You take care of your patients. We'll take care of you.

GE Medical Protective's Strengths:

- Great reputation and 100 years' experience
- Early, aggressive defense
- Joint decision-making – "consent to settle" feature*
- Expert claims handling
- Industry-leading ratings – A.M. Best and Standard & Poor's
- Strong balance sheet
- Innovative products and services
- Access to broad resources of GE

For more than a century, we've been insuring practices like yours against the perils of malpractice lawsuits. We know how to protect your reputation, so you can spend your time practicing medicine. We've also gained a clear understanding of the value of your work. Not just because of what it means to your practice and your family, but because of what it means to the patients you treat. And comfort. And help. So, with all that on the line, we offer you no less than the best. Plus ratings and financial strength that are most formidable. Because at the end of the day, even the folks that do the caring need comfort. You'll find it here. Call 1-800-4MedPro or visit www.GEMedicalProtective.com for a free brochure, or contact your local agent for more information.

THE NC HEALTHCARE ENTERPRISES WORKERS COMPENSATION FUND

The Fund was formed in 1993 by McNeary to offer the healthcare community an opportunity to capitalize on their comparatively lower exposure to loss, as a homogeneous group. Because of the nature of the exposure, as well as, a dedicated commitment to loss control, the Fund has worked well since its inception. Today, over 40 hospitals and medical practices enjoy the financial benefits of the Fund! The program is endorsed by the North Carolina Hospital Association.

REASONS TO JOIN THE GROUP:

- Competitive Pricing
- Coverage for volunteers
- Easy pay plan
- Efficient responses to loss control and renewal-no insurance company bureaucracy
- Experienced claims adjusters who work exclusively for the Fund
- Long term stability of coverage
- Opportunity for ownership equity
- Voice in management of your program

Begin reaping the benefits of a proactive approach to workers compensation costs by joining dozens of your colleagues in this unique program. You will not be disappointed. The group was formed and is managed by McNeary, a name that has been familiar to the medical community for over 35 years.

Moving from Medicaid to North Carolina Health Choice:

Changes in Access to Dental Care for NC Children

Rebecca T. Slifkin, PhD, Pam Silberman, JD, DrPH, Victoria Freeman, DrPH

Abstract

Objective: *The objective of this study is to identify the extent to which access to dental care changes as children move from a public program with low provider reimbursement and a reputation of non-compliant beneficiaries to another public program with higher reimbursement levels and enrollees that may be viewed differently by providers.*

Study Design: *The pre- and post-enrollment dental experience of NC Health Choice enrollees who were previously on Medicaid is compared to those who were uninsured prior to NC Health Choice enrollment.*

Data Source: *Parents of newly-eligible NC Health Choice children were sent a survey within two weeks of enrollment to determine their child's experience prior to program enrollment. Respondents were resurveyed approximately 11 months later regarding their child's experiences after receipt of NC Health Choice.*

Principal Findings: *Medicaid recipients were significantly more likely to have had a dental visit within the year before enrolling in NC Health Choice, to report a usual source of care, and have fewer unmet needs than were uninsured children. After enrollment there was improvement for both groups, and differences between the two groups disappeared.*

Conclusions: *Medicaid coverage appears to improve access to dental services for children who would otherwise be uninsured. Increased access to dental services for Medicaid children after enrolling in NC Health Choice may be due to higher provider reimbursement, but may also result from providers' perception that NC Health Choice beneficiaries are a different population and more likely to keep appointments.*

Relevance: *In a time of fiscal crisis, changes to NC Health Choice should be carefully considered to avoid loss of dental care gains afforded by this public insurance program.*

Access to dental services for low-income children in the United States is a well-documented problem.[1] Studies of dental access for low-income North Carolina children have found results that are consistent with national data. In a presentation to the North Carolina Task Force on Dental Care Access, Rozier noted that 36% (>31,000) of all NC children entering kindergarten had a history of dental caries and 25% had untreated dental disease.[2] Childhood caries are more prevalent in low-income children and those residing in rural areas without fluoridated water, and low-income children with dental caries are more likely to go untreated.[3]

The absence of regular dental care can impair the health of children in a number of ways. Untreated dental disease can affect a child's appetite and ability to eat, thereby leading to nutritional or growth problems.[4] A report of the US Surgeon General suggests that children miss approximately 52 million hours of school a year due to dental problems and related care.[5] Further, the inability to access dental services leads to more expensive use of the emergency room for care. In 1997, for example, North Carolina Medicaid paid $1,686,565 for 62,000 preventable emergency dental visits.[6] Children with oral and craniofacial conditions also can face problems with speech or their psychological well-being. Finally, poor dental health in children can also affect their dental and physical

health as adults. There is now a growing body of research that suggests an association between periodontal infections and diabetes, heart disease and stroke, and adverse pregnancy outcomes such as prematurity and low birthweight.[7]

Barriers to the receipt of dental care are particularly acute for NC children receiving Medicaid. Only 16% of North Carolina dentists actively participated in Medicaid in 1998, which was at that time one of the lowest rates of participation in the country.[8] Lack of provider participation in Medicaid, coupled with other access barriers, has led to low use of dental services among Medicaid-eligible children. North Carolina Medicaid claims data from 1998 showed that only 12% of children ages 1-5 years, 27% of children 6-14 years, and 19% of children ages 15-20 made at least one visit to the dentist.[9]

A statewide task force convened by the North Carolina Institute of Medicine studied access to dental services among low-income populations in 1999.[10] The task force identified low provider reimbursement levels as the primary barrier to dental provider participation in Medicaid. On average, the North Carolina Medicaid program paid dentists 62% of the usual, customary and reasonable rates (UCR) for 44 of the most common dental procedures for children and only 42% of UCR for other procedures. Dentists reported losing money by seeing Medicaid patients. A 1996 study of North Carolina dentists reported that 56% of dentists in the state would be willing to see more Medicaid patients if reimbursement rates were increased to 80% of UCR.[10] In addition to low reimbursement rates, dentists also stated other reasons for their unwillingness to participate in Medicaid, including a high no-show rate among Medicaid recipients.

In October 1998, North Carolina implemented its State Child Health Insurance Program (SCHIP), called North Carolina Health Choice for Children (NC Health Choice or NCHC). NC Health Choice provides health insurance to uninsured children with family incomes that are too high to qualify for Medicaid but that are at or below 200% of the federal poverty guidelines. Most of the children enrolled in NC Health Choice come to the program immediately after losing Medicaid coverage, either because they are no longer eligible due to an increase in family income or because they are too old to qualify within their income category.

Like 19 other states, North Carolina chose to implement a stand-alone SCHIP program rather than expand Medicaid eligibility. The NC Health Choice program is administered jointly by the NC Division of Medical Assistance (which is responsible for administering the Medicaid program), and the Teachers' and State Employees' Comprehensive Major Medical Plan (hereinafter the State Employees' Health Plan). NC Health Choice is modeled after the State Employees' Health Plan, but includes coverage for vision, hearing and dental services. Blue Cross Blue Shield of North Carolina is contracted to pay NC Health Choice claims, and reimburses dentists for care delivered to children enrolled in the NC Health Choice program at its prevailing commercial dental rates of approximately 100% of UCR. Thus, while NC Health Choice is a form of public insurance, children enrolled in the program have slightly higher family incomes than children on Medicaid, and their insurance reimburses dentists at a higher rate than does Medicaid.

Although several studies document the difficulties that Medicaid recipients have in accessing dental services[1,11,12,] little has been written about the experience of Medicaid recipients as they move to other sources of dental insurance coverage. Further, there have been only a few studies that have examined access to dental services in SCHIP or comparable public insurance programs.[13,14,15] In this study, we compare the dental experience of NC Health Choice enrollees who were on Medicaid prior to NC Health Choice enrollment to that of NC Health Choice enrollees who had no insurance for at least a year prior to NC Health Choice enrollment. The pre-enrollment experiences of these two groups and the change in access once enrolled in NC Health Choice are examined. This analysis will help identify the extent to which access to dental care changes as children move from a public program with low provider reimbursement and a reputation of non-compliant beneficiaries to another public program with higher reimbursement levels and enrollees who may be viewed differently.

METHODOLOGY

The data for this study were collected as part of a larger evaluation of NC Health Choice conducted by researchers at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill under contract to the North Carolina Division of Medical Assistance.[16] The findings from that study as they relate to access to general health services have been previously reported, as was an earlier analysis of access to dental care for school-aged children that did not consider enrollees' prior dental coverage.[13,17]

Beginning in July 1999, parents of newly-eligible NC Health Choice children were sent a survey within two weeks of enrollment to determine their ability to access medical and dental services for their child prior to enrolling in the program. Respondents to the first survey were resurveyed approximately 11 months later to examine their child's experiences after receipt of NC Health Choice. Although the sample for the larger study was stratified by three age groups (ages 0-5, 6-11, and 12-17 years, all at the time of enrollment in NCHC), in this study we report results for the two older age groups only. Because of survey space limitations, we were unable to ask enough dental care questions to explore why the children in the 0-5 year age group were or were not receiving dental care. An increase in dental service use is expected as these youngest children grow up and more teeth erupt. It is, therefore, difficult to determine the extent to which an increase in dental service use in this age group is attributable to the new NC Health Choice coverage. Patterns of care for children in this youngest age group are also difficult to interpret because there is not consensus between dental and medical professionals as to when children should begin receiving regular dental services. For these reasons, the results presented in this paper pertain only to school-aged children.

Baseline surveys were sent to the parents of 599 younger school-aged children (ages 6-11) and 599 adolescents (ages 12-

17). Seventy-three percent (N=875) responded. Respondents to the baseline survey were mailed a follow-up survey and again 73% responded, for an overall response rate of 53% of the parents originally surveyed. The resultant cohort for whom data were available at both baseline and one year later consisted of 639 children (325 younger school-aged children and 314 adolescents.) In the baseline survey, parents were asked to report whether their child's most recent dental visit had been within the last year, more than a year ago, or never. In the follow-up survey, they were asked if their child had seen a dentist in the year since enrollment in NC Health Choice. Their usual source of dental care and whether their child experienced any dental access barriers were also queried. Parents who reported access barriers were asked why they were unable to obtain needed dental services.

This analysis focuses on two subsets of school-aged children, those who had Medicaid coverage during the entire year prior to their enrollment in NC Health Choice (391 children, referred to as "Medicaid graduates") and those who had no insurance for the year prior to enrollment (201 children, referred to as "uninsured"). Medicaid graduates were defined as those with Medicaid coverage that ended within 31 days of enrolling in NC Health Choice. Since North Carolina provides 12-month continuous eligibility for children enrolled in Medicaid, these children would have been covered for a full year prior to NC Health Choice enrollment. Children in the uninsured group had neither Medicaid coverage nor any other medical care insurance (by parental report) at any time during the year prior to NC Health Choice enrollment. Our survey did not specifically ask whether children had private dental coverage prior to NC Health Choice enrollment, so it is possible that some uninsured children had private dental insurance at some time in the year before NC Health Choice. However, low income families nationally have low dental insurance coverage rates, so it is highly unlikely that many of these children had private dental insurance.[18] The remaining school-aged children (N=47) were excluded from this analysis because their insurance status changed during the year prior to NC Health Choice enrollment, with insurance (typically Medicaid) for part of the year, and no insurance for the remainder of the year. It was, therefore, impossible to determine whether those children's reported dental care experience prior to enrolling in NC Health Choice reflected their experiences while insured or not.

All data were analyzed using STATA 7 statistical software.[19] McNemar's Chi was used to compare change in dichotomous categorical data (yes/no questions) over time. Changes in questions that had multiple, ordered responses were tested for significance with the Wilcoxon signed-rank test. A paired t-test was used to compare changes in means for continuous ordinal data.[20] When data are presented for all children combined, they have been weighted to adjust for the distribution by age groups of the NC Health Choice enrollees. Throughout the paper, differences in statistics pre- and post-NCHC are considered significant if p<.05.

At the time of the follow-up survey, the baseline survey was sent to a comparison group of parents of children who were newly-enrolled in NC Health Choice to ensure that observed changes in the original sample were not due to changes in the health care delivery environment. There were no significantly different responses to dental access questions before NCHC enrollment between the two groups. It does not appear that changes in the dental health care environment occurring over the time of our study account for the change observed post enrollment.

RESULTS

Demographic Characteristics

Demographic characteristics that might explain differences in access to and/or use of dental services are compared for Medicaid graduates and uninsured children (Table 1). Rural areas traditionally have fewer dentists per population than do urban areas which limits access to care. The difference between the percent of respondents residing in rural areas across the two groups, while statistically significant, is small.

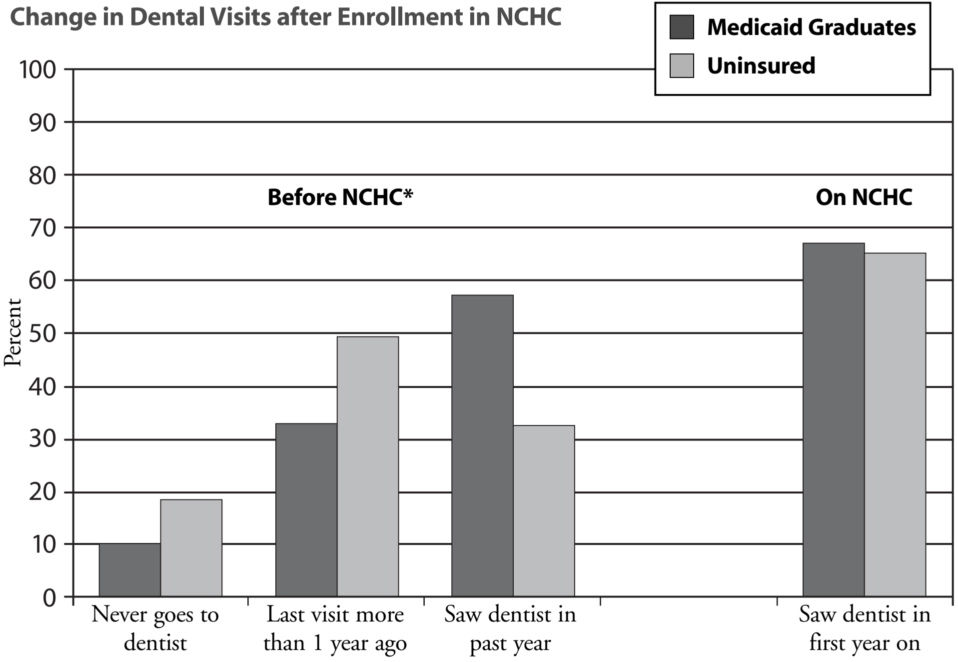
Table 1.
Demographic Characteristics

	Insurance Status in Year before NCHC Enrollment	
Characteristic	Uninsured (n=201) %	Medicaid Graduates (n=391) %
Rural Residence*	49	46
Race*		
White	51	42
Black	42	48
Hispanic	3	4
Mother's education*		
Less than high school graduate	15	15
High school graduate	36	44
Some college	35	32
College graduate	15	9

** The difference in distribution is statistically significant at p<.05*

There were significant differences in the racial composition of the two groups. Children who were uninsured prior to NCHC enrollment were more likely to be white (51%) than were Medicaid graduates (42%), and the mothers of uninsured children were more likely to have post-secondary education. Finally, although data on income prior to enrollment in NC Health Choice was not available, it is reasonable to assume that many of the uninsured children had family incomes that were slightly higher than that of the children on Medicaid, which is why they were uninsured rather than on Medicaid.

Figure 1.
Change in Dental Visits after Enrollment in NCHC



**Difference in distribution across insurance groups is statistically significant at p<.05.*

Dental Visits

In both surveys, parents were asked about the timing of their child's most recent dental visit. They were also asked where their child received dental care. There were significant differences in receipt of dental care prior to NCHC between the two groups: 57% of Medicaid recipients had a dental visit within the year before enrolling in NC Health Choice, compared with only 33% of uninsured children (Figure 1). Parents of uninsured children were more likely to report that prior to program enrollment their child had gone more than a year since receiving dental care (49%) or that s/he had never had dental care (18%), compared to the responses of parents of Medicaid children (33% and 10% respectively).

After program enrollment, differences in receipt of dental care between the two groups disappeared: 65% of previously uninsured children and 67% of Medicaid graduates made a dental visit during their first year on NC Health Choice. Although there was an increase for both groups in the percent of children who received dental care after NCHC enrollment, the improvement was much more dramatic for the uninsured children. The percent of uninsured children who had a dental visit in the previous year doubled after enrollment in NCHC compared to an increase of 18% for Medicaid graduates.

Source of Dental Care

Parents were also asked where they took their child for dental care. Children were considered to have a usual source of care if their parents reported taking them to a community clinic or health center, public health department or private dental office. Children were considered to have no usual source if their parent reported that they got care anywhere they could or that they never got care. In the year prior to NCHC enrollment, Medicaid recipients were significantly more likely than uninsured children (76% versus 64%) to have had a usual source of dental care (Figure 2). After enrollment, the percent of children with a usual source of dental care increased to 85% for both groups. As was seen with dental visits, the improvement was greater for the uninsured group, resulting in no significant difference between groups post-enrollment.

When receipt of care in the private sector is the only consideration, a different picture emerges (Figure 2). Prior to program enrollment, Medicaid children were significantly more likely than uninsured children to receive dental care at a private practice (61% versus 57%). After program enrollment the relationship was reversed, with children who were previously uninsured (77%) significantly more likely to receive care in the private sector than were

Medicaid recipients (69%), although there was a significant increase in private sector access for both groups.

Reported Unmet Need for Dental Care

Parents were asked if there was any time in the previous six months that they felt their child needed dental care that he or she could not get. For those with unmet need, barriers to care were queried (Table 2). To get a sense of the portion of all publicly insured children facing specific barriers, the percent reporting any particular barrier is reported as a portion of all those responding to the survey, not just those with unmet need for care.

In the six months prior to NCHC enrollment, a greater percentage of parents of uninsured children reported unmet need for dental care (58%) than did parents of Medicaid recipients (33%). For uninsured children, lack of insurance coverage and money were the main obstacles to care. Medicaid parents also reported these barriers, but they were significantly less likely to do so. Surprisingly, parents of 17% of Medicaid recipients (half of those with an unmet need) reported that they did not have insurance that would pay for the care although Medicaid does cover dental services. This may reflect need for a service that Medicaid does not cover, the parent's lack of knowledge about their child's benefits, or may indicate that dentists were unwilling to accept Medicaid coverage, so as to render the child's dental coverage ineffective. An almost equal proportion of Medicaid parents (17% of all Medicaid children and 49% of those with an unmet need) reported that they could not find a dentist who would see their child, an access barrier reported significantly more often for Medicaid recipients than for the uninsured.

After a year on NCHC, significantly fewer parents in both groups reported that their child had unmet need for dental care. On an additional positive note, the percent of Medicaid parents who reported that they could not find a dentist that would see their child dropped by two-thirds after enrollment in NCHC. Finally, after enrollment Medicaid parents were more likely than uninsured parents to report lack of money as a barrier to care.

DISCUSSION

The significant differences in access to dental care between the two groups prior to enrollment in NCHC suggest that Medicaid coverage does improve access to dental services for low-income children who would otherwise be uninsured, despite the known problems of low provider reimbursement and the reported reluctance on the part of providers to accept clients they believe will not keep appointments. Prior studies have found that whites and those with higher income and/or education are more likely to use dental services.[4] Those findings, however, might be attributed to private dental insurance coverage as those same groups are more likely to have such coverage, which itself predicts use of dental services regardless of socio-economic and demographic characteristics.[18] Since the uninsured group in our study was more likely to be white, have higher income and more education, one might expect this group to have greater access to dental services before NC Health Choice than did Medicaid graduates, and the pre-NCHC differences may understate the true difference between the two groups.

In general, the experience of former Medicaid children and uninsured children appears comparable after enrolling in NC Health Choice. Almost the same percentage of children in each group was reported to have visited a dentist in the first year on the program and to have a usual source of care. However, after NCHC enrollment Medicaid children were significantly less likely to report having a private dentist as their source of care than were uninsured children. Consistent with prior research identifying low reimbursement rates as a barrier to Medicaid children's receipt of care,[6] there was an increase in the percentage of Medicaid children who were able to access care in the private sector after NCHC enrollment. But, the fact that after enrollment in NCHC access to the private sector for Medicaid children was more limited than for the previously uninsured may be due to patterns of care prior to enrollment in NC Health Choice. Dental providers in Community and Migrant Health Centers and public health departments are far more likely to accept Medicaid coverage than are many private providers. Thus, Medicaid recipients may have continued to see a public dental provider with whom they had already established a relationship. It is also possible that differences in demographic characteristics between the two groups contributes to the higher likelihood that the previously uninsured group was seen in the private sector, as this group is more likely to be white and more educated.

Moving from Medicaid to NCHC improved dental access for all children in our study. The most obvious explanation for the improved access to dental services for Medicaid children after enrolling in NC Health Choice is the improvement in provider reimbursement, a known barrier to provider participation in the Medicaid program. The fact that NC Health Choice is administered by Blue Cross Blue Shield, coupled with higher reimbursement rates, may convince previously reluctant providers to participate in the program.

However, what is unknown is the extent to which the improved access afforded by NC Health Choice is a result of providers' perception that NC Health Choice beneficiaries are a different population and more likely to keep appointments. The social factors that make keeping appointments difficult, factors such as transportation problems and inflexible work schedules, will not have changed substantially with a child's transition from Medicaid coverage to coverage by NC Health Choice. It is not known if dentists even realize that the majority of NC Health Choice enrollees were previously on Medicaid. There is a public perception that NC Health Choice is a program for the working poor and that Medicaid is a welfare program, even though many children are served by both programs at different times in their lives.

Regardless of motivation of dental providers, NC Health Choice has improved access to dental care for North Carolina's poor children. In a time of fiscal crisis, changes to this insurance program, which currently covers approximately 100,000 children,[21] should be carefully considered to avoid loss of dental care gains afforded by this public insurance program.

This study was supported by a contract from the North Carolina Department of Health and Human Services.

ARTICLE

Race and Colorectal Cancer Screening:
A Population-based Study in North Carolina

Deborah A. Fisher, MD, MHS, Karen Dougherty, MSN, ANP, Christopher Martin, MPH, Joseph Galanko, PhD, Dawn Provenzale, MD, MS, and Robert S. Sandler, MD, MPH

Abstract

Objective: *National and state data document racial differences in colorectal cancer (CRC) mortality and incidence. Screening for CRC reduces cancer incidence and deaths. Racial differences in colorectal cancer screening behavior may contribute to the racial disparity in incidence and mortality. The purpose of this study was to determine if colorectal cancer screening rates are different between blacks and whites while controlling for potential confounders.*

Study Design: *Cross-sectional survey.*

Data Source(s)/Study Setting: *We used data from the North Carolina Colon Cancer Study, a population-based case-control study conducted in 33 counties of North Carolina. We analyzed data from 598 control subjects who were eligible for colorectal cancer screening.*

Methods: *Trained nurses conducted face-to-face interviews from October 1996 through October 2000.*

Results: *Overall, 50% of the respondents were compliant with CRC screening guidelines. In the multivariable logistic regression model having a regular doctor and participation in a general medical exam were significantly associated with current screening status with odds ratios (OR) (95% confidence interval (CI)) of 3.8 (1.7-8.3) and 3.7 (2.1-6.7), respectively. Older age was a significant predictor of current screening status with an OR (95% CI) of 2.9 (1.7-4.8) for those 60-69 compared to respondents 50-59 and OR 3.2 (1.9-5.5) for those 70 and older compared to respondents 50-59. After adjusting for age, having a regular doctor and participation in general medical exams, race was not significantly associated with current CRC screening status, with an OR of 1.1 (95% CI 0.7-1.6).*

Conclusion: *CRC screening rates in North Carolina were low. Race was not a significant determinant of screening behavior and therefore does not explain the racial disparity in incidence or survival. Older age, having a regular doctor and participating in general medical exams were significant predictors of CRC screening.*

Relevance: *This study reinforces the fact that screening rates in North Carolina are low despite the strong evidence that colorectal cancer screening reduces cancer deaths.*

Nationally, colorectal cancer incidence and mortality is higher for blacks than whites.[1] State-level data in North Carolina also reveal this racial disparity.[2] The American Cancer Society and other organizations have endorsed several screening strategies[3,4] because colorectal cancer screening decreases colorectal cancer mortality and incidence.[5,6,7,8,9] Racial differences in colorectal cancer screening behavior may contribute to the racial disparity in incidence and mortality. Other possible predictors of colorectal cancer screening behavior include income, insurance status, education, participation in regular

Methodology

We used information from the North Carolina Colon Cancer Study (NCCCS), a population-based case-control study conducted in 33 contiguous counties of central and eastern North Carolina from October 1996 to October 2000. Control subjects younger than 65 were selected from Department of Motor Vehicle Registry tapes. Control subjects age 65 and older were selected from the Centers for Medicare and Medicaid Service's tapes. Trained nurses conducted face-to-face interviews with the subjects. Questions about screening tests included the total number of each test [fecal occult blood test (FOBT), colonoscopy, flexible sigmoidoscopy, and barium enema] done in the past 10 years, the date of the most recent test and whether the most recent test was for screening or a problem. The interviewers also asked about physical activity, tobacco use, family history, occupation, income, health insurance, source of health care, health seeking behavior and health status.

We considered a subject "current" for colorectal cancer screening if he or she had been tested within the time frame endorsed by the American Cancer Society and others at the time of the study: FOBT within one year, flexible sigmoidoscopy within five years, barium enema within five years, or colonoscopy within 10 years beginning at age 50.[3,4] We restricted the study sample to individuals eligible for screening. Thus, we only used data from the control subjects. In addition, we excluded subjects younger than age 50 and those who had tests performed for symptoms or problems. Individuals in the latter category would be at a higher risk for colorectal cancer and therefore would be surveillance candidates and not screening candidates who are, by definition, at average risk for a condition.

Analysis

Logistic regression modeling was the primary analytic technique. We performed all analyses using PC-SAS Version 8.2 for Windows (SAS Institute, Cary, NC).

We constructed unadjusted and adjusted logistic regression models with colorectal cancer screening status as the dependent variable and race as the independent variable. We developed the adjusted model by first including race and any predictor variables with a p value <0.1 in univariate analysis (chi-square test). We reduced the model by stepwise backward regression. We chose, *a priori*, p<0.05 as the level of significance for the models.

We categorized variables as follows: age (50-59, 60-69, 70 and older), education level (less than high school graduate, high school graduate, at least some college, college graduate), insurance status [government (Medicare, Medicaid, CHAMPUS, CHAMPVA), private/HMO, none], income (< $20,000, $20-50,00, >$50,000), residence (rural, urban), marital status (married, not married), health status (mental component summary and physical component summary from the Short Form-1216, smoking status (never, former, current), physical activity (MET-minutes per day by quartile) and participation in a general medical exam (yes, no).

The University of North Carolina at Chapel Hill Institutional Review Board approved this study. All subjects gave written informed consent.

Results

Sixty-two percent of the subjects screened agreed to participate in the NCCCS for a total of 1,051 subjects. After elimination of patients younger than 50 and those with a history of colorectal cancer testing for symptoms, 700 subjects remained. We further excluded 102 subjects with missing data for a response or explanatory variable, leaving 598 subjects. Approximately half all of the patients were men, 59% were white and 41% black. Table 1 lists additional characteristics of the study sample. Univariate analysis revealed associations between current colorectal cancer screening and the following predictor variables at the p<0.1 level: age, income, health insurance type, education, having a regular doctor, marital status, and participation in a general medical exam. In the unadjusted model, race (black vs. white) was not significantly associated with current screening status with an odds ratio (OR) of 0.74 (95% confidence intervals (CI) 0.53-1.02). The adjusted logistic regression model included race (black vs. white), age (50-59, 60-69, (70), income (< $20,000, $20-50,00, >$50,000), having a regular doctor (yes, no) and participation in general medical exams (yes, no). Having a regular doctor, participation in a general medical exam, higher income and older age were significantly associated with current screening status (Table 2). Race was not significantly associated with current CRC screening status, with an OR of 0.98 (95% CI 0.67-1.43).

Table 2.
Independent predictors of current participation in colorectal cancer screening*

Variable	Odds Ratio	95% Confidence Intervals
Race		
Black vs White	0.98	0.67-1.43
Household income		
>$50,000 vs $20-50,000 per year	2.38	1.47-3.85
>$50,000 vs <$20,000 per year	2.86	1.69-4.76
Age		
≥70 vs 60-69	2.84	1.68-4.78
≥70 vs 50-59	3.17	1.89-5.32
Had a Regular Doctor		
Yes vs No	3.79	1.67-8.63
Participated in General Medical Exam		
Yes vs No	3.79	2.13-6.71

* *each item was simultaneously controlled for other items in the table*

The sample size was insufficient to construct logistic regression models for gender subsets to explore the relationship between participation in breast or cervical cancer screening and colorectal cancer for women or participation in prostate cancer screening and colorectal cancer screening for men. Gender, itself, was not significantly associated with current colorectal cancer screening at the p<0.1 level in univariate analysis, and therefore, was not included in the logistic regression model.

Discussion

This North Carolina population study of subjects eligible for colorectal cancer screening confirms other reports of low colorectal cancer screening rates.[13,14,17] Race, however, was not a significant determinant of current screening participation. Income and age were associated with colorectal cancer screening behavior, but the strongest predictors of adherence to colorectal screening guidelines were having a regular doctor and participation in general medical exams. While 53% of the patients with a regular doctor were current with colorectal cancer screening only 17% of those without a regular doctor were current. Similarly, 55% of those who had participated in a general medical exam were current with colorectal cancer screening while only 20% of those who had not participated in a general medical exam were current. In multivariate analysis, the odds of being up-to-date with colorectal cancer screening were reduced by 74% for those without a regular doctor and for those who had not participated in general medical exams.

Other large survey studies have examined predictors of fecal occult blood testing or lower endoscopy and none have found a clear association between race and participation in the tests. An analysis of the 1997 Behavioral Risk Factor Surveillance System (BRFSS) data, a national telephone survey, found no difference in colorectal cancer screening rates between blacks and whites. Having health insurance and increasing age (up to 79), income, and education were associated with screening status. Healthy behaviors were examined and non-smoking status, seatbelt use, physical activity, increased fruit and vegetable intake and recent cholesterol screening were all associated with current colorectal cancer screening. Participation in medical examinations and having a regular doctor were not examined in this study.[14] Analysis of the 1998 National Health Interview Survey data (NHIS), a face-to face national survey, again found increased education and having insurance predict colorectal cancer screening status. The NHIS study found no association between race and colorectal cancer screening. The strongest predictor of colorectal cancer screening was having a usual source of care, which, while not identical to continuity of care (i.e. having a regular doctor), is related.[18] Another analysis of the same 1998 NHIS data did find a small but statistically significant association of white race compared to black race or "other race" and reported colorectal cancer screening. One explanation for the discrepancy was that different screening intervals were used in the two studies.[17] A face-to-face interview study performed in the Mid-West found that having had a physician visit in the prior year was a strong predictor of ever having had a FOBT and ever having undergone sigmoidoscopy. Higher education was also a predictor of having had each test. Smoking status was only associated with the FOBT and increased income was only associated with sigmoidoscopy. The sample was over 98% white and therefore racial differences in screening behavior could not be addressed.[15]

While our study does not provide an explanation for the racial gap in colorectal cancer incidence or mortality, it does offer insights to increase colorectal cancer screening participation for the general population. Our results suggest that health maintenance visits and continuity of a primary care provider may be facilitators of colorectal cancer screening participation. The association of higher income and screening behavior is likely related to an increased ability to afford the tests, both the costs associated with the test itself and the costs of missing work, traveling to the doctor's office and related expenses. Even in an insured study sample (97%), colorectal cancer screening is not without expense because of variable insurance coverage for colorectal cancer screening and the indirect costs listed above. Increased ability to afford colorectal cancer screening should increase compliance with provider screening recommendations. Additionally, subjects with higher incomes may have been more likely to request screening, knowing that they had the financial resources if the screening was not covered by their health insurance. Ensuring adequate coverage and educating consumers about their colorectal cancer screening benefits are important to increase colorectal cancer screening participation.

The strengths of our study include identification of test indication, determination of all endorsed screening strategies, use of a representative population sample and adequate response rate. The use of radiologic and endoscopic tests for diagnosis or therapy is important, but the accuracy of predictors of screening behavior relies on determination of the test indication. In contrast to the Behavioral Risk Factor Surveillance System (BRFSS) survey, we distinguished between CRC testing for screening and for diagnostic purposes.[2,14] Further, we asked about all recommended screening options allowing us to correctly identify screened patients who may have been missed using surveys, such as the BRFSS and National Health Interview Survey (NHIS) that only asked about certain screening modalities.[14,17] This study has the limitation of using self-reported data without validation from another source. However, a study in a community family practice setting found high correlations for fecal occult blood testing (0.78) and sigmoidoscopy (0.90) when comparing chart audit with patient survey.[19] In addition, two studies in the managed care setting investigating the relative sensitivity of patient survey compared to medical record audit found a 92-96% sensitivity of the survey to detect fecal occult blood testing, 79%-95% sensitivity to detect flexible sigmoidoscopy and an 89% sensitivity for detecting colonoscopy.[20,21]

In conclusion, older age, higher income, having a regular physician and participation in general medical exams were associated with colorectal cancer screening behavior. Several patient, provider and system level factors are likely to be responsible for the low colorectal cancer screening rates in North Carolina and nationally. Our study demonstrates that there are continued financial barriers. It also supports the importance of factors related to the primary care setting. Future directions include testing interventions that increase continuity of primary care and health maintenance visits.

INTRODUCTION

Policy Forum:
Organ Donation and Transplantation

Almost every week, we hear stories from North Carolina and elsewhere in the nation about an individual who is desperately waiting for word that a bodily organ is available to replace one that is seriously diseased or malfunctioning. Life is both literally and figuratively "in the balance" as the waiting game goes on, sometimes for months or years. Why is it that so few people, particularly so few from minority population groups, are willing to take the necessary steps before the time of their own death to assure both healthcare providers and their families of their intention to donate organs that might save or improve the lives of others? Why are we burying so many of these vital organs day-after-day, rather than extending the lives of those in need? Why is it so difficult to find live donors of organs that might offer the same life-saving benefits, without compromising the health of the donor? These are important questions of health policy significance, as well as tremendously important personal issues for those whose lives have been touched by the events and circumstances which have made either organ donation or receipt major issues of concern.

The other dimension that captured the interest and concern of our editors is that the science and skills of transplantation are now such that most recipients of donated organs have the prospect of living full and functional lives without overwhelming concerns they once would have had with rejection and the need for further transplantation. The rapid diffusion of transplantation technologies and skills and the development of multi-organ transplantation services within our state's largest hospitals, has given all North Carolinians access to some of the world's most advanced medical care for conditions where only transplantation offers hope.

In this issue of the *Journal* we are pleased to offer a set of articles providing a broad overview of many of these concerns in the hope that more attention will be given to this important aspect of contemporary medical care for those who could benefit from an expansion of both our donor networks and participation, as well as from the advancing science of transplantation. Erika Rager, MD, MPH, a surgical resident at UNC-Chapel Hill who is currently taking a two-year residency in preventive medicine, offers a comprehensive issue brief on the topic. We are pleased that leading figures from the transplant services of both Duke Medical Center and UNC-Chapel Hill have agreed to participate in this special issue forum. In addition we are pleased to include contributions from our two donor organizations in the state, Carolina Donor Services and LifeShare Of The Carolinas. Because of our concern over the rather low rate of participation of minority populations in organ donation and transplantation, we have invited Dr. Lynt Johnson of Georgetown University, an African American transplant surgeon, and Debbie Mann Gibbs of LifeShare Of The Carolinas to help address these issues. Finally, Contributing Editor Donald Madison, MD, offers an interesting interview with a North Carolina family who has experienced a broad spectrum of these issue first-hand.

For those who may not have previously signed (and had witnessed) a donor card, one is provided in this issue of the *Journal*, which may be clipped and placed in one's wallet along with a driver's license.

As always, we invite the comments and reactions of our readers to these and other topical issues covered in these pages.

The Donation of Human Organs and the Evolving Capacity for Transplantation:

Exciting Developments and Future Prospects

Erika L. Rager, MD, MPH

Solid organ transplant is the best treatment and only cure for many people suffering from end-stage disease. Over the past 20 years, improvements in immunosuppression and increasing experience in caring for transplant patients has resulted in massive increases in the use of this therapy. Now, the numbers are truly staggering. As of December 15, 2003, there were 83,686 patients with end-stage organ disease awaiting transplant in the US. In 2002, there were 12,801 deceased and living organ donors; 24,900 patients underwent transplantation; and 6,187 died while waiting on the list.[1] About 56 people receive an organ transplant every day in the US and four North Carolinians die each week waiting for an organ transplant. The therapeutic application of organ transplantation is limited only by a shortage of donor organs.

Brief history of organ transplantation

Development of organ transplantation as a widely applicable therapy depended on technical advancements in the field of surgery and increased understanding of immune function. The initial technical advancements in vascular anastomosis (surgical techniques to sew together blood vessels) that were necessary for later organ transplantation were developed by French surgeon Alexis Carrel in the early 1900's. Animal studies over the next 50 years resulted in techniques for the transplantation of kidneys, abdominal and thoracic organs.[2]

Based on studies of skin grafting, by the 1940's scientists understood that rejection of transplanted tissues was an immunological event. Initial attempts to modulate the immune system in humans used sublethal doses of total body irradiation to suppress bone marrow production of white blood cells. This immunosuppression led to occasional long-term survival of transplanted organs, but was unreliable. By the early 1960's, researchers were using drugs to suppress the bone marrow. Medication regimens based on azathioprine and prednisone improved patient survival in the 1960's and 1970's, especially for living-related kidney transplants.[2,3] In the late 1970's, the immunosuppressive drug cyclosporine was introduced. Cyclosporine dramatically changed the course of organ transplantation. One-year survival rates increased from 30-60% to 70-90%.[4] Transplantation of kidneys, livers, hearts, and lungs became widespread.

The first transplant that enjoyed long-term success was a living-related renal transplant performed between identical twins in 1954 by Dr. Joseph Murray. In 1990, Dr. Murray was awarded the Nobel Prize for Medicine for his achievements in the field of transplantation. Aside from the first successful renal transplant in 1954, most of the first successful solid organ transplants occurred in the late 1960's.

Table 1.
Milestones in Transplantation in North America

1954	First successful kidney transplant
1966	First successful kidney-pancreas transplant

Organ procurement and preservation, tissue matching, and immunosuppression are the principal ingredients for successful solid organ transplantation. The technical aspects of the organ procurement operation allow multiple teams to work together to procure all useful organs from a single donor. Modern preservation fluids increase the length of cold ischemic time (time outside the donor's body for transport to the recipient)

Erika L. Rager, MD, MPH, is a Preventive Medicine resident in the Department of Social Medicine and General Surgery resident in the Department of Surgery at the University of North Carolina at Chapel Hill. She can be reached at rager@email.unc.edu or Department of Social Medicine, CB#7240 Wing D, UNC-CH, Chapel Hill NC, 27599-7240. Telephone: 919-843-8077.

that an explanted organ can tolerate. Preservation fluids are ice-cold solutions that include electrolytes, antioxidants, hydrogen ion buffers and sugars.[5] Appropriate tissue matching depends on blood group matching (e.g. blood type A, B, or O) for all organs. Kidneys are also tissue-matched based on HLA (human lymphocyte antigen) type and lymphocyte (white blood cell) cross-matching tests.[2] Cross-matching mixes the recipient's serum with the donor's lymphocytes to test immunologic compatibility. Today's immunosuppressive regimens typically include three drugs: a glucocorticoid such as prednisone, an antimetabolite such as azathioprine or mycophenolate, and a calcineurin inhibitor such as cyclosporine or tacrolimus.

STRUCTURE OF THE NATIONAL ORGAN PROCUREMENT AND TRANSPLANTATION SYSTEM

Current Scope of Solid Organ Transplantation

Solid organs that are transplanted in the US include kidney, liver, heart, lung, pancreas, and small intestine. There is an allocation policy specific to each donor organ. Potential recipients are listed based on objective criteria that include blood type, tissue type, size of organ needed, medical urgency of the recipient, time on the waiting list and distance between the donor and recipient.[1] The process of identifying potential organ donors, placing their organs with appropriate recipients and coordinating the transplant operations is a complicated process involving many organizations working together.

Organ Procurement and Transplantation Network

The Organ Procurement and Transplantation Network (OPTN) was created by the National Organ Transplant Act of 1984. The OPTN facilitates organ matching. It develops policies and procedures for organ recovery, allocation, and transportation. It also collects, manages and distributes data about organ transplantation. Finally, it provides both professional and public education about organ donation and transplantation. In order to receive Medicare funds, all transplant centers and OPO's must be members of the OPTN. The OPTN has a variety of other members, including independent histocompatability laboratories, professional organizations, patient advocacy organizations and members of the general public.[1]

All organ transplant programs in the US are members of the OPTN. Members of the OPTN are certified as compliant with the rules that are in place to ensure the public safety, and highest level of care for organ donors and recipients. The OPTN membership bylaws explicitly outline the requirements for a transplant center. Program staffing requirements include a medical director, clinical transplant coordinator (usually a nurse), financial coordinator, and staff to provide social support. Transplant centers must have specially-trained transplant surgeons and transplant physicians with extensive qualifications. The OPTN also monitors survival rates at each transplant center, and those who fall below a given threshold level are reviewed.[1,6]

United Network for Organ Sharing

The United Network for Organ Sharing, or UNOS, is a private, nonprofit organization that contracts with the federal government to administer the Organ Procurement and Transplantation Network. The centralized computer network at the UNOS Organ Center links OPO's and transplant centers. All patients on the transplant waiting list are registered with UNOS.[1] On average, UNOS receives 350 calls per day from OPO's.[7]

Regions

The US is divided into 11 regions. North Carolina is in Region 11, along with Kentucky, South Carolina, Tennessee and Virginia.

Organ Procurement Organizations

Organ Procurement Organizations (OPO's) are private, nonprofit organizations that are members of the OPTN and certified by the Health Resources and Services Administration. Each OPO has its own board of directors and medical director, usually a transplant surgeon or physician. Procurement coordinators work for the OPO. They are highly trained professionals, often nurses, who coordinate each step of the transplant process.

The OPO's are involved in every step of a deceased-donor (cadaveric) organ transplant, from evaluating potential donors, to obtaining consent from the donor's family, placing the organs and traveling with the procurement team to obtain the organs. The OPO's other primary role is to promote organ donation within the community. They engage in public and professional education efforts in the community and in the hospitals they serve.

The OPO's have defined service areas designed to assure maximum effectiveness in organ procurement and equitable distribution of organs. There are currently 59 OPO's. The OPO's serve all the hospitals in their designated geographical areas. North Carolina is served by two OPO's. Carolina Donor Services serves 79 counties in North Carolina, and Danville, Virginia. LifeShare Of the Carolinas serves 23 counties in southwestern North Carolina and York County, South Carolina.[1,8,9]

LEGISLATIVE HISTORY

Uniform Anatomical Gift Act

The Uniform Anatomical Gift Act (UAGA), promulgated in 1968, established the legal framework for organ donation. A version of the UAGA was adopted in each state and the District of Columbia. The scope of the act is limited to organ procurement. It requires hospitals to establish affiliations with regional organ procurement organizations to coordinate the procurement of organs. The UAGA holds that all citizens aged 18 and over have the right to decide for themselves if they choose to be organ donors. It established the Uniform Organ Donor Card as a legal document. The law does not require the consent of next of kin for the procurement of organs from a brain dead patient with written documentation of intention to donate, such as a signed donor card or driver's license.[10] However, in practice, the OPOs require consent from the patient's family prior to organ donation. The law also establishes the order of priority in obtaining consent: spouse; adult son or daughter; parent; adult sibling; grandparent; and legal guardian.[1]

National Organ Transplantation Act

In 1984 Congress passed the National Organ Transplant Act (NOTA). This act established the Organ Procurement and Transplantation Network (OPTN). The OPTN has two primary goals: to increase the effectiveness and efficiency of organ sharing and equity in the national system of organ allocation; and, to increase the supply of donated organs available for transplantation.[1] NOTA also expressly forbids the buying or selling of organs.

The US Department of Health and Human Services, through the Health Resources and Services Administration, contracts with a private, nonprofit organization to operate the OPTN. Since 1986, the United Network for Organ Sharing (UNOS), based in Richmond, Virginia, has administered the OPTN. UNOS operates the national wait list.

Omnibus Budget Reconciliation Act

A 1986 amendment to the Social Security Act requires hospitals that receive Medicare or Medicaid funding to have written protocols for the identification of potential organ donors and notification of the local OPO. It also requires hospitals to make families aware of the option to donate or to decline to donate. Transplant hospitals are required to be members of the OPTN and abide by the Network's rules. Finally, it added limited coverage for immunosuppressive drugs for Medicare patients.[1,8]

Medicare ESRD Program

Prior to the 1960's, End-Stage Renal Disease (ESRD) was a certain death sentence. In that decade, two powerful treatment options emerged: dialysis and transplantation. Congress created the ESRD Program in 1972. It covers most medical care for almost all ESRD patients. When the program was created, there were 10,000 eligible patients. By 2000, there were over 323,000 patients receiving treatment for ESRD. This number is expected to continue to grow rapidly. Current estimates are that in 2010, there will be 651,000 ESRD patients.[11] For those patients for whom it is medically appropriate, transplantation is preferable to dialysis. It leads to longer life expectancy, better quality of life, and lower costs than dialysis.[12]

Other Legislation

In 1998, the US Department of Health and Human Services made changes to the Conditions of Participation for hospitals that receive Medicare and/or Medicaid funding in an attempt to increase organ donation. Hospitals are required to notify the local OPO of all deaths or imminent deaths. The individual who initiates family discussions about organ donation must be a representative of the local OPO or someone who has been specially trained to request organ donation.[8] This is not typically a physician. Decoupling the discussions about brain death and organ donation is thought to increase the consent rate. Requests for organ donation that come from someone specially trained, such as an OPO representative, are also thought to increase consent rates.

This year the Organ Donation and Recovery Improvement Act was introduced in the US Senate. If passed, it would fund a public education campaign and hospital organ donation coordination programs. It would also allow reimbursement to organ donor families for travel and subsistence expenses. However, the idea of providing reimbursement to donor families is controversial and in contradiction to the National Organ Transplantation Act.

North Carolina Legislation

The "Gift of Life Act," passed in 1997, requires hospitals to notify the local OPO of all cardiac deaths or impending brain deaths of patients up to age 75. It also designates OPOs as responsible for evaluating all referrals for potential donation and informing families of the option to donate.

THE PROCESS OF ORGAN DONATION AND TRANSPLANTATION

When a transplant center initially decides that a patient with end-stage disease is appropriate for transplant, the potential organ recipient's name and medical information are entered into a computer database at the UNOS Organ Center. At this point, the patient has been "listed" for transplant. The potential transplant recipient then waits on the list until a donor organ becomes available. As the waiting lists grow longer, so do the waiting times. Almost half of all transplant candidates in North Carolina who are waiting for kidney or heart transplants have been waiting more than two years. More than half of those waiting for liver, lung, and heart-lung transplants have been waiting more than two years.[1]

Brain Death

The donor process begins when a local OPO is contacted by a hospital caring for a patient with impending brain death. The vast majority of organs procured from deceased donors come from donors who have sustained brain death under circumstances that allow their respiration and circulation to continue to be supported by artificial means. The acceptance of organ procurement for transplantation depends on understanding the concept of brain death. Under the Uniform Determination of Death Act,[13] drafted in 1980 and adopted by 43 states, death is defined as either irreversible cessation of circulation and respiration, or irreversible cessation of all brain and brainstem function.[8] Prior to the declaration of brain death, several other diagnoses must be ruled out, including hypothermia, circulatory shock, drug intoxication, metabolic intoxication from kidney or liver failure, and the prolonged effects of neuromuscular blocking drugs.[14]

A physician must certify a patient as brain dead in order for that patient to be an organ donor. The criteria for diagnosing brain death vary from hospital to hospital, but they include some combination of physical exam and other tests. The usual tests include reflexes such as gag, cough and pupillary response to light. An apnea test is performed to determine that the patient cannot breathe without mechanical assistance. A cerebral blood flow test may also be performed to determine whether or not there is blood flowing to the brain.[8]

Brain death can be caused by any condition that interrupts oxygen delivery to the brain. Such conditions include trauma, stroke, intracranial bleed, drowning, carbon monoxide poisoning, drug overdose and others.[8] The most common causes of death for organ donors are head trauma, cerebrovascular accident (stroke), and anoxia (lack of oxygen supply to the brain).[1]

Potential organ donors undergo physiologic changes that require aggressive medical management prior to and after the declaration of brain death. Medical interventions are often required to maintain adequate intravascular volume and blood pressure; maintain body temperature; correct coagulopathy (bleeding disorders); avoid elevated intracranial pressures; and treat hormone imbalances such as diabetes insipidus. The most common complication, occurring in up to 91% of patients, is hypotension (low blood pressure) requiring invasive monitoring and/or support with vasopressors (medicines to increase blood pressure). Timely determination of brain death is important to protect the condition of the donor's organs. A rapid brain death determination protocol can reduce medical failures prior to organ donation and can increase consent rates for donation. It can also increase the number of organs procured per donor to a level well above the national average.[14]

Table 3.
Maximum Cold Ischemic Time

Organ	Preservation Time
Heart and Lungs	4-6 hours
Liver	12-24 hours
Kidney	48-72 hours
Pancreas	12-24 hours
Small Intestine	12 hours

Organ Allocation and Procurement

After the declaration of brain death, the donor OPO performs a medical evaluation and contacts the patient's family to discuss organ donation. Once the family agrees to donation, the procurement coordinator from the OPO takes over medical management of the donor. At the same time, the coordinator contacts the UNOS Organ Center to begin the process of organ placement.

Each time a donor organ becomes available, the UNOS computer compares characteristics of the donor with each individual waiting for that type of organ. The computer then generates a list of potential organ recipients, the "match-run" list, ranked in order based on characteristics such as blood type, body size, medical urgency, waiting time and location. Factors such as race, religion, gender and financial status do not enter into the equation.[8]

The allocation policy is somewhat different for each organ. In general, organs first are offered to patients awaiting transplant within the OPO in which the organs were donated. They are then offered regionally and nationally. Some organs are offered based on recipient distance (in air miles) from the donor hospital. This policy decreases organ preservation time, thus improving organ quality and recipient outcomes. It also reduces costs to the transplant patient and provides more equitable geographic access to transplantation.[1]

Once the match list is available, the procurement coordinator contacts the transplant team caring for the patient at the top of the list. The transplant surgeon determines whether or not the organ being offered is appropriate for that patient. If so, the organ procurement and transplant operations are scheduled. If not, the procurement coordinator moves to the next patient on the list, calls that patient's transplant team and offers the organ. This process continues until all the available organs from a given donor are placed with transplant recipients.[8]

The accepting transplant teams travel to the donor's hospital, where the procurement operation takes place. Transplant teams from widely separated centers can share organs from a common donor. Surgical techniques allow any combination of organs to be removed. Preserving solid organs depends on rapid intravascular cooling done in situ (in the body), followed by removal of the organs, storage of the organs in ice-cold preservation fluid and rapid transport to the recipients' hospitals.[2] The cold ischemic time is the length of time the organs are on ice, without blood flow. The maximum cold ischemic time limits the amount of time that can pass between organ recovery and the organ transplant.

UNOS functions as the middle-man between the donor OPO and the receiving OPO. The donor OPO receives the match-run list, but does not have access to information about other patients who are listed for transplant. The receiving OPO can access wait lists for the hospitals that they serve, but cannot see the match-run list. This system was put into place to prevent individual transplant centers from manipulating the donor system.[7]

From the time consent for organ donation is obtained, all costs incurred in the donation process are billed to the OPO.

INCREASING THE NUMBER OF ORGANS FOR TRANSPLANT

One of the biggest challenges facing the transplant community at this time is a stagnant number of deceased donors in the face of an ever-increasing need for donor organs.

A number of options for expanding the pool of available organs exist. Increasing the rate of consent by families of potential donors could expand the pool of deceased donors. Policy changes in consent for organ procurement may increase available organs. Increased use of living donors for kidney, liver and lung transplants is an attractive option, although this practice is debated as it exposes otherwise healthy people to risk of morbidity and mortality. Compensation to donor families, once taboo, is now being debated. Technical changes include expanded donor criteria and non-heartbeating donors. Biological research aimed at xenotransplantation (animal-to-human transplantation) is ongoing, but this is not currently a viable solution.

Table 4.
Patient Waiting List for Organ Transplants as of January 21, 2004

Organ Needed	Patients in US	Patients in NC
Kidney	56,519	1,945
Liver	17,283	687
Lung	3,915	220
Heart	3,542	73
Kidney-Pancreas	2,417	96
Pancreas	1,527	15
Heart-Lung	189	17
Intestine	171	1
Total	**83,570**	**2,965**

Missed Donors

Over the past 10 years, between five and six thousand organs were procured from deceased donors each year. However, it has been unclear how many potential donors are available but do not donate. Recently, the Association of Organ Procurement Organizations published a large study[15] that indicates 54% of those families asked to donate agreed to do so. Only 42% of potential donors actually became donors. From 1997-1999, it is estimated that about 13,500 potential donors were available each year; this appears to be a stable pool of potential donors. There were about 5,500 actual donors each year. The population base for this study was large, and it probably accurately represents what is happening nationwide. However, the OPOs in the Southeastern United States did not contribute any data to this study.

Increasing the consent rate among potential donor families is one way to significantly increase the number of organs available. In fact, if all potential donors became actual donors, there would be enough hearts and kidneys available to transplant each person added to the list in 2002.[15] This study offered important insight into how this goal might be accomplished. Families of brain dead patients were less likely to donate if the patient was older, non-white or died from a cause other than trauma. Moreover, 89% of potential donors and 91% of actual donors were cared for at hospitals with 150 or more beds; 88% of potential donors who did not ultimately donate were cared for at these larger hospitals. That indicates that efforts to increase donation should be concentrated at these larger hospitals.

In March of 2002, Carolina Donor Services surveyed residents in the counties that it serves in an attempt to better understand residents' attitudes and awareness concerning organ donation. They found that families, friends, medical providers and clergy were most likely to influence the intention to be an organ donor. While 97% agreed that "organ donors provide the gift of life" and 93% agreed that "people are dying because there aren't enough organs available," only 56% intend to donate their organs when they die. As compared to whites, African Americans are more likely to be unsure about donating (45% vs. 22%) and are more likely to be opposed to organ donation (21% vs. 12%).[8]

The main factors that motivate North Carolinians to be organ donors are a sense of altruism and practicality. The chance to help someone else or save a life motivates 65% of donors, while 29% say that they intend to be a donor because "I don't need organs when I die." The most commonly reported reason people decide not to be donors is that they think they are too old or unhealthy to donate (26%). Other common reasons are that they never thought about it (19%) or that they are uncomfortable with the idea (15%).[8] Carolina Donor Services used the results of this survey to plan educational interventions to increase organ donation.

Carolina Donor Services also found that only 63% of people know that major religious groups support organ donation. In fact, all major religions in the US support organ donation and transplantation.[8]

Consent Procedures

The current donor system depends on a patchwork of organ donor cards, driver's licenses, advanced directives, and durable power of attorney for healthcare statements as vehicles for citizens to state their wishes. This is an "opt-in" system; it depends on routine referral of all potentially medically eligible donors to the local organ procurement organization (OPO). Trained professionals from the OPO then initiate contact with the patient's family regarding potential donation. The OPO attempts to ascertain the patient's wishes from documentation and discussions with the family. Even if the potential donor indicated his or her wish to donate, consent is still obtained from the family.

Eighty two percent of Americans believe that the individual, rather than his/her family, should make the decision regarding organ donation. Unfortunately, the same study found that 58% of Americans were unsure about their plans to donate or not to donate after death (30% intended to donate and 12% intended not to donate) and only 38% had discussed their plans with their families.[16]

These numbers are important because, in practice, the OPOs place tremendous weight on the family's wishes when obtaining consent for organ donation. A survey of all OPO's found that 48% rank impact on the deceased's family as the most important factor when obtaining consent, while only 12% rank the deceased patient's wishes as the most important factor.[17]

Other Options for Consent

Some European countries approach consent for organ donation via an "opt-out" system. Citizens are presumed to consent to donation unless they explicitly state that they do not want to be donors. Spain, Austria, France, Portugal, and Belgium have presumed consent policies. The British Medical Association favors such a policy in the United Kingdom.

The Belgian system serves as an interesting example. It allows any citizen to register his objection to donation at the local town hall. A national database tracks those who have opted-out; less than two percent of Belgian citizens have done so. Doctors ask the patient's family to confirm the fact that the patient did not object, rather than asking the family to make the decision to consent to donation. The system also allows physicians to defer procurement for any valid reason. This system, enacted in 1986, led to an increase in the number of organ donors and an increase in the number of organs procured per donor.[18]

Mandated choice is a system that compels competent adults to decide whether or not they wish to be organ donors when they die. The decision could be required when obtaining a driver's license or filing a tax return. Under this system, each person must consider the issue and make a decision; the individual's decision is honored at the time of death.[16]

A Gallup poll conducted in 1993 provides the most recent evidence on public opinion regarding mandated choice. Thirty percent of those surveyed had signed organ donor cards. When asked if they would sign up to donate if mandated choice became law, 63% said yes.[16] Based on the results of this survey, mandated choice would increase the number of available organs. Given that 82% of people think that the individual rather than his family should make the decision about organ donation, and that under mandated choice the individual's decision would be binding, mandated choice could protect individual autonomy while also sparing the potential donor's family an important decision at a difficult time.

> *Some European countries approach consent for organ donation via an "opt-out" system. Citizens are presumed to consent to donation unless they explicitly state that they do not want to be donors.*

A more subtle finding in this study is that the more one thinks about organ donation, the more likely s/he is to donate. Of the 25% who previously gave organ donation serious thought, 76% decided to donate.[16] It appears that mandated choice could further increase organ donation simply by encouraging people to consider the issue on a regular basis. A recent online experiment supported this finding.[19]

The American Medical Association Council on Ethical and Judicial Affairs and the United Network for Organ Sharing both endorse mandated choice.

Living Donors

One viable option for increasing the number of organ donors is to increase reliance on living donors. In 2001, for the first time ever, there were more living kidney donors than deceased kidney donors. That trend continues. In addition to kidneys, livers, lungs, small intestines and pancreases are available from living donors. Living donors may be related, unrelated loved ones, or strangers. They are usually aged 18-60, physically fit and in good health. They must have a blood type that is compatible with the recipient.[1]

Living donation is handled at the transplant center doing the transplant, rather than through OPOs and UNOS.[1] If the recipient has private health insurance, the costs of living donation are usually covered. Medicare covers the costs of living donation for donors whose recipient is covered under the End-Stage Renal Disease program.

Living donation is common for kidneys. Portions of liver and lung are transplanted with increasing frequency, while living donor pancreas and small intestine transplants remain rare. Use of organs from living donors can be controversial because the process exposes an otherwise healthy person to the risks of a donor operation. For this reason, the evaluation and consent of living donors requires special care. In particular, the transplant center must ensure that the donor's decision is voluntary. The transplant center must disclose all potential risks and benefits to the donor and recipient, including information on medical uncertainties and any alternative treatments for the recipient.[20]

Prior to donating an organ, a potential donor should undergo psychosocial evaluation by a mental health professional with special training in transplantation. This evaluator should not be involved in caring for the potential recipient. The goals of psychosocial evaluation are to evaluate social and emotional stability, establish competence to give informed consent, and to ensure that the decision to donate is made without coercion.[20] With these safeguards in place, living donation is a good way to increase the number of organs available for transplant.

The vast majority of experience with living donors is in kidney transplant. Kidneys transplanted from living donors have better outcomes than kidneys transplanted from deceased donors. The organs function better and longer. In fact, the half-life (the time until half of all organs stop functioning) is 21.6 years for organs from living donors, as compared to 13.8 years for organs from deceased donors. Kidney donation has low rates of complications for the donor, with perioperative morbidity of 1-1.3% and mortality of 0-0.03%.[21]

The UNOS Board of Directors recently endorsed new initiatives to increase donation by living donors. These include coverage under the Family Medical Leave Act and a proposal to reimburse living donors for wages lost during the recovery period following transplantation.[1]

Compensation for Donors

The National Organ Transplant Act prohibits the sale of organs. For many years, the transplant community was uniformly opposed to the idea of compensating donors. Organ donation is seen as dependent on intangible benefits to the donor's family—a way to create some good from a personal tragedy, gain meaning from death, contribute to the good of society and honor a loved one's wishes.[22]

In recent years there has been a shift in perspective. The possibility of compensating organ donors is now frequently debated by medical professionals and ethicists. A UNOS telephone survey performed in 1990 found that the public was almost evenly split on whether or not organ donors should be compensated in some form. The state of Pennsylvania recently enacted a program whereby $300 is paid directly to the funeral home to help defray the costs to families of organ donors.[23] Perhaps efforts to increase the tangible benefits of organ donation could increase the rate of donation.

Other Options for Increasing Organ Supply

Expanded donor criteria refers to the use of organs from donors who previously have been considered medically unacceptable. Expanded criteria include using donors at extremes of age or those with underlying medical illnesses that make them suboptimal donors. It may also include using organs from donors with active infection or colonization, those who have been poisoned, or those who were transplant recipients prior to death. Organs from donors with hepatitis B or C infection can be transplanted into recipients with those infections.[24] As experience with donors previously thought to be unacceptable grows, what constitutes an "acceptable" donor continues to change.

Some technical factors can also contribute to increasing the number of organs available. Kidneys from donors less than five years of age have been considered unusable. However, if they are transplanted *en bloc*, giving two small kidneys to the recipient, outcomes are good. Sometimes a donor liver can be split, thus providing livers for two recipients from one donor organ.[21] Organs, especially kidneys, can be procured from non-heartbeating donors. This is also known as controlled donation after cardiac death. It is a more complicated procedure and outcomes are not as good as when organs are obtained from brain dead donors.[24]

Table 5.
Solid Organ Transplants in 2002

	Patients in US	Patients in NC
Patients who received transplants in 2002	24,897	701
Patients who died while waiting in 2002	6,391	210

Source: Adapted from www.carolinadonorservices.org

Xenotransplantation, the use of tissue from an animal donor, may one day provide a solution to the chronic shortage of donor organs. It is not yet a viable option because the human immune response to the animal organ cannot be well-controlled. Also, the potential risks of infectious disease transmission from the animal to the human are poorly understood. In the past, nonhuman primates have been used experimentally to provide organs. In the future, pigs seem most likely to supply organs for transplant because there are fewer ethical concerns than with primates and because they breed quickly. Laboratory research continues and clinical trials may begin soon.[25]

Conclusions

Efforts to increase organ donation continue. Carolina Donor Services recently partnered with UNC Hospitals and Pitt County Memorial Hospital to engage in an initiative by the US Department of Health and Human Services called the "Organ Donation Breakthrough Collaborative." The collaborative will apply best practices of organ donation processes to attempt to increase donation rates to 75%.[8]

Many people are hard at work developing ways to increase the number of organs available for transplantation. For the time being, education and policy efforts aimed at increasing the consent rate for deceased donation appear to offer the most hope. Consent to donate organs usually occurs in concert with an unexpected, tragic death. Organ donor cards and driver's license notations are an important part of organ donation policy. However, family discussions about organ donation prior to an unexpected tragedy are the best way to spare the family a difficult decision and insure that the patient's wishes are respected.

Transplantation is the best hope for many people with end-stage organ disease. And it works. Each year since 1988, the number of patients surviving more than one year after transplant has increased. The future of organ transplantation, and the future of those waiting for transplants, is limited only by a shortage of donor organs.

Increasing Donation:
Key Factors to Save More Lives

Lloyd Jordan

In my role as Executive Director of Carolina Donor Services (CDS), the non-profit, federally-designated organ and tissue recovery agency for 78 counties of North Carolina and one Virginia county, I am blessed to know many people who have received the "gift of life" through organ and tissue donation. In fact, there are more than 200,000 Americans living with transplants, people who are alive today thanks to the donor who saved their life.

As glad as I am to know these remarkable recipients, it is even more rewarding to me when I meet donor families, those who have made the selfless decision to donate their loved one's organs or tissues in order to save another person's life. The enormous courage, faith and generosity that these people share remind me daily of why I have remained in the field of donation for almost 20 years.

Over the years, I have witnessed remarkable advances in the processes of organ and tissue recovery and transplantation. Advances in medicine, surgery and immunosuppressive drug development have provided us with the ability to help more people than ever before and yet we are limited by one very critical factor—the relatively few number of donors.

Desperate need for more donors

Sadly, the number of people who need transplants continues to grow steadily each year, reaching 83,000 people nationwide and almost 3,000 here in our state. At the same time, the number of deceased donors has remained almost the same, rising just three percent last year to 6,185 donors. This gap means that almost 17 Americans die each day while waiting for an organ transplant; four North Carolinians die each week before they get the heart, lung, liver, kidney, pancreas or intestine transplant that they need to survive.

Many of these lives could be saved if only more people chose to donate. Nationally, about half of families choose to donate their loved one's organs when faced with that decision, although the current consent rate is slightly higher in the area served by Carolina Donor Services. Research shows that the main reasons people chose not to donate are due to a general lack of understanding about donation, as well as misconceptions, such as thinking they are too old to donate (in reality, there is no age restriction for organ donation), believing their religion doesn't support donation (all major religions do), or an unfounded, but prevalent fear that doctors won't try to save their lives if they are known donors.

Strategies to increase the number of people willing to donate

Much of the misinformation and myths that exist can be addressed through public education, which is why our organization devotes so much time and energy to community education and awareness programs in high schools, colleges, churches/faith communities, workplaces, Division of Motor Vehicles offices, the media, and other places where people get information. But, much more needs to be done.

One development that is helping to address the shortage of donors is living donation. The number of living donors-people who give one of their kidneys, or a part of their liver or lung while they're still alive-has grown significantly, to 6,607 people in 2002. While that increase has certainly had a very positive impact, each living donor can usually save the life of one person, while a deceased donor can potentially save up to eight lives through organ donation and enhance the lives of 50 people through tissue donation. So, ways to increase the number of deceased donors must also be explored.

A number of programs are currently being considered and studied to see if they will impact donation rates in our country. Donor registries, financial incentives and presumed consent are among some of the most widely-discussed and debated issues right now. I should also point out that xenotransplantation (animal-to-human transplant) research, tissue engineering and artificial organ research may also play a role in addressing the shortage of organs,

Lloyd Jordan is the executive director for Carolina Donor Services in Greenville, NC. Last year, Mr. Jordan served as President of the Association of Organ Procurement Organizations (AOPO), the organization that represents the nation's 59 organ procurement organizations. He is currently Past President of AOPO, and continues to serve as a member of its Executive Committee. He is also a member of the United Network of Organ Sharing (UNOS) Board of Directors. He is recognized as a national leader in the OPO community. He can be reached at ljordon@carolinadonorservices.org or at 205 Plaza Drive, Suite D, Greenville, NC 27858. Telephone: 252-757-0708.

but these are developing technologies, rather than efforts to increase donation rates. Since our organization is committed to saving more lives by increasing donation, I will focus on efforts in this area.

there is no age restriction for organ donation

Donor Registry. Thirty-three states now have active donor registries, where a person can sign up to be an organ donor, either on line or via mail. In these states, an individual's donor information is maintained in a secure database that can only be accessed by certain healthcare professionals, including recovery coordinators. Organ, tissue and eye recovery personnel can access the registry information around-the-clock to determine if a person wanted to be a donor, enhancing their ability to ensure a person's wishes are followed. Studies are now underway to determine the effect that registries have on consent and donation rates.

Here in North Carolina, we do not yet have a donor registry, although we are working diligently to change that. State Senator Steve Metcalf (D-Buncombe) has introduced legislation (SB 852) that would allow the state's two organ procurement organizations and eyebank to access the donor records maintained by the Division of Motor Vehicles. The bill passed the Senate and is headed to the House for consideration in May 2004.

Financial incentives. Financial incentives for donation are also being considered as a possible way to encourage more deceased donors. Legislation has been introduced in Congress that would authorize the federal government to fund demonstration projects on offering incentives in return for donation. (Right now, the practice is illegal since the National Transplant Act of 1984 outlawed the sale of human organs and tissues). Different possible financial incentives are being discussed, including covering funeral expenses, providing a tax credit to the donor's estate, or a direct payment to the family. While the American Medical Association supports these studies, other groups are opposed due to the ethical dilemmas raised by any form of payment for organs.

Presumed consent. Presumed consent, or an "opt-out" system of consent, has also received a lot of attention lately as another possible solution to the donor shortage. In several European counties, including Austria, Belgium, France, Hungary, Poland, Portugal and Sweden, it is assumed that everyone is willing to be a donor, with family consent after death, unless there is written documentation otherwise. The donation rates in these counties are slightly higher than in counties with "opt-in" systems similar to our own.

An interesting study was done recently at Columbia University that seems to support the theory that a "presumed consent" system could potentially boost our nation's donation rates.[1] Three groups of people were involved in this study. The first group was told that they just moved to a new state where it was assumed they would be organ donors, but they were given the choice to confirm or change that status. Another group was told that they would not be considered donors unless they specified they wanted to be. The third group was told simply to choose whether or not they wanted to become a donor. The highest donation rate (82%) was found in the first group, among those who had to opt-out from being a donor. These findings seem to support the need for further study about the impact of presumed consent on donation rates, as well as research regarding how receptive the American public would be to such a change in our current system.

Improving hospital systems and public awareness. Ultimately, the key to increasing donation will likely be a combination of these efforts, along with a continued focus on improving systems that support donation in the hospital setting, as well as an ongoing commitment to public education and awareness activities. At CDS, we have recently begun two new programs that hold promise for the future. One, called the "Organ Donation Breakthrough Collaborative," is an effort being coordinated by the federal US Department of Health and Human Services. The other, called "A License to Give," is a new high school donation curriculum being offered to educators throughout our state.

The collaborative is intended to show that a dramatic increase in the number of lives saved through transplantation is possible. Nationwide, 105 hospitals and 46 organ procurement organizations are participating, including UNC Hospitals in Chapel Hill and Pitt County Memorial Hospital in Greenville. Multidisciplinary teams from each of these hospitals and Carolina Donor Services are working together to learn, adapt, redesign, implement, track and refine their organ donation processes to increase the donation rate to 75% over an eight-month period. If we're successful, we will be able to replicate the "best practices" established through this study in hospitals throughout the rest of the state and country.

The "License to Give" donation education kit, which was named by a ninth grade English class in Elkin, NC, was developed to assist teachers in introducing the topic of donation in a sensitive, engaging way. The free kits, which are available from Carolina Donor Services, as well as other organ/tissue/eye recovery agencies in the state, are just one way that we hope to reach today's youth and tomorrow's generations with life-saving donation information.

Conclusion

Although we have much more work before us, I am encouraged by the developments in organ/tissue donation and transplantation over the last 20 years. I look ahead with hope and optimism that someday our cumulative efforts will result in the end of the national organ transplant waiting list and thousands more lives saved each year, thanks to those who make the decision to donate.

COMMENTARY

The Gift Relationship in Process:
From Donor to Recipient

Julie Landon, RN, CPTC

The diary below is a day and a half in my life as an organ donation coordinator at Carolina Donor Services. A nurse for almost 17 years, I have been an organ donation coordinator since June 1998. I recount my experiences with a recent organ donor with the hope that it will help others understand the complex emotional and clinical processes involved with donation.

Sunday

0730: I receive a referral from a local hospital about a 22-year-old female, J., who was admitted with an intracranial hemorrhage secondary to an aneurysm.

0815: I arrive at the hospital and talk with the staff and the physician concerning the history surrounding her admission. I obtain the patient's course of treatment since admission and inquired about the family and how they are coping. The staff informs me that a Cerebral Blood Flow study has been ordered and is scheduled to be performed at 10:00 a.m.

0830-1000: I review the patient's medical chart and recorded medications, blood pressures, heart rate, lab values, any blood products and I.V. fluids given and urine output. I also record any surgical procedures preformed. Then, I call the CDS Medical Director and obtain authorization to follow this patient as a potential organ donor.

1000-1200: The brain death exam has been completed (most hospitals use both clinical and apnea tests). The clinical exam consists of testing for the absence of pupillary response; no blink response when the eye is touched (corneal reflex), no cough or gag reflex and no response to painful stimulus. The apnea test confirms absent respirations, which is a mandatory finding to support brain death. The Cerebral Blood Flow study was used as a confirmatory test for brain death.

1200-1400: With the brain death exam complete, the physician notifies her husband and parents and explains that J. has died. He answers their questions and tells them the time of her death. The physician informs the family that there is someone available to talk with them about decisions they will have to make. *Note: Legally and medically, brain death and cardiac death are the same as far as pronouncement of death.*

1400-1500: The family has informed the nurse they are ready to speak with me. I find a quiet, private room where I can talk with the family about the opportunity to donate J.'s organs. I answer their questions, which include the steps in the recovery procedure, how long it will take, and whether they can still have an open casket funeral for her. After answering their questions, the family agrees to donation. J.'s husband, her parents, and her husband's parents are there for the conversation. I spend time talking with the family about J. They share with me that she had just been married for one year, that she has a deep religious commitment and that she was always helping other people. J.'s family also shares that she loved the outdoors. While talking with her family, I found it very interesting that they had had a conversation and knew that her wishes were to be an organ donor. The family completed the consent form that would allow for the donation of J.'s heart, lungs, liver, pancreas and kidneys. The family chose not to consent to tissue (e.g. bone, skin) and eye/cornea donation.

1500-1600: Family and friends gather at J.'s bedside to say their goodbyes.

1600-1800: I call the Medical Examiner to see if there will be any restrictions for donation. Depending on the cause of death, the M.E. can restrict certain or all organs for donation if s/he feels it will interfere with an investigation of the circumstances behind the death. In this case, no restrictions have been set, so the donation can move forward. I send blood for serologies, tissue typing (used for placing the kidneys and the pancreas), and values on patient's current organ function. I also begin initiation of standard orders to maintain the patient's organ functions.

1800-2200: I evaluate lab results and make adjustments to I.V. fluids and the ventilator to optimize organ function. Then I call the United Network for Organ Sharing (UNOS) and give them the information on the patient including the patient's height, weight, blood group, age, sex and race. UNOS has all the potential organ recipients listed for the entire country. They will then run a list of recipients that are the same blood group as the patient and close to her height and weight. They will be listed in priority order according to UNOS allocation policies, which vary by organ, with emphasis on placement with local recipients. All of the consults for cardiac and pulmonary function are completed. Next, I start placing organs according to the UNOS list.

Julie Landon, RN, CPTC, is an Organ Donation Coordinator for Carolina Donor Services. She can be reached at 1551 Westbrook Plaza Dr., Suite 200, Winston-Salem, NC 27103. Telephone: 336-774-4450.

2200-2400: The serology and tissue typing results are reported. With these results, I place all the organs for transplantation during this time except the heart because of J.'s size; she was not a match for recipients at our local transplant centers.

Monday

2400-0200: I place both kidneys with UNOS for perfect matches (a perfect match is based on specific DNA tissue typing). The lungs, liver, and the pancreas are placed for recipients listed in North Carolina. I continue to try to place the heart. I call the operating room (OR) to inform them that we would like to go to the operating room around 0400 depending on who would accept the heart and how far they would be coming to recover. *Note: The coordinator is responsible for arranging pick-up and transport of the arriving recovery/transplant teams.*

0200-0300: I place the heart with a hospital in New York. The recipient is a 50-year-old male who was farther down on the list for transplant, but whose size most closely matches the donor's. I would imagine he is very excited. The heart team states that they can arrange a flight and will land at the airport at approximately 0400. I call the OR and arrange for a room for 0400. I call a local ambulance service to be waiting at the airport for the heart team from New York to land and bring them to the hospital. Then I call one of our CDS preservation coordinators responsible for flushing the organs during the case with the time he will need to be at the hospital.

0300-0500: UNOS calls me back to say the kidneys are accepted for two patients in New York pending the anatomy. I continue with donor management, making changes in I.V. fluids to make sure the organs continue to function optimally. I also find time to work on my paperwork and make copies of the chart, which include an official declaration of time of death, copy of the consent form for donation, and blood type information.

0400-0500: The local transplant teams arrive. We take the patient to the operating room. The heart transplant team from New York arrives. Everyone in the operating room introduces himself or herself to each other.

0425-1030: An incision is made from the top of the sternum to 2-3 inches below the umbilicus. The thoracic surgeons work in the chest cavity and visualize the heart and lungs. This takes 20-30 minutes, after which they will leave the operating room to find a place to rest. The abdominal surgeon will take from 2-3 hours to reach the point of being prepared to recover the organs. If the pancreas is being recovered, it will add 1-2 hrs to the surgical process. Once the abdominal surgeon is ready, the thoracic surgeons will return to the table. The coordinator will then ask the anesthesiologist to draw 120-200cc's of blood from the patient, which will be used by the transplant centers to test with their recipient's blood to make sure there will be no adverse reactions. After the blood is drawn, 30,000 to 40,000 units of heparin are given to thin the blood. Next, cannulas are inserted in the aorta above the heart, the pulmonary arteries, the descending aorta below the kidneys and the portal vein below the liver. These cannulas are then connected to cold bags of preservative solution called "UW." The circulation is then clamped off just above the heart and below the kidneys. The flush solution is then started so that all the organs that are to be transplanted are cleared of blood and replaced with the cold preservative. Once the flush is complete which takes 15-30 minutes the heart is then removed. The heart takes approximately 5-10 minutes to remove from the body. The heart should be transplanted within 4 hours after being recovered or there may be irreversible cell and organ damage, which is why most out-of-state heart recovery teams will use jet service to reach their destinations.

