32 patients were referred for evaluation for DT LVAD at Duke University Medical Center (DUMC). Fourteen patients were excluded from treatment due to a variety of factors: (1) heart failure was not sufficiently advanced, (2) patient refused LVAD treatment, or (3) patient had inadequate financial resources. From this larger group, a subset of 18 consecutive patients underwent DT LVAD treatment at DUMC. The institutional review board of the Duke University Medical Center approved prospective collection of patient data and outcomes. Outcomes are reported as either early post-operative events occurring within the first 30 days of the LVAD implantation surgery, or late events occurring more than 30 days from the time of implant. Outcomes are reported as means for normally distributed events and medians for skewed distributions; range and standard deviations are provided where appropriate.

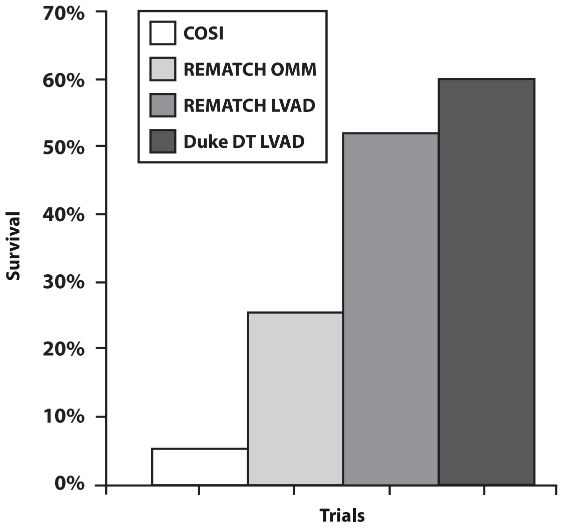
All patients were felt to be poor candidates for cardiac transplantation and did not meet traditional transplant criteria at the time of LVAD implant. Patients were ineligible for transplant due to: advanced age (n = 6), obesity (n = 5), renal insufficiency (n = 2), compliance issues (n = 2), malignancy (n = 2), and pulmonary insufficiency (n = 1). The most common reasons that patients were turned down for transplant were advanced age and obesity.

Results from the Duke DT LVAD cohort are compared to results from established cardiac surgery procedures performed on heart failure patients. Society of Thoracic Surgery data are shown for cardiac transplantation (n = 1,683 cases) and LV aneurysm resection (n = 277 cases) from 2000-2004.[13] In addition, results are compared to published data from the REMATCH and COSI trials (see Figure 2).

Results

Median age for the Duke DT LVAD group was 66 and ranged between 39 and 75; a disproportionate number were

Figure 2.
One-Year Survival for Patients with End-Stage Heart Failure



One year survival is shown for four groups of patients who had end-stage HF. The results of the REMATCH trial are shown for both the optimal medical management (OMM) group as well as the LVAD group. There was significant survival benefit to LVAD treatment compared with OMM in REMATCH. Relative to these results, the survival for 36 end stage HF patients treated by continuous outpatient support with inotropes (COSI trial) is also shown. Finally, the Duke DT LVAD (N = 18 patients) survival is shown.

older than age 65 because this is a common age cut-off for transplant surgery. One third (33%) were females. Fifty percent suffered from non-ischemic cardiomyopathy. All patients had end-stage heart failure with symptoms at rest despite standard medical treatments. Sixty-one percent of the patients were maintained on inotropic infusions preoperatively for clinical and/or hemodynamic evidence of cardiogenic shock. Preoperative mechanical support with intra-aortic balloon pump or temporary LVAD, in addition to inotropic infusions, was present in 28% of the patients (see Table 1). The HeartMate® I pulsatile LVAD was used in 16 of the 18 patients, while two smaller patients received the Heartmate® II axial flow device as part of a prospective FDA-sponsored trial (see Figure 1).

Table 1.
Preoperative Destination LVAD Patient Characteristics (N = 18)

Mean age	66
Sex (% male)	67%
Non-ischemic cardiomyopathy	50%
Mean LV ejection fraction	15% ± 5%
Inotropes	61%
Mechanical support	28%
Mean creatinine	1.5 ± 0.6

Thirty-Day Post-Operative Outcomes (see Table 2). Early death occurred in one of 18 patients (5.5%), which compares favorably to 30-day mortality in the Society of Thoracic Surgeons (STS) national cardiac surgery database of 3% for heart transplant and 7% for left ventricular aneurysm repair.[13] This patient expired due to pulmonary embolism. Most patients had an elevated preoperative creatinine, and many patients experienced elevation in post-operative serum creatinine, but none of the patients progressed to require dialysis during the post-operative period (see Tables 1, 2). There was one peri-operative stroke, which resulted in only a mild motor deficit. The incidence of serious post-operative bleeding that required patients to return to the operating room was 11%. There were no serious mediastinal or pump pocket infections during the early post-operative period. Median duration of hospitalization was 21 days, and median duration of initial intensive care unit (ICU) stay was six days (see Table 2). Discharge to independent living was achieved in 16/18 patients.

Table 2.
Post-Operative (30-day) Outcomes (N = 18)

30-day mortality	5.5%
Median ICU stay	6 days (range 1-76 days)
Median hospital stay	21 days (range 14-111 days)
Major infection	0%
Need for dialysis	0%
Take back for bleeding	11%
Embolic stroke	5.5%

Late Outcomes (see Table 3). The vast majority of patients were discharged to independent living (89%); all of these patients were ambulatory without significant neurological deficits or mental status impairment. None of the patients required permanent placement in a nursing home or chronic care facility. Overall, one-year survival was 60%, which compares favorably to survival rates (52%) for patients receiving an LVAD in the REMATCH trial. In addition to the one post-operative death, there have been a total of five additional deaths in this group. The causes of these late deaths were progression of malignancy (1), intracranial hemorrhage (2), sudden device failure (1), and overwhelming LVAD infection (1). One of the two intracranial hemorrhage deaths occurred in a patient with severe hypertension and was not thought to be attributable to LVAD therapy. Both episodes of intracranial hemorrhage occurred in patients anticoagulated with Coumadin® (one for atrial fibrillation and the other for deep venous thrombosis). Notably, the post-operative protocol for the HeartMate® I device, which was utilized in the majority of these cases, is for aspirin alone. Readmission during the first year after device implantation was 50%. Late embolic stroke occurred in two patients and neither experienced a persistent or disabling deficit. One of these embolic strokes occurred in the setting of LVAD endocarditis; this patient represented the only major LVAD infection in our cohort. A need for device replacement

Table 3.
Late Outcomes (N = 18)

Discharged to independent living	89%
Readmission	50%
Overall embolic stroke	16.5%
Major device infection	5.5%
Device replacement	16.5%
One-year survival	60%

occurred in three late survivors; two of the three replacement procedures were accomplished successfully. Reevaluation for transplantation occurred in four patients with two of these being accepted for transplant listing and ultimately receiving transplants. One patient achieved significant weight loss during LVAD support, enabling transplantation; the other patient maintained smoking cessation, allowing for transplantation.

Discussion

The preoperative status of this DT LVAD group reflects end-stage heart failure with the majority of patients requiring inotropic support or even some form of mechanical support. Most commonly pre-LVAD mechanical support consisted of intra-aortic balloon pump in patients with ischemic cardiomyopathy. Some degree of end-organ compromise existed in this group manifested by elevated serum creatinine. Despite the compromised preoperative status, post-operative survival (30-day) compares favorably to that of more conventional cardiac surgery, which is performed in HF patients. The 30-day Duke DT LVAD survival was slightly better than that reported for LV aneurysm repair, a commonly performed procedure in HF patients. The Duke DT LVAD 30-day survival is slightly less than cardiac transplant survival.

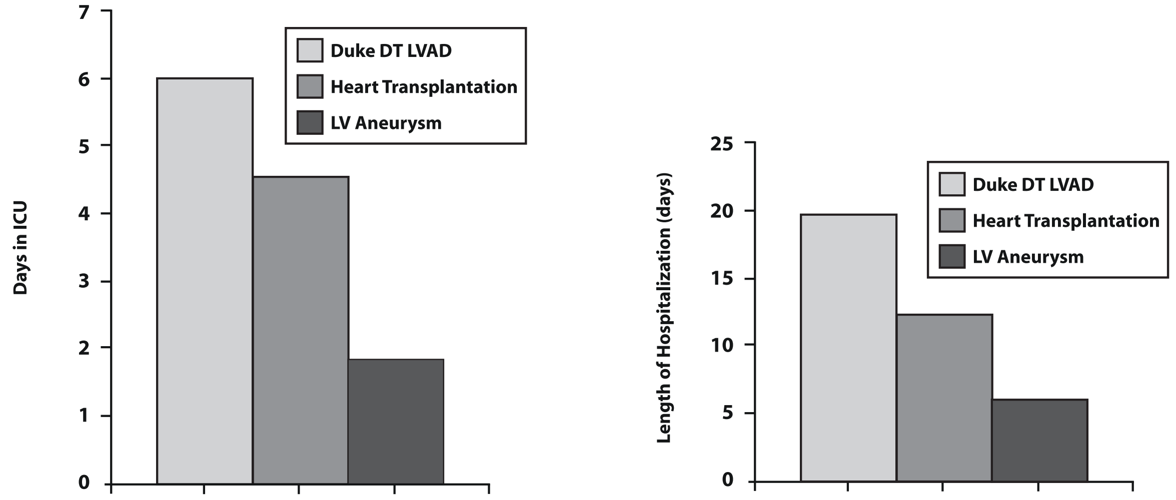
The encouraging 30-day survival rate in this population reflects increased experience with LVAD patients and perhaps improved perioperative strategies to control bleeding and right heart dysfunction.[5] Only 11% of patients returned to the operating room for bleeding, and none of the patients required mechanical support for right heart failure. All 18 patients were supported with inhaled nitric oxide and milrinone during the immediate post-operative period to prevent significant right ventricle dysfunction.

Post-operative length of hospital stay (21 days) and ICU stay (six days) for the Duke DT LVAD cohort remain high and represent an important area for future improvement. Relative to other cardiac procedures performed on HF patients, length of ICU stay and total hospitalization are markedly increased for DT LVAD (see Figure 3). These prolonged stays are important relative to patient quality of life and the economic feasibility of this therapy. The longer stays, in part, reflect the newer technology of LVADs. Furthermore, recovery of nutritional status, restoration of skeletal muscle function, and management of depression and psychological issues are additional factors inherent to this very sick cohort of patients, which prolong the post-operative hospital stay. Anticipation of these problems and a systematic treatment strategy may yield improved results.

Length of ICU stay and duration of hospitalization for surgical procedures on advanced HF patients.

The majority of patients in this series have now survived beyond the first year. Comparison of the Duke DT LVAD group to the REMATCH LVAD group suggests a trend toward improved outcomes at one year.[6] Indeed, the post-approval DT

Figure 3.
Length of ICU Stay/Hospitalization for Surgical Procedures on Advanced HF Patients



The ICU length of stay (in days) during post-operative recovery is shown for the Duke DT LVAD group (N = 18) relative to ICU length of stay for cardiac transplant and left ventricular aneurysm repair (STS national cardiac surgery database 2001-2004). Median values are shown. The total length of post-operative stay (in days) is shown for the Duke DT LVAD group (N = 18) relative to that for cardiac transplantation and left ventricular aneurysm repair (STS national cardiac surgery database 2001-2004). Median values are shown.

LVAD practice at large volume centers has shown trends toward improved one-year survival relative to REMATCH LVAD.[7,9] Relative to groups of patients with end-stage HF, who have been managed solely with infusions of inotropes, survival at one year is markedly improved with DT LVAD treatment. In fact, relative to the COSI trial, the one-year survival for the Duke DT LVAD group is an order of magnitude better (6% versus 60%) (see Figure 2). These results argue strongly that inotrope-dependent HF patients who are not eligible for transplant should be offered the option of DT LVAD.

Embolic stroke historically has represented an important limitation to mechanical heart support, but in this small series of patients, only three patients suffered documented embolic stroke. None of these events led to significant permanent deficits. These three patients remained ambulatory, did not require nursing home placement, and maintained an independent life style. One of these events occurred in a patient who also suffered LVAD endocarditis and, ultimately, died from sepsis. This favorable rate of embolic stroke is probably device-specific and reflects the low thromboembolic risk for the HeartMate® I device, which was used in the majority of cases. The HeartMate® I features a textured blood contacting surface, which allows for "neointimal deposition" and low thromboembolic rates. Most patients were maintained on aspirin as the only form of anticoagulation.

Three out of the 16 patients treated with the HeartMate® I device experienced major device wear with one patient experiencing rapid hemodynamic deterioration and death. Fortunately, device replacement has been successful at our center. Multiple modifications have been made to the HeartMate® I design to reduce valve and bearing wear and improve durability.[8] Furthermore, current destination LVAD trials including the RELIANT (Randomized Evaluation of Novacor LVAS In A Non-Transplant population) trial and the HeartMate® II trial hope to document greater durability with newer pump designs (see Figure 1).

This small series also illustrates how DT LVAD treatment may, in certain patients, enable reconsideration for transplantation. Of the 18 patients implanted, four were re-evaluated for transplant. Two patients were deemed suitable for transplant listing: one experienced substantial weight loss and achieved a specified weight goal, while the other patient achieved sustained abstinence from smoking. Many of the criteria for transplant listing represent variables that may change over time. Therefore, it is expected that some DT LVAD patients may become eligible for transplant listing after a period of extended support. Another example of this scenario is the group of patients who may have severely elevated pulmonary vascular resistance associated with advanced heart failure. Traditionally, these patients are ineligible for transplant because of the risks of right heart failure post-transplantation. Management of these patients with chronic LVAD support may restore more normal pulmonary vascular resistance enabling re-consideration for transplant.

An important limitation to this report is that it is a case series without a formal control group. Furthermore, while a variety of outcomes are reported, quantitative measures of quality of life were not performed for the Duke DT LVAD cohort. Lastly, the current cost of an implantable LVAD is approximately $70,000. Therefore, cost is a limiting factor. This increased cost may be reduced as additional types of LVADs achieve FDA approval.

In summary, implantable LVAD treatment is now a viable option for patients with end-stage HF, who do not qualify for cardiac transplantation. The appropriate population for LVAD therapy includes patients with recurrent decompensation despite optimal medical therapy. Patients who require continuous infusion of inotropic agents have very limited survival and should be offered DT LVAD. The REMATCH trial demonstrated that implantable LVAD treatment offers both a survival and a quality of life advantage for these end-stage HF patients.[6] Operative mortality for the Duke DT LVAD cohort compares favorably to that of other surgical procedures performed for advanced HF. Furthermore, trends are toward improved long-term outcomes, and newer LVAD devices, which offer greater durability (see Figure 1), are now being tested. **NCMedJ**

The Price of Progress:

Destination Left Ventricular Assist Device Therapy for Terminal Heart Failure

Craig H. Selzman, MD, and Jonathan Oberlander, PhD

Heart failure (HF) is a growing epidemic in the United States. Nearly five million patients suffer from this disease, with 400,000-600,000 new cases identified each year. Within this population exists a subset of individuals, estimated between 50,000-150,000, who has a severe form of HF. These patients in New York Heart Association III/IV or class D[a] heart failure are symptomatic despite excellent medical therapy, require frequent hospitalizations, and carry a mortality rate that rivals metastatic malignancies.[1] Although heart transplant remains a viable option for these desperately ill patients, the availability of donor organs limits our use of this therapy to roughly 2,000 each year. Mechanical circulatory devices—ranging from intra-aortic balloon pumps to the total artificial heart—have been utilized to help many of these patients. Over the last decade, widespread use of left ventricular assist devices (LVAD) has significantly impacted the natural history of end-stage HF. Three conceptual paradigms exist for the use of LVADs: bridging a patient until heart function recovers, bridging until a suitable organ for transplantation is available, and implantation as end-of-life therapy in lieu of transplantation—often referred to as Destination Therapy (DT).

As observed in the seminal Randomized Evaluation of Mechanical Assistance for the Treatment of Congestive Heart Failure (REMATCH) trial, which randomized class IV HF patients who were ineligible for heart transplantation to best medical therapy versus LVAD implantation, this disease is aggressive.[2] Compared to optimal medical managements, patients receiving LVADs had an increased one-year (52% versus 26%) and two-year (28% versus 8%) survival rate, as well as an improved quality of life.[2] In late 2003, the Centers for Medicare and Medicaid Services designated more than 50 centers nationwide as implant DT centers. Importantly, for the readers of the *North Carolina Medical Journal*, only two centers in North Carolina, South Carolina, Georgia, southern Virginia, and eastern Tennessee have been given this designation: Duke University Medical Center and the University of North Carolina at Chapel Hill.

In this issue of the *North Carolina Medical Journal*, the HF surgeons and cardiologists from Duke University Medical Center present their early series of patients over the last two years who have received LVADs for destination therapy.[3] Dr. Milano and his team should be commended for their impressive results in this challenging and severely ill group of patients. Eighteen patients deemed ineligible for heart transplant (secondary to age, obesity, renal failure, malignancy, compliance issues, or respiratory insufficiency) with end-stage HF (61% on intravenous inotropes and 28% with intraaortic balloon pumps) received the Heartmate® LVAD. Compared to the REMATCH cohort, the Duke investigators had lower operative mortality, lower stroke rate (well below the nearly 40% neurologic event rate noted in REMATCH), less perioperative bleeding, and preserved right ventricular function. Their infection rate was also markedly lower than the REMATCH group. These technical proficiencies translated to relatively low intensive care unit and hospital length of stays. At one year, 60% patients were alive with the majority living independently; again, better than the REMATCH group.