The lungs are removed next, which again takes 5-10 minutes. Lungs can remain out of the body for approximately 4-6 hours before possible organ damage develops. The thoracic teams will then place the organs in sterile bags surrounded by sterile ice and "UW."

The abdominal surgeon will take another 2-3 hours to recover the liver, pancreas and kidneys. These organs will also be placed in sterile bags, solution and ice. The surgical teams will take the recovered organs back with them to be transplanted. The kidneys that were accepted by New York will have transportation arranged by UNOS. Usually kidneys are transported by commercial airlines. The kidney can remain on ice for 24 hours before there is concern of damage to organ function. The liver should be transplanted within 8-12 hours and the pancreas within 12-16 hours.

1030-1100: The incision is sutured closed; the body is cleaned then taken to the hospital morgue. I call the family to tell them how the recovery went, since that is what they wanted. I also notify the nursing supervisor that the organ recovery is complete. Organ donation will not affect the family's decision to have an open casket or other funeral arrangements. *Note: If the family had consented to eye and tissue donation, this recovery would occur after the organ donation is complete. Tissue donation usually takes from 2-4 hours and eye donation typically takes 30-45 minutes. If the family is going to have an open casket funeral, some types of bone will not be removed. Eye donation does not affect having an open casket funeral. If the patient is a Medical Examiner's case, the M.E. will view the body after all recovery is complete and they will then release the body to the funeral home.*

1130-1230: I thank the hospital staff in the OR and on the inpatient unit for their cooperation, answer their questions, and gather my belongings.

1300: I go to the office to complete paperwork. After the paperwork is completed, I go home to get some sleep.

2-3 weeks after donation: I write a letter to the family informing them of what organs were recovered and transplanted, giving them some general (non-identifying) information about the organ recipients (e.g. their families, work, hobbies) and how well they are doing. With this donor, the heart, lungs, liver, pancreas, and kidneys were transplanted and are functioning well. Hopefully, this information will provide the family with some comfort in their time of grief.

Carolina Donor Services will remain in contact with the donor family for two years or longer, if the family wants to continue a relationship with us. Carolina Donor Services' Life Anew Program invites families to annual Services of Remembrance to honor their loved ones who were donors. The Life Anew Program also facilitates correspondence—and sometimes even face-to-face meetings if both sides request it—between donor families and recipients.

COMMENTARY

The Rapid Development of Solid Organ Transplantation in North Carolina

Michael R. Mill, MD

The first successful solid organ transplant between two individuals occurred in Boston in 1954 involving a living-related kidney transplant between twin brothers. The ensuing three decades were filled with dramatic stories of basic science and clinical research resulting in the successful performance of transplants, mostly with cadaver (brain dead) donors, involving the liver, pancreas, heart, heart-lung, and finally isolated lungs. Despite these successes, the overall survivals were largely measured in months and the procedures were only available in a select few transplant facilities. Clinical transplantation did not become a reliable therapy until the work to develop effective immunosuppressant medications resulted in the release of Cyclosporine in 1982. Thereafter, an explosion of activity occurred, with transplant centers opening at many major academic medical centers across the country. The clinical results achieved led transplantation to become standard therapy for end-organ disease of the organs noted above. At the present time, there are 260 transplant centers in the United States, which encompass a total of 835 individual transplant programs (Table 1).

Table 1.
Transplant Programs by Organ in the United States
Medical Centers with Transplant Programs – 260

Organ	Number of Programs
Kidney	245
Liver	122
Pancreas	169
Heart	141
Heart-Lung	82
Lung	76
Total	**835**

Source: Modified from UNOS Data (www.unos.org).

Transplantation in North Carolina

North Carolina followed the national trend with the development of transplantation programs at each of the academic medical centers. Duke University and the University of North Carolina at Chapel Hill led the way, establishing programs in all transplantable organs. Subsequently programs in selected solid organs have been developed at East Carolina University (kidney), Wake Forest University School of Medicine (kidney, pancreas, heart) and the Carolinas Medical Center in Charlotte (kidney, heart, liver and pancreas).

At the University of North Carolina School of Medicine-UNC Hospitals, solid organ transplantation began with kidney transplantation in 1968. The heart transplantation program was founded in 1986, and was followed in rapid succession by lung transplantation in 1990, heart-lung transplantation in 1991, liver transplantation in 1991 and pancreas transplantation in 1994. In addition, UNC has further developed the expertise to perform pediatric transplantation in each of the individual organ programs (Table 2).

The Effect of Transplantation on Medical Education

The rapid development of these programs has led to dramatic changes in the training of medical students, residents, and subspecialty fellows. Medical students now learn the basics of transplantation immunology

Table 2.
Numbers of Procedures by Transplant Programs at UNC Hospitals, 1968 – present.

Michael R. Mill, MD, is Professor and Chief in the Division of Cardiothoracic Surgery and Director of the Cardiac Transplant Program at the UNC School of Medicine. He can be reached at mrm@med.unc.edu or at The School of Medicine, Campus Box 7065, University of North Carolina, Chapel Hill, NC 27599-7065. Telephone: 919-966-3381.

during their basic science years and are exposed to clinical transplantation during their clerkships. Residency training programs in internal medicine, pediatrics and general surgery, at least at academic centers with transplant programs, now include education and experience with transplantation. In internal medicine and pediatrics, residents (and attending physicians) must learn to care for patients with end-stage organ disease, including when to refer patients for transplantation, and the basic care of these patients post-transplantation when they present with transplant complications (infections, renal failure, and malignancies), in addition to standard health maintenance for the common side-effects of the medications, including hypertension, hypercholesterolemia and diabetes mellitus. General surgery residencies at academic medical centers often include separate clinical services for abdominal transplantation through which the residents rotate.

At UNC-CH, Abdominal Transplantation is now a separate Division within the Department of Surgery with a separate clinical service, a full complement of residents assigned to the service, a transplant fellow, and four attending surgeons, all of whom have completed Abdominal Transplantation Fellowships. General surgery residents gain experience in thoracic transplantation when they rotate on the cardiothoracic surgery service. Our cardiothoracic surgery residents assume responsibility for the heart, heart-lung and lung transplant patients as part of their routine duties. Our faculty at UNC includes three cardiothoracic surgeons who have completed Thoracic Transplantation Fellowships.

Many of the common fellowships now must include experience in transplantation. Adult and pediatric cardiology, gastroenterology, nephrology, infectious diseases, oncology and many other fellowship training programs must now educate their fellows in the care of their specialty-related transplants. In addition, there are now subspecialty fellowship programs specifically in heart failure and cardiac transplantation, hepatology and liver transplantation, and renal transplantation. In surgical training, fellowships have been established in abdominal transplantation, covering liver, kidney, pancreas and most recently intestinal transplantation, and in thoracic transplantation covering heart, heart-lung and lung transplantation. Indeed, medical societies have been founded which focus specifically on transplant medicine. The most prominent are the American Society of Transplant Physicians, the American Society of Transplant Surgeons and the International Society of Heart and Lung Transplantation. In all, an entire new body of knowledge has been added to medical education, largely within the past decade.

Just as medical schools and post-graduate training programs have had to assimilate this new body of knowledge, hospitals have had to evolve as well. All major transplant hospitals must have the appropriate staff and laboratories, as well as the availability of operating rooms, anesthesiologists and trained operating room personnel to perform the transplants and care for the patients afterward. The individual transplant programs are required by Medicare and many insurance programs to ensure thorough evaluation of potential candidates in order to select patients who will be most likely to benefit from the scarce resource of donor organs and the expensive and complex therapy inherent in transplantation. These teams consist of social workers, psychologists, psychiatrists, nutritionists, physical therapists, financial counselors and transplant coordinators, in addition to the physicians and fellows involved in the program. The ability to perform routine laboratory examinations in addition to assays to measure levels of immunosuppressant medications, to perform microbiology cultures to rule out or identify infections and pathology services to interpret biopsy specimens to identify or rule out rejection, is mandatory. And of course, facilities and personnel must be available to perform the transplant procedures at any time, day or (usually) night. The nurses in the intensive care units and wards must develop the expertise to care for these patients. Many hospitals have developed separate transplant units to centralize and improve care for transplant recipients. In addition to academic medical centers, some larger private hospitals across the country, have developed transplantation programs. Overall, it is a huge investment in resources for hospitals to participate in solid organ transplantation.

Transplantation and the Non-Academic Community

In addition to the tremendous investment by physicians and hospitals to develop transplant programs, physicians all across the state and nation have had to learn about transplantation to care for the ever increasing proportion of their patients who need or have undergone transplant procedures. Like their counterparts in the academic medical centers, they have had to learn when to appropriately refer patients, and perhaps more importantly how to care for their patients' routine and potentially catastrophic post-transplant medical problems, including when to refer the patients back to the transplant center. Graduate medical education programs have helped disseminate this information, though perhaps the greatest source of information comes from the transplant centers, and more specifically the transplant coordinators. These highly trained and skilled individuals, usually nurses, nurse practitioners or physician assistants, are the patient's and their local physicians' lifeline for both routine care and emergency intervention. Our coordinators, as well as those at all centers, work very hard to be effective liaisons between the transplant center and the patients, their local physicians, hospitals and pharmacies. In reality, the entire process could not function without these dedicated individuals.

Conclusion

In the past two decades, solid organ transplantation has progressed from futuristic science fiction to life-saving procedures performed hundreds of times every day throughout the United States (over 23,000 transplants were performed in 2002). North Carolina has assumed its appropriate place in this scientific activity, providing its citizens and others from throughout the country, with these services. This activity has changed the practice and education of physicians, nurses and other medical personnel, and greatly impacted the hospital services both in the community and the academic medical centers. Given the successes of transplantation, as well as new advances in immunosuppression, potential new sources of donors (non-heart beating human donors and genetically altered animals for xenotransplantation), and other new therapies for end-stage disease (artificial livers and mechanical assist devices for heart failure), one can predict that 20 years from now, we will have even more sophisticated treatments that will have far reaching effects on medical practice and education, advances likely to eclipse even those of the past two decades.

Table 3.
Transplants by Donor Type and Center in NC Transplants Performed: January 1, 1988 - October 31, 2003

COMMENTARY

Building a Modern Transplant Center

J. Elizabeth Tuttle-Newhall, MD

Organ transplantation is currently the standard therapy for end-organ failure in those patients medically suitable for transplant. At present, there are over 80,000 patients listed for transplantation in the United States.[1] The United States organ transplant waiting list grows on average 16-20% per year. In the past 10 years, the number of registrants has increased from 23,901 to over 80,000. In contrast, the number of deceased organ donors available has increased from 4,526 in 1991 to 5,985 in 2001.[2] Overall mortality for all patients on the waiting list is 7.5% and continues to grow yearly.[1] The number of transplants performed in the United States has also increased from 12,626 in 1988 to over 22,000 in 2000.[2]

Currently, there are over 300 transplant centers in the United States. While the majority of transplant centers are in academic tertiary care facilities, there are several very successful programs in the private arena. In North Carolina there are three multi-abdominal transplant centers (liver, kidney and pancreas transplants) including Duke University Medical Center, Carolinas Medical Center in Charlotte and UNC Hospitals in Chapel Hill. Both Wake Forest University Baptist Medical Center and Pitt County Memorial Hospital with University Health Systems of Eastern Carolina have abdominal transplant programs that perform pancreas and kidney transplants.

The establishment and maintenance of abdominal transplant programs requires enormous planning and resources. Extensive negotiations must take place to ensure institutional and/or departmental commitments prior to initiation of any program. The recruitment and retention of an expert multidisciplinary team of physicians and nurses follows subsequently. Strategic planning is required to adequately deploy resources, lobby referring physicians, and recruit patients in order to achieve success.[3]

Infrastructural Support Requirements

Institutional support is paramount to the establishment and maintenance of a successful transplant program. Fiscal investment is required to establish adequate programmatic infrastructure. Infrastructure is required to not only meet regulatory requirements, but also provides the backbone for provision of excellent clinical care for complex patients. Programmatic infrastructure is required to manage the requirements of data collection and organization that is mandated by the United Network of Organ Sharing (UNOS). Information systems are necessary to capture and organize patient information that is analyzed to determine patient outcome, graft survival and programmatic performance. Required UNOS data are also used regionally and nationally to assess performance of UNOS allocation policies to ensure the best patient outcomes and effective utilization of limited resources. Individual programmatic data should be available to assess programmatic performance, not only in terms of clinical outcomes, but in the financial aspects of all phases of transplant as well. Support staff must include not only database managers but also patient contact personnel. Clinical systems must be available to assist in efficient patient access and easy physician referrals. These clinical systems must also facilitate patient throughput once the patient is in the system at the specific transplant center.

Institutional support is paramount to the establishment and maintenance of a successful transplant program.

Institutions must invest in space and equipment for care of the complex organ failure patient in all of the phases of transplant (pre-operative, peri-operative and post-operative). Clinic space and adequate time in that space must be available for the medical and surgical specialist to see the volume of pre-operative patients necessary to establish a program and assist in the multi-disciplinary management of the post-operative patients. Operating room equipment must be available, and personnel

---

J. Elizabeth “Betsy” Tuttle-Newhall, MD, is the Director of Liver Transpant and Assistant Professor of Surgery at Duke University Medical Center. She can be reached at tuttl006@mc.duke.edu or DUMC Box 2910, 10A Bell Building, Duke University Medical Center, Durham, North Carolina 27710. Telephone: 919-684-5923.

must be trained. Call teams should be established for specialized transplant procedures that require a specific level of nursing expertise. Intensive care unit resources must also be available with appropriately trained staff to care for the post-operative and often critically ill transplant recipient. Investment in the clinical enterprise required to support a transplant program can only occur at the institutional level. The incentives for the institution are not only fulfillment of the academic center's mission to provide tertiary levels of care, but also financial gain if the program can achieve a profitable clinical volume.

Personnel Requirements

Personnel recruitment and retention are of foremost importance to achieving success in any transplant program. Medical, surgical and nursing expertise in transplant are required. For example, a kidney transplant program requires a transplant nephrologist, a transplant surgeon, and several nurse coordinators who have specific interest and expertise in the work-up and management of kidney transplant patients. A kidney transplant program also requires a histocompatibility lab, a lab director and lab personnel to support the transplant program. Social work, medical psychology, financial support staff must all be available to assist those patients who may require evaluation prior to transplant and support during all phases of the transplant process. All of these individuals maintain a pivotal role in the daily management of their particular program. Likewise, liver transplant programs require a transplant hepatologist, a specialized anesthesiologist, critical care specialists, transplant infectious disease specialists, radiologists with experience in transplantation, pathologists and nursing personnel that are familiar with care of the transplant patient. If the transplant center is associated with a medical school and academic center, lab support and time must be made available to the involved physicians who have an interest in research and/or clinical teaching in order to support the academic and educational missions of their individual institutions. Transplantation requires the development of a multi-disciplinary team of experts who are dedicated to providing excellent clinical care for those patients with organ failure.

Relationships with Recipient's Referring Physicians

Finally, in order to assure the success of any program, involvement and recruitment of referring physicians and their patients must occur. While transplant patients are specialized in many aspects of their care, their primary and referring physicians are still involved during all phases of transplant. Resources must be available and deployed to ensure adequate communication between the transplant center and the referring physicians in order to ensure the best possible patient care. Ease of communication and exchange of up-to-date information between physicians ensure excellent patient care and patient outcomes. Access for the patients to the transplant centers must be simple and timely in order to expedite work-up and as is of the patient. If the patient is not a candidate for transplant, an alternative care plan can be quickly developed.

In summary, development of a transplant program requires fiscal investment, recruitment and retention of personnel with clinical expertise and the ability to assess and evaluate resources and their outcomes to deliver the best possible quality of care to those patients most in need.

COMMENTARY

Some of the Challenges of Encouraging Organ Donation Among Minority Populations

Lynt B. Johnson, MD, FACS

Organ donation and organ allocation remain important issues for patients awaiting transplantation in the United States. The disparity between the number of deceased donors and the number of patients awaiting transplantation continues to widen each year. The number of deceased donors in the United States has remained stagnant at approximately 5,000 donors per year, while the waiting list for organs in 2004 exceeds 80,000 individuals. Each day in the United States 15 patients die while awaiting life-saving transplants. The method of allocation of these precious gifts is of importance to all patients, but is of particular importance to minorities. Although minorities are represented in all end-stage organ diseases, end-stage renal disease has by far the greatest impact on minorities. Diseases such as hypertension and diabetes, which can lead to end-stage renal disease and the need for transplantation, disproportionately affect minorities. Several key questions should be openly discussed and debated in regard to transplantation policy and minorities. Some of these questions might be: Is there proportionate representation of minorities on organ waiting lists? Does race impact organ availability? What are the reasons that waiting time is longer for minorities awaiting kidney transplantation? How can we increase organ availability for minorities? What should be the guiding principles of organ rationing?

> *In some areas of the country, African Americans account for over 70% of the patients awaiting kidney transplantation.*

For many highly specialized procedures in the United States, racial differences in access to effective medical procedures persist. Minorities are far less represented than their majority counterparts, even when adjustments are made for economic status and education. Coronary artery bypass surgery, total knee and hip replacement, cataract surgery, screening colonoscopy and mammography are examples of such procedures where disparities exist. Access remains a critical issue.

Two significant risk factors for renal disease, hypertension and diabetes, disproportionately affect African Americans. It is estimated that more 30% of adult African Americans are hypertensive, compared to a 20% incidence in the majority population. More importantly the age of onset in African Americans is earlier, resulting in higher age-adjusted hypertension prevalence. This early onset subsequently leads to more target organ damage and greater overall mortality burden when compared with the majority white population. Although the difference is not as drastic with the incidence of diabetes, the risk of end-stage renal disease in African Americans with diabetes is three times as great as that of the majority population.

Due to the greater burden of disease, the incidence of end-stage renal disease is much higher in African Americans. Thirty-five percent of all patients awaiting kidney transplantation in the United States are African American. In some areas of the country, African Americans account for over 70% of the patients awaiting kidney transplantation. Thus, issues of organ allocation are of paramount importance to understand. Organ allocation begins with timely referral to transplant centers. In a study by Ayanian et al., they showed that despite equivalent desire for transplant, the number of patients referred for evaluation and the number of patients placed on the waiting list were significantly less for African Americans than for their majority white counterparts.[1] One recent proposal to level the playing field is for patients to be assigned waiting time from their initial diagnosis of renal dialysis and not with their referral to the transplant center. This proposal, if implemented, may allow for those patients with less access to the referral process to gain a more equitable footing. However, there remains some opposition to this proposal in the transplant community. Not only must we provide better access to transplantation, but the method of allocation has great importance

Lynt B. Johnson, MD, FACS, is Associate Professor and Vice-Chairman in the Department of Surgery and the Chief Division of Transplantation Surgery at Georgetown University Hospital in Washington, DC. Dr. Johnson can be reached at johnso13@gunet.georgetown.edu or Georgetown University, 4 PHC, 3800 Reservoir Road, NW, Washington, DC 20007. Telephone: 202-444-4557.

since the demand far outweighs the supply of deceased donor organs. For patients listed in 1997, African Americans waited an average of two-and-a-half years longer than their white counterparts on the waiting list. This disparity is most notably accounted for by the limited supply of genetically closely matched organs, and to some extent by the continued use of tissue type matching in the algorithm for kidney allocation. Traditionally it has been shown that in the prior era of immunosuppressant drugs, tissue type matching played a role in the longevity of functioning kidney transplants. As the immunosuppression drugs have improved, these differences have been lessened. Certain tissue types are much more common in the majority of white populations than in minority populations. Since the majority of deceased donors are Caucasian, this limits opportunities for closely matched organs in some instances. Over the years the preference given to tissue type matching has been reduced. The question remains: should we eliminate tissue type matching altogether and apply severity of illness and waiting time as the only factors for recipient selection in kidney transplant allocation? Previous studies have shown that the impact of elimination of tissue type matching reduces long-term kidney survival.[3] It is my belief that this difference may be mitigated by utilizing different immunosupressive strategies for African Americans than for their majority white counterparts.

Other issues of importance include increasing organ donation, especially in the minority population. The African American deceased organ donor consent rate is far less than it is in the white population. Boulware, et al. recently studied racial and gender issues relating to donation in a Baltimore community.[2] Their results suggest that mistrust of hospitals and concerns about racial discrimination in hospitals accounted for the significant differences in willingness to donate between non-Hispanic blacks and whites. Black males were particularly resistant to organ donation. White males were most likely to identify themselves as organ donors on a driver's license (65%), compared to white females (60%), black females (38%). Only 19% of black males indicated their willingness to donate. Ironically in the year 2003, in the service area of the greater metropolitan Washington, DC area, the percentages of actual deceased organ donation show great similarity to the data provided by Boulware and her colleagues. Of eligible African American families that were approached concerning organ donation the consent rate was 25%, compared to 60% for the Caucasian population.[2]

Targeted education in the minority community will likely provide greatest benefit to increasing organ donation in the minority population. Central figures of trust within minority communities can be used as advocates for dissemination of this critical information. Dissemination of information regarding the need for organ donation in the minority community will be more effective if simultaneous education about disease prevention occurs, especially in relation to hypertension and diabetes, which ravage our community. The future looks grim with almost 20% of minority group children facing obesity. More often than not, they will carry this problem into adulthood leading to a greater incidence of hypertension and diabetes. We must confront these lifestyle issues now by targeting exercise, nutrition and disease prevention in our children. These and other issues must get on the agenda in our organizations, community and political debates. We need to not only emphasize the needs of end-stage organ disease patients, but also preventive strategies for our communities.

A Minority Perspective
The State of Minority Donation in North Carolina

Debbie Mann Gibbs

Derrick Floyd will celebrate a big birthday, his 40th, in March. There will be the usual ice cream, cake and presents. What will really make the day special, however, is what will be missing. This year Derrick won't be tethered to a dialysis machine—the piece of equipment that artificially replaced his failing kidneys for three and a half years.

Thanks to the generosity of a donor family, Derrick received a kidney transplant last summer at Carolinas Medical Center in Charlotte. Hello to new-found energy, dark-colored soft drinks and time on the basketball court with son, DJ. Goodbye to shunts, loss of work and family time.

Table 1.
Organ by Ethnicity: Current NC Waiting List

	All Organs	Kidney	Liver	Pancreas	Kidney/ Pancreas	Heart	Lung	Heart/ Lung	Intestine
All Ethnicities	3,065	1,965	684	15	91	73	220	16	1
White	1,521	638	563	13	66	49	181	10	1
Black	1,445	1,261	95	2	25	22	34	6	0
Hispanic	36	24	9	0	0	1	2	0	0
Asian	35	24	10	0	0	0	1	0	0
Other	28	18	7	0	0	1	2	0	0

Derrick was lucky. His transplant came exactly six months after his mother died of the same kidney disease, focal segmental glomerulosclerosis. Like many African Americans in desperate need of a kidney transplant, the call to tell her a kidney was available did not come in time.

The Statistics are Startling

According to figures from the United Network for Organ Sharing (UNOS), the organization that maintains the nation's database of waiting-list candidates, 220 North Carolinians died in 2002 (the last full year for which statistics are available) before a compatible organ was found. Ninety-six of them were African American.

There are more than 3,000 people in North Carolina on the waiting list for an organ transplant—1,965 need a kidney transplant. The situation is critical for minorities, particularly African Americans.

As of January 14, 2004, there were 1,257 African Americans on North Carolina's kidney waiting list or 64%—a staggering figure considering 21.5% of North Carolina's population is African American.

Minorities represent over half of those on the national kidney waiting list with African Americans comprising 35% and Hispanics, 16%.

The reason for the disparity is simple. African Americans and Hispanics are four times more likely to suffer from hypertension and diabetes, both of which lead to end-stage renal disease. Despite advances in medicine and technology, demand for organs continues to far outpace supply. As a result, minorities are at higher risk for longer waiting times on transplant waiting lists and ultimately, death.

There were 220 people who died in North Carolina in 2002 as a result of the critical shortage of donors. There were 112 whites, compared to 96 African Americans and three Hispanics.

Because of the genetic matching of antigens, minorities have a better chance of receiving a kidney transplant if the donor is

Debbie Mann Gibbs is the Public Relations Manager for LifeShare Of The Carolinas, the organ procurement organization serving southwestern North Carolina. She is the Chair of the UNOS Communications Committee, on the board of the Coalition on Donation and served as vice-chair of the Coalition's Campaign Committee, which developed an African American ad campaign. She can be reached at dgibbs@carolinas.org or at LifeShare Of The Carolinas, 5000-D Airport Center Parkway, Charlotte, NC 28208. Telephone: 704-697-3303.

from the same ethnic background. The common perception that minorities do not donate is not borne out by the statistics.

National Studies Reflect State Trends

UNOS data indicate that nationwide the proportion of white donors has decreased over a 10-year period while the proportion of minority donors has increased. A study by the Association of Organ Procurement Organizations (AOPO) of death record reviews from 30 organ procurement organizations showed that when African Americans do refuse to donate, the reason is not always the result of a family saying no. In some instances, the potential donor was never referred by the hospital nor was the family ever approached.[1]

Meanwhile in North Carolina, the trend for minority donation is on the upswing. Out of 551 deceased donors in the state in 2002, 143 (or about 25%) were minorities (92 African Americans and 42 Hispanics). Meanwhile, out of 701 citizens who received various types of transplants in 2002, minorities received only 206 of them.

The *Journal of the National Medical Association* published a national study[2] in January of 2002 which showed that the gap between the number of whites and minority groups that received organ transplants actually widened during the 1990's. While the rates for all groups were similar in 1988, almost 10 years later in 1997:

- Heart transplantation rates for Caucasians were more than five times greater than for African Americans.
- Kidney transplant rates were nearly nine times higher for whites than for other ethnic groups.

No data were collected separately for North Carolina in that study. That, however, has not stopped LifeShare Of The Carolinas and Carolina Donor Services (CDS), the state's two organ procurement organizations, from developing various programs to increase donation rates among the state's minority populations.

LifeShare has formed strategic collaborations with black physicians and lawyer's groups in Charlotte to distribute information on organ and tissue donation to the African American community. The organization has also partnered with the Links, Inc., a black women's civic organization, on a two-year grass-roots project that targets black churches among other groups. CDS received a $373,000 federal grant from the Health Resources and Services Administration (HRSA) for a three-year study. The project is a campus-wide intervention to increase intent to donate among African American students at four of the state's historically black colleges and universities.

Transplants Performed: January 1, 1988 - November 30, 2003

Ad Campaigns Respond to Crisis

Both LifeShare and CDS support national advertising campaigns developed by the national Coalition on Donation. Two of the campaigns consist of a series of print, broadcast and out-of-home public service ads targeted at African American and Hispanic consumers. They have been a good investment of time and effort. To date, they have been played 2,337 times on North Carolina radio and television stations, generating over $229,000 in donated media time.

The ads are the first to be created as part of national campaigns that are based on research. Focus groups convened among the target groups in several cities across the country, including the southeast, had several similarities. African American and Hispanic participants revealed several barriers to donation including:

- Concern about the fairness of the system
- Lack of available information
- Mistrust of the medical community and fear of being declared dead prematurely

Loletha, a Charlotte transplant recipient, is featured in the African American brochure and on the Coalition's web site at www.donatelife.net. Loletha received a kidney transplant at Carolinas Medical Center in 1993. Like Derrick, she also waited over three years on the transplant waiting list. Since then, she has continued a prosperous career in banking and even more significant, given birth to a daughter, two things she wasn't sure she would ever be able to achieve.

LifeShare and CDS are active members of the North Carolina Coalition on Donation, a local affiliate of the national Coalition on Donation. The Coalition is a not-for-profit alliance of national organizations and local coalitions dedicated to inspiring all people to donate life through organ and tissue donation. Since 1992, the Coalition has developed several ad campaigns and national projects which have been implemented at the local level in North Carolina.

Derrick and his son are featured in a new general market brochure developed by the Coalition coined "Empowering Testimonials." He is one of seven transplant recipients depicted and the only African American. His profile can be found in the newest Coalition brochure.

You Can Help

How can the public help? There are several ways. Minority transplant recipients and donor family members are available to share their stories with church, school or civic groups. The presentations are free and may be arranged by contacting LifeShare at 800-932-GIVE(4483) or CDS at 800-200-2672.

North Carolina residents are encouraged to get a donor card, sign it and carry it in their wallet. More importantly, everyone is encouraged to share their wishes on organ and tissue donation with their families. In North Carolina, a driver's license is not legally binding. A signed donor card is. A donor card can be obtained by calling either of the OPO's or by downloading one from the LifeShare web site at www.lifesharecarolinas.org.

Life is full of decisions. Paper or plastic? Cash, check or charge? All it takes to save the lives of ALL patients in North Carolina who need a transplant is for more people to decide to become donors, to share their organs when they no longer need them.

To borrow a line from the Coalition's African American ad campaign, "When you do nothing, everybody loses."

Thank You Letter from Derrick to His Donor's Family

Dear Guardian Angel,

How do you begin to thank someone for giving you your life back? I am in constant thanks for your gift of life.

I would like to extend great sorrow and compassion for the loss of your family member. I know that the pain of such loss can be unbearable, as I lost my Mother of the same disease that I suffer just six months prior to receiving the kidney.

Your gift has made a tremendous change in my life and in the lives of my family. I can now do simple things without the feeling of fatigue or dizziness. I can play catch with my son and attend his football game while standing the entire time. I know that these tasks sound simple, but they were major challenges before you gave me my life back.

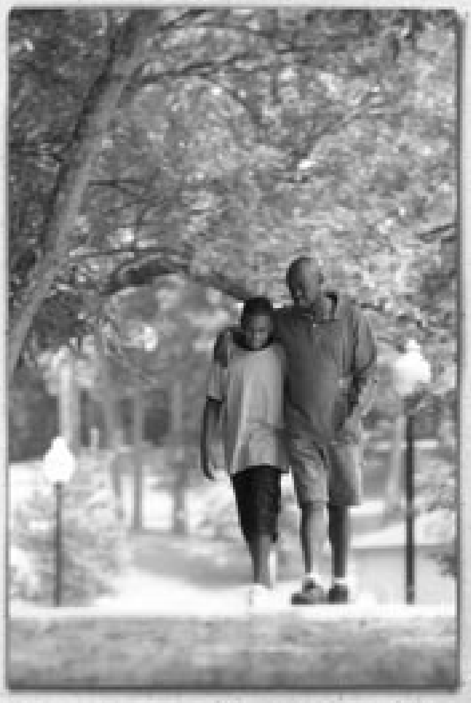
I thought you might find this poem comforting. As my mother was losing her battle to this disease, she told me that I would receive a kidney and you made it possible. I would like to share one of her favorite poems with you:

If I Knew

If I knew if would be the last time that I'd see you fall asleep, I would tuck you in more tightly and pray the Lord, your soul to keep. If I knew it would be the last time I would see you walk out the door, I would give you a hug and a kiss and call you back for one more. If I knew it would be the last time I'd hear your voice lifted up in praise, I would video tape each action and word so I could play it back, day after day. If I knew it would be the last time I could spare an extra minute to stop and say, "I love you" instead of assuming you would KNOW I do. Take time to say "I'm sorry," "Please forgive me, "Thank You" or "It's okay,'" And if tomorrow never comes, you'll have no regrets about today.

I hope that you find some comfort in those words. I thank God for you and your family daily and we as a family will continue to pray for you. By the way, my family and I would love to meet you.

May God Bless You and Keep You.



COMMENTARY

“What’s in your wallet?”

Will Your Intentions Be Known?

Betsy J. Walsh, JD, MPH, and Judy Jones Tisdale, PhD

Think that little heart on your NC driver’s license makes you an organ donor? Think again! In North Carolina, only a valid donor card is recognized as a legal document for organ donation. The intent on a driver’s license is not enough. This often comes as news to both medical professionals and laypersons alike. “But I already am an organ donor,” most say as they whip out their driver’s license. As the number of organs available continues to fall behind the number of North Carolinians in need, we must dispel this misconception.

The American Medical Association (AMA) encourages healthcare professionals to promote organ donation awareness. In fact, in 1998, the AMA started the “Live and Then Give” program to educate physicians about this issue and to encourage them to promote donor awareness in their communities.[1] While physicians are uniquely positioned to talk with patients about donation, they are not the only ones who can make an impact on the increasing shortage of needed organs. Whether you are a healthcare professional or an interested layperson, you can help—share this message with family, friends, clients, patients, and colleagues.

Guarantee Your Right to Be an Organ Donor

To guarantee your wishes about organ donation are honored, do the following:

1. **Carry a signed, witnessed donor card.** You can print one off the Internet at Carolina Donor Services (www.carolinadonorservices.org), LifeShare Of The Carolinas (www.lifesharecarolinas.org), or the Coalition on Donation (www.donatelife.net/become.asp). The AMA also has a downloadable card on its web site (www.ama-assn.org) on the Organ and Tissue Donation page. Sign the card in front of two individuals (not related to you) so that they can serve as witnesses. You can even specify on the card, if you choose, which organ(s) you want to donate. This card is THE legal document in North Carolina to indicate your desire to be a donor.
2. **Tell your family members.** Let your family know that you want to be a donor so that they do not have to make that decision for you. They will have enough decisions to make if you are ever in a position to donate; make this one for them. Healthcare providers are, understandably, hesitant to act against the wishes of family members in these situations, so ensure your family knows what you want. The decision to donate at the time of death can be heart-breaking if family members do not know their loved one’s wishes about donation. Make a decision about this issue well before this point and share your choice with family members.
3. **Show your decision on your driver’s license.** When renewing your license, say “yes” to the organ donation question. Although the license is not a binding legal document for donation purposes, it does indicate your intent and encourage healthcare providers to begin the dialogue with your family.

Healthcare Professionals Should Give Patients and the Public the Facts to Make an Informed Choice

Did you know before reading this commentary that the NC driver’s license is not a legally binding document for donation purposes? If not, that is a good place to start the conversation with patients and the public alike. If you did know this fact, you will be surprised at how many people do not know-and many of them are people who want to be donors.

The AMA publishes “Organ Donation Tips for Patient Education” to guide healthcare professionals in this important education effort.[2] One suggestion, for example, is that physicians choose a non-crisis office visit, such as a check-up, to initiate a conversation about donation. And if staff members talk with patients, they should be clear that they are discussing this topic with all patients at the physician’s request. Of course, if patients

Betsy J. Walsh, JD, MPH, is Vice President and Deputy General Counsel at Novant Health, Inc.

Judy Jones Tisdale, PhD, is an adjunct associate professor at UNC’s Kenan-Flagler Business School. Professor Tisdale also is a kidney recipient and serves as an at-large representative on the UNOS/OPTN Board of Directors. She is the project director for “Life Takes Guts,” an annual organ donor awareness event at UNC-Chapel Hill sponsored by UNC Kenan-Flagler Business School, the UNC APPLES Service-Learning Program, and Carolina Donor Services. She can be reached at Judy_Tisdale@unc.edu or at the Kenan-Flagler Business School, CB # 3490, University of North Carolina, Chapel Hill, NC 27599- 3490. Telephone: 919-962-4355.

are not receptive to talking about donation, physicians and staff should not pursue the topic. Organ donation is a "gift of life," and individuals should decide what is right for them. However, more than likely, patients will have questions. Share your knowledge as a healthcare professional to help them make an informed decision about being a donor.

For other healthcare professionals and laypeople, there are plenty of additional resources to help you get involved in raising organ donation awareness. The Coalition on Donation provides several easy-to-implement suggestions to promote donation education (www.donatelife.net/promote.html). This site offers a downloadable web banner, an e-card to send to friends and family, and a presentation kit. The United Network for Organ Sharing (UNOS) offers ideas on its web site for individuals to promote donation in their local areas, as well as a reminder about the Workplace Partnership for Life initiative sponsored by the US Department of Health and Human Services. This campaign encourages US businesses to share information about organ donation in the workplace and encourages workers to sign up as donors. To learn more, simply go to the UNOS web site (www.unos.org) and click on the "Help Save a Life" link. Carolina Donor Services provides helpful information for teachers, clergy, minority interests, and employers; click on the "Special Interests" link on the home page (www.carolinadonorservices.org). And LifeShare Of The Carolinas invites interested people to contact them for speakers and to learn more about the Workplace Initiative. Additionally LifeShare has a web page dedicated to educating children about donation issues (www.lifesharecarolinas.org/kids/index.html).

Answering Patient's Common Questions About Organ Donation

Here are the most common questions or concerns that you will be asked about organ donation-and facts you can use in responding:[3]

- "I'm afraid that the doctors may not try hard enough to save me if they think my organs will fit someone who needs them." FACT—healthcare providers will do whatever is necessary to try to save lives. Individuals are eligible to be donors only after they have been declared brain dead.
- "I might want an open casket funeral." FACT—individuals can still have an open casket funeral if they choose to donate organs. Donating does not affect how an individual looks in an open casket.
- "How much money will it cost my family?" FACT—the answer is $0. Once a decision is made to donate, the deceased's family bears no financial costs from that point forward.
- "What if they take my organs before I'm dead?" FACT—before being eligible for donation, several tests must be made to determine if an individual is brain dead. Only once someone is declared brain dead can that person be eligible to be a donor.
- "I don't think my religion approves." FACT—most religions either support donation or make no statement, instead supporting individual choice. Want to look up a particular religion's stance on donation? Check out Carolina Donor Services' web page (www.carolinadonorservices.org), click on "Get the Facts," and then on "Religious Views."
- "What about family members in other states?" FACT—states have different laws governing donation. Visit the Coalition on Donation web site (www.donatelife.net/) to learn more about each state's laws.

After you answer such questions and provide facts, some people may elect to sign a donor card; some may want to review printed material before making a decision, and some may decide against being a donor.[4] Even if individuals elect not to be an organ donor, you have at least provided them with information to make an informed choice.

Call to Action

At the end of November 2003, 2,976 North Carolinians were on waiting lists hoping for a call to a better life. Healthcare professionals and laypeople alike can save lives. Offer family, friends, colleagues, clients, and patients the same chance by asking them "What's in your wallet?"

The opinions in this commentary are those of the authors as individuals and not as representatives of any employer or organization.

SPECIAL ARTICLE

Giving and Receiving When Vital Organs Fail

Donald L. Madison, MD (with Andrew, Jim and Susan Pike)

Andrew Pike is 25 years old. He lives in Chapel Hill. Seventeen years ago, when he was eight, Andrew received a heart transplant. He received a kidney transplant on June 24, 2003. The donor of the heart was an unknown child. Andrew's father, Jim, donated the kidney.

Seventeen years is a long time for a heart recipient to remain free of life threatening complications (although kidney failure was in fact a complication of one of the immunosuppressive drugs that was administered following the heart transplant). Andrew Pike is not yet setting the bar, but he is approaching it. The longest survival for a first heart transplant in a child that Dr. Michael Mill (who heads the heart and lung transplant team at UNC Hospitals) knows of is 25 years.

Andrew's mother, Susan Pike, had been the donor of choice for his new kidney, but she failed to pass muster during the workup.

SUSAN: My kidney was fine, but the blood vessels weren't. Instead of being straight and having regular thickness of the walls, mine were curved and had overgrowth of some kind. So the doctor did not want those blood vessels because you must take part of the vessels along with the kidney to transplant. And they thought that it was not going to be good for me to have only one kidney.

JIM: They had a name for that condition.

SUSAN: Dysplasia. Some kind of dysplasia. It's nice that we've forgotten.

DLM: Dysplasia means shaped wrongly.

SUSAN: That's me alright.

DLM: Actually, it means that something developed wrong. That's pretty common in and around the kidney.

Jim and Susan have another son, Ben, who is six years older than Andrew. Ben lives near Chicago and might also have qualified as a donor except for his high blood pressure. But beyond that physical disqualifier was another, social one: Ben is the recent father of triplets.

When Andrew was born, on the second day of 1979, the Pikes were living in Wilmette, Illinois, a suburb just north of Chicago, not far from the lake.

ANDREW: I was born between two of the worst blizzards. I've only heard stories about it. I guess it was the day after I was born that they noticed that I had transposition of the great vessels.

DLM: I imagine that it doesn't take long to notice.

Susan, Jim and Andrew Pike

ANDREW: I think it was my dad who looked in on me when I was lying in the isolette, and he noticed that I was breathing twice as fast as the other babies. And I was turning blue. After that the cardiologists came in to figure out what was what. I'm a little fuzzy on all the details. But between then and my ninth birthday I had, I think, five open heart operations, with physical therapy, I suppose, after each one, and probably hundreds of tests and procedures. And when I was eight years old I had my heart transplant. I was in the

Note: For help with this article I wish to thank the Pike family, Erika Rager, MD, Michael Mill, MD, Romulo Colindres, MD, and Jonathan Oberlander, PhD.

Donald Madison, MD, is Professor of Social Medicine in the UNC School of Medicine and Contributing Editor for the North Carolina Medical Journal. He can be reached at donmad@med.unc.edu or at the Department of Social Medicine, UNC School of Medicine, CB# 7240, Chapel Hill, NC 27500-7240. Telephone: 919-962-1140.

hospital for seven weeks. Finally, I think it was on Christmas Eve, I was released from the hospital.

It was a struggle to get used to everything after that. I had to relearn a lot of things, because I had a stroke during the procedure.

DLM: While you were on the operating table?

ANDREW: I think that's the way it happened. And after that the right side of my body was pretty much paralyzed for a while. I had to relearn how to use my right hand, which still has a lot of weakness—a lot of physical therapy after that, speech therapy, too. But it was also a time to celebrate even while I was going through so much hardship. I would have to make sure I wasn't around people with germs, because after an organ transplant—any organ transplant—you have to take anti-rejection medicine, and a side effect of that is that you are immune-suppressed. Well, actually, that's not a side effect; it's the main purpose of it.

It was difficult for me, being at such a young age, to understand why this was all happening to me. I would see my friends, who would be leading normal lives, going to school, playing outside and all that, and they didn't have to deal with any of this. That was probably the most challenging part for me—not having the slightest idea why this should happen to me and not somebody else. I've been on medication since, I guess, day one. My nickname when I was in the hospital used to be Human Pin Cushion, because I had to get so many shots. By now I'd guess it's probably been 2,000 or so. I'm used to it. After the transplant I had to have heart biopsies done, I guess twice a week to start out with, and then every week, and then every other week and so on. Now it's every couple of years.

DLM: What are they looking for?

ANDREW: A biopsy is the surest way to check to see whether or not I'm experiencing rejection. They take a catheter, which is really a long, thin wire, and insert it into a vein, thread it up to my heart, and take a sample of tissue and then look at it under a microscope to determine if there is rejection. That was probably the most difficult thing for me as a kid in terms of dealing with pain. I would wake up sometimes maybe 10 or 15 minutes before the whole thing was over, and they would have to hold gauze with pressure against the site. I remember that as the most painful thing.

DLM: And there has been no sign of rejection?

ANDREW: So far, no. Most people experience rejection or coronary artery disease after about 10 years. To go this long without experiencing either of those is—not unheard of, but it's unusual.

Jim and Susan Pike met in Madison, Wisconsin. Susan was a graduate student in Spanish at the University of Wisconsin; and she attended the church where Jim came as Associate Pastor following his graduation from divinity school at Colgate Rochester (in Rochester, New York) and his ordination in the American Baptist clergy.

Susan's roots are in North Carolina and Tennessee. She was born in Elizabeth City and attended school in Lexington and Raleigh before moving to Nashville, where she finished high school and attended college at Vanderbilt. Her father was a Southern Baptist minister who became editor of a Sunday School periodical and other church literature for young people.

Jim grew up in Terre Haute, Indiana. After high school he attended his hometown college, Indiana State. Both of his parents were high school teachers: his mother taught Latin, and his father was a football and basketball coach whose most illustrious pupil—probably—was the Terre Haute Terror, future inductee into the Basketball Hall of Fame, future teammate of both Dean Smith and Bill Russell and, eventually, the most physically imposing one-term sheriff in the history of Vigo County, Indiana. (I think I impressed Jim by knowing that Clyde Lovellette was from Terre Haute.)

After graduate school, Susan taught for five years. She and Jim married and moved to Chicago, where he became Pastor of the Community Church of Wilmette. They lived in Wilmette for 22 years and during that time raised their two boys.

Eight years ago the family came to North Carolina when Jim accepted a call to become Pastor of the Olin T. Binkley Memorial Baptist Church in Chapel Hill.

On the day after he was born Andrew underwent his first heart operation. His congenital malformation included transposition of the great arteries (the aorta emerged from the wrong ventricle and so did the pulmonary artery) with stenosis of the pulmonary valve, along with a faulty tricuspid valve, and a defect of the septum between the two atria (a hole in the wall that separates them) and also of the septum between the two ventricles. Transposition of the great arteries means that the stronger left ventricle is pumping blood into the lungs (instead of out into the body) and that this oxygenated blood when it returns from the lungs comes back to the same side of the heart, only to be pumped through the lungs again and again. At the same time, the right side of the heart is pumping blood out into the body, and this blood returns to the right side of the heart, bypassing the lungs altogether. The entire circulation looks like a figure 8, except that the two loops of the 8 don't connect. One loop has oxygenated blood; the other one doesn't. The only way that any oxygenated blood from the lungs can reach the rest of the body is through the defect: The small hole in the septum between the two atria allows mixing of oxygenated blood from the left heart with deoxygenated blood from the right heart. This mixing allows *some* oxygen—though not enough—to reach the rest of the body. But the greater amount of blood that is being forced into the lungs by the stronger left ventricle causes pulmonary hypertension; and the extra work placed on the weaker right ventricle (which now has to pump against the much greater resistance put up by the circulatory system of the entire body) causes heart failure. So if the defect (hole) between the atria can be enlarged by performing a balloon septostomy, which was Andrew's first operation, more of the blood can be mixed and therefore oxygenated, and the heart failure can be slowed, temporarily.

The balloon septostomy didn't require opening Andrew's chest, but later operations did. When he was 18 months old, he underwent a Mustard Procedure. During this operation (no longer performed in the U.S.) the surgeons actually used the pericardium (the sack that surrounds the heart) to construct a baffle inside the atrium that then forced more of the oxygenated blood returning from the lungs to pass down into the right ventricle, which in transposition of the great arteries is the pumping ventricle for the aorta and the rest of the body. At the same time the surgeons also repaired Andrew's ventricular septal defect, the stenosis of the pulmonary artery, and the tricuspid valve. But during the post-operative course Andrew developed a complication—an infection beneath the sternum, which required a second, clean-up operation.

Three years later, Andrew's heart was again opened, this time because his tricuspid valve was failing. The surgeons then put in a new, artificial St. Jude valve.

DLM: When you were very young, before the heart transplant, could you exert yourself at all? What kind of shape were you in physically?

ANDREW: I wanted to be active—run, climb, jump—I wanted to do everything, which made it all the more difficult for my mother and father to prevent me from going against the doctors' instructions and what not.

JIM: When he was a baby Susan had to check his heart rate every two hours. Once, we were on vacation, and I can still picture her putting him on the hood of the car and counting his heart rate. It was a pretty constant thing.

Andrew at seven months with his mother, Susan.

SUSAN: Later, the doctor had to say things like, "Well, I don't want you to become a couch potato, but..." and asked him not to play quite so hard. Before he was ready for the transplant he won two blue ribbons in the Cub Scout Olympics, which involved foot races, throwing a basketball and the like. And the next week he was in the hospital with congestive heart failure.

Physical activity mixed with a taste for high adventure has been a theme of Andrew's life both as a child and adult. But his active life came to an abrupt deceleration at about age seven.

SUSAN: When Andrew experienced a TIA (transient ischemic attack)—I'm going to say he was six and a half—the doctor said, no, he should not use his skateboard anymore, should not ride a bicycle, should not climb trees. And that was hard.

JIM: That's when we talked with him about having a heart transplant and asked him whether he wanted to do it. And he said, "Will I be able to climb a tree again?" And I said, "Yes, you will." "Then I want to do it," he said.

Andrew's heart failure progressed from that point. In September of 1987 he underwent yet another heart operation, an attempt to reverse the earlier Mustard Procedure and take greater advantage of the stronger of the two ventricles' capacity to pump blood to his body. The surgeons referred to this as a "last ditch" operation. Susan remembers that Andrew did show some modest improvement afterward, but only for about two weeks. It was clear that he would need a heart transplant to survive.

In 1987 only three centers—Stanford, the University of Minnesota and Childrens Hospital of Pittsburgh—were performing heart transplants in children. Michael Mill was, at that time, the transplant fellow in cardiac surgery at Stanford; he recalls that in those days hearts were "relatively plentiful, mainly because so few centers were performing transplants, and we could establish direct personal relationships with other hospitals that would often put us in touch with a donor." The national organ procurement regulations were still in the future. Today, instead of three hospitals performing heart transplants in children, somewhere between 60 and 70 hospitals have pediatric heart transplant programs. Altogether, the United States now has 141 heart transplant programs (adult and children) and 245 kidney transplant programs. In the year 2000 these centers performed a total of 2,246 heart transplants and 14,283 kidney transplants.

In the summer and fall of 1987 eight-year-old Andrew Pike was in severe congestive heart failure. He needed a transplant; but there was a problem.

JIM: We were told that the scars from Andy's previous heart surgeries would keep him from having a transplant. They told us that he wasn't going to make it.

Then our cardiologist—her name was Theresa Berry—went to New Orleans to a heart convention, and she talked to the people from Pittsburgh, and they said that they'd like to see Andy and maybe consider him, but that it would be an exception.

I remember that weekend was Halloween. I had carried him out trick-or-treating, because he couldn't walk at that point; he just didn't have the strength. The next week he was on an "Angel Flight" to Pittsburgh, and a week later he had a new heart.

(NOTE: "Angel Flight" is an umbrella organization of regional associations of volunteer pilots who provide free emergency transportation for medical purposes such as this one.)

DLM: So you went to Pittsburgh for evaluation?

ANDREW: Well, before the transplant I think everyone had decided that it was going to happen. Right?

SUSAN: Well, you had to be evaluated. And the surgeons pointed out that there were risks, including the risk of stroke.

Disney World, July 1987. Suffering from severe congestive heart failure, eight-year-old Andrew would have a new heart four months later.

JIM: But they determined after a couple of days that he was a candidate. And the last few days we were just waiting.

SUSAN: It just happened that a heart was available after a week. The same donor who gave Andrew a heart also gave a liver and two kidneys.

DLM: Do you know anything about the donor or the circumstances of the donor's death?

SUSAN: At that time they did not introduce donor families. But it was a good heart, they said. The doctor would not tell Andrew the gender of the donor. We did understand that an auto accident caused the other person to lose his/her life. And the person was older than Andrew—I think 13—so the heart was a little bigger than what he normally would have had.

DLM: When you say that at that time they did not introduce donors' families to recipients and that the doctor wouldn't tell you the donor's gender, it suggests how terribly important it was that the identity of the donor be kept confidential.

ANDREW: Yes, and even now, the only way I could meet the family is if I wrote a letter to the organ procurement organization of North Carolina—they have people there who would evaluate the letter and decide whether or not it was possible and appropriate to contact the family. If it was they would make contact and ask them how they felt about this. And if the family wanted to meet with me then that agency would help set it up.

DLM: It sounds like you've looked into this.

ANDREW: I have, and there was one time about three years ago when I thought seriously about going to see them or at least getting in touch. So I did learn then about how it was done; but in the end I decided that my life just wasn't where I wanted it to be, and I wanted to be at my best when I did that. It's really important to me that I be at least somewhat successful and independent and on my own before I meet them.

DLM: So it's still something that you have on your agenda, long term?

ANDREW: Yes, it is.

JIM: At the time of the transplant we did write a letter to the family, anonymously, and the hospital saw that they received it. We did not hear from them.

DLM: After the heart transplant, your main medical problem, besides the need for immunosuppression, must have been rehabilitation from stroke.

ANDREW: Yes, the stroke was a main issue. I was in the hospital for seven weeks after the transplant. I did have to take third grade over again. I had missed 117 days of school that year. That was difficult getting stuck back a year away from my friends. How long after the operation did I have to stay there (in Pittsburgh)?

JIM: We rented an apartment not too far from the hospital with the help of the social work department there, and Susan and Andy stayed there almost until the middle of February, and then they came home for a few days and then had to go back. Because Andy had to have these biopsies every week or so for so long, it was well into April before we gave up that apartment. But his care was not transferred to Chicago until that summer. So we continued to make trips to Pittsburgh until June or July.

SUSAN: Andrew had to deal with the stroke, of course, but

The summer after the heart transplant.

there were other problems. He always had strong side effects from the medications. Cyclosporin and his body were just not compatible. Not only did he have overgrowth of hair, and darker hair—he did not look like his old self. One of his friends told him: "You're not Andy." And by junior high and the onset of puberty, he was having terrible headaches that would cause him to miss school. Or he'd get to school and then call me and say, "I'm in the nurse's office." They tried to play around with the medication to alter it or do something that would help. And he took Neurontin for a long time—to be sure there were no seizures. We finally sought help from a man who was both a neurologist and knew acupuncture. He was about the only one who could get the headaches to stop.

JIM: It turned out that they were Cyclosporin headaches. It took a while for them to decide that. We thought they were migraines.

SUSAN: Andrew's older brother had headaches, so we were predisposed to think that Andrew was getting the same kind. I don't think they knew then that Cyclosporin in some people caused these severe, debilitating headaches.

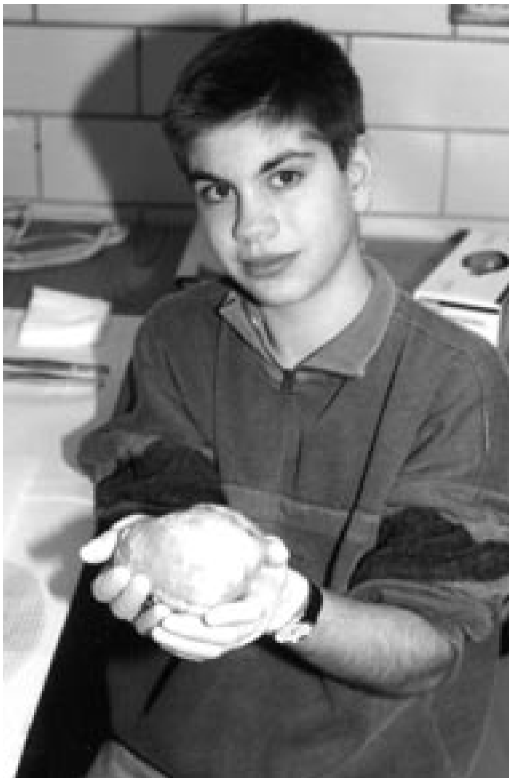
JIM: One of the immunosuppression problems is warts. Remember that horrible wart, two inches wide, on your foot, the year after the transplant? You were on crutches for a long time.

ANDREW: I remember that. It was right on the bottom of my foot, and it hurt. It was not fun.

SUSAN: He couldn't do gymnastics because of it. One of the other patients in Pittsburgh, a little Canadian girl, had little tiny warts all over the bottoms of both feet. She had also had a stroke, but hers was such that she had to learn to write with her left hand. And the Make-A-Wish Foundation gave her a computer so that she could do her work that way.

Andrew is reminded of the part in his story played by the Make-A-Wish Foundation, an organization that took on the important responsibility of providing a pleasurable episode at a painful time.

ANDREW: They came into my hospital room—some representatives of the Make-A-Wish Foundation. They asked me what I wanted and, as I remember, the first thing I wanted to do was go skydiving. I'd seen it on TV and I thought it was what I wanted to do. The doctors thought that would be a little too risky for someone who has just had a heart transplant, so that was out. Then I thought about maybe meeting Arnold Schwarzenegger, because he was my hero at



Andrew at 10 years of age. He is holding his "old" heart, which he wanted to see after being told that it was in a repository (of congenitally malformed hearts) at Children's Memorial Hospital in Chicago.

the time, the big action hero in the movies, and I loved all that stuff. I wanted to be in a movie with him. But then I realized that it would be just meeting and talking to him for maybe 15 minutes and it would be over. Eventually I decided I wanted my own tree house. So the Make-A-Wish Foundation paid for a builder to come to our home and build this two-story tree house with rope ladder, bridge, monkey bars, trap doors, and a slide and a pole and all this fun stuff. It was pretty much the biggest news in our neighborhood. All the kids were really impressed. It was the coolest thing in the world. My brother was disappointed, though. He wanted to go to Hawaii. But he couldn't convince me of that.

Apart from dealing and coming to terms with the side effects of Cyclosporin and Prednisone, Andrew was soon able to lead a more active life than he had ever been able to before.

JIM: The summer after the transplant we were at Ben's Little League baseball game. Ben is our older son. And we couldn't find Andrew anywhere. We finally did. He was at the next diamond, and he'd climbed up the backstop and was perched on the top.

I asked Andrew when it first became apparent that kidney failure had progressed to the point that he might need a kidney transplant.

ANDREW: Well, the kidney failure started when I was born. It came from the heart failure. And then the anti-rejection medication (Cyclosporin) after the heart transplant caused the progression of the kidney failure. So, pretty much that's been going on my whole life. They said that my Creatinine level was OK where it was and as long as it didn't go any higher... But it continued to go higher, little by little. And then ...

SUSAN: Wait. When he was in high school, just before we left Illinois, Andrew got a kidney infection. He had to go to Children's Hospital and have a kidney biopsy. And at that point they said that he was 50% below normal functioning. I would say he had more fatigue after that, but it did not become more than that until this past year.

JIM: I remember that when we were still in Chicago, and I had just accepted the job at Binkley (in Chapel Hill) and we went to see the doctor, who told us that Andrew had glomerulosclerosis and might need a kidney transplant. I know that's when it was because I said, "How can I go to a new church and have this facing us?" It wouldn't be fair to the new congregation; that was my fear. I remember that Andy and I went for a walk and talked about it, and he encouraged me to do it. I thought—and maybe I said it then: "Well, it feels like God is in this, so it must be alright."

Andrew also remembers the Pike family's decision to move to Chapel Hill, but he recalls a different "sign."

ANDREW: Actually, this is the way it was: There was a program by all the singing groups at my high school; all the groups were there. And the very first song that these 400 or 500 kids sang at that concert was "Nothing could be finer than to be in Carolina in the Morning." That was the sign that it was time to go.

JIM: When we got to North Carolina one of the first things we did was to get Andrew connected with a neurologist, a cardiologist, and a nephrologist.

DLM: No primary care physician?

SUSAN: Oh, yes, Dr. Allen Daugird. And he's done a good job, not only with the ordinary medical things that happen, but also things like helping Andrew get a driver's license.

ANDREW: Every couple of years I have to have a form filled out that says that I'm taking all my medications and doing what the doctor says, and so on, and that I can drive a car safely.

JIM: Well, after we got here Andrew went to see the nephrologist, Dr. Ronald Falk, and he said that most of the deterioration of the kidneys had probably occurred before the heart transplant. And he weaned Andrew off of the Prednisone he'd been on, which required biopsies once a month for about four or five months to assure that there was no rejection. Prednisone is a mean drug that causes a lot of side effects. Andrew was much better after that for quite a while.

During this time Andrew graduated from Chapel Hill High School, took some classes at Durham Tech, and got a job at Blockbuster Video. He also, finally, indulged his long-held wish to try skydiving.

ANDREW: Even today being active is very important to me. And when my kidneys prevented me from doing that, it was really hard. But when I was 19 I wanted to try skydiving. We knew someone in our church whose son did it, and so I got together with them, and I got to do it for the very first time. I remember going up in the airplane and thinking, "I can't believe I'm going to do this." But I was also so excited that it took the fear away. I remember getting to the door of the plane—I was doing a tandem jump so I was actually attached to someone behind me, the expert, who was wearing the parachute. Anyway, I remember kneeling down at the door, looking down 13,500 feet, and thinking this is the most exciting thing I've ever done, this is just awesome! And the next thing I know I'm given a little shove, and I go out, and the first three seconds my stomach did ten or twelve flips. But after that we got into neutral position, which is just hands raised like you are surrendering to the police or something. It was just incredible. We were falling at 120 or 125 miles per hour. It was so fast, and the wind... It was very windy, let's put it that way. And then when he pulled the cord we went from 120 miles an hour to 20 in just a split second. It's just like going from total, complete, amazing exhilaration to the most peaceful experience —because you're just floating down like a bird. I did it seven more times. The next four were tandem (you have to do five tandem) and then I did a few solo. But it eventually became

> too expensive. It was about $150 per jump. But it really taught me something: my limits were not as much as I thought they might be.

So, for much of the time between age eight, when he had his heart transplant and age 24, when he had the kidney transplant, Andrew was an active boy and young man who liked to push his limits and was sometimes able to. Then, last January a year ago he had a scheduled heart biopsy. At the same time the doctors ordered a Creatinine level—he hadn't had that particular blood test (a test of kidney function) for about a year. His serum Creatinine was elevated significantly and alarmingly. The test was repeated every other week, and the level continued to rise until by the end of April it was at seven and a half. By then Andrew was starting to be "...not incoherent, but fuzzyheaded." He was showing the signs of kidney failure.

Graduation day, Spring of 1998. Andrew, posing here with Ben, is 18 years old.

> **ANDREW:** I was feeling a lot of disorientation and dizziness, confusion, and a lot of fatigue.

This is when the testing for a donor began, testing that Susan eventually failed and Jim eventually passed. But Andrew's advanced kidney failure signaled that he could not wait for a transplant. He began hemodialysis. I asked him to describe it.

ANDREW: Imagine all of your energy being drained out of your body completely. That's what it was like. I didn't have all that much energy to begin with by then. But it made me feel so miserable. I was tired all the time. The only hope I had of getting better was the transplant.

DLM: What was your schedule for the dialysis?

ANDREW: Three days a week for two and a half to three hours.

DLM: And did you feel different afterward?

ANDREW: I felt more disoriented afterward. And very weak. I just think that being on dialysis means that you don't have a life anymore. You're alive, but there's nothing good about it.

JIM: My observation was that the day of the dialysis you felt horrible, the next day was not quite as horrible, and the next day you were back in dialysis. On the day off you seemed to feel a little better. But let me go back. Andrew had a temporary port for his dialysis. And when Susan couldn't be a donor Dr. Falk arranged for him to have whatever the next stage is to get started, because this temporary port did not function as well as another kind of dialysis would do—the abdominal kind. What's that called?

DLM: Peritoneal.

JIM: Yes. Andrew chose that. And he was scheduled to begin it two or three days after I was approved, so they cancelled it. And the surgery was performed a little more than a week later, on June 24. They began testing on Susan in early April and that went on for four or five weeks. And when she was disqualified, they started on me, and I was at the hospital two or three days a week for three weeks just going through the tests. We were both so thoroughly examined it was incredible. I think that at one time I counted that there were 27 different tests that they did on me, including adding tests like colonoscopy. It was so thorough that you wonder how anybody could qualify after all those tests. That I did is a miracle.

DLM: You may qualify more easily, though, if you have health insurance.

JIM: That's true. Before any of this started they verified that our insurance company would cover all of it, including our testing.

SUSAN: However, the insurance will only pay for testing one potential donor at a time. I had to finish before Jim could begin.

DLM: Then, I suppose, at some point they said to you, "You pass."

JIM: Yes, my blood pressure and cholesterol and lipids were all at acceptable levels. Which was amazing. They told me that if my blood pressure were too high I would be disqualified, or if my cholesterol or lipids were too high. So the testing was not just to see if I were qualified to give a kidney to Andrew, it was also to see whether I would be healthy enough, whether my health might be compromised by making this donation. And they determined that I was fit, physically. And then we had meetings with the social worker, financial consultant, and an interview with the psychologist to make sure that I was doing this for appropriate reasons. Those were all appointments required by the hospital—in addition to all the medical things. But we had wonderful experiences with all of the staff at the hospital. We're very grateful.

DLM: Who does the surgery? It must take two different surgeons.

SUSAN: Yes. There are four on staff who do kidney transplants. One was in Afghanistan with the Army. And so they had to schedule it among the other three. Otherwise they could have done it sooner.

DLM: What was the post-operative course like for both of you?

SUSAN: They told us ahead of time that it would be easier for Andrew than for Jim. The donor would have a harder time because the surgeons would be doing more traumatic things inside—in order to take the kidney out whole. In the recipient they just need a place to put it in. They don't have to twist things around so much.

JIM: They did not take out either of Andy's kidneys. So he now has three. But, of course, two of them don't work. They needed a place to put in just one kidney. With me the surgery was more extensive, but we both had quite a time.

ANDREW: I remember thinking before the operation that with dialysis I don't have a life. So it was a choice between not having a life and having a life, and if that meant having a transplant.... On the day of the operation they took me in and on the operating table, and before they put me to sleep I thought, "Well, here we go," and, "I hope it works." And when I woke up there were maybe four or five nurses screaming at me, telling me to wake up. I was having a really hard time waking up. I don't know if they were afraid that I was never going to wake up or what, but it seemed like they were screaming their heads off. Finally I did wake up, and as I remember, they put me in a hospital bed, and they brought my dad alongside me on another hospital bed, and we just looked at each other and said, "We did it."

DLM: What was the screaming to wake up about? Do you know?

ANDREW: I have no idea. Maybe the anesthesia was... I've always had trouble waking up.

JIM: Even without anesthesia!

ANDREW: Anyway, during the course of the next week I experienced severe cramps and lots of sharp pains where the incision was made, just like everybody. But it was easier for me to deal with being in the hospital and all the tests and people coming in and out, because I was so used to it. They did say to me that it would be a lot easier for me in terms of the surgery and recuperating from it because I had already been through so many of them. But for my dad it was all very new.

Assuming the "neutral position."

JIM: And the transplant was easier for you than for many other recipients because you were already immunosuppressed.

SUSAN: And the kidney started working very soon after the operation. So Andy felt better.

JIM: The hardest part of the whole thing for me was the fear that I might not be able to do it, that I might be disqualified and that Andrew might have to continue the dialysis, which was so hard. So we were elated when we learned that it could happen, and we went in with a sense of celebration, even though they were very clear that it was going to be a difficult recovery.

They told me to plan to take eight weeks off work, which I did. I think they said, "You'll be able to function after eight weeks off work." But they didn't tell me very vividly how I would feel after that. I found that I needed lots of rest and was very weak and tired. But as for the surgery itself, I just woke up in the room and it was all over and the worst part afterwards was gas pain. They did it laparoscopically—made a four-inch incision and then two other incisions for camera and lights and all. I haven't really noticed any difference in terms of kidney function or urinary function. But regaining my energy level has taken a long time, much longer than I thought. I had mistakenly thought that after eight weeks I would be ready to go back full steam, and that was definitely not the case.

ANDREW: After the procedure was done—I don't remember why it happened—I became diabetic.

SUSAN: Many people after this surgery become diabetic, and Andrew did, too.

JIM: Because of the additional Prednisone.

ANDREW: Because of the Prednisone, that's right. And just like anybody with diabetes I had to check my blood sugar levels with the machine, four times a day to start with. And it wasn't until I got out of the hospital, the very first day, that I took it and it was down.

DLM: This was an additional dose of Prednisone to guard against rejection of the new kidney?

ANDREW: Yes.

DLM: With your new kidney do you have to have biopsies or something else that's analogous to the way you still have to test your heart—to see if there's rejection?

ANDREW: Luckily, the only thing I have to do now is blood work. It's much easier. I go in once every couple of weeks now, for blood work and to see that all of my medications are where they need to be.

JIM: And they're continuing to lower Andrew's medications, like Prednisone, over a period of time, so that he will be taking much less medication after a year.

DLM: But transplant recipients must continue to receive some level of immunosuppression medication for their lifetime, isn't that right?

ANDREW: Yes, absolutely. Anytime you have an organ transplant there's a foreign object in your body and the immune system's going to think it's not supposed to be there. So it's going to try to kill it. So you have to take immunosuppression to make sure that the immune system won't be strong enough to (do that).

JIM: One thing that was very helpful in terms of recovery time was home healthcare. For the first three weeks home, a nurse came here every other day, the first week almost every day. Andrew's wound was open, so it needed to be dressed and packed for about six weeks. And they came to do the blood work for several weeks. It meant that we didn't have to take Andrew and get over to the hospital ourselves. We were very grateful for that service; it made a lot of difference.

SUSAN: We also took care of the wound, but being rank amateurs we needed the home healthcare here to get us started. I should point out, too, how very helpful friends and church members were, especially to bring food from church. And then Jim's twin sister, and my sister came; our other son came, and Jim's brother and sister-in-law and niece also came for a couple of days right after the surgery. So we were well supported, and it was good to have them here. So many people have helped, both then and earlier. Andrew's third grade teacher taught him to write again after the stroke. The community where we lived then began a fund to help on their own accord when he needed the heart transplant. They sent letters and a videotape and all kinds of things to the hospital when we had to leave Chicago and go to Pittsburgh, which back then was a place of last resort for kids with severe problems, when transplants weren't done very frequently.

DLM: Is Andrew eligible for Medicare?

JIM: Well, that just took effect, what was it, two months ago? We did not apply until after the kidney transplant, although Dr. Daugird had suggested it two years ago.

DLM: He would have been eligible then as someone who had end-stage renal disease.

JIM: With end-stage renal disease you're automatically qualified for Medicare. But if you get a transplant then the assumption by the government is that you're going to be fine and be back in the workforce. So Medicare coverage lasts for only three years following the transplant. But Andrew is on Medicaid now. And we have yet to experience how that's going to function. I don't know whether Medicaid would have supported a transplant or not. We've been trying to reach someone who will talk to us about questions like that. Of course, I would like to know the facts before we take Andrew off of my private insurance. Which is going to have to happen when I retire, but right now it doesn't. That's one of the big worries of transplant families.

SUSAN: How to pay for the medicine.

JIM: I have piled up here probably three or four hundred letters from UNC Hospitals that have come in the mail since June 24th. Literally—and the cost of the mailing from the hospital must be enormous. And for every one we get from them we get another letter from the insurance company. It's just bizarre. I need a full-time accountant here.

SUSAN: When Andrew was quite small, I could recite by heart all of his medications. I had them on the tip of my tongue. In the process of his growing up and taking over his own care, I don't now have all the facts at my fingertips. And I don't have to do it the same way. But it makes me extremely anxious when we start talking about it, because I'm thinking that some of the facts may not be right or that we may not have them straight.

The volume of clinical information that Andrew's father and mother—and now Andrew himself—have had to remember is enormous. Each of the many first-doctor-visits over 25 years in two different communities (three, counting Pittsburgh) involves taking a new history. Finally, the family has gotten in the habit of taking along a four- or five-page synopsis of the history and handing it to the doctor. But, says Jim, "They don't pay attention to that, they still want to hear it all verbally."

DLM: I'm wondering, is there a support group, locally, for organ transplant recipients?

ANDREW: Well, not long ago I got a letter from a person who had had a heart transplant and a kidney transplant, and who just wanted to get together some people who had had these experiences, to meet casually and talk, and that sort of thing. And I'm planning on getting together with that group, which is just now starting. I don't know much more about it yet.

Brother Ben feeding Andrew's three nephews.

Twice a recipient, Andrew Pike is now an advocate and campaigner for organ donations.

He referred to his own experience when he spoke briefly at church on the occasion of National Organ Tissue Donor Sabbath.

"It marks a chance for you to become a true hero," he told the assembled congregants, mentioning also that one of his own heroes, Michael Jordan, was the Organ and Tissue Donor Spokesperson.

Andrew then told the story of the family that invited him to visit with their ten-year old son, who was in the hospital awaiting a heart transplant. A week after the visit, still waiting for a heart to arrive, the boy died.

A year and a half ago Andrew wrote of the reason the pleasures of his own life had been his. It was "because of the good faith and kindness of one family... whom I have never met..."

Become a donor, he says, "if you are looking for a chance to show God's love. Give the gift of life."

Letters to the Editor

Mental Health Reform

To The Editor:

Congratulations on your September/October, 2003 issue focusing on Mental Health Reform, a masterpiece of diplomacy. Unfortunately it left out input from, or representation of programs which have been closed, staff who have been discharged or have left and patients who have been informed they will no longer be provided services. Reform is needed, but we need to reform the current implementation. We need to reform the reform.

Doctors Swartz and Morrissey refer to the "mental health care system" as having lagged behind the rest of the nation. In fact the initial development of what was to become the mental health system was a model for the nation in the early 1970s but has remained a "nonsystem". In his book, *People, Patients and Politics*, Clark Cahow, reviewing the history of North Carolina mental hospitals from 1848 to 1960, cites the need to "comprehend the complex interplay in the roles of the Governor, the Commissioner [now the Director of the Division of Mental Health, Developmental Disabilities, and Substance Abuse Services (MH/DD/SAS)], the Legislature and the medical centers." Further he states "future leaders must remain aware of the continual necessity to sell the concept of this relationship to the ever-changing political community." Unfortunately, Mental Health has suffered from a lack of leadership from the Governor's office, administration, the Legislature and the medical centers, since the reorganization of state government at the tail end of Governor Bob Scott's tenure.

The current implementation of "Reform" is in the process of creating a new bureaucracy in the form of Local Management Entities which will not provide direct services. Moreover it has made divestiture and privatization primary goals, supplanting quality direct patient care and invites corruption in place of what at times may have been misguided efforts to provide services in a few area programs. Doctor Visingardi's article is brief and cryptic, and refers to "managers of public policy," "divesting public service," as activities operant in moving forward. He closes with a question: "Have we positively contributed to the lives of people with disabilities and their families?" The answer to that at present is not only NO, but we have contributed negatively. His propensity to issuing multipage memoranda, stifling employee input, and issuing invitations to state-level meetings take the place of a process of interaction with the people to be served and serving.

> *a lack of accountability among the local area authorities and the state's excessive reliance on our state institutions. Both in fact, are failings of state-level leadership.*

Representative Insko reminds us that the Auditor's report related to two major issues, a lack of accountability among the local area authorities and the state's excessive reliance on our state institutions. Both, in fact, are failings of state-level leadership. If the benign neglect of the past continues, the only thing that will come of these efforts will be increased chaos. Perhaps in our more urban areas where political, professional and consumer and public leadership is substantial, what is good will be salvaged. Mr. Campbell (State Auditor) clearly identifies problems of "no funding to create programs" and the fact that "mental health programs had been underfunded for years." He emphasizes "the local structure for providing services must be in place this time as we shift care back to the community." However, reform implementation proceeds without funds and alternative services in place. Ms. Flamino provides clarity regarding the separateness of the nonsystem of mental health, homelessness and criminal justice, a dynamic sure to continue to obscure the true needs.

Dr. Bridges, the long-term optimist, neglects to say that the program of Vance, Granville, Warren and Franklin Counties where he served for over 20 years has been dismantled and the staff discharged without adequate alternative services, only one example of program closures. "A Parent's Tale" provides ample substance and argument for the fact that state/local funded and operated services will always be necessary and the unfortunate likelihood is that those individuals affected by mental illness, developmental disabilities and substance abuse will continue to be the lowest priority of leadership. In view of this it seems that parsimony when it comes to the elaboration of bureaucracy and preservation of current staff and services must assume primary roles.

Finally, it is no coincidence that the golden years of the early 1960s to the mid-1970s saw the Division of MH/DD/SAS led by a number of highly respected licensed medical doctors. The deterioration of the nonsystem occurred parallel to the systematic removal of physician positions. The current reform has been without a physician at the state level until recently, when, after relenting to pressures from the NC Medical Society and NC Psychiatric Association along with that of consumers, one position has been adverised. Consistent with this policy to abolish medical doctors from leadership in programs which are medical, the entire Division continues without a physician director which the General Statutes still called for the last time I looked.

The Cost of Prescription Drugs

To The Editor:

I have been reading your latest issue (Vol. 64, No. 6), which is a nice job. I liked the Ingram, Hooker Odom, and Millstein pieces in particular. I disliked Marks, whose European perspective shines through as smug superiority; I don't recall any acknowledgment of the Europe-as-free-rider hypothesis.

The Oberlander piece oversimplifies some things. For example, I don't quite accept the parallel between the original enactment of Medicare and the new drug benefit. To be sure, Congress in 1965 did appease the medical/hospital monopoly and leave costs for future attention. The new bill, however, instead of leaving the cost issue completely unaddressed, tries to provide some competitive alternatives to price controls on drugs. Original Medicare left the BCBS models in place, and made no provision for competition, which entered the picture only with the HMO Act, the antitrust initiative, and the Reagan administration's attempt to bring HMOs into the program. The new law certainly will hasten the coming train wreck, because there is nowhere near enough money to pay for the entire entitlement package for all who will be entitled to it. Inviting a crisis may not be a bad idea, however, since no one wants to reform Medicare until they have no option. Oberlander may be right that the Democrats will eventually impose drug price controls (he might at least have acknowledged that there's a downside to squeezing industry profits), but it's more likely that the crisis will be of such a magnitude that the whole entitlement philosophy will finally have to be rethought, with a shift to defined contributions—the obvious solution.

In general, the problems with drugs, especially the high cost of promoting them and their inefficient use, lies in the professional paradigm, which says that doctors should make all the choices (perhaps with some input from non-cost-conscious patients) and that health plans should be limited to pleading from the sidelines. Most all of our problems lie ultimately, of course, in a payment system in which health plans are barred from acting as purchasing agents and must be simply payers (at negotiated prices, perhaps) for whatever professionals deem necessary to protect our health.

— Clark Havighurst, JD
William Neal Reynolds Professor Emeritus of Law
Duke University

The new law certainly will hasten the coming train wreck, because there is nowhere near enough money to pay for the entire entitlement package for all who will be entitled to it.