Others have reported post-REMATCH improved outcomes with DT.[4] Although the reported results are indeed admirable, the technology with pump refinement as well as new, innovative, and smaller axial flow pumps will likely make short- and long-term results for LVAD even better. Unfortunately, these therapies come with great cost. The authors spend little time discussing the economic and health policy issues intrinsic to such expensive device therapy. Although they mention the current cost of the

---

[a] Heart failure is frequently classified by the severity of symptoms. The New York Heart Association (NYHA) classified heart failure into Class I, II, III or IV. Classes III and IV are moderate and severe, respectively. The ACC/AHA have created guidelines that complement the NYHA classification.

Craig H. Selzman, MD, is an Assistant Professor in the Division of Cardiothoracic Surgery at the University of North Carolina at Chapel Hill. He can be reached at selzman@med.unc.edu or 3040 Burnett Womack, CB #7065, Chapel Hill, NC 27599. Telephone: 919-966-3381.

Jonathan B. Oberlander, PhD, is an Associate Professor in the Department of Social Medicine, at the University of North Carolina at Chapel Hill. He can be reached at jonathan_oberlander@med.unc.edu or CB# 7240 Chapel Hill, NC 27599. Telephone: 919-843-8269.

LVAD at $70,000, that only buys the actual device at the time of surgery. For this particular device, nearly $35,000 is needed to purchase components to allow their discharge from the hospital. In addition, hospital and intensive care stays are typically quite high for these patients, such that total implant costs are typically more than $200,000.

Consequently, all hospitals offering LVAD therapy as destination therapy, including Duke and UNC, as well as public and private insurers, must confront a host of ethical and economic dilemmas as use of such devices becomes more widespread. Is this a just and efficient use of medical care resources? Who should have priority to receive such treatments? Do the benefits of LVADs as DT justify their high costs at a time when healthcare inflation is pricing millions of Americans out of the health insurance market? How much money should cash-strapped state Medicaid programs spend on this technology given other competing demands? And what are the implications for a Medicare program, which already faces substantial fiscal pressures in coming years as the baby boomers retire?

These questions will not be easily resolved. Preliminary assessments of LVAD's cost effectiveness have not been favorable.[5] Clear assessment of cost-effectiveness ratios are difficult to calculate, ranging from $37,000 per quality-adjusted life year (QALY)[6] to $802,700/QALY.[7] These costs must be weighed in the context of other valuable therapies, including cholesterol testing ($330/QALY) and home hemodialysis ($25,000/QALY). Yet, given the scarcity of available transplants, the life-saving difference they make for some HF patients, and the prior contribution of medical technologies to improving cardiovascular health outcomes,[8] LVAD's promise cannot be easily dismissed. This is a rapidly changing area of medicine, and as pump technology evolves, so too will calculations of costs and benefits. That is, the cost effectiveness of LVADs is likely to improve with further technological developments and clinical experience. Conversely, even if LVAD costs decline, total spending on this technology will rise considerably if it is utilized more widely and indications broaden. Studies such as those reported in this issue of the *North Carolina Medical Journal* indeed show both the feasibility and utility of LVAD therapy as end-of-life therapy for HF patients. As LVAD therapy continues to evolve, attention to clinical effectiveness should also be accompanied by awareness of the compelling ethical and economic implications raised by widespread implementation of this innovative therapy. **NCMedJ**

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

INTRODUCTION

Policy Forum:
Prostate Cancer: Screening, Diagnosis, Treatment, and Follow-Up Care

In this issue of the *North Carolina Medical Journal*, we focus on one of the most common cancers among men in our nation—a cancer for which there are excellent technologies for early detection and definitive diagnosis, as well as several options for treatment. It is a disease where North Carolina's adult male population seems to exhibit an incidence greater than for the nation as a whole, with African American men being diagnosed with the disease more frequently than whites. Similar findings have been observed with regard to mortality from prostate cancer as well, with dramatic disparities between United States men and North Carolina men, as well as between African American and white men. Such data raise questions about disparities in access to (or participation in) proper screening for the disease, and also about the accessibility of treatment options and possible biological differences among racial groups in susceptibility to the disease itself.

Prostate cancer is a condition for which there should be fairly low mortality if screening and definitive diagnosis occur early, when the disease is localized to the prostate. Yet, it remains the second leading cancer-related cause of death among men in this country. Educational campaigns about this disease, the availability of both screening and treatment facilities, and efforts to dispel the widespread fear of the consequences of treatment (such as incontinence and/or sexual dysfunction) have not had the desired effect.

In this issue of the Journal, Dr. Culley Carson, Chief of the Division of Urology at the University of North Carolina (UNC) School of Medicine, has written an Issue Brief summarizing the overall situation with regard to the screening for and detection, diagnosis, and treatment of prostate cancer. Dr. Carson's overview is followed by North Carolina Senator David Hoyle's personal reflections on being diagnosed and treated for prostate cancer. Those who have gone through the various steps toward surgery will find familiarity in his commentary. These two papers provide both a contemporary overview of the medical science and available treatments for this condition, as well as an appreciation for how the disease can affect an individual faced with this diagnosis.

We have included commentaries by a number of experts from North Carolina and elsewhere dealing with the diagnosis and treatment, as well as the epidemiology, of this disease. Drs. Gaston and Pruthi of UNC offer a detailed discussion of the disparities among white and African American men in the experience of prostate cancer, its natural progression, and response to treatment. Similar data are reported in a succinct way by Dr. Deborah Porterfield of the North Carolina Division of Public Health in our regular "Running the Numbers" section.

Drs. Paul Maroni and David Crawford of the University of Colorado provide a detailed discussion of contemporary methods and programs for screening adult men for this disease. We invited Dr. Michael Weinstein of Director of WakeMed's Department of Clinical

Laboratories to discuss how the clinical pathologist deals with the diagnosis of prostate cancer, as well as new technologies for the assessment of laboratory specimens in reaching a definitive clinical diagnosis. Dr. Eric Wallen from the UNC Department of Surgery describes contemporary surgical approaches to the treatment of prostate cancer. Dr. Scott Sailer from Wake Radiology Associates describes current approaches from the perspective of radiation oncology. Dr. William Berry from the Cancer Centers of North Carolina provides a detailed description of endocrine and chemotherapeutic interventional options and their appropriateness for the treatment of this disease.

Following this rather comprehensive array of clinical commentaries, we are fortunate that Drs. Rachael DiSantostefano and John Lavelle of UNC-Chapel Hill have been willing to discuss the economic aspects of prostate cancer, including the implications of policies related to screening, diagnosis, and treatment.

We are grateful to our colleagues for summarizing the latest in available technologies for screening, diagnosis, treatment, and after-care and for making this information available to our extensive readership. We know there are controversial aspects to some prostate cancer approaches and unknown implications of some recently developed therapies, but this is one area of contemporary medical science and practice where considerable progress has been made. It is our view that understanding this forward movement cannot take place without an appreciation of the many clinical disciplines involved in both the diagnosis and the treatment of this disease.

As always, we welcome the comments and observations of our readers on these and other contributions to the Journal.

Gordon H. DeFriese, PhD
Editor-in-Chief

Carcinoma of the Prostate:
Overview of the Most Common Malignancy in Men

Culley C. Carson III, MD

In the United States and North Carolina carcinoma of the prostate is the most common non-cutaneous malignant process and second most common cause of cancer death among United States men. Since carcinoma of the prostate strikes middle-aged and elderly men and usually has a prolonged progression, the controversy regarding the health effects, treatment, survival, and, most importantly, screening continues throughout the medical literature. Because of this prolonged course and the difficulty with identifying the most indolent tumors, it has been widely suggested that prostate cancer is over diagnosed, as many men may live with prostate cancer with no effect on either their quality of life or ultimate longevity.

More than 230,000 men are diagnosed with prostate cancer in the United States annually. Of these, more than 30,000 die of their disease. Mortality from prostate cancer is, therefore, second only to lung cancer for men in the United States.[1] The possibility of an American man acquiring prostate cancer during his lifetime is approximately 15%. Of great importance, however, is the fall in prostate cancer mortality witnessed since 1994. Similarly, the incidence of prostate cancer in all populations has begun to decline, with the initial decline beginning in 1993. This decline is observed in both white and black patients.[1] While the etiology of carcinoma of the prostate remains elusive, some associated risk factors have been identified.

> *"...it has been suggested that the PSA threshold for biopsy of 4.0 ng/ml should be lowered. Such lowering, however, will increase the number of biopsies performed..."*

Risk Factors

Genetic influences may determine the risk of carcinoma of the prostate in some men. Indeed men with first-degree male relatives with prostate cancer have more than a two-fold increase in their incidence of prostate cancer, and men with two or three first-degree relatives with carcinoma of the prostate may have as high as a five-to-ten fold increased risk. Approximately 10-12% of prostate cancer cases are genetically influenced, and these most often manifest as prostate cancer in patients under age 60. This genetic increase is most marked in African American men. The highest risk for prostate cancer for African American men is seen in eastern North Carolina.[2] The reason for the high prevalence of prostate cancer remains controversial. Men living in Africa have one of the lowest prevalences of prostate cancer in the world. Diet may have an influence, as diets high in saturated fat have been associated with increased risk for prostate cancer, while antioxidants, such as selenium, lycopenes, and vitamin E, have been reported to decrease risk.

Indeed, the lifestyle trait in United States men that is most highly associated with both the incidence and mortality of prostate cancer is diet. Diets high in meat with high animal fat and low levels of fruits and vegetables appear to be associated with higher risks and mortality from prostate cancer.[3] A prospective study of more than 50,000 men reporting diet and associated risk of prostate cancer demonstrated that red meat consumption was highly associated with carcinoma of the prostate.[3,4] Studies have also demonstrated decreased prostate cancer among men consuming the antioxidant, selenium, and vitamin E.[4] A current, ongoing study (SELECT) further elucidates this association.[5] Because of the many basic science and epidemiologic studies that suggest there is decreased prostate cancer prevalence with the intake of antioxidants, it appears that oxidative stresses may contribute to the genesis of prostate

Culley C. Carson III, MD, is Rhodes Distinguished Professor and Chief, Division of Urology, Department of Surgery, School of Medicine, UNC. He can be reached at carson@med.unc.edu or CB# 7235, Chapel Hill, NC 27599-7235. Telephone: 919-966-9144.

cancer. These oxidants, in addition to diet, may be produced by environmental exposures and inflammation. Indeed androgens (steroid hormones, such as testosterone) associated with prostate cancer may increase oxidant effects in prostate cancer cells.[6]

Increasing evidence suggests that chronic inflammatory processes may have an etiologic role in human cancers, including prostate cancer.[7] While the symptoms of inflammation or infection in the prostate are uncommon preceding the diagnosis of prostate cancer, radical prostatectomy specimens often demonstrate evidence for chronic inflammatory conditions. Although the association of these prostatic conditions continues to strengthen, no specific etiology has been defined. Inhibition of GSTP1 gene expression, which encodes glutathione S-transferase capable of cell damage from oxidant stress, and is frequently found in prostate cancer cells. Lesions of proliferative, inflammatory atrophy with activated inflammatory and epithelial cells may be precursors to prostatic carcinoma.[7] Clinically, other non-specific inflammatory markers, such as C-reactive protein also have been associated with rising PSA levels and prostate cancer.[8]

Prostate Cancer Prevention

The fact that prostate cancer occurs in such high numbers of men and later in life in addition to evidence suggesting environmental influences in its etiology, chemoprevention has long been discussed and investigated. Prostate cancer prevention, if simple and well tolerated, would significantly limit the financial costs of screening and treatment, as well as, the psychological cost and morbidity and, ultimately, the mortality from prostate cancer of a large portion of the 30,000 or more men who die each year from this difficult disease. Because it is well known that males with low androgen levels have a decreased prevalence for prostate cancer (and eunuchs rarely are afflicted with prostate cancer), androgen manipulation is a natural target for prostate cancer prevention.

Certain Pharmaceuticals May Help Prevent Prostate Cancer

The Prostate Cancer Prevention Trial (PCPT) was the first large population-based trial to test chemoprevention in men with carcinoma of the prostate.[9] This study, begun in 1993, accrued more than 18,000 men over age 55 with normal digital rectal examination (DRE) and prostate-specific antigen (PSA) values of less than or equal to 3.0 ng/ml. Because men with congenital deficiency of Type II, 5 alpha reductase[a] do not suffer from either benign prostatic hyperplasia (BPH)—enlargement of the prostate or prostate cancer, Finasteride (a pharmacologic agent designed to block Type II, 5 alpha reductase) was used in this trial. Men were randomized into two groups: (1) a placebo group or (2) a treatment group that took 5 mg of Finasteride each day for seven years. Subject's in both groups received a biopsy during the study if any of the following three indications occurred: (1) PSA level exceeded 4.0 ng/ml, (2) digital rectal examination was abnormal, or (3) PSA values rose significantly with Finasteride. Subjects who completed the seven-year study without indication received an end-of-study biopsy. Because the National Institutes of Health (NIH) Data Safety and Monitoring Committee identified a substantial reduction in risk among subjects taking Finasteride, the study was concluded 15 months prior to its scheduled end date. Once analyzed, data from this study demonstrated a reduction in the prevalence of prostate cancer by 24.8% in patients randomized to Finasteride. However, a larger percentage of subjects treated with Finasteride (6.4%) were found to have more severe malignant tumors (Gleason scores[b] of 7-10) than subjects in the placebo group (5.1%). While sexual side effects were experienced by patients in the Finasteride arm, urinary symptoms (lower urinary tract symptoms) were more common in the placebo group. Although researchers found that a reduction in prostate cancer risk among patients treated with Finasteride was present in subjects who received biopsies due to the three indications and to those who completed the study without indication, there were equal numbers of deaths due to prostate cancer in each group. While this study continues to be controversial, and the increased incidence of higher-grade cancers in the Finasteride-treated men appears to be explained by changes in prostate size and tumor interpretation, the PCPT trial is the first convincing demonstration that prostate cancer can be prevented by a tolerable oral medication without significant adverse events.

Prostate Cancer Screening

Because prostate cancer rarely causes early symptoms, the diagnosis of prostate cancer is best performed by physical examination and laboratory testing. Digital rectal examination (DRE) has long been the cornerstone for the diagnosis of carcinoma of the prostate. Areas of palpable induration (hardness), firmness, and asymmetry of the prostate gland strongly suggest the presence of carcinoma. While BPH produces prostate enlargement, induration of the posterior prostatic lobe strongly suggests a diagnosis of prostate cancer. However, cancers found on DRE are more often of advanced pathologic stage; a diagnosis before nodules are formed improves prognosis.[10] DRE alone may miss as many as 45% of cancers subsequently identified by prostate biopsy following observation of rising PSA.[11] Abnormal DRE appears to

---

[a] Type II, 5 alpha reductase is an enzyme responsible for regulating the conversion of testosterone to dihydrotestosterone (DHT) in the liver.

[b] The Gleason scoring system grades prostate cancer patterns from 1 (well differentiated malignancy) to 5 (poorly differentiated malignancy). The Gleason combined score or grade is then computed by adding the most abundant Gleason grade pattern to the second most abundant Gleason grade pattern to obtain a Gleason sum. This score from 2 to 10 has been demonstrated to be accurate in predicting patient outcomes. Gleason scores of 2 to 6 respond best to primary treatment with significantly lower recurrence rates than Gleason scores of 8 to 10. In a group of more than 8,000 men diagnosed between 1989 and 2001, men with low-risk histories rose from 29.8% to 45.3%.[27]

be dependent upon PSA level, patient race, and age. There is a higher predictive value for DRE in African American men, older men, and men with higher PSA levels.[12]

PSA testing has significantly changed the diagnosis of prostate cancer since its introduction in the early 1990s. PSA is an enzyme (human kallikrein serine protease) that is encoded by the genes of chromosome 19. PSA is produced predominantly by the columnar secretory cells of the prostate and is present in high levels in the ejaculate. PSA first becomes detectable in the serum during puberty when steroid hormone levels increase. As patients age, their PSAs continue to rise, and there is an age-associated PSA value. Similarly, PSA rises with prostate volume and can be used as a surrogate marker for prostate size. Baseline PSAs in patients without prostatic malignancies are higher in African American men than in white men.[13]

Produced by the prostate in both benign and malignant conditions, PSA is a more accurate *prostate marker* than a *prostate cancer marker*. Any condition that produces prostate inflammation or disrupts prostate tissue will produce an elevation in PSA. This includes benign conditions such as BPH, prostatitis, urinary retention, prostatic infarction, prostate biopsy, and vigorous prostatic massage. While these inflammatory and surgical conditions produce changes in PSA, studies of ejaculation prior to PSA determination have not demonstrated convincingly a change in PSA level.[14] The 5 alpha reductase inhibitors, such as Finasteride and Dutasteride, reduce PSA levels to approximately 50% of baseline by six to 12 months following treatment.[15] While the use of PSA screening in identifying prostate cancer continues to be controversial, there are many studies that have demonstrated the importance of PSA testing to diagnose prostate cancer. Because PSA is more sensitive and specific than DRE alone, the detection of prostate cancer with a combination of PSA and DRE has a significantly higher predictive value than either study alone. In fact, PSA values in screening populations have the highest predictive value.[11] Longitudinal follow-up population studies using banked serum samples have reported a five-year lead time of prostate cancer diagnosis from PSA levels with 4.0 ng/ml as initial cutoffs.[16] Because PSA can be elevated by benign conditions, and elevations in PSA trigger prostate biopsies, efforts have been made to improve the accuracy of PSA determinations. Newer tests, such as the free and total PSA ratio,[c] prostate specific membrane antigen (PSMA),[d] complexed PSA,[e] and others, are under investigation for improving PSA accuracy. Current practice, however, can employ *PSA density*, an adjustment in PSA level to account for prostate volume. Adjusting the PSA level for prostate volume permits increased accuracy. More commonly, however, *PSA velocity* is used. PSA velocity measures changes in serum PSA values over time.[17]

> *"Because a single PSA value may be less accurate, PSA velocity, rise in PSA over time, may be a better indicator for prostate biopsy."*

PSA Threshold for Prostate Biopsy

Controversy continues regarding the interpretation of PSA values and the threshold for which a biopsy is required. The ideal PSA value for differentiating prostate cancer from benign prostates remains elusive. The standard PSA value differentiating normal from abnormal prostates of 4.0 ng/ml was established in 1990.[18] Because many prostate cancers can be present and even significant at PSA levels below 4.0 ng/ml, investigation has focused on the percentage of cancers missed at levels below 4.0. In the PCPT trial, end-of-study biopsies were correlated to PSA levels. Of 2,950 men biopsied, 449 (15.2%) were found to have prostate cancer with PSA levels less than 4.0. Of those men with PSAs between 3.1 and 4.0, 26.9% had positive biopsies, of which 25% were high-grade malignancies. Even among patients with PSA levels less than 0.5 ng/ml, 6.6% had positive biopsies at end-of-study. These data strongly suggest that PSA is better when focused on *density* or, more conveniently, *velocity* to differentiate those patients at high risk for prostate cancer and positive biopsies.[19] Based on this study, it has been suggested that the PSA threshold for biopsy of 4.0 ng/ml should be lowered. Such lowering, however, will increase the number of biopsies performed. The controversy continues.

PSA velocity appears to be more helpful in a clinical setting. Outcome studies have demonstrated that PSA velocity of greater than 2.0 ng/ml per year is associated with significantly higher death rates from prostate cancer when compared with lower PSA velocities.[20,21] Thus, annual PSAs in patients at risk are important for the identification and treatment of carcinoma of the prostate. Because a single PSA value may be less accurate, PSA velocity, rise in PSA over time, may be a better indicator for prostate biopsy. In a prospective screening study, a velocity threshold of 0.75 ng/ml per year was used to differentiate patients. Using this threshold of velocity, 47% of men with velocities greater than 0.75 ng/dl were diagnosed with prostate cancer compared with only 11% of those with velocities less than 0.75 ng/ml.[22] In a European study where men were followed for four years, PSA velocity was 0.62 ng/dl per year for men with prostate cancer compared with

---

[c] The free and total PSA ratios are used to measure the percentage of free PSA relative to the total amount of PSA in a patient's blood sample.

[d] Prostate specific membrane antigen is a PSA produced by the membrane of prostate cancer cells.

[e] Complexed PSA is a test that measures the level of PSA, which has been complexed or bound with a certain protein (alpha-1-antichymotrypsin) in a patient's blood sample.

0.46 ng/dl per year for those without cancer. PSA doubling time was 5.1 years with prostate cancer and 6.1 years with negative biopsies.[23] In men with low PSAs, however, PSA velocity appears to be less accurate in selecting men for prostate biopsy.[24] Thus, PSA change over time appears to be more valuable than static values in selecting which men will require prostate biopsy.

Biopsy

Once a suspicious PSA has been identified by value, density, or velocity, a transrectal, ultrasound-guided prostate biopsy is the most accurate technique for identifying prostate cancer. This outpatient procedure is usually performed using local anesthetic injection of the periprostatic nerves and can be done in an office setting. Although transrectal ultrasound typically does not demonstrate specific areas of suspicion, the procedure permits prostate targeting, which allows accurate sampling of all portions of the prostate. For repeat biopsies where initial malignancy is not identified and PSA continues to rise, careful sampling of the transition zone is important to eliminate less common foci of prostate malignancy.

Biopsies of the prostate are safe and have a low incidence of morbidity. In a series of more than 5,800 prostate biopsies, fewer than 0.5% of men required hospitalization; however, only 2.6% of men reported self-limiting hematuria (blood in urine) and occasional 50.4% hematospermia (blood in semen) early following biopsy.[25]

The diagnosis of prostate cancer, once made through transrectal needle biopsy of the prostate, is graded by histopathology using the previously mentioned Gleason grading system.[26] Staging of prostate cancer is performed using the standard TNM system (see Table 1). TNM describes the extent of the primary *tumor* (T stage), the absence or presence of spread to nearby lymph *nodes* (N stage), and the absence or presence of distant spread, or *metastasis* (M stage). Staging can be performed pre- and post-treatment, and the most definitive staging occurs following radical prostatectomy. With the advent of PSA testing, there has been a dramatic shift to diagnoses at lower stages and, thus, more likelihood of organ-confined cancer.[27] While imaging studies can be helpful in patients with extensive carcinoma of the prostate, further staging assistance using cross sectional imaging of the pelvis by computerized tomography or magnetic resonance imaging have not added to the accuracy of cancer staging.

Treatment of Localized Prostate Cancer

Treatment of localized prostate cancer requires significant discussion with patients regarding outcomes, morbidity, mortality, and requirement for treatment. Choices include: watchful waiting, radical prostatectomy, interstitial brachytherapy (radioactive seed implantation), and external beam radiation therapy. Choice of treatment alternative is based upon the individual, his family, and prognostic factors, such as stage, grade, and the patient's general physical condition. Over the past decade with the use of PSA, treatment of prostate cancer patients has decreased in average patient age and average stage. During this same time, surgery and radiation therapy for prostate cancer has significantly improved. Radiation therapy applied with conformal external beam techniques or the implantation of small radioactive seeds using brachytherapy has improved the efficacy of cancer control and decreased treatment morbidity. The combination of these treatment modalities with androgen deprivation therapy using luteinizing hormone-releasing hormone (LHRH) agonist[f] treatment has further improved outcomes.[28]

Radical prostatectomy has likewise improved markedly over the past two decades. The introduction of the bilateral nerve sparing radical prostatectomy in the early 1990s has improved continence levels and potency post-radical prostatectomy, while preserving cancer control rates and limiting positive margin rates. The introduction of laparoscopy and robot-assisted laparoscopic prostatectomy has further improved the morbidity from radical prostatectomy. With these inventions, the hospitalization time of patients undergoing modern robotic-assisted laparoscopic prostatectomy has declined from more than seven days in the mid 1990s to one day or less in the 21st century.

Table 1.
Clinical TNM Staging of Prostate Cancer

T1	Cancer is clinically inapparent, not palpable or visible by imaging
T1a	Incidental histologic finding, less than or equal to 5% of resected tissue
T1b	Incidental histologic finding, greater than 5% of resected tissue
T1c	Tumor indetified by needle biopsy, for any reason (e.g., elevated PSA)
T2	Palpable or visible tumor, confined within the prostate
T2a	Less than or equal to one half of one lobe
T2b	One lobe
T2c	Both lobes
T3	Tumor extends through the capsule
T3a	Extracapsular extension, unilateral or bilateral
T3b	Seminal vesicle involvement
T4	Tumor is fixed or invades adjacent structures
T4a	Tumor invades bladder neck, external sphincter or rectum
T4b	Tumor Invades to the floor and/or the wall of the pelvis

---

[f] Luteinizing hormone-releasing hormone is a naturally occurring hormone that controls sex hormones in both men and women. LHRH agonist is a compound similar to LHRH (luteinizing hormone-releasing hormone) that serves in a manner similar to LHRH to control the same sex hormones.

This decreased hospitalization time has been accompanied with improved potency and continence rates, decreased blood loss, and decreased mortality rates. In a landmark randomized study comparing radical prostatectomy with watchful waiting with median 8.2 year follow-up, there was a 44% decrease in cancer death, 40% decrease in metastatic disease, and 67% decrease in disease progression.[29] Thus, radical prostatectomy appears to reduce disease-specific mortality, overall mortality, and risks of metastases and local progression.

Because prostate cancer is associated with slow progression and few deaths within ten years of diagnosis, men with life expectancies of less than ten years or significant comorbidities may be safely and effectively managed with a watchful waiting program. Watchful waiting generally consists of follow-up with regular PSA, monitoring PSA velocity, symptomatic treatment for obstructive uropathy and lower urinary tract symptoms (LUTS), and repeat biopsy if necessary.[30]

Systemic treatment of progressive prostate cancer continues to evolve and improve. The association of prostate cancer control with castrate levels[g] of testosterone was first identified by Huggins et al. in the 1940s.[31] The use of physical castration was widely used until the introduction and wide acceptance of luteinizing hormone releasing hormone agonist (LHRH). These agents, which rapidly produce castrate levels of testosterone, are associated with prostate cancer suppression. Androgen deprivation therapy, therefore, appears efficacious irrespective of method of treatment. Current depo preparations allow LHRH agonist to be administered monthly, or every three or four months. Implantable devices permit yearly changes of LHRH implants. While androgen deprivation therapy is associated with the side effects of castration including: hot flashes, osteoporosis, loss of libido, and decreased muscle mass and strength, prostate cancer control is quite satisfactory. In fact, survival can be increased by many years (average 3.5 years). Timing of initiation of androgen deprivation therapy, however, has been controversial. Since recent studies have demonstrated a prolongation of survival, many feel that androgen deprivation therapy should be initiated with initial detections of PSA rise.[32] Due to the significant morbidity, including an increase in osteoporosis and fracture risk, however, patients and physicians may chose to delay androgen deprivation therapy to preserve sexual function, muscle mass, and bone health.[33]

Newer concepts in LHRH agonist therapy with intermittent therapy are being utilized and investigated throughout the world. With this technique, testosterone is decreased using an LHRH agonist to castrate levels and until PSA response is observed. LHRH agonists are then withdrawn until the PSA value again climbs. Survival outcomes and effectiveness of treatment of this approach remain controversial.

Other methods for treatment of advanced prostate cancer have now progressed to agents beyond androgen deprivation. Newer chemotherapeutic agents, such as mitoxantrone and paclitaxel, have improved the outcomes of systemic chemotherapy.[34] These agents, which are currently reserved for patients with systemic malignancy unresponsive to androgen deprivation, provide some promise for improving survivals and prostate cancer control in patients with advanced disease.

Future Directions

Over the past decade, PSA testing, screening, and evaluation has revolutionized the diagnosis and treatment of prostate cancer. Indeed, urologists in clinical practice in the United States have observed a significant shift in stage of disease at diagnosis with few patients presenting in the 21st century with locally advanced or metastatic prostate cancer. This "stage shift" has permitted better diagnosis and more effective treatment of those patients at risk. Unfortunately, however, PSA as a prostate marker and prostate-specific marker is an imperfect screening tool. Current research on newer, more specific markers continues; however, PSA with modified use that incorporates measures of PSA density and velocity remain the mainstay for diagnosis. Newer imaging modalities are being developed to localize prostate cancers with the goal of localized treatment. Treatment of localized prostate cancer continues to be best carried out with radiation therapy or radical prostatectomy.

Modifications in radical prostatectomy over the past two decades, to include nerve sparing, laparoscopic approaches, and robotically assisted laparoscopic approaches, have improved morbidity, mortality, and outcomes. The United States' decrease in prostate cancer mortality over the past decade may, arguably, be a result of this improved diagnosis and treatment. Better serum diagnostic testing and imaging studies are being investigated in an effort to improve the specificity of diagnosis. Similarly, studies to identify tumors that are biologically aggressive and important, versus those that are more indolent, are ongoing. Identification of biologically less active and more indolent tumors may increase the number of men eligible for safe watchful waiting and active surveillance. Active investigation into gene and vaccine therapy may assist in the treatment of men with locally advanced or metastatic cancer. Similarly, this sub-categorization of prostate malignancies may assist in identifying patients most in need of early androgen deprivation therapy. With the advances in systemic chemotherapy and post-operative radiation therapy, more patients with aggressive, advanced prostate malignancies can be effectively treated with expected increased survival and decreased morbidity. **NCMedJ**

---

[g] Castrate-level occurs when the levels of the body's testosterone drop 90-95%, which is consistent with the loss of the testicles.

COMMENTARY

Confronting Prostate Cancer:
A Personal Reflection

Senator David W. Hoyle

Editorial Note: Because prostate cancer, its early detection and treatment, raise so many issues of personal concern, we considered it important to include a discussion of some of these matters from a personal perspective. We are fortunate that one of our state's leading public policy makers, Senator David Hoyle of Gaston County, was willing to share his own experience with all phases of the process from detection and diagnosis to surgical intervention and post-operative care. We hope that this narrative will help bring clear focus to many of the issues raised by the authors in this issue of the Journal and encourage men who are not regularly screened at appropriate ages to raise these issues with their personal physicians.

No one likes the sound of the word "cancer," especially when it applies to you. In this respect, I was just like everyone else.

But, I had heard from many that "most of us [men] have this condition, whether we know it or not, and that we may all die from this disease if we live long enough. Although most of us die from something else long before symptoms of prostate cancer appear." The fact that the disease is slow-growing (in most) and more prevalent in older men makes many feel less concerned at younger ages. I was one of those, although I had been having prostate-related problems for many years, since my mid-40s. Off and on, I had experienced problems with discomfort, inflammation, and something my doctors referred to as prostatitis. My PSA levels had been slowly rising (from around 2, then 3, then 4, and eventually to 6; the so-called "velocity" of change was notable, but still failed to raise the concern of my physician).

Finally, my primary care physician, who had been taking care of me for years, after a usual digital rectal examination as part of a normal physical, noted a lump or hard spot on my prostate. My doctor thought it would be good for me to see a urologist for a consultation visit.

This preliminary unusual finding from a regular primary care visit began a long and convoluted series of events that caused no small amount of anxiety for me and my family.

Importance of Follow-Up to Preliminary Findings

Right away, my physician helped me get an appointment at the University of North Carolina Hospital (UNC) in Chapel Hill. A biopsy was performed and laboratory results came back with the unwelcome news that I did have cancer of the prostate, with a Gleason score of "6." My urologist at UNC explained several (surgical and non-surgical) options, but recommended that I consider surgery to remove the prostate.

I consulted a number of friends, including friends in the field of surgery and urology, about my situation and asked several of them: "If you had this condition, where would you go to have the surgery performed." A physician friend, with whom I had often played golf, recommended a surgeon at Johns Hopkins University in Baltimore. On his recommendation, I contacted that surgeon and arranged an appointment to be seen in his clinic. He recommended surgery within two weeks of that appointment.

The "Ups and Downs" of Good and Not-So-Good News

Then, a startling thing happened. A week later, after I returned to my regular work at the North Carolina General Assembly, I was summoned from a committee meeting by my secretary who said the surgeon from Baltimore was trying to reach me rather urgently. I rushed from the room and spent a nervous 20 minutes or so trying to page the surgeon. I had all sorts of images racing through my mind. Were the results of my laboratory tests found to be even more serious than they first appeared to be? Was it necessary for surgery to take place even sooner for some reason? What could it be?

When my surgeon and I managed to speak, he explained that when the pathologists at Johns Hopkins looked at the slides I brought with me from North Carolina, they concluded that I did not have prostate cancer after all! My surgeon was

Senator David W. Hoyle represents the 25th Senatorial District in the North Carolina General Assembly, which includes portions of Cleveland, Gaston, and Lincoln counties. He lives in Gastonia and can be reached at davidh@ncleg.net or 300-A Legislative Office Building, Raleigh, NC 27603-5925. Telephone: 919-733-5734.

calling to tell me that he had cancelled my scheduled surgery for the next week.

Even though there was a certain sense of "relief" in this news, my surgeon followed his announcement of these results with the request that I try to have an immediate second biopsy done here in North Carolina. He felt that was necessary to confirm the Hopkins pathologist's opinion that no disease existed, and then we would re-evaluate further options.

So, a few days later, I was scheduled for a second biopsy. This time, different from my first experience, the procedure was less painful and more extensive. Instead of six "punches," they did 12. But this time, I was more psychologically prepared and knew what to expect.

Two days later, the results were disappointing in that they confirmed the initial diagnosis: I did have prostate cancer. Surgery was scheduled for a second time, just before Christmas, after my prostate had time to heal from the extensive biopsy procedure. I got out of the hospital after surgery two days before Christmas and checked into a Baltimore hotel to rest for a few days before traveling home. The Hopkins surgeons wanted to make certain that I had no post-operative complications.

> *"No one likes the sound of the word "cancer," especially when it applies to you. In this respect, I was just like everyone else."*

After the surgery, I had a catheter to assist with bladder issues, which I kept in place for 20 days when it was removed by my own physician in Gastonia. I also wore paper diapers to make certain that I did not have a problem with incontinence. Thankfully, these were necessary for only a few days. I had no problems with urination or anything else after that.

I was relieved to learn that the surgical margins of my disease were contained (localized) within the prostate, and the disease had not spread to other parts of my body. Therefore, I had no post-surgical radiation. I am now followed on a regular basis (every six months) by a urologist in Charlotte, and my PSA has dropped to "zero." Several other tests have been done, such as a bone scan in Chapel Hill, to make certain that the disease was not transmitted to other parts of the body. In every respect, this has been a complete success, and I am pleased to have been disease-free for the seven-to-eight years since the surgery was performed.

Lessons Learned

This experience provides a number of "lessons" that I would pass along to others who may yet have to confront this same set of circumstances. First, it is important to have a regular primary care physician who knows you and your health situation well. It was important that my physician who had been seeing me off and on for many years was able to note the appearance of a "hard spot" on my prostate during a routine examination. Were it not for that finding, one might have concluded that an elevated PSA level alone, which had remained high for many years, was simply benign prostatic hypertrophy (BPH) and no cause for concern. I have a family history of prostate cancer, so I knew that this was something that might likely develop in my case.