The North Carolina Institute of Medicine

Since January 2002,
Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the NC Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The NC Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 when the North Carolina Medical Society reached the decision to cease support for its publication. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The *Journal* provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The *Journal* makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

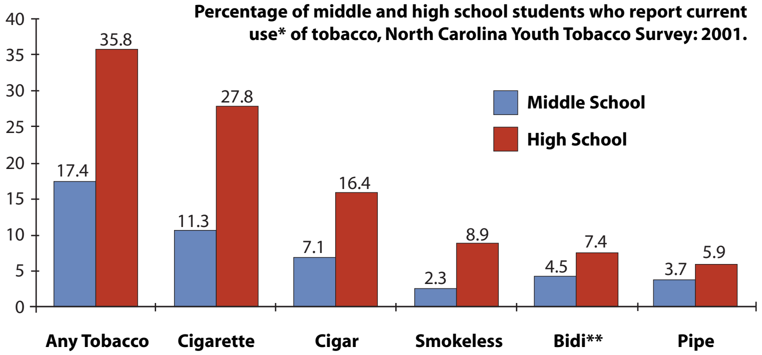
Youth Tobacco Use in North Carolina

Tobacco is the leading cause of preventable death in the nation and the state.[1] Many negative health outcomes are associated with tobacco use, most notably lung cancer and cardiovascular diseases.[2] More than 80% of tobacco use starts before the age of 19; therefore prevention efforts among youth are an important opportunity to curb use. Healthcare professionals play a critical role in youth tobacco prevention. Even brief clinical efforts to "ask and advise" lead to a reduction in use or ever starting.

The North Carolina Youth Tobacco Survey (NC YTS) is the largest, most comprehensive source of data on youth tobacco use, behaviors, and attitudes in the state. The NC YTS is conducted in coordination with the North Carolina Department of Public Instruction and the Centers for Disease Control and Prevention. In 2001, more than 10,000 middle and high school students from across the state participated in the survey. The overall survey response rate was 71%. The survey data were weighted to be representative of the entire population of middle and high school students in North Carolina.

Results from the 2001 NC YTS indicate that an estimated 36% of high school and 17% of middle school students had used some type of tobacco on one or more of the past 30 days. There is a marked difference between use by middle (6th - 8th grade) and high school (9th - 12th grade) students for each type of tobacco. Cigarette smoking accounted for the majority of tobacco used in both middle and high school students followed by cigars, smokeless tobacco, bidis, and pipe tobacco. Some students reported using more than one of these types of tobacco during the past 30 days. Most of these percentages are slightly higher than national rates of tobacco use among middle and high school students.



Percentage of middle and high school students who report current use* of tobacco, North Carolina Youth Tobacco Survey: 2001.

Note: * Current use of cigarettes, cigars, smokeless tobacco, pipes, or bidis on 1 or more of the 30 days preceding the survey.
** Bidis are small round hand-wrapped cigarettes typically from India.

Based on data from the NC YTS, the state allocated $18.6 million to address teen tobacco use through the Health and Wellness Trust Fund, created as part of the multi-state Master Settlement Agreement with the tobacco companies. It is hoped that school and community interventions will decrease youth consumption and reduce North Carolina's tobacco-related morbidity and mortality.

***North Carolina Medical Journal*: Call for Papers**

Herbert G. Garrison, MD, MPH
Scientific Editor, North Carolina Medical Journal

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The *Journal* seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The *Journal* is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

Blue Cross and Blue Shield of North Carolina salutes you!

We salute the doctors, dentists, nurses, pharmacists and other health care professionals who generously donate time, skill and financial resources to support North Carolina's free clinics and pharmacies.

In 2003, more than 6,000 volunteers provided more than $75 million in health care services to 150,000 patients at the free clinics. BCBSNC's own chief medical officer, Dr. Robert Harris, volunteers regularly at the Open Door Clinic in Raleigh. These volunteers are united by one principle: that access to medical care should not be limited by one's ability to pay.

Given the sluggish economy and job losses, free clinics face greater challenges than ever. Most clinics are forced to turn away more patients than they are able to see.

To help address this need, the Blue Cross and Blue Shield of North Carolina Foundation is providing a grant of $10 million to the North Carolina Association of Free Clinics over the next five years. The grant's goal is to double the number of people that free clinics and pharmacies can serve and to provide statewide access to these facilities. The grant is expected to result in a 50 percent increase in the number of free clinics and pharmacies across our state.

Meeting these ambitious goals will continue to require the commitment of dedicated volunteers. While this grant will provide the impetus for the creation of new clinics, establishing clinics also requires the involvement of community leaders, medical professionals and other volunteers willing to organize and sustain such an effort.

No one entity can solve the problem of the uninsured. However, by continuing to work together, we can all make a big difference.

For more information about free clinics, we would invite you to check out the Web site of the N.C. Association of Free Clinics, at **www.ncfreeclinics.org**.

You can learn more about the BCBSNC Foundation at **www.bcbsnc.com/foundation**.

Dozens of health plans and networks.

One standard credentialing form.

It's just what the doctor ordered.

America's leading health plans and networks introduce a simple way to satisfy your credentialing requirements.

Credentialing is a time-consuming burden for physicians and their office staffs. Now there's a better way to submit and update credentialing information. With Universal Credentialing DataSource, you only need to submit information once, with periodic updates, to satisfy the credentialing requirements of many leading health plans and networks. And you can submit your credentials paper free on the Web, at no cost to you.

Universal Credentialing DataSource was developed by America's leading health plans and networks collaborating in a partnership called the Council for Affordable Quality Healthcare (CAQH). This innovative new tool will incorporate data from more than 600,000 physicians and providers nationwide – data that is completely secure and accessible only with your authorization to credentialing organizations.

For more information on the advantages of Universal Credentialing DataSource and the other ways America's leading health plans and networks are working to reduce administrative burdens for physicians and their staffs, visit **www.caqh.org**.

How to Prescribe Healthy Lives

Health care professionals are always on the front lines to protect and improve the well-being of North Carolinians. During the challenging flu season, doctors and nurses safeguarded our residents with timely counsel, treatment and vaccines.

Year round, health care professionals prescribe appropriate medications for chronic diseases and short term illnesses, but what can they prescribe for the patient who simply does not engage in enough physical activity?

Obesity and inactivity are mounting problems in North Carolina, and the nation as a whole. 82 percent of adults in North Carolina do not engage in enough physical activity. Though inactivity has been linked to increased risk of heart disease, high blood pressure, osteoporosis, arthritis, and diabetes, little has been done in past years to mitigate the effects of this growing phenomenon. Unlike a vaccine or a painkiller, the solution to these problems cannot be bottled and prescribed.

One step at a time, Be Active North Carolina aims to improve the health of North Carolinians by promoting increased physical activity and healthier lifestyles that will result in happier, longer lives. Most people cannot fit a daily, intricate exercise routine into their schedule, which is why the answer to becoming more active lies in modifying their habits in minor ways.

Be Active North Carolina is offering a free brochure that physicians can use to prescribe healthier lifestyles for their patients. This tool highlights simple yet effective ways to become more active everyday such as taking the stairs instead of the elevator and a checklist of activities for physicians to prescribe to their patients.

Given a little direction and motivation, North Carolinians will be on their way toward developing habits that will result in more active lives. With your help, Be Active North Carolina can continue to promote a healthier, brighter future for all North Carolinians. For more information on these free brochures, please contact Chris Stover at (919) 765-7171 or chris@beactivenc.org.

Blue Cross and Blue Shield of North Carolina is proud to be the founding sponsor of Be Active North Carolina.

THE NC HEALTHCARE ENTERPRISES WORKERS COMPENSATION FUND

The Fund was formed in 1993 by McNeary to offer the healthcare community an opportunity to capitalize on their comparatively lower exposure to loss, as a homogeneous group. Because of the nature of the exposure, as well as, a dedicated commitment to loss control, the Fund has worked well since its inception. Today, over 40 hospitals and medical practices enjoy the financial benefits of the Fund! The program is endorsed by the North Carolina Hospital Association.

REASONS TO JOIN THE GROUP:

- Competitive Pricing
- Coverage for volunteers
- Easy pay plan
- Efficient responses to loss control and renewal-no insurance company bureaucracy
- Experienced claims adjusters who work exclusively for the Fund
- Long term stability of coverage
- Opportunity for ownership equity
- Voice in management of your program

Begin reaping the benefits of a proactive approach to workers compensation costs by joining dozens of your colleagues in this unique program. You will not be disappointed. The group was formed and is managed by McNeary, a name that has been familiar to the medical community for over 35 years.

Universal Childhood Vaccine Distribution Program: North Carolina's Strategy to Ensure All Children are Age-Appropriately Immunized

As one of the greatest public health achievements of the twentieth century, immunizations have been described as both cost-efficient—saving $15 for each $1 spent—and effective in reducing incidences of disease throughout the world.

North Carolina's immunization program was developed to prevent and control transmission of vaccine-preventable diseases, with emphasis on accelerating interventions to improve the immunization coverage rates of children under two years of age. In 1994, the North Carolina Department of Health and Human Services, Division of Public Health, Immunization Branch, instituted the Universal Childhood Vaccine Distribution Program (UCVDP) to keep children in their medical homes and remove cost as a barrier to age-appropriate immunizations.

The UCVDP program provides all of the required childhood vaccines—at no charge—for any child present in the state of North Carolina from birth through 18 years of age. More than 97 percent of providers who administer immunizations in North Carolina (more than 4,200 physicians) have signed up for the UCVDP program. Because of the success of this program, North Carolina ranks fifth in the nation, with an immunization coverage rate of 85.6 percent.

The benefits of the UCVDP program for health care providers are numerous and include:

- ✓ one-stop shopping for ordering vaccines;
- ✓ reduction of risk of paying for vaccines for which payment may not be collected;
- ✓ vaccine consultation;
- ✓ elimination of the need to keep two sets of vaccine supplies for most vaccines;
- ✓ health care provider 'friendly' program; and
- ✓ minimal paperwork.

For information about becoming a participant in the UCVDP program, call the North Carolina Immunization Branch at 1-800-344-0569 or visit the Branch online at **www.immunizenc.com**.

FORWARD

Policy Forum:
The North Carolina Nursing Workforce

Recently, a family member was in a local hospital for an extended period. The experience reminded me once again that, in the midst of all of the wonderful miracles and technology at our disposal in today's modern hospitals, nurses are still of critical importance in the process of caring for patients. My family's inevitable questions (What is happening? What should we expect? Where is something located? What hours is a service available?) were all directed to the nurse of the hour. And the nurse invariably could calm the anxious patient and the family with professionalism and expertise. Such is the expectation that our society places on the nursing profession.

Yet, those of us who work in healthcare recognize the challenges that are before the profession today. These challenges are enumerated in detail in the report of the Task Force on the NC Nursing Workforce, summarized in this issue of the *North Carolina Medical Journal*. This important and timely report includes some suggestions and recommendations for improvements and modifications in the way nurses are recruited to the profession, trained, and practice in North Carolina. Some of the subjects discussed have been with us for decades; others are ever-changing and call for new and clear thinking about the possibilities for the future.

The Duke Endowment, as one foundation, has long supported projects to address some of these challenges. However, at a meeting of our Board of Trustees in May 2002, there was a lively conversation about how we might best support a statewide discussion of the issues that could lead to a consensus for new actions. The North Carolina Institute of Medicine gave wonderful leadership by developing the format of such a process, and provided the all-important neutral voice in the discussions needed to arrive at the printed recommendations that appear in this report. The members of the Task Force were indispensable. They came to the meetings with enthusiasm, interest, and high ideals for the future of nursing in North Carolina. The final product would not have been nearly as valuable without their participation and contributions.

We believe the groundwork for the future is being laid by this report. Already, work has begun to assist foundations like the Endowment as we strive to understand where we can maximize our investments to address nursing workforce issues. We encourage your thoughtful consideration of the information and recommendations contained in these pages. And we encourage lively and constructive discussions of the actions that will lead North Carolina toward a more healthy future.

In hospitals, in nursing facilities, in home visitation, in public health, in school health centers, in rural health centers, in nursing education classrooms, and in many other locations, nursing is vital to the care that we all wish to receive—for ourselves and for our communities. It is our collective responsibility to do what we can to ensure that we have an excellent nursing workforce in 2004, and for many years to come.

Please join with us in moving these dreams to reality.

ISSUE BRIEF

North Carolina Institute of Medicine Task Force on the North Carolina Nursing Workforce (2004)

Cynthia M. Freund, RN, PhD, FAAN, Joseph D. Crocker, Pam C. Silberman, JD, DrPH, Kristie K. Weisner, MA, and Gordon H. DeFriese, PhD

Background and Purpose of the Task Force

By 2002, several states were reporting severe nursing shortages. At the same time, some North Carolina employers were reporting difficulties filling nursing positions. Whether there is currently a nursing workforce "shortage" or "crisis" in North Carolina is open to debate. Yet, there is little question that, without some intervention, North Carolina is likely to experience a severe nursing shortage in the coming decade due to the combination of an aging population and an aging nursing workforce. Long-range forecasts of registered nurse (RN) supply and demand in North Carolina predict a shortage of anywhere from 9,000 nurses in 2015 to almost 18,000 by 2020.

Rather than wait until North Carolina is in the midst of a full-blown nursing crisis, the North Carolina Institute of Medicine (NC IOM), in partnership with and at the request of the NC Nurses Association, the NC Center for Nursing, the NC Area Health Education Centers Program, the NC Board of Nursing, and the NC Hospital Association, decided to act proactively to prevent a future nursing shortage. In the fall of 2002 the NC IOM created the Task Force on the North Carolina Nursing Workforce to undertake a major study of issues surrounding the present and future supply of and demand for nursing personnel in this state. Co-Chairs of the Task Force were Cynthia M. Freund, RN, PhD, FAAN, Dean Emerita of the School of Nursing at the University of North Carolina at Chapel Hill, and Joseph D. Crocker, Senior Vice President, Wachovia and Manager of Community Affairs of The Carolinas Bank in Winston-Salem.[1] The 55-member Task Force included representatives of all levels of licensed nursing personnel, the NC Board of Nursing, NC Division of Facility Services (charged with registration of nursing aides), professional nursing associations, the NC Center for Nursing, the University of North Carolina System, the NC Community College System, the NC Independent Colleges and Universities, the NC Hospital Association, the NC Healthcare Facilities Association, home health and assisted living services providers, the NC Area Health Education Centers Program, school health nurses, and mental health nurses. The work of the Task Force was supported by a grant from The Duke Endowment.

The Task Force examined the current and projected demand for nursing professionals and paraprofessionals in all segments of the North Carolina healthcare industry. The Task Force also studied the degree to which current and developing educational and in-service educational programs are meeting, and are likely to meet, these demands. In addition, the Task Force examined school-to-work transitions, as well as the work environment for nursing personnel and methods to recruit and retain nurses. The Task Force tried to examine these issues for the full range of nursing personnel, including nurse aides, Licensed Practical Nurses (LPNs), Registered Nurses (RNs), Advanced Practice Registered Nurses (APRNs), as well as other registered nurses with graduate degrees at the master's and doctoral-levels. However, most of the Task Force's attention focused on Registered Nurses, who make up approximately 82% of the state's licensed nursing workforce.

Cynthia M. Freund, RN, PhD, FAAN, is Professor and Dean Emerita at the University of North Carolina at Chapel Hill School of Nursing and co-chair of the Task Force on the NC Nursing Workforce. Dr. Freund has had extensive experience in all aspects of nursing education and is herself a nurse practitioner who has practiced in North Carolina.

Joseph D. Crocker is Senior Vice President for Wachovia and Manager of Community Affairs of The Carolinas Bank in Winston-Salem, NC and co-chair of the Task Force on the NC Nursing Workforce. Mr. Crocker is an experienced hospital trustee, member of the North Carolina Medical Care Commission, Chair of the Board of Trustees of Western Carolina University.

Pam C. Silberman, JD, DrPH, is Vice President of the NC Institute of Medicine and helped staff the Task Force on the NC Nursing Workforce.

Kristie K. Weisner, MA, is Assistant Vice President of the NC Institute of Medicine and helped staff the Task Force on the NC Nursing Workforce.

Gordon H. DeFriese, PhD, is President and CEO of the NC Institute of Medicine and helped staff the Task Force on the NC Nursing Workforce. The authors can be reached at gordon_defriese@nciom.org or at 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713. Telephone: 919-401-6599 ext. 27.

The Current and Future North Carolina Nursing Workforce

Determining the exact number of nurses that will be needed in North Carolina in the future is difficult, as both the supply of nurses and the demand for nurses are constantly changing. But there are good reasons to believe that without some intervention, North Carolina will experience a shortage of registered nurses and other nursing assistive personnel over the next two decades. North Carolina's population continues to grow at a rapid pace and the age groups most likely to use healthcare services (those aged 65 and older) are among the fastest growing age groups. The nursing workforce in North Carolina is aging at an even faster rate. The average age of the North Carolina workforce in general grew from 37.7 (1984) to 40.4 (2001),[1] but the average age of RNs increased from 38.3 in 1983 to 43.6 (2001), and the average age of LPNs increased from 40.5 (1983) to 44.9 (2001). Traditionally, registered nurses move out of full-time employment rapidly after the age of 55. In 2001 about 14% of the RN workforce and 18% of the LPN workforce was age 55 or older. Another 31% of RNs and 32% of LPNs was between the ages of 45 and 54. These two factors, along with others, will exert enormous pressure on the balance between supply and demand for nurses in North Carolina over the next ten to 20 years.

As the general population ages, the use of healthcare services will increase. But this is not the only factor that drives demand for nursing services. Demand is driven by the number of people needing services, the acuity level of patients, healthcare technological and informatics changes, medical advances, labor productivity, regulatory and market changes, and advances designed to improve quality of care (including required nurse staffing levels). The current and future *supply* of nurses in North Carolina is also affected by a variety of other factors, including: the rate at which North Carolina can enroll and graduate new professionals from our educational institutions, the capacity of our educational system to expand or contract to meet market demands, the rate at which nurses move out of or into our state from other states or other countries (in- and out-migration), new and expanding career options for women and people with nursing degrees, demographic trends that affect the size and age of the labor force now and in the future, and workplace issues such as wage levels and working conditions that affect people's willingness to work in certain environments.

An obvious solution to a pending nursing shortage is simply to produce more nurses. However, before encouraging more people to enter the nursing profession, it will be necessary to expand the capacity of the state's nursing education programs to accommodate new students.

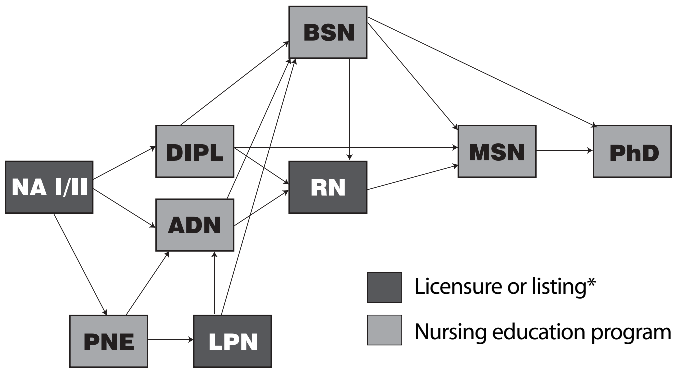
The state should also take additional steps to attract a more diverse workforce into nursing, as the characteristics of North Carolina nurses do not reflect the diversity of the state's population. For example, only about 6% of the RN workforce and about 5% of the LPN workforce is composed of men, compared to 52.8% of the state's workforce in general.[1] Twelve percent of RNs and 26% of LPNs represented racial or ethnic minority groups in 2001. In contrast, racial or ethnic minorities account for 28% of the state's population. These statistics are not inconsistent with national profiles of the US nursing workforce.

While the nursing workforce situation in North Carolina has not yet reached "crisis" proportions, the projected loss of our most experienced nurses due to aging and retirement, at a time when demand for nurses will be increasing, will undoubtedly lead to a severe shortage of nursing personnel by the end of the decade unless remedial steps are taken. The Task Force recommendations are aimed at attenuating what many have anticipated will be a "crisis" in regard to our state's nursing workforce.

Educating the Future Nursing Workforce

The entry-level credential for nursing practice is the basic license as a Registered Nurse (RN) or Licensed Practical Nurse (LPN). Nurses obtain their RN or LPN licensure by completing a basic course of study from a baccalaureate (BSN), associate degree (ADN), hospital-based diploma, or practical nursing education (PNE) program and passing the National Council Licensure Examination (NCLEX-RN or NCLEX-PN). Once licensed, there are also multiple routes to obtain advanced professional education (Figure 1).

Figure 1.
Possible Educational Pathways in Nursing



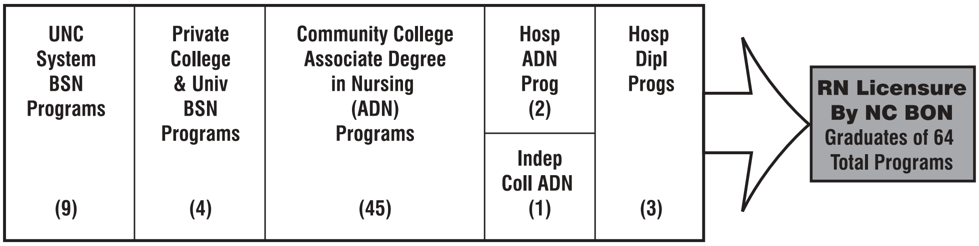
There were 64 nursing education programs in North Carolina offering credentials for entry-level RN licensure (BSN/ADN/Diploma) in 2004 (Figure 2). Among states in the Southeastern Region (i.e., those states served by the Southern Regional Education Board or SREB), only Texas has more nursing education programs than North Carolina. Moreover, North Carolina has the lowest proportion of BSN programs in relation to ADN and hospital diploma programs of any of the SREB states.

While we have many geographically dispersed educational programs to educate nurses and nursing assistive personnel, our educational system lacks the necessary infrastructure to significantly

---

* North Carolina does not "certify" nurse aides. These personnel are "listed" after successfully completing the required training and competency evaluation program of the Nurse Aide I or Nurse Aide II Registry.

Figure 2.
North Carolina Nursing Education Programs Preparing Graduates for Entry-Level RN Licensure, 2003



An additional BSN program is in the second phase of development as of February 2004.

increase the number of new nursing students at this time. Increased funding for faculty positions, faculty recruitment and retention and securing appropriate clinical sites for nursing education are key components affecting the capacity of these nursing education programs to educate students. Our problem is not one of needing to attract more young people into nursing. Each year we are turning away hundreds of applicants who meet entry requirements from our North Carolina nursing programs. Altogether more than 5,446 potential new RNs and 1,707 potential new LPNs were denied admission to North Carolina nursing education programs last year because these programs were unable to add more faculty, more clinical practice sites, and/or more space for students, due largely to budget constraints. Once admitted to nursing education programs, tuition support and student support services (such as academic and educational financial counseling) are critical to the success of nursing education programs.

North Carolina must increase the number of nurses in every category (LPN, ADN, BSN, Diploma, MSN and PhD), and expand education programs that have demonstrated acceptable levels of quality, accessibility, effectiveness and efficiency. However, the issue isn't just the numbers of new nurses produced, but the mix of nurses with a range of educational credentials. In the future, with changes in medical technology and acuity levels of patients seen in certain inpatient or institutional settings, North Carolina is likely to need not just an increased number of new nurses, but nurses who have enhanced educational preparation. For example, there is growing evidence that hospitals that have smaller staff-to-patient ratios and more staff with higher levels of nursing education, also have decreased mortality rates, fewer medical errors and nursing practice violations, and better patient outcomes.[2,3,4,5,6]

Regardless of how nurses enter the profession, they should be offered opportunities to enhance their educational preparation for nursing practice. By greatly expanding the opportunities to pursue education at higher levels, the overall educational level of North Carolina nursing care will increase, and, in turn, provide a variety of nursing career options to a broad spectrum of North Carolina citizens. By expanding prelicensure BSN, RN-to-BSN, and accelerated BSN programs, the Task Force envisioned that the current ratio of 60% ADN/Diploma and 40% BSN nurses could gradually change over the next 10-15 years to 40% ADN/Diploma and 60% BSN. This ratio change is also important because it will increase the number of nurses qualified for graduate programs that prepare nursing faculty.

School-to-Work Transitions

Unlike the experience of other professionals, nurses are often expected to practice fully in a relatively short time span after licensure. However, studies have shown that new nurses often have difficulties translating their educational experience into practice, particularly as it relates to skills in recognizing abnormal findings, assessing the effectiveness of treatments and supervising care provided by others.[7] This, in turn, causes new graduates to feel insecure in their job responsibilities and be less satisfied in their jobs. To better prepare nursing students for the transition into the workplace, students should be given a more intensive clinical experience during their final semester of school, followed by a more intensive orientation or internship opportunity once the new nurse begins practice. Once employed, new graduates should be provided supervised on-the-job skills training, along with a system of peer support. Ensuring an adequate school-to-work transition will help new nurses understand their job responsibilities and obtain the confidence and skills necessary to provide higher quality care.

The Work Environments of North Carolina Nursing Personnel

Nurses report lower job satisfaction than other professionals. This is problematic because job satisfaction is strongly correlated with turnover and retention. In North Carolina, only about half of all nurses report being happy with their jobs; close to one-fifth of all nurses report being unhappy with their work situations (19.9% of staff RNs and 17.7% of staff LPNs), and the rest are neutral.[8] The aspects of job satisfaction vary among work settings, with nurses in hospitals and long-term care settings being least satisfied with their jobs; and those in community settings much more satisfied. Job dissatisfaction in nursing often results in low morale, absenteeism, turnover, and poor job performance.

When nurses are dissatisfied at work, they are more likely to change jobs. Not only does staff turnover reduce the number of experienced staff who are familiar with the organization, it brings added expense to employers. Some North Carolina nursing employers reported significant financial outlays to recruit and train new nursing staff. A recent study suggested that the cost of turnover for one hospital nurse ranges between $62,000-$68,000.[9]

In addition to affecting turnover and performance in a particular job, job satisfaction can also affect satisfaction with nursing as a career. Nurses, especially those working in inpatient hospital settings, were less willing to recommend nursing as a career to other people. Only 40% of hospital inpatient RNs, and 50% of inpatient LPNs reported that they would encourage others to become a nurse.

The Task Force considered the role of nurses in different workplace settings in North Carolina, including institutional settings (e.g., hospitals, psychiatric institutions), long-term care facilities (nursing homes and assisted living facilities) and community-based settings (home health and hospice, public health and school nursing). There are several critical elements for a successful nursing work environment that cut across workplace settings. These include: management support and skilled nurse managers; an environment that promotes positive team relationships with coworkers; orientation and mentoring programs; the involvement of nurses and nurse aides in policy and decision making at both the institutional and unit level; competitive salaries and benefits; reasonable work loads; a safe working environment; career ladders and opportunities for advancement; minimizing paperwork and administrative burdens; flexible scheduling; supporting nurses in their role as patient care integrators; and professionalism and process standards in all departments with accountability.

Advanced Practice Nursing

There are four types of advanced practice registered nurses (APRNs) practicing in North Carolina: nurse practitioners (NPs), certified nurse midwives (CNMs), clinical nurse specialists (CNSs), and certified registered nurse anesthetists (CRNAs). All APRNs are licensed registered nurses, have advanced academic preparation and many categories of APRNs are nationally certified. The Task Force heard testimony that advanced practice registered nurses in North Carolina are not currently permitted to practice to the full extent of their educational preparation. Although the education and certification requirements for each APRN group are similar across the country, the allowable scope of practice for each type of APRN varies depending on the state in which they practice. The Task Force was unable to fully explore these issues, but recommended further study of APRN practice issues.

Summary of Recommendations and a Blueprint for Action

The Task Force built upon these findings to formulate a series of recommendations to prevent a future nursing workforce crisis. These recommendations were grouped into seven areas: (1) nursing faculty recruitment and retention, (2) nursing education programs, (3) transition from school to work, (4) nursing work environments, (5) Advanced Practice Nursing, (6) building an interest in nursing as a career, and (7) cross-cutting issues. Absent new faculty, the state may be unable to expand the production of new nurses, and absent the production of new nurses, North Carolina may have insufficient nurses to meet the demands of the nurse workforce environment. In addition, efforts need to be made to smooth the transition from school-to-work, so that nurses are better prepared to assume clinical responsibilities. Finally, the Task Force recognized that North Carolina needs to address workplace issues in order to retain nurses in their jobs and the profession.

In total, the Task Force made 47 recommendations, which, if implemented, would expand the numbers, educational level, and retention of nursing personnel. The 16 *highest priority* recommendations are identified in shaded cells. Recommendations that require legislative action are separately noted, as are those that can be addressed through educational institutions, employers, foundations, the NC Board of Nursing or other organizations. The full text of all recommendations can be found in the corresponding chapter listed after the summary recommendation (for example, Rec. #4.1 refers to the first recommendation in Chapter 4). We hope that segmenting the Task Force recommendations in this way will facilitate a more systematic response to the findings and recommended actions discussed throughout this report.

	ACTION TO BE TAKEN BY ORGANIZATION, INSTITUTION OR GROUP						
RECOMMENDATIONS	**Legislature**	**Educational Institutions or AHEC**	**Employers**	**Nursing Community**	**Foundations**	**Board of Nursing**	**Other**
Nursing Faculty Recruitment/Retention							
Priority Recommendation:							
The Faculty Fellows Program (as proposed in House Bill 808 in last session of NC General Assembly) be enacted and funded to support the effort of BSN nurses who wish to pursue MSN degrees in preparation for nursing faculty careers. (Rec. # 3.25)	✓				✓		
Other Recommendations:							
The NC General Assembly should increase funding to the NC AHEC to offer off-campus RN-to-BSN and MSN nursing programs using a competitive grant approach which is available to both public and private institutions statewide. (Rec. # 3.20)	✓	✓			✓		
Nursing doctoral programs should be expanded. (Rec. # 3.21)	✓	✓			✓		

	ACTION TO BE TAKEN BY ORGANIZATION, INSTITUTION OR GROUP						
RECOMMENDATIONS	**Legislature**	**Educational Institutions or AHEC**	**Employers**	**Nursing Community**	**Foundations**	**Board of Nursing**	**Other**
RN Education Programs							
Priority Recommendations:							
Production of prelicensure RNs should be increased by 25% from the 2002-2003 graduation levels by 2007-08. The NC Community College System (NCCCS), UNC System, private colleges and universities, and hospital-based programs affected by these goals should develop a plan for how they will meet this increased production need and report to the NC General Assembly in the 2005 session. Greater priority should be placed on increasing production of BSN-educated nurses in order to achieve the overall Task Force goal of developing a nursing workforce with a ratio of 60% BSN: 40% ADN/hospital diploma graduates. (Rec. # 3.1a-c)	✓	✓				✓	
Nursing education programs in the community colleges should be reclassified as “high cost” (therefore increasing per capita funding of these programs). (Rec. # 3.6)	✓						
The NC General Assembly and/or private philanthropies should invest funds to enable NC community colleges to employ student support counselors specifically for nursing students and to provide emergency funds to reduce the risk of attrition for students in ADN and PNE programs. (Rec. # 3.8)	✓				✓		
The NC General Assembly should restore and increase appropriations to enable UNC System institutions to expand enrollments in their prelicensure BSN programs above current levels. These funds should be earmarked for nursing program support and funneled to university programs through the Office of the President of the UNC System. Funds should be allocated on the basis of performance standards related to graduation rates, faculty resources, and NCLEX-RN exam pass rates. (Rec. # 3.15)	✓						
The NC General Assembly and private foundations are encouraged to explore new scholarship support for nursing students in NC’s schools of nursing. (Rec. # 3.19)	✓				✓		
Nurse Scholars Program should be expanded, per-student loans increased and new categories of eligible students added (as specified in Chapter 3). (Rec. # 3.24a-f)	✓						
Private institutions offering the BSN degree should be encouraged to expand their enrollments. (Rec. # 3.17)		✓		✓			
NC residents with a baccalaureate degree who enroll in an accelerated BSN or MSN program at a NC private college of nursing should be eligible for state tuition support equivalent to students in these institutions pursuing the initial undergraduate degree. (Rec. # 3.18)	✓						
The Comprehensive Articulation Agreement between community colleges and UNC System campuses should be further refined and implemented fully. a. Associate Degree nursing curricula should include non-nursing courses that are part of the Comprehensive Articulation Agreement (CAA) between the NCCCS and the UNC System. b. The UNC System and Independent Colleges and Universities offering the BSN degree should establish (and accept for admission purposes, UNC System-wide) General Education and Nursing Education Core Requirements for the RN-to-BSN students who completed their nursing education in a NC community college or hospital-based program after 1999. (Rec. # 3.28a-b)		✓					

	ACTION TO BE TAKEN BY ORGANIZATION, INSTITUTION OR GROUP						
RECOMMENDATIONS	**Legislature**	**Educational Institutions or AHEC**	**Employers**	**Nursing Community**	**Foundations**	**Board of Nursing**	**Other**
Other recommendations:							
Approval for (and funding to support) enrollment growth should be limited to those nursing education programs where attrition (failure to complete) rates are lower than the three-year average attrition rate for that category of education program (BSN, ADN, or PNE) and the pass rates on the NCLEX-RN or NCLEX-PN examination exceed 80%.) (Rec. # 3.2)		✓			✓	✓	
NC BON-approved "slots" should be realigned with current enrollment in NC nursing education programs by 2006. (Rec. # 3.3)		✓				✓	
Clinical facilities, in collaboration with local/regional nursing education programs, should identify and make available more clinical training sites for nursing education. (Rec. # 3.4)		✓	✓				
Nursing education programs and clinical agencies should work together to develop creative partnerships to enhance/expand nursing education programs and help ensure the availability and accessibility of sufficient clinical sites: a. AHEC should convene regional meetings of nursing educational programs and clinical agencies to develop creative educational opportunities for *clinical* nursing experiences. b. Nursing education programs of all types at every level should work together to develop creative educational collaborations with clinical facilities and programs that promote educational quality, efficiency and effectiveness. (Rec. # 3.5)		✓	✓				
An alternative method of financing the expansion of community college-based nursing programs should be considered by the NC General Assembly (instead of the dependence on external resources for such expansions). (Rec. # 3.7)	✓						
Funding should be made available to enable every nursing education program to apply for and attain national accreditation by 2015. (Rec. # 3.9)	✓	✓					
The Community College System should include in the comprehensive data and information system being developed data on nursing student applications, admissions, retention and graduation. (Rec. # 3.10)	✓	✓					
A consistent definition of “retention” (or “attrition”) should be developed by the Community College System and used in every community college. (Rec. # 3.11)		✓				✓	
A consistent standard should be developed and used within the Community College System for the evaluation of retention-specific performance criteria for each nursing education program. (Rec. # 3.12)		✓				✓	
The NC General Assembly or private philanthropies should fund the Community College System to undertake a systematic study of the relationship between competitive, merit-based admission policies and graduation/attrition rates. (Rec. # 3.13)	✓	✓					
Admission criteria in community college nursing programs should be coupled with competitive, merit-based admission procedures in all community college-based nursing education programs. (Rec. # 3.14)		✓					
The UNC Office of the President, utilizing data provided by the NC Board of Nursing, should examine the percentage of first-time takers of the NCLEX-RN exam who are BSN, ADN and hospital-based school of nursing graduates. If necessary, the UNC Office of the President should convene the UNC System deans/directors of nursing for baccalaureate and higher degree programs to plan for increases in funding to support enrollment that will assure, at a minimum, a 40% or greater ratio of BSN prelicensure		✓					

	ACTION TO BE TAKEN BY ORGANIZATION, INSTITUTION OR GROUP						
RECOMMENDATIONS	**Legislature**	**Educational Institutions or AHEC**	**Employers**	**Nursing Community**	**Foundations**	**Board of Nursing**	**Other**
graduates (in relation to ADN and hospital graduates) and, where possible, a gradual increase in the BSN ratio over the next decade. These ratio increases should take into consideration increases in prelicensure BSN program enrollment, as well as ADN-to-BSN and accelerated BSN program productivity. (Rec. # 3.16)							
Hospitals and other nursing employers are encouraged to consider tuition remission programs to encourage their nursing employees to pursue LPN-RN, RN-BSN, MSN or PhD degrees. (Rec. # 3.27)			✓				
An RN-to-BSN statewide consortium should be established to promote accessibility, cost-effectiveness and consistency for these programs. (Rec. # 3.29)		✓					
PN Education Programs							
Priority recommendation:							
Production of prelicensure LPNs should be increased by 8% from the 2002-2003 graduation levels by 2007-08. NCCCS and private institutions affected by this goal should develop a plan for how they will meet these increases. NCCCS should convene this planning group, including representatives of private institutions offering these nursing programs, and a plan should be reported to the NC General Assembly in the 2005 session. Each year thereafter, the PNE programs should provide a status report to the NC General Assembly showing the extent to which they are meeting these goals; and whether production needs should be modified based on job availability for new graduates, changes in in-migration, retention or overall changes in demand for nurses in NC. (Rec. # 3.1d-e)	✓	✓				✓	
Other recommendations:							
All NC BSN and ADN nursing education programs should explore creative LPN-to-ADN and LPN-to-BSN pathways to facilitate career advancement and avoid unnecessary duplication of content in these curricula. (Rec. # 3.30)		✓					
The State Board of Education and the NCCCS should promote dual enrollment programs for PNE programs in high schools. (Rec. # 3.31)	✓	✓				✓	
All PNE programs in NC should seek and attain national accreditation by 2015 with adequate funding provided for faculty resources, student support services, and NLN accreditation application fees. (Rec. # 3.32)	✓	✓					
Nursing Assistant (Nurse Aide) Education Programs							
NC DHHS should develop special designation for licensed healthcare organizations providing LTC services that choose to meet enhanced workplace environmental and quality assurance standards. (Rec. # 4.5)			✓				✓ NC DHHS
The NC General Assembly should appropriate funds to be used as a wage pass-through to enhance the salaries of nursing assistants, especially within LTC facilities that have chosen to enhance workplace and quality assurance standards. (Rec. # 4.9)	✓		✓				
Efforts of NC DHHS, NC BON and NCCCS to create “medication aide” and “geriatric aide” classifications should be encouraged and supported. (Rec. # 3.33)				✓			✓ NC DHHS
NC Division of Facility Services in conjunction with the NC BON should develop a standardized Nurse Aide I competency evaluation program, to include a standardized exam and skills demonstration process. (Rec. # 3.34)		✓					✓ NC DHHS

RECOMMENDATIONS	ACTION TO BE TAKEN BY ORGANIZATION, INSTITUTION OR GROUP						
	Legislature	Educational Institutions or AHEC	Employers	Nursing Community	Foundations	Board of Nursing	Other
Transitions from Nursing School to Nursing Practice							
Priority recommendation:							
NC BON should convene a group to study options to improve school-to-work transitions, including: ■ intensive clinical experience in direct patient care during the final semester of study for nursing students, and ■ a supervised/mentored clinical internship experience either pre- or post-licensure. (Rec. # 4.3)		✓	✓	✓		✓	✓
Nursing Work Environments							
Priority recommendations:							
Employers should take steps to create "positive work environments" (meeting several defining criteria). (Rec. # 4.1)			✓		✓		
AHEC and the professional nursing schools should offer educational opportunities for leadership development, conflict resolution and communication skills training, interdisciplinary team building, and preceptor training. (Rec. # 4.2)		✓	✓				
NC BON and Division of Facility Services should implement regulations to prohibit nurses from providing direct patient care more than 12 hours in a 24 hour time period, or 60 hours in a 7 day time period. (Rec. # 4.10)						✓	✓ NC DHHS
Other recommendations:							
NC nursing organization leaders and healthcare trade associations should develop model programs and best practices (e.g., Magnet Hospital principles) for statewide dissemination. (Rec. # 4.4)			✓	✓	✓		✓
Trade associations, AHEC and private philanthropies should take the lead in disseminating best practices that help create a positive workplace culture for nursing personnel. (Rec. # 4.6)		✓	✓		✓		✓
NC Nurses Association should promote consumer advocacy efforts toward a well-educated, adequately staffed healthcare system in the interest of higher quality of care. (Rec. # 4.7)				✓			✓
Philanthropic organizations should support the provision of technical assistance to healthcare organizations as they attempt to make the changes necessary to improve the nursing workforce environment and enhance the quality of patient care. Financial assistance should be targeted to those facilities that would be unable to make these changes without financial assistance. (Rec. # 4.8)					✓		
Advanced Practice Registered Nurses							
The NC IOM should convene a workgroup to study issues specific to the practice of APRNs. (Rec. # 5.1)				✓		✓	✓ NC IOM
Trade and professional associations in NC should initiate an aggressive statewide effort to effect changes in federal and state legislation and regulations that affect Medicare, Medicaid and commercial managed care reimbursement in order to promote the full utilization of APRNs in long-term care and in other healthcare arenas. (Rec. # 5.2)			✓	✓			✓

	ACTION TO BE TAKEN BY ORGANIZATION, INSTITUTION OR GROUP						
RECOMMENDATIONS	**Legislature**	**Educational Institutions or AHEC**	**Employers**	**Nursing Community**	**Foundations**	**Board of Nursing**	**Other**
Building an Interest in Nursing as a Career							
Priority recommendation:							
Existing programs via AHEC, the health science programs in community colleges, universities and colleges, the NC Center for Nursing, and employers that target a diverse mix of middle and high school students to encourage them to consider health careers and prepare them for entry into programs of higher learning need to be strengthened and expanded. (Rec. # 3.22a-d)	✓	✓	✓	✓	✓		
Other recommendation:							
High school and college-level guidance counselors should receive additional training in the requirements of NC's nursing education programs, with counselors designated to provide nursing-specific advice to interested students. (Rec. # 3.23)		✓					
Additional Cross-Cutting Recommendations							
Employers of nurses (RN and LPN) who hold licenses in compact states other than NC should be required to report annually the names, states in which licensed, and period of employment of these nurses working in their facilities and programs. (Rec. #2.1)	✓		✓				✓
Any NC resident enrolled in a public or private nursing education program should receive a state income tax credit to offset their nursing education expenses. (Rec. # 3.26)	✓						

Summary

North Carolina is indeed fortunate to have avoided many of the extreme shortages of nurses reported in other states. Yet, there are important developments on the horizon that have the potential to cause such shortages. Taking action today to expand the production of new nurses, enhance their education, augment school-to-work transitions, and improve the nursing workplace environment can help reduce the likelihood of a future nursing workforce crisis. Some steps will require new financial commitments either from public or private sources. Others will require a renewed commitment on the part of employers, educators, regulators and the nursing community. However, these steps are necessary if we are to recruit and retain well-prepared and motivated nurses who are needed to meet our healthcare needs now and in the future. Nursing, especially nursing at the bedside in hospitals and in long-term care, requires increasingly sophisticated technical skills and continues to demand intellectual, physical and emotional energy beyond what would be required in many other professions and occupations.

It is hoped that the recommendations offered here will help focus the efforts of legislators, educators, employers, the nursing community, trade associations, foundations and the public at large to ensure an adequate supply of well-trained nursing personnel for the future. **NCMJ**

COMMENTARY

Why is Nursing Important?

Susan F. Pierce, PhD, RN

As defined by the American Nurses Association, nursing is the protection, promotion and optimization of health and abilities, the prevention of illness and injury, and the alleviation of suffering.[1] Nursing has its historical roots in the poorhouses, the battlefields, and the industrial revolutions in Europe and America. Nurses cared for the sick in their homes, the wounded on battlefields and the suffering in institutions. While tending to the needs of their patients, nurses also observed their patients' progress or lack thereof, and the environments that either promoted or impeded their recovery.

This is not work that can be "outsourced." This is not work that can be "moved overseas." This is not work that can be performed by robots. Rather, this is hands-on, human-to-human, intimate work that all persons will need at some point in their lives. It is work that is intellectually challenging, physically demanding and spiritually enriching. Nurses bear witness to birth, death, and the many joys and sufferings in between. Nurses are not only providers of direct care, but are also designers, managers and coordinators of care.

As Virginia Henderson said in an excerpt from *Principles and Practice of Nursing (6th edition)*,[2] "Nursing is helping people in the performance of those activities that they would perform unaided if they had the necessary strength, will or knowledge." Thus, nurses are helping people at their most vulnerable, dependent times—when they need help the most. At every working moment, nurses are responsible for the lives of the patients in their charge and the peace of mind of their anxious visitors. While providing this complex care, nurses are also advocates and educators of these patients and their families.

> *"...this is hands-on, human-to-human, intimate work that all persons will need at some point in their lives."*

To succeed in all of these roles, professional nurses have been taught a set of core values which they continue to embrace: altruism, respect for human dignity, integrity, and social justice. Nurses have been the eyes, ears, hands and minds of those in need for over 100 years. About 2.7 million registered nurses in the United States (75,000 in North Carolina) go to work each day and accomplish just that. And according to repeated Gallop polls, people have come to know, respect, expect and trust that nurses will continue to do so.

Why the Task Force Report on the NC Nursing Workforce Is Important

The provision of nursing services is in crisis—both nationally and in North Carolina. The demand for more nurses is increasing faster than the supply, and those in the profession are nearing retirement at a faster pace than they are being replaced. The institutional work environment is not always supportive to the work the nurse is trying to accomplish, making retention of nurses at the bedside a critical problem.

North Carolina has a rich history of taking a leadership role in providing nurses and expert nursing care. In 1903, North Carolina was the first state to establish a Nursing Practice Act that created a Board of Nursing to safeguard the health of the public and provided for the legal registration of women (initially) as nurses based on their education and practice experience.

This hallmark event occurred over 100 years ago, but the tradition of "firsts" continued. In 1989, at the recommendation of the General Assembly's Task Force on the Nursing Shortage, the legislature established and funded the first Nursing Scholars Program in the country. Nursing students were given the opportunity to participate in a scholarship/loan program leading not only to initial licensure but to advanced education in this increasingly demanding field. Two years later, the General Assembly passed legislation that created and funded the North

Susan Pierce, PhD, RN, is President of the North Carolina Nurses Association and an Associate Professor of Nursing at the University of North Carolina at Chapel Hill. She can be reached at spierce@email.unc.edu or at CB# 7460, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7460. Telephone: (919) 843-7636.

Carolina Center for Nursing to monitor supply, demand and utilization of nurses. Another Task Force initiative was to provide funding to the NC Area Health Education Centers (AHEC) Program for recruitment and educational mobility initiatives and grants to institutions to stimulate improvement in nurses' work environments. All of these approaches helped keep North Carolina from experiencing the effects of nursing shortages... until now. After twelve years, it is time to act again.

For the last 14 months, the Task Force established by the North Carolina Institute of Medicine has brought together the best minds in North Carolina. These minds have carefully crafted a 21st Century plan to provide our citizens with the continued high quality nursing services they deserve. The solutions to a potentially devastating nursing shortage are in this report. Hence, it is critical that the recommendations in the report come to fruition. The time for study is over. The time for debate has closed. The time for action is at hand if the health and well being of our citizens is to be protected. **NCMJ**

COMMENTARY

Employers and the Nursing Workforce:
Seeking Local Solutions to a National Problem

J. Luckey Welsh, Jr., FACHE

The nation's healthcare industry is under stress—driven by an increased demand for services from a sicker, poorer and older population, coupled with reimbursement that does not keep up with the cost of caring. At the same time, we are on the precipice of the greatest shortage of healthcare workers in the state and nation's history. Leading this wave of shortages are registered nurses of the "baby boomer" generation who will be retiring or leaving the workforce in great numbers within the next 10 years. Patients are admitted to hospitals, long-term care facilities, and substance abuse centers because physicians determine that 24-hour nursing care is required. The simple fact is quality patient care cannot be provided without the required number of professionally educated and competent nurses.

There are many employers of nurses in the healthcare industry including hospitals, long-term care facilities, home health agencies, hospices, schools, public health departments, colleges, universities, and physicians. As an employer of approximately 500 nurses in a regional hospital in rural southeastern North Carolina, I appreciate and applaud the role that nurses play. Nurses are there to:

- Provide care to the poor,
- Help make our sick children well,
- Provide comfort and healing to our elderly mothers and fathers,
- Help bring new life into the world, and
- Be there to provide compassion and love to our dying patients.

Much has been written about the impending shortage of nurses in our state and in our nation. I applaud the efforts of the NC Institute of Medicine (NC IOM) for convening a task force with the assistance of The Duke Endowment to study and to develop recommendations toward the resolution of this problem. Many of our state's leading authorities in nursing and nursing education worked side by side with nursing employers and the NC IOM staff to address this most important issue facing the healthcare industry.

It has often been said, "Like politics, healthcare is a local issue." Whether you define "local" as state, a region within a state, a county or a community, that is where healthcare is delivered and where the shortage of nurses will be felt. I, therefore, believe many of the solutions to this problem should be developed and implemented at the local level. Every employer must take ownership of this problem and, more importantly, take ownership of the solutions in their own locale. The work of the NC IOM Task Force on the NC Nursing Workforce provided recommendations that employers of nurses should embrace and commit their time and resources toward implementating. Several of the recommendations that employers can have direct and meaningful impact on are as follows:

- Encourage the youth of our state to consider health careers with a special emphasis on nursing,
- Provide scholarships and loans to beginning students and those seeking to advance their level of educational attainment,
- Support and expand nursing education programs,
- Implement nursing recruitment and retention strategies,
- Provide a positive nursing work environment,
- Advocate collaboratively with state nursing leaders and trade associations for the NC IOM Task Force recommendations to the NC General Assembly.

Promote Healthcare Careers

Employers should begin initiatives to recruit the youth of our state and our nation into the healthcare professions. Employers should meet and develop strategies with public and private schools to expose and encourage young people to consider health as a career. Many examples across our state have already begun to develop, including the establishment of school academies, scouting explorer posts and school partnerships with community colleges, public schools and healthcare institutions. These programs allow middle and high school students to enter the nurses' places of employment to learn firsthand of

J. Luckey Welsh, Jr., FACHE, is president and CEO of Southeastern Regional Medical Center and a member of the Task Force on the NC Nursing Workforce. He can be reached at Harrel01@srmc.org or PO Box 1408, Lumberton, NC 28359-1408. Telephone: 910-671-5089.

this most rewarding profession. Bringing young people face-to-face with practicing nurses enables them to make a conscious choice in choosing their future area of study.

Provide Scholarships and Loans

Employers of nurses will find it advantageous to help with the educational costs of training new nurses. Employers can provide scholarships and/or loans to students who meet the admission criteria of their educational institutions. Employers can also encourage community foundations to fund these scholarships. "Growing your own" by helping to fund training of local people who have roots in the community is often more successful and less expensive than trying to recruit nurses from other regions or from abroad.

For those nurses already working in your facility, the employer will want to find innovative ways to help them advance in their field through further education and training. The employer can offer support through scholarships, loans and flexible work schedules to accommodate classroom schedules. This kind of support enables NAs to advance to LPN status and LPNs to earn an ADN degree. RNs need support as they work toward their BSN degrees and advance training for careers as CRNAs or NPs.

Support and Help Expand Educational Programs

Employers must proactively support and help to expand nursing education programs in their communities, whether at the community college or university level. For years, hospitals have served as clinical training sites, and we must continue to do so. It is also imperative that we take a look at our clinical site training and re-focus on how we can improve it. Employers with the resources may want to fund a faculty position at a local nursing school for a limited time in order to jump-start the expansion of that program. Finally, we, as employers, can advocate for our legislators to increase funding for nursing education programs throughout the state.

Develop Nursing Recruitment and Retention Strategies

Of course, employers will want to review regularly their pay and benefits for nurses to make sure that these are keeping pace with the state and region. Some hospitals have had success in recruiting nurses from abroad as a short-term measure that can supplement current staffing levels until other long-term efforts, such as those mentioned above, produce results.

One of the best retention strategies is the establishment of a mentorship program wherein a new nurse is paired with a more experienced mentor during the first year of work. This school-to-work transition is proving to be invaluable for the beginning professional, who needs orientation and guidance during the initial phase of employment.

Provide a Positive Nursing Work Environment

Improving the work environment for nurses is an important responsibility for employers. Hospitals, home health agencies, physician offices and other facilities can do many things to increase job satisfaction despite the fact that only about half of NC nurses report satisfaction with their current jobs and about the same percentage would recommend nursing as a career to others. In turn, improved job satisfaction could reduce soaring turnover rates and save the employer resources by cutting down on the burden of costly recruitment of new nurses.

Hospitals, especially, report lower levels of satisfaction among their nurses than in community settings. As employers, we must find ways to address the stress and other work patterns that raise turnover rates and increase the recruiting of new nursing staff. For example, we must develop work assignments that promote a balance between work and home life for the nurse.

Our nurse managers are key players in improving the work environment for staff nurses. Employers must make sure that these managers have the leadership training and support of management to make the workplace both challenging and rewarding for their staff. Employers should invest in new technologies that can cut paperwork and other administrative tasks so that nurses can do what they entered their profession to do—take care of patients. This emphasis on support and collaboration should filter through all levels of the workplace, from administration to other healthcare professionals, including physicians and allied health personnel. Furthermore, employers should familiarize themselves with the principles of the Magnet Hospital and adopt similar strategies for their workplaces.

Advocate Collaboratively

While we work locally to solve nursing workforce challenges, we must also remember that we, as employers, must advocate for statewide and national solutions to the nursing shortage. We can do this by proactively bringing these issues to the attention of the members of the NC General Assembly and the US Congress. We must not leave the solution of these problems to our trade associations or to the state nursing leadership. Although local solutions must be developed and implemented to counter nursing workforce issues, the employer must also take ownership of the grassroots effort to solve this problem through advocacy at both the state and national levels.

Employers of nurses can choose to sit idly by and expect Washington, Raleigh or our educational system to solve the nursing shortage. Or we can choose to implement many of the recommendations of the NC IOM Task Force and to participate actively in the resolution of the nursing workforce challenges we face. The choice is ours! **NCMJ**

The Long-Term Care Nursing Workforce:

Who Will Take Care of Our Rapidly Growing Aging Population?

Polly Godwin Welsh, RN, C

Nursing in Long-Term Care Facilities Is Complex

Approximately 40,000 North Carolinians reside in skilled nursing facilities. These patients are often medically complex and functionally frail. The acuity level continues to rise and many patients require intensive nursing rehabilitative services in addition to close medical and nursing supervision. Multiple diagnoses, co-morbidities and confounding complications are common. Nurses employed in nursing facilities work with the highest degree of independence and skill.

> *"This nurse must bring the patient and his/her family into the "team" and lead the team in making decisions to face the challenges ahead."*

Unlike hospital settings, long-term care nurses work without the continuous presence of physicians, emergency teams and advanced practice clinicians. These nurses must thoroughly assess patients who are likely to have communication deficits or some degree of dementia, and then communicate their findings to attending physicians, initiate nursing care plans, and respond to acute changes in patients whose conditions are unstable.

Not only are the keenest of clinical skills required to meet the needs of a medically complex patient population, the nurse working in a skilled nursing facility must utilize exceptional communication skills and navigate artfully through the emotions of patients and families. Patients and families are often overwhelmed by a recent catastrophic health event, immediate need for placement in a nursing facility and the stress of the many decisions to be made. Placement in a nursing facility is a major life event.

The guilt families may feel, along with the new responsibilities they face often render them somewhat in the care of the nurse as well. Nurses in skilled nursing facilities must ease the adjustment to this new phase in life for their patients and families. This nurse must bring the patient and his/her family into the "team" and lead the team in making decisions to face the challenges ahead. Extreme demands are placed on the emotions of the nurse who forges deep and important relationships that endure far beyond rendering immediate care. Nurses in skilled nursing facilities are there for the patient and family over the long term.

Patients in nursing facilities require extensive assistance with activities of daily living such as bathing, grooming, toileting and mobility. Statewide, over 20,000 nursing assistants are employed by facilities to assist with this care. Like the professional nurses with whom they work, they must possess special skills and caring hearts. The professional nurse must interact with these indispensable paraprofessionals with honed delegation and supervisory skills while functioning as the cornerstone for multi-disciplinary teamwork.

A metamorphosis has begun in skilled nursing facilities. The patients traditionally served comprise one facet of needs and expectations. Skilled nursing facilities have begun to see a new generation of customers emerge with a new generation of needs and expectations. Because of this emergence, North Carolina's nursing facilities will be facing an explosion in the demand for services. Not only are adequate numbers of professional nurses essential, but appropriate educational preparation and an assessment of models of care for the future are crucial.

Factors Affecting the Supply of Nurses and Nurse Aides Prepared to Work in Long-Term Care

To embrace these future demographics we must carefully examine the current external and internal factors relevant to the

---

Polly Godwin Welsh, RN, C, is the Director of Regulatory Systems for the NC Healthcare Facilities Association and a steering committee member of the Task Force on the NC Nursing Workforce. She can be reached at pollyg@nchcfa.org or 5109 Bur Oak Circle, Raleigh, NC 27612. Telephone: 919-782-3827.

supply and demand for nurses. Among the external factors specific to nursing facilities operating in every county:

- Regional access to nursing education
- Bias against long-term care in the academic settings
- Utilization of "slots" in approved nurse aide training programs for nursing students as a prerequisite for nursing programs, thereby greatly limiting the availability of classes for nursing assistants
- Limited supply of experienced faculty with geriatric training and experience
- Uniqueness of the medically complex and frail elderly patient population
- Age-related pharmacological issues

These factors result in few graduates interested in or possessing adequate preparation for the unique challenges demanded by the long-term care healthcare environment. The complexity of the regulatory environment not only limits the skilled nursing facility's access to registered nurses, but also to Family and Geriatric Nurse Practitioners and Clinical Nurse Specialists. There is little research to identify efficacious staffing models for skilled nursing facilities. Even so, there is strong evidence that the presence of advanced practice nurses improve care outcomes. Many barriers make it difficult to infuse these types of practitioners into long-term care.

Where Will Long-Term Care Facilities Find More Nurses?

In response to the deficits in the preparation of a nursing workforce adequate in numbers to meet the needs of a frail geriatric population, nursing facilities have, for a long time, "grown their own" by indoctrination of new employees to skilled nursing care, by promoting from within, and educating nursing personnel on an on-going basis through their own resources and their professional associations. This pattern will soon escalate and expand through the development of technically trained workers in areas such as dementia, mobility and medication administration.

At a time when the nursing workforce in North Carolina is being analyzed, skilled nursing facilities must be at the forefront of the discussion. The world is preparing to welcome the aging baby-boomer to its rightful place in society, the new "up and coming" senior. Nursing academia must capture the exciting opportunity to join the evolution of healthcare by focusing on the change and challenge of the very population that will demand so much of the expanding field of nursing. **NCMJ**

COMMENTARY

Our Future Nursing Workforce:
A Regulatory Perspective

Polly Johnson, RN, MSN

Our History

North Carolina has the distinction of being the first state in the country, and second jurisdiction in the world, to pass laws in 1903 related to the practice of nursing—to register nurses who had completed formal education programs. Beginning in 1905, nurses also had to successfully complete a licensing exam in order to be registered. In those early years, formal nursing education took place in hospitals scattered across the state. By the mid-20th Century, practical nurse (PN) education programs were developed and registered nursing (RN) education moved beyond the hospitals, first into universities and then into the Community College System.

During this period of nursing education development and expansion, major regulatory emphasis was placed on standardizing and strengthening nursing education in the state—requiring all programs to meet a set of minimum standards for preparing new graduates to provide safe, effective nursing care to the citizens of our state. These standards focused on administrative structure of programs, resources, faculty preparation, curriculum including didactic and clinical learning opportunities, student services and minimum standards for passing licensure examinations. The NC Board of Nursing continues to set standards and approve nursing education programs as we move into the 21st Century. Today, there are close to 100 approved RN and PN education programs across our state.

> "North Carolina (is)...the first state... to (license) nurses who had completed formal education programs."

In addition to authorizing the Board of Nursing to set regulatory standards for the approval of nursing education programs, by the early 1920s the Nursing Practice Act began defining the scope (or components) of practice for RNs, expanding to include LPN scope of practice by the mid-20th Century, and then scopes of practice for advanced practice registered nurses (APRNs) by the last quarter of the 20th Century. Through the years, the NC Board of Nursing has worked diligently to assure that these regulatory standards not only meet our mandate for public protection, but also facilitate the evolution of nursing practice within an increasingly complex healthcare environment. Beginning in 2000, North Carolina entered the new age of multi-state nursing regulation through the enactment of the Nurse Licensure Compact-an agreement among states enabling licensees of one state to have the multi-state privilege to practice in other compact states according to the states' practice requirements, but without obtaining a license in those states.

Regulatory Challenges in Our Current and Future Healthcare Environment

Today, we face not only the demands for nursing care in a high tech, high touch, fast-paced acute care environment, but also the demands for care by an aging population and others with multiple chronic care needs. As the NC Institute of Medicine Task Force concludes its study of and makes recommendations to address a nursing workforce that is both aging and declining in number, the NC Board of Nursing is also addressing how best to assure that this future nursing workforce is not only adequately prepared to provide safe, effective care, but also remains competent as practice evolves and expands. Equally important is the regulatory imperative to assure that providers are permitted to practice to the fullest extent of their educational preparation and competence. As a regulatory board whose mandate is to protect the public, we are committed to removing unnecessary barriers that deny full utilization of our nursing workforce in order for our citizens to have access to a full range of appropriately qualified healthcare providers. The Board of Nursing continues to be committed to helping create the appropriate regulatory frame-

Polly Johnson, RN, MSN, is the Executive Director of the NC Board of Nursing and a member of the Task Force on the NC Nursing Workforce. She can be reached at polly@ncbon.com or PO Box 2129, Raleigh, NC 27602-2129. Telephone: 919-782-3211.

work that provides for the utilization of advanced practice registered nurses to the fullest extent of their preparation without binding them to unnecessary oversight. We look forward to working with the NC Institute of Medicine in expanding this initiative.

Assuring Competence among Healthcare Providers

Following the release of the reports *To Err Is Human* (1999) and *Crossing the Quality Chasm* (2001) by the Institute of Medicine (IOM) of the National Academies[1,2] regulatory and accrediting bodies involved in health professions education and healthcare delivery systems are being challenged to establish standards that will improve patient safety and dramatically enhance the quality of healthcare in this country. Consistent with these initiatives, the NC Board of Nursing has reframed our overall approach to assuring the on-going competence of the North Carolina nursing workforce. Within a quality improvement framework, the Board is committed to supporting individual practitioners with deficits in their knowledge, skills and abilities by keeping them in the work setting while further enhancing their competence to practice safely. To this end, we are piloting a non-punitive, collaborative early intervention program that addresses concerns which have been raised about competency of individual licensees by several hospitals and long-term care facilities across our state. Through mutual agreement with the employer, the licensee and the Board of Nursing, we are offering remedial education and monitored practice to enhance the individual's competence while at the same time addressing mechanisms within delivery systems that could be changed to better support the delivery of safe care. The Board hopes to offer this program statewide within the next few years. More information about this innovative approach to enhancing the delivery of safe patient care can be found on the Citizen Advocacy Center's website www.4patientsafety.net.

As we plan for our future workforce, the Board is also addressing the need to assure the public that licensees maintain competence throughout their careers. Rather than requiring licensees to obtain a certain number of continuing education hours on an annual or biannual basis, our Board, along with nursing representatives from across the state, has developed a reflective practice model for licensees to evaluate their own practice, develop a learning plan, and provide evidence of steps taken to maintain or enhance their competence. Implementation of this continuing competence model will require statutory changes to authorize the Board of Nursing to collect evidence of competence at the time of licensure renewal. The Board plans to seek this statutory authority in the 2005 General Assembly. As our workforce numbers decrease and fewer nursing personnel will have greater patient care responsibilities, it is imperative that regulatory bodies play a primary role in assuring the public that our licensees maintain competence throughout their careers.

Core Competencies Every Healthcare Professional Should Have

Consistent with the challenge to reframe health professions education as proposed by the IOM Report *Health Professions Education—A Bridge to Quality*, (2003),[3] state Boards of Nursing and other health professions oversight bodies are formulating standards to include five core competences that clinicians across all health professions should possess in order to achieve the vision of a 21st century quality healthcare system. These core competencies are: (1) providing patient-centered care; (2) working within interdisciplinary teams; (3) employing evidence-based practice; (4) applying a quality improvement framework for all care provided; and (5) utilizing informatics to communicate, manage knowledge, mitigate error and support decision making. To prepare all health professions to deliver care in this manner will require a significant shift from our traditional "silo" approach of education for each health profession to integrating educational opportunities across the health professions—from pre-licensure through career-long continuing education.

The NC Board of Nursing is currently in the process of drafting revisions to our education program standards to address these core competencies and other requirements for building a workforce prepared to deliver the level of care envisioned by the *Quality Chasm* report. The Board will carefully review the recommendations from the NC IOM Task Force on the NC Nursing Workforce related to enrollment, attrition, National Council Licensure Examination (NCLEX) pass rates, and national accreditation to assure our future standards will support an adequate supply of nurses who are well-prepared to provide care in this complex world of healthcare. We envision program standards that support innovative learning opportunities for nursing students which incorporate new teaching-learning modalities as well as more creative utilization of settings for clinical learning experiences. With the increasing body of evidence that strongly suggests the need for a better transition from education to entry-level practice, the Board, through its Foundation for Nursing Excellence, has begun to explore mechanisms to address this need. Consistent with the NC IOM recommendation for convening a group to study options to improve school-to-work transitions, we plan to work with a wide spectrum of stakeholders to develop, pilot and recommend a transition-to-practice model for statewide implementation within the next five-to-eight years.

Finding Solutions to Other Nursing Workforce Issues

Since the year 2001, the Board has been asked to approve the development of six new PN education programs and four new RN education programs in a state that already has the second highest number of nursing education programs in the southern region of the US. As we look at the number of new programs that are seeking Board approval in light of the projected faculty shortages that will become most acute by 2010, North Carolina must find a way to share these vital resources across programs if we hope to produce the number of nurses needed for the future. Although the NC IOM report addresses funding needs and mechanisms to assure that current resources are maximized within the existing educational programs, little has been done to address the impending faculty shortage in terms of sharing resources among programs either on a regional or statewide basis. In this new information age, the technology is available to support non-traditional resource sharing and teaching-learning opportunities across programs. If this does not occur, some programs may cease to exist within another 10-to-12 years.

Other Questions that Need to Be Debated (with solutions to be formulated by key stakeholders)

How many nursing education programs can North Carolina support? Should the state institute a more formalized process for the approval of new programs that considers a variety of factors, including type of program, geographic overlap with existing programs, and demographics of the population to be served? Should there be a cap on the number of new programs or should this continue to be a market-driven process?

In addition to NCLEX pass rates, what outcome measures are needed to better assure the competence of entry-level practitioners? As referenced in the NC IOM report, NCLEX pass rates were never intended to be used as a single outcome indicator of the quality of a nursing education program.[4] As we develop further evidence through research studies, how do we articulate and measure the entry-level competencies that one needs in order to practice safely in this complex healthcare environment?

In order to further support the delivery of safe care, should there be limitations set on the number of hours a nurse could work in a 24-hour period and within a seven-day work week? Should there be standards set related to nurse:patient ratios? If so, by whom?

Moving Forward

For more than 100 years, North Carolina has had a rich history of advancing nursing practice to meet the needs of our citizens. We are now at another critical time in our history where changes need to be made in all aspects of our profession—education, practice and regulation—to continue the legacy. Thanks to the coordinating efforts of the NC Institute of Medicine, grant monies from The Duke Endowment, and the commitment of nursing and related healthcare leaders across our state, the Task Force on the *North Carolina Nursing Workforce Report* lays out a plan of action that we must implement if we wish to have a sufficient and well-qualified nursing workforce to meet the needs of our citizens in the 21st Century. The next chapter of our nursing history is in our hands—may we be good stewards of our legacy and committed to meeting the healthcare needs of all North Carolinians. **NCMJ**

COMMENTARY

North Carolina's Community College Commitment to Nursing Education

H. Martin Lancaster

The most important task of North Carolina's community colleges is to prepare the people of our state for good jobs with great futures. Now and for the foreseeable future, healthcare, particularly nursing, offers a tremendous number of those jobs.

Health programs make up one of the largest, fastest growing and most important areas of study in the community colleges of North Carolina. Our community colleges educate most of the nurses and allied health personnel working in our state's hospitals, long-term care facilities, home health agencies, health clinics and doctors' offices.

About 60% of North Carolina's registered nurses (RNs) come from community college programs. The report of the Task Force on the NC Nursing Workforce notes that community college nursing graduates do very well, performing above the national average on their licensure exams; and that approximately 90% of our RN graduates stay in North Carolina to begin their nursing careers.

It just makes sense for the NC Community College System to devote time, talent and money to allied health programs, and it makes sense for our state to increase dramatically its investment in those programs.

Community College Nursing Programs

We are working hard to increase the number of associate degree students prepared to sit for their RN licensure exam. Currently, 51 of our 58 comprehensive community colleges campuses have associate degree programs with an enrollment of approximately 5,300 students.

We collaborate with baccalaureate institutions to increase the education level of the state's nursing graduates as well as to increase the number of graduates prepared to complete their degrees to become registered nurses. A number of our community colleges work with institutions within the University of North Carolina (UNC) System to provide degree-completion programs for nurses (RN-to-BSN) who have earned associate degrees in nursing and wish to obtain a bachelor's degree in nursing (BSN). While the bachelor's degrees come from the universities, many of these programs are physically located on community college campuses and linked to universities by distance learning technology. Locating these programs on our campuses increases student enrollment and greatly strengthens the likelihood that underserved rural areas will have community college and university graduates who remain in that area.

We also offer a pre-major within our college transfer program for students who want to transfer into a nursing program at a university. This program is part of the Comprehensive Articulation Agreement with the University of North Carolina.

Our practical nursing programs have also grown in recent years, with more than 1,100 students enrolled in 34 programs. With the support of the healthcare industry, we have put significant effort into establishing and expanding programs for nursing assistants.

We are also involved in early recruitment of talented young people who should consider health as a career. A number of community colleges participated in the establishment of Allied Health Science Academies which provide courses in the health sciences areas to high school students. More than half of the system's colleges administer placement tests to approximately 8,000 students still enrolled in high school to determine the student's readiness for college level work.

In addition to these external partnerships, our community colleges work together to meet the needs of our students and the healthcare industry. These efforts involve collaborative agreements between our colleges. We have more than fifty health-related collaborative agreements between our colleges. These agreements assist in providing educational resources to as many students as possible by:

1. Providing classroom instruction in remote areas of the state;
2. Pooling available resources to provide cost-efficient education;
3. Providing arrangements for joint utilization of clinical sites; and
4. Eliminating the repetition of course requirements for our students.

H. Martin Lancaster is President of the North Carolina Community College System and a member of the Task Force on the NC Nursing Workforce. He can be reached at martinl@ncccs.cc.nc.us or 5001 Mail Service Center, Raleigh, NC 27699-5001. Telephone: 919-733-7051.

Barriers to Community College Nursing Program Growth

Despite all these programs and all these students, we know that we are not keeping up with demand. The nursing shortage is acute and growing. Community college programs at every level need to grow to meet that demand. However, we face significant obstacles to that growth.

First, the state provides funds neither to establish new community college programs nor to expand existing ones. Colleges must depend upon the generosity of private funders, such as The Kate B. Reynolds Charitable Trust, for start-up money. Neither does the state provide sufficient funds through the "FTE"[1] formulas to cover the actual costs of providing nursing education. Because health programs require low student-teacher ratios, specialized equipment and facilities, expensive supplies and highly qualified faculty, they cost much more than does the average community college program.

Second, many students come to us unprepared for the rigor of nursing programs. Most of our students are adults in their thirties and older. Many must strengthen reading, writing and math skills before they start their nursing courses. Many juggle complex family challenges along with their studies. These students can and do succeed; however, they need strong counseling and student support services along the way. Without that support, too many of them switch to less challenging programs or drop out completely, leaving community college nursing programs with a significant problem of student retention. Unfortunately, North Carolina's community colleges simply do not have enough counselors and other student support personnel to do the job that must be done for retaining these students.

Third, we are on the brink of a crisis in recruiting and keeping qualified faculty members. Part of the problem is money, plain and simple. Last year our system celebrated its fortieth anniversary. The dedicated men and women who were "present at the creation" are retiring in great numbers. Will we be able to pay enough to attract the next generation of great teachers? Not if we continue to stay mired at the bottom—literally—of community college faculty salaries in the southeast and near the bottom nationally. Current salary levels make it easy for business and industry to recruit faculty from our system. Another part of the recruitment problem is a shortage of nurses with advanced degrees. Currently, community college nursing directors must have at least a master's degree in nursing. To acquire a voluntary National League of Nursing (NLN) accreditation for each program, all faculty must hold a master's degree. A number of our colleges have had great difficulty in recent years convincing qualified directors prepared at the master's level to move into their communities for the modest salaries they can offer.

> *"About 60% of North Carolina's registered nurses (RNs) come from community college programs."*

Fourth, community colleges compete for clinical space with hospital and university programs and with each other.

Recommendations that Would Bolster Community College Nursing Programs

I am pleased that the Task Force on the NC Nursing Workforce has put forward thoughtful, significant recommendations addressing these important challenges in nursing education in North Carolina's community colleges.

I consider five of them to be of particular urgency.

1. The NC General Assembly should reclassify community college-based nursing education programs (ADN and PNE) as "high-cost" programs and provide additional funds ($1,543.39) per FTE student to cover actual costs of operating these programs. (Rec. # 3.6)

While this would not solve the problem of funding for start-up and expansion, it would help keep community colleges from losing money on every student enrolled in these essential programs.

2. The General Assembly and/or private philanthropies should invest funds to enable NC community colleges to employ student support counselors specifically for nursing students and to provide emergency funds to reduce the risk of attrition for students in ADN and PNE programs. (Rec. # 3.8)

I find it difficult to imagine a better use of new money than this one. According to the report of the Task Force, "If these ADN nursing education programs could increase their retention/graduation rates by just 10%, given the fact that such a high proportion of these ADN graduates stay to practice in North Carolina, it could increase our annual number of new registered nurses by over 450 per year."

I believe that the best way to accomplish that goal is to provide the strongest possible assistance to motivated students who want to succeed and simply need extra attention to make sure they do. Yes, it is tempting to say that we could achieve similar results if we raised admission standards and enrolled only those students who had already succeeded in school. If we do that, however, we will close the "open door" to opportunity for many, many North Carolinians. The "open door" is more than a logo for North Carolina's community colleges; it represents what we do and why we do it.

---

[1] Full-time equivalent student

3. The Comprehensive Articulation Agreement between the Community College System and the UNC System campuses (Associate in Arts degree), and the bilateral articulation agreements for students with an Associate in Applied Science degree (AAS) in Nursing and the UNC System, should be carefully evaluated and improved by the Transfer Advisory Committee (TAC) so that students wishing to advance from one level of nursing education to another will experience these transitions without course duplication. (Rec. # 3.28)

While not every registered nurse educated at a community college wants a baccalaureate degree, those who wish to specialize, teach and take on significant management responsibilities do. Some of our existing programs that help students earn BSNs work well; others, particularly the pre-major, need significant work. Following the mandate of the NC General Assembly in 2003, our System and the UNC System are now working with an independent consultant on a comprehensive review of our transfer programs, including those in nursing.

4. The NC General Assembly should increase funding to the NC Area Health Education Centers (AHEC) to offer off-campus RN-to-BSN and MSN nursing programs using a competitive grant approach which is available to both public and private institutions statewide. (Rec. # 3.20)

Graduate nursing education is not, of course, the business of community colleges. However, we depend upon this education for our instructors and directors and will support its expansion through shared facilities, distance learning technology and innovative collaboration. The Community College System is in strong support of having all of its already NC Board of Nursing-approved programs take an additional step of becoming nationally accredited by the National League of Nursing (NLN) voluntary accreditation process. This voluntary process requires that all nursing faculty hold a master's degree. To achieve this goal requires the availability of nurses with master's degrees and the funds to pay the salaries required.

5. Clinical facilities (hospitals and nursing homes, particularly), through their statewide trade associations, and in collaboration with all nursing education programs in their respective geographic areas/regions, should undertake to foster a more transparent and equitable system for the allocation of clinical training sites among nursing education programs on a sub-state regional basis. (Rec. # 3.4)

Increased collaboration between and among all educational institutions must be done to put into practice the use of all available clinical facilities by all educational agencies, if we are to collectively increase the number of graduates prepared to sit for the licensure exams.

Necessary Resources

How quickly will the NC Community College System and our partners be able to act on these recommendations? As do so many things, a large part of that answer depends on money.

The state of North Carolina has been struggling for the past few years with one of its worst fiscal crises in recent memory. While the NC Community College System has been spared the depth of budget cuts that some other agencies have received, we have had to make many reductions even as we face escalating enrollments. Any more cuts, particularly in health areas, will severely limit colleges' ability to meet student and industry demand.

There is no feasible way, from a budget perspective, that the NC Community College System can maintain its current production and supply additional highly educated and qualified healthcare professionals to the marketplace with the current funding stream. The NC Community College System may soon be faced with enrollment caps, especially in nursing and allied health programs.

We would not be able to provide the quality or number of educational opportunities for our citizens if not for collaborative efforts with our local high schools, universities, local Area Health Education Centers, the NC Board of Nursing and the NC Center for Nursing. Financial support from hospitals and foundations and other state and private agencies is critical for implementing and expanding programs. We must develop a coordinated, comprehensive and systemic resource development framework statewide to capture resources, and include more state funds, which are needed to provide educational opportunities.

With our continued efforts and commitment to meeting the needs of our citizens, we will strive to reduce the shortage of nurses and other healthcare professionals. **NCMJ**

The University of North Carolina System and Nursing in North Carolina

Gretchen M. Bataille, DA, and Alan R. Mabe, PhD

For over a year, North Carolinians committed to ensuring a strong nursing workforce within the state have met to review data, study "best practices" in our own and other states, and make recommendations for how North Carolina institutions that educate and employ nurses can best serve our citizens. The University of North Carolina (UNC) is committed to taking the steps necessary to address both the number of nurses needed and the appropriate educational level for those nurses. Board of Governor's Chair J. Bradley Wilson charged the Committee on Educational Planning, Policies and Programs of the Board of Governors to examine the current nursing shortage in North Carolina and to make recommendations for UNC's role in responding to the shortage. The statewide NC Institute of Medicine Task Force on the NC Nursing Workforce has been critical to UNC's examination of its own role in responding to the nursing shortage issue. Now that the Task Force has completed its work, Chairman Wilson has appointed a special committee of the Board of Governors to review their findings and develop a set of recommendations for UNC's response to the nursing shortage issue.

Nursing Education Programs and Enrollment

UNC has nine campuses providing prelicensure baccalaureate nursing (BSN) degrees. The same nine campuses also offer Registered Nurse (RN)-to-BSN degrees and, in addition, Fayetteville State University (FSU) and UNC at Pembroke (UNCP) have a joint RN-to-BSN degree program. FSU and UNCP are planning to establish prelicensure BSN programs on each campus to provide increased access to students seeking baccalaureate degrees in nursing in their regions. Two campuses, UNC at Chapel Hill (UNC-CH) and Winston-Salem State University (WSSU), have developed accelerated BSN programs for students who already have a bachelor's degree in some other field, but with intensive study for 14-16 months these students can receive a BSN degree that will qualify them to sit for the nursing exam.

UNC responded to the nursing shortage in the late eighties and early nineties by increasing enrollment and the number of graduates at the bachelor's-level, doubling the number of BSN graduates between 1990-91 and 2000-01 (509 to 1,017). Similar to the national picture, the enrollment and number of graduates at the baccalaureate level began a slow decline in the late nineties. For fall 2003 we have seen a dramatic reversal of this enrollment trend with a 16 % increase over 2002 to 2,303 students, the largest enrollment in undergraduate nursing ever for UNC. The number of baccalaureate graduates has continued to decrease, but we expect a reversal of that trend once these enrolled students complete their programs. At the master's level the number of graduates more than doubled between 1990-01 and 2000-01 (100 to 253). Master's enrollment for fall 2003 has climbed to 794, the highest level ever. The number of graduates for fall 2003 was 244, which was an increase over 2001 but slightly below the previous high of 253. UNC now has doctoral programs at UNC-CH and East Carolina (ECU), and the Board of Governors has approved UNC Greensboro (UNCG) to plan a new doctoral program in nursing. Enrollment in doctoral work is growing. Sixty-two students were enrolled fall 2003, and seven students received doctorates in 2002-03. UNC is well aware that the expansion of nursing

> *"Each of the existing undergraduate programs turns away qualified students because of limited faculty, space, or insufficient clinical sites."*

Gretchen M. Bataille, DA, is Senior Vice President for Academic Affairs for the University of North Carolina System and was a member of the Task Force on the NC Nursing Workforce.

Alan R. Mabe, PhD, is Vice President for Academic Planning for the University of North Carolina System and was a steering committee member for the Task Force on the NC Nursing Workforce. They can be reached at bataille@northcarolina.edu and mabe@northcarolina.edu or in the Office of the President, University of North Carolina, CB# 9000, Chapel Hill, NC 27599-9000. Telephone: 919-962-1000.

programs will require additional nursing faculty, and has particularly focused on producing master's-level (MSN) students in nursing education to respond to the needs for faculty in the community colleges in North Carolina. In addition to the site-based programs, two UNC campuses, ECU and UNCG, offer an online MSN in nursing education accessible from anywhere in the state.

Creating More Nurses and Nursing Faculty

The core recommendations from the Task Force for UNC are for more nurses, for higher levels of education for current and future nurses, and for producing more faculty members for nursing programs at the associate and bachelor's levels as well as for our graduate programs. This means that UNC campuses should expand the number of students enrolled in prelicensure BSN programs and accelerated BSN programs to increase the number of RNs in North Carolina. UNC's contribution to raising the educational level of nurses in North Carolina will involve more nurses coming into the profession at the BSN level, an expansion of the number of nurses enrolled in RN-to-BSN programs, and an expansion of nurses enrolled in master's and doctoral programs. The nursing faculty shortage will be addressed by expanding opportunities in master's and doctoral programs. At the master's level it will be particularly important to expand opportunities in MSN programs in Nursing Education because that credential is crucial for the community colleges to be able to expand their programs to meet accreditation requirements. The Task Force on Nursing recognized this as a critical contribution of UNC campuses.

The Office of the President has been supportive of increasing access to baccalaureate and master's programs using online technologies, having allocated over $500,000 to the campuses to expand online access at both levels in the past two years.

Each of the existing undergraduate programs turns away qualified students because of limited faculty, space, or insufficient clinical sites. The requirement for a 10:1 student/faculty ratio in clinical courses is not consistent with existing enrollment patterns on the campuses and, in this difficult budgetary climate, makes it harder to expand. Some of the campuses have received support from local hospitals that provide classroom space, clinical preceptors or funds to hire additional faculty, and such partnerships need to be explored further. The Area Health Education Centers (AHEC) has been very supportive and helpful in seeking additional clinical sites.

Throughout the year, we have explored with the deans of nursing the conditions that preclude the production of more nurses at every level. The issues are many. There is a need for faculty development funds for existing faculty to learn new skills or for master's trained faculty to seek doctoral degrees. For most campuses, faculty salaries are an issue, making recruitment difficult. Doctoral-level (PhD) trained faculty have opportunities for high-paying positions outside the academic environment. Some campuses have no space to grow larger programs or no large classrooms to accommodate larger classes. Additional graduate fellowships are needed to meet the financial needs of students engaged in doctoral study. All of these issues are compounded by the extensive budget cuts our campuses have faced over the past three years even as the university has received new enrollment funding.

Articulation

UNC supports the nursing programs at the community college campuses and recognizes the importance of seamless articulation of students from the community college Associate Degree in Nursing (ADN) programs to four-year programs. Increasingly, such needs are being met through bilateral or system-wide agreements, and we agree that it is time for another review of general and specific articulation issues as they relate to nursing. We also recognize the need to expand enrollment at every level, including licensed practical nurses (LPNs) and nurse aides.

Student Support

Another need is the expansion of the Nurse Scholars scholarship to provide more support for those students in the program. Graduation rates would be improved if students did not have to work while in school. A Nursing Fellows program modeled on the NC Teaching Fellows program could provide resources to campuses to support nursing students. Rather than a four-year program, this could be a two-year upper-division program for universities as well as a two-year program for ADN students.

UNC and the NC Center for Nursing have provided support for the College Foundation of North Carolina to establish an online module directed to students seeking a career in nursing. Information about existing programs and scholarship support is available at that site (www.CFNC.org). This is part of a larger effort that will need to be expanded to make career opportunities in nursing known to a wider group of students as they make career choices. It will be very important for this work and the work of others to promote a more diverse nursing workforce that will include more underrepresented minorities as well as males.

Conclusion

While our focus has been on those recommendations for UNC, other recommendations are of equal importance, particularly those focusing on retention in the workplace. Our nursing deans look forward to working with the committee on advanced practice nursing proposed in the report.

Few of these recommendations come without costs. The University of North Carolina intends to take the recommendations of the Task Force seriously and to craft the biennial budget request to maximize the use of limited state funds to address the shortage that exists and is anticipated in the future. We are fortunate to be in a state that recognizes that the health of its people is critical to its future. **NCMJ**

COMMENTARY

Private Colleges and University Nursing Programs in North Carolina

Mary Champagne, PhD, RN, FAAN

American nursing and healthcare are at a critical juncture. We are in the beginning years of a deepening shortage of registered nurses and nurse faculty, and headed toward two possible futures. In one scenario, we look to old solutions or continue as we are: the nurse shortage increases in severity, patient care suffers, and, as noted in the Robert Wood Johnson report (*Healthcare's Human Crisis: The American Nursing Shortage,* April, 2002) a major public health crisis occurs. In the second scenario, we are innovative and proactive in increasing enrollment in nursing programs, improving the educational level of all nurses, and improving the work environment of nurses; and we leverage public-private partnerships in education, industry, government and philanthropic foundations to enhance our efforts. The result is a recovering nurse supply, nurses well prepared to provide excellent care in our complex and increasingly technologically sophisticated care system, and a sufficient investment in the health of the public that ensures all North Carolinians will receive the nursing care they deserve.

We are presented at this time with the proverbial "window of opportunity," with choices to make in securing a preferred future to ensure the health of the public. The North Carolina Institute of Medicine (NC IOM), with financial support from The Duke Endowment, has developed a blueprint for our state's preferred future. The plan is wise and forward thinking, noting that a multi-modal long-term approach is needed, and that all must fully "do their part" if we are to succeed.

Growth of the number of nurses educated at the BSN-level and growth of graduate programs to prepare nurse faculty are key recommendations of the NC IOM report. The private colleges and universities in North Carolina make substantial contributions in each of these areas, and are committed to doing even more. As the report notes, the "privates" educate about one-third of all baccalaureate and master's prepared nurses in North Carolina. The programs are of high quality-retention, graduation and NCLEX pass rates are high; and remarkably between 75% to 95% of graduates stay in North Carolina to practice. In some instances this reflects a greater than expected benefit, as out-of-state students relocate to North Carolina to practice nursing following graduation.

Expanding Private Colleges and Universities

Increasing the capacity of private colleges and universities is largely tied to the funding mechanisms in place in each to allow for expansion. For the most part our schools are funded through tuition dollars and philanthropic gifts. Starting or expanding programs requires "seed money" for the first few years. Philanthropic dollars are incredibly important in this

---

Mary Champagne, PhD, RN, FAAN, is Dean and Associate Professor, School of Nursing, Duke University Medical Center and a member of the Task Force on the NC Nursing Workforce. She can be reached DUMC Box 3322, Durham, NC 27710. Telephone: 919-684-3786.

effort. Two recent examples illustrate the impact of private foundation support for growth of private colleges and university nursing programs. Our school, the Duke University School of Nursing (DUSON), was able to re-instate a pre-licensure BSN program which now admits 50 students each year thanks to funding from the Helene Fuld Health Trust. And while 50% of the first graduating class was from "out of state," 81% stayed in North Carolina and are providing care at the bedside. Philanthropic funds were also critical to our collaboration with the Southern Regional Area Health Education Center to deliver a master's degree in nurse education to nurses in rural North Carolina. This program, funded by The Duke Endowment, has, in the last two years, graduated over 30 students, who will teach in community colleges and hospitals in underserved areas of our state.

The Importance of Student Support

A unique challenge faced by private colleges and universities is providing sufficient scholarship support to students. The majority of students in the "privates" are North Carolinians, and need help in financing their education. They are not wealthy. I know from my personal experience as dean, that scholarship support often makes the difference between a student pursing or not pursuing education in nursing. My experience is validated by the comments of other deans and directors in North Carolina's private colleges and universities. Expanding the North Carolina Nurse Scholars program, extending the state tuition support to second degree baccalaureate and master's degree nursing students, and enacting the Faculty Fellows Program would markedly impact the ability of private colleges and universities to increase enrollments. Most important to this effort, is philanthropic scholarship support in the form of endowments from private foundations to the private schools of nursing. Philanthropic support of students has long lasting and far reaching effects. This investment in students reaches all the patients they expertly care for over the years of their nursing career; it is an investment with untold dividends.

"...scholarship support often makes the difference between a student pursing or not pursuing education in nursing."

Hospitals and other healthcare agencies can also play a critical role in supporting students in private colleges and universities. Innovative examples include "loan repayment" programs for students who agree to work in the healthcare agency following graduation, direct scholarships to students, faculty support through actual dollars to the college, joint hospital and school faculty appointments, and provision of clinical staff to supervise students in clinical rotations. Careful analysis will demonstrate that these arrangements, properly structured, result in a winning situation for all parties. Our school, for example, partners with the Duke University Health System (DUHS) in a "loan repayment" program for our baccalaureate students. Using traditional methods, students can borrow total tuition costs for their education, and sign an agreement with DUHS that guarantees employment, and payment of one-third of the loan plus interest for each of three years worked. Financial modeling, which included weighted costs of recruitment and retention of nurses and salary for staff and traveling nurses, demonstrated that DUHS would fully recoup its investment.

The private colleges and universities look forward to working with the many partners involved in the NC IOM Task Force on issues that affect us all in increasing and improving the nurse workforce. We support measures to build an interest in nursing as a career, collaborations to enlarge and more efficiently use clinical training sites, improving the scope of practice of APRNs, and enhancing the work environment of all nurses. We aim to do our best in partnering to ensure a highly educated nurse workforce for today and tomorrow. Working together to secure our preferred future, we cannot fail. The best is surely yet to come. **NCMJ**

Are Hospital-Related Nursing Programs the Answer?

Anita A. Brown, RN, MEd

Hospital-related nursing education has been a part of the fabric of healthcare and healthcare education in North Carolina for well over a 100 years. During the 1950s there were as many as 44 hospital-related nursing schools preparing graduates for registered nurse licensure and employment positions in North Carolina hospitals. In the 1960s more than 80% of the Registered Nurses (RNs) in the United States were educated in hospital-related programs. With the advent of the community college as well as the ever-changing financial challenges of the hospital industry, many hospitals began closing their nursing education programs or merged them into those new community colleges. By the 1990s, 10% of the United States' nurses were educated in hospital-related programs. It is well documented that in the United States and North Carolina, 60-70% or more of working RNs are employed in hospitals.

Historically, hospital-related programs have awarded the "diploma" as the educational credential to those students who graduated. When hospital-related education began, associate and baccalaureate degree programs in nursing did not exist and the "diploma" was the accepted academic credential. Because hospital-related education began as apprentice-type programs, the perception has lingered that these are nothing more than on-the-job training or workforce development programs. As nursing education has evolved, hospital-related programs have changed from the apprentice style educational formats to curriculum plans, which mirror today's associate and baccalaureate degree programs, including college-level general education courses with nursing major courses. Throughout the United States many hospital-related nursing programs have transitioned to associate degree (ADN) or baccalaureate (BSN) programs as part of becoming colleges of health sciences offering allied health programs as well as nursing. In 1998 a report on hospital-related colleges prepared by the Lewin Group, identified 348 hospital-related colleges/programs in the United States.

There are five hospital-related colleges/programs in North Carolina: Mercy School of Nursing at Carolinas Health Care System in Charlotte, Presbyterian Hospital School of Nursing at Presbyterian Hospital/Novant in Charlotte, Watts School of Nursing at Durham Regional Hospital in Durham, Cabarrus College of Health Sciences at NorthEast Medical Center in Concord, and Carolinas College of Health Sciences at Carolinas Health Care System in Charlotte. While Mercy, Presbyterian, and Watts' programs continue to award diplomas as the academic credential, the curricula in these programs are comparable to associate degree programs currently offered in North Carolina's community and private colleges. Cabarrus College of Health Sciences and Carolinas College of Health Sciences have developed associate degree nursing programs as part of their strategic development as colleges of health sciences. It is worth noting that both of these institutions include a variety of allied health programs at the associate degree level and Cabarrus College also has baccalaureate degree programs including BSN completion.

While the number of hospital-related programs is small, the impact of each is large in their respective areas. With their inception dates varying from 1895 to 1947, collectively these five programs have graduated approximately 11,000 nurses. Of

Table 1.
North Carolina Hospital-Rated Nursing Programs

	% Graduates Staying To Practice In NC	Average Retention Rate	Average Graduation Rate
Cabarrus College of HS	98%	65-70%	60-65%
Carolinas College of HS	97%	65-70%	64%
Mercy SON	96%	60-65%	57%
Presbyterian Hospital SON	98%	60-65%	65%
Watts SON	97%	56%	69%

Program survey data - March 2004. (SON = School of Nursing HS = Health Sciences)

Anita A. Brown, RN, MEd, is Chancellor of the Cabarrus College of Health Sciences and a member of the Task Force on the NC Nursing Workforce. She can be reached at abrown@northeastmedical.org or 401 Medical Park Drive, Concord, NC 28025, Telephone: 704-783-1557.

the 2,467 first-time NCLEX-RN takers in North Carolina in 2002, 10.2% (252) were from the five hospital-related programs. Of the six largest registered nurse education programs in the state (in terms of students taking the NCLEX), two are hospital-related programs, Presbyterian and Carolinas. These five programs also produce graduates who, on average, pass the RN licensure exam at a rate of approximately 90% on first writing.

A hospital-related nursing student tends to be older than the average university student with age ranging from 25-29 years. Most students have prior college experience, degrees, and/or careers in other fields. According to a survey of the five hospital-related programs, (March 2004), 97% of their graduates remain in North Carolina to practice. Most graduates stay within the community where they were educated and many of these associate degree and diploma graduates pursue BSN or master's (MSN) degrees.

Advantages of Hospital-related Nursing Education Programs

Several advantages of hospital-related programs are due to the relationship with their sponsoring hospital. The students in hospital-related programs typically have the best of both the education and the healthcare provider worlds as these hospitals provide excellent, often cutting edge, clinical opportunities. While the programs tend to get first choice for clinical experiences at their sponsoring hospital, most negotiate, as do other programs, for selected and limited clinical sites. All hospital-related programs report that 100% of their full-time faculty are master's prepared and all meet or exceed the NC Board of Nursing requirements for clinical experience. Hospital-related programs provide a significant recruitment resource to their affiliate hospitals, as many of the graduates choose to work in the hospitals where they receive their clinical experiences. Frequently, students in hospital-related programs can find meaningful work experience in the hospital as nursing assistants or other related jobs while they are enrolled in the nursing program. This sets the stage for a seamless transition from the role of student to employee when the student accepts employment beyond graduation. This seamless transition is beneficial for financial, human resources, and orientation reasons. Obviously, it can therefore significantly reduce the cost to hospitals for recruiting and orienting these new graduates. Hospitals sponsoring these programs report consistently lower RN vacancy rates than other hospitals in the state.

Although hospital-related programs are somewhat insulated from state and political budget considerations, a disadvantage for these programs is there is no state or federal funding to support their operations. A prevailing myth is that hospital-related programs are adequately funded due to the Medicare pass-through funding available to hospitals that support nursing and allied health education. While hospitals that sponsor nursing programs are eligible to receive the Medicare pass through funding, it is up to the institution as to how the funding is allocated and that funding represents a modest portion of overall program costs.

Hospital-related programs in North Carolina tend to utilize approximately 80% of their approved NC Board of Nursing slots. It is important to note that on average the hospital-related programs also retain 65-75% of their students in contrast to significantly lower rates of 50% or lower reported by the community colleges. Hospital-related programs report average graduation rates of 60-70%. While some 60-70% of their graduates remain at the sponsoring institutions for employment, these graduates tend to be mobile, but do remain in North Carolina in much higher percentages.

Hospital-related programs have the same concerns as other programs regarding "aging of the professorate" and availability of academically and experientially qualified nursing faculty for replacements. Salaries at these programs generally are more competitive due to internal equity issues including clinical salaries and lower faculty turnover rates. These factors contribute to higher faculty satisfaction rates and stable work environments.

The attributes of hospital-related college programs as described in the Lewin report, which make them valuable to student and local healthcare providers are:

- Programs are closely aligned with and responsive to the healthcare marketplace.
- These programs substantially contribute to local workforce development.
- These programs provide important career mobility opportunities.
- Expertise in clinical teaching is a hallmark of hospital-related programs.

While anecdotal comments reflect that there are hospital administrators who believe that working with the community colleges and the universities is preferable to sponsoring a hospital-related nursing education program, it is worth noting that one major hospital in North Carolina reactivated its nursing education program in the 1990s after many years of working with a local community college, citing issues of insufficient quantity and quality of graduates under the existing relationship. Given the vagaries of today's healthcare economies, especially for hospitals, it may not seem prudent to recommend reactivating hospital-related nursing programs. However, for five hospitals in North Carolina, which have weathered the financial and educational trend storms, nursing shortage issues have been removed from or are very low on their list of priority concerns.

Although the NC Institute of Medicine Task Force on the NC Nursing Workforce did position itself in support of strengthening and expanding all types of nursing education programs in North Carolina in order to meet the projected needs, it became apparent that due to the small number of hospital-related programs as compared to the community college and university systems, these programs would receive limited attention in the Task Force deliberations and recommendations.

Therefore, it is imperative that as policy makers and stakeholders determine how best to respond to the recommendations of the Task Force, hospital-related programs and their students must be included as part of the answer. **NCMJ**

How LPNs Can Be Part of the Solution

Patricia A. Beverage, LPN

One of the most common questions I am asked is: What is the difference between a registered nurse (RN) and a licensed practical nurse (LPN)? My standard response has been their level of education and the dependence or independence of their practice. It is surprising how many medical professionals do not know the difference in the levels of nurses working with them. To them, a nurse, is a nurse, is a nurse.

Licensed practical nurses (LPNs) use specialized knowledge and skills to provide care for the sick, injured, convalescent, and disabled under the direction of physicians and registered nurses. LPNs are required to pass a licensing examination (NCLEX-PN) after completing a state-approved practical nursing program. Thirty-two of the 33 North Carolina PN education programs are a part of the NC Community College System. The Department of the Army runs the one other PN educational program.

LPN Origin and Practice

LPNs were created amidst another severe nursing shortage during World War II. The NC Nurse Practice Act was amended to regulate the practice of a Licensed Practical Nurse. These nurses were to be taught the basic knowledge of pathophysiology and would be educated primarily in the delivery of hands-on nursing care. This would enable RNs to care for a larger number of patients with the assistance of educated and licensed personnel.

Depending upon location, LPNs work in operating rooms, nurseries, and labor and delivery units. LPNs work on medical/surgical units, cardiac and intensive care units. LPNs work in emergency rooms, ambulatory care clinics, public health and occupational health clinics. LPNs provide care in assisted living facilities and in nursing homes. In fact, LPNs supervise care provided by nursing assistants in most nursing homes.

LPNs take vital signs, treat wounds, give medications, and perform venipuncture. LPNs insert catheters, nasogatric tubes, assist with hygiene, feed patients, record intake and outputs in addition to caring for their patient and their family's emotional needs. In some facilities, LPNs can give intravenous medications, hang blood, or other higher levels of care. LPNs can also assist in developing care plans. In doctor's offices and clinics LPNs perform tasks such as giving immunizations or clerical duties. LPNs also work in private homes, which may include providing simple meals for patients, doing light housekeeping, and teaching the family members to perform simple nursing tasks.

Practical Nurse education prepares LPNs to "assess" patients—just like RNs—and report these assessments to direct supervisors, as do the RNs. The difference is that LPNs are not permitted to perform an intervention without first reporting their findings.

LPN Employment

Over the past 20 years, NC LPNs have seen major changes in the location of their employment opportunities—from being primarily hospital-based to nursing home-based. More LPNs have found employment in community agencies, such as health departments, mental health facilities, hospice and home care.

The US Bureau of Labor Statistics (BLS) predicts a continued decline in LPN positions in hospitals.[1] The BLS also predicts an increase in the use of LPNs in medical offices and clinics, ambulatory surgical centers and emergency medical centers as the occurrence of sophisticated procedures that were only performed in hospitals move to these facilities. Advancing technology will play a major role in the growth of the use of LPNs in these healthcare arenas. LPN employment in nursing homes is also expected to grow, as the need for long-term care expands along with our growing aging population.

Table 1.
LPN Place of Employment in 1982 and 2001

Place of Employment	1982	2001
Hospital	62%	19.5%
Nursing Home	15%	39.5%
Community Agencies	1%	9.5%
Medical Offices	8.4%	18.9%

Patricia A. Beverage, LPN, is the President of the NC LPN Association and a member of the Task Force on the NC Nursing Workforce. She can be reached at patriciabeverage@hotmail.com or 910-450-3192.

Suggestions from LPN leaders

The elected professionals representing LPNs believe the state of North Carolina could help alleviate part of its nursing shortage by allowing LPNs to play an active role in all aspects of nursing. A noted national leader in nursing, Dr. Margaret McClure, RN, EdD, FAAN, President of the American Academy of Nursing, said it best, "Nursing needs people with different skill sets and talents—whether it's an aptitude for technology or interpersonal communications. Everyone can find a place to thrive and be happy and be useful in this broad and challenging field."[2]

The NC LPN Association Executive Board recommended the following to the NC Institute of Medicine Task Force on the NC Nursing Workforce:

1. Ask employers to help LPNs obtain continuing education. If LPNs do not meet employer needs in facilities, employers should help and/or allow LPNs to obtain those courses or certifications needed to meet these needs.
2. Provide LPNs with career ladders. Offering LPNs an opportunity to advance will inspire them to seek further education or certifications. Recognition, money and benefits are attractive incentives.
3. Involve LPNs and the rest of the staff in developing more flexible and amiable work schedules to help meet their personal needs. This could help decrease the number of "call outs" and the scramble for last minute replacements.
4. Challenge LPNs to improve. LPNs have untapped potential to succeed. Challenge them to do so.
5. Respect LPNs. LPNs would like to feel respected and recognized for the critical role they play in healthcare.

The Task Force Report aptly stated that:

> "For adults, with or without family commitments, wishing to enter the nursing workforce, the PNE program is an efficient way of doing so. It assures access into the nursing profession for nontraditional, high school and adult students who do not have more than 12 months to invest in educational pursuits because they must support a family. LPNs have limited opportunity with regard to career ladders and educational programs that allow them to advance their nursing careers. Considering the need for nurses at the bedside, program length and accessibility, the PN education may be one of the more cost-effective ways to increase direct care nursing workforce numbers."

The Task Force also made recommendations in Chapters 3 and 4 that address some of the NC LPN Association requests. The Task Force recommended that community colleges expand the production of prelicensure PNs (Rec. # 3.1d); hospitals and other nursing employers consider tuition remission programs to encourage their nursing employees to pursue LPN-RN, RN-BSN, MSN or PhD degrees (Rec. # 3.27); and healthcare employers improve the work environment (e.g., by involving nurses in policy making and governance decisions and providing opportunities for advancement) (Rec. 4.1a-j).

We feel this is a first step toward using LPNs as part of the solution to the predicted nursing workforce shortage. Again, as Dr. McClure said, there is a place for everyone in healthcare and nursing. My hope is that this Task Force report helps us to find the means to that end and to make healthcare safe and available for the citizens in North Carolina. **NCMJ**

COMMENTARY

A Critical Need for a More Diverse Nursing Workforce

Virginia W. Adams, PhD, RN, and Patricia J. Price-Lea, PhD, RN, C

As we face a potential nursing shortage, we should consider who is missing from the current nursing workforce. Racial and ethnic minorities are underrepresented in the North Carolina nursing workforce, as are men. Only about 12% of the RN workforce were racial and ethnic minorities in 2001, compared to 28% of the state's population.[1] This percentage has increased only slightly over the last 20 years when only 8% of the RN workforce was part of a racial or ethnic minority (1982). LPNs more closely reflect the state's diverse population: 26% of the LPN workforce was from a racial or ethnic minority in 2001.

Males are even more under-represented in the nursing workforce: only 6.6% of RNs, and 5.1% of LPNs are men, compared to 49% of the state's population.[2] While it is important to address both of these issues—the recruitment of racial and ethnic minorities and men into nursing—this paper focuses on efforts to increase the supply of racial and ethnic minorities in the nursing profession.

Table 1.
Racial Composition of Licensed RNs and LPNs in the NC Nursing Workforce (2001)

	RNs	LPNs
White	87.8%	73.7%
African American	8.7%	23.2%
American Indian	0.6%	1.2%
Asian or Pacific Islander	1.6%	0.4%
Hispanic	0.5%	0.7%
Other	0.5%	0.6%
Unknown	0.3%	0.3%

Source: Lacey, Linda M. and Shaver, Katherine. North Carolina Trends in Nursing: 1982 - 2001 RN and LPN Workforce Demographics. March, 2003. www.nursenc.org/research/Trends2001/workforce_demos.pdf

Why Diversity in Nursing Is Important

Attracting a more diverse population into the profession serves many purposes. First, studies have shown that racial and ethnic minorities are more likely than their white cohorts to serve underrepresented communities.[3] This helps improve access to healthcare for minority patients and reduce healthcare disparities. When given a choice, patients are more likely to select a healthcare professional of their own racial or ethnic background and are generally more satisfied with the care provided them by these providers. Minority health providers are also more likely to practice in community-based settings that serve low-income populations or in settings less coveted by non-minority nursing professionals. In North Carolina, for example, African-American RNs are more likely to practice in public health clinics, mental health facilities or long-term care settings: they comprise 9% of the total RN workforce, but 13% of the long-term care, 13% of the public health, and 20% of the mental health facility workforce.[4]

Minority providers can also help bridge cultural and language gaps in practice and in education. For example, Latino nurses can help bridge language gaps. Currently, more than 5% of the state's population is Latino, many with limited English proficiency. Increasing the numbers of Spanish-speaking Latino nurses could help ameliorate language and cultural barriers that exist for many of the recent Latino immigrants to our state. Bilingual nurses in practice and education contribute substantially in diminishing these barriers.

A diverse student body and workforce can also improve the cross-cultural training of all students. The interaction of students from diverse backgrounds provides a broader perspective of racial, ethnic, and cultural differences. Reaching out to racial and ethnic minorities could also help broaden the pool of potential nurses. In short, creating a more diverse workforce is beneficial in creating a sense of community, narrowing the health disparity gap, and promoting the health of all people.[5]

Virginia W. Adams, PhD, RN, is Dean and Professor at the School of Nursing at the University of North Carolina at Wilmington and a member of the Task Force on the NC Nursing Workforce. She can be reached at adamsv@uncw.edu or at 601 S. College Road, Wilmington, NC 28403-3297. Telephone: 910-962-7410.

Patricia J. Price-Lea, PhD, RN, is Dean and Associate Professor at the North Carolina A&T State University School of Nursing and a member of the Task Force on the NC Nursing Workforce. She can be reached at pricelea@ncat.edu or 1601 East Market Street, Greensboro, NC 27411. Telephone 336-334-7751.

Recruiting, Admitting, and Graduating Racially Diverse Nusing Students

To achieve a more diverse RN workforce in North Carolina, we must do more to recruit, admit and graduate racial and ethnic minorities in nursing programs.

Recruiting minorities into nursing: Ideally, recruitment should begin by reaching out to underrepresented populations while in elementary and high schools to encourage them to explore a career in nursing and to advise appropriate classes that will academically prepare them for nursing programs. The NC Institute of Medicine Task Force Report on the NC Nursing Workforce has partially addressed this problem. It recommended:

> The North Carolina General Assembly should appropriate additional funds to the NC Center for Nursing (NCCN) for the next five years to expand and enhance the outreach and recruitment efforts targeted to racial and ethnic minorities and males. The NCCN should report to the NC General Assembly on an annual basis on the progress in recruiting minorities and men into nursing. Funding should be tied to meeting certain performance thresholds. An image campaign about nursing and nursing work targeted specifically to the African American and Hispanic/Latino communities, as well as males in general, should be strengthened and promoted. Such a public information campaign should make clear the multiple pathways available to any person interested in a nursing career, as well as the opportunity for advanced educational opportunities following entry to the profession through any portal. (Rec. #3.22d).

Further, the Task Force also recommended that high school, community college and university guidance counselors receive additional training to provide better information to students who may be interested in a nursing career (Rec. #3.23).

While these recommendations are helpful, they will not fully address the problem. The NC Center for Nursing can help create an interest in nursing programs among underrepresented populations, but it is not an educational institution, so consequently has no authority to admit these students. In addition to the new appropriations to the NCCN, funds should be appropriated directly to nursing education programs for targeted outreach and recruitment efforts. Not only can educational institutions reach out directly to students, but they can also develop partnerships with community leaders to create trust and a positive image of the institution. The nursing educational programs that receive funding should be held accountable for increased admissions and subsequent graduation of nursing students from the various racial and ethnic populations.

Nursing education programs: To achieve a more diverse nursing workforce, nursing programs first must admit and graduate students from diverse backgrounds. Together, leaders in education and practice must be accountable for the preparation and graduation of a critical mass of registered nurses from racial ethnic backgrounds beginning with African Americans.

Segregation and Nursing Education: Historic Barriers and Progress

Historically, the opportunity to provide a quality education for African American students was limited, as the education of African Americans was restricted to Historically Black Colleges and Universities (HBCUs), first through laws and later through practice. The legal right for African Americans to attend predominantly white institutions was not guaranteed until 1954, when the Supreme Court in *Brown v. Board of Education of Topeka Kansas*, 347 U.S. 483 (1954), nullified *Plessy v. Ferguson*, 163 U.S. 537 (1896), which had supported "separate but equal" education. One year after the *Brown* decision, North Carolina was still fighting against admission of black students to the University of North Carolina. This was resolved in 1955, when UNC was legally required to admit black students in *Frasier v UNC Board of Trustees*, 134 F.Supp. 589 (1955).[6] Despite the Brown decision, educational institutions in this state and around the country made it difficult for black students to enroll.

Historically, when black students were denied admission to all-white programs, both black and white leaders initiated nursing programs for black students. HBCUs boast of graduating most of the African American registered nurses in North Carolina.[7] From 2001-2003, 65% of the African American nursing graduates in the public baccalaureate and higher degree programs were awarded degrees from three of its HBCUs.[8] In 2001, for example, HBCUs in North Carolina educated 3.4% of the active RN workforce, but 26% (~1,750) of the practicing African American RNs.[9]

Although Historically Black Colleges and Universities have produced a disproportionate proportion of the African-American nurses currently practicing in the state, it is the responsibility of all public nursing programs in North Carolina to produce a more diverse workforce. To achieve this goal, institutions and nursing programs must be committed to a more diverse student body. In addition, they can employ other strategies which can help improve their records of training and graduating a diverse student population:

- **More inclusive admissions policies.** Rather than relying primarily on standardized tests, traditionally white educational programs need to consider additional methods for admitting students to nursing programs. Because minority students are more likely to be educated in lower-wealth schools with fewer educational opportunities, they often score lower than whites or Asian-Americans on standardized tests. Admissions committees should consider other qualities linked with professional success in their selection process, including leadership, personal life experiences, commitment to service, and multilingual abilities. In addition, minority faculty should be asked to serve on admissions committees.
- **Hire more minority educators and help prepare white faculty to be more attuned to the needs of a diverse student population.** Nationally, only 9.5 % of full-time nursing faculty represent racial/ethnic minority groups.[10] This statistic

suggests a dire need for more minority educators. However, all educators, not just those from racial and ethnic minority groups, need to be culturally sensitive to the needs of underrepresented student populations. One option to help sensitize white faculty to the needs of minority student populations is to encourage white faculty to have visiting professor immersion experiences on campuses with a more diverse student population.

- **Mentoring and social support.** A critical mass of underrepresented groups should be admitted to ensure their social support rather than admitting one or two students in the typical class. Further, while not unique to a minority student population, nursing schools should provide academic and social supports needed to ensure academic success, including faculty mentoring, academic tutoring and educational counseling services.
- **Removing financial barriers.** Minority students often come from lower-income families and may find the cost of education to be prohibitive. Scholarships, loan forgiveness and stipends are needed to help assist these low-income students (of any racial or ethnic background) to pay for their nursing education.
- **Other strategies.** Other reliable strategies include avoiding labels that create unnecessary hurdles for students or perpetuate old stereotypes of racial/ethnic groups, developing curricula and teaching standards that recognize commonalities and respect for differences, and ensuring the history of underrepresented groups as part of the curriculum.

If North Carolina and its public nursing education system intend to remain strong and be a model for the rest of the country, it has to provide quality education for all of its citizens. Moreover, it needs to acknowledge and embrace the benefits of a diverse registered nurse workforce. Proficiency in relating to cultures different from one's own becomes an essential ingredient in the skill set for the 21st century healthcare professional. Success for students from diverse populations means success for the state and improved healthcare for its citizens. Due to widening racial disparities in healthcare, this phenomenon is significant.

Students who learn together are more likely to work well together. Microbiology teaches us that organisms improve their chances of survival by interacting with one another. Therefore, if individuals tend to work only with their own ethnic group, everyone's existence is threatened. Leveraging diversity expands one's capacity to learn and survive. Patients, communities, and the healthcare system will be the beneficiaries of a more diverse registered nurse workforce. **NCMJ**

Developing an Adequate and High Quality Nurse Aide Workforce in North Carolina

Susan Harmuth, MS, and Jesse S. Goodman, III

North Carolina is experiencing a shortage of direct care workers. Direct care workers include an array of paraprofessional caregivers such as nurse aides, home health aides, and personal care aides.[1] Nurse aides work under the supervision of a registered nurse and represent a significant portion (54%) of North Carolina's direct care workforce.[2] Nurse aides are employed in a variety of healthcare settings such as hospitals and doctors' offices and are also widely employed in an array of long-term care settings such as home care agencies, adult care homes and skilled nursing facilities.

Nurse aides (and other direct care workers) are recognized as the front-line caregivers in the long-term care arena and are the staff likely to have the most direct contact with residents. Nurse aides help residents with basic daily living tasks such as bathing, dressing and toileting and also perform various healthcare tasks such as taking vital signs, changing dressings, skin care, transferring, positioning and turning, and basic restorative services.

Direct Care Worker Turnover Rates

The North Carolina Department of Health and Human Services, in collaboration with the UNC Institute on Aging, annually compiles turnover data on direct care workers employed in licensed home care agencies, adult care homes and nursing facilities. Data collected through this process helps illustrate that the average annual turnover rate for Nurse Aides in North Carolina's nursing facilities was 95% in 2002. This compared to 115% for direct care workers in North Carolina's assisted living facilities and 37% for direct care workers employed in licensed home care agencies. Table 1 shows average annual turnover rates for 2000 through 2002 for direct care workers in three major categories of long-term care settings.

Table 1.
Average Annual Turnover Rates of Direct Care Workers in NC, 2000-2002

Setting	2000	2001	2002
Skilled Nursing Facilities	100%	103%	95%
Adult Care Homes	119%	113%	115%
Home Care Agencies	50%	50%	37%

Note: All percentages have been rounded to the nearest whole number. Turnover data for these settings is collected and analyzed annually through a collaborative effort between the NC Department of Health and Human Services and the UNC Institute on Aging.

According to the US Bureau of Labor Statistics, nurse aides are among the top 10 occupations nationally with the largest projected growth rate between 2002 and 2012. The number of nurse aides needed nationally will increase by 25% between 2002-2012. In contrast, North Carolina is projected to see a 36% increase in the number of nurse aides needed between 2000 and 2010 (most recent state-specific data available) increasing from 44,850 in 2000 to 61,050 in 2010. This equates to 2,220 new job openings per year over the ten-year period. The projections are inclusive of both new jobs created and existing jobs that are vacated.

North Carolina's Nurse Aide I Registry includes all individuals who have successfully completed a North Carolina approved Nurse Aide I Training and Competency Evaluation Program or a Competency Evaluation Program. Over the last three years North Carolina has seen an increase of over 16,500 individuals eligible to work as Nurse Aide I's. While this increase has helped to relieve the workforce shortage, much of this increase may be attributed to the reduction in employment opportunities in other competing sectors as a result of the soft economy. It is anticipated that improvements in the economy will bring added competition from other employment sectors for these

Susan Harmuth, MS, is a Long-Term Care Specialist with the Office of Long-Term Care in the NC Department of Health and Human Services and can be reached at Susan.Harmuth@ncmail.net or at 2001 Mail Service Center, Raleigh, NC 27699-2001. Telephone: 919-733-4534.

Jesse S. Goodman, III, is Chief of the Health Care Personnel Registry Section of Division of Facility Services in the North Carolina Department of Health and Human Services and a member of the Task Force on the NC Nursing Workforce. He can be reached at Jesse.Goodman@ncmail.net or 2701 Mail Service Center, Raleigh, NC 27699-2701. Telephone: 919-855-3750.

individuals. Therefore, the challenge that faces the state is the development of incentives, both financial and career advancement, which will keep these individuals in the healthcare field.

Recruitment and Retention Efforts

The NC Department of Health and Human Services, in collaboration with many partners, has a number of initiatives underway to improve the recruitment and retention of direct care workers as well as improve the quality of direct care jobs. The Kate B. Reynolds Charitable Trust provided grant funding for the design and planning of the recruitment and retention initiative, which included the initial funding for the Win-A-Step-Up program as well as the turnover and labor market data collection efforts outlined earlier in this article.

Major activities underway include the development of two new job categories intended to provide career advancement opportunities for paraprofessionals and respond to staffing needs of long-term care related providers. The two job categories include a medication aide and a geriatric nurse aide.

> *"North Carolina's population and nursing care workforce, like the nation's, is aging and there will not be enough people in the workforce to fill healthcare positions when they are needed the most."*

The Medication Aide Project is a cooperative effort between the NC Department of Health and Human Services and the NC Board of Nursing, and is in the second year of development. The project is now in the final stages of developing standards for prerequisites and training requirements for faculty and students, statewide competency testing and the creation of a statewide registry. Pilot testing is expected to begin in the spring of 2004. Legislation that may be needed to implement this initiative will be developed for introduction in the 2005 session of the North Carolina General Assembly.

The Geriatric Aide Project is a cooperative effort of the NC Department of Health and Human Services and the NC Community College System. A curriculum is currently under development and is focused on more in-depth education for nurse aides in the areas of prevention and care of pressure ulcers, unplanned weight loss/dehydration, infection control, pain management, behavioral management, resident depression, safe mobility, care of the terminally ill and care of the caregiver. This educational program will require Nurse Aide I training as a prerequisite and will be a key component of the state's overall career ladder initiative for direct care workers.

- A program, known as Win-A-Step-Up, is a voluntary program that provides financial and other incentives to nurse aides working in nursing facilities in exchange for completion of certain training components and agreeing to stay with their employer for a specific period of time. Employers must agree to provide either a wage increase or bonus (or both) to participants who complete the training and retention commitment. This program is a collaborative effort between The NC Department of Health and Human Services and the UNC Institute on Aging.
- North Carolina is one of five state-based coalitions funded nationally to implement a *Better Jobs Better Care* demonstration grant. These 42-month demonstration grants, funded by The Robert Wood Johnson Foundation and The Atlantic Philanthropies, are intended to implement policy and practice changes that will improve the ability to attract and retain high-quality direct care workers to meet the needs of long-term care consumers in both home-and-community and facility-based settings.

Specifically, North Carolina's *Better Jobs Better Care* coalition will develop, pilot, and implement a uniform set of expectations and criteria. These will be applied on a voluntary basis in home care, adult care homes and nursing facilities across the state and will result in a special licensure designation for entities that meet the voluntary criteria. Expectations and criteria being developed will address issues such as: effective care teams; peer mentoring, coaching supervision and other supportive workplace criteria; staff development and career advancement opportunities, safe and balanced workloads, etc. This special licensure designation is intended to potentially serve as the basis for awarding a differential reimbursement increase or eligibility for labor enhancement funds.

Nurse Aide Training

Because nurse aides represent such a large component of the direct care workforce, statewide availability of nurse aide training programs is a key factor in the success of any direct care recruitment efforts being implemented. The NC Community College System has taken on the responsibility of serving as the primary resource for nurse aide training across the state. In some parts of the state, access to a community college-sponsored nurse aide training program by persons interested in working as a nurse aide is limited. This is due to a variety of reasons, including insufficient clinical lab space and demand for nurse aide training programs by students interested in enrolling in registered nurse training programs. The Community College System's ability to respond to training needs of both persons seeking further professional nursing education and nurse aide training will be an important building block to developing an adequate and stable

supply of nurse aides available to provide care in long-term care related settings, hospitals and other healthcare-related settings.

Conclusion

The nursing workforce challenges that North Carolina faces are complex, with even more complex solutions. The current workforce shortage is seen as short-term, but the labor shortage that is predicted for the next 30 years is not. North Carolina's population and nursing care workforce, like the nation's, is aging and there will not be enough people in the workforce to fill healthcare positions when they are needed the most. According to the US Bureau of the Census *1999 Statistical Abstract of the United States*, between 2010 and 2030, there will be a 7% increase in the number of people 65 and over as a proportion of the total population and a 6% decrease in the proportion of people ages 18 to 64, relative to the total population. Competition for qualified individuals to enter the healthcare workforce of the future will be keen and the North Carolina Institute of Medicine and the Duke Endowment should be applauded for their foresight in recognizing the need for North Carolina to act now to develop a comprehensive approach to address this complex issue. We believe that the initiatives that are currently underway and supported by the Task force on the NC Nursing Workforce to address the direct care workforce shortage are a good start. **NCMJ**

REFERENCES

1 The US Bureau of Labor Statistics classifies direct care workers into three major categories including: 1) nurse aides, orderlies, and attendants; home health aides; and personal and home care aides and attendants. It should be noted that the term "direct care workers is not to imply theat licensed nurses are not involved in direct patient care.

2 US Bureau of Labor Statistics, 2002 Employment and Wage Data, North Carolina specific data. It should be noted that the term "direct care workers" is not to imply that professional nurses are not involved in direct patient care.

COMMENTARY

The North Carolina Area Health Education Centers' Role in Addressing Nursing Workforce Issues

Thomas J. Bacon, DrPH, Gail O. Mazzocco, RN, EdD, and Karen D. Stallings, RN, MEd

Introduction

The need for nurses at all levels of the healthcare system continues to grow at a pace that outstrips the current supply, both nationally and in North Carolina. The report of the North Carolina Institute of Medicine Task Force clearly documents the multiple strategies that will be required to address this highly complex problem. We must increase the output of nurses from our educational institutions, although that alone will not solve the problem. We must improve the retention of nurses in the profession by strengthening the work environment, empowering nurses as decision makers, recognizing outstanding performance, and fostering career growth opportunities. We must also attract young people and second career professionals into nursing that represent the rich diversity of the North Carolina population.

For over 30 years the North Carolina AHEC Program has worked in close collaboration with academic nursing programs, employers, and practicing nurses to prepare and retain a nursing workforce that can meet the healthcare needs of our state and our communities. We remain committed to developing innovative approaches to improving the recruitment, retention, and quality of the nursing workforce. AHEC nursing faculty work with the NC Center for Nursing, the NC Board of Nursing, the NC Nurses Association, and a wide variety of nursing groups to maximize efforts.

Core AHEC Nursing Initiatives

Promoting Careers in Nursing

To prepare a more diverse healthcare workforce, the AHEC Program conducts programs to recruit underrepresented and disadvantaged middle and high school students into health careers. AHECs work annually with over 25,000 young people in order to inform them of opportunities in the health field, including nursing. These programs offer mentoring, hands-on experiences in clinical settings, and also include academic work to strengthen students' skills in math, science, and communication, so that they can succeed in entering and completing nursing programs.

Nursing Student Training in AHECs

Education of nursing students takes place in a variety of healthcare institutions, agencies, and educational settings throughout AHEC regions, and, whenever possible, in underserved rural and urban areas with vulnerable populations. Essential clinical training for primary care nurse practitioners (NPs) and nurse midwives is provided under the auspices of the Area Health Education Center (AHEC) Offices of Regional Primary Care Education. Last year 2,551 student weeks of community-based experiences for NP students were supported through AHEC.

> *"North Carolina continues to require more nurses prepared at the baccalaureate level and above."*

Continuing Education

Continuing Education (CE) plays a major role in professional career development. The state's nine AHECs offer a variety of nursing CE programs and technical assistance services to address changing technology, clinical guidelines, patient safety, new medications, specialized nursing care, physical assessment, transition from acute care to home, and long-term care.

Thomas J. Bacon, DrPH, is Executive Associate Dean at the UNC-Chapel Hill School of Medicine and Director of the NC AHEC Program and a member of the Task Force on the NC Nursing Workforce.

Gail O. Mazzocco, RN, EdD, is the Statewide AHEC Nursing Liaison for the UNC-Chapel Hill School of Nursing.

Karen D. Stallings, RN, MEd, is an Associate Director of the NC AHEC Program and a steering committee member of the Task Force on the NC Nursing Workforce. The authors can be reached at tom_bacon@med.unc.edu, karen_stallings@med.unc.edu, and mazzocco@email.unc.edu or at Campus Box 7165, Chapel Hill, NC 27599-7165. Telephone: 919-966-2461.

Spanish language and cultural competency training programs help nurses work more effectively with our growing Latino population. Last year, AHEC offered 650 nursing continuing education programs, attended by more than 16,750 nurses. The NC Institute of Medicine (NC IOM) Task Force Report on the NC Nursing Workforce points to the fact that nurse retention in workplace settings is increased with progressive management practices, when nurses feel empowered in the decisions that are made, and when education is valued. AHEC continuing education programs teach nurses to become effective managers, a fundamental element in workforce retention.

Special Legislative Initiatives

In 1989, the NC General Assembly allocated funding to the NC AHEC Program for three initiatives: nurse refresher programs, educational mobility programs, and clinical site development.

Nurse Refresher Program

The AHEC Program collaborates with UNC-Chapel Hill to offer a refresher program for registered nurses. The course, which includes self-study modules and preceptored clinical experiences, helps registered nurses who have not been employed return to the workplace. Additionally, nurses who are currently employed but would like to move into new clinical areas may also use the program to update their knowledge and skills. Over the last 13 years, approximately 1,300 nurses have enrolled in this recruitment and retention program and almost two-thirds of them have returned to clinical practice.

Educational Mobility through Off-Campus Degree Programs

North Carolina continues to require more nurses prepared at the baccalaureate level and above. AHEC nurse faculty collaborate with schools of nursing to develop and operate off-campus RN-to-BSN and MSN programs in underserved areas of the state. These programs meet the need for flexible distance education formats, allowing nurses to advance their educations while continuing to work in their home communities and care for their families. AHECs provide on-site assistance such as classrooms, library resources, information services, logistical help, and student support. Given current faculty shortages in schools of nursing, master's degree programs that prepare faculty with both clinical and didactic educational preparation are especially needed. The 120 students who are currently enrolled will soon join the more than 1,000 graduates of AHEC sponsored off-campus programs.

Clinical Site Development

New clinical training sites in rural, long-term care, and critical care settings assist schools of nursing to maximize enrollment and provide significant periods of training in workforce shortage areas. As directed by legislation, the NC AHEC Program provides clinical site development grants to the schools of nursing within the community colleges and the constituent institutions of the University of North Carolina. AHEC nurses work with schools of nursing to identify new clinical sites for development, assist with funding, provide preceptor training, and consult on areas related to student use of clinical sites. More than 250 clinical sites have been developed as part of the grants program and 52 new sites are currently being developed.

New Initiatives

While existing endeavors have been both effective and supportive, AHEC is also working on new strategies that address current employment challenges. Several of these approaches enhance nurses' continuing education opportunities, even while assisting with the development of supportive work environments.

The Nursing Management Institute (NMI), funded through The Duke Endowment, offers training for nurses to develop the administrative skills that are required in today's healthcare environment. This on-line certification program, which includes essential management content, is convenient, inexpensive, and may be completed either as a series or as individual modules. Moreover, an organization may enroll a group of staff members in the program and benefit from the shared knowledge and understanding of an entire employee cohort.

Magnetizing Your Organization is an initiative that has a similar purpose. This statewide program assists healthcare institutions that may not be able to achieve magnet status learn about and institute enhancements that are typical of Magnet organizations. Day-long programs have already been presented in three regions of the state, where over 300 participants have benefited by the program.

Finally, the **Clinical Teaching Associate (CTA) project**, designed by Northwest AHEC has been piloted this year by North Carolina Baptist and Forsyth Hospitals, Winston Salem State University and Forsyth Technical Community College. According to the NC IOM Task Force *Report on the NC Nursing Workforce*, many able students are turned away from nursing programs, in part because of the lack of clinical faculty. The CTA project, funded by an AHEC grant, allows appropriately prepared staff nurses to work at their employing institution as clinical faculty members for part of their regular work time. Clinical teaching associates have the opportunity to explore a new role, introduce current clinical skills to students and increase student enrollment.

Current Challenges and Opportunities for the Future

The three initiatives described above are examples of ways that AHEC has expanded its historical role to create additional training capacity and sharpen its focus through its traditional continuing education efforts. Unfortunately, all three of these initiatives have been funded with grant support, either from foundations or through special AHEC grants. Due to state revenue shortfalls, the AHEC budget has been reduced by approximately 15% over the last four years. As a result, all new initiatives in nursing and other fields have been funded by either reallocating existing funds or utilizing grant dollars.

There are a number of additional training needs that exist across the state that AHEC is prepared to address, assuming funding is forthcoming in future years. As the state grows out of the recession, it is hoped that additional state resources will be appropriated to address these critical nursing issues, as well as those affecting other health professions. Some of the areas where AHEC is prepared to take the lead, either building on existing programs or developing new initiatives, are as follows:

a. **Expanded training capacity.** Building on its current efforts, AHEC is prepared to fund additional clinical site development grants, and fund companion efforts in preceptor and faculty development. These will be essential if the baccalaureate and community college programs are to add the kind of clinical training capacity they need in order to expand enrollments. As it has in the past, AHEC will focus these grants in underserved areas, and in specialty areas where clinical sites have historically been in short supply.

b. **Expansion of educational mobility grants.** A clear recommendation of the IOM Task Force is to expand greatly the career mobility opportunities for nurses at all levels. With additional resources, AHEC is prepared to both expand existing educational mobility grants and to develop new areas of focus. Areas where there continues to be unmet need include:

   - LPN-to-RN Programs
   - Educational Masters Degree Programs in remote site locations, in order to prepare additional faculty to fill vacancies in community colleges and universities
   - PhD Outreach Programs, in order to prepare additional faculty for baccalaureate and masters programs
   - Grants to Private Schools of Nursing, most of whom were excluded in the Legislation of 1989 creating the current grants program

c. **Retention Strategies.** Programs such as the Nurse Management Institute as well as the Magnetizing Hospital Series are designed to strengthen the working environment for nurses and improve retention. With additional resources, AHEC can provide permanent funding for these programs and similar efforts to strengthen the work environment. Programs are also needed to create skills labs for smoothing the transition from education to work, and AHEC is prepared to support the development of these programs as well.

d. **Diversity Initiatives.** Building on its prior work in health careers with young people, the AHEC Program is prepared to expand its work to the undergraduate level as well. AHEC proposes to develop a new grants program, patterned after the clinical site development grants, which would support innovative programs by community colleges and universities to recruit a more diverse student body. AHEC would offer grants to the schools to develop programs that recruit and retain more underrepresented groups, including minorities and men, into the field.

Conclusion

The AHEC Program has a long history of offering programs to improve the recruitment and retention of nurses for all types of healthcare settings in the state. As a partner organization of the NC IOM Task Force, and as part of its strategic vision for the future, the AHEC Program is prepared to build on successes of the past and develop new programs to assure that North Carolina has an abundant supply of high quality nurses to meet its needs well into the next decade. **NCMJ**

Transitioning from School-to-Work:
One Successful Model

Cindy Craven, RN, BSN, CCRN, Tammi Mengel, RN, MSN, CNAA, and Martha Barham, RN, MSN, CNAA

In the mid-1990s, the environment at High Point Regional Health System (HPRHS), like that of other healthcare organizations, was becoming increasingly complex. The healthcare team was challenged to meet the needs of a "sicker" patient, hospitalized for a shorter period of time, without compromising the quality of care delivered. Despite this increasing complexity, the orientation process for new graduate nurses remained unchanged. Orientation for a new graduate at HPRHS consisted of two weeks of general nursing orientation followed by department-specific orientation. The duration of department specific orientation varied from eight to 26 weeks, depending on the clinical specialty. Although each new graduate was assigned to a preceptor, learning opportunities and skill development were limited, as was constructive feedback. Inadequacies of the current program to successfully transition the individual from school environment to practice environment were demonstrated by the frequent need to extend the customary orientation period. This method of orientation did little to foster growth and development, especially critical thinking skills, and frustrated both the preceptor and the graduate nurse.

> *"Producing a competent, successful and happy nurse requires a partnership between nursing schools and healthcare organizations."*

At the same time, another nursing shortage was looming. Enrollment in area schools was declining and fewer student nurses were graduating. This new reality forced organizations to closely examine their recruitment and retention strategies as they positioned themselves to compete for the limited nurse resources. In examining retention effectiveness, HPRHS discovered an alarming trend related to retention of new graduates. In-depth analysis revealed the turnover rate of new graduates at 24 months was 48%. This unacceptable turnover rate was attributed directly to the stress of the transition from recent graduate to competent practitioner. As a result, in the spring of 1997, following painful open and honest dialogue between staff educators and department directors, it became clear that the current orientation process was in need of a major overhaul. The consensus was that new graduates were minimally prepared to care for patients, yet organizationally we expected an almost overnight transformation from student to expert clinician. This indeed was a very unrealistic expectation. A new program was desperately needed to support the recent graduate's transition from student to professional nurse, while reducing the level of stress experienced by the new graduate and preceptor.

Adopting a New Orientation Model

In the spring of 1997, a committee was formed, including staff educators, department directors and the Chief Nursing Officer, to create a new orientation model. To gain further understanding of opportunities for improvement, graduate nurses employed within the previous year were included in the process to provide feedback on the strengths and weaknesses of the current orientation process. Patricia Benner's "Novice-to-Expert" model provided the theoretical framework for development of the Graduate Nurse Orientation-Success in Specialty Program or GNOSIS (a Greek word meaning specialized knowledge).[1] The goals of the program were to implement an orientation process that would assist the new graduate in

Cindy Craven, RN, BSN, CCRN, is the Director Clinical Practice at High Point Regional Health System.

Tammi Mengel, RN, MSN, CNAA, is the Administrative Director of Nursing High Point Regional Health System.

Martha Barham, RN, MSN, CNAA, is Vice President and Chief Nursing Officer at High Point Regional Health System and a member of the Task Force on the NC Nursing Workforce. The authors can be reached at MBarham@HPRHS.COM or PO Box HP-5, High Point, NC 27261. Telephone: 336-878-6025.

his/her transition from student to novice practioner and to improve the retention of new graduates. Additionally, it was believed that improvements in the orientation process would also positively impact the work environment by reducing the stress levels of precepting nurses and nursing colleagues.

Given the critical role preceptors play in the success or failure of an individual's orientation, adequate preparation of the preceptors was deemed essential to ensure a successful transition to the GNOSIS program. To facilitate the shift in thinking, each preceptor was educated on Benner's model. Emphasis was placed on preparing the preceptors to provide new graduates with experiences designed to develop organizational skills, set priorities, and develop critical thinking and technical skills.

GNOSIS

The ten-week GNOSIS program includes both didactic and clinical experiences. Greater emphasis is placed on clinical "hands on" learning opportunities, as this is the area in which the new graduate has the least experience. Identification of personality type and learning style was felt to be an important factor in promoting optimal learning and growth experiences and, therefore, was a new addition to the orientation process. The structure of each week consists of one classroom day focused on a specific body system or care process with the remainder of the week spent in clinical areas that will enhance the knowledge gained in the classroom. Classroom activities draw from the expertise of a variety of disciplines including staff educators, case managers, respiratory therapists, chaplains and other healthcare providers. The classes cover topics related to all clinical areas including:

- Basic patient care skills (nurse aide skills/tasks)
- Basic nursing care skills (physical assessment techniques, admission and discharge process, equipment, skills such as insertion/removal of feeding tubes, catheters)
- Basic cardiac, neurological, respiratory, renal and gastrointestinal (anatomy and physiology, assessment, commonly seen diseases, medical care, nursing care, routine orders and common medications)
- Drug administration (review of drug classes, medication administration documentation, administration techniques, use of intravenous pump)
- Wound care (wound care protocols)
- Spiritual and ethical issues
- Pain management

Clinical experiences are designed to develop and enhance skills and increase the new graduate's comfort level and confidence in the clinical setting. To ensure that new graduates have the opportunity to maximize their learning experience, they are not counted in the staffing mix. As a result, this allows new graduates an opportunity to observe and participate in experiences frequently not available to them as students such as, cardiac catheterizations, invasive diagnostic procedures and surgical cases. These opportunities assist the new graduate in understanding the dynamics of the total patient care experience and increase their exposure to the organization.

To process the events of the week, new graduates meet with the GNOSIS Program Coordinator at the end of each week and share experiences. This provides an opportunity for the entire group to learn from each other and gives them the opportunity to build relationships. New graduates value time spent in this activity as it facilitates closure to the experiences of the week, enabling them to move forward to the experiences of the coming week.

> *"GNOSIS has given the new graduate the basic skill set necessary to begin this transition and the confidence needed to function in the clinical setting."*

Department-Specific Orientation Follows GNOSIS

Once GNOSIS is completed, new graduates begin department-specific orientation. This orientation time varies based on the clinical specialty. GNOSIS has given the new graduate the basic skill set necessary to begin this transition and the confidence needed to function in the clinical setting. He or she is now able to focus on further development of organizational skills and critical thinking as applied to their clinical specialty. Preceptors acknowledge that the new graduates are better prepared to embrace departmental orientation as a result of the time spent in the GNOSIS program. Graduates of the GNOSIS program have said, "The GNOSIS program not only helped me to develop my skills, it allowed me to see what happens in other areas of the hospital that I won't be working in," and "GNOSIS gave me the time to develop my skills and put what I learned in school together with what I was learning here."

Return on Investment

In terms of financial support, the program is included in the annual operational budget and funded to cover the orientation of 36 new graduates annually. Recognizing the organization's financial commitment for operating this program, new graduates sign a three-year work agreement. Failure to complete the work agreement results in a monetary "fine" to the nurse. The requirement of a work agreement has not proven to be a deterrent to participation in the program as new graduates have recognized the value and uniqueness of this program.

Implementation of the GNOSIS program has resulted in immediate and sustained success. To-date, 22 GNOSIS sessions have been completed. Currently the turnover rate at 24 months is 22% with the majority of turnover being unavoidable, such as relocation or return to school. When asked to evaluate the program, both new graduates and preceptors continue to validate the program's success in preparing the new graduate to practice effectively in the clinical setting.

The program requires an additional human and financial commitment from HPRHS; however, this expense is easily offset by the reduction in turnover, improvements in the work environment, and satisfaction of new graduates and preceptors. One might argue that it is the responsibility of the nursing schools to produce a more qualified, capable clinician. Unfortunately, given the constraints placed on today's educational programs and the complexity of the healthcare environment, it is impossible for one entity to accomplish this lofty goal alone. Producing a competent, successful and happy nurse requires a partnership between nursing schools and healthcare organizations. In this time of nursing shortage, visionary thinking and risk taking will be necessary as strategies are developed to prepare, grow and develop the future nursing workforce. As Florence Nightingale said, "For us who nurse, our nursing is a thing, which, unless in it we are making progress every year, every month, every week, take my word for it, we are going back." Our future nursing colleagues and the public we serve are depending on us to make progress every year, every month, every week. **NCMJ**

Advanced Practice Registered Nurses:
Current Problems and New Solutions

E. Harvey Estes, Jr., MD

The central focus of the Task Force on the NC Nursing Workforce was the chronic shortage of nursing personnel in hospitals, nursing homes and other healthcare facilities, and the steps that can be taken to alleviate and permanently correct this problem within our state. There is not a shortage of advanced practice registered nurses (APRNs), so the problems of this segment of the nursing profession might be considered tangential to or even irrelevant to the work of the Task Force. Nevertheless, practitioners of this segment of the nursing profession presented eloquent testimony to several problems which were perceived as imposing limitations on the full function and effectiveness of their practice. These are addressed in Chapter 5 of the report and in the recommendations within the chapter.

> *"The concept of collaborative practice, in which all practitioners understand and respect the abilities and knowledge of each other has merit and deserves attention..."*

Three major issues were identified: joint regulation by the NC Board of Nursing (NC BON) and the NC Medical Board (NCMB), requirement for physician supervision of practice, and unequal reimbursement for services.

Regulation

Understanding the impact of these issues requires some background review. One might presume that the scope of practice of various professional groups is precisely defined in the licensure laws of these professions. Instead, the scope of practice of the health professions, including medicine and nursing, is defined in very broad and vague terms. While this has been useful in accommodating new functions, as medical and nursing knowledge and experience has grown, it generates conflicts as these professions compete for the same functions. Licensure statutes generally prohibit the practice of that profession by those who are not duly licensed or approved as a practitioner, based on education and examination. The practice of medicine is restricted to those who are licensed as physicians by the NCMB, but there are a number of exceptions, under which physician assistants (PAs), nurse practitioners (NPs), etc., meeting specified education and examination requirements, are permitted to perform medical services under supervision of a licensed physician.

The exceptions, permitting licensed registered nurses (RNs) to perform medical acts, recognize that these practitioners are also licensed and regulated by another professional board, the NC BON. North Carolina statutes provide for a subcommittee of NCMB and NC BON, to establish rules and regulations for the function of these dual-licensed practitioners. The authority of the two subcommittees, relating to NPs and certified nurse midwives (CNMs), differ in composition and authority, in that the latter has members who are not members of either Board, and has the authority to promulgate rules and regulations which do not require approval by either of the parent boards.

This legal and regulatory framework, for all its complexity, has served the professions involved well over the past quarter century. APRNs have rapidly increased in numbers and in public respect, while permitted functions have expanded, and required documentation of physician oversight has been relaxed. Nevertheless, conflicts and friction have been encountered, as evidenced by the concerns expressed by APRNs in testimony before the Task Force. One component group of APRNs, Clinical Nurse Specialist (CNS), is not defined in the statutes, and lacks the protection of its title against use by untrained individuals who do not meet the standards of the group.

As pointed out in Chapter 5 of the Task Force report, some

E. Harvey Estes, Jr., MD, is University Distinguished Professor Emeritus at the Duke University Medical Center, Chair of the NC Institute of Medicine Board of Directors, and a member of the Task Force on the NC Nursing Workforce. He can be reached at eestes@nc.rr.com or 919-489-9780.

states license and regulate the practice of APRNs in a very different manner than in North Carolina. About half do not require physician supervision, and regulate practice through the nursing board alone. Some APRNs would prefer that North Carolina join this group. This action would be opposed by the NCMB, by most physicians, and their professional society, the NC Medical Society. These groups strongly favor some form of oversight by physicians.

A time honored method of resolving such differences between professions is to promote the introduction of a legislative act, changing current statutes to accomplish the new intent. This approach has inherent limitations, the most important one being that the NC General Assembly has only secondhand information about the working environment in which these conflicts arise, and the practicality of the proposed remedies. In their desire to please as many of the interested parties as possible, while still protecting the public interest, they may pass legislation which does not meet the needs of either the proposing or the opposing parties.

Instead, the Task Force recommends that the NC Institute of Medicine form another task force, with appropriate membership representing the major concerned groups, to consider these issues, and recommend action. Hopefully, if new legislation is required, it will be supported by all sides on the issue as it is discussed in the NC General Assembly.

Payment Inequities

The issue of payment inequities is not one which can be solved by this approach, as reimbursement policies are set by many parties. Medicare policies are established at a federal level, and insurance company policies are set by the individual companies. Nevertheless, the new task force may want to include this issue with the others as it discusses actions for the future.

Physician Supervision

Potential legislation to resolve the issues cited in Chapter 5 may not be the most important function of the new task force. The second issue, required physician supervision, brings with it an implied hierarchy of expertise, physician over APRN, which may or may not be accurate. One can easily envision a practice setting in which a NP may have the highest level of expertise in diabetes management, in which case it might be more appropriate that the NP "supervise" the physician. The concept of collaborative practice, in which all practitioners understand and respect the abilities and knowledge of each other has merit and deserves attention by the task force. A joint statement by the American College of Obstetricians and Gynecologists and the American College of Nurse-Midwives[1] embraces this approach, and has been helpful in resolving similar problems between these two groups. The process of discussion, seeking mutual understanding and thinking together about new directions may be the single most useful function of the new task force.

Both physicians and nurses choose to enter their respective professions in order to serve their patients. Traditionally, they have worked together to accomplish this joint purpose. I hope that the suggested new NC Institute of Medicine Task Force, if it comes about, will promote and enhance this tradition, and lead to an outcome as useful and productive as that of the most recent Task Force on the NC Nursing Workforce, whose work and recommendations are summarized in this issue of the *Journal*. **NCMJ**

COMMENTARY

North Carolina Center for Nursing and the Nursing Workforce

Brenda L. Cleary, RN, PhD, FAAN

The NC General Assembly created the NC Center for Nursing in 1991 "…to address issues of supply and demand for nursing, including issues of recruitment, retention, and utilization of nurse resources. The mission of the Center for Nursing is to assure that the State of North Carolina has the nursing resources necessary to meet the healthcare needs of its citizens." Legislatively mandated goals include:

1. To develop a strategic statewide nursing workforce plan for North Carolina, addressing issues of supply and demand.
2. To convene various groups that include representatives from nursing, other healthcare professions, the business community, consumers, legislators, and educators to review the policy implications of the Center's work.
3. To enhance and promote recognition, reward and renewal activities for nurses in North Carolina, through a comprehensive statewide recruitment and retention program.

Since its inception, the NC Center for Nursing (NCCN) has become a model for the nation, as more states take a long-range strategic view of nursing workforce issues. We have amassed a comprehensive database on state-level nursing supply and demand. We developed winning recruitment and retention materials and initiatives that are being adapted throughout the country. In addition to a primarily politically appointed Board of Directors, we have an Advisory Council of over 50 stakeholders in nursing and healthcare who inform the work of the Center. In recent years, we received a grant from The Robert Wood Johnson Foundation to partner with the NC Area Health Education Center Program on workforce planning activities and a related grant from the Helene Fuld Trust to support articulation among North Carolina's nursing education programs and enhance educational mobility for North Carolina nurses.

While the NC Center for Nursing has the most comprehensive state-level database on nursing supply and demand, this information becomes more powerful when it is used not only to guide workforce planning efforts, but also to directly influence policy. Having served as a member of the NC Institute of Medicine (NC IOM) since 1996, I have come to admire and appreciate the effective process of the Institute in studying relevant issues and making thoughtful health policy recommendations. I was very enthused when early planning efforts developed to pursue a partnership with the NC IOM and other key stakeholders to address nursing workforce issues. Other NCCN staff and members of our Board of Directors quickly became engaged in this important evolution of our work.

Immediately preceding the early discussions of convening a statewide Task Force on the nursing workforce, NCCN convened forums in conjunction with the NC Nurses Association (NCNA) and the NC Board of Nursing (NC BON) in every Area Health Education Center (AHEC) region of the state. The purpose of these nine forums was to allow local stakeholders to weigh in on strategies to strengthen the state's future nursing workforce.

I will use the major themes emanating from the regional forums as a framework to tie in emerging priorities with the recommendations of the Task Force on the NC Nursing Workforce in order to note the progress we are making, as well as to identify some challenges that lie ahead.

> *"The Task Force on the NC Nursing Workforce took painstaking efforts to examine nursing education issues in terms of both quality and quantity, as reflected in several Task Force recommendations."*

Brenda L. Cleary, RN, PhD, FAAN, is Executive Director for the NC Center for Nursing and a member of the Task Force on the NC Nursing Workforce. She can be reached at bcleary@ga.unc.edu or 222 N. Person Street, Raleigh, NC 27601. Telephone: 919-467-5132.

Greater Collaboration between Nursing Education and Practice

Nursing is an applied science and discipline. However, at times it seems that there are separate "silos" of nursing education systems and nursing care delivery systems. Through a collaborative effort of NCCN and AHEC funded by the Robert Wood Johnson Foundation, regional and state planning alliances of leaders in all types of nursing education programs and major nursing practice settings were formed. In discussions of how to disseminate and implement Task Force recommendations, Task Force members recognized the need for these relationships to be sustained. Leaders in nursing service should be more integrally involved in curriculum development and nursing educators should be grounded in the practice arena through joint appointments and other arrangements. Clinical preceptor models will become increasingly important, owing to faculty shortages.

Better Preparation of New Nursing Graduates in Critical Thinking, Time Management, Accountability, Interpersonal Skills, and Leadership Abilities as well as Hands-on Clinical Skills

Strengthening meaningful collaboration between nursing education and service also relates to this priority. The Task Force on the NC Nursing Workforce took painstaking efforts to examine nursing education issues in terms of both quality and quantity, as reflected in several Task Force recommendations. The NC BON is facilitating significant work in this area with their recent focus on the congruence between education and practice.

The Need for a Formal Transition from School to Work

The Task Force addressed this looming issue in a free-standing recommendation, acknowledging that it was a challenge that belonged to both nursing education and the nursing service sector. In my Robert Wood Johnson Executive Nurse Fellowship project, I am focusing on ways to increase the number of master's prepared nurses in direct patient care who can provide clinical leadership to nurses with varying levels of preparation in order to improve patient outcomes and cost-effectiveness; who can help patients and families navigate the complexities of today's healthcare system; and who can mentor new graduates, thereby reducing healthcare errors and decreasing nurse turnover. Key staff from NCCN are collaborating with key staff at the NC BON and the NC BON Foundation to develop a proposal for a more standardized internship/residency for every North Carolina nursing graduate. We will seek external funding to pilot proposed models.

Support for Better Articulation and Access in Nursing Education

There are four Task Force recommendations related to enhancing educational mobility options that are so important in a profession that offers multiple pathways to initial licensure as a Registered Nurse (RN). Associate degree curricula that include transferable courses, articulation agreements, a common core of course requirements at the baccalaureate level, as well as a statewide RN-to-BSN Consortium are all recommendations that are derived from the work of the Statewide Steering Committee on Articulation in Nursing Education, convened by the Center for Nursing. These actions will not only reduce barriers and duplication for nurses pursuing additional education, but also offer promise in terms of sharing faculty and other resources across nursing education programs. Resource sharing will become more critical than ever in ensuing years, with tight budgets and faculty shortages. We will also need to continue to look at better career pathways for qualified Licensed Practical Nurses (LPNs) and Nurse Aides (NAs) as the demand for RNs skyrockets. Finally, as reflected in the Task Force report, we need to reach more men as well as racial and ethnic minorities, with the aim of doubling their numbers entering the RN workforce by 2010.

Address Capacity of Nursing Education, with Emphasis on Faculty Resources

The Task Force recommendations regarding nursing education address funding of nursing programs, financial aid for nursing students, and other means of strengthening the quantitative and qualitative dimensions of the capacity of our nursing education programs. Pass rates on licensure exams among NC nursing graduates are higher than national averages. However, of special concern to NCCN, in light of our mission, is the number of students we lose prior to graduation through attrition, a factor limiting our educational capacity that was illuminated in the NC Center for Nursing's survey of nursing education programs in North Carolina. The California Community College System has developed a research-based model for predicting success of applicants to nursing education programs. This work may be relevant for our own community colleges as they study the relationship between admission policies and graduation/attrition rates as recommended by the Task Force. The recommendation on enhancing support services is also very important as success in nursing school nearly always involves an interaction of multiple variables and not simply academic attributes. Funding for the Faculty Fellows Program will be a significant step in addressing an evolving faculty shortage. But we must also look further at non-traditional methodologies for delivering nursing education, as represented in the recommendation for expansion of distance learning and on-line formats, as well as in prior discussion in this commentary regarding sharing resources.

Healthier Workplaces: Magnet Principles and Other Healthy Workplace Models

The Task Force on the NC Nursing Workforce built on the previous work of the Professional Practice Coalition convened by the NC Nurses Association as well as joint efforts of NCNA and the NC Hospital Association in empowering nurses and creating healthier workplaces. As an appraiser for the American Nurses Credentialing Center Magnet Recognition Program, I have witnessed the synergy that occurs with strong nursing leadership and governance, nurse satisfaction and retention, and the ability to enhance patient outcomes and satisfaction.

Innovative, Cost-effective Strategies to Reduce Nurse Workload and Paperwork

A survey of staff nurses conducted by NCCN in 2001 revealed an increasing paperwork burden. This paper work burden was perceived by nurses to be up an average of six percent from the previous year. Just as we need to enhance the use of technology in education, we need to streamline patient care with point of care data entry systems and other innovations that improve safety and accuracy while saving time and energy. The NCNA House of Delegates has resolved to look at these issues further.

Better Understanding and Management of the Effects of Staffing, both in Terms of Numbers and Credentials, on Patient Outcomes

Dr. Sean Clarke of the University of Pennsylvania described the work of a team of researchers led by Dr. Linda Aiken to the Task Force. The research he described, which needs further replication, used large sets of patient data to look at the impact of staff mix (RNs, LPNs, NAs) as well as the educational preparation of the RNs in the staff mix on surgical mortality and failure to rescue. Findings reveal that having a higher ratio of the RNs in the staff mix and more RNs with baccalaureate and higher degrees lowers mortality and failure to rescue rates. These kinds of findings and the increasing complexities of healthcare support movement toward a more educated workforce.

Nursing workforce issues are complicated issues and many challenges lie ahead. Fortunately, this great state brings multiple strengths to the table. Our more than 100-year professional nursing history, since the very first nursing license in the country was issued here in 1903, is a story of courage, fortitude, and innovation. We have not suffered from the recent much more dramatic shortages that have plagued other states. This reflects a track record of the willingness of multiple stakeholders to work strategically together and to take the long view toward a healthier future for all North Carolinians. **NCMJ**

The North Carolina Center for Nursing provides seed grants to assist hospitals, health departments, schools of nursing and other healthcare related agencies in creating innovative programs to recruit and/or retain people in the nursing profession. SPECTRUM LABORATORY NETWORK

Spectrum Laboratory Network is a rapidly growing **regional** laboratory providing "hospital-quality" clinical laboratory testing to physicians, hospitals, urgent care facilities, and home healthcare agencies.

Services include:

- Personalized attention
- Full menu of testing capabilities
- Pathology consultation
- Contracted with most plans
- Locations throughout the Carolinas
- Excellent turn around time
- Extensive courier system
- Exceptional quality

Computer Capabilities:

- *Cutting edge* technology
- Easy to use "touch screen"
- Direct interfaces
- Electronic Medical Record (EMR) capability
- Prompt response to requests

Spectrum's Quality, Service, and Computer Technology are unsurpassed!

MedMD

NORTH CAROLINA:

Primary Care positions immediately available for Internal Medicine/Family Practice physicians to provide outpatient primary care to veterans at the Salisbury VA Medical Center. Affiliated with Wake Forest University School of Medicine. Board certification or eligibility and U.S. citizenship required. Liberal benefits with 401K, 30 days paid vacation and paid federal holidays. 40-hour workweek. Also emergency room physicians and some subspecialty positions in Medicine needed.