Second, once I followed-up this initial finding with a more thorough urological examination and biopsy, and once I had a definitive diagnosis, I asked lots of questions of my doctors and my friends who had gone through this before. I read everything I could get my hands on about this condition, so I would know what courses of action were available to me, and what the likely (or possible) outcomes might be of any given course of action. One of my friends, who had considered the option of the implantation of radiological "seeds" instead of surgery, had worried (before taking that route) about problems with both incontinence and impotence. Neither of these problems resulted in his case. But, I learned that once radiation is chosen as an option, surgery is no longer an option.

Third, it is important to realize that medicine is not "perfect." Mistakes do happen, and test results are often inaccurate. It is important, especially with diseases like cancer, to double check test results and, if possible, with a different laboratory or clinical setting. I was fortunate that my Hopkins physicians recommended that I have another biopsy performed here in North Carolina. That second set of biopsy results confirmed the findings of the first biopsy—I did, in fact, have cancer and needed surgery. I've tried many times to figure out how the Hopkins pathologists could have been so certain that I didn't have cancer. My only explanation is that somehow the slides I brought with me from Chapel Hill were either the wrong slides, or they got mixed up in some way in the lab at Hopkins. In any event, a second set of biopsy results were necessary to actually detect the disease.

Finally, the combination of early diagnosis and immediate follow-through with a detailed diagnostic workup and consultation can lead to better treatment outcomes. Also, although there are risks of post-operative complications, for large numbers of men who undergo these procedures, results are similar to mine. In this day and age, there is really no reason for men to die from prostate cancer if they follow these recommended procedures for clinical examination and testing.

I am one of those grateful patients who has been well-served by many healthcare professionals here in North Carolina and elsewhere, as my family and I have confronted what, for some, is a very unnerving diagnosis. **NCMedJ**

COMMENTARY

Racial Differences in Prostate Cancer

Kris E. Gaston, MD, and Raj S. Pruthi, MD

Prostate cancer is the most common non-cutaneous cancer diagnosed in American men and the second leading cause of male cancer deaths.[1] African American men suffer disproportionately with almost double the incidence of and death from prostate cancer. Many sociologic and biologic theories have been applied to solve this conundrum; however, there is still great contention over what the isolated causes of these racially divided outcomes are.

Epidemiology

United States Statistics

In 2006, it is estimated that 234,460 men will be diagnosed, and 27,350 men will die from prostate cancer.[1] Data from the Surveillance, Epidemiology, and End Results (SEER) database 1998-2002 revealed the median age at diagnosis for prostate cancer was 69 years of age. Approximately 0.0% were diagnosed under age 34; 0.5% between 35 and 44; 8.0% between 45 and 54; 26.1% between 55 and 64; 37.5% between 65 and 74; 23.2% between 75 and 84; and 4.7% at 85 years of age or greater.[2] The age-adjusted incidence rate from 1998-2002 was 173.8 per 100,000 men per year. SEER data from 1998-2002 also revealed the median age at death from prostate cancer was 79 years of age. Approximately 0.0% died under age 34; 0.1% between 35 and 44; 1.2% between 45 and 54; 6.3% between 55 and 64; 22.1% between 65 and 74; 42.3% between 75 and 84; and 27.9% at 85 years of age or greater. The age-adjusted death rate was 30.3 per 100,000 men per year.[2]

African Americans suffer a disproportionately high incidence of and mortality from prostate cancer compared to whites. Relative to whites, African Americans suffer from a 1.6 times higher incidence of prostate cancer. According to SEER 13 registries from 1998-2002, whites were diagnosed with prostate cancer at a rate of 169.0 per 100,000 men compared to African Americans diagnosed at a rate of 272.0 per 100,000 men.[2] African Americans compared to whites also suffer from a 2.5 times greater mortality from prostate cancer. Whites died with prostate cancer at a rate of 27.7 per 100,000 men compared to African Americans who died at a rate of 68.1 per 100,000 men.[2]

North Carolina Statistics

In 2006, it is estimated that 7,120 men will be diagnosed and 830 men will die from prostate cancer in North Carolina.[1] The age-adjusted incidence rate for all races from 1999-2001 in North Carolina was 159.4 per 100,000 (United States 161.2 per 100,000).[2] The age-adjusted death rate from 1999-2001 for all races in North Carolina was 35.6 per 100,000 (United States 30.3 per 100,000).[2] More alarmingly, some North Carolina counties have the highest incidence of and death from prostate cancer in the world, irrespective of race (see Table 1 and 2). The etiology for such high prostate cancer incidence remains unknown.

Racial differences in the incidence of and death from prostate cancer persist when examined at the state-specific level. SEER data from North Carolina from 1999-2001 showed that whites had an incidence rate of 143.6 per 100,000 (United States white incidence in 2001 was 144 per 100,000) compared to African Americans who had an incidence rate of 238.5 per 100,000 (United States African American incidence in 2001 was 234.1 per 100,000).[2] During a similar time period (1998-2002),

> *"African Americans should be screened aggressively and early (after age 40) if any survival benefit from treatment is to be shown."*

Granville County	58.8	Montgomery County	38.5	***Pender County***	108.2
Hoke County	57.2	Yancey County	37.7	Wayne County	103.6
Halifax County	55.8	Craven County	36	Duplin County	99.8
Richmond County	55.2	Carteret County	35.9	Caswell County	98.9
Northampton County	55.1	Granville County	35.9	Gaston County	97.7
Vance County	55.1	Halifax County	35.9	Northampton County	97.1

Bold italic indicates counties with the highest incidence of prostate cancer shared by African Americans and whites.

whites in North Carolina had a mortality rate of 27.9 per 100,000 (United States white mortality rates 1998-2002 were 27.7 per 100,000) compared to African Americans who had a death rate of 79.3 per 100,000 (United States African American mortality rates 1998-2002 were 68.1 per 100,000).[2] African Americans in North Carolina suffer a 1.6 times greater incidence of and 2.8 times greater mortality from prostate cancer compared to whites. These differences are similar to differences seen on a national level.

Possible Explanantions for Prostate Cancer Differences

Access and Allocation of Healthcare

Many studies have shown that minorities do not receive the same allocations of procedures as do whites who have the same disease processes.[3-5] Peterson et al. showed in a Veteran Affairs study of 33,641 men that African Americans with an acute myocardial infarction were 33% less likely than whites to undergo cardiac catheterization, 42% less likely to receive coronary angioplasty, and 54% less likely to receive coronary bypass surgery.[3] Similar outcomes were demonstrated by Ayanian et al. who studied a retrospective cohort of 27,485 men and women from various hospital systems who underwent inpatient angiography for coronary heart disease in 1987.[4] Results showed that whites are more likely than African Americans to receive revascularization procedures after coronary angiography. With regard to cancer care, Armstrong et al. studied 408 women with a family history of breast or ovarian cancer, of whom 217 underwent genetic counseling for breast cancer (BRCA1/2) testing (cases), and 191 women did not (controls).[5] Results showed that African Americans were significantly less likely to undergo genetic counseling for BRCA1/2 testing than were white women.

Access to and allocation of healthcare alone cannot explain the racial differences in prostate cancer outcomes. Robbins et al. studied men insured within the Kaiser Permanente organization and found that African American men presented with higher stages and worse survival from prostate cancer compared to white men.[6] This study showed that even in an equal access system, racial differences in prostate cancer outcomes still remained. In contradiction to the Kaiser study, Freedland et al. found an equal percentage of African American and white men presenting with clinically localized and metastatic prostate cancer in the Veterans Affairs system.[7] No differences were found in patient age or clinical stage of prostate cancer between black and white men at the time of diagnosis, but African American men presented with higher median serum prostate-specific antigen (PSA) values (14.2 versus 9.4 ng/mL, p = 0.0001) and slightly higher median Gleason scores (6.2 versus 5.9, p = 0.025).[7] More recent studies have shown that African Americans and whites, when matched by pathologic stage and grade after radical prostatectomy, have similar disease outcomes.[8] Eastham et al. demonstrated that African American and white men with clinical T1c[a] prostate cancer (diagnosed by PSA alone) have similar pathologic outcomes and PSA recurrence rates after radical prostatectomy, which further illustrates that in the modern era of PSA testing, stage for stage/grade for grade, African Americans and whites have similar outcomes.[9] These data re-enforce the argument that African Americans should be screened aggressively and early (after age 40) if any survival benefit from treatment is to be shown.

Prostate Cancer Screening Participation

The frequency of incidental prostate cancer detection in African Americans and whites appears similar;[10] however, African Americans are more frequently diagnosed with higher tumor volumes,[11] more advanced tumor stages,[12] more diffuse and greater volumes of high-grade prostatic intraepithelial neoplasia (HGPIN),[13,14] higher Gleason grades,[15,16] and higher PSA levels[11,14,16,17] compared to whites. Several studies have shown that when African Americans and whites are matched for stage and grade and undergo radical prostatectomy, there are no differences in PSA recurrence or risk of death from prostate cancer. [18-20] In light of the disparity in the incidence and mortality statistics, it would be reasonable to think that African American men would participate in more prostate cancer screening when offered. Unfortunately, several studies have shown quite the contrary. Ashford et al. evaluated 404 African American men in Harlem, New York and analyzed those who received prostate cancer screening.[21] Results showed that the prevalence of self-reported PSA screening in Central Harlem was lower than that reported for other populations, with only 24% of men 50-74 years of age ever having had a PSA test.

Choice of Definitive Therapy

Many studies have shown that African Americans compared to whites choose radical prostatectomy less often. Hoffman et al. studied 1,144 African American and white men with clinically localized prostate cancer and found that among men with more aggressive cancers (PSA greater than or equal to 20 ng/mL or Gleason score greater than or equal to 8), African Americans were less likely to undergo radical prostatectomy than whites (35.2% versus 52.0%), but more likely to receive conservative management (38.9% versus 16.3%, p = 0.003).[22] Treatment differences may reflect the greater likelihood for African Americans to present with pathologically advanced disease. Yan et al. analyzed men that underwent PSA screening and followed outcomes of therapy in men subsequently detected to have prostate cancer.[23] Non-African American patients had a greater than four times likelihood of selecting radical prostatectomy versus watchful waiting compared to African Americans. In an analysis of SEER data from 1995-1999, Denberg et al. showed that African Americans received equal amounts of definitive therapy for curative intent; however, African Americans compared to whites were significantly more likely to choose radiotherapy versus radical prostatectomy.[24]

Biologic Explanations for Prostate Cancer Differences

Androgen Axis:
Steroids

In studies that would later win the Nobel Prize in Medicine, Charles Huggins and Clarence Hodges demonstrated that withdrawal of testosterone causes prostate cancer to go into remission, but that it is almost certainly to recur in its testosterone-insensitive form.[25] Since prostate cancer is an androgen-stimulated cancer, could racial differences in prostate cancer be attributable to differences in androgen levels? In a study by Ross et al., male college students (mean age 20 years) living in southern California had testosterone levels measured. Total testosterone and free testosterone levels were 15% and 13% higher, respectively, in African Americans compared to whites.[26] Ellis et al. also measured androgen levels in over 4,000 male Army veterans ranging from 31-50 years of age (mean 38 years), but found that African Americans had only a 3.3% higher mean testosterone level compared to whites.[27] Kubricht et al. reported serum testosterone levels were similar between 189 African American and 264 white men undergoing biopsy for prostate cancer.[28] Beyond 40 years of age, African Americans and whites appear to have similar testosterone levels. If there are any differences in androgen levels, it occurs earlier in life and not in the prostate cancer-risk group after age 40.

Dihydrotestosterone (DHT) binds to the androgen receptor with affinity similar to testosterone, but DHT reduces androgen receptor degradation rates more than testosterone because of its slower dissociation.[29,30] Small racial differences in DHT or 5-alpha

---

[a] Prostate cancer with a T1c stage is traditionally characterized as being early-stage disease and having the best prognosis.

reductase, which catalyzes the conversion of testosterone to DHT, may increase androgen receptor protein levels in African Americans compared to whites. Accordingly, Ross et al. studied serum DHT metabolites in 100 university students and 54 Japanese medical students.[31] African Americans and whites, respectively, had 25% and 31% higher levels of the DHT metabolite A-diol-glucuronide compared to Japanese students. Four recent studies have reported serum levels of DHT, and none found differences between cases and controls; however, in each of these studies, African Americans were either not included or race was unspecified.[32-35]

The aforementioned studies measured serum androgens that may not accurately reflect the true androgenic environment within the prostate. Mohler et al. analyzed steroid hormones that were extracted from snap frozen prostate tissue obtained intraoperatively from radical prostatectomy specimens of 36 African Americans and 59 whites.[36] Although tissue levels of testosterone and DHT did not differ by race, African American men had higher tissue androstenedione (ASD) and sex hormone-binding globulin (SHBG) than white men.

Androgen Receptor Expression

Lubahn et al. at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) was the first to isolate the androgen receptor in 1988.[37] Extensive androgen receptor research continues at UNC-Chapel Hill. Recently, Gaston et al. performed a study looking at archived radical prostatectomy specimens obtained from 25 white and 25 African American men who had androgen receptor protein antigen retrieved and immunostained.[38] Androgen receptor protein expression was 22% higher in the benign prostates and 81% higher in the cancerous prostates of African American men when compared with white men. Similar results were found in a study by Olapade-Olaopa et al. The Olapade-Olaopa study compared androgen receptor expression in benign prostatic hyperplasia (BPH) and prostate cancer tissue of non-American blacks and non-American whites and found a similar increased expression of androgen receptor in blacks compared to whites.[39] Accordingly, prostate cancer may occur at a younger age and progress more rapidly in African American men compared to white men due to racial differences in androgenic stimulation of the receptor.

Racial differences in androgen receptor gene polymorphisms have also been described in the literature. African Americans, compared to whites, have been shown to express more androgen receptor polymorphisms, which may increase the risk of developing prostate cancer.

Racial Polymorphisms in the 5-alpha Reductase

Reichard et al. described genetic polymorphisms in the gene encoding the 5-alpha-reductase type II enzyme and compared allelic frequencies between three major United States populations—African Americans, whites, and Asian Americans. The authors found three different allelic families [containing 87 base pairs (bp), 103-107 bp, and 121-131 bp].[40] Whereas 18% of African Americans exhibited the 121-131 bp alleles, these alleles were not found in white or Asian Americans. Consequently, this 5-alpha-reductase type II enzyme polymorphism may result in more efficient conversion of testosterone to DHT within the prostate, and thereby may have a role in carcinogenesis.

Diet and Nutrition

Genetic differences cannot be the sole basis for difference of prostate cancer incidence. Epidemiological studies have demonstrated that as populations migrate from geographic areas with a low-incidence rate of prostate cancer to areas with higher-incidence rate, the migrating population begins to exhibit higher-incidence rates of prostate cancer. The incidence of prostate cancer varies throughout the world, yet African Americans have the highest incidence of prostate cancer in the world. The highest incidence of prostate cancer is in the United States, and the lowest is in Asia (as low as 0.5 per 100,000 in Qidong, China).[41] Asia also has a low consumption of saturated animal fat and a high consumption of fiber and soy protein.[41] Soy protein is abundant in the Asian diet, but is rarely consumed in the American diet. Soy has long been thought to have broad anti-neoplastic effects.[42] There are two broad isoflavonoid components found in soy—genistein and daidzein, both of which may have mild estrogenic effects, which may cause apoptosis (cell death) of prostate cancer cells.[42-44]

Dietary fat intake is thought to be a major factor involved with the increased incidence of prostate cancer in the United States.[45-48] Omega-6 fatty acids are thought to act as promoters of prostate cancer.[49] It is thought that at the cellular level, these fatty acids influence cellular proliferation, the immune system, and the potential for the tumor to invade locally and metastasize.[49] It is also thought that Omega-6 fatty acids (found in cereals, eggs, poultry, most vegetable oils, etc.) affect prostaglandin synthesis.[49] It has been shown that increased levels of prostaglandin E_2 increases oncogene Bcl-2 expression leading to carcinogenesis.[50] On the other hand, Omega-3 fatty acids found in fish oils, appear to be protective against prostate cancer.[49] These Omega-3 fatty acids are consumed in high amounts in Asia, whereas Omega-6 fatty acids are consumed in low amounts. The opposite occurs in the United States where Omega-3 fatty acids are consumed in low amounts and Omega-6 fatty acids are consumed at high amounts. Subsequent studies have shown that the African American diet contains the highest overall saturated fat and Omega-6 fatty acid content in the world.[47,48]

Obesity may be an independent factor of prostate cancer progression. Amling et al. examined the relationship between obesity and race in predicting adverse pathological variables in patients undergoing radical prostatectomy.[51] This was a multi-institutional retrospective analysis of the clinical and pathologic parameters on 860 patients with prostate cancer undergoing radical prostatectomy between 1992 and 1998. Obesity was defined as a Body Mass Index (BMI) greater than 30 kilograms/meter^2 (kg/m^2). Obese patients presented with prostate cancer at younger ages, higher Gleason grades, and more advanced pathologic stages. These data suggest a racial correlate of prostate cancer because African Americans tend to have higher grade prostate cancer and significantly higher average BMI compared to whites.