Salisbury is a lovely, historic city in the Piedmont area of North Carolina, less than one hour from Charlotte and Winston-Salem. Enjoy a mild year-round climate; within easy driving distance from the Blue Ridge Mountains and beautiful Carolina beaches.

Call or forward a current CV to:

Janet Rasmussen, Human Resources
W.G. "Bill" Hefner VA Medical Center
1601 Brenner Ave.
Salisbury, NC 28144
Phone (704) 638-9000, ext. 2880.
FAX to (704) 638-3322, or e-mail to
Janet.Rasmussen@med.va.gov.

Equal Opportunity Employer.

POSITION:	**Medical Director/CEO**
ORGANIZATION:	**North Carolina Physicians Health Program** **501(c)(3) Non Profit Organization**
ADDRESS:	**220 Horizon Drive, Suite 218** **Raleigh, NC 27615**
APPLICATION CLOSING DATE:	**July 15, 2004**

Application Instructions:
Interested applicants should send current resume, bio, salary expectations, marked CONFIDENTIAL, to the attention of Ms. Kim McCallie, North Carolina Physicians Health Program, 220 Horizon Drive, Suite 218, Raleigh, NC, 27615

Experience:
Two years of experience as a medical administrator, such as Department Chair, Director of an inpatient or outpatient unit, Program Director, Chief of Staff or similar position or physician in private practice with similar or appropriate experience. Particular emphasis should be given to organizational skills, communications skills and fundraising abilities. A keen knowledge of chemical dependency is a requirement and personal recovery is preferable.

Education:
A medical degree from an AMA accredited medical school and licensure by the North Carolina Medical Board is required. Successful completion of a medical residency recognized by the Residency Review Committee of the AMA is highly desirable. Certification by the American Society of Addiction Medicine is also strongly recommended.

Mental Health Reform

To The Editor:

Thank you for dedicating a recent issue to a discussion of mental health reform in North Carolina. While waving the flags of lower costs and better services, politicians and administrators in state government are radically changing the mental health delivery system. The Department of Health and Human Services is reducing the number of hospital beds for severely mentally ill; thereby, forcing these patients to seek treatment, if they so choose, from private or community resources. At the same time, the administration is pushing local communities to reduce direct service and hire private providers to meet the needs of the mentally ill, developmentally disabled, and substance abuse patients. Doctors Marvin Swartz, Joseph Morrissey, and Nicholas Stratas have written extensively of the numerous problems with proposed reforms. It strikes me that these problems encompass three primary areas with financial concerns at the heart of each.

First, there are limited numbers of well-trained private clinicians who can offer wide-ranging multidisciplinary services to the targeted population. I suspect only a small fraction of this population of clinicians will be willing to provide services for reimbursement typically offered by the government. And which of these clinicians will cooperate with quality assurance requirements (assuming the state will demand and measure quality service)?

Second, community resources either don't exist, are grossly inadequate, or severely under-funded. Alternative treatment services are simply unavailable in many areas. And don't underestimate the confusion and diffusion of responsibility that will occur when two areas or counties argue over which is responsible for treating a particular patient. In addition some patient care providers working in community as well as state facilities have sought employment elsewhere because they are fearful of losing their jobs as a result of the state's plans to "reform" the mental health system.

Third, under the state's plans, patients and family members will face one more hurdle in seeking treatment since the facilities where they have been treated will not provide direct services. They will be directed elsewhere. One can only guess how much support and guidance these persons will receive as they navigate the "reformed" system. And one can only guess about the financial concerns and questions these persons will have when they are sent to private providers. Indeed, this assumes that the patient makes a rational decision to continue to pursue treatment at another time, in another place, from another provider, and while facing uncertain financial responsibilities.

Many letters and articles highly critical of the state's mental health "reform" have been printed. It is unfortunate how timely and prescient those admonitions have been. A few weeks ago a store in Raleigh was robbed and police were called. A man scuffled with them and bystanders and reached for a policeman's pistol. The man was subdued but then dropped dead. Police officers and rescue personnel made heroic efforts, but the lives of all involved were forever altered. We later learned the man was mentally ill, not taking medications or receiving treatment, abusing cocaine, and a danger to himself and others. To complicate matters even further, there had been some sort of dispute between two counties centering on whether and how to have this individual committed.

In the past this man may well have been readily committed to a state psychiatric hospital; his illness stabilized, and he and the public protected from harm. Today there are fewer hospital beds and limited community resources available to treat the mentally ill, and patient care providers are leaving the system. Those that remain in the system face the impossible task of providing quality care with fewer resources. Sick, vulnerable people are being denied appropriate care. If the state has its way, the future may hold for us more senseless crime, violence, homelessness and death. And we'll be reading and hearing more tragic stories involving the mentally ill and developmentally disabled.

Charles L. Johnson Jr., PhD
Clinical and Clinical Neuropsychology
Cary, NC

"Today there are fewer hospital beds and limited community resources available to treat the mentally ill, and patient care providers are leaving the system."

2002 North Carolina Live Births Attended by Certified Nurse Midwives

Deliveries attended by a Certified Nurse Midwife (CNM) are increasing rapidly in the United States and in North Carolina. In 2002, there were 307,527 CNM-attended live births in the United States, accounting for 7.6% of all live births.[1] Since 1983 when the North Carolina legislature passed the "Midwifery Practice Act" making CNMs legal birth attendants, the percentage of resident live births attended by CNMs has risen dramatically. In 1983, CNMs attended less than 2% of all live births; by 2002 CNM-attended births had risen to 9.2%, or more than 10,800 births in the year (Figure 1).

Table 1 shows demographic characteristics, risk factors, and birth characteristics for CNM-attended deliveries compared to all North Carolina resident live births.

Demographic Characteristics

Mothers with CNM attendants were more likely to be unmarried, have less than a high school education, and to have received WIC (a program which provides nutritional assistance to low-income mothers) while pregnant. Under Title XIX of the Social Security Act, state Medicaid programs are required to cover CNM services. In 2002, 43% of CNM-attended births in the state were covered by Medicaid, compared to 42% of all live births. Women whose delivery was attended by a CNM were slightly less likely to be of a racial minority and a little more likely to be a resident of a rural region. This may be related to the fact that CNM-attended deliveries were more prevalent in the Western portion of the state where the minority population is smaller and the rural population is larger.

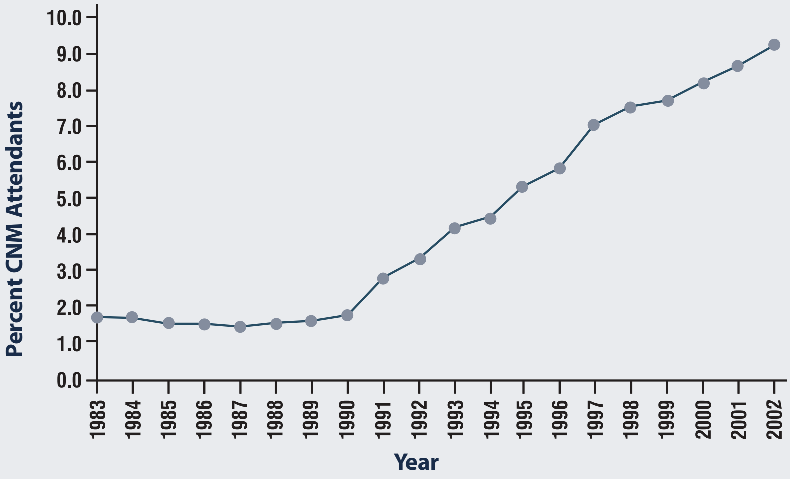
Risk Factors

Mothers with CNM birth attendants were more likely to report smoking during pregnancy and receiving late (after first trimester) or no prenatal care, compared to all live births. In addition, women attended by CNMs were more likely to give birth outside a hospital setting (2.5% vs. 0.5% for all live births). CNM-attended deliveries were less likely to have medical risk factors recorded on the birth certificate (27%) compared with all live births (30%). In addition, CNM-attended deliveries were much less likely to involve twins, triplets, or other multiple births.

Birth Characteristics

Nearly all CNM-attended births (99%) were vaginal deliveries compared to 73% of all North Carolina live births. CNMs used obstetrical procedures such as ultrasound, electronic fetal monitoring, or stimulation of labor to aid delivery at about the same rate as other attendants (97-98%). Approximately 28% of CNM-attended deliveries had one or more labor or delivery complications reported on the birth certificate compared to 36% of all live births. Infants delivered by CNMs were less likely to be of low birth weight (less than 2500 grams). In 2002, 4.3% of

Figure 1.
1983-2002 North Carolina Resident Births: Percent with Certified Nurse Midwife Attendants



CNM-delivered babies were low birth weight, compared to 9.0% of all live births. This is likely to be related to their lower medical-risk clientele.

It should be noted that the quality of the attendant data on the North Carolina birth certificate has not been assessed. CNMs have expressed uncertainty regarding the validity of the coding of the delivery attendant on the birth certificate. A survey conducted in 1993 by the American College of Nurse Midwives found that 6% of the deliveries CNMs attended were not attributed to them.[2] Also, continuity of care cannot be assessed from the birth certificate attendant data. For example, a woman may have received all of her prenatal care with a CNM, but if a labor complication led to a cesarean section, the delivery would be attributed to a physician. Thus, some poor birth outcomes associated with delivery complications may be recorded as physician-attended deliveries, even though a CNM provided the prenatal care.

Table 1.

2002 North Carolina CNM-Attended and Total Resident Live Births by Demographic Characteristics, Risk Factors, and Birth Characteristics.

	CNM Attendant		Total Live Births	
	Number	**Percent**	**Number**	**Percent**
Total Births	**10,840**	**9.2%**	**117,307**	**100.0%**
Demographic Characteristics:				
Minority race	2,775	25.6%	32,190	27.4%
Hispanic	1,410	13.0%	15,063	12.8%
Maternal age less than 18	527	4.9%	4,890	4.2%
Less than a high school education	2,728	25.2%	26,652	22.7%
Medicaid	4,704	43.4%	48,833	41.6%
Received WIC during pregnancy	4,899	45.2%	45,820	39.1%
Resident of rural region	6,141	56.7%	64,235	54.8%
Unmarried	4,035	37.2%	40,646	34.6%
Risk Factors:				
Maternal medical risk factors[a]	2,954	27.3%	35,179	30.0%
Mother smoked	1,603	14.8%	15,440	13.2%
Late/no prenatal care	1,915	17.7%	18,236	15.5%
Delivered outside a hospital	267	2.5%	540	0.5%
Multiple birth	55	0.5%	3,880	3.3%
Birth characteristics:				
Vaginal delivery	10,749	99.2%	85,811	73.2%
Obstetrical procedures[b]	10,623	98.0%	113,632	96.9%
Delivery complications[c]	3,080	28.4%	42,446	36.2%
Low birth weight (< 2500 grams)	464	4.3%	10,550	9.0%

[a] Includes pre-existing maternal medical problems such as anemia, diabetes, & hypertension as reported on the birth certificate.
[b] Includes procedures such as ultrasound, electronic fetal monitoring, & stimulation of labor as reported on the birth certificate.
[c] Includes delivery problems such as breech , fetal distress, and long labor as reported on the birth certificate.

The North Carolina Institute of Medicine

Since January 2002,
Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the NC Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The NC Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 when the North Carolina Medical Society reached the decision to cease support for its publication. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The *Journal* provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The *Journal* makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

North Carolina Medical Journal: Call for Papers

Herbert G. Garrison, MD, MPH
Scientific Editor, North Carolina Medical Journal

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The *Journal* seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The *Journal* is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

ANNOUNCING THE BIGGEST PLANS

FOR THE LITTLEST PEOPLE.

INTRODUCING THE LEVINE CHILDREN'S HOSPITAL

Carolinas Medical Center has just announced plans to build the most advanced, most comprehensive children's hospital in the region.

It will be like no other facility in the area, offering you services you won't get anywhere else.

And it will all be geared to children's needs – and support systems that cater to families.

You'll be hearing more in the months ahead about how you can be a part of making this dream come true.

The plans are big. For our littlest patients.

Your dimes conquered polio.

Give us a hand with premature birth.

Fifty years ago, Americans joined together to help the March of Dimes fund polio research. Your generosity led to the vaccines that have saved generations of children. Today a new epidemic threatens our babies—premature birth. Each year more than 460,000 are born premature. It's the leading cause of newborn death and many disabilities. Please go online to help us raise research funds. Together we can find the answers that will save premature babies.

A partnership that's working for eastern North Carolina

Kinder, gentler heart surgery

A sophisticated robotic device has helped cardiothoracic surgeons take the heartache out of mitral valve repair. Surgeons associated with the Brody School of Medicine at East Carolina University and the Cardiovascular Center at University Health Systems of Eastern Carolina have developed and perfected a minimally invasive procedure that uses the da Vinci™ Surgical System to repair mitral valve defects. This technique reduces trauma and pain and allows patients to recover faster.

The first multi-center clinical trial, which led to FDA approval of the procedure, was supervised by Dr. W. Randolph Chitwood, Jr., director of the Cardiovascular Center in Greenville. The Center now trains physicians from around the world to perform mitral valve repair using the da Vinci system. The Brody School of Medicine and University Health Systems are making things happen — in the region, in the state and in the world.

fittogether

Fit Together Launched for a Healthier NC

As medical professionals you see the evidence every day – the Centers for Disease Control and Prevention report that 27 percent of North Carolina high school students are overweight or at risk of being overweight and more than half of North Carolina adults are overweight or obese.

In April, Blue Cross and Blue Shield of North Carolina and the N.C. Health & Wellness Trust Fund Commission announced a $4.5 million comprehensive statewide campaign to battle obesity and promote healthy lifestyles.

A study in the Journal of the American Medical Association reports that obesity can cut 20 years off the expected life span of young people. Some public health experts believe that the coming generation of adults may have a shorter life expectancy than the current generation if current trends do not change.

The Fit Together partnership is designed to help create a climate of change. The good news is that simple steps, such as regular, moderate physical activity, can improve health. That can mean something as easy as yard work, family walks or playing outdoors.

There are many innovative initiatives already underway in communities across our state. Fit Together will serve as a clearinghouse for information about obesity and "best practices" in obesity programs across North Carolina. And Fit Together will include a three-year public education campaign. We all know that obesity is becoming a health crisis; now we have to help North Carolinians create healthier habits.

As the state's largest health insurer, BCBSNC has made tackling obesity a top corporate priority. In the coming months, we will be announcing new services for our members designed to prevent and treat obesity and tools for medical professionals so you can help your patients improve their physical activity and nutritional habits.

We will be announcing more details about Fit Together soon, including a television ad campaign, an awards program and a Web site. We invite you to share information about programs in your area that could help us overcome obesity and to start the conversation with your patients today.

For more information about Fit Together or to share information about successful programs in your community, e-mail us at **feedback@fittogether.org**.

Demand for Continuing Medical Education Programs on Cancer Care Among Primary Care Physicians in North Carolina

Roger T. Anderson, PhD, Kathleen Dziak, BA, Jeffery McBride, MA, MBA, Fabian Camacho, MS, Anita C. Hege, MPH, and Frank M. Torti, MD

Abstract

Background: *Primary care physicians have a central role in cancer prevention and control services, yet relatively little attention has been given to their needs for continuing medical education (CME) that clarify or update screening guidelines, enhance recognition of signs or symptoms of cancer, and address ongoing health issues in patients treated for cancer (e.g., pain control, lymphedema, tertiary prevention).*

Methods: *A random sample of 600 primary care physicians practicing in urban and rural locations in North Carolina was selected to assess past cancer-related CME sessions, and demand for current cancer education topics.*

Results: *Of 539 eligible, 231 surveys were returned (43%). Approximately 37% of respondents had attended no cancer-related CME in the last two years. Highest interest for cancer CME topics was found for screening for breast and skin cancers, general update diagnostic skills, pain management and patient/family support, side effects from treatment, lymphedema management and lymphedema diagnosis, genetic susceptibility, diet and smoking cessation. Interest levels by CME topic did not vary by urban/rural practice settings.*

Conclusion: *There is low access but high demand for cancer-related CME topics among primary care physicians. Strategies are needed to fill this need and to assess impact.*

Keywords: *cancer screening, CME, primary care.*

Introduction

Cancer is an increasingly common diagnosis and cause of death nationally among adults. In North Carolina, one in every two men and one in every three women will be diagnosed with cancer during his or her lifetime. The economic costs of cancer care and impact to families in North Carolina are estimated at $2.9 billion annually.[1] Primary care physicians occupy an important position in delivering effective and high quality care for cancer prevention and control, through screenings, referrals, patient education, and, for those treated for cancer, coordinating longer-term disease management. For cancer prevention, guidelines for early detection through routine screening have been established for breast, cervix, colon, and prostate cancers conditioned on considerations of patient age and known risk status.[2-8] However, evidence exists that life-saving prevention, early detection, and control may not be carried out even when beneficial support is overwhelming.[9] Reasons for this gap are complex, but potential confusion over cancer screening detection policy from a lack of uniformity in type and interval screening specifications among the various medical professional organizations guiding primary care has been cited as important.[7] At the same time, technology for cancer screening is advancing as genetic markers and new immunologic assays replace traditional tests, potentially adding to the complexity of obtaining and interpreting the screen for the patient. For patients with a history of cancer, the primary care physician may play a pivotal role by leading the patient's general health maintenance (in the context of a cancer history) and promoting the prevention of recurrence. Physician education in comprehensive, state-of-the-art cancer prevention and detection and health maintenance is therefore central to delivering effective cancer screening and prevention services.

Keeping abreast of new developments in cancer prevention

Roger T. Anderson, PhD, is an Associate Professor in the Department of Public Health Sciences, Wake Forest University School of Medicine (WFUSM). He can be reached by email at rtanders@wfubmc.edu or Piedmont Plaza Building, 2000 West First Street. Winston-Salem, NC 27157. Telephone: 336-716-7057. **Fabian Camacho, MS**, and **Anita C. Hege, MPH**, are Research Associates in the Department of Public Health Sciences, Wake Forest University School of Medicine.

Frank M. Torti, MD, is Professor and Chair of Cancer Biology and Director of the Comprehensive Cancer Center, Wake Forest University School of Medicine, Piedmont Plaza Building, 2000 West First Street. Winston-Salem, NC 27157. Telephone: (336) 716-2693.

Kathleen Dziak, BA, and **Jeffery McBride, MA, MBA**, served as research assistants in the Department of Public Health Sciences, Wake Forest University School of Medicine.

and control can be a challenge for primary care physicians (PCPs).[10] Many physicians rely on formal continuing medical education (CME) courses to provide information. There are a number of formats by which physicians receive CME credit (e.g., didactic, large or small discussion groups, workshops, internet access, etc.). Each format has strengths and/or weaknesses.[11-14] There is a growing body of literature regarding which type of CME format primary care physician's prefer[15-17] and which patient care topics physicians seek most.[18] However, in the area of cancer control, no studies have been published on PCP interest or need for CME programs for primary care providers despite the fact that cancer is a leading chronic disease with formal best practice recommendations for screening[19] and vigilance. Given competing community resources for educational programs to fulfill category 1 credit requirements and the availability of funds to attend such sessions, the most effective cancer CME programs are likely to be those meeting the demand and interest of the intended physician audience.

In North Carolina, an Advisory Committee on Cancer Coordination and Control (NCACCC) has been established to develop and coordinate a comprehensive cancer control plan for the state.[20] A centerpiece of the committee's strategy is collaboration with primary care systems and medical associations to identify resources needed to promote cancer prevention and control. To meet this objective, this study was conducted to assess demand for cancer care and treatment CME in both urban and rural areas of the state. This report: **1**) describes interest levels in the four distinct aspects of cancer-related healthcare services: screening, diagnosis, treatment, and follow-up care by physician characteristic and patient groups served; and **2**) examines the preferred method of accessing a cancer-related CME program.

Methods

A sampling frame was assembled of all primary care physicians listed on the North Carolina Physician Roster, and grouped according to urban and non-urban area using the North Carolina Data Center designations of metropolitan place names.

The survey was designed to collect data on screening, diagnosis, treatment, follow-up care, and preferred method for receiving CME on cancer related topics. A 66-item needs assessment survey was developed by study collaborators at the Wake Forest University School of Medicine (WFUSM). The prototype instrument was pre-tested at WFUSM among physicians in the gynecology and primary care clinics and reviewed for content. New items were generated from content review and physician feedback. Modifications to the survey were finalized and approved by the NCACCC office. The final format included content areas in the following cancer care and prevention topics: cancer prevention and risk factor reduction, screening and interpreting test results, diagnostic techniques, treatment options and prognosis, and follow-up care to surgery. A survey sample of 300 physicians was selected per urban and non-urban grouping (N=600). The sample was mailed a questionnaire with a postage-paid return mailer. Returned and completed surveys from the initial mailing were tracked and a replacement survey was sent after a two-week non-response period. After the second mailing, telephone calls were placed to the physician's office when the phone numbers were available in the listing. Arrangements were made with office staff to deliver a faxed copy of the survey.

Data analysis was performed to describe means and proportions of the survey category responses. Tests of significance were performed using two sample t-tests with pooled variance estimates, and judged to be significant at $p < .05$ without correction for multiple comparisons. To describe CME topics of most interest, ratios of 'very interested' (VI) to 'not at all interested' (NI), were calculated as VI/NI. This ratio served as a means of ranking CME topics in terms of strong preference (or demand) among items in the case where there may be considerable variability in interest for the topics considered. For example, a topic where 30% of respondents are 'very interested,' 40% are 'interested' and 30% are 'not interested' (30/30 = 1) has much less widespread appeal than a topic with interest ratings of 30%, 60%, and 10%, respectively (30/10=3). In the former case the number of respondents who desire the CME topic is balanced by the number who have no interest at all, whereas in the latter, the CME topic is appealing to most. Thus, a ratio larger than 1 indicates more interest than disinterest for the topic; a ratio below 1 suggests that high level interest may be specific to subgroups, such as practice type. Tests of significance were performed on the logarithms of the demand ratios, using asymptotic statistics described in Agresti.[21] The null hypothesis in this case was that the logarithm of the demand ratio is equal to 0 (so that the demand ratio is equal to 1).

Results

Survey Return Completion Rate

Removal of invalid addresses (N=21) and non-practicing physicians (N=40) resulted in a final sample size of 539 physician names. Of these, 97 (18%) initial mailings were returned, with a replacement survey being sent after a two-week non-response period yielding 54 additional responses (10%). After the second mailing, telephone calls were placed to the physician's office when the phone numbers were available in the listing. Arrangements were made with office staff to deliver a faxed copy of the survey resulting in another 80 (15%) completed surveys for a cumulative total of 231 (43%) surveys completed and returned.

Physician Profile

The physician mean number of years in practice was 16.6 years (±12) and the provider mean age was 48.2 years (±11). As shown in Table 1, approximately 48% of physician respondents classified themselves as family medicine, 27% internal medicine, 20% gynecological, and 4.5% as other. Most respondents were male (89%), with a majority serving rural group practice settings (55%). Survey respondents estimated that more than one-third of their patients were smokers (34%) and nearly one-third (32%) had an estimated income below $20,000 per year.

Table 1.
Respondent Physician Profile: Gender, Type of Practice, Type of Specialty, Patient Population Served, and Estimated Population Low Income/Underserved

Category	Sub-Category	N (%)
Gender	Female	(11.1)
	Male	(88.9)
Practice	Private	(21.3)
	Group	(71.0)
	Other	(07.7)
Specialty	Family Medicine	(48.4)
	Internal Medicine	(26.9)
	Gynocology	(20.2)
	Other	(04.5)
Patient Population/Service area	Urban practice	(44.6)
	Rural	(55.4)
Estimate of low-income/Underserved	Patients with income < $20,000	(31.7)
	Patients with high school diploma	(24.3)
	Current smokers	(34.1)

A substantial proportion of physicians, nearly 37%, had not attended any cancer-related CME sessions in the past two years, and only 22% indicated attending one session (see Table 2).

Table 2.
Continuing Medical Education: Number of Sessions Physician Attended in Past Two Years

Number of Sessions	Percentage
0	36.9%
1	21.7%
2	15.2%
3	12.0%
4+	14.7%

CME Interest

Table 3 summarizes physicians' interest in participating in cancer-related CME topics. The highest interest in the *Screening* category was in general screening, with 58% being 'very interested.' For the *Diagnosis* and *Treatment* categories, 47% of primary care physicians surveyed were 'very interested' in a general update of diagnostic skills and 35% were 'very interested' in side effects from treatment for follow-up care. For cancer *Prevention* topics, 53% of physicians were 'very interested' in methods to identify and address high risk.

Demand ratios

In Table 4, the item response, or 'demand,' ratios show that within the *Screening* CME topic category, general screening (23.12), breast (7.63), and skin (3.67) drew highest levels of interest (demand), while colonoscopy (0.47) exhibited lowest interest. In the *Diagnosis* and *Treatment* topic categories, general update diagnostic skills (8.12), pain management (4.49) and patient/family support (3.28) were reported to be of high interest, while research protocols (0.53) had the lowest interest. The highest interests in *Follow-up care* were side effects from cancer (3.35), side effects from treatment (2.72), long-term follow-up (1.88), lymphedema management (1.20) and lymphedema diagnosis (1.05), while lowest demand was therapist availability (0.92). For *Risk factor prevention* and *Risk reduction* topics, genetic susceptibility (4.04), diet (2.97), and smoking cessation (2.45) showed highest interest, while sun exposure (1.08) exhibited comparably lower interest.

There were no statistically significant differences in CME interest and demand proportions by urban/non-urban practice location (data not shown). For medical specialty type (Table 4), family medicine practitioners had a statistically higher ($p < .05$) level of interest in pain management, general prevention, and long-term follow-up of patients treated for cancer. Obstetrics/gynecology practitioners had significantly higher interest in CME topics addressing breast, cervical and ovarian cancer screening, and genetic susceptibility than either internists or family practice physicians.

As shown in Table 5, the preferred method of accessing a cancer-related CME course/program was by in-person lecture (63%), rather than a video-conference or lecture format (6%), which was not favored. In terms of sponsorship, the Area Health Education Centers (AHECs) were viewed as the most favorable mode of sponsorship (37%). Finally, 23% of physicians reported a 'very favorable' attitude toward accessing a CME session over the Internet.

Discussion

This study found a high interest for CMEs focused on selected cancer topics for primary care providers. Further, self-reported attendance at formal CME sessions targeting cancer care was not high, with more than one-third (37%) attending no sessions in the past two years.

Most interest was reported for CME information relating to screening for breast, ovarian, skin and prostate cancers, all of which are highly relevant to primary care and have guidelines for screening that are evolving through evidence-based medicine. Also of interest were sessions on identifying high risk for cancer and strategies for risk factor reduction (e.g., smoking cessation), pain management and side effects of treatment, lymphedema and long-term follow-up care. Relatively low interest was found for specific procedures such as biopsy, sigmoidoscopy, and tumor staging, which primary care providers usually do not perform.

While on-site lectures are the most preferred means of attending a CME session, nearly one-quarter of the respondents viewed Internet CME access as a favorable means of attending CME programs. Unlike CMEs targeted to hospital staff or

healthcare providers within academic clinical departments capable of attracting large numbers, primary care physicians in the community may find it more difficult to attend off-site CMEs, making video conferencing an attractive media format to adopt for category 1 credit.

While needs assessments, such as this one, are the cornerstone of sound education, studies are needed on the effectiveness and impact of various continuing education formats in terms of number reached and, ultimately, in changing cancer prevention and control practices or outcomes. The effectiveness of CME programs as

effective instruments of change has been challenged.[22-24] Davis and colleagues[25] reviewed the general research literature covering 24 separate CME-based interventions and found that benefit, in terms of provider practice or healthcare outcomes, was dependent upon method of delivery, nature of the interaction, and enabling resources provided. Didactic CME-based interventions failed to change physician behavior, despite effects on knowledge and attitude. Studies using interactive techniques, such as case discussion or demonstrations, were more effective, as were sequenced interventions allowing practice and feedback loops, and enabling materials (brochures, patient reminder cards, etc.) designed to facilitate implementing the recommended changes.

As cancer screening methods and technologies evolve to encompass genetic screens and refinement of risk estimation, the need among primary care providers for continued cancer control and prevention education is likely to grow. Studies are needed to develop effective CME-based interventions for cancer care.

Conclusion

Results of this survey indicate that strong interest exists for cancer CME topics among primary care providers, with more than one-third (37%) of respondents reporting no previous attendance of CME-provided cancer care educational sessions.

INTRODUCTION

Policy Forum:
Infant Mortality in North Carolina: A New Perspective on a Persistent Problem

For decades, North Carolina health professionals and public health activists have confronted stark statistics, which indicate an inability to adequately prevent infant deaths in our state, especially among racial and ethnic minorities. While comparisons of our infant death rates with those in other states no longer put us at the absolute bottom of the national distribution, we are clearly among the few states at the lower levels of accomplishment with regard to this important indicator of health and healthcare disparity.

For health professionals who have worked so hard to address these issues, the persistence of these problems has been an especially frustrating and challenging part of their careers. Yet, it is important to recognize that measurable and positive changes have occurred, slowly but surely, over the past decade or so. Important changes have been brought about through: assurance of better access to primary healthcare services for pregnant women and children, a campaign to promote consumption of folic acid during women's childbearing years and pregnancy, state and federal nutritional and dietary supplement programs, the availability of excellent neonatal care services across the state, and the Back To Sleep Campaign and other child care initiatives. For a problem as pervasive and complex as this, there is no single intervention that can stem the tide and result in dramatic results overnight.

The Editors of the *North Carolina Medical Journal* are pleased to have an opportunity to focus on these perennial public health issues. The Policy Forum in this issue is made possible through a grant from the March of Dimes of North Carolina, with whom we are pleased to have undertaken a close collaborative relationship in addressing the many issues discussed in these pages. While the March of Dimes did provide funding for the printing and distribution of this issue, the opinions expressed are those of the authors and not the March of Dimes.

We think our readers will find the initial paper in the Forum by Dr. Julia DeClerque and colleagues of great interest. Dr. DeClerque et al. argue for a change in the way we have conceptualized and approached infant mortality in North Carolina and the nation. Drawing on the work of the World Health Organization and a number of agencies and programs here in the United States, these authors call our attention to the fact that the largest proportion of infant deaths are associated with general health conditions and health factors present (and in many cases preventable) among women of childbearing ages prior to pregnancy. Hence, it is suggested and statistically demonstrated that the greatest potential impact on infant mortality rates may be realized by addressing the more general health of women in these age groups, whether or not they are pregnant.

This "paradigm shift" will not be easily explained, or accepted by policy makers who often prefer to invest in healthcare services and programs targeted to specific health conditions, with the expectation that clearly associated results will be demonstrated in the near-term. The proposal for focusing infant mortality reduction efforts with an approach that addresses the general health of women in childbearing ages (whether or not pregnancy has been established) will require a very different perspective and a very different set of programmatic investments. We hope the commentaries that follow this Issue Brief will help clarify the importance of this paradigm shift, as well as provide an update on what is arguably one of North Carolina's most persistent public health dilemmas.

North Carolina's Infant Mortality Problems Persist:

Time for a Paradigm Shift

Julia L. DeClerque, DrPH, MPH, Janice A. Freedman, MPH, Sarah Verbiest, MSW, MPH, and Stuart Bondurant, MD

Improvements over the past two decades in the medical care of women during pregnancy and of newborn infants have contributed to North Carolina's success in reducing its high infant mortality rate to an historic low. These efforts are to be applauded and they must be sustained. One of the largest remaining gaps, however, is the absence of significant initiatives that focus on improving a woman's health before she becomes pregnant. Future improvements in reducing rates of infant death or improving birth outcomes will depend upon a renewed sense of urgency to provide the best healthcare to pregnant women and their babies and a willingness to expand the current focus on improving pregnancies to improving the health and psychosocial well-being of *all* women of reproductive years.

Background

Infant mortality is the leading cause of child death, affecting close to 1,000 North Carolina babies and their families every year. While the state's rate is at an historical low (8.2 deaths/1,000 live births in 2002), North Carolina continues to post one of the highest rates in the nation (Table 1). Racial and ethnic disparities in infant death rates persist: African American babies have a two to three times greater rate of death than white babies (14.2/1,000 and 5.9/1,000, respectively, in 2002). Interestingly, Latino women in North Carolina, many of whom are newly arrived immigrants, have among the best birth outcomes at present. However, experience from other states suggests that the longer immigrants live in this country the more likely they are to experience infant loss. North Carolina currently has a window of opportunity to learn about and sustain the factors that lead to these healthy births. With the rapid growth of a young, Latino population, taking action now may serve to prevent a worsening of the state's infant mortality rate among this group in the future.

While death rates have declined over time, the major causes of infant death have remained fairly constant. North Carolina's babies, like those in other states, are most likely to die as a result of conditions related to prematurity and low-birth weight, congenital anomalies and Sudden Infant Death Syndrome (SIDS). Preterm birth, the leading correlate of newborn death, is increasing for *all groups* in North Carolina. Preterm birth affects more than 15,000 North Carolina babies annually, including one out of every eight white babies, and one out of six for African American babies (Table 1). Young African American women have worse health status (obesity, diet, exercise, exposure to disease) than young white women. Efforts to further reduce infant mortality should emphasize reduction in the glaring health disparities experienced by African Americans in North Carolina—especially children, teenagers, and women of child-bearing years. More than 10,000 babies are born with low-birth weight (less than 5.5 pounds), and more than 3,000 infants are born with birth defects each year in North Carolina causing death, illness, emotional trauma and great economic burden for families and the state.

Studies show that poor birth outcomes can be caused by a myriad of problems. Women with unintended pregnancies or closely spaced pregnancies, those who are under age 18 or older than 35, smokers, and those with high stress and limited resources all have a higher risk of having premature or low-birth weight babies.[1 2 3]

North Carolina's Programs to Reduce Infant Mortality

North Carolina has a long-history of services and programs aimed at reducing the state's high infant mortality rates. Over the years, the state has expanded access to prenatal care and the

array of pre- and post-natal services available to pregnant women and infants, increased the state's outreach and education efforts, and expanded family planning services to reduce unwanted pregnancies (see pages 170 and 172). In addition, the state and local communities have helped launch targeted infant mortality campaigns aimed at high-risk groups or communities; and have created special programs aimed at reducing some of the causes of infant deaths. These efforts have helped contribute to a 35% reduction in the state's infant mortality rate since 1988 when provisional data from the Centers for Disease Control and Prevention listed North Carolina as having the worst infant mortality rate in the country. While these efforts have been critically important in reducing the state's infant mortality rate, there is a need to analyze existing data with new eyes to better pinpoint the underlying cause and specific patterns of risk that should be addressed, and therefore the appropriate timing of interventions that will have the most impact.

A New Way of Analyzing the Problem: Perinatal Periods of Risk (PPOR) Analysis

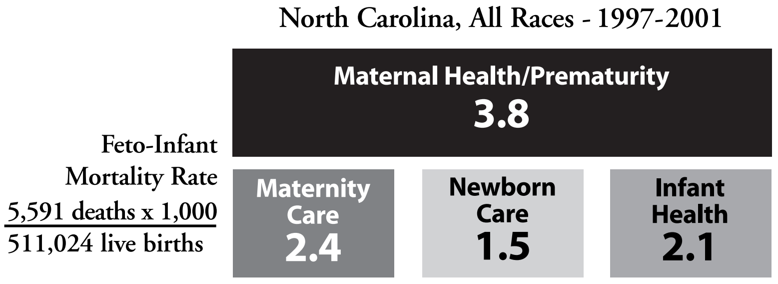
For more than a decade, the World Health Organization has used an analytic approach, the "Perinatal Periods of Risk Analysis" (PPOR) to analyze the cause of feto-infant mortality, and to develop appropriate interventions.[4] In 1997, the Centers for Disease Control and Prevention (CDC), City MatCH at the University of Nebraska Medical Center, the National March of Dimes Foundation, and the Health Resources and Services Administration/Maternal and Child Health Bureau created a partnership to test this model in the United States. PPOR helps to "map" fetal and infant deaths into four distinct periods based on when the deaths occur and the birth weight of the baby or fetus at the time of death. The three categories for the age of death are broken into fetal deaths (24 weeks or greater of gestation), neonatal deaths (within the first month after birth), and postneonatal (1-12 months of life). Birth weight is divided into two categories: low-birth weight (500-1,499 grams) or higher birth weight (1,500 + grams). Because of large reporting differences in vital records across geographic locations, fetal deaths are limited to those occurring after 24 weeks of gestation, and to those fetuses or infants weighing at least 500 grams at the time of death. This analysis creates four groups: maternal health/prematurity, maternity care, newborn care, and infant health (See Figure 1). The maternal health/prematurity category covers all low-birth weight feto-infant deaths, regardless of whether the death occurs in the fetal, neonatal, or post-neonatal time period.

Figure 1.
Perinatal Periods of Risk Analysis

	Pre-birth Fetal (24+ weeks)	Neonatal (first month)	Post Neonatal (1-12 months)
Low-birth weight (500-1,500 grams)	Maternal Health/Prematurity		
1,500+ grams	Maternity Care	Newborn Care	Infant Health

Deaths linked to maternal health/prematurity result from risk factors that are present before a woman becomes pregnant, such as a history of substance abuse, tobacco use, unstable

Figure 2.
Focus on Overall Infant Mortality by Periods in which Deaths Occur



housing/family structure, effects of poverty and stress, or a recent previous delivery. These problems can be addressed by focusing on preconceptional health, unintended pregnancy, smoking, drug abuse, and specialized perinatal care.

Deaths in the maternity care period link to factors that are most prominent during pregnancy, like poor weight gain, infection and lack of prenatal care. Some of these deaths can be prevented by ensuring women have early and continuous prenatal care, referral of high-risk pregnancies and good medical management of women with diabetes, seizures, postmaturity or other medical problems. Deaths in the newborn care period are attributed to risks that occur during delivery and through the first month postpartum. Prevention of newborn deaths focuses on advanced neonatal care and treatment of congenital abnormalities. The final period, infant health, includes deaths that occur due to factors occurring after the first month of life through the end of the first year—factors such as injuries, SIDS, congenital anomalies and infections. These deaths can be addressed through SIDS risk-reduction activities, breast-feeding promotion, access to medical homes, and injury prevention. PPOR is more of an heuristic exercise to help clarify the relative risk of these different periods of time and each periods' contribution to the likelihood of perinatal death, and is a tool for examining whether programs are focused appropriately in timing and emphasis of their efforts.

With this in mind, feto-infant deaths can be "mapped" for a geographic area to identify which of the four periods are associated with the greatest mortality risk. Each cell includes the number of fetal or infant deaths that meet the age and weight criteria. For example, a death to an infant in the 26th week of gestation that was under 1,500 grams would be counted in the maternal health/prematurity cell.

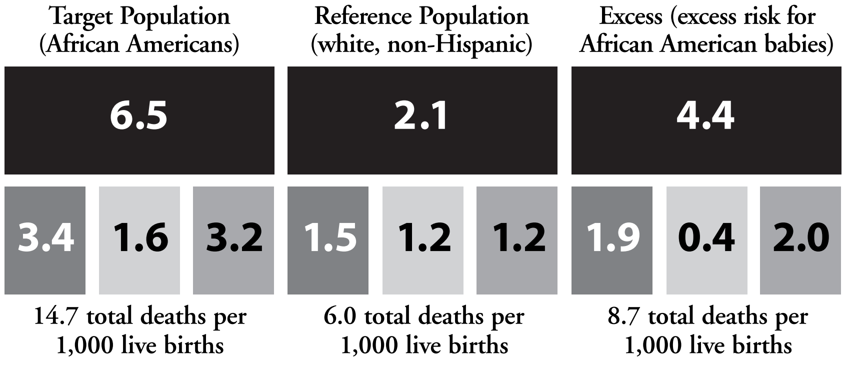
So, what does this analysis look like for North Carolina? There were 5,591 feto-infant deaths in North Carolina between 1997-2001 that met the age and weight thresholds. This yields a feto-infant mortality rate of 9.8 deaths for every 1,000 live births. More than a third of the feto-infant deaths fall into the maternal health/prematurity cell with risks attributable primarily to maternal factors (see Figure 2).

This same analysis can be used to compare rates across different subpopulations. For example, PPOR can be used to compare a high-risk group with a reference group of women expected to have better birth outcomes. Because we know that we have a high infant mortality rate among African-Americans in North Carolina, we can use the PPOR analysis to compare feto-infant birth outcomes of African Americans with a reference group of white, non-Hispanic women, over the age of 20, with greater than a high school education.[5] The difference between the reference and target population risks is the excess risk that exists. This excess risk must be addressed if all members of the local community are to have equal access and opportunity to optimize their health and if there is to be further progress in reducing overall infant mortality rates.

The feto-infant mortality for African American births is extremely high; at 14.7 deaths per 1,000 live births it is more than double that of whites (6.0 per 1,000). It also shows that, for the target population, almost half of the deaths are related to maternal health/prematurity (6.5 of the 14.7 deaths per 1,000 live births). Interestingly, the feto-infant deaths attributed to maternity care and those related to infant health are not as high as those associated the maternal health/prematurity, but at 3.4 and 3.2 per 1,000, respectively, these risks must still be addressed. One surprise that the data show is the extremely *low* rates of excess death attributable to the newborn period (0.4 per 1000). This tells us that African American babies in North Carolina have mortality rates associated with newborn care that are comparable to those among whites. This is cause for celebration, but also a signal that our efforts to address the problem of infant-mortality in North Carolina need a new and targeted approach.

To summarize, this PPOR review tells us that the most prominent period of excess risk for mothers and babies in North Carolina, especially African Americans, is the stage where the majority of the excess risk occurs (4.4 of the 8.7 or

Figure 3.
Excess Feto-Infant Mortality for African Americans in North Carolina 1997-2001



51%) and calls attention to the importance of factors related to the general health of women in childbearing ages. Efforts to improve this situation would direct our attention to the preconceptional period, or the health of women of childbearing ages before they become pregnant or between pregnancies.

This analysis also highlights North Carolina's current strengths and recent accomplishments in newborn care as it relates to infant mortality prevention. Intensive care nurseries and hospitals are doing an excellent job caring for sick neonates and transferring at-risk infants to appropriate facilities. The state's medical technology, expertise, and infrastructure are strong and have had demonstrable success. It is important that this system be maintained, particularly through regionalization, to ensure that tiny and sick babies are born in facilities with the personnel and resources to manage their complex care. Moderate numbers for the maternity care and infant health periods likely also reflect the impact of the many public health and community-based programs already in place that serve pregnant and parenting women.

Women's Health Status in North Carolina

So how does the health of North Carolina's women measure up? The NC Program for Women's Health Research, a collaborative program of the UNC School of Medicine, the UNC School of Public Health and the Cecil G. Sheps Center for Health Services Research, produces an annual North Carolina Women's Health Report Card.[6] The purpose of the report card is to allow the state to chart progress and problems on a large number of women's health indicators. Grades are given based on the percentage change from previous years and/or how satisfactory the current measure of each health indicator is.

As in previous years, the 2003 Women's Health Report Card documented that the state of women's health in North Carolina has much room for improvement. Data show that 45% of all live births were the outcome of unintended pregnancies (66% for African Americans) and that almost 16% of all women received late (after the first trimester) or no prenatal care. There were three cases of HIV/AIDS per 100,000 white women and 54 cases per 100,000 African American women; 248 sexually transmitted disease cases (syphilis, gonorrhea, chlamydia) per 100,000 white women and 2,522 per 100,000 for African American women.

Women's health in North Carolina received an "F" for its high rate of binge drinking among women (4.5%), high percentage of women with diabetes (6.7%), high percentage of women who are obese (23%), and high percentage of women with high blood pressure (28.9%). Indicators for African American women are even higher than those listed here. Additionally, 23% of women in North Carolina smoke (almost 14% during pregnancy), and there were 3,883 hospitalizations per 100,000 women for substance abuse or mental health diagnoses.

Research has shown that women who begin their pregnancies either underweight or overweight, with high blood pressure or diabetes, women who drink, smoke, have mental health problems, or sexually transmitted diseases are at greater risk for poor birth outcomes. The NC Women's Health Report Card clearly documents that North Carolina's women, especially its African American women, have not achieved the health status they need (as reflected by their scores) for achieving healthy birth outcomes. This report card underscores the conclusions reached by the PPOR model. Prenatal care, neonate care and infant health are important, but ultimately the ability to achieve and sustain improved birth outcomes will coincide with improved health status and increased access to care for women before they become pregnant or between pregnancies.

Time for a Paradigm Shift

In light of consistently falling short of the standards set by most other states in the nation, as well as the racial disparity and increasing rates of premature birth seen in North Carolina, there is a clear need to expand our perspective by adding a strong and effective intervention to improve the health of all women of childbearing age, especially young women. Research to find more effective evidence-based prevention strategies should be supported while the sound knowledge we now have provides a basis for the design of reasonable and promising health programs to reduce the burdens of unhealthy lifestyles.

Prenatal care has improved pregnancy outcomes in many ways. However, it has not been shown to be effective in reducing the incidence of premature births.[7] One possible reason for such a failure is that the causes of prematurity are predominately related to a woman's general health, social, environmental, and emotional circumstances.[7-11] In order to reduce the incidence of prematurity, it is reasonable to assume that it will be necessary to address those circumstances before, as well as during, pregnancy. Thus, it is time to reshape the focus of infant mortality reduction efforts. In addition to images of pregnant women and mothers holding newborns, the faces of all women of reproductive age should be part of the picture. A *life course* approach—that acknowledges the cumulative effects of risks and stressors over decades and even generations—should be considered in this new perspective.

To shift to this paradigm a number of things must happen. First and foremost our schools, the healthcare system and community agencies need to help all women, and especially the young, to gain understanding and motivation for healthier lifestyles. There needs to be increased access to and coverage for women's wellness services in many venues. These services need to be comprehensive, widely available, personally tailored, user-friendly and rewarding, and employ a bio-psychosocial approach. Reproductive health measures need to include other health indicators such as oral health, diabetes, blood pressure, smoking status and exposure to secondhand smoke, drug use, nutritional status, domestic violence, levels of stress and coping strategies, and mental health status.

Women must be educated about the need for these services and a demand created. Services should be designed to provide such rewards for participation that recruitment occurs naturally and continuation of participation is sought. Further, providers will require training on topics related to preconceptional or interconceptional health and the need for wellness visits. A screening tool adapted for women's life cycles could be used to help a woman and her provider track her health over her life course. More research will be required and must be conducted outside of the clinical setting and no longer limited to prenatal patients in a medical context. Studies must be designed to incorporate psychosocial, environmental and biological contexts of women's situations to understand multi-level effects. They must also be designed to take place within communities and families.

North Carolina's current initiatives focusing on smoking cessation, folic acid supplementation and family planning should be expanded and instituted statewide. Improving our delivery of these messages to targeted audiences and expanding our reach on these three factors alone will have an impact on the health of future children. In addition, the NC Department of Health and Human Services' focus on reducing health disparities is one that should be embraced widely. Within the mosaic of issues that are part of infant health, it is time that attention be paid to the pieces which represent maternal health and maternal well-being.

Women who are healthy are a vital component of North Carolina's future, whether they are pregnant or not. It's time to make the investment, to assure the health of women, and to have a long-term, positive impact on the health of newborns. **NCMJ**

Programs and Policies to Address the Problem of Infant Mortality: A Long History

Reducing infant mortality has been on North Carolina's agenda for several decades, albeit with varying levels of intensity and funding. Concerted efforts to prevent infant death began in 1972 when Governor Robert Scott created the Maternal and Infant Health Task Force to determine why North Carolina had such high infant mortality rates. Subsequent groups, including a statewide Perinatal Council (late 1970s to late 1980s) and Governor James Martin's Governor's Commission on the Reduction of Infant Mortality (1989-1995), addressed the same issue and championed legislation and policies, mobilized local coalitions and funded community-based organizations to address this problem. The NC General Assembly also played a leadership role in the fight to reduce North Carolina's infant mortality rate. Between 1990-1994, Senator Russell Walker and Representative David Diamont introduced a four-year infant mortality reduction campaign that helped create or expand many of the existing programs aimed at reducing infant mortality. Subsequently, the NC General Assembly has continued to support legislation and/or funding to address this issue.

Private foundations and organizations such as: the March of Dimes, the Kate B. Reynolds Charitable Trust, The Duke Endowment, and the North Carolina Healthy Start Foundation have also played pivotal roles in helping raise awareness about infant mortality and in supporting programs and research. At the local level, partnerships have developed between the business community, the faith community, local organizations, and coalitions to address the specific needs in the community, to strengthen networks and referrals that serve a common public and to fill gaps in services.

Over the years, efforts to reduce North Carolina's high infant mortality rate have focused on family planning and adolescent pregnancy prevention; improving the quality, comprehensiveness and accessibility of prenatal care; interventions that target particular populations or areas of the state; and interventions targeting specific risk factors or causes of infant deaths. These statewide and local efforts have lead to a 35% reduction in the state's infant mortality rates since 1988 when the state trailed the rest of the nation. However, recent budget cuts could jeopardize the progress that has been made.

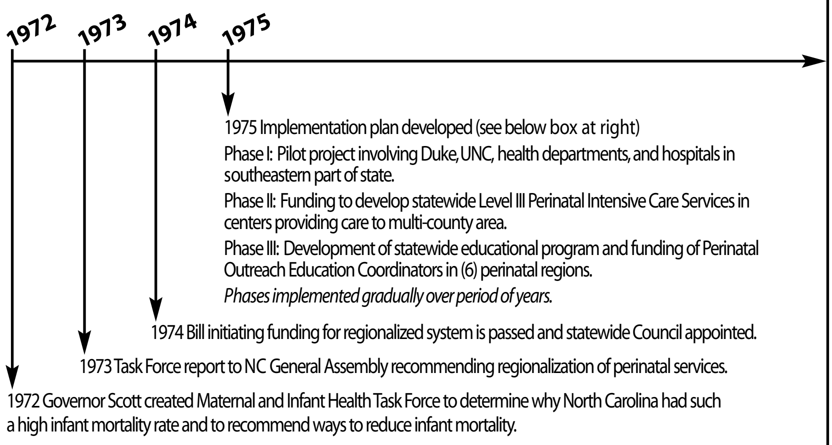
Family Planning and Adolescent Pregnancy Prevention Programs

Pregnancies that are planned by women who are physically, emotionally, socially, and financially ready are more likely to produce healthy babies. Unfortunately, almost half of all pregnancies in North Carolina and in the nation are unintended—often with serious consequences for the babies, women, families, communities, and the state. Family planning services are offered across the state through local health departments and physicians in private practice.

In 1999, the NC General Assembly mandated that insurers provide contraceptive coverage in their private health insurance plans. Women who are on Medicaid also have access to family planning services, and others can access services through local public health departments or community agencies. Nonetheless, there are many women who still lack access to family planning services. The NC General Assembly authorized the NC Department of Health and Human Services to seek a Medicaid waiver to extend family planning services to women and men (ages 19-55) with incomes below 185% of the federal poverty guidelines (See Holliday article, pages 170-172).[1] If implemented, this initiative will provide North Carolina's families with improved access to the services they need to lengthen the intervals between pregnancies (birth spacing), to reduce the likelihood of unintended pregnancies and subsequent abortions, and ultimately to improve the outcomes of subsequent pregnancies once they occur.

In addition, state funding over the years has supported specific programs to reduce adolescent pregnancies, including

A Very Brief Historical Sketch of Perinatal Care in North Carolina



1975 Implementation plan developed (see below box at right)

Phase I: Pilot project involving Duke, UNC, health departments, and hospitals in southeastern part of state.

Phase II: Funding to develop statewide Level III Perinatal Intensive Care Services in centers providing care to multi-county area.

Phase III: Development of statewide educational program and funding of Perinatal Outreach Education Coordinators in (6) perinatal regions.

Phases implemented gradually over period of years.

1974 Bill initiating funding for regionalized system is passed and statewide Council appointed.

1973 Task Force report to NC General Assembly recommending regionalization of perinatal services.

1972 Governor Scott created Maternal and Infant Health Task Force to determine why North Carolina had such a high infant mortality rate and to recommend ways to reduce infant mortality.

PERINATAL PLAN DEVELOPMENT

Mission: To reduce infant mortality and morbidity in NC by developing a statewide voluntary, cooperative, multilevel regionalized system for inpatient and outpatient perinatal healthcare, emphasizing medical, psychosocial, and financial aspects of patients needs. The goals are listed below.

1) Develop (6) Perinatal regions, each will have an active regional committee composed of multi-disciplines.
2) Describe and designate hospitals into one of three types.
3) Recruit the participation of health departments to provide routine screening of pregnant women and infants. Some will establish high-risk clinics.
4) Appoint a Perinatal Statewide Education Committee.
5) Manual "Regionalized Perinatal Health Care Program" published.

STATEWIDE PERINATAL COUNCIL

Discuss and address issues related to perinatal care. Special interest group and committees formed to:

- Study preterm labor - "White Paper" on preterm labor developed.
- Develop "Guidelines for Perinatal Care"
- Develop a Statewide Perinatal Professional Educational Plan
- Appoint a Perinatal Statewide Education Committee

the competitive Adolescent Pregnancy Prevention Program, Targeted Adolescent Pregnancy Prevention Program, the Adolescent Parenting Program and the Adolescent Pregnancy Prevention Coalition of North Carolina. (The state's adolescent pregnancy prevention programs are now under one combined program using TANF funds for teen pregnancy prevention.) Through these concerted efforts, teen pregnancy rates have declined in North Carolina to their lowest since the mid-1980s, thereby reducing the number of high-risk pregnancies, impacting overall infant mortality, and giving more teens a better chance to succeed in life. Funding for these projects, with demonstrated results, has come under attack in recent years due to the state's financial situation.

Improving the Quality, Comprehensiveness, and Accessibility of Prenatal Care

North Carolina ranks sixth in the nation for its excellent track record in ensuring that pregnant women get early and continuous prenatal care.[2] Statewide programs include the Baby Love Program (Medicaid for Pregnant Women), which provides prenatal care and care coordination to pregnant women who are at or below 185% of the Federal Poverty Level (FPL); high-risk maternity clinics, a regionalized Perinatal Referral System; the Perinatal Outreach Education and Training program; prevention and treatment programs for sexually transmitted diseases and HIV/AIDS; residential Perinatal Substance Abuse Treatment Programs; Special Supplemental Nutrition Program for Women, Infants, and Children (WIC); the NC Family Health Resource Line (1-800-FOR-BABY / 1-800-367-2229)—a statewide, toll-free, bilingual information and referral line; and the bilingual First Step Campaign coordinated by the North Carolina Healthy Start Foundation, which distributes free educational materials statewide. These services provide information to pregnant women and help link them with available resources, provide prenatal care in an appropriate setting, address known risk factors, and offer educational opportunities and resources to healthcare providers. Recent budget cuts have threatened some of these critical mainstays of prenatal care and infant mortality prevention (for example, the 2004 NC General Assembly considered proposals to cut the number of pregnant women eligible for Medicaid by reducing the income eligibility criteria). These cuts threaten the state's previous progress in improving the health of pregnant women and babies.

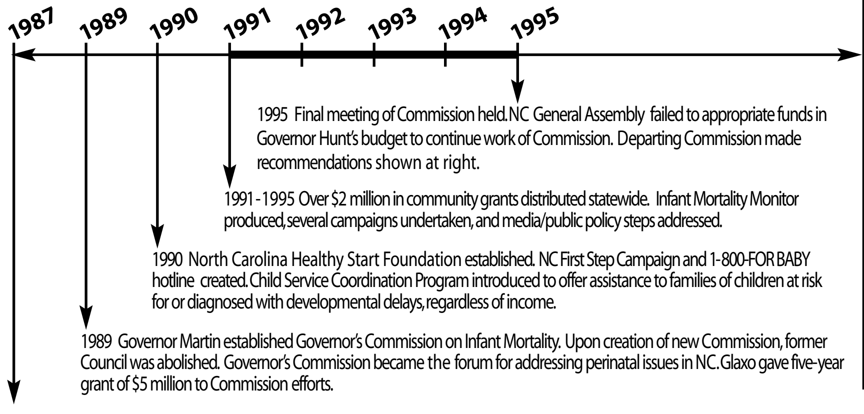
Targeted Interventions Based on Population and Geography

Infant mortality rates vary in North Carolina based on geography, race, and income. A number of unique initiatives in the state address special populations at high risk. The state-funded Healthy Beginnings Program (formerly the Minority Infant Mortality Reduction Program) provides 15 multi-year grants to local organizations that address unique issues in their communities, and the Targeted Infant Mortality Reduction Projects provide funding to eight local health departments to address factors in their community related to reducing infant death. In addition, the federal Maternal and Child Health Branch, US Department of Health and Human Services funds the NC Healthy Start *Baby Love Plus* and the UNC Pembroke *Healthy Start Corps* projects, which are used to coordinate four regional consortia in 17 counties (Triad, Eastern, Southeastern and Northeastern regions). These consortia provide outreach and other services to pregnant and postpartum women such as peer support, transportation, and enhanced case management.

Other programs initiated in the past addressed inequities between prenatal services available in rural and urban regions of the state. Both the Nurse-Midwifery Project and the Rural Obstetrical Care Incentive Program increased rural women's access to quality prenatal care by bringing medical providers to underserved areas; however, these programs were eliminated in prior years' budget cuts.

Targeted Interventions Based on Risk Factors and Causes of Infant Death

North Carolina strategically addresses certain causes of infant death, including SIDS, prevention of birth defects, and risks associated with low-birth weight. For example, the North Carolina Back To Sleep Campaign is a public-private partnership aimed at reducing Sudden Infant Death Syndrome (SIDS),



1995 Final meeting of Commission held. NC General Assembly failed to appropriate funds in Governor Hunt's budget to continue work of Commission. Departing Commission made recommendations shown at right.

1991 - 1995 Over $2 million in community grants distributed statewide. Infant Mortality Monitor produced, several campaigns undertaken, and media/public policy steps addressed.

1990 North Carolina Healthy Start Foundation established. NC First Step Campaign and 1-800-FOR BABY hotline created. Child Service Coordination Program introduced to offer assistance to families of children at risk for or diagnosed with developmental delays, regardless of income.

1989 Governor Martin established Governor's Commission on Infant Mortality. Upon creation of new Commission, former Council was abolished. Governor's Commission became the forum for addressing perinatal issues in NC. Glaxo gave five-year grant of $5 million to Commission efforts.

1987 Baby Love Program implemented. Baby Love designed to improve access to healthcare and service delivery system for low-income pregnant women and children.

Members of Governor's Commission on the Reduction of Infant Mortality final meeting recommendations:

- Maintain widespread attention on importance of healthy babies to North Carolina.
- Continue to publish Infant Mortality Monitor.
- Provide support to local health departments and other local organizations to promote the involvement of community groups, business, health providers and government.
- Continue initiatives to work with NC Business and Industry and their role in infant mortality prevention.
- Research into causes of prematurity, birth defects, and other causes of infant mortality and morbidity should continue and be expanded.
- Modern medical treatment should be in wide use and available to all women in need.
- Improve education for persons planning a family (for pregnant women and young mothers).

the third leading cause of infant death. This statewide, public education campaign, coordinated by the North Carolina Healthy Start Foundation and the state's SIDS Program, helps to promote behaviors before, during, and after pregnancy that reduce the risk of SIDS. As a result, SIDS deaths have decreased 36% in North Carolina since 1995. A new state law, effective December 1, 2003, should help further reduce SIDS deaths in childcare facilities. The law mandates that: babies under the age of 12 months who are cared for in licensed childcare facilities be placed to sleep on their backs, facilities have written safe sleep policies, and all childcare providers receive state approved training.

The prevention of birth defects, the second leading cause of infant death, is addressed in several ways. Pregnant women receive Maternal Serum Alpha-Fetaprotein screening to detect birth defects in utero and genetic counseling services are offered to families before and during pregnancy to assess their genetic risks and/or to receive counseling about a detected condition. The NC Birth Defects Monitoring Program records detailed information about all infants born with birth defects. Not only does this provide critical information for health monitoring and research, the program has a mechanism to refer affected children to Child Service Coordinators as needed. Utilizing a primary prevention strategy, the interagency NC Folic Acid Council works to decrease North Carolina's high rate of neural tube defects through: a statewide public education campaign to encourage women to take a daily multivitamin with folic acid, professional education, a statewide college campus outreach project, and focused initiatives in the western and eastern parts of the state. The Fetal Alcohol Syndrome Coalition addresses prenatal alcohol consumption, the leading cause of mental retardation. Perinatal Substance Abuse Treatment Programs provide gender-specific, in-patient treatment for pregnant women or women with young children. Since the mid-1990s the NC Family Health Resource Line has served as a bed locator service for healthcare providers who need referrals for their pregnant patients or patients with young children.

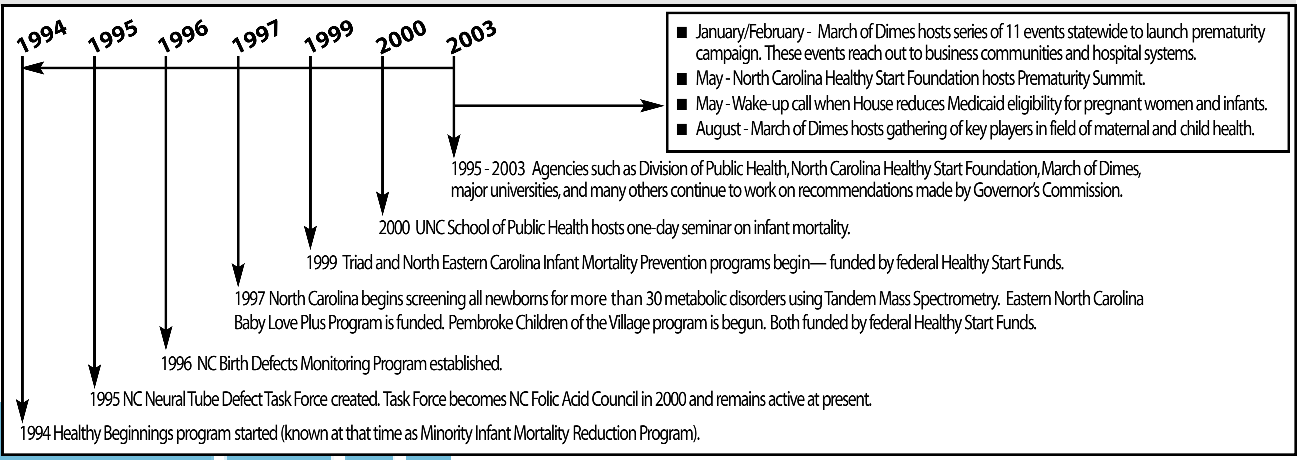
Smoking during pregnancy is the single most preventable cause of low-birth weight, yet North Carolina women smoke at a rate that is greater than the national average (13.2% versus 12.0% in 2001). The statewide Women and Tobacco Coalition for Health has evolved over the years and now plays an important role in promoting smoking cessation for women of reproductive years. North Carolina's "Guide for Counseling Women Who Smoke" has been a national model for healthcare providers since 1996. Trainings have been institutionalized and are now available for public and private providers through *QuitNow NC* and the state's Perinatal Outreach and Education Trainers.

The state also has 12 Level-Three Neonatal Intensive Care Nurseries, which are equipped to care for North Carolina's sickest babies. The Neonatal Transport Program, annual cross-hospital provider conferences, and Neonatal Outreach Educators and Trainers are some of the ways the state addresses prematurity and other birth related problems once they have happened.

In addition, North Carolina leads the nation in newborn screening services that are offered to all babies born in the state. It was the first state to use tandem mass spectrometry—an innovation in newborn screening. North Carolina screens for every disorder including hearing (with the exception of biotinidase[3]) allowing for early detection and treatment of a variety of lethal and potentially debilitating conditions.

Even within the programs described above, and using current proven best practice strategies, there is room for improvement. More pregnant women need to get early prenatal care and to be screened and treated for infections. All pregnant women should be taught the signs and symptoms of preterm labor. More healthcare providers need to be trained, reimbursed and willing to talk with their pregnant patients about alcohol, tobacco and other drugs, and to provide counseling and follow-up services. All new parents should be advised to place their children to sleep on their backs. Additional mental health services are needed and public awareness must be raised about North Carolina's "Safe Surrender" law, which allows a new mother, unable or unwilling to care for her baby, to surrender a young infant (up to seven days old) to a responsible adult and not face criminal charges.

There is no doubt that focusing on pregnancy and neonatal care has improved North Carolina's birth outcomes. Current services and programs are vital to maintaining the hard-earned progress that has been made on behalf of the women and infants of this state.



- January/February - March of Dimes hosts series of 11 events statewide to launch prematurity campaign. These events reach out to business communities and hospital systems.
- May - North Carolina Healthy Start Foundation hosts Prematurity Summit.
- May - Wake-up call when House reduces Medicaid eligibility for pregnant women and infants.
- August - March of Dimes hosts gathering of key players in field of maternal and child health.

1995 - 2003 Agencies such as Division of Public Health, North Carolina Healthy Start Foundation, March of Dimes, major universities, and many others continue to work on recommendations made by Governor's Commission.

2000 UNC School of Public Health hosts one-day seminar on infant mortality.

1999 Triad and North Eastern Carolina Infant Mortality Prevention programs begin— funded by federal Healthy Start Funds.

1997 North Carolina begins screening all newborns for more than 30 metabolic disorders using Tandem Mass Spectrometry. Eastern North Carolina Baby Love Plus Program is funded. Pembroke Children of the Village program is begun. Both funded by federal Healthy Start Funds.

1996 NC Birth Defects Monitoring Program established.

1995 NC Neural Tube Defect Task Force created. Task Force becomes NC Folic Acid Council in 2000 and remains active at present.

1994 Healthy Beginnings program started (known at that time as Minority Infant Mortality Reduction Program).

North Carolina is Moving in the Right Direction

North Carolina continues to post improving infant mortality rates. The rates have fallen to 8.2 per 1,000 live births in 2002. While we continue to rank near the bottom in national comparison, we are slowly moving in the right direction.

The number of babies lost to SIDS continues to decline and the number of babies born with birth defects, particularly those of the brain and spine, continues to decline.

Adolescent pregnancy is at an all time low for North Carolina. Many more women are receiving early and adequate prenatal care.

In Our Favor

1. Major medical centers, universities, and pharmaceutical companies are doing cutting edge research on the topic of prematurity and maternal and infant health. These not only benefit the larger population, but they have the potential to make the latest medical treatment options available to North Carolina's women and infants. They also hold a wealth of information about their study populations.
2. There is strong leadership in the arena of smoking cessation—particularly for youth and pregnant women. This includes having Smoke Free Families leadership in North Carolina, the QuitNow NC campaign supported by NC Prevention Partners and many others, the Women and Tobacco Cessation for Health (WATCH) committee, and award-winning products such as the *Guide for Counseling Women Who Smoke*—a self-help guide for healthcare providers who want handbooks to help pregnant women quit and to reduce second hand smoke exposure. The state has access to national quit lines with one available specifically for pregnant women—and plans to start such a line just for women in North Carolina. The National American College of Obstetricians and Gynocologists (ACOG) organization has supported a strong partnership with North Carolina and is bringing important resources and connections to the table. A number of groups have supported innovative smoking cessation grants across the state. The NC DHHS Division of Public Health has a position dedicated to this issue and the perinatal outreach educators and trainers consider smoking cessation a cornerstone issue.
3. Non-profits such as the March of Dimes and North Carolina Healthy Start Foundation are strong and collaborative players in North Carolina. Through grassroots outreach and excellent education products, these and other agencies build on their strengths to make an impact.
4. The state has a very strong Folic Acid Campaign and a very strong Back To Sleep Campaign.
5. The Division of Public Health's Women's and Children's Health Section is well respected and organized—it manages a host of excellent programs and services.
6. The state receives significant funding from the Federal Healthy Start Intiative (Health Resources and Services Administration/Maternal and Child Health Bureau).
7. The State Center for Health Statistics has a number of key data collection tools, including the NC Birth Defects Monitoring Program (recently funded by the Centers for Disease Control and Prevention as a Center of Excellence), Pregnancy Risk Assessment Monitoring System (PRAMS), and Behavioral Risk Factor Surveillence System (BRFSS). The Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill is an active partner in data organization and evaluation.
8. Healthcare professions in neonatology and maternal/fetal medicine have begun to meet jointly on issues of relevance to both groups.

3 Biotinidase Deficiency is caused by the lack of an enzyme called biotinidase. This disorder can lead to seizures, developmental delay, eczema, and hearing loss.

COMMENTARY

Improving Pre-pregnancy Health Is Key to Reducing Infant Mortality

Robert G. Dillard, MD

We could have asked our grandmothers. They would have told us what has otherwise taken at least 30 years, countless studies, and millions of dollars to discover. In order to have a healthy baby, a woman must be healthy, not only during pregnancy, but perhaps more importantly, before she conceives.

Efforts to Reduce Infant Mortality Since 1970

North Carolina's high rate of infant mortality compared with other state and national rates has been a source of puzzlement and embarrassment for years. Blessed with superb medical facilities and a reputation for advanced healthcare planning, our state has perennially ranked among the worst in rates of infant death among all 50 states. In hopes of improving the state's position, state leaders in the mid-1970s began developing a system to provide universal access to high-risk prenatal care and neonatal intensive care. It seemed logical that exposing women with pregnancy complications to the best care available would result in improved pregnancy outcomes.

Fifteen years later, few states had a more remarkably successful regional perinatal system than North Carolina's. During those 15 years, North Carolina's infant mortality rate dropped by a dramatic 36%.[1,2] The other 49 states had similar rates of improvement. Most did so without strong regional programs like North Carolina's. Virtually all of the nation's improvement in infant mortality, including North Carolina's, had come as a result of improvements in birth-weight-specific deaths among premature infants. In 1988, only Georgia had a higher rate of infant mortality than North Carolina's.[3]

In 1988, a task force appointed by the NC Secretary of Health and Human Resources reported that the state's excessive rate of infant mortality resulted from an excessive number of premature births. It made a number of recommendations to address the problem, including recommendations to improve prenatal services, but recognized that prematurity and infant mortality reduction required "social and economic interventions" as well as healthcare approaches.[4]

> *"As attractive and relatively inexpensive as prenatal care is, a medical model directed at a six-to-eight month interval in a woman's life can not erase the influence of years of social, economic, and emotional distress and hardship."*

In the first half of the 1990s, the NC Governor's Commission on the Reduction of Infant Mortality was charged with the task of implementing programs to address the problem of premature birth. It disbursed funds from a variety of sources to enhance prenatal services and to focus on social and emotional issues among poor pregnant women during their pregnancy. Acknowledging the dramatic disparity between white and minority populations, the Commission targeted initiatives to minority women.

Prenatal Care Is Not Enough

By the mid-1990s, prenatal care had not been shown to reduce rates of premature birth, especially among poor and minority women.[5] As attractive and relatively inexpensive as prenatal care is, a medical model directed at a six-to-eight month interval in a woman's life can not erase the influence of years of social, economic, and emotional distress and hardship.

Premature birth is strongly associated with poverty, stress, racism, substance abuse, short inter-birth intervals, previous premature delivery, certain types of work activities, and inadequate nutrition. Lower genital tract infections are strongly associated with premature delivery. However, treatment of such infections does not reduce preterm births.[6] It seems increasingly likely that

Robert G. Dillard, MD, is a Professor of Pediatrics at Wake Forest University School of Medicine. He can be reached at rdillard@wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157. Telephone: 336-716-4663.

such infections are a manifestation of stress in pregnancy.[7]

It is time to disabuse ourselves of the notion that prenatal care is the key to reducing infant mortality by reducing premature deliveries. It is time now to focus on the health of women of childbearing age before they become pregnant. Such a task will be far more difficult than establishing a regional perinatal network or ensuring access to prenatal care. It will entail enhancing education for minority populations to break the vicious cycle of poverty and the stress that comes from it. Communities must own up to the pervasive and devastating effects of racism and then begin to eliminate racism in our culture. We must address the serious consequences of smoking and illegal substance abuse. Women, especially poor women, must have the right to become pregnant when they want to be pregnant and not to become pregnant when they don't want to be. In a time of job shortages in North Carolina, it will be difficult to ensure that pregnant women can avoid jobs that make it less likely that they will deliver a premature baby. However, the short- and long-term economic and social consequences of not doing so overwhelm the modest expenses of temporary reassignment. The overwhelming nutritional problems that lead to poor pregnancy outcomes have their roots in childhood. We must do a better job teaching our children to eat well, and more importantly, we must provide them with better food choices.

> *"It is time now to focus on the health of women of childbearing age before they become pregnant."*

New Approach to Providing Health Services to Women of Childbearing Age.

In addition to community-based initiatives, we need to develop a new approach to providing health services to women of childbearing age.[8] Such an approach would begin in early adolescence and continue until menopause. The system would combine elements of standard medical care, public health, and social services. It would start with a comprehensive, age-linked, annual assessment. The assessment tool would address traditional medical topics, but also focus on social, economic, and environmental issues. Analysis of such a broad individual assessment would facilitate appropriate referral to clinical, public health, and other community resources.

Each community would identify its available resources and link them to applicable sections of the assessment. Such a linked catalog of services would facilitate timely and appropriate referrals. Community care workers, familiar with available resources, would be assigned to women whose assessments indicated the presence of high-risk factors in order to ensure that such women had ready access to the best available resources.

Implementing such a system, including identification of funding sources, development of culturally-sensitive and specific tools, creation of the best methods for gaining access to women who would benefit from the system, and evaluation of the impact of the system will require considerable effort on the part of community leaders. However, if the system were successful in addressing and correcting the serious health, economic, social, and environmental factors that lead to premature birth and other poor pregnancy outcomes, infant mortality rates would drop. North Carolina could then deserve the reputation it has as a forward-looking southern state. **NCMJ**

COMMENTARY

Infant Mortality:
1963 to Present Medical Developments and Legislative Changes

William R. Purcell, MD

On August 8, 1963 a premature infant boy, Patrick Bouvier Kennedy, was transferred from Otis Airforce Base near Hyannis Port to Boston Children's Hospital. He died the next day at age 39 hours from respiratory distress syndrome.

There was little we could do in 1963 to care for premature and low-birth weight babies. In many hospitals small prematures were kept warm, given oxygen and subcutaneous fluids and sometimes placed on "rocking" beds. Some even suggested that if kept cool they would better tolerate low-blood oxygen levels. As expected, many of the low-birth weight infants who survived were more likely to be "small for gestational age" than "premature."

High Infant Mortality Rates Led to Legislative Changes

In 1963, 31.1 out of every 1,000 babies born alive in North Carolina died before they reached their first birthday. The infant mortality rate for white infants was 22 and 50.6. There were premature nurseries but no real neonatal intensive care units. There were no ventilators designed for premature infants and there was no simple way to measure newborn blood gases. Vascular access through the umbilical cord was used mainly for exchange transfusions. The role of continuous positive airway pressure and surfactant were not generally understood. This was five years before Dr. J. F. Lucey published his article in *Pediatrics* regarding the use of "blue lights" for the treatment of neonatal hyperbilirubinemia.[1] Neonatal hypoglycemia was rarely considered.

Historically, North Carolina has always had one of the highest infant mortality rates in the country. In the early 1970s, the NC General Assembly and the Governors' Office tried to address this problem by establishing a regional perinatal care system and providing funds for maternity clinics, family planning and delivery services. Later, in the mid-1980s, the General Assembly expanded Medicaid to increase coverage for pregnant women and infants. Reimbursement rates for delivery services and prenatal care were increased as well.

In the fall of 1989, the Centers for Disease Control and Prevention (CDC) reported that North Carolina had the worst infant mortality rate of any state in the nation (1988 provisional data). Governor Martin created the Governor's Commission on Infant Mortality and changed Medicaid policies to cover all pregnant teens, regardless of parental income, in an effort to encourage them to seek prenatal care. In 1990, the NC General Assembly implemented a four-year plan to reduce infant mortality by expanding access to prenatal care, primarily through the reduction of financial barriers to that care. This involved expanding Medicaid to cover women and infants with incomes up to 185% of the federal poverty guidelines and again increasing reimbursement for prenatal care and delivery. The Rural Obstetric Care Incentive program was expanded to help offset malpractice insurance premiums for providers who were willing to provide maternity care in medically underserved areas. Funding was provided for teams of nurse midwives to provide obstetrical services in these areas and a nurse midwifery program was created at East Carolina University.

Infant malnutrition became a rarity after the onset in 1974 of the federal Supplemental Nutrition Program for Women Infants, and Children (WIC) Program. The WIC Program provides vouchers to low-income pregnant and post-partum women to purchase food for themselves, their infants and their children up to age five. The Legislature also created a birth defects registry and helped the March of Dimes fund a folic acid awareness program.

Although most infant deaths occur in the perinatal period, measures were taken to reduce the death rate and injury to older infants. Legislation was adopted requiring infant car seats for all infants and back to sleep programs

> *"Historically, North Carolina has always had one of the highest infant mortality rates in the country."*

Senator William R. Purcell, MD, has been member of the NC General Assembly for seven years. He is a retired pediatrician from Laurinburg, NC, and can be reached at Williamp@ncleg.net or 625 Legislative Office Building, Raleigh, NC 27603-5925. Telephone: 919-733-5953.

for infants in childcare centers. Severe penalties were adopted for operating unlicensed childcare centers or for giving medications to children in childcare centers without parental permission. During this time North Carolina developed one of the best childhood immunization programs in America.

Medical Developments in Obstetrics and Neonatology

Since 1963 there has been a revolution in obstetrics and neonatology with technology leading the way. The use of ultrasound and fetal monitors are now routine procedures and amniocentesis has become a common tool in pregnancy management. The use of Rh (D) immune globulin has made exchange transfusions a rarity. The devastating effects of alcohol usage, smoking, and inadequate folic acid are generally understood.