Insulin Growth Factor Pathways

Insulin-like Growth Factor 1 (IGF-1) stimulates cellular proliferation and inhibits apoptosis.[52] IGF-1 is a stimulator prostate cancer growth factor and 95% circulates bound to specific high-affinity IGF binding proteins (IGFBPs 1–6).[53] Blood levels of IGFs in each individual are relatively constant with no apparent diurnal or circadian variation. Studies have shown that African Americans have low IGFBP-3 compared to whites.[54] This may allow for more free IGF-1 to stimulate neoplastic growth of the prostate. Abdominal obesity and hyperinsulinemia are associated with decreased serum levels of sex hormone-binding globulin, with a resultant increase in testosterone, lower serum levels of IGFBP-1, increased serum levels of IGF-1, and estrogenic compounds.[55-58] Since African Americans have the highest BMI in the world, one can assume these IGF pathways may directly affect carcinogenesis of the prostate.

Vitamin D

Vitamin D may have protective benefits against prostate cancer. Vitamin D is believed to decrease bcl-2 expression increasing apoptotic cell death.[59] Some have suggested that endogenous Vitamin D synthesis may be impaired in African Americans because of the darker skin pigmentation.[60]

Conclusion

Striking differences in the incidence of and mortality from prostate cancer between African Americans and whites have persisted even after the advent of PSA testing. African Americans do not appear to fair worse than whites when matched by cancer stage and grade. More must be done to target this population for early and aggressive screening. **NCMedJ**

Screening for Prostate Cancer in 2006:
PSA in the 21st Century

Paul D. Maroni, MD, and E. David Crawford, MD

Few issues in urologic oncology seem so intrinsically correct, but empirically unproven as the utility of screening for prostate cancer. For a predominantly asymptomatic disease until an incurable stage, preemptive diagnosis at a time when intervention might be curative seems intuitively beneficial. As treating physicians, we have patients with clear elements of biologically aggressive disease found through screening and cured with local therapy, who otherwise should have succumbed to the disease. We attribute this "cure" to the screening process, and this serves as anecdote for future patients facing the decision of whether to screen or not. We also have patients with low-volume, low-grade cancers detected through screening and experiencing chronic mental or physical debilitation as a result of their cancer diagnosis or treatment, which may serve as anecdote as well, especially considering the potential that the disease may have followed a benign course.

Critics of screening typically cite concerns related to overdiagnosis and the attendant overtreatment, diagnosis at a time when cure is not possible, economic issues, and the morbidity of screening. Autopsy studies demonstrate that about 35% of men in their fifties have prostate cancer, yet only 15% of men are diagnosed and 3-4% die from it.[1] This contributes to the idea that "men die *with* prostate cancer, not *from* it." Others worry that prostate cancer screening could potentially misuse important resources with initial estimates of about $25 billion per year for screening men between ages 50 and 70. Critics also raise the issue of patient morbidity with the anxiety and discomfort associated with the biopsy, the complications of treatment, and the potential for disease recurrence. Additionally, the heterogeneous behavior of prostate cancer allows a relatively narrow window for screening to be effective in the men most likely to benefit from it. The diagnosis and treatment of incurable, but asymptomatic disease is debatable for some when diagnosis and treatment upon symptomatic progression might have avoided emotional morbidity. One might argue that prostate-specific antigen (PSA) screening is more efficient at identifying the less important, slow-growing tumors and, therefore, contributes to overdiagnosis. These seemingly potent arguments cast doubt on the overall utility of screening and leave the internist or general practitioner wondering what to do since the burden of complaints among patients with low-volume, low-grade cancers primarily falls on them.

> *"While screening might not benefit certain individuals, taken as a whole, screening appears to decrease morbidity and mortality.*

While an issue of reasonable contention, overdiagnosis tends to not burden men that typically proceed to surgical therapy. In analyses of radical prostatectomy series, less than 10% of tumors removed are considered "insignificant" as generally judged by pathologic stage, grade, and size.[2] Over-diagnosis has not been overlooked by oncology care providers, and most men diagnosed with prostate cancer will have a care plan considering comorbidities, the benefits/side effects of treatment, and the likelihood of disease progression. While broad screening could potentially incur high costs, as a matter of resource allocation, the cost of prostate cancer screening would be between $9,000 and $145,000 (best and worst case scenarios, respectively) per quality-adjusted life year (QALY) saved.[3] This is on par

Paul D. Maroni, MD, is a resident in Urology, Division of Urology, Department of Surgery, University of Colorado Health Sciences Center. He can be reached at paul.maroni@uchsc.edu or 4200 East Ninth Avenue, C-319, Denver, Colorado 80262. Telephone: 303-315-0911.

E. David Crawford, MD, is Professor of Surgery and Radiation Oncology and Head of Urologic Oncology at the University of Colorado Health Sciences Center. Dr. Crawford can be reached at david.crawford@uchsc.edu or 1665 N. Ursula Street, Suite 1004, Aurora, CO 80010. Telephone: 720-848-0170.

with using hydrochlorothiazide or captopril for treating hypertension and much less expensive than mammography screening ($232,000/QALY gained). There are other ways to make screening more cost effective. Early data from the Prostate, Lung, Colorectal, and Ovarian (PLCO) trial suggests that men with PSA values between 1 and 2 ng/mL might only require screening every two years, while men with PSA levels less than 1 ng/mL might be screened every five years.[4] This alone would still detect 99% of men eventually progressing to a PSA greater than 4 ng/mL and would result in savings up to $1 billion per year. Morbidity reduction and management are well-developed areas of prostate cancer treatment. Prostate biopsies are much more tolerable with local anesthesia, and pathology results are typically available within a week. The competition of local therapies has enticed providers to pursue and achieve real decreases in rates of side effects. Also, our understanding of what constitutes aggressive cancer has advanced, allowing for active surveillance trials in patients with low-risk disease. While screening might not benefit certain individuals, taken as a whole, screening appears to decrease morbidity and mortality.

Most of the data supporting screening has been inferential by analyzing trends in morbidity and mortality before and after the addition of the PSA blood test. Analysis of the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) database has demonstrated a 20% reduction in prostate cancer mortality between 1991 and 1999.[5] Over a similar time period, men in Mexico have experienced a small increase in mortality presumably due to the lack of screening available.[6] These inferences are complicated by the fact that improvements in treatments, including the massive expansion of androgen-deprivation therapies, may have affected prostate cancer survival and the development of metastasis. In Tyrol, Austria, men over 50 years old were offered screening while men in other regions were not. Tyrol men have experienced greater than a 40% decrease in mortality from prostate cancer, which has not been experienced in other regions in Austria.[7] Numerous large randomized trials are currently underway regarding prostate cancer screening, including the PLCO Cancer Screening and the European Randomized Screening for Prostate Cancer (ERSPC) trials that have collectively accrued over 230,000 men. Results from these trials will not be available for several years and are eagerly awaited. Currently, most expert organizations recommend some form of cancer screening using PSA and/or digital rectal exam beginning at the age of 50 in men with a life expectancy of more than ten years with informed decision making. The United States Preventive Services Task Force does not recommend prostate cancer screening with the absence of supportive Level 1 evidence.

Informed Consent and Ethical Concerns

Along with this lack of Level 1 evidence and the need for informed consent are numerous ethical concerns. Unfortunately, most PSA screening performed today does not involve a thorough consent process. The "required" discussion is an impediment to PSA screening, as internists might forego the discussion and, thus, the test, focusing instead on other prudent medical issues. Given time constraints in today's practice environment, this lengthy discussion cannot happen in a practical manner without some sort of supplemental material in the form of videos or pamphlets that would ideally be reviewed prior to the office visit. Many institutions have constructed these sorts of materials (see Table 1). Even with results of randomized trials, some level of informed consent would still be beneficial prior to including PSA in a general lab panel. Maybe prostate cancer screening is not for "everyone." Patients may forgo diagnostic procedures based on individual utilities of sexual and urinary function. Our philosophical approach is that "knowledge is power," and patients may make educated decisions about treatment choice (including active surveillance) after diagnosis.

Several years ago, enthusiasm was building for the next round of PSA-related markers, such as free, complexed, and pro-PSA. The use of these markers has been examined, but has not realized wide acceptance. While their use results in increases in sensitivity and specificity of diagnostic testing, the benefits are incrementally small, and the complexity of interpreting results is often an intellectual endeavor. Newer diagnostic tests using advanced laboratory techniques are also in development. The addition of these tests also creates a logistic and systemic problem. Some combination of tests may be optimal, but how can this be prospectively studied in a randomized fashion when these types of trials are time-consuming and potentially obsolete when results are available? At this point, PSA velocities have proven more clinically valuable. Recent studies have demonstrated a link between prostate cancer mortality and pre-treatment PSA velocity. Generally, an increase of PSA greater than 0.75 ng/mL in a year would support prostate biopsy, while an increase of greater than 2 ng/mL in a year carries a worse prognosis.[8,9] The threshold for PSA screening has also decreased, with some authorities recommending biopsies in patients with age-specific

PSA values as low as 2.0 ng/mL. This approach can diagnose a number of potentially aggressive cancers at a more curable stage.

Screening techniques for other malignancies, such as cervical, breast, and colon cancer, tend to be much more invasive than a blood test or digital rectal exam (DRE). Yields of these exams vary widely based on risk group, age, etc., but tend to be less than 10% for the detection of a malignancy (pre-malignant lesions not included). By logical extension, a prostate biopsy could almost be considered as a screening device as the degree of invasiveness is on par with other screening exams, and the yields are universally greater than 10% in men over the age of 62 regardless of age or rectal exam.[10] Improvements in ultrasound probes, biopsy devices (smaller, spring-loaded needles), and local anesthetic techniques have made a diagnostic prostate biopsy fast and tolerable for most men. This approach is not accepted, considered, or even being examined with large trials in regard to prostate cancer screening. Clearly, the approach to prostate cancer is different largely due to estimates of over-diagnosis of up to 50%. The above diseases are universally more fatal in a shorter period of time. Additionally, the social consequences of local prostate therapy tend to be more personally destructive. As a requirement of expanding the indication of prostate biopsy to a screening instrument, we would need to have a better understanding of morbidity and lethality after diagnosis, more accurate staging tools, and embrace an active surveillance approach, initiating treatment at a time prior to the development of advanced disease. Ongoing active surveillance trials and the use of molecular markers hold much promise in this area.

One of the problems with screening trials is the approach to treatment after diagnosis. While treatment of other malignancies tends to follow a step-wise course based on evidence, in the prostate cancer literature, there is only one randomized trial that demonstrates that local treatment of prostate cancer will extend life (prostatectomy versus no treatment) and one other comparison trial with only 100 patients.[11,12] Numerous impediments limit academic production in this area and accruals in head-to-head treatment trials have historically been dismal, resulting in early abandonment. Most sources accept that treatment choice probably does not substantially affect mortality in a seven-to-ten-year window, but time periods beyond this, parenthetically the most important, are subject to speculation and debate. Hopefully, retrospective analysis of treatment choice in the larger screening studies will contain homogenous groups of the different treatment modalities, but these results could be decades away. Unfortunately, questions in this area may never be fully answered through randomized trials without an acceptable short-term end-point that is a surrogate for death from prostate cancer.

Conclusion

On speculation, the future for prostate cancer screening will likely consist of: (1) occasional PSA (or other unspecified blood or urine molecular marker) checks at long intervals based on risk group in the fifth decade, (2) PSA/molecular marker checks based on level after the sixth decade, and (3) 12-core prostate biopsy with local anesthesia and digital rectal exam at intervals based on risk group after the sixth decade. Screening will probably be discontinued when a patient has a negative prostate biopsy and a functional index score that would predict an eight-to-ten year life expectancy. Using this hypothetical algorithm for experiment generation, simultaneous advances would need to occur for more sensitive screening instruments, individual risk assessment (including genetic susceptibility testing pre/post-diagnosis), and screening interval modification.

As physicians who treat prostate cancer, we have an enormous problem with expectation management related to imperfect predictive modeling and unique nuances increasing the complexity of patient discussion. Our patients reasonably expect that we will recommend care that will extend the quality and the quantity of their lives. Clearly, not all prostate cancer behaves the same; however, the connotations of a cancer diagnosis from a patient's perspective are usually different from the clinical reality. Actuarial estimates of average gain from prostate cancer treatment are between zero and three years of additional "quality-adjusted life years" per patient.[13] True or perceived effects of treatment on urinary and sexual function appropriately guide many men's choice of treatment, but results of treatment (e.g., potency after prostatectomy) are not universally reproducible. The empathetic physician thoroughly reviews these and other issues and generally receives reward in conscience only. The wise physician recommends directed patient research and deliberate decision making, while the unwise recommends urgent and narrow treatment options. Walking hand-in-hand with better knowledge about PSA screening will be improvements in treatment, morbidity reduction, and other technological advances in detection. In theory, a negative PSA screening study may not be valid considering this dynamic process. The face of prostate cancer screening might change substantially in the future and may no longer even involve PSA blood testing. **NCMedJ**

COMMENTARY

The Role of the Pathologist in Diagnosing Prostate Cancer and Guiding Therapy

Michael H. Weinstein, MD, PhD

Introduction

The recognition that serum prostate-specific antigen (PSA) concentration is a marker for adenocarcinoma of the prostate and the ability to measure PSA concentration represent major watersheds in the treatment of prostate cancer. Prior to these advancements in the 1980s, enlargement of the prostate gland detected by digital rectal exam, local symptoms, or sequelae of metastatic disease were the usual means of discovery of prostate cancer. In this pre-PSA era, prostate cancers were usually incurable at the time of diagnosis. PSA screening has lead to earlier detection and, although interpretation of recent epidemiologic data is still being debated, there is good evidence that PSA screening, prostate biopsy, and therapy with curative intent have lead to decreased morbidity and mortality from this disease.[1]

Also during the 1980s, refinements in the surgical technique for radical prostatectomy, which is potentially curative, yielded significant advancement in the treatment of prostate cancer by reducing the risk of morbidity associated with the surgery. These refinements hinged on two discoveries. First, elucidation of the venous plexus in the region of the prostate allowed operation in a "bloodless" field. This led to more accurate dissection, especially at the prostatic apex and, thus, greater preservation of urinary continence. Second, understanding the anatomy and function of the network of nerves around the prostate allowed "nerve-sparing" surgery and greater preservation of sexual function following radical prostatectomy.

These advancements required better means of screening and definitive diagnosis. PSA measurement and the thin-needle biopsy technique and equipment, although not perfect, are powerful tools for these purposes. Thin-needle biopsies cause less morbidity than open biopsy or biopsy with larger needles. As the pieces of tissue obtained by biopsy became much smaller, pathologists had to develop new techniques and expertise in interpreting these very thin biopsies.

PSA measurement has limitations, primarily in specificity, making this non-invasive test most useful as a first-line or screening detection method. While a few patients with prostate cancer have a normal serum PSA concentration, there are a significant number of men without cancer who have an abnormal concentration for whom therapy would not be warranted.

Thin-needle biopsy, by contrast, has essentially 100% specificity. The sensitivity of this test is estimated to be at least 75%, meaning that it will accurately detect three-out-of-four true cancers. Although more than one set of biopsies may be required for diagnosis, the morbidity associated with thin-needle biopsy is very low.

> *"PSA screening has lead to earlier detection, and... there is good evidence that PSA screening, prostate biopsy, and therapy with curative intent have lead to decreased morbidity and mortality from this disease."*

Pathologists have played a crucial role in the accumulation of the data upon which modern therapy is based, and they continue to provide essential information upon which medical oncologists, radiation oncologists, surgeons, and patients base their therapeutic and management decisions. This commentary is meant to outline the ways in which the clinical pathology laboratory and the work of pathologists serve as crucial components of the clinical decision-making process.

Michael H. Weinstein, MD, PhD, is Director of Pathology Laboratories at WakeMed Health and Hospitals in Raleigh, NC. Dr. Weinstein can be reached at MWeinstein@wakemed.org or 3000 New Bern Avenue, Raleigh, NC 27610. Telephone: 919-350-8260.

PSA Testing

Prostate-specific antigen (PSA) is a serine protease enzyme secreted by the glandular epithelium of the prostate into the ducts of the gland. It ultimately contributes to the composition of the seminal fluid. Its normal function is thought to be liquefaction of semen. Much lower concentrations are typically found in the blood, where the majority of PSA is protein-bound. Measurement of PSA concentration is based upon binding of a PSA-specific antibody to the substance. Multiple tests have been developed using different antibodies, and there is a variation in results between laboratories of up to 25% or more in the range of 0-6.0 ng/ml.[2] Moreover, some methods show greater precision than others. PSA testing has two principal uses. It is widely used to screen for prostate cancer and to monitor individual patients, either following therapy or during a "watchful-waiting" period. The variation between laboratories is of less significance when PSA testing is used for screening purposes than when following an individual patient. In the latter circumstance, it may be helpful to use a single, reliable laboratory for serial testing.

PSA Screening

The "normal" PSA concentration in men has been given as less than 4.0 ng/ml, although there is considerable disagreement over the threshold value that should prompt additional testing for prostate cancer. More recently, age-specific ranges have been given, including an upper limit of 2.5 ng/ml for men under the age of 50.[3,4] Elevated serum PSA concentration is associated with multiple pathological processes and some situations in which there is no disease. Benign prostatic hyperplasia (BPH), prostatitis, and prostate cancer are the main pathologic states in which increased serum PSA is often seen. Prostate biopsy itself, ejaculation, and, possibly, exercise may also lead to an increase in the PSA.

It is the association of elevated PSA concentration with prostate cancer that has lead to its utility in screening. The test is non-invasive (requiring only a blood sample through venipuncture) and is relatively inexpensive. Unfortunately, the range of PSA concentrations seen in patients with prostate cancer overlaps with the range seen in benign processes. The essential limitation is that there is no single value separating men with cancer from those without.

The *sensitivity* of a test is defined as the fraction of individuals with a specific disease for whom the test will yield a positive result. The *specificity* of a test is defined as the fraction of all abnormal results that represent individuals who do have the disease for which they are being tested. Decreasing the maximum PSA value that is considered "normal" increases the sensitivity of the test in detecting prostate cancer. However, this also leads to an increase in the number of men who are labeled "abnormal" who do not have this disease (decreased specificity). Thus, while measurement of serum PSA concentration has proved to be a powerful tool in the ability to detect prostate cancer, appreciation of its limitations is critical for maximization of its utility. In fact, average PSA concentration in men without prostate cancer increases with age. This is largely due to BPH, which increases in incidence and severity. In truth, the PSA test is best used to estimate the chance that an individual has carcinoma of the prostate. PSA testing cannot be used to render a definitive diagnosis.

In an effort to increase sensitivity and specificity, derivative PSA tests have been developed. These include measurement of free PSA and calculation of the ratio of free/total PSA. These methods have yielded some increase in sensitivity and specificity with increased cost, but still suffer from an overlap in ranges in the populations of men with and without prostate cancer.[5,6] They may provide additional guidance in difficult circumstances, such as when PSA levels are significantly elevated, multiple sets of biopsies have been negative, and no other explanation for the elevation in PSA level is apparent.

The ratio of free/bound PSA is considered abnormal by many when it falls below 25%. This cutoff is associated with sensitivity and specificity of approximately 90% and 25%, respectively, for the detection of prostate cancer.

PSA velocity is the rate at which the serum PSA concentration rises over time. This calculation is of some use in men with borderline elevated PSA.[7] A PSA velocity greater than or equal to 0.75 ng/ml per year with measurements spanning at least 18 months has sensitivity and specificity of approximately 70% and 90%, respectively. Specific measurement of bound PSA has not been demonstrated to offer a significant improvement in detection.

PSA density, which is defined as the serum PSA concentration divided by the volume of the prostate as measured by transrectal ultrasound, has proven to have limited value.

Other tests potentially on the horizon include pro-PSA and human kallikrein-2, but these are not ready for routine clinical use in screening for prostate cancer.

PSA Monitoring

Serum PSA concentration is also useful for monitoring patients for progression of disease. Until late in the disease when the tumor may become so poorly differentiated that its ability to produce PSA protein becomes impaired, increasing PSA concentration is associated with advancing disease. Thus, the serum PSA typically falls to near zero following prostatectomy, since all of the prostate tissue, both benign and malignant has usually been removed. Minute amounts of tumor that may have spread beyond the prostate prior to surgery may not produce enough PSA to be detected until they grow, at which time the PSA concentration begins to rise.

The PSA often does not fall to zero in patients who have received radiation therapy without surgery. However, the PSA does fall for months following the treatments. In fact, the lower the nadir (lowest concentration detected) in PSA, the greater the chance of cure or long-term remission. Moreover, the longer the time it takes to reach the PSA nadir, the better the prognosis.[8]

Some patients with proven prostate cancer choose "watchful waiting" over therapy in order to avoid the morbidity associated with prostatectomy, radiation therapy, and hormonal therapy. A significant rise in serum PSA concentration may prompt physicians to recommend therapy to avoid morbidity and mortality associated with progression of the disease.

Prostate Biopsy

The thin-core needle biopsy technique and equipment allow multiple biopsies to be performed in the doctor's office with minimal morbidity (significant complications less than 0.5%) and provide material for definitive diagnosis of prostate cancer. The sensitivity of this procedure is very difficult to gauge. In the absence of metastatic disease, there is no way to tell with certainty whether a man has prostate cancer without pathologic examination of the entire prostate gland, which requires removal. Moreover, the sensitivity likely varies with the prevalence and type (i.e., grade, stage) of prostate cancer in the population being studied. However, based on data that do exist, a reasonable estimate for the sensitivity of needle biopsy of the prostate in patients with elevated PSA is at least 75%, if cancers detected on a second or later set of biopsies are included.

There is little debate about which areas of the prostate to biopsy, at least on the initial attempt to demonstrate tumor. However, the optimal number of biopsies to perform is not clear. The sextant biopsy technique (six biopsies) was considered adequate and was, by far, the most commonly used technique for approximately a decade. In recent years, it has become clear that performing more biopsies improves the chances of detecting cancer on the first attempt.[9] This is especially true when the prostate is markedly enlarged due to BPH. However, more biopsies are associated with greater discomfort, a greater chance of complications, and greater cost. Moreover, the incremental increase in sensitivity with each additional biopsy diminishes progressively. At the present time, there is no agreement on how many biopsies more than six should be performed.

In addition to identifying the presence of cancer, the pathologist interpreting the biopsies routinely provides other indispensable information regarding the tumor. The following diagnostic categories should be included in the pathologist's report. The clinical significance of each is summarized in Table 1.

Tumor Grade

Tumor grade is probably the single most important tumor characteristic assessed on needle biopsy of the prostate. The Gleason grade, also termed Gleason score or Gleason sum, is very useful in predicting the behavior of a given patient's tumor. Thus, it is used in planning therapy and estimating prognosis. Although the grade of the tumor in the biopsies is not a perfect predictor of the grade of the tumor in the prostate as a whole, the correlation is good. The lack of perfect correlation is not surprising, since the volume contained in an entire set of biopsies usually comprises less than one thousandth of the volume of the entire prostate gland.

It is worth noting that each type of cancer specific to an organ in the body has its own histopathologic (microscopic) grading scheme. The Gleason grading scheme is very unusual in that it ignores the appearance of the individual cancer cells and concentrates purely on the patterns of growth of the malignant prostate glands. The method takes into account the common occurrence of multiple glandular patterns of cancer being present in a single patient's tumor. Numerals 1-5 have been assigned to recognized categories of tumor patterns, and, traditionally, the two most prevalent pattern types are given as well as the numeric sum. Thus, a Gleason grade of 3+4 = 7 might be reported, where "3" represents the tumor pattern most prevalent in a specimen and "4" represents the second most prevalent pattern. The Gleason score of a homogeneous tumor will simply have the same number repeated in the sum (e.g., 3+3 = 6). A consensus of genitourinary pathologists has recommended long-overdue modifications to the original scheme, which was devised around 1970, but the essential concepts remain unchanged. It is now recommended that small amounts of high-grade tumor (i.e., Gleason pattern 4 or 5) be reported even when they represent neither the first nor second most prevalent pattern, as this finding correlates with more aggressive tumor behavior.[10]

The combination of PSA concentration, findings from digital

Table 1.
Pathologic Parameters Assessed on Thin-Needle Core Biopsy of the Prostate and the Clinical Significance of Each Parameter.

Parameter	Clinical Importance
Tumor Grade	Used to predict aggressiveness of tumor, stage, response to non-surgical therapy, and chance of cure with various types of therapy.
Location and Extent of Tumor in Biopsy Cores	Used to predict stage and response to some types of therapy (e.g., radiation therapy).
Perineural Invasion	May be used to plan extent of surgery (e.g., whether to sacrifice neurovascular bundle).
Atypical Glands	Re-biopsy should be performed—indicate ~50% chance of finding cancer on re-biopsy.
High-Grade Prostatic Intraepithelial Neoplasia (HGPIN)	~30% or less chance of finding cancer on re-biopsy, depending on how many biopsies originally performed. HGPIN may represent a precursor of prostate cancer.
Tumor Characteristics Following Therapy: Grade of tumor and whether therapy effect is present.	Used to assess prognosis and predict whether additional therapy is likely to be of benefit.

rectal exam, and biopsy Gleason grade has been used to estimate the stage of the tumor. The likelihood that the tumor is confined to the prostate, the chance of local spread into the surrounding fibroadipose tissue, the chance of invasion into the seminal vesicles, and the chance of local lymph node metastases can be estimated. These data have been compiled in the "Partin Tables,"[11] providing useful summary information to help each patient and his physician to make sensible decisions regarding choice of therapy.

Location and Extent of Tumor

The pathologist should report the amount of cancer present in the biopsy core(s) originating from each biopsy site. This information can be useful in estimating stage and predicting long-term outcome following therapy (e.g., prostatectomy, radiation therapy), especially when combined with other parameters, such as PSA concentration and tumor grade.[12,13]

Perineural Invasion

The presence of invasion of small nerves in the biopsy cores by the cancer is predictive of spread beyond the prostate when viewed in univariate analyses.[14] The reasoning behind these initial studies stemmed from the hypothesis, which is still accepted, that one of the main routes of tumor escape from the prostate is by tracking along nerves that traverse the surface of the prostate and comprise a portion of the periprostatic neurovascular bundles. However, most of the predictive power of the finding of perineural invasion on needle biopsy disappears in multivariate analyses when other variables, such as Gleason grade, are taken into account. Still, it may provide marginal additional information and may play a role in deciding whether or not to sacrifice one or both neurovascular bundles during surgery.

Atypical Glands

Unfortunately, a significant minority (≈5%) of prostate biopsies are neither definitively benign nor definitively diagnostic of carcinoma. The term often used in this situation is "atypical," sometimes in the phrase "atypical small acinar proliferation" (ASAP). The frequency of this occurrence is somewhat dependent on the experience of the pathologist interpreting the biopsies. Special studies (e.g., immunohistochemical staining) can occasionally lead to a more definitive diagnosis, but diagnosis usually hinges on tried and true ordinary techniques (i.e., H&E staining). The finding of atypical glands suspicious for carcinoma without other, definitively diagnostic areas warrants repeat biopsy.[15,16] In fact, the chance of finding prostate cancer on subsequent re-biopsy (one or more sets) is approximately 50%. Should re-biopsy prove inconclusive, other factors, such as total PSA concentration, free/total PSA ratio, clinical findings, and patient desire, provide guidance in choosing a course for repeat re-biopsy or longer-term follow-up with measurement of PSA velocity.

It should be noted that it is important for each biopsy to be separately labeled to designate the area of the prostate from which it originated. One reason for this is that 90% of all cancers discovered following an initial atypical, non-definitively diagnostic biopsy are identified in the same region or an area adjacent to the one from which the atypical biopsy originated. Thus, these areas are preferentially sampled on re-biopsy in order to maximize the sensitivity of the procedure in detecting tumor.

High-Grade Prostatic Intraepithelial Neoplasia (HGPIN)

Other findings that may increase the suspicion of cancer in the absence of definitively diagnostic biopsy material include the presence of high-grade prostatic intraepithelial neoplasia (HGPIN). Early studies indicated that the risk of unsampled carcinoma in the prostate gland associated with the isolated finding of HGPIN on needle biopsy was approximately 30%.[16,17] At the time, re-biopsy was required. However, if no carcinoma was detected on two sets of re-biopsies, additional biopsies were unlikely to contain tumor. More recent data, especially in the case of more than six biopsies to a set, suggest that the increased risk associated with this circumstance may be less than originally estimated, and the significance of this finding is somewhat diminished.

Since HGPIN is thought by many to represent a precursor of prostate cancer, it is postulated that potential chemopreventive agents may help to prevent prostate cancer in men who have been diagnosed with isolated HGPIN.

Other Clues to Tumor Behavior

Needle biopsy may provide other clues to tumor behavior. For example, prostate cancer clearly identifiable within fat at one end of a core biopsy is indicative of extraprostatic tumor spread. Clearly such information must be factored into therapeutic decisions.

Biopsy Following Therapy

Biopsy following therapy for prostate cancer is useful in a limited set of circumstances and poses challenges for the pathologist interpreting the biopsy. Therapy often alters the microscopic appearance of the tumor, sometimes making recognition of the malignant prostate tissue difficult. It can also alter the appearance of the tumor in ways that abolish the correlation between microscopic pattern and biologic behavior, so that Gleason grading of tumor following therapy is not meaningful in some circumstances.

A rising PSA following therapy is indicative of growing tumor. However, it does not indicate whether the tumor is growing at the primary site (i.e., in the prostate or in the prostatic bed after prostatectomy) or at a metastatic site. Radiographic studies (e.g., x-ray studies or computerized tomography scans) can be used to detect metastases. In the absence of detectable metastatic disease, biopsy of the prostate or prostatic bed may be performed to assess for local tumor growth. As with initial biopsy, skill is required on the part of the pathologist to properly interpret the changes due to therapy and to give an accurate assessment of the presence of cancer and, sometimes, whether it shows effects of therapy.

Pathologic Assessment of Prostatectomy Specimens

Pathologic review of the prostate after it has been removed for cancer also provides important information regarding prognosis and whether further therapy (e.g., radiation therapy) might be of benefit. The main pathologic parameters evaluated are tumor grade, stage (extent of cancer), and whether there is cancer at the surface of the specimen, which might indicate that not all of the tumor was removed. Other parameters may also have prognostic impact.

Tumor Grade

As with prostate biopsy, the recently modified Gleason grading system is used to grade prostate cancer in the prostatectomy specimen. Tumor grade is a powerful predictor of outcome, including risk of recurrence and time to recurrence. Minor discrepancies between the grade assigned on biopsy and the grade obtained from the whole prostate specimen are common. This is typically due to the fact that prostate cancers are usually heterogeneous. Only about one thousandth of the prostate is sampled even with multiple thin-needle core biopsies, and the tissue obtained may not be perfectly representative of the entire tumor.

Lymphvascular Invasion

Careful microscopic examination of the prostatectomy specimen may reveal the presence of tumor within minute lymphatic or blood vessels. It is a significant factor indicative of a poorer prognosis. This finding is rarely discernable on biopsy.

Tumor Stage

Tumor stage is crucial in determining whether adjuvant therapy is likely to be of benefit. Staging is performed according to the American Joint Committee on Cancer (AJCC) guidelines.[18] For example, invasion of the tumor into the adjacent fibroadipose tissue is designated stage T3a. Tumor invasion into either or both of the seminal vesicles is designated T3b, which supercedes T3a, and invasion into surrounding organs, such as the bladder, is designated T4. The absence or presence of metastatic spread into local lymph nodes (i.e., pelvic lymph nodes) is noted as N0 or N1, respectively, and the absence or presence of metastatic spread beyond this is designated M0 or M1. Thus, one might have a patient with staging "T3b N0 M1" if tumor has spread to the seminal vesicles and the spine, but is absent from the pelvic lymph nodes.

Margin Status

The final feature that must be assessed on the prostatectomy specimen is whether prostate cancer is present at the surface of the specimen. This is termed margin positivity and may, especially if it is present in more than a small area, be indicative of local tumor that could not be excised at the time of surgery. The pathologist should report the extent and location of tumor present at the margins. Like tumor stage, this information is needed to make decisions regarding subsequent adjuvant therapy.

Summary

In summary, the role of the pathologist has proven indispensable in diagnosing prostate cancer, planning initial therapy,

assessing prognosis, estimating the likely benefit of adjuvant therapy following prostatectomy or radiation therapy, and in following patients for possible recurrent disease. Moreover, the work of pathologists has been pivotal in the research that has lead to our present understanding of the natural history of prostate cancer and the present methods for estimating the likelihood of benefit from various therapies. Such work continues to be integral to scientific advancement in these areas. **NCMedJ**

Treatment for Localized Prostate Cancer:
Surgical Approaches

Eric M. Wallen, MD

Men who are diagnosed with prostate cancer face a dizzying and growing array of treatment options. These include watchful waiting, two forms of radiation, and three types of surgery. In addition, ever more therapies are entering the field of prostate cancer treatment, such as cryosurgery and high-frequency ultrasound therapy.

Each option comes with a set of risks, including inadequate treatment of the cancer, rectal problems, urinary incontinence, and erectile dysfunction. In the medical field, a great deal of controversy exists regarding the treatment of prostate cancer, and the patient is faced with a great deal of uncertainty when considering his treatment options. The patient's urologist and his primary care physician play crucial advisory roles in the patient's treatment decision. Ultimately each patient must navigate this complex process and make the decision himself.

Most, if not all, urologists are trained to be capable of discussing three major pathways for patients to consider once the diagnosis of prostate cancer is made. These are watchful waiting, radiation therapy, and surgery. Unlike many medical diagnoses, there is not an absolutely correct treatment for prostate cancer, and given this uncertainty, the patient (and his spouse or partner) must participate in the decision-making process. Notably, research has shown that most patients are comfortable in this role.[1]

> *"Unlike many medical diagnoses, there is not an absolutely correct treatment for prostate cancer, and given this uncertainty, the patient (and his spouse or partner) must participate in the decision-making process."*

Watchful Waiting

Watchful waiting is an important option for urologists to discuss with patients and for patients to seriously consider. The rationale for watchful waiting is based on the high incidence but low mortality of prostate cancer in the United States. As of 2005, a man in the United States has a one in six chance of being diagnosed with prostate cancer during his lifetime.[2] However, due to the biologic nature of prostate cancer, most men are destined to die from other causes before they die from prostate cancer—the likelihood of a man dying from prostate cancer is approximately one in 34.[2] More than ever, it is becoming clear that many men do not need to undergo treatment for prostate cancer. Given the risks and the costs of treatment, watchful waiting is an important option to consider, both as a patient and for healthcare systems.

Watchful waiting requires that patients have semi-annual examinations and testing for changes in the prostate-specific antigen (PSA) blood test. In addition, watchful waiting in healthy patients mandates that the patient undergo a repeat prostate biopsy to assess for changes in cancer grade and volume. This should be performed approximately one year after the initial biopsy.

Radiation or Surgical Treatment?