A real revolution has occurred in the care of premature and sick newborns. A fantastic transport system now brings the medical centers' neonatal intensive care nursery into the local hospital. Pediatricians across the state are trained in the resuscitation and stabilization of sick newborns while awaiting transport teams. Blood gases can be measured percutaneously or with only a few drops of blood. The impact of assisted ventilation, continuous positive airway pressure, surfactant, hand washing, sepsis, hypoglycemia, and phototherapy on the survival of sick newborns is well recognized. Touch and loving care have been shown to increase the chances for survival so now we even encourage parents to touch and hold their ill newborns. This is a far cry from the days when parents weren't even allowed in the nurseries! The recognition of the importance of breast milk in nutrition and resistance to infections have also had a major impact on infant survival and well being.

We Have Reduced Infant Mortality Rates, but Challenges Remain

In 1963 there were 107,322 live births in North Carolina and there were 3,342 infant deaths (31.1 deaths per 1,000 live births). In 2002 there were 117,307 live births with 957 infant deaths for an infant mortality rate of 8.2, the lowest ever recorded in North Carolina. Clearly, the advances in medical knowledge and expertise, coupled with policy changes that made it easier to access prenatal care have helped to improve the state's infant mortality rate. However, we cannot rest on these accomplishments. North Carolina still has a higher than average infant mortality rate. Nationally, there were seven infant deaths per 1,000 live births in 2002. Further, while North Carolina's infant mortality rate has improved for all races, the infant mortality rate is still more than two times higher for minorities (14.2 per 1,000 live births) than whites (7.0 per 1,000 live births).

Patrick Kennedy brought the difficulties faced by premature infants to the world's attention and made all of us in healthcare aware of the inadequacy of our knowledge, our technology, and our ability to provide the help that was needed. Surely some of the credit for the revolutionary advances in obstetrics and neonatology must be given to that tiny baby boy born to Jacqueline Kennedy at Otis Airforce Base in 1963.

Despite the advances in care and treatment, many questions remain only partially answered. What causes prematurity? What causes birth defects? What causes SIDS? What causes racial disparity? We do know that healthy lifestyles help prevent prematurity. We know that adequate folic acid prevents neural tube defects. We do know that placing infants on their backs to sleep reduces the incidence of sudden infant death syndrome. We know that lifetimes of poverty, stress, and subclinical infections may contribute to racial disparity in birth outcomes.

All of these partially answered questions and many more must remain on the front burner of our state and national government and on the front burner of all involved in providing healthcare to pregnant women and their infants. We must continue to find ways to improve North Carolina's unacceptable levels of infant mortality, and especially, racial disparities.

North Carolina Makes Strides to Reduce SIDS, but Challenges Lie Ahead

Christine O'Meara, MA, MPH

Sudden Infant Death Syndrome (SIDS) is the third leading cause of infant mortality in North Carolina. Five-year trends show that approximately 100 babies under the age of one year continue to die suddenly and unexpectedly in North Carolina each year.

The SIDS landscape is one in which North Carolina's rate has consistently exceeded the national rate. In 1988 the NC SIDS rate was 1.87 per 1,000 live births compared to the US rate of 1.4 per 1,000 live births. In the intervening thirteen years, SIDS rates have dramatically decreased. The state's lowest SIDS rate ever, 0.7 per 1,000 live births, was reported for 2002. From 1995 to 2002 the NC SIDS rate has fallen 36%.[1]

While this decline in SIDS is certainly good news, it tells only half of the story and should be viewed with cautious optimism. As with infant mortality, the SIDS rates reflect an unacceptable disparity among populations. African American infants are dying from SIDS at twice the rate of white infants. From 1998-2002 NC African Americans accounted for 41% of SIDS deaths, a rate of 1.35 per 1,000 live births, compared to the white rate of .66 per 1,000 births or 58% of SIDS cases. American Indians accounted for 1% of SIDS deaths, a rate of .83 per 1,000 live births, during this same timeframe.

Public education and awareness campaigns have contributed to reductions in SIDS rates. The reversal in the infant sleep positioning message from the prone to the supine or to the side by the American Academy of Pediatrics (AAP) in 1992 and the 1994 National Back To Sleep Campaign's reinforcement of this message resulted in a greater proportion of infants positioned on their back or side for sleeping and a corresponding 50% drop in SIDS deaths nationally.[2] The AAP revised its infant sleep position recommendation for healthy infants from stomach to back only in 2000. Closer to home, the statewide NC Back To Sleep Campaign, also launched in 1994, is credited with contributing to the more than 30% reduction in SIDS we have today.

Figure 1.
1998 Infant Sleep Position – NC PRAMS Data

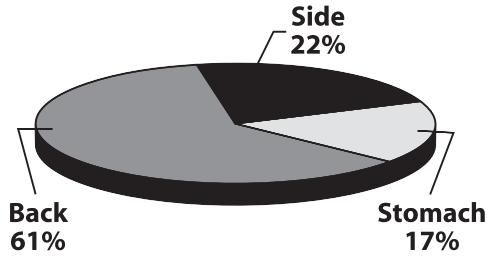
Figure 2.
2001 Infant Sleep Position – NC PRAMS Data



Source: NC State Center for Health Statistics 2004

NC Pregnancy Risk Assessment Monitoring System (PRAMS) data collected by the State Center for Health Statistics documents a significant shift in infant sleep position by North Carolina parents and primary caregivers since 1998.[3]

Both Figures 1 and 2 demonstrate that the back sleep position is the most commonly used position for sleeping infants, followed by the side. A comparison of sleep position changes from 1998 to 2001 shows a marked increase of 19% for infants placed on their backs to sleep with corresponding decreases in the side (15%) and, to a lesser degree, the stomach (4%) sleep positions. The NC Back To Sleep Campaign goal, in keeping with the national goal, is to reduce the prone sleep position for infants to not more than 10%.

According to PRAMS data, two-thirds of whites and Latinos place their infants on their backs for sleeping, a practice that is much less common among African Americans (43%). African Americans are much more likely to favor the stomach sleep position for infants (24%) compared to whites (14%) or Latinos (8%). The side sleeping position for infants is also preferred more often among African Americans (32%) and

Latinos (25%) and occurs less frequently among whites (18%). Cultural practices, the influence of a grandmother in the household, medical conditions, parent's preference, modeling and parent education by medical professionals such as newborn nursery staff, and experience with a previous infant contribute to infant sleep position practices. Concerns about choking, plagiocephaly (flat heads), or a bald spot are oftentimes barriers to placing babies supine for sleeping.

Epidemiological and PRAMS data are critical elements for the NC Back To Sleep Campaign's social marketing strategies and are used to identify audience and sleep position messaging. Statewide data depicting the distribution of SIDS deaths are used to target media markets at the county level. These data point to a continued need to inform North Carolinians about SIDS risk reduction and to particularly engage the African American community in infant safe sleep strategies. State efforts are challenged to keep up with the demand for culturally competent Spanish language SIDS education and outreach for Latinos.

SIDS is a Leading Cause of Deaths in NC Childcare

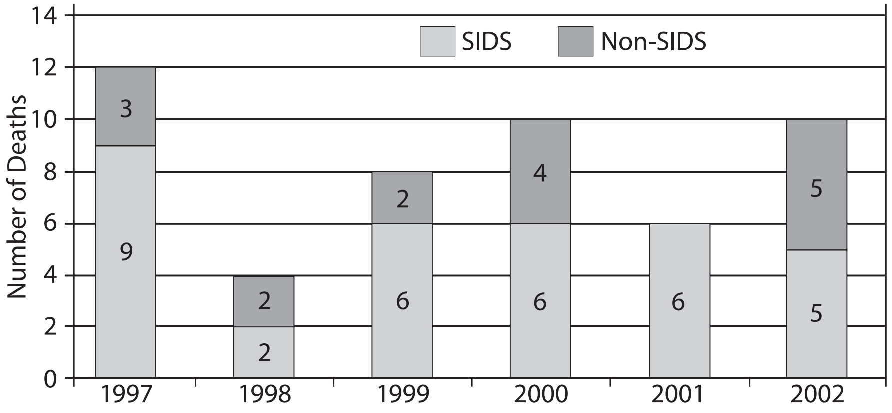
National research suggesting that a disproportionately high number (20%) of SIDS deaths occurred in childcare sounded an alarm that prompted the targeting of childcare providers for SIDS risk reduction education and training. Researchers found that, while more infants were positioned for sleep on their backs in childcare, those succumbing to SIDS in childcare were more likely to have been placed on their stomachs for sleeping. Of the smaller subset of babies (N=99) for whom information about the length of time in childcare was available, one-third had died during their first week in childcare and one-half of these occurred on the first day.[4] Unaccustomed prone sleepers may be at a higher risk when positioned prone. Approximately 7% of North Carolina's SIDS deaths occur in childcare settings, a figure one might expect to observe given Census data and the amount of time infants spend there.

The state has almost 16,000 infants in licensed childcare, according to the NC Division of Child Development (DCD). Figure 4 illustrates that two-thirds of all deaths from 1997 to 2002 in NC childcare were attributed to SIDS. During this six-year period, there were 34 SIDS deaths and 16 deaths due to other causes.

SIDS Risks Present in NC Childcare

Observational and survey data collected in 2002 prior to the implementation of the Infant/Toddler Safe Sleep and SIDS Risk Reduction in Child Care (ITS-SIDS) initial training, and prior to SIDS risk-reduction legislation in 2003, showed that SIDS risk factors were present in a sample of 217 regulated childcare centers and homes in North Carolina. Sleep position varied and included side, stomach, back, and sitting. Babies

Figure 4.
Proportion of SIDS to Non-SIDS Deaths in North Carolina Childcare from 1997 to 2002



Source: NC Division of Child Development slept in a variety of places such as cribs, bassinets, playpens, bouncy-seats, car seats, and, in the case of one childcare home, on a sofa. The immediate sleep environment contained toys, stuffed animals, and excess bedding. Although rare, there was evidence of cigarette smoke in one family childcare home. Very few facilities had a written safe sleep policy in place. Though some caregivers had attended SIDS workshops, childcare providers identified SIDS training and policy development as needed and most expressed a desire to have educational print materials for parents.

Media is a Catalyst to Combat SIDS

A cascade of recent events has impacted how North Carolina's babies are sleeping at home and in childcare. SIDS has been in the media spotlight frequently in the past year, not only as a news feature but also in the halls of the NC General Assembly. Consequently, we are witnessing a ripple-effect of safe sleep policies being implemented in a variety of childcare settings and adopted in private homes.

Beginning February 16, 2003, the Raleigh *New & Observer* published a three-day investigative series entitled *Case Closed: Deaths in Day Care*[5] that focused attention on SIDS, the unauthorized administration of medication in childcare and the operation of unlicensed, illegal childcare in the state. A strongly worded editorial on February 19, described the shortcomings in North Carolina's regulation of day care center's as not only unacceptable, but despicable! This editorial demanded that the Governor and legislative leaders toughen childcare oversight and regulation and outlined several strategies to address health and safety concerns in the state's more than 9,000 licensed childcare facilities. To tackle SIDS, the *News & Observer* called for a state law requiring that infants in day care not be put to sleep on their stomachs. Representative Martha Alexander, a stalwart child advocate, was quick to act, and by late February House Bill 152, the precursor to the NC SIDS Law, had been filed.

The NC SIDS Law

December 1, 2003 is an historic moment in the state's battle against SIDS. North Carolina joined the ranks of a handful of states legally mandating that licensed childcare providers position babies 12 months of a age or younger on their backs for sleeping, having written policies in this regard, and obtaining training for childcare workers. House Bill 152 expanded General Statue 110-91 pertaining to mandatory childcare standards and was ratified as GS 110-91-15. The NC Prevent SIDS law includes a waiver provision based on medical need, for infants six months of age or younger. The law also allows a parent or legal guardian to waive the back to sleep requirement for infants older than six months. This allowance represents a political compromise and is not a best practice in accordance with recommendations of the AAP and the National Resource Center for Health and Safety in Child Care. Nonetheless, other elements of the law do reinforce standards designed to lower SIDS risks in childcare, including the mandate to develop a written safe sleep policy and to discuss it with parents prior to the child's enrollment. The type of required SIDS-related training was unspecified in the law.

NC Childcare Licensing Rules

The next step was to codify the more broadly written law into specific licensing rules for childcare providers. Developing guidelines for everyday practice is the responsibility of the NC Child Care Commission (CCC). The Commission is comprised of legislative appointees and includes childcare providers, community leaders, a pediatrician and Division of Child Development (DCD) staff. The Commission's rules committee, faced with the task of weaving legal requirements into childcare licensing rules, included a subset of Commission members, child advocates, legal counsel, DCD staff members and this author. Rule changes affecting behaviors and environmental factors associated with SIDS risks were proposed, reviewed by the Commission, tweaked, and then posted for public comment for two months from December 2003 to February 13, 2004. Revisions to the proposed rules incorporated feedback from the public review process and were then subjected to legal review by the Rules Review Commission in March and entered into the Code by the Office of Administrative Hearing in April. The resulting licensing rules went into effect May 1, 2004.

Of significance, the rules pertaining to safety and sanitation include prohibitions on tobacco use around children in family childcare homes and vehicles when transporting children, where none had existed heretofore. Secondhand smoke more than doubles the chances of SIDS, exacerbates asthma, is an allergen, and triggers respiratory infections. Tobacco products are a leading cause of childhood poisoning.

The revised licensing rules addressing infant/toddler sleep safety and SIDS apply to childcare providers licensed to care for infants 12 months of age or younger and are summarized as follows:

1. An infant 12 months of age or younger is to be positioned on the back for sleeping unless a waiver states otherwise. A physician waiver exempting back to sleep for infants six months of age or younger is required. Childcare providers may choose to implement a parent waiver for infants older than six months.

   Note: *The Alternative Sleep Position Waiver—Physician Recommendation* form, developed by the DCD, must be completed by the child's primary care physician in the event a medical condition necessitates it. The waiver states the medical reason for a sleep position other than the back and the recommended alternative sleep position must be identified.
2. A notice indicating that a waiver is in effect and stating the recommended sleep position must be posted near the child's crib. The signed waiver is to be kept in the child's file.
3. A written safe sleep policy or poster must be prominently posted and this information communicated to parents before a child is enrolled. The policy must be discussed with

parents of currently enrolled infants within 30 days of the rules' effective date.

4. The crib, bassinet or playpen will have a firm padded surface.
5. Baby's head or face shall not be covered.
6. Tobacco products can not be used at any time children are in care; and smoking or use of tobacco products is not allowed indoors when children are in care, or in a vehicle when children are transported.
7. The room temperature where babies sleep cannot exceed 75°F.
8. Sleeping babies must be visually checked and the frequency of checking and observations documented. This record must be kept on file for one month following the reported month.
9. Awake infants shall have a daily opportunity to play while on their stomachs.
10. The Infant/Toddler Safe Sleep and SIDS Risk Reduction in Child Care (ITS-SIDS) training is the designated training.
11. Owners/operators/directors, lead infant teachers, substitutes and volunteers counted in the child-to-staff ratio must obtain ITS-SIDS training. Providers must renew their ITS-SIDS certification every three years. New hires shall receive ITS-SIDS training within four months of hire or within four months of the rules becoming effective, whichever comes later.

ITS-SIDS Training Project

The Infant/Toddler Safe Sleep and SIDS Risk Reduction in Child Care (ITS-SIDS) Project is a train-the-trainer initiative developed as part of the NC Back To Sleep Campaign, a program of the North Carolina Healthy Start Foundation. It adheres to the AAP recommendations, national child health and safety gold standards and best practices aimed at reducing SIDS. ITS-SIDS was initially funded for two years by the NC Division of Child Development on July 1, 2002—almost one and a half years before the NC SIDS law went into effect. Given the sequence of events and training needs, the Division expanded funding for Phase Three from December 1, 2003 through June 30, 2005.

Project goals are to: (l) introduce a safe sleep standard in NC childcare, (2) develop a cadre of certified ITS-SIDS trainers and (3) provide contact hour credits for childcare providers. The objective is to train 180 certified ITS-SIDS trainers who would, in turn, train 14,500 childcare providers over the course of the three years. ITS-SIDS trainers are made up of Child Care Resource and Referral staff, Smart Start Partnership staff, Child Care Health Consultants, Cooperative Extension Service Agents, Migrant Head Start staff, childcare directors and private trainers.

With changes in the legal and licensing requirements the demand for ITS-SIDS training across the state has skyrocketed. A total of 208 ITS-SIDS trainers have been certified. As of May 28, 2004, over 17,950 childcare providers have received ITS-SIDS training and 982 trainings have been scheduled or completed. While not all North Carolina counties have a resident ITS-SIDS trainer, all 100 counties do have training coverage. A fourth train-the-trainer series is planned for fall 2004 to address trainer attrition and to provide updated information.

How Will the NC Licensing Laws Affect Healthcare Providers?

There are several areas where physicians, perinatal healthcare providers and parent educators are impacted by the sleep safety and SIDS risk-reduction childcare requirements. First, physicians may be approached by parents to complete the *Alternative Sleep Position Waiver—Physician Recommendation* form. This waiver exempts a child 12 months of age or younger from being placed on his or her back to sleep based on a medical condition and specifies the recommended sleep position for that child. The baby's doctor is also asked to indicate the time frame for which the waiver applies. The onus of responsibility for the baby's sleep safety in childcare is shared by both the caregiver and the baby's primary care physician.

Parent-physicians desiring to waive the back sleep position for their child and attempting to sign the medical waiver themselves, muddy the legal waters and place the caregiver in an awkward situation. This scenario has already occurred in North Carolina and in other states. In Illinois, for example, providers are instructed to tell the parent-physician that they must choose. Either they assume the role of parent or that of doctor, but not both.

Particularly striking is the juxtaposition between what parents observe in the hospital or are taught by newborn nursery staff and what is played out in the childcare arena. Tension around the issues of infant sleep position, swaddling, use of sleep positioning devices such as blanket rolls or wedges and co-sleeping twins is a dynamic situation already occurring downstream from the hospital setting and now surfacing in childcare settings.

Not all of North Carolina's hospital nurseries practice the back to sleep standard of care for healthy babies. Some, but not all, of the state's Neonatal Intensive Care Units (NICU) have guidelines for transitioning infants from their stomach or side sleep position to their back; this should be as routine as the testing done for car seat safety among preemies. Similarly, educating about infant sleep safety and transitioning to the back sleep position should be incorporated into routine hospital practices as part of preparing all infants for discharge.

Parents are being taught in the hospital to swaddle infants for comfort and for security, but are they being informed about the signs of overheating, a SIDS risk factor? Are they instructed about when to discontinue swaddling? When parents insist that their four-week, six-week, or three-month old infant be swaddled in childcare, providers are in a quandary. Is swaddling helpful or harmful at these ages? The likelihood of overheating increases for a swaddled child. Furthermore, is the childcare provider using correct swaddling techniques that will prevent the blanket from covering the baby's head?

Bed sharing or co-sleeping with a parent or with a sibling poses dangers to infants by increasing the likelihood of SIDS, overlay (parent or sibling rolling onto infant), suffocation, overheating, entrapment, and injury due to falls from a bed without railings.

The pros and cons of co-sleeping are extremely controversial.[6] Breast feeding advocates promote bed sharing while professionals involved in SIDS risk-reduction education and sleep safety discourage it.

Data suggest that twins are at a greater risk for SIDS due to several factors: being born with a lower birth weight, a shorter gestation, and more complications during pregnancy. The co-bedding of twins in hospitals, at home, and in childcare settings remains a complex issue. Hospital practices for twin sleeping arrangements influences the infant sleep practices that parents adopt at home.[7] In North Carolina childcare, crib sharing among infants—even twins—is a violation of childcare licensing rules, yet parents have sought and have obtained a physician's waiver to allow this practice. In one case the physician stated there was no medical reason for co-sleeping the twins, but that the parent had requested it. Again, the safety of the infants, the reasoning of this decision, and the legality of this action are called into question.

SIDS Risk Reduction in Childcare Reaches Parents

One favorable consequence of the safe sleep standards now required in NC childcare is that caregivers are informing parents about the steps they are taking to reduce SIDS risks. This has a spillover effect and extends the arm of SIDS awareness from the childcare setting into the infant's own home. Indeed, many of the ITS-SIDS trainers are being asked by childcare providers to present at parent orientations or to conduct workshops with parents. Providers can share free educational materials with parents that are developed and distributed by the North Carolina Healthy Start Foundation.

Childcare providers are also taking the safe sleep and SIDS risk reduction message home. Many professional childcare workers are themselves parents or grandparents. Evaluations from their ITS-SIDS training show they plan to adopt the recommendations in their personal lives and to share the information with others.

Growing National Efforts to Address SIDS

The American Academy of Pediatrics has recently reconvened their task force on Infant Sleep Position and SIDS to reassess SIDS-related research and to address issues such as hospital nursery guidelines, waivers in childcare, swaddling and co-sleeping. A position statement updating their 2000 recommendations[8] is expected in autumn 2004. Hospital nurseries and Neonatal Intensive Care Units (NICUs) nationwide are re-examining their sleep position guidelines in light of the earlier standards set forth by the AAP. And, the AAP together with the National Resource Center for Health and Safety in Child Care and other national SIDS organizations has initiated a nationwide "Back To Sleep Campaign" for childcare facilities and has incorporated elements of North Carolina's ITS-SIDS training curricula. The AAP is partnering with the National Conference of State Legislators to promote safe sleep/back to sleep and SIDS risk reduction legislation in states across the county.

North Carolina is Leading the Way in SIDS Risk Reduction

North Carolina is an active leader in SIDS risk reduction in childcare. The state has adequate SIDS-related legislation, carefully revised licensing rules, a robust ITS-SIDS training program and an active Back To Sleep public education and awareness media campaign in motion. Networking occurs on a national level and statewide provider and parent education is fostered through the solid cadre of ITS-SIDS trainers. However, challenges and gaps remain, particularly in the areas of developing and sustaining more in-depth and interactive parent and grandparent SIDS risk-reduction interventions. There is a pressing need to competently address targeted SIDS risks for African Americans and among our growing Latino population and to make culturally and linguistically appropriate outreach available to Latino childcare providers and families. And there remains a need for hospital nurseries and NICUs across the state to convey and model a clear and consistent safe sleep/back to sleep message to parents.

Limitations on workplace tobacco use in childcare settings and growing awareness among childcare providers and parents via the ITS-SIDS training that smoking triples the SIDS risk (babies' secondhand smoke exposure doubles it) may stimulate an increased demand for smoking cessation services. Healthcare providers can play a significant role in reinforcing information about the link between SIDS and smoking. Counseling women not to smoke or to avoid secondhand smoke during pregnancy is an essential first step to combating SIDS. The relationship between pre-term/low-birth weight births and SIDS needs to be more clearly understood. This information should then be conveyed to women and families.

While we have a steady compass and a roadmap to help plot our fight against SIDS, only time will tell the extent to which recent policy changes will impact the tragedy of SIDS in childcare and possibly in family homes. It is clear that too many North Carolinians have experienced heartbreak because of SIDS and that we must adequately support community-based efforts to promote infant/toddler sleep safety and SIDS risk reduction in culturally and linguistically appropriate ways for families, other caregivers, and for healthcare professionals. More can and should be done to inform parents and caregivers that lowering SIDS risks begins before the baby is born as well as afterward. **NCMJ**

Baby's Safe Sleep

Keep room temperature 68° - 72° F. Not over 75° F

Use a firm mattress with a tight-fitting sheet

Remove toys, stuffed animals and pillows when baby sleeps

Check on sleeping baby

Keep cigarette smoke away

Keep baby's face and head uncovered

Do not use wedges and bumper pads

Keep baby from overheating, dress baby in layers that can be easily removed

Place baby at the foot of the crib
If you use a blanket:
- Use a light blanket
- Tuck it along the sides and foot of crib
- Cover baby from chest down

ALWAYS PUT HEALTHY BABIES ON THEIR BACKS TO SLEEP

Take these steps to lower the risk of Sudden Infant Death Syndrome (SIDS)

STOMACH TO PLAY BACK TO SLEEP

N.C law and child care licensing rules require that babies 12 months of age or younger be placed on their backs to sleep in child care. A waiver may apply under certain conditions.

COMMENTARY

Folic Acid and Birth Defects Prevention:
A Public Health Success Story

Robert E. Meyer, PhD, MPH, and Anna Bess Brown, MPH

Not very many years ago, prevention of birth defects was rarely given serious consideration as an important public health strategy for reducing infant mortality and improving birth outcomes. Some common misconceptions about birth defects—that they are rare events which account for relatively few infant deaths, and that they are essentially unpreventable—probably contributed to the fact that birth defects were largely overlooked as a focus of most infant mortality reduction efforts. Yet, contrary to the perception of many people, birth defects (or congenital malformations, as they are sometimes described) are not that rare. Approximately 3% of all infants are born with serious birth defects. In North Carolina, that translates to about 3,000-3,500 babies affected each year—a number that is 50% greater than the number of babies who are born with very low-birth weight. Birth defects are listed as the underlying cause of death in about one in every five infant deaths in North Carolina, and approximately 30% of all infants who die in the first year of life have one or more birth defects diagnosed. Moreover, many types of birth defects are largely or entirely preventable. Some examples include fetal alcohol syndrome, retinoic acid embryopathy, congenital rubella syndrome, and folic acid preventable birth defects such as anencephaly and spina bifida. While it is true that the etiology of the majority of birth defects is currently unknown, the same is also true for most preterm births, yet the latter still has been a chief focus of infant mortality reduction efforts for decades.

"Birth defects are listed as the underlying cause of death in about one in every five infant deaths in North Carolina..."

Beginning in the early 1990s, a series of landmark events began to set the stage for a significant change in the perception of birth defects as an issue deserving of public health attention. The first of these was the completion of the randomized controlled trial conducted by the Medical Research Council in the United Kingdom which, building upon previous observational studies, demonstrated that preconceptional intake of the B-vitamin folic acid could prevent up to 70% of spina bifida and anencephaly, the two most common types of neural tube defects (NTDs).[1] In September 1992, the US Public Health Service published the recommendation that "All women of childbearing age in the United States who are capable of becoming pregnant should consume 0.4 mg of folic acid per day for the purpose of reducing their risk of having a pregnancy affected with spina bifida or other neural tube defects."[2] In 1996 the Food and Drug Administration promulgated a rule requiring all enriched grain products to be fortified with folic acid, effective January, 1998. Subsequently, the national Institute of Medicine reaffirmed the US Public Health Service recommendation and added that women of childbearing years should take 0.4 mg of *synthetic* folic acid daily.

In North Carolina during this time, a concerted effort took root to reduce the prevalence of neural tube defects by promoting awareness and consumption of folic acid among women of childbearing age. In 1994, the NC Neural Tube Defect Task Force, later renamed the NC Folic Acid Council, was created. North Carolina was among the first states in the United States to establish such a council, and the group has achieved national recognition for the leadership role it has taken to promote the benefits and consumption of folic acid. Recognizing the need for better surveillance data to help design, target, and evaluate folic acid interventions, the Council worked with the NC General Assembly to establish the NC Birth Defects

Robert E. Meyer, PhD, MPH, is the Director of the NC Birth Defects Monitoring Program, State Center for Health Statistics, Division of Public Health, NC Department of Health and Human Services. He can be reached at Robert.Meyer@ncmail.net or 1908 Mail Service Center, Raleigh, NC 27699-1908. Telephone: 919-733-4728.

Anna Bess Brown, MPH, is the Coordinator of the North Carolina Folic Acid Campaign at the NC March of Dimes Birth Defects Foundation. She can be reached at abrown@marchofdimes.com or 4112 Pleasant Valley Road, Suite 208, Raleigh, NC 27612. Telephone: 919-781-2481.

Monitoring Program (BDMP) in 1995. The purpose of the BDMP is to collect, analyze, and disseminate critical information needed for the prevention and treatment of birth defects in North Carolina.

Data from the BDMP indicated that the neural tube defect rate in North Carolina was approximately twice the national rate, and that the rate in the western part of the state was nearly three times that of the United States. Thus, the initial focus of the state's folic acid awareness efforts concentrated in the western region, in partnership with the Fullerton Genetics Center and other key healthcare providers in the region. The results of these efforts were impressive. Between 1995 and 2002, the prevalence of NTDs in the western region has decreased by about 75%—or approximately twice the decline seen compared to the state as a whole which, concurrently, had also reaped significant benefits from an array of local, state, and national folic acid initiatives. These initiatives include the fortification program and numerous public awareness campaigns both within and outside the state. The success of these efforts are evident by recent data from the BDMP. Statewide in the year 2002 alone, there were an estimated 80-90 fewer pregnancies affected by NTDs compared to the number that would have been expected had the rates remained the same as in 1995 (prior to folic acid interventions). More than one-half of these pregnancies probably would have ended in medical termination or fetal/infant death, while the remaining infants would have been born with significant disability and other serious health problems.

The BDMP provides the foundation for the Folic Acid Campaign. The program's surveillance data inform the Campaign regarding populations of greatest need, help the Campaign evaluate its effectiveness, and aid in strategic planning. It is also useful to combine these data with information from the Pregnancy Risk Assessment Monitoring System (PRAMS) and the Behavioral Risk Factor Surveillance System (BRFSS) in order to track trends in folic acid knowledge and consumption. With longstanding support from the March of Dimes, the NC Folic Acid Campaign conducts community and healthcare provider education, vitamin distribution, and media campaigns in its efforts to educate North Carolinians about preventing neural tube defects by taking folic acid daily.

The Campaign has succeeded in raising awareness about the benefits of folic acid. Data from NC PRAMS show that in 2001, 86% of women who gave birth that year had heard or read about folic acid (up from 74% in 1998); however, the fact that still only 27% of women reported taking it every day before becoming pregnant indicates that much work remains to be done before all folic acid preventable birth defects are eliminated. The major challenge now lies in reaching those sociodemographic populations in which the prevalence of NTDs has not declined substantially, and in which multivitamin use remains low. For example, a recent analysis by the BDMP found that the prevalence of spina bifida had decreased very little among women who were less than 25 years of age, who had less than a high school education, and who were on Medicaid compared to their counterparts who were older, better educated, and not receiving Medicaid.[3] Efforts to refocus the Campaign on these populations are already underway.

There is still much work to be done by the Folic Acid Campaign and by healthcare providers. Of the women who know that folic acid prevents birth defects, but do not take vitamins, 89% say they would take vitamins containing folic acid if their healthcare providers recommended they do so.[4] This is a tremendous opportunity for healthcare providers to create public health change by causing a change in the behavior of patients. Every woman who is capable of becoming pregnant should be encouraged by her physician to take 0.4 mg (400 mcg) of folic acid in the form of a multivitamin every day, in addition to eating a well-balanced, healthy diet. Because the development of the neural tube occurs within the first few weeks of pregnancy (often before a woman even knows she is pregnant), it is essential to stress that folic acid must be taken *every day before pregnancy* and continued through at least the first trimester.

In their article elsewhere in this issue of the *Journal*, DeClerque et al.[5] highlight the need for infant mortality prevention efforts to place a greater emphasis on improving the health of women before they become pregnant. Those who have been involved with birth defects prevention have long recognized the fact that the preconceptional period is the only viable window for effective primary prevention, because most major structural congenital malformations occur very early in pregnancy. Although we do not yet fully understand the mechanisms leading to early preterm birth and we do not know when the optimal window for prevention is, it is only reasonable to assume that, in general, the healthier a women is before pregnancy, the better her chances are of having a full-term, healthy infant. In their paper DeClerque and colleagues call for a "paradigm shift" toward focusing on improving preconceptional health—and more generally *women's health*—as a strategy for combating infant mortality. That recommendation, which has the potential for reducing infant morbidity and mortality related to both birth defects and low-birth weight, is a welcome one indeed. **NCMJ**

Addressing Perinatal Health Disparities:

Another Place for a Paradigm Shift

Vijaya K. Hogan, DrPH

There are persistent racial and ethnic disparities in infant mortality in the state of North Carolina that are preventable and unjust by all standards of social justice. The five-year infant mortality rate (1998-2002) for African American infants was 15.4 compared to 6.3 for white infants—a greater than two-fold excess mortality risk for African American infants.[1]

Prematurity/low-birth weight is the leading contributor to neonatal mortality in the United States,[2] and the leading cause of overall infant mortality in many states including North Carolina.[3] Preterm birth has been the leading cause of death for black infants for more than a decade and is the greatest contributor to the excess mortality experienced by black compared to white infants in this state.

One of the *Healthy People 2010*[†] goals is to eliminate health disparities.[4] Among this goal's objectives is to address the racial and ethnic disparities in all aspects of perinatal health, including prematurity. The *Healthy People 2010* objective is to reduce the rate of preterm births to 7.6 by 2010. Yet, the preterm birth rate continues to increase, both among multiple and singleton deliveries. There has been little progress over time in reducing the rates of preterm births and similarly little sustained progress in reducing the disparity.[5] If we are to begin to make progress toward the 2010 objective, it is critical to step back and assess why we have not made more aggressive progress in eliminating the excess risk of infant mortality and preterm birth experienced by African American infants.

> *"Preterm birth has been the leading cause of death for black infants for more than a decade..."*

Barriers to Reducing Perinatal Health Disparities

One problem lies in the fact that little progress has been made in understanding the etiology of preterm birth. Another problem is the failure to define effective mechanisms to address known risk factors. These problems affect women of all ethnicities, but most acutely, African American women. The third problem—which uniquely affects women of color—rests in a failure to correctly conceptualize the causes of health disparities, and approach their elimination in a logical and scientific way. While discussion and action are needed to address all three of these problems, this paper attempts to focus attention on the latter in order to spur discussion and action toward the needed paradigm shift in disparity elimination.

The existence of a national objective to eliminate health disparities as specified in the *Healthy People 2010* goal effectively charges all of public health and medicine with a responsibility to actively work toward the elimination of these disparities. Receipt of federal funding, such as Title V, often requires that states include strategies for monitoring and addressing health disparities, and states may often additionally require local accountability and plans to address disparities. There is no doubt that the existence of the *Healthy People 2010* objective has elevated the issue of health disparities and their elimination to a higher level of national and state priority. But despite this, there does not appear to be a systematic process for understanding and addressing health disparities.

Vijaya K. Hogan, DrPH, is the Director of the Curriculum on Health Disparities and a Clinical Associate Professor in the Department of Maternal and Child Health, School of Public Health, University of North Carolina at Chapel Hill. She can be reached at vijaya_hogan@unc.edu or at CB# 7445, Chapel Hill, NC 27599. Telephone: 919-843-3886.

[†] *Healthy People 2010* is a set of national health objectives for the first decade of 2000. *Healthy People 2010* builds on initiatives pursued over the past two decades. The 1979 Surgeon General's Report, Healthy People, and Healthy People 2000: National Health Promotion and Disease Prevention Objectives both established national health objectives and served as the basis for the development of state and community plans.

Indicators of the Existing Paradigm's Failure to Reduce Disparities

First, the current approach assumes that everyone in medicine and public health is scientifically prepared to conduct planning and research around health disparities. Second, there is a predominant notion that to address the disparity, one simply needs to target "evidence-based" interventions specifically to African American (or other vulnerable) populations. Neither of these assumptions is necessarily correct.

Not everyone is scientifically prepared to conduct planning and research around health disparities. It would be hard to imagine someone addressing diabetes without having some training it the subject area, yet most in public health and medicine do not have any preparation for addressing health disparities. The curricula of schools of medicine, nursing, or public health do not routinely require study of health disparities.

One of the fundamental components of a prevention approach to any disease is to know its contributing factors and then act to reduce the effects of these factors.[7] Yet, most people either do not know what factors contribute to health disparities or do not act on them. Factors cited in literature as affecting disparities overall include: healthcare, behavior, culture/acculturation, social factors, psychosocial factors, environmental factors, racism, stress, genetic factors, economic factors, socioeconomic position, neighborhood factors, national, state or local policies, historic and life course exposures, weathering, and other intergenerational factors as contributors.[8-11] Currently, there is little empirical data to define the relative contribution of each of these factors to any specific disparity, but for perinatal outcomes, individual studies have shown a persistence of a disparity when behavioral, healthcare, and, in some cases, socio-economic status factors are considered.[12] Genetic factors are unlikely to be a major contributor to health disparities.[13] In fact, in the summer of 2000, the acting director of the National Institutes of Health stated before the US Senate Subcommittee on Public Health that:

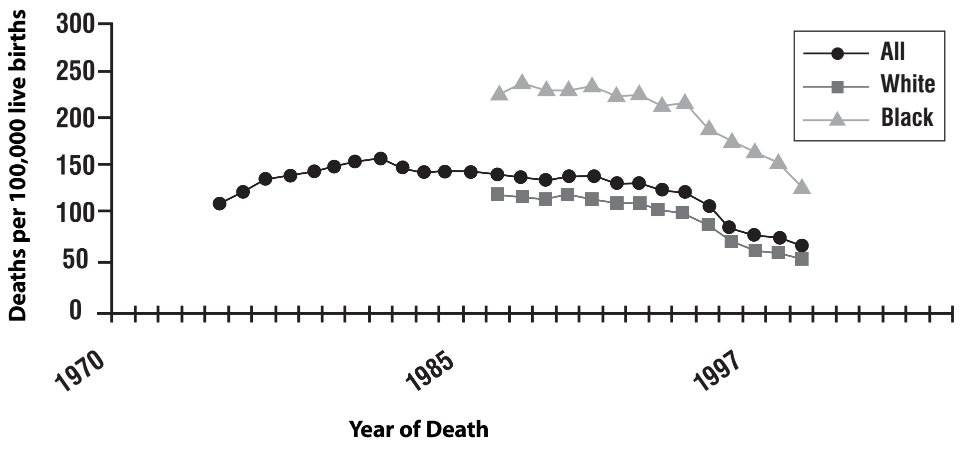
> "The causes of health disparities are multiple. They include poverty, level of education, inadequate access to medical care, lack of health insurance, societal discrimination and lack of complete knowledge of the causes, treatment and prevention of serious diseases affecting different populations. The causes (of health disparities) are not genetic, except in rare diseases like sickle cell... The elimination of health disparities will require a cross-cutting effort, involving not only various components of the Federal Government, but the private sector as well...."[14]

Additionally, a highly touted national Institute of Medicine (IOM) report reviewing evidence on healthcare inequities recognized that:

> "...racial and ethnic disparities in health status largely reflect differences in social, socioeconomic, behavioral risk factors and environmental living conditions. Healthcare is therefore necessary, but insufficient, in and of itself to redress racial and ethnic disparities in health status. A broad and intensive strategy to address social-economic inequality, concentrated poverty, inequitable and segregated housing and education... individual risk behaviors as well as disparate access to medical care is needed to seriously address racial and ethnic disparities in health status"[15]

Yet, recent trends in research and intervention focus on healthcare factors, genetic research, and downstream clinical factors. The language used, and the implicit approaches to disparity elimination, reflect a certain naiveté (or maybe denial) about what it takes to truly eliminate disparities. For example, it is not unusual to hear public health and medical professionals interchange the use of the terms "health disparity" and "healthcare disparity." They are two distinct phenomena, with disparities in healthcare being only one contributing factor to overall health status disparities. Understanding the distinction is not unimportant as it is reflected in subsequent actions to eliminate health disparities. While healthcare factors are estimated to cause 10-30% of the morbidity disparities,[16] we spend 90% of our resources on this one contributor. Some of this spending should be reallocated to address the social determinants of health and to the pertinent research issues that will generate new knowledge to fuel progress toward eliminating disparities.

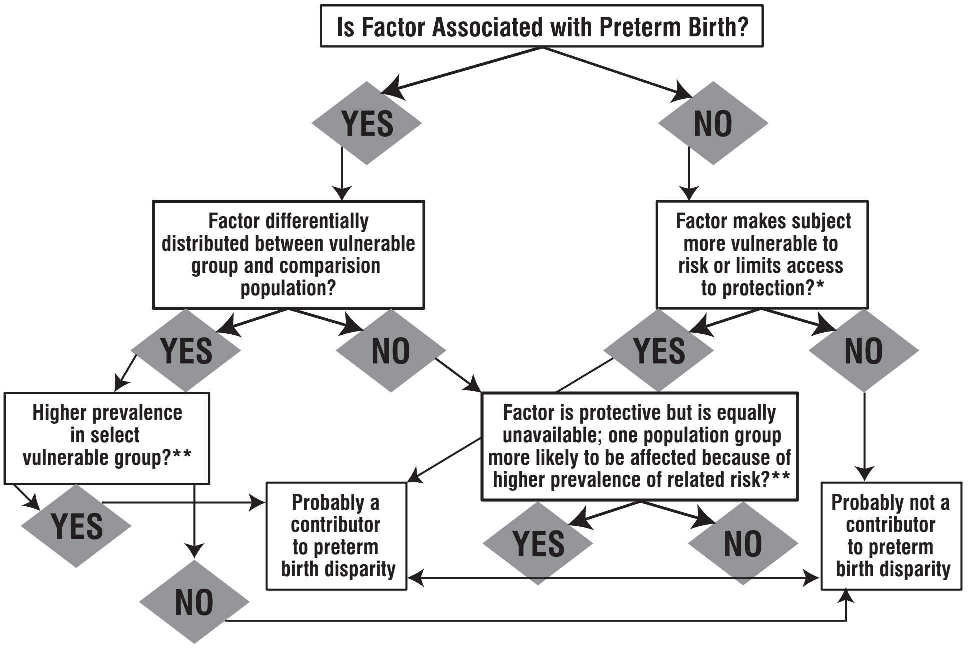
Figure 1.
Infant Mortality Rates Due to SIDS, United States by race, 1973-1998



Another limitation of the current paradigm for disparity elimination is a sole reliance on targeting evidence-based interventions for the disease as a strategy to reduce disparities. Targeting evidence-based interventions as a disparity elimination strategy assumes that reducing specific risk factors for the disease in vulnerable populations is all that is needed to reduce the disparity. Factors that cause the disease are not necessarily the same as those that cause the disparity. Efforts to reduce the disparity may require interventions above and beyond those that reduce the disease. Take for example the decline is Sudden Infant Death Syndrome (SIDS) rates (Figure 1).

The significant declines over the past several years are widely attributed to the impact of one "evidence-based intervention" (i.e., the Back To Sleep campaign). However, these declines occurred among all population groups, including African Americans; yet the magnitude of the *disparity* between African American and white populations remained unchanged. This indicates that something more than the standard evidence-based interventions targeted to vulnerable populations may be necessary. Additional attention needs to be paid to the factors that make some populations more vulnerable to specific health threats. That is, strategies to reduce/eliminate disparities must target the risk factors for the disease as well as risk factors for the disparity. It will take more than business as usual to really get at the causes of the disparity.

Figure 2.
Logic Model: Determining Contributors to Preterm Birth Disparity



* The factor may be an "upstream" contributor that has not been directly associated with preterm birth, but has been associated with increased prevalence of other more proximal risk factors for preterm birth. One example might be "racism."

** Caution is advised in ruling out factors by this criterion. Even if prevalence of a single risk factor is lower, the prevalence of co-existing risks (with which this factor may interact) may be higher and interactive effects may contribute to disparity. For a hypothetical example, smoking prevalence may be lower among African Americans, but a higher percentage of African American smokers may have other co-occurring risks, increasing the risk of disease outcome.

Logic Model: Determining Contributors to Preterm Birth Disparity

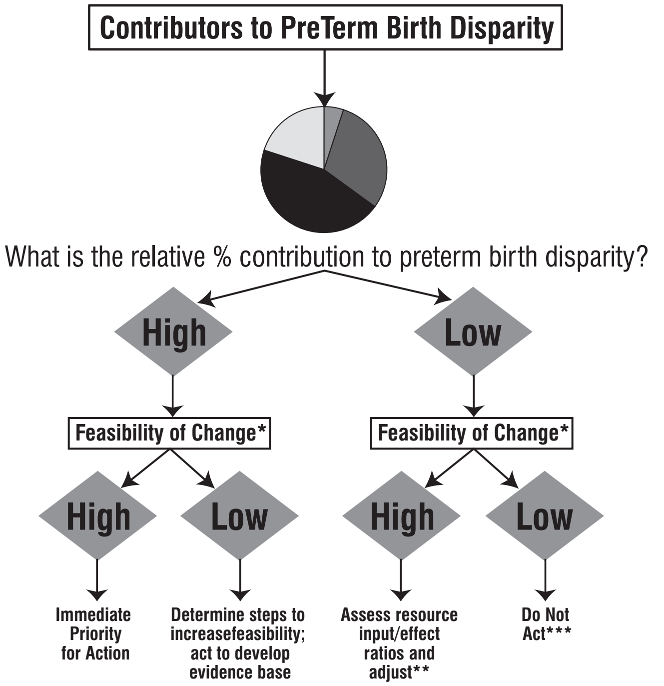
If we want to address the disparity as well as see continued declines in all groups in troublesome perinatal outcomes, we have to take a more strategic, logical, and scientific approach. First, we have to improve the knowledge base within public health, medicine, and society as a whole with respect to what causes, and how we could eliminate, health inequities. Second, we need to focus research more strategically toward the issues that will bring more bang for the buck—that is, to support and conduct research that sheds light on how we can more effectively address social determinants of health, as these factors are acknowledged to be the strongest contributors to the disparities in health status. Third, we need to take a more logical approach with the use of existing knowledge to define strategies, and in defining what the priority research issues should be.

One logic model for determining if a factor is a potential cause for perinatal disparities is proposed in Figure 2. To begin with, we have to determine if a factor is a contributor to the disparity in preterm birth, and if so, include this on the list of factors that need to be addressed (Figure 2). This model is most useful for including additional factors that may not be otherwise considered. To be defined as a contributing factor to the disparity, the variable in question should be a risk factor for preterm birth or affect the distribution of a known risk factor. It should also be more prevalent in the vulnerable group. For example; maternal infection (e.g. bacterial vaginosis) is associated with preterm birth (YES), is differentially distributed between African Americans and whites (YES), and with higher prevalence among African Americans (YES). Therefore, it is very likely a contributor to the disparity. In contrast, smoking is associated with preterm birth (YES), is differentially distributed between these two groups (YES), but the prevalence is higher among whites (NO); therefore, it is probably not a major contributor to the disparity. This does not mean, however, that smoking cessation should not be included in an intervention strategy. Since smoking is a risk factor for preterm birth and other serious diseases, it should be included. Genetic factors are another example. These may be associated with preterm birth, but are not shown to be differentially distributed, and therefore are not likely to be a contributor to the diparity.

Logic Model: Planning Strategies to Eliminate Preterm Birth Disparities

Once a set of factors is determined to be associated with the preterm birth disparity, the factors can then be prioritized to determine where to place resources more effectively. Figure 3 offers a model that can be used to determine intervention priorities. In the model, if prenatal healthcare factors contribute little to the disparity (LOW), but the feasibility of improving the quantity or quality of care was high (HIGH), then one needs to reassess the amount of resources placed on this factor and consider reallocation to a degree proportionate to the relative impact. Maternal infection is considered a strong contributor to preterm birth disparity, with estimates of up to 30% of disparity attributed to this cause (HIGH). The feasibility of mediating this risk is minimal at this time because of the conflicting nature of results from existing treatment trials (LOW). This does not, however, suggest that one should do nothing. In fact, since it is a strong contributor, even more action is needed to develop the evidence base for effective intervention strategies.

Figure 3.
Logic Model: Planning Strategies to Eliminate Preterm Birth Disparities



* *Feasibility of change:* evidence base for best practices to address the factor exists; prevailing economic, political, and institutional climate will be supportive with reasonable effort

** If proportion of resources put toward addressing this factor exceeds its percent contribution to disparities, consider reallocation of resources toward factors with greater importance

*** Spending resources on these factors may be wasteful, counterproductive, and inefficient in efforts to eliminate disparity

A risk factor that is a strong contributor should have higher priority compared to one that is a lesser contributor. If a risk factor is a strong contributor and is relatively easy to change, this should be included in a disparity elimination strategy. If it is not easy to change (e.g., racism), then instead of passing over it, we need to focus attention on increasing the feasibility of change and support the research needed to develop an "evidence base" for successfully mediating these risks. Conversely, if a factor is a small contributor, whether easy or difficult to change, we need to reassess our efforts and the resources spent on these factors. An example might be genetic factors, which are not likely to be strong contributors to the disparity, have a low feasibility of change, thus resources (research and other) would be better placed toward addressing stronger contributors.

Conclusion

Health disparities have not been approached with the same scientific rigor that we use for addressing other health conditions. Before defining strategies to eliminate health disparities, professionals should be required to study or understand the underlying contributors. Assumptions and personal biases about causality also need to be critically examined. The probability of success in eliminating disparities will be affected by the depth of healthcare professionals' knowledge of the causes of health disparity. The responsibility for eliminating health inequities lies with all of society. Thus, it is important for all to have a strong conceptual understanding of: why it is important for the health of all that disparities be addressed, what contributors affect health inequities, how much certain risk factors contribute, and how they exert their effects. This understanding can increase the probability that efforts to eliminate health disparities are realistic and holistic, have a strong conceptual basis, are reasonably keyed to the true causes, and thus have greater probability of successfully reducing inequities. It is important to avoid spending considerable resources on a strategy or intervention that addresses a minor contributor at the expense of large ones, all the while promising to eliminate overall health inequities. In the current political climate, the price of failure to make progress could significantly reduce future prioritization of funding to address health inequities. **NCMJ**

North Carolina Efforts to Address Perinatal Health Disparities

Belinda Pettiford, MPH

The NC Office of Minority Health and Health Disparities (OMHHD), within the Department of Health and Human Services (DHHS), released its health disparities' report in January 2003. In this report, the state received a "D" in perinatal health disparities, specifically infant mortality. As part of the follow-up to this report, the DHHS has made eliminating health disparities a higher priority.

In its ongoing efforts to address perinatal health disparities, the Women's and Children's Health Section (WCHS) of the NC Division of Public Health, DHHS, has implemented several programs within the last 5-10 years.

The state's Minority Infant Mortality Reduction Program, Healthy Beginnings, is a collaborative effort between WCHS and OMHHD. This program provides $50,000 yearly to 13 community-based organizations, faith entities, health departments, and health centers. These organizations provide outreach to bring people into care, education for parents, and support services to primarily African American women, infants, and families within certain geographic areas (one project focuses on American Indian families).

North Carolina's federally funded Healthy Start Program, Baby Love Plus, is also designed to address perinatal health disparities. This program has covered 14 counties with a primary focus on improving birth outcomes in African American and American Indian communities. Services include community consortia development, case management from prenatal to two years postpartum for mother and child, health education, outreach, and perinatal depression screening.

All of these efforts emphasize strong community, family, faith, and health provider relationships, along with a key focus on community leadership development. Due to funding cuts with both programs and other budgetary limitations, WCHS continues to look for resources to expand these efforts as part of the overall DHHS's disparity plan.

Belinda Pettiford, MPH, is the Supervisor of the Perinatal Health and Family Support Unit in the Women's Health Branch, NC Division of Public Health, NC DHHS. She can be reached at belinda.pettiford@ncmail.net or 919-715-3399.

Health and Economic Consequences in North Carolina

Three of the top four causes of infant death in North Carolina are directly associated with either maternal smoking during pregnancy and/or infant exposure to tobacco smoke after birth.[1] Rates of preterm birth/low-birth weight, respiratory distress syndrome and Sudden Infant Death Syndrome (SIDS) could all improve dramatically if pregnant women and their partners did not smoke during and after pregnancy, and if infants were always in smoke-free environments, especially in their homes, child care locations, public places and automobiles.

> *"If no pregnant women smoked during pregnancy, the overall infant mortality rate for the state would drop an estimated 10 to 20%."*

In 2002, 15,440 women, or 13.2% of all women giving birth in North Carolina smoked while pregnant. A 2002 report on the association of maternal smoking during pregnancy with infant mortality in North Carolina showed that mothers who smoked had nearly twice the risk of an infant death or low-weight birth as mothers who did not smoke.[1] For SIDS, the risk associated with maternal smoking was more than five times as high.[1] Low-birth weight rates (per 1,000 live births) for smokers were 12.6 compared to 6.4 for non-smokers and 'small for gestation age' rates for smokers were 10.0 compared to 4.0 for non-smokers. When data by cause of death were examined, 50% of the infants who died of SIDS had mothers who smoked during pregnancy.[1]

If no pregnant women smoked during pregnancy, the overall infant mortality rate for the state would drop an estimated 10 to 20%.[1] Furthermore, the mortality rates would improve most in underserved and disadvantaged communities where women are more likely to smoke while pregnant.

Secondhand smoke is a known human lung carcinogen, and there is increasing evidence of its threat to both the short- and long-term health of pregnant women and infants.[2] Regardless of whether mothers smoked while pregnant, infants living in households or being cared for outside the home where they are exposed to secondhand smoke (SHS) may be at greater risk for SIDS.[3,4] These infants are also at greater risk than infants without this exposure for respiratory and growth-related problems.[3,4] In 2001, 11.7% of new mothers in North Carolina reported that their infants were often in the same room with someone who was smoking.[5]

Not only does prenatal exposure and/or exposure to SHS endanger the lives of infants, they also result in higher public expenditures for the care of mothers and infants participating in the Medicaid program in North Carolina. Costs during the first year of life for infants of women who smoked while pregnant were $4,353 compared to $3,769 for infants of non-smoking women.[1] Overall this difference amounts to nearly $6.5 million in excess Medicaid costs during one year for the infants of mothers who smoked.[1]

What Works to Reduce the Impact of Smoking on Infant Death?

A number of strategies have been proven to help pregnant and parenting smokers quit smoking and to increase the number of smoke-free environments for families. *The Guide to*

Cathy L. Melvin, PhD, MPH, is the Director of the Child Health Services Program at the Cecil G. Sheps Center for Health Services Research and a Research Associate Professor in the Department of Maternal and Child Health, University of North Carolina at Chapel Hill School of Public Health. She can be reached at melvin@mail.schsr.unc.edu or CB# 7590, Chapel Hill, NC 27599-7590. Telephone: 919-966-8072.

Sally Herndon Malek, MPH, is Head of the Tobacco Prevention and Control Branch, Division of Public Health, NC Department of Health and Human Services. She can be reached at sally.malek@ncmail.net or 1915 Mail Service Center, Raleigh, NC 27699-1915. Telephone: 919-733-1340.

Community Preventive Health Services presents recommendations for use by communities and healthcare systems on population-based interventions to promote health and to prevent disease, injury, disability, and premature death. Three strategic areas for intervention in tobacco use and prevention were identified through systematic reviews of the literature: reducing exposure to environmental tobacco smoke; reducing tobacco use initiation by children, adolescents, and young adults; and increasing tobacco cessation.[6] (See www.thecommunityguide.org for a complete listing of proven strategies to prevent and reduce tobacco use.)

Brief clinician counseling with pregnancy-specific self-help materials for pregnant smokers has been found to increase cessation rates by 30 to 70%.[7] Depending on the underlying prevalence of smoking in a particular group, this improvement could double or even triple cessation rates and save $3 for every $1 invested in treatment.[8] Similar counseling interventions along with appropriate pharmacotherapies for non-pregnant smokers have also been shown to significantly increase their chances of quitting smoking.[9]

Telephone support, when combined with other efforts such as educational approaches or medical therapies, is effective in helping smokers to quit when implemented in both clinical and community settings.[6] These help, or quit, lines are a valuable resource for clinicians who may need to refer their patients to external sources of counseling and support during their quit attempts.

Mass media education campaigns when combined with other interventions have also proven to be effective in preventing and reducing tobacco use.[6] Advertisements aimed at promoting cessation coupled with other interventions such as provider cessation services using the "5A's"[10] and full service, proactive quitlines are strongly recommended strategies.[6]

Increasing the numbers and types of smoke-free environments for pregnant women and children can reduce their exposure to SHS and its consequences. Policies and legislation aimed at creating smoke-free environments in worksites and public places have been found to increase cessation rates among smokers and to reduce SHS exposure for smokers and non-smokers alike.[6]

Strategies that increase the price of cigarettes and other tobacco products also have an impact on initiation of smoking and smoking cessation. Pregnant women seem to be especially sensitive to changes in price; for every 10% increase in the price of cigarettes, maternal smoking falls by 5%.[11] Increasing excise taxes on tobacco products in many states has prompted a significant number of smokers to quit smoking altogether.[11] Since many pregnant women are already motivated to quit smoking for their baby's health, the increase in price provides one more incentive to help them quit smoking.

Is North Carolina Using These Strategies?

North Carolina is making substantial progress in some, but not all, of these areas. To help clinicians who care for pregnant women gain the skills, confidence, and materials they need to help pregnant women quit smoking, the state has pursued a number of strategies. The Maternal and Child Health (MCH) Program within the NC Department of Health and Human Services (DHHS) has established a performance standard for treating tobacco use among pregnant clients. MCH programs must identify pregnant smokers and treat them using the Public Health Service "5A's" approach to cessation counseling. Award winning training materials for providers have been developed and training sessions have been held across the state. The Health and Wellness Trust Fund Commission has provided funding to increase tobacco cessation services for pregnant teens. Backup support and consultation is also available for clinicians working with pregnant smokers. Each year, programs compile data to assess their progress and identify areas for improvement in their approach to treating pregnant smokers.

The Women and Tobacco Coalition for Health (WATCH) has been working through a grant from the American College of Obstetricians and Gynecologists to conduct a number of activities designed to increase smoking cessation rates in North Carolina. This group is currently conducting a survey of clinicians providing prenatal care in North Carolina to understand how clinicians currently treat tobacco use among pregnant women they serve and to identify training and other needs that clinicians may have. Information gathered in this survey will help organizations involved in the coalition to develop new programs, materials, and approaches to help clinicians.

As part of an effort to reduce SIDS risk, the NC Child Care Commission recently approved changes to North Carolina's childcare licensing rules to address tobacco use and SHS exposure in child care facilities, including family child care homes. Recognizing that the risk for SIDS is more than doubled when babies breathe SHS and that tobacco products are a leading cause of childhood poisoning, the Commission expanded the prohibition on smoking in family child care homes so that the operator(s) cannot use tobacco products at any time children are in care; and that smoking or use of tobacco products is not allowed indoors when children are in care or in a vehicle when children are transported. Changes in policy and regulations such as these dramatically reduce the exposure of infants and young children to SHS and the risks associated with it.

North Carolina's local school boards are increasingly promoting 100% tobacco free school policies to eliminate secondhand smoke exposure and provide positive role modeling at school and school events. Thirty-six of North Carolina's 117 school districts have 100% tobacco-free schools policies; this is up from six school districts in 1999.

Significant progress has been made in North Carolina's private sector to protect workers from exposure to SHS, however this progress is considerably greater in the white collar sector. Disparities exist in blue collar and service industry sectors where many low-income women work. State law is a barrier to local government protections for secondhand exposure. The 1993 law entitled "Smoking in Public Places" (GS 143-597), states legislative intent "...to address the needs and concerns of both smokers and nonsmokers in public places by providing for designated smoking and non-smoking areas." This law requires state-controlled buildings to set aside 20% of space for smoking and preempts local governments from passing stricter rules.[12]

Are There Other Things North Carolina Can Do?

The state can expand efforts to train all clinicians in evidence-based interventions for pregnant and parenting smokers and take steps to assure adequate reimbursement for these interventions, especially through the Medicaid program and the state employee's health insurance plan(s). One of the barriers clinicians frequently cite as a reason for not providing cessation services is the lack of reimbursement for such services. An investment in the reimbursement of cessation services for pregnant smokers brings short-term cost savings for healthcare systems and the state, and has been shown to increase the likelihood that clinicians will offer these services.

Currently two quitlines are available to North Carolina residents. The American Legacy Foundation Great Start Quitline for pregnant smokers can be reached at 1-866-66-START. The National Cancer Institute Quitline for all smokers/tobacco users at 1-888-44-UQUIT is currently available during weekday hours. Plans are in place to have this line become a full-service, proactive quitline in January 2005. These quitlines bring evidence-based cessation help directly to smokers. They are also an important referral resource to clinicians as they work with pregnant and parenting smokers. Marketing these quitlines in North Carolina will enhance their utilization and result in more successful quit attempts. Mass media campaigns designed to promote quitting and the use of local and national resources such as these quitlines among pregnant women and the members of their households are strongly recommended by the Community Preventive Services Task Force, but currently not funded in North Carolina.

An increase in the state excise tax on cigarettes would also increase the likelihood that pregnant and parenting smokers would quit smoking. North Carolina's tobacco tax is currently five cents per pack, the third lowest in the nation. With an increase to 75 cents, North Carolina's tax would be close to the national average (currently 72.9 cents). And, a 75-cent increase in the cost of a pack of cigarettes would result in a 17.5% decrease in the number of pregnant women in North Carolina who smoke.

Adoption of a 100% tobacco-free school policy by North Carolina school boards would eliminate smoking at school and school events by students, staff, and visitors so that students, faculty and staff are protected from secondhand smoke and nonsmoking is promoted as a social norm. Blue collar and service industry sector worksites should be smokefree in order to provide worker protection from secondhand smoke, a known, preventable health hazard. If private sector worker protections are not adequate, the law prohibiting local rulemaking to protect people from secondhand smoke in public places and workplaces should be reconsidered in light of new evidence of the serious risks of secondhand smoke exposure for pregnant women and other vulnerable populations, and the effectiveness of nonsmoking policies in protecting pregnant women and infants from harm.

Summary

North Carolina faces major challenges in dealing with smoking and its consequences during pregnancy and infancy. Evidence-based strategies exist to help pregnant and parenting smokers to quit, to discourage young people from becoming smokers and to reduce exposure of infants to SHS. North Carolina is making progress in implementing these strategies, but more infant lives could be saved each year if the state adopted a more comprehensive approach to addressing tobacco use by improving cessation services for pregnant and parenting smokers, reimbursing clinicians for providing cessation services, increasing state excise taxes on tobacco products, establishing statewide help or quitline services and adopting tobacco-free school policies. These proven strategies can make a difference. **NCMJ**

Preterm Birth in North Carolina

Mary Lou Moore, PhD, RN, FAAN

Decreasing infant mortality is closely linked to decreasing preterm births. Unfortunately, the rate of preterm births in North Carolina and in the United States, after declining in the 1980s, has been rising again for the past several years. The goal of this commentary is to examine North Carolina data related to both preterm births per se and to those factors that have been associated with preterm birth.

At times, low-birth weight (LBW) rates will be used in this paper when preterm data are not available. While both rates follow similar patterns, readers should recognize that LBW refers to the birth of infants weighing less than 2,500 grams (5 pounds, 8 ounces), while preterm births are those before 37 weeks gestation. Some of the data reported here (smoking and intimate partner violence, for example) are based on self-report by women who are pregnant or delivering; such self-reporting may result in underestimation of the true rate of the outcome or exposure reported.

> *"...births to teen mothers have dropped each year in both the United States and in North Carolina."*

Preterm births may be medically indicated because of the health of the mother or fetus, may follow preterm premature rupture of the fetal membranes, or may be the result of spontaneous onset of labor. The antecedents of preterm birth are multifactoral and vary from one birth to another. Thus, the reasons for increasing rates of preterm birth are not clear. Two factors have been identified in both national and North Carolina data as potentially contributory: increasing maternal age and an increasing number of multiple gestation births.[1,2]

Maternal Age and Multiple Births

More women are delaying childbearing until their mid-thirties and into their forties than in previous generations. In North Carolina in 1998, 10.5% of all births were to women over the age of 35. By comparison, only 3.6% of births in 1978 and 5.8% of births in 1988 were to North Carolina women ages 35 or greater. The birth rate (births per 1,000 women in a population) for women ages 35 to 39 was more than twice as great in 1998 (32.7%) than in 1978 (13.8%). Although both rates were somewhat lower than comparable rates for the United States (34.7% and 19.0%), the trend is the same. During this same period, LBW rates for mothers in this age group increased from 8.8% to 10.2%. in North Carolina.[1]

Multiple births increased from 2.0 % of live births in 1980 to 2.8% in 1997, a 40% relative increase. Women over the age of 35 naturally have higher rates of multiple births.[2] In North Carolina the 1999-2001 rate was 43.3 for women ages 30-39 and 51.5 for women ages 40 and over, compared to 17.6 for women under age 20.2 In addition, the increased use of in vitro fertilization with the implantation of two or more embryos appears to be a contributory factor. The rate of preterm birth in multiple gestation pregnancies in North Carolina for 1999-2001 was 61.2, slightly higher than the rate of 59.2 for the United States.[3] The increase in multiple births between 1980 and 1997 appears to account for 70% of the increase in the LBW rate in NC during these years.[2]

At the other end of the childbearing age continuum, births to teen mothers have dropped each year in both the United States and in North Carolina. In the ten years from 1992-2001, pregnancy rates for North Carolina teens ages 10-14 decreased from, 3.3 per 1,000 to 1.7 per 1,000, a decrease of 48.5%. For adolescents ages 15-19 rates decreased from 30.7% to 16.4%, a decrease of 46.6%.[4] These decreases surpass the national rate of decrease of 26% since 1991.[5] Nevertheless, rates continue to be higher than in many developed nations.[6] In a review of 14,718 births, teens under 15-years of age were almost 50% more likely to have a preterm infant than adult women. Teens ages 16 and 17 were not found to be at increased risk in this study.[7]

Mary Lou Moore, PhD, RN, FAAN, is an Associate Professor of Obstetrics and Gynocology at Wake Forest University School of Medicine. She can be reached at mmoore@wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157-1066. Telephone: 336-716-3662.

Cigarette Smoking

Cigarette smoking and preterm labor, addressed in another paper in this issue,[26] has been linked to preterm and low-birth weight births for more than half a century. In a five-year study of low-income women receiving care in a public clinic in Forsyth County, North Carolina, cigarette smoking had a far greater effect on both low-birth weight and preterm births in African American women than in white women, even though fewer African American women smoked. In this study, 21.2% of African American women reported smoking cigarettes. African American women who smoked more than one-half pack of cigarettes a day had a preterm birth rate of 20.4% compared with a rate of 9.2% for non-smokers (p=.003 after adjusting for age and other risk factors).[8]

Physical and Emotional Stress

Stress has been associated with preterm birth in a number of studies.[9] Accumulation of trauma over one's lifetime (allostatic load),[10] job related stress,[11,12] and racism are examples of stresses experienced by many pregnant women in North Carolina. Through a complex physiologic pathway, stress raises levels of corticotropin-releasing hormone (CRH) leading to the production of Adrenocorticotropic hormone (ACTH) and glucocorticoids with subsequent preterm labor. Stress has also been associated with decreased immune competence, increasing the likelihood of infections which, in turn, are associated with preterm labor.

Intimate partner violence, a particular form of stress, was first identified as a correlate of preterm birth in 1989[13] and has since been confirmed in a number of studies. In a study using data from the population-based NC Pregnancy Risk Assessment Monitoring System (PRAMS) for 1997 though 2000,[14] the prevalence of physical violence during the 12-month period prior to pregnancy was 6.9% and 5.5% during pregnancy. These rates decreased from 8.4% and 8.1% for the two periods in 1997 to 6.5% and 5.2% in 2000. Rates of preterm birth were 10.1% for women experiencing violence and 9.6% for those who did not report violence. Rates of LBW were 10.1% for women reporting violence and 7.6% for those who did not. Women experiencing violence were more likely to begin prenatal care after the first trimester; to smoke before, during, and after pregnancy; to report high levels of stress in the 12 months before birth; and to experience postpartum depression.

Infection

Two groups of infections have been associated with preterm birth, infections of the genitourinary tract and periodontal infections. Genitourinary infections have been recognized as important correlates of preterm birth for a number of years. Identification and treatment of these infections necessitates access to and utilization of prenatal care.

Less attention has been given to periodontal disease. In a case control study of 124 pregnant and postpartum mothers, controlling for other risk factors, women with periodontal disease were found to be 7.9 times more likely to have preterm LBW births.[15] In a randomized study of 351 women in Chile, women treated for periodontal disease prior to 28 weeks gestation had a preterm rate of 1.84% compared to 10.11% for untreated women.[16] In North Carolina the availability of periodontal care for low-income women must be examined and, if it is not adequate, this issue must be addressed in plans to reduce preterm births.

Preventive Interventions

Two studies conducted entirely or partially in North Carolina suggest potential preventive interventions. A randomized multisite study of natural progesterone (17 alpha-hydroxyprogesterone caproate: 17P) injected intramuscularly beginning at 16 to 20 weeks gestation until 36 weeks included women from two North Carolina sites. All of the women in the study had experienced one or more previous preterm births. There was a statistically significant difference in births less than 37 weeks (36.3% vs. 54.9%; p=.0001) and less than 32 weeks (11.4% vs. 19.6%; p=.018) with the lower rates in women receiving 17P. There was also a significant difference in infant mortality rates: 2.6% for the 17P group and 5.9% for the placebo group (p=.05), as well as a decreased incidence in morbidity, including necrotizing enterocolitis and intraventricular hemorrhage (p=.05).[17] A study of 17P in Brazil using vaginal progesterone in a population with additional risk factors for preterm birth, also found a statistically significant reduction in preterm births.[18] The American College of Obstetricians and Gynecologists Committee on Obstetrical Practice has stated that "further studies are needed to evaluate the use of progesterone" in women with conditions other than a previous documented history of preterm birth "because unresolved issues remain, such as optimal route of drug delivery and long-term safety of the drug."[19]

In a five-year randomized study of nurse telephone intervention in low-income women receiving care in a public clinic in Forsyth County, North Carolina was highly effective in 759 African American women aged 19 and over with a 34% reduction in LBW births and a 44% reduction in preterm births. There was no difference in younger African American women or in white women.[20] Telephone intervention led to a cessation in smoking in 25%, of participants and reduction in an additional 21%.[21] Specific interventions included two or more phone calls per week with assessment, behavioral suggestions as appropriate (e.g. smoking cessation, need to contact healthcare providers at the clinic), education about preterm labor, and emotional support. When study data were examined by risk for preterm labor using a modification of the risk factors of Papiernik[22] and Creasy,[23] the greatest impact was on women identified at low risk. Previous studies by others have shown that only 50% of women who will have preterm births can be identified in a risk screening; the other 50% will have no identifiable risk factors and will be considered at low risk, but should nevertheless not be ignored in prevention efforts.[24]

A Changing Paradigm for Prematurity Prevention

The data reviewed here suggest several directions that may lead to the reduction of preterm births. As stated in the lead paper in this issue of the Journal,[25] the prepregnancy period is an ideal time for intervention. Unfortunately, all women do not have access to preventive healthcare during this time, and nearly half of all pregnancies are unplanned. Whenever possible, prior to pregnancy, we should:

- Educate women and their partners about the increased risk of preterm birth when pregnancy is delayed beyond age 35;
- Encourage abstinence from smoking at each health encounter and provide specific assistance for smoking cessation;
- Screen women for intimate partner violence at each health encounter and have a protocol for appropriate referral;
- Be aware of the possibility of periodontal disease and refer women for dental care;
- Encourage the use of contraception to reduce the number of unwanted pregnancies.

During pregnancy, we can:

- Support efforts to assure accessibility to prenatal care for all pregnant women;
- Continue assessment and intervention for identifiable stressors, smoking, intimate partner violence, and infection, including periodontal infection;
- Consider strategies such as nurse telephone intervention or other forms of frequent contact for pregnant women, particularly those with limited incomes and education.

Conclusion

Just as many pieces of fabric form a patchwork quilt, many factors contribute to preterm birth in North Carolina. Approaches to prevention of preterm birth must be multifaceted, should begin early in a woman's life, and must continue though the prenatal period, creating an environment in which every woman achieves the best possible pregnancy outcome. **NCMJ**

COMMENTARY

Expanding Medicaid Income Eligibility for Family Planning:
An Opportunity to Improve Reproductive Outcomes and Lower Medicaid Costs

Joe L. Holliday, MD, MPH

The State of North Carolina is requesting federal approval from the Centers for Medicare and Medicaid Services (CMS) to extend eligibility for family planning services to all women and men from 19 to 55 years of age with incomes at or below 185% of the federal poverty level. Unlike the Medicaid expansions for pregnancy-related care, which are specifically provided for in the federal statute, a family planning expansion must be approved by CMS as a Medicaid Family Planning 1115 Demonstration. To be approved, the proposal must be budget neutral—the added Medicaid family planning costs must be offset by at least a similar decrease in maternity and infant healthcare costs. As with maternity care, services may be offered by both public and private providers.

Current Medicaid regulations provide coverage to pregnant women and to infants (younger than a year) at or below 185% poverty. However, these women are eligible for Medicaid benefits only during the period following the confirmation of their pregnancy through 60 days postpartum. After 60 days postpartum, women who no longer meet the state's more stringent financial criteria for participation in the Medicaid program lose eligibility for all benefits, including family planning. It has been estimated that more than two-thirds of the approximately 45,000 women eligible for Medicaid each year due to pregnancy lose their Medicaid coverage after 60 days postpartum, leaving them without family planning or preventive health services coverage.

Among all North Carolina women of childbearing age, there are estimates that more than 318,000 women aged 20-44 are in need of publicly supported contraceptive services and do not have Medicaid coverage for these reproductive health services.[1] Although the 170 publicly supported family planning clinics in North Carolina serve 125,500 women aged 20-44, this represents only 39% of all women in need. Publicly supported contraceptive services are provided to 179,340 low-income women of all ages each year in North Carolina, and these women avert over 41,000 pregnancies each year.[2]

Unintended Pregnancies

A key goal of the Medicaid Family Planning 1115 Demonstration is to reduce the rate of unintended pregnancies within a state's low-income female population. Unintended pregnancies are those that are unwanted or occur before a woman intended to become pregnant (i.e., mistimed). More than half of all pregnancies in the United States and North Carolina are unintended.[3] In North Carolina, an estimated 45% of the more than 115,000 live births each year were unintended at the time of conception.[4] In addition, there are approximately 27,000 induced abortions each year in North Carolina, and presumably the vast majority of those result from unintended pregnancies. Women ages 20 and older account for over 85% of all unintended pregnancies.[5] More than three out of every five (61%) pregnancies to low-income women (income less than the federal poverty level) are unintended, compared to 41% of pregnancies for higher-income women (income more than double the federal poverty level).[6] They also are less likely to use effective contraceptive methods and to use contraception consistently.[7] Women whose prenatal care is paid for by Medicaid are significantly more likely than other women to report an unintended pregnancy resulting in a live birth.[8] The national *Healthy People 2000* goal was to reduce unintended pregnancies to 30% of all pregnancies, while the *Healthy People 2010* goal is to increase intended pregnancies to 70%.[9]

Reproductive Outcomes

Unintended pregnancy is associated with delayed entry into prenatal care as well as low-birth weight, poor maternal nutrition, smoking, and use of alcohol and other drugs.[10,11,12] Additionally, the opportunities and benefits of preconceptional healthcare are lost. As reported in the Running the Numbers column in this Journal (page 177),[4] North Carolina Pregnancy Risk Assessment Monitoring System (PRAMS) data from

Joe L. Holliday, MD, MPH, is Head of the Women's Health Branch in the Division of Public Health, NC Department of Health and Human Services. He can be reached at joe.holliday@ncmail.net or 1915 Mail Service Center, Raleigh, NC 27699-1915. Telephone: 919 715-3400.

1997-2000 showed a strong association between an unintended pregnancy and low-socioeconomic status, never taking a multivitamin (folic acid) before pregnancy, late entry into prenatal care, smoking during pregnancy, postpartum depression, and not breastfeeding.[13,14]

The overall premise for the Medicaid Family Planning 1115 Demonstration supports the concept that providing Medicaid coverage for family planning services increases the likelihood that low-income women will use these services and thus be less likely to have unintended pregnancies. In turn, fewer pregnant women and subsequent infants and children will need Medicaid coverage. Also, fewer of these pregnant women, infants, and children will have complicated medical conditions, because women with unintended pregnancies are at a higher risk for preterm delivery and other complications. Moreover, improving the spacing of births among the low-income, postpartum population will result in reductions in the overall number of births that will be supported by Medicaid funding.[15] The provision of this benefit might also be expected to reduce the number of low-birth weight and premature deliveries and infant deaths attributable to closely spaced pregnancies among those families whose poverty limits their access to health services. This, in turn, impacts the costs that are incurred for the lifetime care of infants who are born with a disability due to their premature and/or very low-birth weight. Additionally, expanding coverage for family planning and related preventive services offers a major health benefit to low-income populations.

Proposed Family Planning Services

The proposed family planning demonstration will cover family planning clinical services currently covered by Medicaid as well as some limited sexually transmitted disease (STD) treatment for STDs identified during the initial family planning visit. Additional covered clinical services could be added in the future if funds were available and budget neutrality could be maintained. Services recommended for coverage are the following:

- Family planning initial or annual examinations (including appropriate physical exams)
- Family planning counseling and supply visits
- All FDA-approved and Medicaid covered methods of birth control (including removal of implants/inserts)
- Tubal ligations and vasectomies and necessary post-procedure follow-up (upon receipt of proper federal sterilization consent form per current Medicaid regulations)
- Laboratory tests that are in conjunction with the family planning visit, including STD screening tests, pregnancy tests, and Pap tests
- Antibiotics for STDs detected during a family planning initial or annual visit
- HIV testing including pre- and post-test counseling visits
- Referral to a primary care physician or clinic, when needed

Abortion services will not be covered under this program nor will infertility services and related procedures. Unfortunately, except for treatment of some STDs, treatment will not be covered for medical conditions/problems discovered during screenings (e.g., urinary tract infections, diabetes, or hypertension) or caused by or following a family planning procedure (i.e., medical complications from family planning procedures). Treatment for AIDS and cancer will not be covered.

Projected Cost Savings

The purpose of family planning demonstration waivers such as the one North Carolina has requested from CMS is to prove that approaches that expand family planning services to low-income adults will ultimately reduce Medicaid costs for maternity and infant care. Other states (including South Carolina and Arkansas) have already demonstrated that significantly expanding family planning services to low-income populations results in savings greater than the government expenditures needed to provide the family planning services. This is true because the annual cost of family planning services per participant is approximately $350 while the average cost of prenatal, delivery, and infant healthcare is almost $9,000. In addition to savings for maternity and infant healthcare costs, reducing the number of unintended pregnancies will result in savings in future government expenditures for social services, public assistance, and other healthcare costs.