The next level of discussion regarding treatment for prostate cancer involves consideration of intervention in the form of radiation or surgery (i.e., local radical treatment in an attempt to cure what is expected to be organ-confined disease). Both radiation and surgery in all forms generally confer a disease-

Eric M. Wallen, MD, is Assistant Professor of Surgery at the University of North Carolina and Director of Urologic Laparoscopy at UNC Hospitals. Dr. Wallen can be reached at ewallen@med.unc.edu or CB# 7235 Chapel Hill, NC 27599-7235. Telephone: 919-966-9251.

specific survival of at least ten years. Of course, disease-specific survival varies greatly based on the individual patient's disease biology. Most patients with screen-detected prostate cancer have a disease with slow biological progression and can expect little, if any, impact on their lives for 15-20 years. A smaller proportion of patients have more aggressive disease as identified by PSA levels found in their blood and Gleason[a] parameters and may indeed, succumb to the cancer.

Urologists are familiar with the efficacy and side effects of both radiation and surgical treatment, and they can discuss both with patients. Ideally, the radiation modality should be discussed with a radiation oncologist familiar with both brachytherapy (permanent or temporary implantation of the prostate with radioactive seeds) and external beam radiation therapy, so the patient may obtain a balanced view of his treatment options. It is well known that urologists, as surgeons, and radiation oncologists each favor their own treatment modality, and the best way for a patient to navigate this complexity is to discuss treatment with both specialists. However, many urologists perform brachytherapy and can discuss this treatment with the patient in terms of disease control and the potential side effects of lower urinary tract symptoms and erectile dysfunction.

Dr. Wallen controls the robotic instruments using sophisticated joysticks.

At the robotic console, the surgeon views the operation through a 3-D viewfinder and controls the instruments.

Surgical Options

Radical Retropubic Prostatectomy

The discussion of surgery for prostate cancer has become more complex in the past five years, as laparoscopic approaches to surgery have increased the number of surgical techniques available to the patient. The current standard of care, radical retropubic prostatectomy (RRP), has been performed and refined for several decades. This technique, also known as "open surgery," is performed through a vertical incision made below the umbilicus. Data on disease control and the two major functional outcomes, erectile dysfunction and urinary continence, are well known, and these complications are much less common than even ten years ago.[3] Research into healthcare quality is also well defined and indicates that outcomes are better and complications are fewer at medical centers where many RRPs are performed.[4] Similar findings have also been demonstrated when looking at individual surgeons. In the community setting, this information may be difficult for the patient to obtain. Patients who research their treatment options usually learn that an important question to ask their urologist is how many RRPs he or she has performed and how often.

Laparoscopic Radical Prostatectomy

Laparoscopic techniques for performing radical prostatectomy have become more common since the start of the new millennium. Laparoscopy has supplanted open surgery for many surgical procedures, including gall bladder removal, appendectomy, adrenal surgery, Nissen fundoplication (a procedure to alleviate gastroesphageal reflux), and some gynecologic surgeries. Laparoscopic surgery is performed through buttonhole-sized incisions with the aid of a scope placed internally to visualize the operation. The major driving force for laparoscopic surgery is decreased pain and faster recovery; additional benefits are improved visualization of anatomic structures and cosmetic outcomes.

Initially, laparoscopic radical prostatectomy (LRP) was developed as a standardized series of steps by surgeons in France. Adoption of this technique worldwide was limited due to the difficulty in learning this procedure, and it was

---

[a] The Gleason scoring system grades prostate cancer patterns from 1 (well-differentiated malignancy) to 5 (poorly differentiated malignancy). For more information see page 123 of Dr. Culley Carson's article in this issue of the Journal.

abandoned by many urologists after their initial efforts. At a small number of medical centers, however, the technique for LRP has been mastered and is the standard surgical treatment offered to patients. Data evaluating outcomes for cancer control, complications, continence, and erectile function show that LRP is equivalent to RRP in experienced, capable hands.[3]

Robotic-Assisted Radical Prostatectomy

Robotics came to the field at approximately the same time that laparoscopic prostatectomy was being attempted around the world. Surgical robotics was developed over the past two decades by the military, and private companies brought these instruments to the bedside in the late 1990s. Only one surgical robotic platform, the da Vinci® Surgical System, is in widespread use today, with approximately 300 of these systems in place around the United States. The major benefit of this instrument is that it makes LRP feasible for many more surgeons, by virtue of creating a three dimensional (3-D), immersive environment for the surgeon and providing instruments with superior manipulation. The downside of this tool is its cost—more than $1 million—to individual hospitals and to the healthcare system in general.

Due to widespread purchase and use of the da Vinci® Surgical System, robotic-assisted radical prostatectomy (RARP) is rapidly becoming a new standard of care in the surgical treatment of prostate cancer. Access to the prostate is very similar to LRP, in the sense that small incisions are made to permit scope and instrument placement. However, the instruments used to perform the operation are controlled by a surgeon who sits away from the patient at a console. There, the surgeon looks into a viewfinder that provides 3-D visualization of the surgical field, and controls the instruments with sophisticated joysticks and foot pedals. Compared to traditional laparoscopic instruments, the robotic-controlled instruments have more flexibility to perform the delicate nerve sparing and sewing parts of the procedure. In addition, the robot eliminates tremor, thereby steadying the surgeon's hands.

Results from RARP appear to be at least as good as RRP and LRP, and some studies have claimed that oncologic and functional outcomes are even better.[5,6] Compared to RRP, LRP and RARP have shorter hospitalizations and lower rates of blood transfusion.[7] The results of RARP, as with the other techniques, are best at medical centers where many of the procedures are performed.[8] Indeed, patients undergoing surgery for prostate cancer by an experienced surgeon can expect to have an excellent chance for recovery of urinary control and baseline sexual function, regardless of the technique. Currently, the field of urology is witnessing patient migration to centers where RARP is performed, based on good results and effective marketing of the robot. I expect that over the next decade, robotic-assisted laparoscopic radical prostatectomies will become the most common surgery performed for patients with prostate cancer.

Conclusion

Prostate cancer as a disease entity is rife with controversy. As common as it is, it certainly does not warrant aggressive treatment in many patients. This is a difficult concept for physicians and patients alike to understand. Over and beyond the next decade, the option of watchful waiting will be further explored by researchers and recommended for more and more patients, spurred by the recognition that most prostate cancer is not lethal. The presence of newer surgical techniques should not obscure this, and urologists, as well as other physicians must recognize this.

At the same time, surgery for prostate cancer is in a state of evolution. The emergence of RARP as a less invasive option has encouraged more physicians and patients to consider surgical treatment. So how are patients supposed to make sense of these developments? Urologists play a crucial role in facilitating patient education through discussion, providing or recommending written material, and directing them to appropriate Internet resources. Patients should be made aware of all options, including watchful waiting, and should understand that the slow pace of the disease process allows them time to carefully consider these options. Patients should advocate for their healthcare by inquiring about the experience of their potential surgeon, investigating outcomes through prostate cancer support groups, becoming educated via media resources, and discussing options with their partner and other family members. At the conclusion of this process a patient is empowered to make a choice with which he is comfortable. **NCMedJ**

COMMENTARY

Radiation Therapy for Prostate Cancer:
External Beam, Brachytherapy, and Salvage

Scott L. Sailer, MD

Radiation is a viable curative treatment option for localized prostate carcinoma. It can be used as primary therapy and can also be used to cure patients who have failed surgery or are at high risk of recurrence after prostatectomy. For locally advanced tumors, radiation is the preferred treatment and, based on randomized trials, should be combined with hormonal therapy for optimal results. Watchful waiting is another option for patients with low-risk disease.

Radiation as Primary Therapy

Radiation can be delivered using external beam radiation therapy, brachytherapy (permanent or temporary implantation of the prostate with radioactive seeds), or a combination of these methods. There are no randomized trials comparing the various radiation techniques to each other or to radical prostatectomy, so comparisons of outcomes after various treatments is based on retrospective reviews. Risk groups have been developed to categorize the aggressiveness of prostate carcinomas so that patient cohorts who have similar prostate cancers can be compared. One of the more popular risk-group categorizations has been developed by D'Amico et al.[1,2] (see Table 1).

Table 1.
Risk Groups for Clinically Localized Prostate Carcinoma[1,2]

Risk Group	Characteristics	Expected ten-year PSA failure-free survival
Low	PSA < 10 and Gleason score < 6 and 1992 AJCC stage T1c, T2a	80-85%
Intermediate	PSA > 10 and < 20 or Gleason score = 7 or 1992 AJCC stage T2b	50-60%
High	PSA > 20 or Gleason score > 8 or 1992 AJCC stage T2c, T3	30-40%

American Joint Committee on Cancer (AJCC).

These risk groups can be used to compare patients treated at different institutions with different techniques, but as always, there are pitfalls with retrospective reviews arising from patient selection and unknown bias. Patients treated with radiation tend to be older, have more advanced local disease, have higher prostate-specific antigen (PSA) levels, and have higher Gleason scores.[a] Because of this bias, outcomes after radiation will be inferior to surgery unless there is an attempt to compare patients with similar prostate cancers. Risk-group stratification is a simple way to adjust for this bias, but is obviously not as rigorous as randomized trial data. Another difficulty that limits retrospective comparisons is that both surgical and radiation techniques have improved over the past ten-to-15 years, so there is no long-term follow-up of prostate cancer patients treated with modern techniques.

Nevertheless, retrospective comparisons using appropriate risk groups are the best datasets available during patient counseling. Kupelian et al.[3] reported results for 2,507 patients treated with external beam radiation (greater than or equal to 72 Gy), surgery, brachytherapy, or a combination of brachytherapy and external beam from 1990 to 1998 (see Table 2). The data are not "clean" in that a fraction of patients in each treatment group also received hormonal therapy. For some patients receiving radiation, hormonal therapy can improve survival, but at a minimum, patients treated with hormonal therapy will have a delay in PSA recurrence. Hormone use was limited to six months in this study, so the impact of hormonal therapy should be minimal. The patients in the intermediate- and high-risk

Scott L. Sailer, MD, is in private practice at Wake Radiology Oncology in Cary, NC. Dr. Sailer can be reached at ssailer@wakeradiology.com or 300 Ashville Avenue, Suite 110, Cary, NC 27511. Telephone: 919-854-4588.

group were primarily intermediate risk. There were no T3 patients (patients with tumors that had spread outside the prostate capsule), 27% of patients had a PSA level greater than 20, and 19% had a Gleason score greater than 7. D'Amico has also reported outcomes for surgery and radiation based on risk groups.[1] No patients received hormonal therapy (see Table 3). These retrospective series show that the results after surgery and radiation are similar at five years. There is also little difference between brachytherapy and external beam radiation. Of note, even within the same risk group, the outcome after surgery is better at the Hospital of the University of Pennsylvania in Philadelphia than it is at Brigham and Women's Hospital in Boston (see Table 3), implying selection of more favorable patients at the University of Pennsylvania even within similar risk groups (assuming surgery is equivalent at the two institutions). While some patients in these series have been followed for ten years, the number of patients followed for ten years is too small to provide reliable data. With additional follow-up, long-term comparisons within these databases will be possible.

> *"...both surgical and radiation techniques have improved over the past ten-to-15 years, so there is no long-term follow-up of prostate cancer patients treated with modern techniques."*

For patients with intermediate- and high-risk prostate cancers, however, comparing surgery to radiation alone no longer reflects clinical practice. There are randomized data that support the use of hormonal therapy in patients with intermediate- and high-risk prostate carcinoma who are treated with radiation.[4-6] Several studies have shown a statistically significant survival advantage from the addition of hormonal therapy to radiation (see Table 4). Patients in the D'Amico et al. study[5] had slightly less severe prostate cancer compared to the other two studies, although many of the patients would still be considered high risk. The optimal duration of hormonal therapy when combined with radiation is not known, but higher-risk patients are probably best treated with two-to-three years of hormonal therapy.

Table 2.
PSA Failure-Free Survival for Stage T1-T2 Prostate Carcinomas at the Cleveland Clinic and Memorial Sloan Kettering at Mercy Hospital, 2003[3]

	Five-year PSA failure-free survival			
Treatment	Number	Low risk	Intermediate and high risk	Percent with hormonal therapy (duration < 6 months)
Radical Prostatectomy	1,034	90%	70%+	17%
External Beam Radiation (> 72 Gy)	301	92%	75%*	39%
Permanent Implant	950	90%	75%++	24%
External Beam and Implant	222	92%	75%**	36%

+ 21% Gleason score > 7, 26% PSA > 20

++ 12% Gleason score > 7, 21% PSA > 20

* 22% Gleason score > 7, 35% PSA > 20

** 22% Gleason score > 7, 35% PSA >20

Table 3.
PSA Failure-Free Survival after Surgery or Radiation[1]

		Five-year PSA failure-free survival		
Treatment	Number	Low risk	Intermediate risk	High risk
Radical Prostatectomy*	1027	90%	71%	40%
Radical Prostatectomy+	1100	85%	55%	30%
External Beam Radiation^	473	90%	61%	42%

* Hospital of the University of Pennsylvania, Philadelphia

\+ Brigham and Women's Hospital, Boston

^ Joint Center for Radiation Therapy, Boston

Over a five-to-ten-year time frame, the outcome after radiation or surgery is similar, based on the above retrospective reviews of patients stratified by risk groups. Outcome beyond ten years is less certain. On theoretical grounds, surgery should have a slight advantage over radiation because, if a prostate cancer is truly localized to the prostate gland (without extracapsular spread or occult distant metastasis), surgical removal of the gland should be permanently curative. Surgery is not always successful in clinically localized, low-risk tumors, however, because of inadequate surgical technique or tumor biology, which often leads to early dissemination or extracapsular spread. If the "horse is out of the barn," no local therapy is curative, although radiation probably has an advantage if there is only local

Table 4.
Randomized Trials Evaluating Hormonal Therapy in Intermediate and High-Risk Prostate Carcinoma

			Five-year survival	
Study	Number	Duration of hormones	Radiation alone	Radiation and hormones
D'Amico[5]	206	6 months	78%	88%
Hanks[6*]	361	2 years	71%	81%
Bolla[4]	415	3 years	62%	78%

* Gleason score 8-10 only

extension of disease, since radiation delivers a margin of effective dose around the prostate gland and seminal vesicles.

In contrast, the long-term efficacy of radiation, if a cancer is truly localized to the gland, is less certain based on a number of theoretical arguments. Although atrophied, the prostate is still present after radiation, and new cancers may develop ten-to-20 years after initial treatment. Second, there is variability in the sensitivity of prostate cancer cells to radiation. Finally, radiation kills clonogenic (replicating) cells in a random fashion. A given dose of radiation theoretically kills a fixed fraction of clonogenic cells, and with repeated doses of radiation, the fraction of surviving cells approaches, but never reaches, zero:

$$\text{survival fraction} = e^{-\text{(constant * radiation dose)}}$$

For a given survival fraction, the chance of cure is mathematically described by the tumor control probability. If the surviving fraction is 0, the tumor control probability is 100%:

$$\text{tumor control probability} = e^{-\text{(surviving fraction*number of clonogens)}}$$

Although the above is supported by laboratory work, tumor control probability *in vivo* is also dependent on host factors that are not well characterized. Radiation can definitely cure many prostate cancers, but if a large number of similar, truly localized tumors are radiated, there will likely be a few that are not cured because of the random nature of radiation killing, variability in radiation sensitivity, and variability in host factors. These tumors would have been cured with adequate surgical resection.

Based on these theoretical arguments and the lack of long-term randomized or retrospective data, I usually recommend radical prostatectomy for patients with low- and intermediate-risk cancers who are healthy and have a greater than ten-year life expectancy. For patients in poor health or older than 70 years, I will usually recommend radiation, since I am fairly confident that the ten-year results are similar to surgery. The patient with high-risk, localized prostate cancer, however, may be better treated with radiation and hormonal therapy, regardless of age, although there may be a role for surgery and adjuvant radiation in the younger patient.

Radiation Modality

For patients choosing brachytherapy, the most important consideration is the experience of the brachytherapy center. The quality of the prostate implant as judged by dosimetric parameters increases with the number of implants performed. If appropriately proctored, however, treatment is likely satisfactory at less-experienced centers.

For external beam radiation, newer techniques that allow greater doses of radiation to be delivered safely should be used. At a minimum, this should include three-dimensional (3D) conformal therapy, which allows more accurate targeting of the prostate and seminal vesicles while avoiding the rectum and bladder. Intensity-modulated radiation therapy (IMRT) should also be considered in patients with intermediate- and high-risk disease. IMRT is an extension of 3D, which modulates the intensity of each radiation beam in a way that allows for dose escalation while minimizing dose to sensitive normal structures. A similar dose escalation with standard 3D techniques results in excess late rectal toxicity.

Image-guided radiation therapy (IGRT) is another new technology that is being introduced into the clinic. Using a variety of techniques, IGRT increases the daily accuracy of tumor localization, which results in lower doses to surrounding normal tissue by allowing a decrease in the margin from the tumor to the edge of the radiation beam.

The choice of radiation modality is partially based on disease characteristics. Treatment with brachytherapy alone is best for patients with low-risk disease as long as the prostate is not too large (greater than 60-70 cc) or too small (less than 30 cc). Hormonal therapy is occasionally used with brachytherapy to decrease the size of the prostate prior to the implant. External beam radiation is used alone for low-risk disease and is combined with hormonal therapy for intermediate- and high-risk disease. Some centers will combine external beam radiation, hormonal therapy, and brachytherapy for patients with intermediate- or high-risk disease. As briefly reviewed above, there are no data to support one type of radiation over another for appropriate patients.

Patient preference and expected side effects also influence treatment choice. Brachytherapy as sole therapy has the distinct advantage of being completed in a single appointment although it requires general or spinal anesthesia, and treatment effects are felt for several months after the implant. External beam radiation typically involves daily treatments for seven-to-eight weeks (35-to-40 treatments). During treatment, brachytherapy tends to result in more urinary symptoms (frequency, burning, and urgency), and external beam radiation tends to cause more rectal symptoms (tenesmus, increased bowel frequency, hemorrhoid discomfort, and diarrhea), although both treatments can result in urinary and rectal symptoms. A small percentage of brachytherapy patients require bladder catheterization during the first few months after implantation, while this rarely occurs during or after external beam radiation. Both techniques can result in rectal injury, which manifests as rectal bleeding several months to years after treatment. Urinary incontinence is rare with both treatments, although it is more likely following brachytherapy. Sexual dysfunction is probably more frequent after external beam radiation compared to brachytherapy.

Radiation after Radical Prostatectomy

After prostatectomy, the PSA should become undetectable. If the PSA fails to fall to zero or becomes detectable after initially falling to zero, radiation is often used in a curative attempt to "salvage" the failure. As a local modality, radiation will only be effective if residual disease is confined to the prostate bed or pelvic nodes, although pelvic (nodal) radiation is less frequently used than prostate bed radiation after prostatectomy. Post-prostatectomy radiation is more effective with lower post-prostatectomy PSAs, an initially undetected PSA after surgery, a long disease-free interval prior to PSA failure, and adverse pathologic features, which predict residual local disease (extracapsular extension or positive margin). If a patient's PSA does not initially decline to zero, he likely had occult metastatic disease at diagnosis and would not benefit from localized radiation, unless the source of the residual PSA is a positive margin and the Gleason score less than 8. A ProstaScint® scan[b] is often used to confirm a prostate bed recurrence or, at least, attempt to rule out distant disease, but the low sensitivity and specificity of this examination limits its usefulness. The PSA disease-free survival after salvage radiation for all patients is approximately 25-40% at five-to-ten years after radiation.[7,8] Favorable patients (PSA less than 2.0, Gleason score less than 8, positive surgical margins) may experience PSA disease-free survivals of 60-70%.[8]

Adjuvant radiation for high-risk prostate cancer after radical prostatectomy is rarely used. Adjuvant refers to a situation where all clinically detectable disease has been removed. Most urologists will follow patients with high-risk prostate cancer and only consider radiation if the PSA does not fall to zero or if it becomes detectable, at which time the treatment is considered salvage therapy. The rationale for this "wait-and-see" approach is that not all high-risk patients are destined to fail, failures can be picked up "early" with PSA, and many patients are spared the toxicity of unneeded radiation. Arguments pointing out that PSA becomes detectable only after a million cells are present[9] have not increased the use of adjuvant radiation. Theoretically, radiation is most effective when the tumor burden is smallest. A randomized study of adjuvant radiation showed that the biochemical relapse was reduced from 47% to 26% at five years with the use of radiation.[10]

Watchful Waiting

For the older patient with low-risk prostate carcinoma, watchful waiting is a reasonable option. This is especially true if the patient has multiple co-morbidities or the Gleason score is less than 6. A group of patients identified from the Connecticut Tumor Registry had data extracted from chart review. For patients with Gleason 2-5 carcinomas who were not treated with local therapy, only 4-11% died from prostate carcinoma.[11] D'Amico showed that for low-risk prostate carcinoma, the risk of dying from prostate cancer after radiation or surgery was 1-2% at ten years, while the risk of dying from other causes was ten-to-30%.[12]

Most radiation oncologists are comfortable following patients without treatment, although this is usually done in conjunction with an urologist. Ideally, these patients should be enrolled in a study so outcomes of watchful waiting can be determined, but this is not usually possible in a community setting. A reasonable approach to watchful waiting is to monitor PSA every three months and consider treatment if the PSA doubling time (velocity) is less than 12 months. If the PSA is fairly stable after one-to-two years, monitoring can be decreased to every six months. While patients initially agree to watchful waiting, many elect to proceed with treatment as their anxiety rises with the rise in their PSA, even if the doubling time is greater than 12 months.

Summary

Radiation is a curative treatment for prostate cancer that is most appropriate for the older patient or the patient with significant co-morbidities. Younger patients with a greater than ten-year survival are probably best treated with surgery unless the disease is high risk. For all patients, high-risk disease is best treated with hormones and radiation. The long-term superiority of surgery over radiation, however, has not been demonstrated in randomized or retrospective studies, and the recommendation for surgery in the younger, healthy patient with favorable local disease is largely based on theoretical considerations. If chosen for appropriate indications and delivered with appropriate techniques, radiation can be delivered using external beam or brachytherapy with equal efficacy. The choice of radiation treatment is based on tumor characteristics and patient preference. Radiation can be used after prostatectomy to cure patients who are not cured with surgery. Watchful waiting may be appropriate for patients with low-risk disease. **NCMedJ**

---

[b] ProstaScint® scan involves injecting a small amount of radioactive material into the body to determine if and where any prostate cancer cells may be.

Systemic Therapy for Prostate Cancer

William R. Berry, MD

Systemic therapy plays an important role in the management of prostate cancer. Since the pioneering work of Dr. Charles Huggins in the 1930s, medical science has known that prostate cancer cells were, to some extent, dependent on the presence of androgens (steroid hormones) for their growth and survival.[1] Hormonal therapy, with various forms of androgen manipulation and androgen receptor interaction, has been the primary form of systemic therapy for prostate cancer since that time. In recent years, a role has been proven for systemic chemotherapy as well. Clinical research trials are now investigating the role of new biologic agents and immunotherapy. This commentary will review the current status of the systemic therapy for prostate cancer.

Hormonal Therapy: General Principles

The androgen receptor is the primary driver of cell growth for prostate cancer.[2] Stimulation of the androgen receptor can be reduced by depletion of circulating androgens, blocking the binding of androgens to the androgen receptor, or a combination of the two methods.

Depletion of androgens can be accomplished directly by bilateral orchiectomy (castration) or indirectly by administration of estrogens or luteinizing hormone releasing hormone (LHRH) analogues.[3] Both of these classes of drugs exert their effect indirectly via reduction of the production of luteinizing hormone by the pituitary, with subsequent loss of luteinizing hormone signal to the testicles to produce testosterone. Both classes of drugs are capable of reducing serum testosterone levels to levels equivalent to orchiectomy.

Blocking the binding of androgens to the androgen receptor can be accomplished with anti-androgens. Anti-androgens accomplish inhibition of prostate cancer cell growth by competitive binding to the androgen receptor versus androgens. Anti-androgens administered to a patient with functional testes do not decrease testosterone levels, but actually cause some increase.

A third means of manipulation of the androgen and androgen receptor interaction could have a role in the management of prostate cancer, but has not been well studied. Medications approved only for the treatment of benign prostatic hypertrophy, such as 5-alpha reductase inhibitors, block the conversion of testosterone to dihydrotestosterone (DHT).[3] DHT binds more strongly to the androgen receptor than testosterone, and theoretically, blocking the conversion of testosterone to DHT could diminish prostate cancer cell growth.

Roles of Hormonal Therapy

Hormonal therapy has been used to treat various states of prostate cancer, including metastatic disease, disease manifest only by a rising prostate-specific antigen (PSA) after primary therapy, as adjuvant therapy[a] post primary therapy, as neoadjuvant therapy[b] prior to and/or with primary therapy, and as a primary therapy for localized disease.

Metastatic Disease

The role of hormonal therapy in metastatic disease is well accepted as first-line therapy. All of the three methods of testosterone depletion, (e.g., orchiectomy estrogens, or LHRH analogues) are equally effective.[3] LHRH analogues, although expensive, are the primary therapy used in most patients. Many patients prefer injections to orchiectomy, and estrogens can be associated with significant thrombo-embolic cardiovascular risk. Between 70-90% of patients will respond initially with a decrease in PSA and clinical improvement in symptoms. Median duration of response to this therapy is about 18

---

[a] Adjuvant therapy is treatment, such as chemotherapy, radiation therapy or hormone therapy, given to a patient after the primary treatment to increase the chances for a cure.

[b] Neoadjuvant therapies are similar to adjuvant therapies except they are given prior to the primary treatment.

William R. Berry, MD, is a private practice physician at the Cancer Centers of North Carolina in Raleigh, NC and Chairman of the Genito-Urinary Cancer Research Committee, United States Oncology. Dr. Berry can be reached at william.berry@usoncology.com or 216 Asheville Avenue, Suite 20, Cary, NC 27511. Telephone: 919-854-6930.

months. There is controversy over whether treatment should begin when metastatic disease is diagnosed or only at the onset of symptoms. A review of the randomized clinical trials suggests that there is a benefit with higher rates of one- and five-year disease-free progression and ten-year survival among those who receive immediate versus deferred therapy.[4]

Anti-androgens in standard doses as monotherapy have been demonstrated to be inferior to testosterone depletion.[5] Their use as single agents in general should be restricted to patients who refuse testosterone depletion because of concern over loss of sexual function.

Combined androgen blockade (CAB), the addition of anti-androgen to testosterone depletion, is also controversial. Randomized trials have produced mixed results. Three meta-analyses of the data have all suggested a small improvement in five-year survival as opposed to simple testosterone depletion with orchiectomy or LHRH analogues.[6,7,8,9] There are some minor side effects with anti-androgens (e.g., diarrhea, gynecomastia, etc.), but the biggest objection to the addition of anti-androgens is the significant monetary cost of these drugs as compared to marginal survival benefit. It should be determined by each patient and his physician whether the potential benefit of CAB is worth the cost.

> *"Since the pioneering work of Dr. Charles Huggins in the 1930s, medical science has known that prostate cancer cells were, to some extent, dependent on the presence of androgens (steroid hormones) for their growth and survival."*

PSA Recurrence as the Only Sign of Disease

It has become common clinical practice in the PSA era to treat patients who have a PSA level that begins to rise but have no evidence of metastases, at some point after primary surgery or radiation therapy. The rationale is to prevent or delay the onset of overt metastatic disease. Not all patients who have a PSA recurrence die of prostate cancer. Recent studies have demonstrated that several factors, including time to PSA recurrence, Gleason score at diagnosis, and PSA doubling time, are all important in determining a patient's risk of dying of prostate cancer when he does have a rising PSA.[10,11,12]

There has also been a trend toward the use of intermittent hormonal therapy in patients with a rising PSA. The rationale for intermittent therapy is to have periods of time away from the side effects (hot flashes, fatigue, etc.) and toxicities (deterioration of bone density, loss of muscle mass, etc.) of testosterone depletion, but also there is speculation that the onset of hormone refractory prostate cancer could be delayed.[13] This method is not yet supported by data from a large randomized clinical trial, but is attractive to many patients and physicians.

Adjuvant Hormone Therapy

There are minimal data on the use of hormone therapy after prostatectomy. In a trial reported by the Eastern Cooperative Oncology Group (ECOG), men who were discovered to have positive lymph nodes when their pathology was reviewed after surgery were given continuous LHRH analogue therapy either immediately post surgery or at the time of recurrence .[14] At ten years there was a dramatic survival benefit (72% versus 49%) for those men who received immediate versus deferred treatment, respectively. This trial has been criticized because there were only 98 men accrued. However, the data are so compelling that one would be hard pressed not to recommend immediate adjuvant hormonal therapy to all men who have positive nodes at the time of prostatectomy.

Neoadjuvant Hormonal Therapy

Neoadjuvant hormonal therapy has been tested in clinical trials prior to surgery and also prior to (as well as concurrent to and after) primary radiation therapy. The neoadjuvant surgical studies have consistently failed to demonstrate any disease-free or overall survival benefit for neoadjuvant hormonal therapy given for anywhere from three-to-eight months pre-surgery.

On the other hand, several large clinical trials have shown a disease-free and, in some, a survival benefit for hormonal therapy administered prior to and continued concurrent with radiation therapy for patients with high-risk prostate cancer. Three of these important trials include RTOG 86-10, the Bolla study from EORTC, and the D'Amico trial.[15,16,17] There are preclinical data to suggest that androgen depletion does make prostate cancer cells more sensitive to radiation, and this phenomenon could explain why neoadjuvant hormonal therapy is beneficial with radiation and not surgery.[18]

Hormonal Therapy as Primary Therapy

Some physicians advocate hormonal therapy as primary therapy for prostate cancer.[19] There are no data to suggest that primary hormonal therapy can be done with curative intent. For that reason, the use of primary hormonal therapy should probably be reserved for those who need treatment, but are unwilling or unable due to co-morbidities or age to pursue a curative primary treatment, such as surgery or radiation.

Hormonal Resistance

As noted previously, the median duration of response to hormonal therapy in patients with metastatic prostate cancer is about 18 months. Virtually all patients develop disease that progresses in spite of this first-line hormonal treatment. This condition has variably been termed androgen-independent prostate cancer or hormone-refractory prostate cancer (HRprostate cancer). Regardless of the terminology, there is evidence to suggest that the androgen receptor is still the predominant driver of prostate cancer cell growth, even in this state of the disease.[20] Therefore, LHRH analogues are usually continued.

Secondary hormonal manipulations may be effective in some patients with HRprostate cancer, with reported response rates of 20-60%.[21] These secondary therapies include the addition of anti-androgen, anti-androgen withdrawal, estrogens, corticosteroids, and suppression of adrenal androgen production with drugs like ketoconazole. There are no clinical trials to suggest a survival benefit from any of these second-line therapies, but in general, they are not especially toxic and are, therefore, useful in selected patients.

Systemic Cytotoxic Chemotherapy

As in other metastatic cancers, clinical trials using chemotherapeutic agents have been undertaken in an attempt to find effective therapy for HRprostate cancer. Early trials were limited by the lack of conspicuously effective agents and the lack of significant numbers of patients with measurable disease. After the discovery of PSA, declines in this serum protein could be used as a marker of disease response to therapy in phase II trials. The PSA Working Group recommended a sustained decline in PSA of 50% or more from baseline as an indicator of response in phase II trials.[22]

In the 1990s, two phase III trials compared mitoxantrone and a corticosteroid to the steroid alone in patients with HRprostate cancer.[23,24] Both of these trials showed a significant benefit in terms of palliation of pain, although there was no survival benefit. Based on this palliative benefit, the combination of mitoxantrone and prednisone was the first chemotherapy regimen to be approved by the Food and Drug Administration (FDA) for the treatment of HRprostate cancer.

The results of these trials led to renewed interest in the use of chemotherapy in HRprostate cancer and a more rigorous preclinical and clinical search for new active agents. Drugs that affected intracellular microtubules, including vinca alkaloids, taxanes, and the combination of either of these classes with estramustine, had enough activity to generate a large number of phase II trials. Docetaxel was the most active of these agents.

The documentation of 50% PSA decline rates in 30-65% of the phase II trials with docetaxel led to the initiation of two large phase III trials using docetaxel in combination with another agent versus the then standard mitoxantrone and prednisone.[25,26] Both of these trials, SWOG 9916 and TAX 327, demonstrated an improvement in overall survival for docetaxel given every three weeks in combination (with estramustine or prednisone, respectively) versus mitoxantrone and prednisone. In addition, patients on docetaxel did better in terms of pain relief and quality of life than those receiving mitoxantrone. These were truly historic studies, which were the first phase III trials to demonstrate that chemotherapy can prolong survival in patients with HRprostate cancer (hazard ratios 0.80 and 0.76). There were increased adverse thromboembolic events in the SWOG 9916 trial, which used estramustine with docetaxel. For that reason, docetaxel every three weeks with daily oral prednisone is now FDA-approved and the standard of care for chemotherapy in HRprostate cancer.

The Next Steps

Now that we have a regimen that can prolong survival in HRprostate cancer, the next steps will be to improve on the first-line therapy of docetaxel and prednisone, develop new agents or regimens for patients who have progressed on docetaxel, explore the role of chemotherapy in the earlier states of prostate cancer, and develop effective biologic and immunotherapy for prostate cancer.

Agents that have been combined with docetaxel include carboplatin;[27] high-dose calcitriol;[28] thalidomide;[29] various small molecule growth factor tyrosine-kinase inhibitors, such as gefitinib and imatinib;[30,31] large molecule antibody-to-cell-surface receptors, such as vascular endothelial growth factor;[32] the endolthelin A receptor antagonist atrasentan;[33] proteosome inhibitors, such as bortezomib;[34] and even vaccines for prostate cancer.[35]

Currently no agents are approved for second-line treatment of HRprostate cancer after failure of initial chemotherapy. A phase III trial of the oral agent satraplatin has recently been completed, and the results are awaited with anticipation.[36]

Systemic chemotherapy, which is effective in an advanced cancer, is often more effective in early states of disease. Two large clinical trials of chemotherapy in combination with androgen depletion in earlier states of prostate cancer are underway as adjuvant therapy post-prostatectomy in patients with high risk for recurrence. An Intergroup United States trial is comparing mitoxantrone and hormone therapy to hormonal adjuvant therapy alone. A large international pharmaceutical company-sponsored trial will test the addition of docetaxel to hormonal therapy in the adjuvant setting. In addition neoadjuvant chemotherapy with docetaxel will be tested in combination with hormonal therapy prior to and concurrent with radiation in patients with high-risk disease. The results of these trials will determine the effectiveness of these chemotherapy strategies in early stage prostate cancer.

Finally, as we learn more about the cancer genome and the immune system, new biologic agents that can be directed at specific targets and new ways to stimulate the host immune system to recognize and destroy prostate cancer cells are being developed and nearing routine use in patients. The progress being made should greatly enhance our ability to alter the course of prostate cancer with systemic therapy. **NCMedJ**