The match for Medicaid family planning services is an especially favorable one for the state—$1.00 in state match for every $9.00 in federal Medicaid expenditures. The favorable Medicaid match will allow existing state family planning funds, when used as the state match, to expand family planning services nine-fold. No additional state funding will be required to fund the Medicaid Family Planning 1115 Demonstration. Thus, even with the State's current budget shortfall, the importance of implementing this waiver—with support and involvement of both the public and private sectors—cannot be overstated.

Evaluation of Efforts by Other States

The first national evaluation of the Medicaid Family Planning 1115 Demonstrations funded by the CMS has just been completed.[16,17] There are currently 18 Medicaid Family Planning 1115 Demonstrations located throughout the United States.[18] Some have operated longer than others. The South Carolina demonstration, which began in 1993, was first, Rhode Island followed in 1994, and demonstrations in Virginia, Mississippi, and Illinois are the most recent to be approved. This evaluation concluded that all of the state programs evaluated were budget neutral. Savings from averted births exceeded the cost of expanded family planning coverage when the proposed model budget neutrality formula was applied.

Timeline

Preparations to expand Medicaid income eligibility for family planning services in North Carolina are well underway. The proposal has been approved by the NC General Assembly.

Once CMS approval is obtained, implementation can begin within three to four months. Within the NC Department of Health and Human Services, the Division of Medical Assistance, with support from the Division of Public Health, will be responsible for the Medicaid Family Planning 1115 Demonstration. Postpartum women, especially those at high risk for poor pregnancy outcomes, will be given priority for enrollment. Approximately 4,000 women and men will be provided family planning services during the first full year. This annual number will increase each year, with 20,000 people being served by the fifth year.

There Is Life (and Death) Beyond the Infant Year:

North Carolina's Recent Experience in Reducing Child Deaths

Tom Vitaglione, MPH

The 1990s witnessed a significant reduction in infant mortality in North Carolina, and this success has continued into the new millennium. For several years this success was guided by the NC Governor's Council on the Reduction of Infant Mortality, established in response to the dreadful news that the state had experienced the worst infant mortality rate in the nation in 1988.

Traditionally, the infant mortality rate has been considered a key indicator of the overall status of children within a society. Thus, it deservedly receives significant attention in public policy-making and in the media. Interestingly, the death rate of children after their first birthday receives less attention, perhaps because there are fewer of them (in 2001, for example, there were 1,005 infant deaths in NC and 524 deaths in children ages 1-17), or perhaps because the loss of an infant engenders a greater sense of tragedy. Nevertheless, an important measure of a society is the protection it affords its most vulnerable citizens, and especially its children of all ages.

This brief article is thus focused on North Carolina's experience in reducing death rates in children ages 1-17 in the period 1991-2001, a period in which the infant mortality rate declined by 22%. What progress did North Carolina make with regard to older children, and how did this progress occur?

Introduction

The road to progress in reducing deaths in older children began much the same way it began for infants: with bad news.

In 1991, a series of child abuse homicides in North Carolina received wide publicity. Data reviews indicated that this was an all too common phenomenon. Further reflection revealed concerns about all child deaths in the state. A few years earlier, North Carolina had achieved the distinction of having the worst infant death rate in the nation. It was now becoming apparent that, while the state's ranking in overall child deaths was not that bad, preventable child deaths were a tragically large problem.

As a response, the NC General Assembly held hearings on child abuse homicide, and interest grew in having an ongoing study of its cause and possible prevention. The interest then expanded to cover all child deaths, culminating in a watershed legislative decision to adopt an initiative known informally as the "child fatality prevention system."

The Child Fatality Prevention System

Three critically important components of the child fatality prevention system were established:

- Local Child Fatality Prevention Teams, with multi-agency membership established by statute, were directed to review all child deaths in each county. (A prior Executive Order had established similar teams to focus exclusively on deaths suspected to have resulted from abuse or neglect. Under the new legislation, counties were given the option of combining these teams or operating them separately.) Teams make recommendations to change local procedures, policies and ordinances aimed at preventing future deaths. Recommendations with statewide ramifications can be referred to the other components of the prevention system described below.
- A State Child Fatality Review Team, with statutory multi-agency membership and chaired by the Chief Medical Examiner, was directed to assist in the review of unexplained, unexpected child deaths, with particular focus on those suspected to be the result of abuse or neglect. Once again, the purpose of the reviews is to develop recommendations that could prevent future child deaths. The State Team is specifically required to report its findings and its recommendations to the Child Fatality Task Force described below.
- The NC Child Fatality Task Force is the lynchpin of the entire system. It is a 37-member legislative study commission, including legislators and multi-agency membership, with the overall charge to study the incidence and causes of child deaths, as well as to make recommendations for changes in legislation, rules and policies that would prevent deaths and promote the safety and well-being of children. It is responsible for assuring that multidisciplinary reviews of child deaths

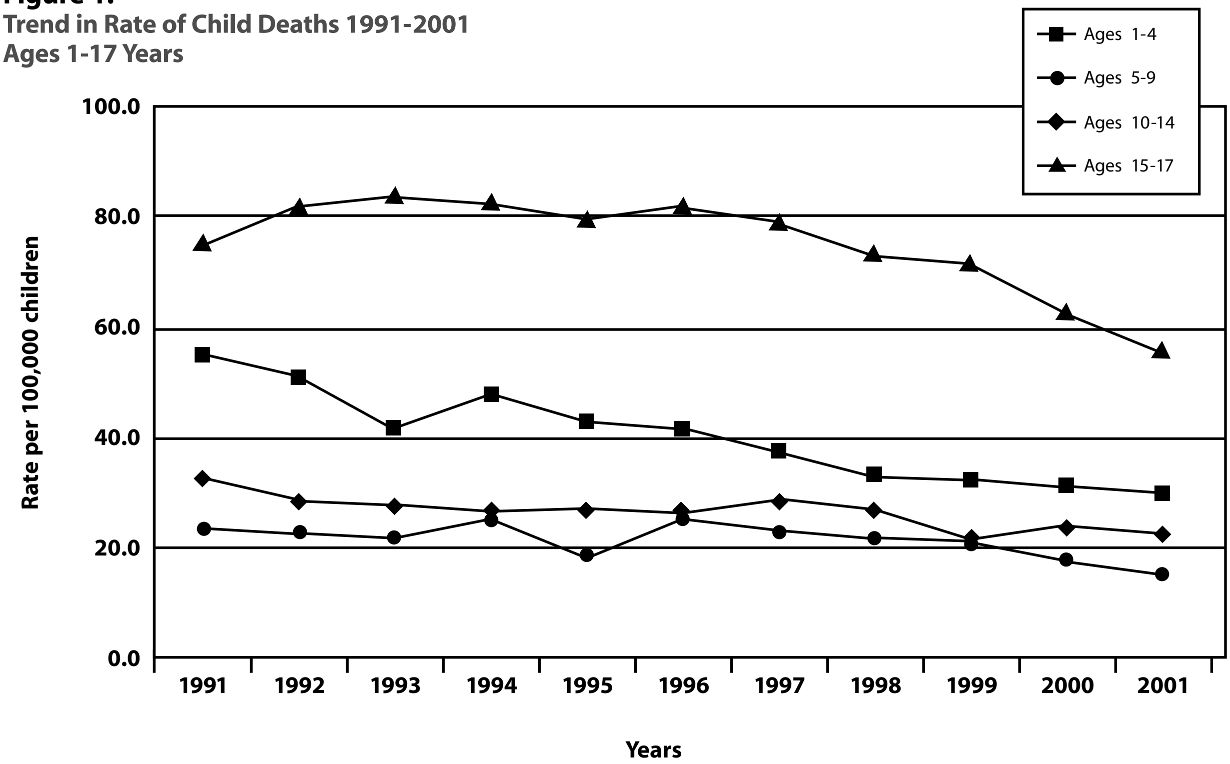
Figure 1.
Trend in Rate of Child Deaths 1991-2001
Ages 1-17 Years



are taking place, and is also responsible for assuring that, as noted above, local and state recommendations to reduce child deaths are studied and transmitted to state agencies and the NC General Assembly.

A Decade of Activity

All three components of the child fatality prevention system have been very active since inception. Though virtually the entire system is volunteer-based, the objective of saving children's lives and promoting their well-being stimulates a high degree of participation.

It is not possible to document all of the many accomplishments of local teams in changing local procedures, policies and ordinances. Changes in medical referral systems and emergency responses, heightened collaboration among child-caring agencies, street signs and traffic signals at hazardous intersections, and swimming pool safety ordinances are just some of the highlights that have made a difference in protecting children. In addition, many problems noted locally were referred to the State Review Team and the Child Fatality Task Force for review and action.

Because it operates in a more public venue and focuses on fewer, but more far-reaching issues, the activities and legislative accomplishments of the Task Force are more easily recounted. Since even these accomplishments would create a very lengthy list, below is a non-exhaustive list of highlights:

- Child passenger safety laws were strengthened twice.
- A Graduated Drivers License System was adopted.
- Smoke detectors are now required in all rental property.
- The sale of fireworks to youth under age 17 is now prohibited.
- "Zero tolerance" for alcohol in drivers less than 21 was adopted.
- Comprehensive kindergarten health screening is now required statewide.
- Numerous measures were adopted to reduce infant mortality, including expansion of Medicaid services for pregnant women and infants, a birth defects monitoring system, a folic acid awareness campaign, "safe sleep" practices in child care facilities, and overall awareness efforts under the auspices of the Healthy Start Foundation.
- Bicycle helmets for riders less than 16 are now required.
- The Infant Homicide Prevention Act, providing a "safe haven" for abandoned infants, was adopted.
- The penalty for illegally selling firearms to a minor was changed from a misdemeanor to a felony. In addition, safe storage of firearms is now required in homes where children reside.
- NC General Statutes, Chapter 7A was re-written to strengthen the protective services system.
- State funds for additional child protective services workers were appropriated at least twice.
- Protective services "hot lines' were established in each county.
- Additional funds were appropriated for the medical evaluation of children suspected to have been abused.

The Outcomes

All of the above, as well as all of the local efforts, were intended to reduce child deaths in North Carolina. As the child fatality prevention system reached its tenth birthday in 2001, some remarkably good news was reported in this regard.

Figure 1 depicts the steady decline in the child death rate for each age group since 1991.

Table 1 compares the percentage decline in death rates in the period 1991-2001 for each age group, including infants. The percentage decline in each of the older age groups exceeded that for infants, producing a remarkable overall decline of 28% for all groups birth through age 17 combined.

Table 1.
Death Rates By Age

Age	Death Rate*		% Change
	1991	2001	
Infant	10.9	8.5	**- 22%**
1-4	54.0	30.1	**- 44%**
5-9	22.8	15.0	**- 34%**
10-14	32.8	21.7	**- 34%**
15-17	74.9	57.6	**- 23%**
Overall	107.0	76.4	**- 28%**

* For infants, the death rate is the number of deaths per 1,000 live births. For all other groups, the death rate is the number of deaths per 100,000 children.

Table 2 depicts another startling outcome. For each and every major category of death, there was a substantial decline in the death rate in the period 1991-2001. (Beyond the infant year, injuries in their various forms are by far the leading causes of death.)

Discussion

The data depicted in the figure and tables taken together, are a firm indication that the remarkably good news about the decline in North Carolina's child death rate is not the result of happenstance. The overall decline has been steady and significant, the declines were enjoyed by all age groups, and the declines occurred in all cause of death categories.

It would not be scientifically accurate to conclude that the implementation of the child fatality prevention system in 1991 is solely responsible for the ten-year decline in child death rates. However, considering all the state and local activity generated by this system, it must surely be highly correlated with the positive outcomes.

North Carolina's success in reducing death rates for both infants and older children offers some interesting comparisons.

First, enhanced attention to both areas (with concomitant attraction of resources) was the result of media coverage. For infant deaths, it was the coverage of the state's last place national showing; for older children, it was coverage of a series of child abuse homicides. The state's infant and child death rates had not been previously ignored by public health officials, and proposals to reduce those rates had frequently been made. It took media coverage, however, to create a political environment that would entertain these proposals.

Second, the establishment of public commissions—the Governor's Council on the Reduction of Infant Mortality and the Child Fatality Task Force—was critical to the success of prevention efforts. Though these commissions have had neither administrative authority nor funding for services, they have exerted influence on the development and coordination of services. Perhaps most importantly, they have enhanced awareness of the critical issues, and have not been tethered by the administrative bureaucracy in advocating for solutions. (Note: The Governor's Council was dissolved in 1995, and its functions were undertaken by the Task Force.)

Third, the causes of death for infants and older children are quite dissimilar. Almost all infant deaths are attributable to birth defects, sudden infant death syndrome, and perinatal conditions related to low-birth weight and prematurity. Indeed, the underlying causes of many infant deaths are still not well understood. On the other hand, most deaths in older children are due to injuries, both intentional and unintentional. The specific causes of these deaths are well-understood.

Table 2.
Death Rates By Cause

	Percentage Change from 1991 - 2001
Cause of Death	Children (1-17)
Birth Defects	- 25.6%
Perinatal Conditions	- 29.6%
SIDS	N/A
Illness	- 39.4%
Motor Vehicle	- 13.8%
Bicycle	- 61.3%
Fire	- 80.2%
Drowning	- 40.3%
Other Injuries	- 52.0%
Homicide	- 51.0%
Suicide	- 17.9%

Fourth, because of the differences in causes, the interventions-educational, medical and political-are also quite different. For infant deaths, interventions focus on education during the preconceptional, prenatal, and postpartum periods; access to prenatal care; and newborn intensive care. Interventions are

"Beyond age one, injuries in their various forms are by far the leading causes of death."

fairly costly, and political support is usually a function of awareness and the availability of public funds. For deaths in older children, interventions focus on injury prevention, which is largely a function of education to guide and/or change behaviors. These interventions are often at low or no public cost. However, legislation is often sought to reinforce educational/behavioral messages (e.g., the safe storage of guns, or requirements for bicycle helmets and smoke alarms). These proposals usually engender much political debate, for they are often viewed as an infringement on individual rights or on the rights of the family to make decisions on behalf of children.

An Invitation to Physicians

As noted above, most of the deaths in children beyond the infant year are not related directly to the provision of hands-on medical care. This does not mean, however, that physicians do not have a large role to play in reducing such deaths. Health education and behavior-risk counseling are the critical interventions needed at the child/family level, and advocacy is often needed at the state and community level to enhance child safety.

At both levels, physicians can use their expertise and their positions of respect to raise awareness of issues and to effect remedies that will enhance the health and safety of children and youth. Physicians are encouraged to become involved with the efforts of the local child fatality prevention team in their respective counties. (Information can be obtained from the local health department.)

While North Carolina's progress in reducing infant and child death rates has been remarkable, there is much more progress to be made. Physicians are invited to increase their participation in these efforts. **NCMJ**

Unintended Pregnancies in North Carolina

More than half of all pregnancies in North Carolina and the United States are unintended. Unintended pregnancies are those that are unwanted (now or at any time in the future) or occur before a woman wanted to become pregnant. In North Carolina, an estimated 45% of the more than 115,000 live births each year were unintended at the time of conception. In addition, there are approximately 27,000 induced abortions each year in North Carolina, and presumably the vast majority of those result from unintended pregnancies.

Among live births, women with unintended pregnancies are less likely to seek early prenatal care, more likely to smoke during pregnancy, less likely to breastfeed, and more likely to have a low-weight birth. Women with unintended pregnancies are likely to also have other risk factors (such as low-socioeconomic status), but the evidence suggests that a well-timed pregnancy in itself leads to better health behaviors and improved infant health.

The North Carolina Pregnancy Risk Assessment Monitoring System (PRAMS) is a mail and telephone survey of a random sample of North Carolina women who have recently had a live birth. It is supported by the Centers for Disease Control and Prevention (CDC) and is currently conducted in more than 30 states. In North Carolina, approximately 1,800 women are interviewed each year. Pregnancy intendedness is captured from the PRAMS survey question that asks mothers to indicate how they felt about becoming pregnant just prior to conception. Those who answered that they wanted to be pregnant "'sooner" or "then" were categorized as intended; those who answered "later" or "not then or at any time in the future" were categorized as unintended.

Forty-five percent of 1997-2000 PRAMS survey respondents indicated that their pregnancy was unintended, with 34% saying that they wanted to be pregnant later and another 11% saying that they did not want to be pregnant then or at any time in the future. The following categories of women had a particularly high percentage of live births that were unintended: age less than 20 years (76%), less than a high school education (61%), household income below $14,000 (66%), and unmarried (73%). Having a live birth that was unintended was strongly associated with never taking a multivitamin (folic acid) before pregnancy, late entry into prenatal care, smoking during pregnancy, domestic violence, postpartum depression, and not breastfeeding.

A planned pregnancy gives women the opportunity to prepare for a healthy pregnancy. Healthy behaviors before and during pregnancy reduce the risk of a low-weight birth. Though the risk of unintended pregnancy is higher among younger women, more than 75% of all unintended pregnancies are to women ages 20 and older. Therefore, efforts to reduce unintended pregnancies must include all age groups. Access to appropriate contraceptive services is certainly very important. Many family planning programs also provide a broad range of preventive health services such as patient education and counseling; breast and pelvic examinations; cervical cancer, STD, and HIV screenings; pregnancy diagnosis and counseling; and referral to appropriate medical and social services.[1] This emphasis on pre-conceptional health means that women who do choose to become pregnant are better prepared physically and mentally. Federal funds from the Title X program and Medicaid support family planning services for low-income individuals. These publicly-funded services are available on a voluntary and confidential basis.

The full report from which these results were taken was published by the State Center for Health Statistics in November 2002 (SCHS Studies No. 136) and can be accessed at http://www.schs.state.nc.us/SCHS/pubs/title.cfm?year=2002

Letters to the Editor

Latino Health in North Carolina

To The Editor:

In your May/June 2003 issue, you focused on Latino health in North Carolina—a subject in need of attention. The issue did not mention domestic violence and I wanted to share some information with you and your readers about this serious problem. The following paragraph is an excerpt from a client's story (with names changed). It paints a picture of the issues battered Latinas face.

> *"I remember once when I was three or four months pregnant with my second child, he beat me. I was crying and begging him not to hit me, but he kept on and his mom and step-dad did nothing. After he beat me, he left the house like he always does. When I asked his mom to call the ambulance she said she was not going to get her son, José, in trouble. His mother threatened to call immigration and said she would keep my son, José, Jr., because I would be taken back to Mexico."*

Numerous organizations, such as the American Medical Association, the American Nurses Association and the Joint Commission for the Accreditation on Healthcare Organizations, endorse addressing domestic violence through the healthcare system. Domestic violence has serious physical and mental health consequences and healthcare visits may be among the few opportunities for isolated victims to receive the support they need. However, in accessing the healthcare system, battered Latinas face multiple barriers in North Carolina. In general, the Latino population faces greater challenge accessing the healthcare system due to language barriers, cultural differences, immigration status and a lack of awareness of services. For Latinas who are victims of domestic violence, these barriers are increased by the isolation that is endemic to being a domestic violence victim. To further complicate matters, other common tactics by abusers such as threats of deportation, use of children and economic abuse hinder the ability of battered Latinas to access services.

"Language barriers first and foremost result in deterring a victim from obtaining necessary assistance."

Language barriers first and foremost result in deterring a victim from obtaining necessary assistance. Although linguistically accessible healthcare services should be provided by recipients of federal funding pursuant to Title VI of the Civil Rights Act of 1964, few such services exist. Several of our clients have feared getting medical help on their own because they are monolingual and were used to relying on the abuser for interpretation. One battered Latina client told us "[h]e was the only person who helped me in situations where I needed to communicate, and in this situation I could not rely on him." Even if the battered Latina is actually able to get to a healthcare provider, if the batterer acts as the interpreter, the information given health workers may be skewed.

Since not all Latinas in North Carolina are US Citizens, immigration status is also a barrier for many battered Latinas. Some immigrants are not eligible for Medicaid or Medicare except in life threatening emergencies, thereby limiting their access to healthcare. Domestic violence victims may choose to avoid receiving healthcare because they do not know how they can pay for such services and fear reprisals from the abuser. Furthermore, it is not uncommon that abusers will threaten an undocumented victim that a phone call to 911 for emergency services will result in her deportation and removal of children from her custody. Finally, cultural differences create an additional barrier for battered Latinas to access relevant services, although defining cultural differences can be a tricky enterprise. We know that cultural differences operate on both ends of the system. Healthcare providers may lack culturally competent staff. From the perspective of battered Latinas, they may be surprised to learn that they may be eligible for services. Many of our clients, for example, are unaware that they can receive mental health counseling as victims of domestic violence. One client informed us that in her home country, there were no services available for "women who are abused by their husbands." Many women, therefore, do not attempt to obtain assistance due to a lack of familiarity with the system especially since it may be quite distinct from the system in their home country.

Taken all together, the power and control dynamics inherent in a domestic violence situation further aggravate the cultural isolation created by language barriers, cultural differences, and immigration status. These dynamics create special difficulty for battered Latinas in accessing medical assistance.

Special Laws Applicable to Battered Latinas Who Are Immigrants

There are certain laws that offer battered immigrant Latinas some assistance from the extreme isolation created by their situation. The Violence Against Women Act (VAWA) can help certain battered immigrants obtain lawful immigration status and employment authorization—both crucial to a victim's ability to survive independently.[1] If an undocumented immigrant is married to a Legal Permanent Resident or to a US Citizen, she may have remedies under VAWA. Normally, the undocumented immigrant would get immigration status through the traditional family-based immigration process, where the spouse with legal status would control the application process. In domestic violence situations, the abusive spouse often exploits the family-based immigration process by refusing to apply for lawful status in order to exert further control. VAWA was passed to remedy the traditional family-based immigration process so that the victim herself could apply for legal immigration status by filing a Self-Petition.

The VAWA Self-Petition process not only allows victims to obtain lawful immigration status, but it also may make some battered immigrants eligible for important federally-funded benefits, such as Medicaid.[2] Battered immigrants can qualify for federally-funded benefits it they have filed a VAWA Self-Petition and can show a substantial connection between the abuse and the need for the benefit. The victim is required to show: (1) a prima facie determination or an approval of a VAWA Self-Petition or a Family-Based Petition; (2) battery or extreme mental cruelty; (3) a substantial connection between the abuse and the need for the benefit; and (4) that she no longer resides in the same household as the abuser. Children of VAWA Self-Petitioners will also be eligible. Many of our clients have been able to show a substantial connection between the need for medical attention or mental health counseling and the effects of the abuse.[3] Unfortunately, not all VAWA Self-Petitioners will automatically be eligible for Medicaid since they are still subject to the complicated restrictions facing non-US Citizens who apply for federally-funded benefits.[4] This exception, however, at least places VAWA Self-Petitioners on the same footing with Lawful Permanent Residents in terms of accessing federally-funded benefits.

Moreover, there are certain federally-funded benefits that are available to all battered Latinas regardless of immigration status, since many battered Latinas are otherwise ineligible to file a VAWA Self-Petition. Some federally-funded benefits that are especially relevant to the health and safety of victims are: emergency Medicaid, crisis counseling and intervention programs, public health assistance for immunizations, treatment of symptoms of communicable diseases, violence and abuse prevention, medical and public health services and mental health, disability or substance abuse assistance necessary to protect life or safety.[5] Finally, battered Latinas, regardless of immigration status, have the right to access important criminal and civil court remedies necessary to protect their health and safety.

Suggestions for Healthcare Providers

Healthcare providers can take steps to increase battered Latinas' access to the healthcare system and to identify and assist victims. Common recommendations for increasing access for the Latino population generally are to offer bicultural and bilingual services and to conduct community education and outreach about available services. To serve battered Latinas as well, providers should be trained about the issues that are particular to battered Latinas, including the extreme isolation aggravated by their domestic violence situation and legal options for battered immigrants. Having some understanding of these issues is significant because it will shape how healthcare practitioners understand and choose to pursue treatment.

Healthcare providers should also have an adequate referral system in place for when they encounter a battered Latina who needs assistance. A good starting point is to establish contact with the local domestic violence program. Many programs are increasingly facing populations of battered Latinas and are learning about the special intricacies in assisting this population. Several of the programs within the state have also made a special effort to hire someone on their staff who is bilingual and/or bicultural; however, only a minority of the programs has bilingual staff. In addition, it is important to connect with the other local community-based organizations that serve Latinos. Many of them, particularly in communities where the domestic violence program does not have bilingual staff, serve as a de facto domestic violence program for Latinas.

Finally, a couple of statewide coalitions have worked on issues facing battered immigrants. These coalitions bring together individuals from a variety of backgrounds, including law, social work, public policy, law enforcement, and academics, in order to facilitate cooperation and the exchange of knowledge about the barriers faced by battered Latinas. Project Esperanza focused on issues relating to battered Latinas across the state. For more information, please contact the Coalition for Family Peace in Siler City, North Carolina: (919) 742-7320. There is also a larger statewide coalition called the NC Network on Behalf of Battered Immigrant Women, which addresses issues facing battered refugee and immigrant women generally. To subscribe to their list serve, please e-mail NCNetworkforBIWsubscribe@yahoogroups.com.

These coalitions would welcome the participation of healthcare practitioners who could bring to the table their unique perspective on this very important issue.

REFERENCES

1 Violence Against Women Act of 1994, Pub. L. No. 103-322, 108 Stat. 1902, subsequently amended, Victims of Trafficking and Violence Prevention Act of 2000, 114 Stat. 1464, Pub. L. No. 106-386 (2000). There is also a more limited immigration remedy for victims of crime (U Visa) that could aid domestic violence victims who are otherwise ineligible for VAWA.

2 8 U.S.C. § 1641(c). This same provision applies to other federally-funded benefits such as Work First, Food Stamps, Public Housing and Section 8 Assistance.

3 Despite federal law, our battered Latina clients were being told by the local divisions of the Department of Health and Human Services that they were ineligible for Medicaid and other federally-funded benefits. Only with persistent advocacy on a case-by-case basis were we able to get our clients access to Medicaid and other benefits. In 2003, the Department of Health and Human Services modified their manuals to reflect federal law with more specific guidance to their workers. See “Citizen/Alien Requirements: Battered Alien (Violence Against Women Act),” Family & Children’s Medicaid Manual, MA-3330, Section VI; “Immigrant Access to Benefits,” DMA Administrative Letter, No. 19-03 (April 1, 2003). Similar clarification was made in the Manuals for Work First and Food Stamps.

4 All Lawful Permanent Residents who entered after August 22, 1996, for example, are subject to a five-year bar for Medicaid benefits. There is no exception from this requirement for battered immigrants. Other such restrictions were enacted by the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, Pub. L. No. 104-193, 110 Stat. 2105, and the Immigration Reform and Immigration Responsibility Act of 1996, Pub. L. No. 104-208, 110 Stat. 3009.

5 8 U.S.C. § 1611; 66 Fed. Reg. 3613 (January 16, 2001), A.G. Order No. 2353-2001, Final Specification of Community Programs Necessary for Protection of Life and Safety Under Welfare Reform Legislation. Federally-funded community health centers which provide primary and preventative healthcare serve all people regardless of immigration status or ability to pay. Mental health centers do not have restrictions on who can receive services based on immigration status; however, individual centers may have funding restrictions that are linked to immigration status.

Mental Health Reform

To The Editor:

In several of the analyses of the State Mental Health Reform Plan published in the September/October 2003 issue of the *North Carolina Medical Journal*, veteran observers of the reform effort raised concerns about the capability of the state mental health workforce to meet the challenge. Basic elements in the Plan—conservation of resources for the most severely mentally ill, increased accountability of clinicians and communities for mental health policy, consumer involvement, transfer of service delivery to the private sector and provision of evidence-based best practices for the targeted populations—pose challenges to the clinicians in the workforce as it is currently configured. The limitation of the most expensive forms of public mental healthcare to all but the most severely ill citizens will exclude some consumers from public sector facilities where they are currently being served, requiring that they seek care in different settings. Care of the uninsured and indigent citizens who do not meet target criteria is still undetermined.

Furthermore, by downsizing public mental hospitals and shifting public funding to community-based services for severely mentally ill citizens, the Plan inherently calls for a compensatory array of primary mental health services that are characterized by easy access, quick, comprehensive response, and that use an arsenal of interventions to restore normal function and divert hospitalization or incarceration. A shift to more primary mental health services means that the traditional equation of incremental intensity of services is reversed. Consumers, whether mildly or severely mentally ill, currently have access to intensive intervention immediately through multiple portals to care. Evidence-based early intervention precedes tertiary care, a wider array of clinicians are empowered to make gate keeping decisions and service authorizations, and relationships among individuals and institutions are collegial, not hierarchical. These elements require a level of seamless integration among frontline systems (e.g., emergency departments), mid-level systems (e.g. community mental health providers, clubhouses) and tertiary systems (e.g. inpatient facilities and mental healthcare hospitals). If a commitment is made to truly change mental healthcare, this necessary configuration must be addressed honestly rather than “patching” the current system in a way that preserves existing interests. As the Plan and the Journal analysis noted, meeting the reforms in the Plan is beyond the composition and configuration of the current state workforce.

In that same issue of the Journal, Schwartz and Morrissey called for bold training and recruitment and retention initiatives to intensify clinicians’ skills, while Bacon and Stallings proposed increased use of advanced practice psychiatric nurses, in particular, the psychiatric nurse practitioner (PMH-NP). We would like to focus on this one role, not as a solution to the challenges of reform, but as an exemplar of the way in which existing clinicians within the mental health system could be prepared to bring the innovative elements that were in the Plan closer to reality.

The PMH-NP, a relatively new face on the mental healthcare team in North Carolina, has proven to be a cost-effective, quality-enhancing addition to mental healthcare in other states. Currently, there are almost 3,000 registered nurses working in mental health in North Carolina—more than 300 have a master’s or doctoral degree. Most of these clinicians were prepared as

PMH Clinical Nurse Specialists with advanced practice preparation in psychotherapies and primary mental healthcare, but without prescriptive authority in North Carolina. As the state mental health hospitals are downsized and consolidated, some of these experienced nurses could help meet the mental health workforce needs if they were prepared as PMN-NPs to provide the right care at all levels of acuity in these ways:

- As independent practitioners, PMH-NPs could widen the portals of immediate mental healthcare through the provision of individual, family and group psychotherapeutic interventions for less-severely mentally ill adults and children in the community and, in collaboration with a physician, prescribe and maintain psychotropic medication, thus helping to prevent progression of disorders.
- As community-based providers of care for severely mentally ill adults and children in conjunction with local managing entities (LMEs), PMH-NPs could coordinate multiple care systems and construct support systems for families and community groups who will be the primary caregivers of these citizens, and in collaboration with a physician, provide medication prescription and ongoing maintenance and education.
- As institutionally-based providers of care to severely mentally ill citizens in crisis, the PMH-NP could collaborate with physicians to manage complex physical and mental health conditions and psychiatric crises that require readjustment of psychotropic medications and alterations in care treatment plans required to maintain them once they have returned to their communities.
- As institutionally-based providers of care to medically-ill citizens, the PMH-NP, in a consult and liaison role, could collaborate with physicians to correctly identify mental health issues when appropriate, secure early intervention when appropriate and assist in correct placement in community-based treatment facilities.

Nationally, and in North Carolina, existing advanced practice nurse educational programs prepare PMH-NPs to be cost-effective, multi-skilled providers. These programs already have mechanisms such as online courses, executive formats and AHEC liaisons through which many nurses who already have psychiatric experience could be supported to return to school. Through partnerships with existing facilities, faculty can work with LMEs to place these students in preceptored experiences that will prepare them to meet the newly-evolving service roles. With additional preparation enriching their years of experience in the provision of mental healthcare, these PMH-NPs could provide cost-effective, high quality care to North Carolinians based on best-practice evidence. The model that is already in progress for nursing could be adapted by other disciplines, thus creating an exemplar of interdisciplinary care to meet the challenge of mental healthcare reform in North Carolina.

The North Carolina Institute of Medicine

Since January 2002,
Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the NC Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The NC Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 when the North Carolina Medical Society reached the decision to cease support for its publication. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

North Carolina Medical Journal: Call for Papers

Herbert G. Garrison, MD, MPH
Scientific Editor, North Carolina Medical Journal

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The *Journal* seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The *Journal* is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

INTRODUCING THE LEVINE CHILDREN'S HOSPITAL

Carolinas Medical Center has just announced plans to build the most advanced, most comprehensive children's hospital in the region.

It will be like no other facility in the area, offering you services you won't get anywhere else.

And it will all be geared to children's needs – and support systems that cater to families.

You'll be hearing more in the months ahead about how you can be a part of making this dream come true.

The plans are big. For our littlest patients.

Levine Children's Hospital

Your dimes conquered polio.

Give us a hand with premature birth.

Fifty years ago, Americans joined together to help the March of Dimes fund polio research. Your generosity led to the vaccines that have saved generations of children. Today a new epidemic threatens our babies—premature birth. Each year more than 460,000 are born premature. It's the leading cause of newborn death and many disabilities. Please go online to help us raise research funds. Together we can find the answers that will save premature babies.

A partnership that's working for eastern North Carolina

Trauma care — saving lives every day

Trauma — sudden, serious, sometimes life-threatening — it's also one of the most serious health problems in eastern North Carolina. At Pitt County Memorial Hospital, the Level I Trauma Center is led by extraordinary team of seven board-certified trauma surgeons who hold faculty appointments with the Brody School of Medicine at East Carolina University. This team of talented surgeons is available all day, every day, to treat patients from across the region. So it's not surprising that mortality rates associated with our trauma program are below national benchmarks. But the effort doesn't stop there — the medical team and clinical staff are working to improve trauma care throughout the region by providing education and support to other hospitals and EMT personnel. The Brody School of Medicine and University Health System are making things happen — in the community, in the region and in the state.

realmed
your fastest path to payment

Sick of the claims paperwork? Ready for an all-payer web-based solution?

Blue Cross and Blue Shield of North Carolina is always on the lookout for new ways to speed and simplify the claims filing process for our participating physicians and other health care providers.

That's why we're excited to announce that physician practices of all sizes can take advantage of instantaneous, electronic claims submission under an innovation developed by RealMed, a business partner of BCBSNC.

Now, you can "virtually" print and instantly transmit claims to all payers in less time than it takes to stuff envelopes — all with the push of a button.

RealMed's Print Exchange does what its name implies — it changes your workstation's print instructions into electronic claim filings. Using a single, simple process you can instantly transmit claims to all payers — not just to BCBSNC — eliminating posting and handling costs and greatly speeding payment.

Call ReadMed today to find out how easy and affordable it is to submit all claims to all payers, verify eligibility and claim status, automatically check errors, adjudicate claims, receive payment and eliminate your paper — all while being HIPAA compliant.

Find out more at 1-877-REALMED or **www.realmed.com**.

For more than 70 years, our members and providers have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's dependable and reliable health insurer. Learn more at **bcbsnc.com**.

African American Elders' Perceptions of the Influenza Vaccine in Durham, North Carolina

Sohini Sengupta, PhD, MPH, Giselle Corbie-Smith, MD, Angela Thrasher, MPH, and Ronald P. Strauss, DMD, PhD

Abstract

Objective: *To qualitatively explore community perceptions among elderly African Americans about what makes it easy or difficult to get vaccinated for influenza.*

Sample: *A total of 28 elderly (age 65 years or older) African Americans living in Durham County, North Carolina, participated in this study.*

Data Collection Methods: *In-person, open-ended interviews were conducted to perform a content analysis on factors influencing influenza vaccination use, or lack thereof, in an elderly African American population. Interviews were conducted in participants' homes and at senior centers in Durham County, North Carolina. Interviews were transcribed and analyzed to identify themes.*

Principal Findings: *Ten facilitators to encourage obtaining vaccinations were identified, including reminders from a doctor to get the influenza vaccination and the perception that the vaccination prevents influenza. Eight barriers were identified, including community perceptions to not get vaccinated and the fear of getting the "flu" from the vaccination itself.*

Conclusion/Relevance: *The study identified community perceptions of what makes it easy or difficult for elderly African Americans to get vaccinated for influenza. The findings will be useful to design and implement programs targeted to improving vaccination rates in health clinics or private physician's offices since the elderly are more likely to receive influenza vaccinations in primary care settings.*

Key Words: *Aging, Access to Care, Immunization/Vaccines, African Americans/Blacks, Qualitative Research*

Introduction

Every year influenza epidemics cause more than 20,000 deaths and 110,000 hospitalizations in the United States.[1-4] Specific target groups, such as elderly persons (≥ 65 years), young children, and persons with underlying diseases (who are often elderly) are at highest risk of influenza-related complications and hospitalizations.[5] Mortality associated with influenza, however, disproportionately affects the elderly. In a recent study, influenza mortality correlated with age, with persons ≥ 85 years old being 32 times more likely than persons 65-69 years old to die of influenza-related complications.[6] Given that the average life expectancy at birth for men and women in the United States now exceeds 74 and 80 years, respectively,[7] annual influenza vaccination is, and must, remain among the most important public health priorities to control the healthcare burden associated with influenza morbidity and mortality.

The United States Preventive Service Task Force and the CDC's Advisory Committee on Immunization Practices recommend that elderly Americans get vaccinated against influenza as a preventive measure annually.[8-9] The 1996 Medicare Current Beneficiary Survey and the 2002 Behavioral Risk Factor Surveillance Survey—nationally representative surveys to assess influenza vaccination usage and reasons for not getting vaccinated among elderly Americans—demonstrated, however, that influenza vaccination rates differed among elderly racial/ethnic groups; approximately 68%-69% in whites, and 47%-50% in African Americans.[10,11] Furthermore, not getting vaccinated was associated with not perceiving influenza to be a health risk, regardless of race.[12] In *Healthy People 2010*, one of the objectives is to increase the proportion of all elderly Americans vaccinated annually against influenza to 90%.[13] "Eliminating," not just reducing health disparities, is one of the nation's goals for the next decade.

It will be a particular challenge to increase influenza vaccinations in elderly African Americans from 47% to 90%. The Medicare Current Beneficiary Survey provided little evidence as to why elderly African Americans are disproportionately not

Sohini Sengupta, PhD, MPH, Giselle Corbie-Smith, MD, Angela Thrasher, MPH, and Ronald P. Strauss, DMD, PhD, are affiliated with the University of North Carolina at Chapel Hill (UNC-CH). Dr. Sengupta is a Research Assistant Professor, Dr. Corbie-Smith is an Assistant Professor of Social Medicine, Ms. Thrasher is a doctoral student, and Dr. Strauss is Professor and Chair of Dental Ecology. Dr. Sengupta can be reached at sengups@med.unc.edu or at the UNC-CH Department of Social Medicine, CB# 7240, Chapel Hill, NC 27599-7240. Telephone: 919-843-6881.

getting vaccinated for influenza other than they may not know about the benefits of getting vaccinated.[14] Before we can wage a campaign to increase the proportion of elderly African Americans vaccinated against influenza, we must first understand the structural and interpersonal factors influencing their behaviors (i.e., getting or not getting vaccinated). The purpose of this qualitative study is to explore community perceptions of what makes it easy, as well as what makes it difficult, for elderly African Americans to get vaccinated for influenza.

METHODS

The target population was non-institutionalized, community dwelling elderly (≥ 65 years) African Americans living in Durham County, North Carolina. We recruited our convenience sample from senior centers, referrals from study participants already interviewed, as well as from a list of elderly African Americans through the University of North Carolina at Chapel Hill/North Carolina Central University Center for Minority Aging. Of the 41 potential participants approached or contacted over the telephone by our interviewer, 13 (31.7%) refused to participate. Reasons for refusal included that individuals were not interested, did not have the time, or they were not in good health. Our final sample was 28 participants, which was sufficient in achieving data saturation with respect to the expected and emergent issues associated with our research objectives.

Data Collection

The interviewer scheduled a one-hour interview with each of the 28 participants. Interviews were conducted either at the participant's home or at one of the senior centers where recruitment occurred. Written informed consent was obtained, followed by the interview. All interviews were audiotaped, and participants received financial compensation for their participation. The interviews were completed between May and October 2002. The Institutional Review Board of the University of North Carolina School of Medicine approved this study's protocol and consent form on October 19, 2001.

Qualitative Interview Guide

An interview guide was developed for this study to explore three main open-ended questions:

- What are the benefits (or risks) of getting vaccinated for the flu?
- What kinds of things do you think would help older African American adults get the flu shot?
- What makes it difficult for older African Americans to get the flu shot?

The interview concluded with a set of sociodemographic questions, including race/ethnicity of their main physician, age, education level, main source of income, health insurance status, whether or not they lived alone, whether or not they ever had the flu, whether or not they received a flu shot consistently on an annual basis, and whether or not their physicians offered them the flu shot during office visits.

Data Management and Data Analysis

Audiotapes of the interviews were transcribed into a word-processing program. The interviewer checked the accuracy of the transcripts by listening to, and reading along with each tape. Any identifying information in the transcripts was supplanted with generic references (e.g., Person A, Senior Center B) to protect confidentiality. The transcribed interviews were then imported into Ethnograph© v5.07, a qualitative software program for the purposes of content analysis.

For the Likert-type, and sociodemographic questions, data were entered into SPSS© 11.0.1. Frequencies were calculated for categorical variables, and medians were calculated for continuous variables. Content analysis involved the development of a thematic coding structure representing a hierarchy of codes.[15] Level 1 codes reflected each of the open-ended questions asked. Sub-codes reflected themes identified from answers to these questions. For example, *What are the benefits of getting vaccinated for the flu?*, was a theme earmarked by a level 1 code, and a sub-code for this theme was, *Protect myself from getting the flu.* We addressed validity systematically by first developing a codebook through an iterative process that delineated each

Had the flu in the past	20 (71.4%)
Personal doctor offered vaccine in the past	24 (85.7%)
Personal doctor offered vaccine in Winter 2002	21 (75.0%)

Note: "Not sure" responses were excluded from totals that do not equal N = 28.

code (level 1 and sub-codes), their definitions, when is it appropriate to use each code, and when is it not appropriate to use each code after the research team had read a first passing of all of the interviews. The codebook provided the coders a framework of mutual understanding about each of the themes. The second step involved having coding teams independently read and code each interview for intercoder reliability. Percent agreement was compared for each code across interviews for the purposes of assessing intercoder reliability. Any code having less than 80% agreement was discussed, and discrepancies were resolved to improve agreement.

RESULTS

Description of the Sample

The 28 participants were all African American, 65 years of age or older, and living in Durham County, North Carolina (see Table 1). The mean age was 74.9 years, with the oldest participant being 86 years old. Overall, the majority of the participants was female, living on Social Security, and had both Medicare and private health insurance. Twenty (71.4%) of the participants had the flu in the past, and 13 (61.5%) of these participants received the annual flu shot consistently (data not shown in table). For 24 (85.7%) of the participants, a personal physician offered the vaccine to them in the past, and for 21 (75.0%), the personal physician offered the vaccine to them in winter 2002.

Facilitators and Barriers Affecting Influenza Vaccine Usage

To better understand why African Americans are getting or not getting vaccinated for influenza, we asked three open-ended questions to elicit what makes it easy and what makes it difficult for elderly African Americans to get the influenza vaccine. The three questions we asked were intended to improve understanding of community perceptions of the facilitators and barriers to influenza vaccine use. Tables 2 and 3 present the themes for facilitators and barriers, respectively, and quotation examples for each theme.

Facilitators Associated with Influenza Vaccination

All participants were asked about what makes it easy for members of their community to get vaccinated for influenza. Responses were categorized as either structural facilitators or personal factors (e.g., knowledge, attitudes, or health status) facilitating influenza vaccine usage (see Table 2). For structural factors, the predominant facilitator reported was receiving a reminder from their doctor to get a flu shot (N = 19). Reminders could range from an informal postcard in the mail, to a conversation with their personal doctor about the benefits for older African Americans to get vaccinated for influenza. Another important source of external information that facilitated vaccine usage was word-of-mouth from the community that getting the influenza vaccine is an important health behavior (N = 14). The "community" generally referred to other African Americans with whom they had discussed the influenza vaccine, such as friends, relatives, or church and religious leaders who were perceived as a source of positive information that older African American adults could trust. Lastly, it helped that the influenza vaccine was primarily covered by participants' health insurance (N = 7).

Several personal facilitator themes were identified. Seventeen (60.7%) participants strongly felt that being knowledgeable about influenza, its symptoms, and the possibility that it could be fatal, was a strong motivator to get vaccinated. Participants also described their own health conditions (e.g., heart disease or hypertension) as susceptible to the flu (N = 6), or the fact that they were getting older (N = 11), resulted in the need for getting a flu shot. Lastly, participants identified three main benefits about the influenza vaccination. The predominant perceived benefit given was that the influenza vaccination was effective in preventing individuals or communities from getting sick with the flu, or getting sick from cold-related illnesses (N = 24). The second most common benefit was the perception that the vaccine would diminish the severity of flu symptoms if the individual became infected with the flu (N = 12).

Barriers Associated with Influenza Vaccination

All participants were asked what makes it difficult for members of their community to get vaccinated for influenza. As in the analysis of facilitators, responses were categorized as either structural or personal factors (e.g., knowledge, attitudes, or health status) that posed as barriers to influenza vaccine usage (see Table 3). The predominant structural barrier was word-of-mouth from the community to not get a flu shot (N = 20). Within this context, "community" included community leaders, or relatives and friends, but this theme also reflected conversations individuals may have had, or might have heard at the barber shop, eateries, or other public places that were construed as dissuading elderly African Americans from getting a flu shot. Although not frequently mentioned, the theme, lack of access (N = 6), incorporated a number of different issues that prevented elderly African Americans from getting vaccinated, including not enough venues where individuals could go to get a flu shot. Lack of access also related to the issue of influenza vaccine shortages, which were salient even for participants who had regular primary care and could have received the vaccine through their physician's office.

Thirteen (48.1%) participants felt that not knowing about the severity of the flu was a personal barrier for most elderly African Americans. Participants also were influenced by what they perceived to be the risks of the influenza vaccination itself, focusing particularly on the contents of the vaccine. A predominant belief was that the flu shot itself could cause the flu (N = 21).

DISCUSSION

Our study demonstrated that participants' knowledge and attitudes about the severity and likelihood of getting influenza did not explain fully why elderly African Americans are getting or not getting vaccinated. Instead, exploring knowledge and attitudes in concert with structural facilitators and barriers provide a better picture of the challenges health professionals confront to improve influenza vaccination rates in this underserved racial group. We set out to understand the factors affecting influenza vaccination use in one elderly African American sample and to provide recommendations on how to remedy some of the key factors identified.

The study findings focused on the facilitators and barriers affecting influenza vaccine usage among elderly African Americans in Durham County, North Carolina. Interestingly, some themes were identified as both facilitators and barriers to getting vaccinated for influenza. One of these themes was word-of-mouth from the community highlighting both the pros and cons of getting vaccinated. Although more participants expressed this theme within the context of what discourages individuals from getting vaccinated, it raises an important issue about how negative experiences with the influenza vaccine are emphasized, spread, and can linger within a community. Similarly, a predominant perceived risk was that the vaccine itself causes the flu. Most likely, what participants experienced

Table 2.
Facilitators to Getting the Influenza Vaccine

Theme	Text Example	(N=28) N (%)
STRUCTURAL		
Reminder from the doctor to get a flu shot	"...and pamphlets that they [doctor's office] send you in the mail to get the flu shot. And, they [doctor's office] do write you ...And tell you the flu shot will be given such and such a time." (Female, 73 years old)	19(67.9)
Word-of-mouth from the community to get a flu shot	"And that's where a lot of people gather, so around the flu time send notices or information to the churches and the schools informing people about this flu shot and sometimes people in the church will listen if it's coming from somebody else in the church." (Female, 73 years old)	14(50.0)
Written or visual media promoting flu shot use	"I think when you get information when you go to get your flu shot, they also give you pamphlets to hand out and things like that, I think that all is a good awareness." (Female, 67 years old)	11(39.3)
Vaccine is free or low cost	"Also cost, better health insurance for, insurance making it [flu vaccine] available that way." (Female, 65 years old)	7(25.0)
PERSONAL		
Being knowledgeable about the severity of the flu	"I have had the flu, and I know how sick you can get from it." (Female, 77 years old)	17(60.7)
Having a chronic condition that puts them at higher risk for getting the flu	"See I didn't have any serious medical problem. But since I had heart disease, he [doctor] encouraged it [getting flu shot]." (Female, 75 years old)	6(21.4)
Having (Had) a job that puts them at a higher risk for getting the flu	"Because it was part of the hospital's routine, the nurses there had to take, they had to take different vaccinations and all that kind of stuff." (Female, 66 years old)	8(28.6)
Getting older	"And the reason why I took the flu shot this year is because for the last—since I've made sixty five—I see that my resistance to colds and flus are getting worse." (Female, 68 years old)	15(53.6)
Benefits of the flu shot		
* Prevention	"I think it prevents you from being miserable during the winter." (Female, 68 years old)	24(85.7)
* Decreases symptom severity of the flu	"I guess stave, stave off colds, other diseases that might be connected with the flu." (Female, 78 years old)	12(42.9)
* Greater ability to do day-to-day activities	"Because my doctor is still telling me that if I have a breathing condition, that if I got the flu, it would be milder than if I did not take the flu shot." (Female, 73 years old) I think it [flu shot] keeps my immune system stronger, so therefore I feel better, and I'm able to do the things that I enjoy doing and not have to spend time laying around, sneezing, coughing...so it really helps me so I can be more active." (Female, 67 years old)	8(28.6)

Note: Values represent the number (and %) of participants who reported each theme listed.

and were describing was an immunological response or side effects to the vaccine that they interpreted as the flu. Nevertheless, their negative experiences with taking the influenza vaccine will affect their future usage. In attempting to change behaviors among elderly African Americans, and in this case improve annual vaccination usage, we recommend the need to address historical, collective experiences (e.g., being exposed to a "bad batch" in early vaccination efforts), as well as urban myths (e.g., the vaccine causes the flu), in any targeted program developed.

Several other recommendations can be noted with respect to increasing knowledge and awareness of influenza and its vaccine in African American communities. A majority of the participants identified reminders from healthcare providers to get vaccinated

Table 3.
Barriers to Getting the Influenza Vaccine

Theme	Text Example	(N=28) N (%)
STRUCTURAL		
Word-of-mouth from the community to get a flu shot	"Those are the ones that are scared of, of getting the flu [from the flu shot]. They heard from somebody who heard from somebody else that it can give you the flu. It's hard to convince folks once they start thinking that." (Male, 72 years old)	20(71.4)
Irregular or lack of preventive healthcare	"When you're talking about medical visitation, regular visitations, a lot of people my age don't go to a doctor until they're sick. And the doctor, when they find out what's the matter with them, you know where they go first, the Emergency room." (Male, 76 years old)	7(25.0)
Lack of access	*Regarding vaccine shortage:* "When I went to the health department, they said it was somewhat late that they couldn't get the vaccine or something. I went there three times, you know. But anyway she said, 'I'll call you,' but when I did go back there was, something didn't come in... and I was interested in getting my flu shot." (Female, 77 years old) *Regarding location access:* "I think it's access to health, to places where you know the flu shot is given. There may be not as many clinics or places that you know that they can go to, or the distance that they may have to travel." (Female, 77 years old)	6(21.4)
PERSONAL		
Not knowledgeable about the severity of the flu	"Some of them are not knowledgeable enough to know what it can do for you. They don't realize the risks or the advantages." (Female, 76 years old)	13(48.1)
Fear	"I think some people are afraid. They're afraid that they're going to get sick or something from it." (Female, 79 years old)	13(46.4)
Risks of the flu shot		
* Side effects	"I think when they give you the shot, they're giving you part of that, parts of flu? And, if you're not strong enough or you can't fight it off, that's the way I feel about it. Your body's not strong enough, then I guess you just have the flu, it will give you the flu." (Female, 80 years old)	21(75.0)
* Getting the flu from from the flu shot	"My arm swolled up and I had chills and fever. Just like I was having, just like flu. And, I was just sick. And so, that stopped me from taking them [flu shots]." (Female, 80 years old)	18(64.3)
* Past problems with flu shot batches	"...sometimes the flu shot can, depending upon the batch of the flu shots that's being given sometimes they can have adverse effects and that is something I do think about." (Female, 65 years old)	5(17.9)

Note: Values represent the number (and %) of participants who reported each theme listed.

as a facilitator. The reminders can lead to elderly patients asking for the vaccine or just asking questions about the vaccine should they have concerns. Through simple reminder systems, providers can play an important role in reducing racial/ethnic disparities in vaccine use,[16] not to mention encouraging more patient education about influenza and its prevention. A second recommendation is to educate African American communities about the fact that an annual influenza vaccine is covered under Medicare, to which all over the age of 65 are entitled, and cost should not be a barrier to getting vaccinated. Lastly, since influenza immunization is seasonal, it would be useful to develop local media campaigns notifying the public in a timely and coordinated fashion when and where the vaccine will be available. This will most likely target individuals who have a desire to get vaccinated, but have had access difficulties due to vaccine shortages, late arrival of the vaccine, or not knowing locations where to get the vaccine, particularly in cases where individuals do not have a regular healthcare provider and rely on chain pharmacies or health departments for their vaccine source.

Our study has two primary limitations. First, our convenience sample was not heterogeneous with respect to socioeconomic status and gender, i.e., low-income and male participants were not equally represented. Second, our findings have limited generalizeability only to elderly African Americans with similar population characteristics to our sample living in Durham, NC. Further research would need to be conducted on a national sample of older African Americans to determine whether the same facilitators or barriers may apply in other regions of the United States. Despite its limitations, the findings demonstrate what works, and what factors pose as obstacles for elderly African Americans to get the influenza vaccination.

The public health benefits of improving influenza vaccination rates among the elderly include primary prevention, preventing secondary complications, and reducing hospitalizations and deaths associated with influenza.[9] These actual benefits, unfortunately, are not translating into increased vaccination use among the elderly, particularly elderly African Americans. In order to improve vaccination use, any public health intervention should have a multi-system approach that emphasizes what facilitates and overcomes the barriers to vaccine use at the individual, provider, community, and healthcare system levels. In so doing, eliminating health disparities, at least for influenza morbidity and mortality among elderly African Americans, could be a possibility. **NCMJ**

Acknowledgments: The study was funded by grants from University of North Carolina at Chapel Hill (UNC-CH)/North Carolina Central University (NCCU) Center for Minority Aging (#NR04716), the National Institutes of Health (HL04039), and the Robert Wood Johnson Minority Medical Faculty Development Program.

We also would like to thank Mr. Anthony Gauchie from the UNC-CH/NCCU Center for Minority Aging for assisting us with the recruitment of potential participants, and our Community Advisory Board members for their feedback on the design and implementation of this study.

POLICY FORUM

> *"...a good death [is] 'one that is free from avoidable distress and suffering for patients, families, and caregivers; in general accord with patients' and families' wishes; and reasonably consistent with clinical, cultural, and ethical standards.'"*

INTRODUCTION

Policy Forum:
End-of-Life and Palliative Care

The Policy Forum section of this issue of the *North Carolina Medical Journal* gives attention to one of the most complex sets of problems in American healthcare—end-of-life and palliative care. Few topics addressed in this Journal have such profound and relevant implications for healthcare quality and to the lives of all Americans, regardless of social class, gender, religion, race, or ethnicity. The inevitability of death forces all of us to think about the choices we would make at the end of life. But, as these articles make clear, all too often the family and friends of those who are dying are faced with limited choices because few of us make adequate plans for these inevitable circumstances.

In this issue of the Journal, an outstanding group of healthcare professionals, lay activists, and policy analysts with broad-reaching involvement in end-of-life and palliative care have offered a comprehensive overview of the major problems and issues in this field. Geriatrician and medical ethicist, Laura Hanson, MD, MPH, offers a panoramic overview of these issues. Other authors provide detailed analyses of the care and services provided by hospice and hospital-based palliative care organizations and some of the dilemmas of clinical decision making, including a review of current approaches to pain control and the circumstances under which feeding tubes (percutaneous gastrostomy tubes or PEGS) should be used for nutritional supplementation. In addition, we have an explaination of the legal and ethical issues associated with do-not-resuscitate orders (DNR) and the designation of healthcare power of attorney. We have also included reprints of formal statements from the North Carolina Medical Board and the North Carolina Medical Society on these issues, which can serve as useful guidelines and assurances to practicing physicians who care for dying patients.

As one reads these articles, it is clear that despite the complex issues in this field, there are some remarkable successes and indications of a growing professional concern about how we care for dying patients and their families. Given the rapid growth of North Carolina's elderly population, we are likely to see an increase in the demand for more and better trained healthcare professionals who can provide end-of-life and palliative care. Though there are healthcare professionals who have denied the need for a specialized approach to the care of the dying patient, the many facets of end-of-life care described in these articles surely underscore the contrary point of view. There is great need for professionals in a number of disciplines who are dedicated to providing the care and services needed to assure the opportunity for a "good death" when that time comes.

As always, we await your letters and other comments on these issues as we continue to bring you reviews of some of the more important and far reaching health and healthcare policy issues affecting the lives of North Carolinians.

ISSUE BRIEF

Palliative Care:
Innovation in Care at the End of Life

Laura C. Hanson, MD, MPH

What is Wrong with Healthcare at the End of Life?

Americans benefit from rapid innovation in medical therapies to prolong life and ameliorate disease, but innovation in care of dying patients has not kept pace. When efforts to cure or to manage diseases reach their inevitable limits, patients, families, physicians, and nurses question continued use of treatments designed to prolong life. Many physicians and nurses recall using life-sustaining treatments for terminally ill patients—treatments that they considered to be inappropriate at the time.[1] In extreme cases, beginning with the court battle over life support treatment for Karen Ann Quinlan, these poignant personal decisions have become public narratives of suffering. When chances for cure and survival diminish, most dying patients and their families prefer an approach to medical treatment that emphasizes comfort and quality of life. Discerning and then communicating this transition is one of the central dilemmas of end-of-life care.

> *"Palliative care is comprehensive, interdisciplinary care designed to promote quality of life for patients and families living with a serious or incurable illness."*

Good care at the end of life is not accomplished by simply stopping traditional modes of treatment. The alleviation of suffering is one of the primary goals of medicine, yet emerging research in the care of dying patients demonstrates high rates of untreated pain and other physical symptoms. New forms of treatment and care are needed to control symptoms associated with dying. Decisions to withhold or withdraw life-sustaining treatments do not address the needs for effective treatment for pain and other symptoms. The crisis of impending mortality triggers additional emotional and spiritual suffering.[2] Forty percent of conscious patients have moderate-to-severe pain and more than half have moderate-to-severe dyspnea during the last two-to-three days of life.[3] Patients dying in hospitals and nursing homes have high rates of unmet needs for physical symptoms, emotional suffering, personal care services, and communication about treatment options.[4,5] Patients do not suffer alone; during the dying process and after a death, family caregivers experience significant emotional, physical, and financial stress.[6,7,8] Patients, families, and healthcare providers acknowledge profound deficiencies in current end-of-life care, and the need for improved palliative care services that are well matched to the needs of dying patients.

Palliative care is an emerging field in United States healthcare. Palliative care is comprehensive, interdisciplinary care designed to promote quality of life for patients and families living with a serious or incurable illness.[9] Because it is a comprehensive approach to care, providers of palliative care offer expert pain and symptom management, supportive care for emotional and spiritual distress, and bereavement support for surviving family. Palliative care includes and expands on the expert care of dying patients found in hospice services.

How Do Americans Die?

More than two million deaths occur in the United States each year. Depending on the underlying cause of death, a dying patient's "death trajectory," or their functional decline prior to death, may follow a brief or prolonged course. The trajectory of illness before death may have a recognizable terminal phase, or a more uncertain and unpredictable course prior to death. The underlying cause of death and resulting death trajectory strongly influence the quality of the dying experience, the certainty that a patient is dying, and the physician's ability to discuss options for medical treatment.[10,11,12]

Laura C. Hanson, MD, MPH, is an Associate Professor in the Division of Geriatric Medicine, Department of Medicine, University of North Carolina at Chapel Hill and Co-Director of the University of North Carolina Pain and Symptom Care Program. She can be reached at lhanson@med.unc.edu or CB# 7550, Chapel Hill, NC 27599-7550. Telephone: 919-966-2276.

Progressive chronic diseases—heart disease, cancer, stroke, chronic lung disease, and neurodegenerative disease such as Alzheimer's and other dementias—cause the majority of adult deaths. Among these causes, cancer patients have a more precipitous functional decline near death, which may facilitate recognition of a terminal phase of illness. Patients with chronic heart or lung disease have a more uncertain trajectory of worsening and remitting symptoms over months to years prior to death. Elderly nursing home residents with neurologic diseases and varied other chronic illnesses may have a very slow functional decline for many years, with no recognizable terminal phase. These individuals often die of an acute illness such as pneumonia or hip fracture. In the context of advanced dementia, these treatable acute illnesses have a 50% mortality risk at six months.[13,14]

Because Americans expect to live into old age, deaths early in life are especially painful. Premature deaths among children and teens are more often caused by relatively sudden events such as accidental injury, homicide, suicide, or complications of HIV infection or congenital abnormalities.[16] Racial and ethnic minority groups have higher rates of death at younger ages from these traumatic or sudden causes. The national Institute of Medicine's report, *Approaching Death: Improving Care at the End of Life*, emphasizes the need for overall improvements in end-of-life care and lends attention to the diverse needs of these subgroups of dying patients.[15,16]

Where Do People Die?

The site of death may be one of the most important structural determinants of the experience of dying.[5,17] Patients and their families say they prefer terminal care at home,[18] but four of five deaths in the United States take place in hospitals and nursing homes. After-death interviews with bereaved families show an association between site of death and satisfaction with terminal care. Surviving family are consistently more satisfied with hospice and are least satisfied with conventional nursing home and hospital care.[5,17,19] Hospice services, which can be provided in private homes or long-term care facilities, now support one-in-five dying Americans. In 1989 the Medicare hospice benefit was extended to nursing home residents. Hospice has since been added to usual nursing home care for 5.6% of deaths in long-term care facilities.[20] The site of death and use of hospice care varies by state. Oregon, after its highly publicized debate on assisted suicide legislation, has achieved the highest rate of hospice enrollment in the nation (31% of all deaths), and is able to provide terminal care at home for 42% of its citizens who die. North Carolinians' healthcare experiences at the end of life are very similar to the majority of decedents in the nation (See Table 1).

Table 1.
Site of Death in North Carolina, 2001

	NC	US
Site of death		
Hospital	54%	49%
Nursing home	22%	24%
Home	25%	23%
With Hospice	21%	19%

As the population ages, and as economic pressures cause reduced hospital lengths of stay, nursing homes are becoming a more common site of death. Data from the National Mortality Followback Survey, a representative sample of United States deaths in 1986 and 1993, show that the proportion of deaths that occur in hospitals decreased from 65% to 56%, while the proportion of deaths in nursing homes increased from 17% to 19%. By helping frail elders receive treatment and supportive care outside of hospitals, community-based, integrated eldercare programs such as the Programs of All-Inclusive Care for the Elderly (PACE)[22] can result in increased use of nursing homes (34%) and private homes (45%) as sites of death.[23] The availability of services within one's local health system, including readily available hospital beds, nursing home beds, and hospice services are likely to influence where people die, perhaps more than their own preferences about site of terminal care.[24,25]

How Do Patients and Families Define a Good Death?

Most medical treatments are judged to be effective if they are proven to prolong life or to reduce the risk of adverse health events or functional impairments. Good end-of-life care can only be defined by its ability to promote a "good death," or good dying experience for patients. As the potential for medical treatment to improve function and survival diminishes, patient- and family-centered outcomes become paramount. An expert consensus panel convened by the national Institute of Medicine has defined a good death as "one that is free from avoidable distress and suffering for patients, families, and caregivers; in general accord with patients' and families' wishes; and reasonably consistent with clinical, cultural, and ethical standards."[15]

Several well-designed studies explore domains defined as important to seriously ill and dying patients and their professional and family caregivers (See Table 2).[26,27,28,29,30,31] Dying patients and those who provide their care consistently value: (a) relief from pain and other physical symptoms, (b) attention to emotional, psychological, and spiritual needs, (c) compassionate communication, (d) involvement in critical healthcare decisions, (e) affirmation of personhood and dignity, (f) support for family caregivers, and (g) coordination and continuity of care.[32,33]

Innovations in End-of-Life Care

Public demand for appropriate care at the end of life emerged in the controversy surrounding dramatic "right-to-die" court cases. It has been fuelled by the debate over assisted suicide, and by descriptive studies of pain and suffering experienced by dying patients and their families. These problems are well defined, and new approaches to the delivery of medical care to seriously ill and dying patients are beginning to improve care.

Strategies to improve end-of-life care can be conceived as targeted or comprehensive interventions. Targeted interventions

Table 2.
Patient and Caregiver Perceptions of Quality in End-of-Life Care

Study Population	How do patients, family, and healthcare providers define a "good death"?
N = 126 chronically ill patients (Singer, 1999)	Receiving adequate pain and symptom management Avoiding inappropriate prolongation of dying Achieving a sense of control Relieving burden on loved ones Strengthening relationships
N = 137 chronically ill patients, family members, and healthcare providers (Curtis, 2001)	Physician access and continuity Team coordination Communication with patients Patient education Inclusion of family Medical competence Pain and symptom management Emotional support Personalization Attention to patient values Respect and humility Support of patient decision making
N = 75 healthcare providers, patients, and family caregivers (Steinhauser, 2000)	Pain and symptom management Clear decision making Preparation for death Completion of spiritual or meaningful final tasks Contribution to others Affirmation of the whole person

are designed to influence one aspect of the dying experience. Examples could include programs to improve physician communication skills, to implement pain management protocols, or to provide grief counselling for parents of dying children. Comprehensive clinical services such as hospice or palliative care units are designed to improve the overall quality of care for dying patients and their families. These comprehensive services typically include healthcare providers who can address a wide range of communication and symptom management needs for dying patients and their families.

Making Advance Directives Work

Given evidence that patients and families were dissatisfied with current end-of-life care, concerned clinicians and bioethicists reasoned that increasing patient control over major clinical decisions would result in more appropriate forms of treatment. Advance directive documents emerged, in which a patient gave prior direction about who could make decisions on his or her behalf (Healthcare Power of Attorney) and how life-sustaining treatments were to be used in the event of terminal or incurable illness (Living Will). Research on advance directives has shown that education and provision of advance directive forms can increase documentation of patient preferences. Patients generally welcome these conversations, and many are willing to record their wishes in some form.

Unfortunately, advance directives may be necessary but not sufficient to change the experience of care at the end of life. Living wills and other advance directive documents have not had a significant impact on the medical care received by dying patients.[34] In 1995, the Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatment randomized seriously ill patients with limited life expectancy to a nurse-facilitated, written communication of prognosis and treatment preferences. The aim of the intervention was to inform and facilitate decision-making by patients and physicians. This intervention, like similar smaller studies, had no impact on pain treatment, life-sustaining treatment use, or cost of care.[35] Advance directives have the potential to promote communication among patient, family, and provider, but are not sufficient to change care at the end of life.

In retrospect, it is not surprising that advance directives alone are not sufficiently powerful to change care at the end of life. These documents may not be immediately available when patients become acutely ill and are unable to speak for themselves. Living wills are subject to interpretation and may be difficult to apply to specific clinical circumstances. Is a patient with advanced Alzheimer's and a hip fracture "terminally ill"? Is the treatment of pneumonia in a patient with end-stage cancer "life-sustaining treatment"? Another limitation is that traditional advance directives focus on withholding or withdrawing treatments, rather than a positive choice for an overall plan of care.

Advance directive documents are most useful when they serve as an invitation to conversations about patients' real concerns and values, goals of treatment, and a plan of care serving those goals. Some newer advance directives promote more comprehensive advance care planning. One example, The Medical Directive, requires a median time of 14 minutes to discuss, and allows the physician and patient to cover a broad range of health scenarios and treatment options.[36] In the mid-1990s Oregon adopted a portable physician order form which promotes discussion of preferences for resuscitation, overall level of medical treatment, and use of antibiotics, feeding tubes, and intravenous fluids. The form, Physician Orders for Life-Sustaining Treatment (POLST), is a physician order that is portable between healthcare sites.[37] The POLST has been widely accepted in Oregon, and evaluations suggest that it lowers the use of life-sustaining treatments and hospital admission among nursing home residents. A randomized controlled trial of a similar comprehensive advance directive in six Ontario nursing homes had a marked effect on hospital use and cost of treatment at the end of life.[38]

Improving Communication

Meaningful and compassionate communication is the core skill in end-of-life care. Absent this skill, physicians will be unable to help patients decide on appropriate treatments, assess physical symptoms, or address emotional and spiritual suffering. Patients facing the crisis of their own mortality require time to express fears and to seek reassurance of continuing physician attention to their spiritual and emotional needs, in addition to medical aspects of their care.

Family perspectives on the quality of the dying experience are independently important. While the patient lives, physicians must be skilled in communication with family members who make decisions for incapacitated patients, and serve as physical and emotional caregivers. Although they may not accurately represent patient treatment preferences or symptoms, family members are the ethical surrogate for incapable patients, and they will evaluate the quality of care after the patient's death.[39,40] In one study of recently bereaved family members in North Carolina, their most common recommendation for improved care at the end of life was to improve physician communication skills.[17] Their recommendations emphasized the need for communication beyond medical treatment choices, including a desire to talk more about prognosis, and about the humanity and dignity of the patient.

Communication of prognosis is essential if patients and families are to participate in informed decision-making. Prognostic models are accurate for populations, but challenging to communicate to individual patients. In the SUPPORT study population, a patient with a 50% chance of living two weeks also had a 20% chance of living six months.[41] Physicians and patients alike respond to prognostic information with optimism born of hope for survival. Physicians systematically overestimate their patients' life expectancies, and communicate even more optimistic data than they believe.[42] Patients who have cancer and an average life expectancy of six months will nearly all expect to live longer than six months.[43]

Compassionate communication about prognosis seeks to balance optimism with a gentle respect for patients' right to know the truth about their illness. Probabilities are confusing, but physicians can often tell patients whether life expectancy is measured in days to weeks, weeks to months, or months to a year or two. Patients and physicians can travel a careful middle ground together, where they "hope for the best, and prepare for the worst."[44] Prognosis is not simply a question of communicating life expectancy. Patients and family members also need information about what is likely to happen during the dying experience. Their ability to understand and anticipate the natural history of disease, its symptoms, and possible treatments will allow time for practical and spiritual preparation for more serious illness or death. It may also relieve unspoken fears.

Physician training includes little experiential learning about these essential communication skills. However, physicians who have worked to become expert in this aspect of medical practice are demonstrably more capable of comprehensive, patient-centered communication. This communication can be accomplished even within the time constraints of an office visit.[45] Experts in end-of-life communication have published useful examples of the words and approaches they use to promote continued practice of this vital skill.[44,46,47,48,49,50] Innovative continuing education programs that expand didactic education to include experiential learning techniques have a positive effect on physicians' communication skills.[51,52]

Communication about end-of-life treatment decisions may also be improved using ethics consultations for intensive care unit (ICU) patients. In a multi-site randomized controlled trial, ethics consultants led family meetings when value-laden treatment decisions were imminent. These consultations result in high levels of satisfaction, reduced use of life-sustaining treatment and ICU days, and yet had no adverse effect on the length of patient survival.[53,54]

Individualizing Care for Diverse Populations

End-of-life care varies for patients of minority, ethnic, and cultural backgrounds. Terminally ill African-American or Hispanic patients are less likely to receive effective pain treatment or to enroll in hospice than their white counterparts, and are more likely to die in hospitals.[55, 56] Physicians seeking to provide excellent care for dying patients must consider whether these differences in treatment are driven by patient values, or by failed access to or understanding of treatment options. Knowing that African-American patients generally enroll less often in hospice should not lead physicians to assume an individual patient's preference, but it may allow for more sensitivity in discussions of treatment decisions.

Patient characteristics such as education, race, and cultural or religious background may also influence values about patient and family involvement in medical treatment decisions. For example, traditional Navajos may perceive that speaking of potential bad outcomes may cause them to occur; a value quite distinct from a Western European emphasis on truth telling.[57] Patients from some cultural traditions, including African American, Hispanic, and some Asian countries, may place a greater emphasis on the importance of family involvement in medical treatment decisions even when the patient is capable of making his or her own choices.[58] Use of written advance directives and orders to limit life-sustaining treatment vary by patient insurance status, educational attainment, and racial background.[59,60] Dying patients and their caregivers desire spiritual care, and this aspect may engender particular concern among patients from minority, ethnic, or religious backgrounds.[61] Spiritual care, when available for dying patients and their families, needs to be consistent with individual faith traditions and cultural expression of spiritual practices.[62] Understanding these patterns of historical differences may allow for more nuanced communication with patients who do not share the physician's cultural heritage.[63]

Comprehensive Strategies: Hospice

Palliative care is comprehensive, interdisciplinary care designed to promote quality of life for patients and families living with a terminal or incurable illness. Hospice agencies, modelled on the inpatient treatment approach pioneered by Dame Cicely Saunders in Britain, have delivered palliative care in private homes in the United States since the creation of the Medicare hospice benefit in the 1980s. In 1989 Medicare expanded this benefit to nursing home residents, and hospice is now offered under most state Medicaid programs and many forms of private health insurance.

Patients are eligible for hospice if a physician certifies that they have a life expectancy of six months or less "if the disease follows its expected course." Patients are also expected to agree to forgo "curative treatment for their terminal illness." Patients with uncertain disease trajectories may find it difficult to meet the six-month criterion, although non-cancer diagnoses are increasingly represented within the hospice population. For many diseases, curative and palliative treatments overlap and access to specific treatments may vary by provider. For example, patients with cancer may or may not be able to continue transfusions for anemia and patients with chronic obstructive pulmonary disease (COPD) may or may not be able to continue intravenous antibiotics for pneumonia.

For patients who can qualify, hospice improves satisfaction with end-of-life care. After death, family caregivers rate hospice services more positively than any other aspect of terminal care.[5,17] In early studies, hospice inpatient units showed improved satisfaction despite modest impact on symptom scores.[64,65] In nursing homes, family caregivers believe that adding hospice care improves the quality of care for physical symptoms and emotional needs.[66] Comparison of nursing home decedents who do or do not receive hospice care shows increased use of pain medication and decreased use of tube feeding and hospitalization for those enrolled in hospice.[67] Hospice delivered in private homes can reduce the total cost of care for younger patients and those who die from cancer, but not for other dying patients.[68]

Many patients who might benefit from palliative care do not currently access hospice, or do so within only days of death. The length of stay in hospice has slowly decreased over the past decade. Patients may deny they are nearing death, or have an uncertain trajectory of illness that does not fit the six-month criterion. They may be unwilling to forego treatments, such as palliative radiation, that are prohibitively costly to include in the hospice per diem payment. Many individuals may face terrible pain and suffering, but have a cultural or personal imperative to "fight until the end." Hospices and other healthcare organizations are creating newer forms of palliative care services to match the needs of these patients.

Comprehensive Strategies: Palliative Care Programs

New model palliative care programs have increased significantly during the past decade, in response to needs for palliative care outside the traditional hospice enrollment population. Palliative care programs may be affiliated with an acute care hospital, a hospice agency, or with innovative elder care services that provide a continuum of health services.[69]

The number of physicians seeking palliative care certification is rising rapidly. The American Board of Hospice and Palliative Medicine incorporated in 1995, and began administration of its board exam in 1996. By August 2003, there were 43 active or emerging United States fellowships in Palliative Medicine, and over 1,200 physicians have met qualifications for certification in this field.[70]

Seventeen percent of United States hospitals currently house a palliative care service. Unlike hospice, palliative care programs do not yet offer a standardized array of clinical services. Hospital-based palliative care may include a variety of healthcare providers who offer inpatient consultation, outpatient consultation, dedicated inpatient beds, or bereavement programs for families. For example, the Pain and Symptom Care Program at UNC Hospitals, initiated in 2001, now provides inpatient care on 23 different hospital units. Using a consultation model, this interdisciplinary service reaches a diverse patient population; half are under age 65, one-third are African American, and one-third have terminal illnesses other than advanced cancer. Patients' average ratings of pain and other symptoms improve, and 80% of patients and families receive counselling about end-of-life issues.

Because palliative care programs are changing rapidly and are not yet standardized, studies of its impact on care quality and cost are just beginning. One systematic review of 16 relatively well-established services found that these hospital-based inpatient services improved family satisfaction, reduced symptoms of distress, and decreased the intensity or cost of inpatient services for the patients they serve.[71] Like many labor-intensive healthcare services that do not emphasize procedures, palliative care is valued for its ability to reduce costs while improving quality of care.

Conclusion

For several decades, the medical literature has been filled with evidence of shortcomings in end-of-life care. Patients who have acquired the disease that will cause their death receive the same approach to medical care in early and advanced stages of incurable disease. Physicians fail to discuss prognosis, and patients retain hope for cure rather than hope for comfort and quality of life during their remaining days. In recent years palliative care practice and research have stimulated new programs and new clinical approaches to the care of dying patients and their families. Hospice, long the only repository of expertise in palliative care, is now joined by physicians, nurses, and other healthcare providers who have made a career commitment to excellence in healthcare for patients in the final phase of life. **NCMJ**

COMMENTARY

Hospice:
A Vital Service Facing Increasing Demands

Judith Lund Person, MPH

Introduction

For three decades hospice providers in the United States have been changing the care for dying Americans and their families by providing options and choices that enable patients to be in control of their care at the end of life. Yet, hospice faces a number of challenges. The healthcare landscape is changing along with the demographic profile of the nation. In order to meet present and future challenges relating to end-of-life care, it is imperative that hospices build on the successes of the past and carefully listen to the needs of the changing populations served.

The Care Americans Want

The hospice movement in the United States can be traced back to the work of Dame Cicely Saunders at St Christopher's Hospice in the United Kingdom. Hospice care in America grew out of the need for more compassionate care for dying persons. In the American paradigm, hospice is not a place, but an interdisciplinary offering of palliative and support services that allows the terminally ill to be cared for primarily at home. 'Home' is defined by the patient, this may be: the patient's own home, the home of a loved one, an assisted living facility, a long-term care facility, or a hospice residence. The care that the hospice provides reflects the specific care that is in demand. Nearly 90% of adults reported that they would prefer to be cared for in their own or a family member's home if they were terminally ill and had six months or less to live.[1]

Many studies[1-4,23] have documented that when considering issues of death and dying, the American public's chief priorities and concerns include:

- home-based care;
- patient control and choice about the services available to them;
- emotional and spiritual support for patients and families;
- pain control customized to the patients wishes; and
- freedom from financial worry.

In 1982, Congress voted to support the Medicare Hospice Benefit (MHB). In providing a government funding mechanism, Congress established an all-inclusive benefit for hospice that has enabled millions of Americans to receive quality end-of-life care. More than 96% of hospices in the United States are Medicare-certified and just over 80.9% of patients claimed Medicare as their payment source in 2002.[5] Most private insurance plans, health maintenance organizations, managed care providers, and Medicaid in the majority of states also cover hospice services.

The Nation's Demographics Are Changing

Availability of hospice and palliative care is a critical issue as many more Americans begin dealing with end-of-life care decisions, for themselves and older family members. The aging post-World War II generation is bringing on a significant demographic shift that is unprecedented. The elderly population in the United States is expected to double between 2000 and 2030. By 2030, there will be approximately 70 million Americans over the age of 65. The proportion of the elderly falling into the 85 years of age and older category is increasing. This group is expected to increase from 4.2 million in 2000 to 8.9 million in 2030. Never have the chances of reaching 100 years of age been better. It is estimated that more than 72,000 people in the United States are over 100 and by 2050 that number is expected to be 834,000.[7]

As our population ages and life expectancy increases, more sophisticated and costly medical interventions will be required to provide for the nation's healthcare needs. More people will live with long-term illness that requires significant care. The number of deaths will also increase. In 2001, 2.4 million people died in the United States from all causes. The National Center for Health Statistics estimates that the number of deaths per year will grow at such a rate that in 57 years, the number will be almost 5.7 million people annually.[7] These statistics demonstrate a need to prepare for a patient base that is already changing. In order to adequately provide care, access to hospice and palliative care must expand and capacity must increase. An

Judith Lund Person, MPH, is Vice President, Division of Quality End-of-Life Care at the National Hospice and Palliative Care Organization. She can be reached at jlundperson@nhpco.org or 1700 Diagonal Road, Suite 625, Alexandria, VA 22314. Telephone: 703-837-1500.

understanding of how hospice has successfully served the dying in the past will provide a foundation for future care.

Three Decades of Growth

By virtually any measure, the system of hospice care provided in the United States has been successful. One of the most dramatic measures of success has been the growth in beneficiaries. In 1975, there were 1,000 hospice admissions in the United States. By 2002, that number had grown to 885,000 annually. Over 95% of hospice patient visits are for routine home level of care reflecting Americans' preference to be in a home environment at the end of life.[6]

Today's hospice must address a broader range of terminal disease states and a wider range of palliative care services.[10] Hospice providers in the mid-1970s primarily served cancer patients, and the demographic profile of the patient population was almost entirely white and middle-class.[9] By 2002, cancer patients accounted for 50.5% of admissions. Hospices are also serving patients with end-stage heart, kidney and liver disease, along with dementia, lung disease, and other conditions (see Table 1).[8] America's hospices have taken a leadership role in the care of patients with HIV/AIDS as well.

Treatments such as chemotherapy and radiation, traditionally associated with curative care, are being increasingly used in hospice for pain and symptom management. In fact, advances in medical practice and technology for palliative, end-of-life care have prompted a significant increase in the intensity and frequency of services delivered to the hospice patient.[11] Outreach and increased access for diverse populations is also necessary. In 2002, 9.2% of hospice patients were African-American, 4.3% were Hispanic or Latino, 8% were Asian or Hawaiian/Pacific Islander, and 3.7% were classified as multiracial or 'another race.'[8]

Table 1.
Hospice Deaths in the United States, 2002

Diagnosis at admission	2002
Cancer	50.5%
End-stage heart disease	10.7%
Dementia	8.3%
Lung disease	6.7%
End-stage kidney disease	3.0%
End-stage liver disease	1.6%

More Americans Could Benefit from Hospice

Statistics suggest that more terminally ill Americans could gain access to the benefits of hospice. The United States General Accounting Office reported in 2000 that, while more beneficiaries are choosing hospice, many are doing so closer to the time of death. Half of Medicare hospice users are enrolled for 19 or fewer days, and service periods of one week or less are common. This study and other reports attribute this phenomenon to a variety of factors, including physician practices, patient preferences, concerns about compliance with Medicare eligibility requirements, and lack of awareness of the MHB among both the public and professionals.[12] A closer look at the trend toward shorter hospice service periods shows that the average length of service (ALOS) in hospice has declined dramatically since the initial Medicare demonstration project of 1983. The median length of service (MLOS) illustrates the effect of enrollments taking place days before death, and in 2002, 34.7% of those served died in seven days or less.[8]

The trend toward shorter lengths of service, combined with the greater intensity of today's hospice services, is also creating severe financial pressures for hospice providers. The government's original reimbursement mechanism under the MHB assumed a 70-day average length of service, with a per-patient, per-day rate that spread total cost over that 70-day period. With the drop in ALOS, hospices have a shorter period of patient stability over which to spread the high front-end and back-end costs that are unavoidable with hospice care.[11]

Cost of Care

A 1994 Lewin-VHI study found that Medicare saved $1.52 in Medicare Part A and Part B expenditures for every dollar it spent on hospice. That 1995 study also showed that in the last month of life, per-patient savings totaled $3,192, "as hospice home care days often substituted for expensive hospitalizations."[13]

Other more recent studies suggest that the use of hospice and advance directives saves up to 10% in the last year of life, 10% to 17% in the last six months of life, and 25% to 40% in the patient's last month.[9] The dollar value of such savings is dramatic when one considers the staggering costs that can result from efforts to extend life futilely through hospitalization in an intensive care unit (ICU). It has been estimated that the cost of caring for certain categories of cancer patients in an ICU can range from $95,000 to as much as $450,000 per patient for each year of life gained.[13]

Methods of reimbursement for services that are outside current hospice reimbursement streams must be explored and developed. Providers should not depend on the Medicare Hospice Benefit as the only source of reimbursement. Alternative funding sources include foundation grants, research projects, physician fellowships, charitable contributions, and institutional subsidies. These must all be aggressively explored. Providers must think beyond billing income to cover costs of care and operation.[22]

The cost of caring for the terminally ill is a critically important public policy issue, given the fact that one third of all federal Medicare dollars are spent on patients who are dying.[14] However, increasing hospice referrals is not just an economic measure. Hospice provides compassionate, high-quality care with consistently high patient approval ratings. [15,16]

Public Policy Changes

Congress has recognized the need to improve access and care through adjustments to the Medicare Hospice Benefit. While recent legislative changes may not address all the concerns related to access and capacity, they should prove beneficial. In

December 2003, Congress approved a far-ranging package of Medicare reforms, the Medicare Modernization Act of 2003.

There are a number of provisions designed to improve access and make hospice care more available to patients and families earlier in their illnesses. These include an educational consult for patients who would be appropriate for hospice care but have not yet been referred, the ability for hospices to contract for core or specialized services, a provision for nurse practitioners not employed by hospice to continue caring for patients under hospice, and a rural hospice demonstration project to evaluate care delivery.

Demonstration Projects

Additional methods to improve access, capacity, and ensure financial viability could be identified through national and community demonstration projects. Demonstrations that could lift current reimbursement guidelines, offset patients with very short stays, or examine how hospice patients could benefit from higher cost treatments would provide data that would potentially improve access to care for all. Projects that explore ways in which service providers can combine hospice and disease-modifying therapies at the same time must also be examined. There has also been much debate regarding Medicare eligibility requirements—currently, a physician must certify that a patient could die within six months if the terminal illness follows its expected course. Eligibility has often been confused with limits in length of service. A better understanding of how this has become a real and perceived barrier to care should be researched, ultimately leading to improved public and professional outreach and engagement.

> *"Nearly 90% of adults reported that they would prefer to be cared for in their own or a family member's home if they were terminally ill and had six months or less to live."*

Public and Professional Education

Another recognized barrier to greater public education about hospice is the character of American society, with its emphasis on youth, curative treatment, and the reversal of aging.[17] While not everyone with a terminal illness may be receptive to hospice, research suggests that most Americans—including physicians—are not sufficiently educated about hospice to make an informed choice. Also, within the physician community, studies indicate an aversion to the open discussion of death with patients and a lack of medical education about end-of-life issues.[3,18,19,21] An article in the *American Journal of Hospice & Palliative Care* reported that physicians often withhold the truth of a terminal diagnosis from their patients, resulting in the patient not realizing that death is likely until the last month of life.[20]

The national Institute of Medicine published a 1997 study, *Approaching Death: Improving Care at the End of Life*, that reported "the education and training of physicians and other healthcare professionals fail to provide them the attitudes, knowledge and skills required to care well for the dying patient."[9]

Hospital-Hospice-Palliative Care Partnerships

Important opportunities for hospice providers and hospitals in the United States can be found in hospital-hospice partnerships. A report released by the National Hospice and Pallative Care Organization (NHPCO) and the Center to Advance Palliative Care, *Hospital-Hospice Partnerships in Palliative Care*,[19] explores the relationship between hospitals and hospices that actively collaborate in providing appropriate care. The report indicates that partnerships tend to move in two directions. First, an enhanced utilization of the Medicare Hospice Benefit is seen as closer relationships between the hospice and hospital develop. Also, education surrounding hospice care, the creation of in-patient units, and reduction in barriers to hospice admission are documented.

The second trend is the development of palliative care services. In April 2004, the Clinical Practice Guidelines for Quality Palliative Care[24] were released by the National Consensus Project, a consortium of five national organizations in the field intensely interested in improving care for patients and their families at the end of life. The consortium includes the American Academy of Hospice and Palliative Medicine, the Center to Advance Palliative Care, the Hospice and Palliative Nurses Association, Last Acts Partnership, and the National Hospice and Palliative Care Organization. These Guidelines describe core precepts and structures of clinical palliative care programs and are the culmination of more than two years of work. They provide guidance for the assessment and treatment of pain and other symptoms; help with patient-centered communication and decision-making; and coordination of care across settings and through serious illness and are written for any healthcare provider who is interested in a developing palliative care program. More information on these guidelines can be found at www.nationalconsensusproject.org.

Building on What Works

The success of hospice is well documented, yet ongoing challenges in the field are recognized. End-of-life care providers must respond and adapt to the changing environment. The general public has an awareness of hospice, but the vast majority of people lack the specific understanding and knowledge to gain full access to hospice benefits. Physicians are also reluctant to discuss the specifics of death with their patients, and they lack the comprehensive medical education in end-of-life care that would lead to more referrals (and earlier referrals) to hospice. Changing demographics will greatly impact the number of Americans who must be served and the care that must be provided at the end of life.

It is critical that hospice and palliative care providers take their full knowledge and expertise regarding care at the end of life and make it available further upstream, reaching more Americans much earlier in the course of a life-limiting illness. The hospice philosophy of care should be utilized to help patients make the transition from more aggressive therapies to holistic palliative care services. Increasingly, hospitals and critical care units are using the skills of palliative care to more appropriately serve patients in their care.

The National Hospice and Palliative Care Organization (NHPCO) is the oldest and largest non-profit membership organization representing hospice and palliative care programs and professionals in the United States. The NHPCO is committed to improving end-of-life care and expanding access to hospice care with the goal of profoundly enhancing quality of life for people dying in America and their families.

COMMENTARY

Palliative Care:

More than Just Care from a Friendly Relative

Richard C. Stephenson, MD

Overview

A well-meaning board member of a large home health and hospice organization once shared that he thought palliative care must mean, "care from a friendly relative." While half-heartedly playing on the words "pal" and "relative," he was not far from the truth. From a literary point of view, palliative care means care intended to "cloak" symptoms as opposed to curing disease. But most imagine it to be just comfort care only, very supportive and very hospice-like.

For more than a decade, the World Health Organization (WHO) has defined palliative care as active total care of patients not responsive to curative treatment where control of pain and other symptoms and of psychological social and spiritual problems is paramount and the goal is the best possible quality of life for patients and their families. More recently, Diane Meier, at the Center to Advance Palliative Care and others have shied away from this concept of switching from curative to palliative and embraced a concept of palliative care as interdisciplinary care that aims to relieve suffering and improve the quality of life for patients with advanced illness and their families, *offered simultaneously with all other appropriate medical treatment.*[1] From this point of view, palliative care may be present from the time of intensive care unit (ICU) admission, help manage the transition as curative therapies fail, and become the predominant mode of care as terminal illness becomes apparent.

In this issue of the Journal, Laura Hanson has done an excellent job of reviewing existing shortcomings in end-of-life care. She has also reviewed comprehensive strategies such as hospice and palliative care to address these problems and innovations to make advance directives work and other strategies to improve communication and access.[2]

In fact, palliative care may be one of the most rapidly developing service lines in United States hospitals. As Dr. Hanson points out, almost one in five hospitals now has a palliative care service and many more have plans to create them. More than 1,500 physicians are now certified in Hospice and Palliative Medicine.[3] The specialty is in the process of becoming certified by the American Board of Medical Specialties (ABMS) and the Accreditation Council for Graduate Medical Education (ACGME). Palliative care fellowship programs are rapidly developing to meet these growing needs. Existing palliative care and hospice programs have created a more extensive body of evidence-based literature in palliative medicine and achievable, meaningful outcomes are being realized within committed institutions.

All of this must sound very exciting and academic! But from a much more practical point of view, does your institution need palliative care? What can a palliative care service actually do for you? And if you want one, how can you develop one? Many concerned healthcare providers, hospitals, and hospices are asking these same questions. Fortunately, there are tremendous resources available through the Center to Advance Palliative Care (CAPC), a national initiative supported by the Robert Wood Johnson Foundation with direction and technical assistance provided by the Mount Sinai School of Medicine.

The Center to Advance Palliative Care[4]

Diane Meier, Director of CAPC, and staff have created a wide variety of resources to assist institutions with the entire process of developing palliative care services from needs assessment to sustaining and growing existing programs. Resources include conferences, website, monographs, and leadership centers available for site visits and ongoing mentoring. These leadership centers include a variety of settings where palliative care has developed and flourished, i.e., academic medical centers, private hospitals, healthcare systems, and home health and hospice organizations. The process begins with building a case specific to the institution including needs assessment, securing support and financial considerations. While there are formulas that are specific and data driven, it is far from a "cookbook" approach. The CAPC process goes on to help design a program specific

Stephenson, MD, is the Medical Director for the Hospice and Palliative CareCenter in Winston-Salem, NC and for the Palliative Care Consult Service at Wake Forest University Baptist Medical Center. He is also an Asstistant Clinical Professor of Medicine at Wake Forest University School of Medicine. Dr. Stephenson can be reached at Dick.Stephenson@hospicecarecenter.org or 1100C S. Stratford Road, Winston-Salem, NC 27103-3212. Telephone: 336-768-3972.

> *"Palliative care services provide 'specialized care through specific knowledge and skills, including communication with patients and family members; management of pain and other symptoms; psychosocial, spiritual, and bereavement support; and coordination of an array of medical and social services.'"*

to the institution, develop a business plan, implement services, measure quality and impact, and even market the program.

Critical to the success of the CAPC process is the development of a core team, which includes a medical staff leader, nursing leader, hospice representative, and an administrative champion. CAPC is quick to point out that this is an ideal opportunity for hospital/hospice collaboration.

Is this a formula for guaranteed success? Of course not, but generally expected and accepted, evidence-based outcomes include reduction in symptom burden, improved patient and family satisfaction, and reduced costs. Other highly likely outcomes, but less evidence-based, suggest care concordant with patient/family wishes, patient/family/professional consensus on the goals of care, and improved continuity of care.[5]

Local Hospital-based Palliative Care Initiatives

Forsyth County, North Carolina, demonstrates two distinctly different approaches to palliative care programs developed with local initiative, but also tutored by CAPC programs. The local area hospice, a private, independent not-for-profit hospice and home health organization enjoys a longstanding, collaborative relationship with both the academic medical center and the large tertiary care private hospital in Winston-Salem. The hospice owns and operates a 20-bed freestanding inpatient hospice facility, and has an average daily census of 260 patients at home, in nursing homes, and in the facility. Hospice employees include a full-time medical director, a second full-time physician, and a geriatric nurse practitioner.

Over the past five years, the hospice has embraced the concepts of palliative care. Central to their view of palliative care and mission, the hospice strives to improve the quality of care for patients and families facing life-limiting illness across the continuum of care, regardless of diagnosis, prognosis, or treatment.

During this same time period, both the academic medical center and the private hospital responded to needs within their institutions and began to consider the development of palliative care services. Of interest, their approaches were distinctly different if not frankly opposite. The private hospital quickly developed a palliative care unit, whereas the academic medical center conducted a detailed needs assessment and gradually developed a consult service. However, both engaged medical, nursing, and administrative leadership as well as the hospice to collaboratively develop these diverse approaches to meeting palliative care needs within the two institutions. Each has relied on hospice expertise and, under both circumstances, representatives have attended CAPC conferences and relied heavily on CAPC developed tools.

The Acute Palliative Care Unit (APCU) at Forsyth Medical Center (FMC)

Forsyth Medical Center has been a major supporter and referrer to the Kate B. Reynolds Hospice Home in Winston-Salem. Oncologists and hospitalists at FMC became concerned by the development of a waiting list for their patients in need of inpatient hospice referral. This led to the rapid development of the Acute Palliative Care Unit (APCU) to provide quality end-of-life care for hospitalized patients and their families. Hospital staff collaborated with hospice staff in planning, development, and implementation and attended CAPC conferences together. Tools for assessment and treatment were shared, and hospice staff continues to supply clinical expertise and medical direction.

The APCU admitted over 600 patients in 2003 and has achieved superlative results in family satisfaction, while simultaneously demonstrating significant cost savings once patients are transferred to the unit. Their data reflect a cost/day saving of over $1,800 once patients are transferred into their unit from elsewhere in the hospital. In addition, APCU is the focal point for improving end-of-life care in the hospital and provides leadership for quality initiatives surrounding pain and symptom management. In direct contrast to the academic medical center, FMC quickly developed a palliative care unit to meet the needs of patients, families, and physicians. FMC is now taking steps to formally develop a consult service to identify unmet palliative care needs for patients throughout the hospital. The APCU remains one of the major referral sources for the hospice home.

The Palliative Care Consult Service (PCCS) at Wake Forest University Baptist Medical Center (WFUBMC)

The academic medical center took a different approach to meeting palliative care needs within their institution. Not surprisingly, the approach began with a detailed needs assessment to support both the educational and clinical mission of the hospital. The

Figure 1.
Palliative Care Consults by Month at WFUBMC, July 1 - May 31, 2004 = 263 pts.

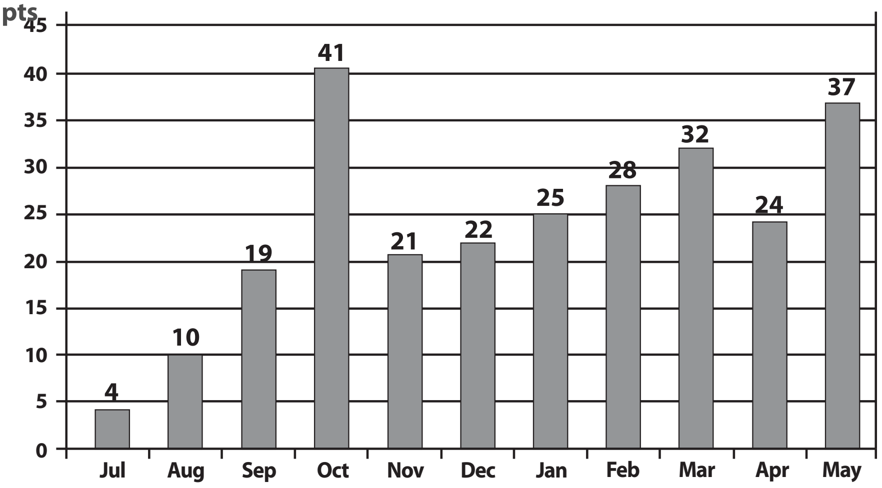

Figure 2.
Service Requesting Pallative Care Consult at WFUBMC

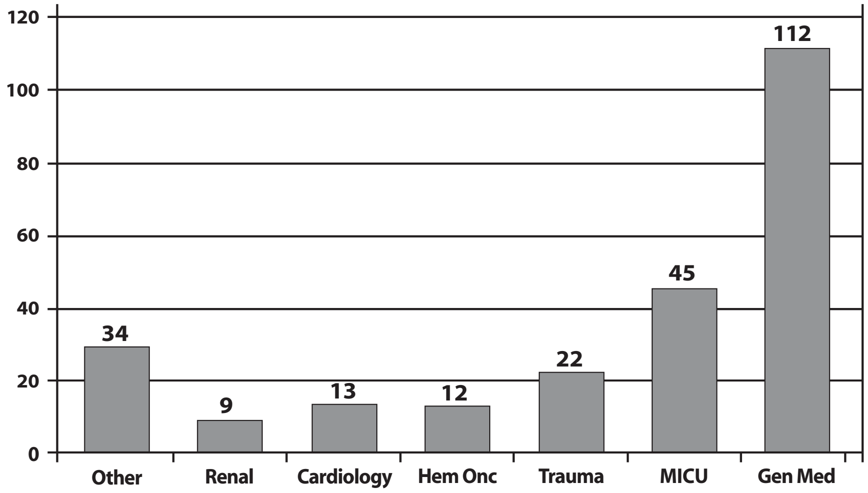

Figure 3.
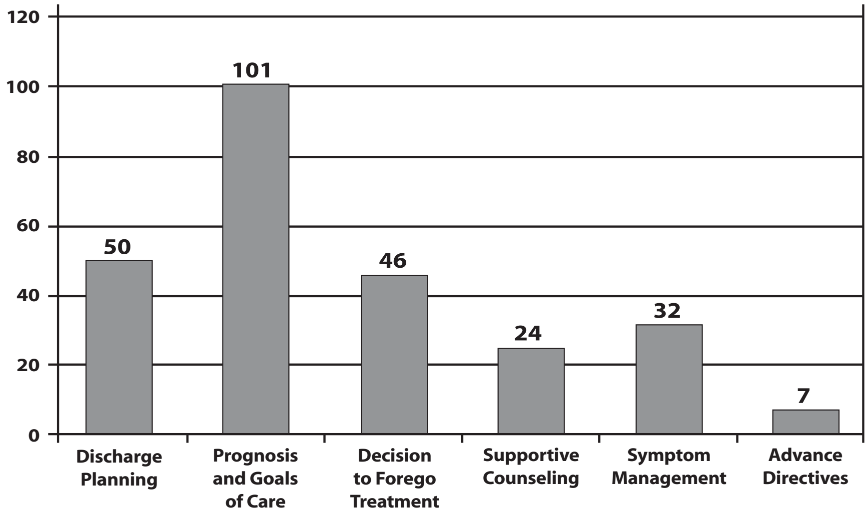
Reasons Pallative Care Consults Were Requested at WFUBMC



needs assessment relied heavily on tools developed by CAPC, and medical center and hospice staff jointly attended CAPC conferences. A palliative care consult service began with voluntary attending support from the Department of Medicine and the hospice. While needs assessment progressed and administrative support was fostered, consultation progressed slowly. Within the last year, the PCCS at WFUBMC formally began with enthusiastic administrative support, including a full-time nurse coordinator and half-time support for medical direction outsourced to the hospice. Once a "face" became associated with the PCCS, the service has grown rapidly to capacity. Plans now include hiring a second nurse coordinator and additional physician resources as well as ultimate development of a palliative care unit.

The PCCS at WFUBMC demonstrates typical growth of a consult service in an academic medical center. Figure 1 demonstrates consults by month. Figure 2 shows the wide variety of services requesting palliative care consultation. While one might expect the general medical service to be the highest, it is clear that palliative care has become a regular part of ICU care. The most common reasons consultations are requested are shown in Figure 3. Communication issues such as establishing goals of care and understanding prognosis clearly lead the way. In fact, the most common interventions of the PCCS are not changes in symptom management, but family conferences. The PCCS has also demonstrated significant cost savings for WFUBMC through decreased length of stay and decreased ICU length of stay, as well as through more appropriate resource utilization. Recently an outside reviewer suggested cost savings based on the current number and type of consults per year will be at least $1 million and are more likely to approach $2 million.

Discussion

Palliative care is clearly more than "care from a friendly relative." Palliative care has unabashedly adapted and adopted principles of care firmly rooted in the hospice movement and applied them to patients with advanced illnesses and their families. Palliative care services provide "specialized care through specific knowledge and skills, including communication with patients and family members; management of pain and other symptoms; psychosocial, spiritual, and bereavement support; and coordination of an array of medical and social services."[1]

The long list of shortcomings in end-of-life care may seem daunting. With the rapid development of palliative care services across the country, it may seem like something hospitals *should* or *must* do. Indeed, developing standards from the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) and other accrediting organizations may make it a "have to" in the near future. There is an old anonymous saying that suggests, "you can't do everything at once, but you must do something at once." As these two examples in Forsyth County demonstrate, it may not matter how you start, as long as you start.

There are individuals within every hospital and community who "want to" develop models and standards of care that could become palliative care services. It is important to find that core group of leaders and champions and start somewhere. A palliative care program will follow; the wheel need not be reinvented. It will become the standard of care and succeed in improving both end-of-life care and care for all seriously ill patients and their families. It may be wise to simply take a deep breath, a leap of faith, and follow the CAPC motto: "Just do it!" **NCMJ**

COMMENTARY

Hospital-Based Palliative Care Units:

Answering a Growing Need

Anthony N. Galanos, MA, MD

The central question confronting healthcare professionals and institutions with regard to end-of-life and palliative care is: How do we relieve the suffering that patients and families experience as they struggle to know what to do with serious and possibly terminal illness when it occurs? How do they navigate a medical system that offers few options if cure is not possible, cannot prognosticate with any certainty, and does not allow for the natural ebb and flow of uncertainty in medical decision making? It would seem that "palliative care," with its attention to caring, as well as curing, and its comfort with aggressive, as well as hospice care, is the philosophy of care that can best assist patients and families as they traverse the continuum from diagnosis through symptoms and treatment to an eventual outcome that may include hospice and bereavement.

There are two ways to look at palliative care: it can be seen as the natural extension of where aggressive, cure-oriented conventional therapy ended, i.e., what do you do for people for whom no evidence-based cure or therapy is available? Or, secondly, palliative care can be conceptualized as hospice, but much further upstream. Indeed, hospice and palliative care are not mutually exclusive. Hospice is ultimate palliative care, but is defined by a time limit and regulations surrounding a Medicare benefit. Palliative care, by contrast, can begin at the time of diagnosis, or any point thereafter, when patients and families may have already begun to suffer secondary to physical symptoms, anxiety and uncertainty, and have needs outside of the traditional biomedical model of care. The clinical events that lead people into the hospital have no predetermined outcome, and there the sorting out process must begin.

As an illustration, Morrison and Meier[1] describe the case of an 85-year-old man with class IV heart failure, hypertension, and moderate Alzheimer's disease who is admitted to the hospital after a hip fracture. This is his fourth hospitalization in the past year and his 84-year-old wife feels overwhelmed by his medical and personal care needs. The question becomes what might his doctor do to address his needs, alleviate his suffering, and facilitate discharge from the hospital and subsequent care at home? While this patient may eventually choose hospice, it is his current dilemma, blossoming in the hospital, which creates the need for palliative care services.

Indeed, when problems with end-of-life care are described, reference is often made to situations that occur in the acute care hospital setting. Concomitantly, while place of death is shifting more and more away from the hospital, it still remains the most likely site of death for North Carolinians and for Americans in general. It is important to ask why the hospital is seen in such a negative light when one has a terminal illness and why there is a need for concentrated palliative care efforts in these facilities. Aren't hospitals the very places where high-quality care at the end of life would be expected?

Why the Focus on the Hospital in Discussions of Palliative Care?

Noting that as many as 50% of patients currently die in acute care hospitals, the Acute Care Hospital Working Group, one of eight working groups convened as the National Consensus Conference on Medical Education for Care Near the End of Life, delineated a host of barriers to good end-of-life care in the acute care hospital:

- Shorter lengths of stay; hence, health professionals being trained in these settings do not see the trajectory of end-stage illnesses and fail to appreciate the needs of dying patients.
- Multitude of specialist physicians, with no one seemingly responsible for the integration of care needs in a patient-centered way.
- Emphasis on the "great case" with an accent on the disease and technical procedures at the expense of the bigger picture of the impact of the illness on the patient and family.
- Subtle messages such as death as a medical failure and that physicians should not express personal emotions, and other negative attitudes about dying.

Anthony N. Galanos, MA, MD, is Associate Professor of Medicine and Director of Clinical Palliative Care Service at Duke University Medical Center. He is also an Associate Faculty Member of the Duke Institute on Care at the End of Life and a Faculty Scholar with the Open Society Institute's Project on Death in America. He can be reached at galan001@mc.duke.edu or Box 3003 Duke University Medical Center, Durham NC 27710. Telephone: 919-660-7552.

- Lack of essential communication and symptom-control skills among supervising physicians.
- Few end-of-life educational resources available for health professionals.[2]

Why Should Hospitals Respond? And in What Ways?

Hospitals should respond because the people they serve and the people who work in them want a better response to incurable disease. Data from public opinion polls and the lay press are unequivocal. The majority of Americans (74%) expect their physicians to be confident and competent in providing them with care when they do develop a life-threatening illness.[4] The public expects that the problem of suffering has been addressed directly in medical education[5] and is not uniformly in favor of aggressive care at the expense of comfort and functional status. For example, an American Association of Retired Persons (AARP) *Modern Maturity* survey of people's attitudes about death and dying, based on 1,800 interviews of Americans 45 years of age and older found that the older you are, the less afraid you are of dying and being in pain at the end of life. In the overall sample, 71% of people believe there is a point at which costly health treatments should be stopped and the numbers were even higher among people in higher income brackets, with 77% of those who earn $50,000 or more a year agreeing that at some point aggressive treatments may do more harm than good.[6]

> *"Palliative care is not a way* out, *but a way* through, *and it allows patients to have hope and an opportunity to live as fully and functionally as they can for as long as they can. Hospitals are a place of miracles and cures, but when that can not be the outcome, we '...palliate often, and comfort always.'"*

Closer to home, the AARP North Carolina End-of-Life Care Survey[7] sampled AARP members age 50 and older and had a response rate of 45%. Of the end-of-life concerns, almost 90% say that total physical dependency would be worse than death, and 70% say that not being able to communicate their wishes or that living with great pain is worse than death. More than 90% had heard of hospice, though only a quarter were aware that Medicare pays for it. Among those who know about hospice, three-quarters reported they would want hospice support if they were dying.

In addition, the national Institute of Medicine report, *Approaching Death: Improving Care at the End of Life*,[8] and policy statements from various clinical organizations, such as the American Board of Internal Medicine and the American Geriatrics Society[9,10] have advanced the argument that the public is better informed with regard to issues pertaining to end-of-life and palliative care through community organizations such as Project Compassion in Chapel Hill, North Carolina[11] or through media such as *Time* magazine,[12] the *Wall Street Journal*,[13] ABC's *NIGHTLINE* with Ted Koppel,[14] and National Public Radio.[15] One outcome of such public discussion of death, dying, and the relief of suffering is that hospitals are now being judged by their ability to provide palliative and or hospice services.[16,17,18] Ultimately, hospitals must listen to the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), which has issued a set of standards/guidelines regarding care at the end of life:

> *"The patient at or near the end of his or her life has the right to physical and psychological comfort. The hospital provides care that optimizes the dying patient's comfort and dignity and addresses the patient's and his or her family's psychosocial and spiritual needs... and staff is educated about the unique needs of dying patients, their families and caregivers."*[19]

This last comment regarding "staff" is significant. Caregivers in the hospital need support and guidance as they care for patients for whom there is no cure. Nurses and physicians have voiced concerns over the lack of patient involvement in treatment decisions and the overuse of mechanical ventilation, dialysis, and resuscitation.[20] Our own research at a tertiary care teaching center has shown that among attending physicians, house officers, nurses, and family members, no two of these four groups saw the last week of life in the hospital in the same way, and levels of satisfaction differed among the four groups.[21] It behooves hospitals to provide better advice and support to those front-line professionals responsible for caring for the terminally ill. A palliative care team can provide the support needed for end-of-life care and aggressiveness of care.

How Should the Hospital Respond? Is the Hospital-based Palliative Care Team Part of the Answer?

In response to the 1998 American Hospital Association Survey, 30% of hospitals that responded to the survey reported having a hospital-based palliative care program with another 20% planning to establish one.[23] Palliative care programs have been based primarily in medical oncology or general medicine divisions and a consultation service was the most common clinical entity. Another report based on the same data concluded that, given the need, palliative care services were slow to be institutionalized in the hospital setting.[24] As Hanson concludes elsewhere in this issue of the *North Carolina Medical Journal*,[30] there are multiple models of palliative care services affiliated with hospitals and the process is "not yet standardized," but outcome data are now starting to build.[25,26]

The Essentials of Palliative Care

Palliative care, by definition, is an interdisciplinary team event. Depending on available resources, most palliative care teams have a nurse practitioner as the hub of the team to assure continuity of care. The nurse practitioner is backed up by an attending physician and, in some centers, a geriatric medicine or oncology fellow. It should be noted that there are roughly 43 active or emerging United States fellowships in palliative medicine and Duke University Medical Center will offer a program as of July 1, 2005.[25] Critical members of a palliative care team include a chaplain, a social worker, and rehabilitation specialists if increased function is needed for quality of life. In some cases, a psychiatrist may be needed to address issues such as depression and delirium if the team is not comfortable with the complexity of these issues at the end of life. It is not the composition of a palliative care team that is important, but rather that personnel with appropriate skills are available to meet the needs of a particular patient at a particular time in his/her continuum of care. The most important player on the team will vary by the patient and by patient need. "No man can be rendered pain free whilst he still wrestles with his faith. No man can come to terms with his God when every waking moment is taken up with pain or vomiting."[28]

Some potential roles of the clinical palliative care team include offering advice and support to the patient's caregiving team on symptom control and psychosocial and existential issues. This kind of support is clearly needed for the patient's family as well. Another role is educating hospital staff (pursuant to the JCAHO standard) and serving as a liaison between the hospital, hospice, or other facets of the continuum of care. This role would suggest that the palliative care team is present to reduce symptoms and suffering, to meet family and patient preferences, and to help negotiate goals of care. Meeting these needs should lead to improved patient and family satisfaction, as well as that of the hospital staff, while improving utilization of hospital resources, e.g., length of stay, number of intensive care unit (ICU) days, readmission rate, unnecessary emergency room use, and the timing and appropriateness of hospice referrals.

Institutions that have a designated geographic area and a defined palliative care unit have demonstrated incredible outcomes.[26] Having the designated area allows for total management of the patient, and for an atmosphere of enlightened patient-centered care. A step down from this level of care that still allows primary care of the patient, but does not entail a separate palliative care unit, is the "scatter-bed" model. In hospitals where beds may be at a premium, the "scatter-bed" model allows the palliative care team to take over the patient's primary care in the same bed that he or she was residing in at the time of initial consultation. In other words, when the palliative care consult team visits a patient in the hospital and finds that the needs of the patient can be better met by the palliative care team, then the patient will stay in that unit bed, but the primary care will be provided by the palliative care team. While it has its disadvantages, one clear advantage of the "scatter-bed" model is that multiple units in the hospital are exposed to and learn the fundamental principles of palliative care. In some arenas, primary care of patients may not be an option, so a "consult-only" service is the best mode of operation.

Whatever model of care is feasible at a particular institution, it is important not to approach the staff with an attitude of "we are here to show you how to do it, because you have been doing it poorly," but rather to provide added value to what is in place. Our experience has shown us that once nurses, chaplains, and physicians working on the unit understand the palliative care clinical team's role and purpose, they welcome our intervention and often participate with us in family meetings and discussions of care goals. While these activities clearly lead to better patient, family, and staff satisfaction, we are collecting data on cost savings to the institution. As in the example of the palliative care unit at Medical College of Virginia,[26] to collect data on patients that are matched on diagnosis and other variables, and then to compare cost and other data for those with and without palliative care intervention, can be a powerful argument to hospital administration and to those who may not be familiar with this type of care.

In essence what we have been talking about is that an either/or (cure or not) approach to medicine does not work for patients, families, and hospital staff. We can expand the options and choices of the people we serve by employing palliative care in the hospital. That way, we relieve suffering and change the

Sources Relevant to Initiating a Hospital-based Palliative Care Unit/Program

The Hospital and Healthsystem Association of Pennsylvania has expanded its Hospital-Based Palliative Care Consortium to serve hospitals nationwide and can be accessed via its website at http://www.hbpcc.org. The Center to Advance Palliative Care, a national initiative supported by The Robert Wood Johnson Foundation with direction and technical assistance provided by Mount Sinai School of Medicine, has produced an outstanding monograph: "The Case for Hospital-Based Palliative Care," that outlines the rationale for starting such a program with an emphasis on data that would appeal to hospital administrators.[22] Readers are directed to the Center to Advance Palliative Care (CAPC) website where voluminous amounts of information are available, eg, "Palliative Care in Hospitals: Making the Case," www.capcmssm.org.

focus from the hospital, to the patient and those close to him or her. It is the patient and family who have come to the hospital for answers to their conundrum. In response, the hospital-based palliative care team does not emphasize what will be taken away, but what will be done *for* the patient and family despite a life threatening illness. Palliative care is not a way *out*, but a way *through*, and it allows patients to have hope and an opportunity to live as fully and functionally as they can for as long as they can. Hospitals are a place of miracles and cures, but when that can not be the outcome, we "...palliate often, and comfort always."[29] **NCMJ**

COMMENTARY

A Brief Review of North Carolina's Law on Dying[1]

Anne Dellinger, JD, and Aimee Wall, JD, MPH[1]

Ten years after Oregon voters first approved the "Death with Dignity Act,"[2] contentious debate continues throughout the country regarding the legal and ethical issues surrounding end-of-life care, particularly on the issue of assisted suicide.[3] Just last year, the North Carolina General Assembly considered legislation proposing to criminalize assisted suicide.[4] The bill did not pass, but the issue is likely to arise in future legislative sessions. In considering how North Carolina should approach end-of-life issues, it is useful to review our state's current law and policy regarding life-sustaining treatment, euthanasia, suicide, assisted suicide, and pain relief. The summaries below are not intended to be comprehensive, but rather provide a basic overview of the legal environment surrounding each of these important issues.[5]

Life-Sustaining Treatment

Refusal, withholding, and withdrawal of life-sustaining treatment all are legal choices under federal and state law. A patient has long had the ability to express his or her wishes regarding life-sustaining treatment orally or in the form of a written document often referred to as an "advance directive" or "living will." Refusal of life-sustaining treatment and advance directives are governed primarily by state law, but the federal government has weighed in on a few important points. While not directly stating it, the United States Supreme Court seems to acknowledge that competent people have a constitutional right to refuse medical treatment.[6] Also, Congress recognized the concept of advance directives in 1991 when it enacted the Patient Self-Determination Act.[7] The law requires health facilities, as a condition of Medicare or Medicaid participation, to ask every patient about advance directives and to explain the options available under state law for creating them. The law does not require providers to comply with advance directives, but they must at least initiate conversations with patients about their wishes.

North Carolina's history of recognizing patient autonomy in end-of-life decisions goes back even further. The state enacted the Right to Natural Death Act[8] in 1978, not so much to create new rights related to advance directives as to recognize existing ones.[9] The law includes a form by which a person may express his or her preferences regarding extraordinary medical interventions, including artificial nutrition and hydration.[10] State law also permits residents to name an agent to make those decisions on their behalf in certain circumstances.[11] In 2001, the state enacted two laws related to patient autonomy. The first is a law that shields providers from liability if they withhold cardiopulmonary resuscitation from a person having a "portable do-not-resuscitate order" on a form developed or approved by the state.[12] The second is a law establishing a voluntary state registry for advance healthcare directives.[13]

Whether North Carolina doctors and hospitals or other facilities must carry out a patient's stated wishes is not settled. Some states require this by statute, subjecting noncompliant providers to criminal or civil penalties and/or professional disciplinary actions.[14] A North Carolina attorney general's opinion advises that a physician or a facility need not follow a patient's wishes or transfer the patient to caretakers who will. But the opinion also says that providers may be civilly liable for assault and battery if they force treatment on a patient.[15] The North Carolina Medical Board, on the other hand, states that "physicians are ethically obligated to follow the wishes of the terminally ill or incurable patient as expressed by and properly documented in a declaration of desire for a natural death" or transfer the patient to another physician's care.[16] Based on this statement, a physician could be subject to disciplinary action if he or she refuses to follow the patient's wishes and fails to transfer the patient.

Euthanasia

"Euthanasia" may be defined as "the intentional putting to death of a person with an incurable or painful disease intended as an act of mercy."[17] This act very likely is murder under North Carolina law. North Carolina's highest court has dealt very harshly with "mercy killing." For shooting his father in a

hospital bed, a man was convicted of first-degree murder and received a mandatory life sentence, which was upheld on appeal. At trial the judge told the jury that they could infer malice[18] (though they did not have to do so) from the defendant's use of a deadly weapon, and further instructed that the defendant's knowing that his father was at the brink of death was not a defense (though they could consider that knowledge). Both instructions were challenged on appeal. The Supreme Court upheld them, but not unanimously. The chief justice urged a lesser sentence than that for first-degree murder because the son's intentions were good.[11]

Personally administering lethal medication to a patient could be first-degree murder, either as "murder by poison" or simply as deliberate and premeditated killing. Like the man who shot his father, a doctor or a nurse would likely not escape punishment because she or he meant to help the patient—not even if the patient had asked for death.

Suicide

"Suicide" is "the act or an instance of taking one's own life voluntarily and intentionally."[19] It is surprising how recently suicide and suicide attempts were crimes in this state. In fact, North Carolina was the last of the states to prosecute an attempt at suicide. In 1961 the state Supreme Court found the act criminal,[20] as it had been for centuries under the common law of England and was later in the American colonies and states. Because suicide was a crime, helping someone carry it out was as well.[21] In 1973 the North Carolina General Assembly abolished the crime of committing suicide and thereby, implicitly, the crime of attempting suicide. The status of providers' acts assisting patients to commit suicide is more complicated.

Assisted Suicide

A leading treatise on death and dying discusses at length what "assisted suicide" means and how it differs from euthanasia and homicide (if it does).[22] Much of the public and a significant minority of physicians do not distinguish meaningfully between assisted suicide and euthanasia.[23] Most people, however, continue to draw a moral distinction between responding affirmatively to "Help me kill myself" and responding affirmatively to "Kill me."[24] How to treat the two acts, and what constitutes each, are problems for all interested parties [patients, health providers, courts, district attorneys, health licensing boards, legislatures, the United States attorney general, and the Drug Enforcement Agency (DEA)]. For present purposes, though, a loose definition of "assisted suicide" may be helpful: it can be thought of as the act of providing a competent person with the means to take his or her own life.

In general, assisting someone in committing suicide is legal. That is, an ordinary person who hands a knife to a desperate stranger or holds a ladder for that person to reach a window ledge should have no legal problem. The situation can be more complicated if there is a special, legally recognized relationship between the helper and the person wanting to die. In certain relationships—such as parent and minor child or doctor and patient—one party is legally obligated to protect the other to some extent.[25] Based on the current state of the law, we simply do not know whether or when a healthcare provider in North Carolina will be seen as failing to protect a patient if she or he helps the patient die. In other words, we do not know whether a provider's decision to help a patient die will subject the provider to civil or criminal liability.

> *"Pain management is probably the most important of the end-of-life issues because of the effect of pain on dying people and the fear it engenders in nearly everyone who contemplates dying in the United States today."*

The means of assistance most often discussed is providing medication for a patient to administer to herself or himself.[26] As discussed above, Oregon law now authorizes a physician to prescribe a lethal dose of medication for a person suffering from a terminal disease if the person requests the prescription and certain other requirements are met.[27] This law came under attack recently when United States Attorney General John Ashcroft issued a directive explaining that assisting a person to commit suicide does not qualify as a "legitimate medical purpose" under the Controlled Substances Act (CSA) and therefore a physician who prescribes, dispenses, or administers a controlled substance for such a purpose would be in violation of federal law.[28] The attorney general directed the DEA to enforce the CSA in Oregon despite the existence of the state law authorizing such prescriptions. In May of this year, however, a federal court of appeals invalidated the attorney general's directive on the grounds that Congress did not provide him with the authority to make such an expansive interpretation of the CSA.[29]

While it appears (for the time being) that terminally ill Oregon residents may be allowed to request physician assistance for suicide, many other states have expressly prohibited providers from providing such assistance.[30] The United States Supreme Court has upheld such prohibitions in two states, finding in both cases that the state laws did not infringe upon constitutional rights.[31] It is not clear, however, how North Carolina courts would interpret and apply this state's law in such a situation. No law expressly prohibits assisted suicide, as was proposed this past legislative session. In laws governing living wills, however, the North Carolina General Assembly declared that the state does not "authorize any affirmative or deliberate act or omission to end life other than to permit the natural process of dying."[32] The state courts have not been called upon to review this statement, but it may be possible to infer from the language that suicide assistance by a healthcare provider is illegal in this state.

It is also possible that a physician or pharmacist providing medication to assist a suicide could be found in violation of the state's controlled substances law. Like the federal CSA, the state law provides that a prescription must be for a "legitimate medical purpose."[33] While the recent federal court of appeals decision invalidated Attorney General Ashcroft's interpretation of that language, it did not place any limits on the states' ability to interpret and apply the same or similar language in their own laws. The North Carolina Department of Justice has not released a formal opinion on this issue.

Based on the policies, position statements, and resolutions adopted by many national and state professional organizations, it appears that many members of the medical profession in this country object to the principle of assisting a person in committing suicide.[34] While these policies do not have the force of law, they are likely to be persuasive to healthcare professionals in states, such as North Carolina, where clear legal guidance is lacking. In some instances, such policies could form the basis for disciplinary action by licensing boards.

Pain Management

Pain management is probably the most important of the end-of-life issues because of the effect of pain on dying people and the fear it engenders in nearly everyone who contemplates dying in the United States today. Despite efforts from several directions to clarify the legality of giving pain-relieving medication that may shorten life or even kill, the matter is not yet clear enough.[35] Health professionals know that a number of drugs may depress breathing, especially opioids (derivatives of opium or similar, synthetic narcotics), which are among the most effective painkillers. They also know that relieving pain is among the highest goals of their professions, that United States medicine has been widely criticized by its practitioners and others for failing in that regard,[36] and that a major malpractice suit for failure to relieve pain succeeded in North Carolina. In that case a Hertford County jury returned a verdict of $15 million against Hillhaven Corporation for a nursing home's refusal to administer pain medication ordered by a physician for a man dying of cancer.[37]

There is clear support for pain management at the federal level. Federal law encourages the use of controlled substances to relieve pain, even if doing so jeopardizes the patient's life. The law requires doctors who prescribe medication for purposes of treating a drug addict to register with the DEA,[38] but regulations state that the act is not meant to limit a physician who prescribes opioids for intractable pain when no relief or cure is possible or has been found after reasonable effort.[39] In his 2001 directive, Attorney General Ashcroft reiterated the distinction between assisted suicide and "providing sufficient dosages of pain medication necessary to eliminate or alleviate pain."[40] National professional organizations, such as the American Medical Association and the American Nurses Association, also support and encourage active management of pain in dying patients.[41]

At the state level, the scope and type of legal guidance related to pain management varies. Many states expressly approve the use of pain-relieving medication, even though it may shorten life.[42] Some states do this by amending their controlled substances laws while others enact freestanding statutes. North Carolina has done neither. In the absence of state law on the issue, providers may rely on guidance from their licensing boards. In the fall of 1999, North Carolina's Boards of Nursing, Pharmacy, and Medicine issued a joint statement on pain management in end-of-life care. The statement identified issues of concern to members of the three professions. Of particular interest is the section of the statement directed toward physicians. It expressly provides that:

> "Opioid use... is appropriate if the responsible physician is familiar with and abides by acceptable medical guidelines regarding such use, is knowledgeable about effective and compassionate pain relief, and maintains an appropriate medical record that details a pain management plan. Because the Board is aware of the inherent risks associated with effective pain relief in such situations, it will not interpret their occurrence as subject to discipline by the Board."[43]

The Medical Board also adopted two other statements discussing opioid use for the management of pain; one applies to pain during end-of-life care[44] and the other applies to chronic non-malignant pain.[45] The Board took care to assure physicians that they will not be disciplined for pain management, saying "no physician need fear reprisals from the Board for appropriately prescribing...even large amounts of controlled substances indefinitely for chronic non-malignant pain."

Even in the absence of state statutes or regulations on the issue, these strongly worded position statements from professional licensing boards should go a long way toward encouraging healthcare providers in North Carolina to provide adequate pain relief in end-of-life care. Without further action by the North Carolina General Assembly, though, providers (and their attorneys) will likely continue to be concerned about potential liability under the state controlled substances law and basic tort law.

Conclusion

North Carolina is clear on a few issues related to end-of-life care: an individual has the right to refuse life-sustaining treatment; euthanasia (or "mercy killing") would likely be considered murder; and suicide is not a crime. The law related to two of the most controversial issues—assisted suicide and pain management—is less clear. Healthcare providers, patients, advocates, and policymakers interested in continuing to develop the state's legal landscape related to end-of-life care have a tremendous opportunity to provide guidance and clarity in these essential components of patient care. **NCMJ**

North Carolina Voluntary State Registry of Advance Healthcare Directives

In 2001, the North Carolina General Assembly passed legislation authorizing the NC Secretary of State to create a voluntary on-line registry of advance healthcare directives for the benefit of the citizens of the state and their healthcare providers under circumstances where immediate access to such directives would be needed. Citizens wishing to register their notarized directives may place three types of healthcare directives and an organ donor card on the Internet web site maintained by the Office of the Secretary of State at the following Internet location:

http://www.secretary.state.nc.us/ahcdr/

Those wishing to take advantage of this service by filing their information by mail may get information to facilitate their registration by calling 1-919-807-2000. Forms are provided for:

- Health Care Power of Attorney
- Declaration of Desire for Natural Death (Living Will)
- Advance Instruction for Mental Health Treatment
- Organ Donor Card

COMMENTARY

Spiritual Care at the End of Life:
What Is It and Who Does It?

Keith G. Meador, MD, ThM, MPH

The inclusion of "spirituality" in medical practice and research has become increasingly commonplace in recent years. Although clarity as to exactly what is meant by this term continues to be elusive, acceptance of its significance in the care of patients has increased as we continue to gain a better understanding of its role and develop related standards of practice. End-of-life care has incorporated some consideration of spiritual care since the advent of the modern hospice movement within the vision of Dame Cicely Saunders in England approximately 40 years ago.[1] Her vision of a community of caring that would attend to the spiritual needs of dying patients, along with addressing their pain management and other medical needs in a more humane fashion, was the foundation for the modern hospice movement. Although much of current end-of-life care has evolved from the challenge extended by Saunders regarding appropriate care of the dying, her commitment to meeting the spiritual needs of dying patients continues to be a challenge for healthcare providers.

These challenges grow out of a number of exacerbating factors concerning the diverse understandings of spirituality in a culturally pluralistic society, as well as the complexities of contemporary healthcare delivery systems. While recent evidence[2] indicates that both patients and their families consider spiritual care to be important in end-of-life care, the understanding of what this means varies considerably. The breadth of expectations expressed by this desire for spiritual care is expansive. It can include the spectrum from some sense of an emotionally sensitive care of the "human spirit" to a highly ritualized religious care incorporating very specific rites for the dying and a multitude of possibilities in between. Even those healthcare providers most sensitive to the inclusion of spiritual care at the end of life may be daunted by the thought of engaging such a fluid and somewhat nebulous expression of need.

Dr. Hanson's description of palliative care and its significance as a practice of medicine in the lead article of this issue[3] lays the groundwork for our considering the role of spiritual care at the end of life. Two primary aspects of palliative care are (1) an understanding of the virtue of caring (in contradistinction to curing) as a practice of medicine and (2) an appreciation of the art of listening well in the care of patients. Both of these resonate with the provision of spiritual care to the dying, and their central roles in palliative care speak to the potential for palliative medicine to remind all of us of the importance of listening and caring as essential aspects of practice throughout all of medicine, not just with the dying. The resolution of who can best provide intentional listening, as well as interpret the stories and struggle faced by those considering their mortality while reviewing their lives for a sense of purpose and closure, is not the same for every person. Those who render such care must examine themselves regarding their capacities and willingness to engage the rich and textured complexities of those for whom there are no illusions of cure, but who none the less need their undivided attention at the junction of life and death. The development of the skills and capacity to do such work has not been a standard part of medical education in the past and we, as well as our patients, have suffered for this inadequacy. Arthur Frank comments in *The Wounded Storyteller* that, "One of our most difficult duties as human beings is to listen to the voices of those who suffer."[4] I fear that we do not adequately equip ourselves as physicians and other healthcare providers to fulfill this "duty" and all that it entails.

Voices of suffering—especially the voices of those who know they are dying and their families—become poignantly focused. Along with asking challenging questions regarding prognosis and other "medical" inquiries, they become seekers and purveyors of "spiritual" understanding and wisdom. The language used for such communication will frequently be very specific to a particular cultural or religious tradition. While considerable strides are being made in improving communication skills for physicians in the care of the dying, lack of familiarity with such tradition—specific language and metaphors through which a dying person expresses her "soul"—can limit the capacity of the physician or other provider to listen well. This lack of familiarity is not a fault in the provider, but acknowledgement of this lack and seeking the assistance of someone more versed in the tradition of the dying patient can be crucial for providing

---

Keith G. Meador, MD, ThM, MPH, is Professor of the Practice of Pastoral Theology and Medicine at the Duke Institute on Care at the End of Life at the Duke Divinity School and Clinical Professor of Psychiatry and Behavioral Sciences at Duke University Medical Center. He can be reached at Keith.Meador@duke.edu or Box 90967, Duke Divinity School, Durham, NC 27708. Telephone: 919-660-3488.

meaningful spiritual care. Awareness of one's lack of familiarity with the religious or cultural tradition and language of a patient may not be readily evident, and patients may be hesitant to point out such gaps of understanding. Only through our attentiveness to the patient's story and the humility to discern our own inadequacies will we best serve the communication needs central to providing optimal spiritual care for dying patients.

The best spiritual care for the dying patient is most likely to be delivered in the same way other types of care are best provided, through partnerships within the team of persons caring for the patient. Although much of medicine is best practiced within a context of teamwork, palliative care particularly denotes a team approach,[5] and vital to a palliative care team is the clergy member of the team or the chaplain. While many physicians, nurses, and social workers have substantial gifts to offer to the spiritual care of patients, the role of a clergy member on the team to give leadership in providing spiritual care cannot be overstated. The other providers on the team may have a greater appreciation of the particular faith tradition of a patient and may serve as the more trusted spiritual confidant and care provider, but the clergy member of the team brings an interpretive, liturgical, and communal sense of spiritual care from her or his pastoral formation unique to that vocational formation. The optimally-trained and wise chaplain provides pastoral services within the entire community surrounding the dying patient and fosters a sense of care for one another that acknowledges the interdependency of the providers, the family, and the dying person in this work of living and dying.

> *"Palliative care informed by spiritual attentiveness allows both the patient and the provider to give up illusions of therapeutic entitlement to cure and at the same time honor the privilege of intentional and reverent caring for the dying."*

We healthcare providers rarely fully attend to the role of this interdependency in forming the health of the community, which ultimately determines how we care for the suffering and dying among us. Wendell Berry provides insight into the shared communal underpinnings of spiritual and palliative care when he says, "Health is not just the sense of completeness in ourselves but also is the sense of belonging to others and to our place; it is an unconscious awareness of community, of having in common."[6] Mindfulness of our interdependence allows us to be less captive to consumerist expectations and their distortion of caring relationships, while nurturing a greater sense of gratitude within an awareness of the limitations and finitude of healthcare. Palliative care informed by spiritual attentiveness allows both the patient and the provider to give up illusions of therapeutic entitlement to cure and at the same time honor the privilege of intentional and reverent caring for the dying.

Good spiritual care is not just calling the chaplain for last rites or prayer with the bereaved family near the time of death. Although these are both valued and legitimate aspects of spiritual care, they fall short of the vision for spiritual care indicated by a comprehensive strategy for palliative care. Spiritual care should inform the practice of palliative care throughout the course of treatment.

There is no substitute for time to do the work of a "good death." While the interpretation of a good death may vary by tradition and culture, most consider the opportunity for a good death to include adequate pain management and the time to make peace with one's neighbor and with God while supported emotionally by family or friends. Adequate spiritual care helps provide the context for such a death for the dying person with an attentiveness to that individual's particular needs. Spiritual care as part of a comprehensive strategy for palliative care provides the opportunity and support to narrate one's story in such a way as to provide a legacy and memory of a "good death" for the family and broader community. The spiritual legacy of such a narrative can be a gift for generations to come and reframes the inevitable experience of loss within death as a reminder of the gift of the life that has been lived.

The importance and value of well-trained clergy as partners in providing the hope of a "good death" and its legacy is evident, but the lack of availability of such persons is all too common. Recent collaborative efforts between the Pastoral Services Department at Duke University Medical Center and the Duke Institute on Care at the End of Life to train specialist chaplains in end-of-life care are an attempt to address this issue. While the equipping of more specialized chaplains for tertiary care centers is helpful, the large numbers of persons dying in smaller hospitals without staff chaplains require our consideration. If we are convinced of the value of spiritual care as a part of palliative care and believe clergy to be important in the rendering of that care, we are challenged to consider how to best address this void of spiritual care providers in smaller hospitals and communities. The Caring Communities Program of Duke Divinity School and The Duke Endowment provides one response to this need in the Pastoral Care in Community program, which offers a curriculum certifying local clergy as Pastoral Care Specialists and equipping them to serve as volunteer chaplains in local hospitals. Although most of these clergy have visited regularly in the hospitals in the past, they are now receiving education in order to more ably partner with healthcare providers as part of palliative care teams in the provision of spiritual care to suffering and dying patients.

Spiritual care is still finding its place as a practice in healthcare.

Standards of practice for spiritual care have not been developed and we are still unsure as to just who should be engaging in its practice. Spiritual care has been part of end-of-life care since the start of the modern hospice movement, but it continues to evolve in content and form in response to increasingly pluralistic societies in the United States and western Europe. Providing spiritual care with integrity to the faith tradition of the dying patient can be challenging, but such care cannot be viewed as an optional luxury within the developing discipline of palliative care. The substantive shared commitments of good spiritual care and palliative care bear witness to spiritual care being inherently constitutive of palliative medicine rightly construed. Support for intentional spiritual care as an integral part of quality end-of-life care should come from many quarters, but support and commitment to spiritual care's place in palliative care at the end of life *must* come from physicians and administrative leaders in palliative care. The health of us all depends on it. **NCMJ**

COMMENTARY

Opioids in End-of-Life Care:
Promises and Problems

Richard C. Stephenson, MD

Introduction

On the surface, it would seem that appropriate utilization of opioid analgesics to relieve suffering at the end of life is a "no-brainer." Concerns about addiction, diversion, tolerance, and other side effects might impede the use of these powerful medications in chronic nonmalignant pain, but certainly terminal pain and suffering must override these concerns. Tragically, nothing could be further from the truth.

For years, the American Alliance of State Cancer Pain Initiatives has presented convincing data showing that the undertreatment of cancer pain at the end of life is a public health crisis.[1] What an interesting and descriptive phrase, "public health crisis!" Why not tragedy, shame, or outrage? A public health crisis implies the scope of the problem is huge, that it is of concern to us all, and that effective preventive therapies and treatment strategies are available, but are simply not being utilized.

A quick look at the numbers is alarming. More than half a million people will die of cancer each year in this country. About two thirds of patients with advanced cancer have significant pain. Numerous studies confirm that almost half of these patients have unrelieved pain. Clearly these numbers are of public health crisis proportions. But even more poignantly, most experts in pain management would quickly agree that more than 95% cancer pains could be effectively treated with the right medication at the right dose at the right time.

Unfortunately it isn't just cancer pain at the end of life that is under-treated. The well-known and often quoted Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments, SUPPORT, clearly showed that more than half of very sick hospitalized patients were in serious pain during their final days.[2] Unrelieved pain is incapacitating—interfering with the ability to eat, sleep, interact with others, and achieve a satisfactory quality of life.[3] Nothing could be more diametrically opposed to our fundamental promise as physicians, to cure sometimes and to relieve suffering always.

How can we all do a better job and keep the promise? It seems simple enough. Terminally ill patients present with complaints of severe pain and healthcare providers respond by diagnosing and treating with appropriate analgesic medication. So simple that hospice, palliative care programs, and others have applied a set of ABC's to pain management at the end of life (See Table 1). Perhaps thorough reflection on this "simple" process will demonstrate both the barriers and potential solutions to adequate pain relief at the end of life.

Table 1.
ABC's of Pain Management

ASK	about pain regularly; ASSESS systematically.
BELIEVE	the patient and family in their reports of pain and what relieves it.
CHOOSE	pain control options appropriate for the patient, family, and setting.
DELIVER	interventions in a timely, logical, and coordinated fashion.
EMPOWER	patients and their families; ENABLE them to control their course to the greatest extent possible.

Ask and Assess

All too often it seems we fail to ask patients with serious illness about pain. Paradoxically, healthcare providers are expecting patients to complain, while patients are waiting for their provider to ask.[4] A long list of potential reasons cancer patients may not complain about increasing pain can be easily generated. Pain may well have sinister implications, including spread of disease, failure of therapy, lack of further therapies, and imminent death. Pain may interfere with the doctor-patient relationship. Patients in pain may feel burdensome to their doctor if they complain of pain not adequately managed, even fear their pain may distract physicians from the business of curing their cancer.

Richard C. Stephenson, MD, is the Medical Director for the Hospice and Palliative CareCenter in Winston-Salem, NC and for the Palliative Care Consult Service at Wake Forest University Baptist Medical Center. He is also an Asstistant Clinical Professor of Medicine at Wake Forest University School of Medicine. Dr. Stephenson can be reached at Dick.Stephenson@hospicecarecenter.org or 1100C S. Stratford Road, Winston-Salem, NC 27103-3212. Telephone: 336-768-3972.

After all, patients fundamentally like and respect their doctors and want the same in return. They may not want to be considered weak, whiney, drug-seeking, ungrateful, or even a therapeutic failure to their physician.

Physicians share some of these same concerns that lead to a failure to ask. In addition, pain evaluation and management are not well taught in most medical schools and residency programs. One recent survey reported the average amount of time spent on teaching pain management in American medical schools is one hour; with just four hours for nurses.[5] Failure to ask may also reflect insecurity about what to do with poorly controlled pain and fears of regulatory scrutiny when prescribing controlled substances. Weber and Huber showed that oncologists in a busy clinic setting documented pain severity and opioid dose only 25% of the time in patients known to have significant pain (see Table 2).[6]

Table 2.
Documentation of Severe Pain, Opioid Doses, and Opioid-related Side Effects *adapted from Weber and Huber*[6]

Finding	Frequency Documented
Pain Severity	24.6%
Opioid Dose	26.9
"Rescue" Dose	4.8
Bowel movements	1.6
Laxative Rx	4.2

Asking is a great place to start, but a more formal pain assessment and regular utilization of a pain assessment tool have been shown to improve pain management. While one might argue that various tools are too long, complicated, time-consuming, or subjective, studies repeatedly show that choosing and consistently using one is far better than using none.[7] Most pain scales and tools are actually quite simple, often done by the patient, and easy to incorporate into regular visits. Even patients with mild-to-moderate dementia can respond to at least one of these simple tools.[8] The simplest of tools are scales. The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) now "recommends" the regular use of pain scales to assess pain severity and relief. The two most common scales are either verbal (none, mild, moderate, severe, or excruciating) or numerical (0-10 where 0 indicates no pain and 10 the worst pain you can imagine).[9]

> *"Unrelieved pain is incapacitating—interfering with the ability to eat, sleep, interact with others, and achieve a satisfactory quality of life."*

In some settings and with some patients, particularly at initial assessment, more detailed tools like the two listed below are helpful. Neither of these tools is new and both have been validated in a variety of settings and many different countries. Many more are available and their use is encouraged.

The Memorial Pain Assessment Card (MPAC)

The MPAC[10] uses a 10-cm Visual Analogue Scale to rate not only pain but also relief and mood. A Visual Analogue Scale (VAS) is a simple 10cm line labeled 0 (none) at one end and 10 (severe) at the other. The patient marks the point on the scale that best indicates the severity of the symptom. A VAS can be used to assess any symptom including pain, nausea, dyspnea, anxiety, depression etc. The patient's response to the card also indicates global symptom distress.

The Wisconsin Brief Pain Inventory (BPI)

The BPI[11] comes in both a long and short form. The long form lends itself to initial pain assessment and the short form to follow-up. Both forms establish pain at its recent worst, least, average, and now using a 0-10 scale. They provide descriptive language about the quality of the pain as well as a body diagram to locate and separate pains. The BPI also asks patients to grade their overall pain relief efforts and quantify interference with mood, sleep, and relationships.

One element that has received recent media attention is incorporating pain as the "fifth vital sign." In reality, this may become the standard of care. The United States Department of Veterans Affairs (VA) has initiated an ambitious program to include pain as the fifth vital sign in not only all of its medical facilities, but all patient encounters. A positive pain score then triggers further assessment, prompt intervention, and follow-up evaluation.[12]

Believe

Patients and their families often note that no one seems to believe in their complaint of pain. Physicians are often stuck in a medical model of care that demands a specific diagnosis before treatment. Treatment may be delayed until proof is found by diagnostic testing or even further delayed if our tests fail to confirm a clear etiology of the pain, e.g., a positive bone scan. Hospice nurses often express considerable frustration that patients with diseases like lung cancer, at high risk for painful metastases, often do not receive adequate pain medications until testing proves the existence of disease spread. With proof in hand, most physicians are then more than willing to prescribe whatever is necessary.

It is abundantly clear that many physicians are very concerned about prescribing opioid medication without "proof" of definitive disease. It is appropriate to be concerned; there are patients trying to scam us. Diversion, abuse, and misuse happen, but fears and concerns about these possibilities should not prevent appropriate prescription of pain medications for patients who need them. This is easy enough to say, but with all the media attention and legal activity surrounding opioid diversion and misuse, fear of regulatory scrutiny, and even legal prosecution, often thwarts adequate pain management.

Few physicians will forget the picture of a Florida physician that appeared in papers all across the country with the caption, "Doctor is sentenced in Oxycontin deaths." Careful review of the article clearly showed that this was a "dishonest doctor" dispensing oxycontin for profit. Unfortunately few people get beyond the headlines. Within just the last year, an equally alarming legal advertisement appeared in the *Winston-Salem Journal* that read, "OXYCONTIN: If you have been prescribed Oxycontin for more than six (6) months for something other than cancer, call...(telephone number)...Prescription users only."

It is precisely for these reasons that the Drug Enforcement Administration (DEA) and 21 health organizations felt compelled to issue a Joint Statement Promoting Pain Relief and Preventing Abuse of Pain Medications: A Critical Balancing Act (see page 234).[13] This joint statement clearly reassures us that,

> *"Preventing drug abuse is an important societal goal, but there is consensus, by law enforcement agencies, healthcare practitioners, and patient advocates alike, that it should not hinder patients' ability to receive the care they need and deserve."*

This consensus agreement goes on to enumerate the following facts.

- Undertreatment of pain is a serious problem in this country.
- For many patients opioid analgesics are the most effective and often the only treatment that provides significant relief.
- Opioids are controlled substances and necessarily regulated.
- Drug abusers obtain these medications by diversion.
- Abuse is a serious problem, but focusing only on abuse could erroneously lead to the conclusion that these medicines should be avoided when indicated—generating a sense of fear rather than respect for their legitimate properties.
- Awareness of both use and abuse will enable all of us to make proper and wise decisions regarding the treatment of pain."[13]

Similarly, state medical boards have issued statements to reassure healthcare professionals that they need not fear sanctions for adequate symptom management of seriously ill patients. In fact, just the opposite is true; physicians have been sanctioned for *undertreatment* of pain at the end of life. The North Carolina Boards of Medicine, Nursing, and Pharmacy issued a Joint Statement on Pain Management in End-of-Life Care, adopted on October 21, 1999 that serves as a model for other states.[14] This statement in part reads,

> *"The Medical Board will assume opioid use in such patients is appropriate if the responsible physician is familiar with and abides by acceptable medical guidelines regarding such use, is knowledgeable about effective and compassionate pain relief, and maintains an appropriate medical record that details a pain management plan."*

The physician's fiduciary responsibility to treat pain at the end-of-life is abundantly clear. These statements serve as excellent guidelines to proceed with effective pain management. As long as physicians carefully follow the tenets of appropriate prescribing within an established doctor/patient relationship, we needn't fear regulatory or legal consequences.

Choose

A pain specialist once shared that effective pain management at the end of life was really quite simple. It comes down to using aspirin and/or opioids. There are a myriad of other potential interventions available including adjuvant medication, surgery, radiation, chemotherapy, central nervous system anesthesia, and even complementary modalities. For the vast majority of patients, pharmacologic therapy with aspirin and/or opioids will do the job. Of course aspirin means the broader class of nonsteroidal anti-inflammatory drugs (NSAIDS). And opioids means a thorough understanding of a number of appropriate opioids used at the right dose, in the right dosing form, at the right time, and by the right route. While NSAIDS have a role in pain management at the end of life, for the large numbers of patients with moderate-to-severe pain, opioids are the mainstay of pharmacologic therapy.

There is little doubt that the most important barriers to effective pain management at the end of life are poor assessment and inadequate utilization of opioid medication.[3] "Inadequate utilization" does not assign blame, but refers to a major problem with education and attitude about opioid medications. This is not just a patient or physician problem, it is everyone's problem —nurse, pharmacist, family, friend, pastor, or volunteer. We all share inadequate education and inappropriate attitudes about opioid medication.

Pain and palliative care specialists speak frequently about morphine myths. These are generally held ideas about opioids that have grown to mythic proportion without much substantial proof as to their existence. These misconceptions interfere with the appropriate utilization of opioids and include undue concerns about addiction, tolerance, and uncontrollable side effects like euphoria, vomiting, constipation, sedation and respiratory depression. Numerous studies have shown that the more firmly held the myth, the more noncompliant the patient will be with their pain regimen.[15] Patients who fear addiction resulting from simply utilizing opioids are unlikely to take them as prescribed. Likewise patients who are afraid that tolerance will develop if they start taking opioids early in the course of their disease, rather than "saving" them for when their pain gets "really bad," are unlikely to take medication appropriately. Healthcare providers must assume that these issues are on the minds of most patients as they write an initial prescription for an opioid medication and ensure appropriate education to explore and dispel the myths.

Perhaps more surprising is how these same myths affect physician attitudes about pain and opioids. A remarkable study done here in North Carolina[16] confirmed the findings of others and demonstrated widespread misconceptions among physicians about pain and opioid medications. In one study,[17] 51% of physicians felt that tolerance to opioids was a significant problem and limited their ability to control pain. Most experts would agree that most of the time tolerance is not a clinical issue. Increasing pain means an increase in cancer-related disease processes and can be relieved by increasing opioid doses and/or other measures. On the other hand, 39% of physicians felt that intolerance to adverse effects of opioids made it difficult to control pain. Interestingly, most patients become tolerant of common side effects of opioids (except for constipation), but not to their analgesic effects. An alarming 20% of these physicians felt addiction was a problem for cancer patients treated with opioids and 19% felt poorly controlled pain was inevitable in advanced cancer.

While a detailed review of specific pharmacologic treatment strategies and recommendations is beyond the scope of this article, many monographs and guidelines are readily available. The American Pain Society has recently published the fifth edition of a remarkable pocket-sized set of guidelines for both acute and cancer pain,[18] which can be ordered at http://www.ampainsoc.org/pub/principle.htm. The American Academy of Hospice and Palliative Medicine also publishes a pocket guide to palliative care with up-to-date recommendations covering both pain and a wide range of other end-of-life care issues.[19] The American Geriatrics Society has recently reissued guidelines for pain management in older persons.[20] All of these resources are clear that opioids may well be both the safest and most effective treatment strategy for persons with serious pain at the end of life. All physicians should be familiar with basic opioid pharmacology, dosing strategies, and the role of common adjuvant medications. In addition, physicians must be knowledgeable about resources and pain consultants available in their communities when pain becomes difficult to control.

> *"Indeed, methadone is probably the ideal opioid in end-of-life care."*

Unfortunately, in a distinct minority of patients, pain isn't nearly as difficult to control as the patient and/or their family. Some patients abuse their opioids, and some families divert patients' medications. Physicians must be thoughtful, careful practitioners willing to confront these possibilities and engage the assistance of specialists who commonly deal with these challenging circumstances. Pain clinics often employ effective strategies, like contracting, to deal with these circumstances.[21] Engaging local DEA authorities may even become necessary to ensure both patient and public protection. *Tolerance* may truly be the issue in patients with a history of opioid abuse. These patients are often *tolerant* of opioid medication, in*tolerant* of both physical and emotional pain, and clearly try the *tolerance* of their healthcare providers.

Deliver

Pain interventions should be delivered in a timely, logical, and coordinated fashion. A thorough understanding of the pharmacology of opioids and other medications is essential for good pain management at the end of life. For example, many physicians dose oral opioids every four hours as needed for pain. However, for patients in pain crisis a more aggressive strategy is indicated. Since oral opioids reach maximum serum concentration within an hour, peak effects and peak side effects also occur in that time frame. As long as adverse effects of sedation or respiratory depression aren't observed, additional medication, including breakthrough doses, can be administered every one to two hours.

Similarly aggressive parenteral dosing strategies exist for patients in pain crisis presenting for inpatient care. One such successful strategy describes a dose doubling every thirty minutes.[22] In this study, cancer pain patients already on opioids as outpatients presented for emergent admission with intense pain sustained for at least six hours and escalating over days. Appropriate to their outpatient opioid dose, patients received 10-20 mg of morphine intravenously over 15 minutes. If inadequate relief and no adverse effects were observed 15 minutes later, the dose was doubled and the process repeated every 30 minutes. Satisfactory pain control without adverse events was achieved in a mean time frame of 90 minutes for all patients.

In a similar study, cancer pain patients were treated with one milligram of morphine per minute for 10 minutes, which could be repeated after five minutes if there was no relief.[23] The goal in this study was also similar; to achieve adequate relief (< 5 pain score) not necessarily with complete relief, but without excess sedation or respiratory depression. In this study, the maximum dose was 30 milligrams over 45 minutes. None of their patients required this high a dose. Once relief was achieved, an hourly dose was calculated at approximately one-third to one-fourth of the loading dose.

Both of these studies depend on a clear understanding of opioid pharmacology. Both were also done in an inpatient setting, with experienced personnel, aware of, and prepared for adverse consequences. Nevertheless, innovative or "best-practice" models like this should be carefully reviewed, adapted and adopted in settings where poor pain control is likely to be encountered and effective pain management expected by patient, family, and providers.

A broader view of delivering interventions in a timely, logical and coordinated fashion suggests taking a harder look at what patients and their families need to achieve pain control. A recent review[24] suggests seven areas of difficulty in putting a pain regimen into practice. The primary difficulty is the cost of medication, but also of major concern are accessing information about the medication, tailoring the prescription to meet individual needs, and managing side effects like constipation. Anticipating these concerns is highly likely, and addressing them with all patients will clearly improve pain management. If opioid cost is an issue, methadone must be an option. While methadone has complex dosing problems and should only be prescribed by those thoroughly familiar with them, oral methadone costs only about a penny per milligram. Topical fentanyl patches for severe pain at 150mcg/hour applied every 72 hours may cost as much as $30/day, whereas an equianalgesic dose of methadone may cost as little as 45 cents/day. In addition, methadone has very specific analgesic properties that make it a more potent and effective opioid for complex, chronic cancer pain. Recent reviews of methadone[25] are essential reading for any practitioner providing care for patients with significant pain at the end of life. Indeed, methadone is probably the ideal opioid in end-of-life care.[26]

Empower and Enable

Unrelieved pain is incapacitating, interfering with the ability to eat, sleep, interact with others, and achieve a satisfactory quality of life.[3] Healthcare providers need to empower patients and their families and enable them to control their course to the greatest extent possible. Information is power. Resources abound to provide patients and their families with information with which they can better manage pain at the end of life. From drug companies[27] to end-of-life care advocacy groups,[1] print and Internet resources are readily available. Hospices cover every square inch of North Carolina and probably the entire continental United States. Palliative care services exist in many hospitals and all regions of the country. Both are committed to effective pain management. Use your local hospice and consult your palliative care service.

JCAHO standards, at least the pain control standards, are terrific guidelines and are the rules we must live by in many settings. As much as we often rebel against "have to" standards, these are worth embracing and implementing. Most guidelines and standards "suggest" that institutions should promise excellent pain control, express it clearly in statements of patient's rights and responsibilities, and put mechanisms in place to live up to the promise. One such statement reads,

"As a patient at Rockford Memorial Hospital, you can expect:

- Information about pain and pain relief measures.
- A concerned staff committed to pain prevention.
- Health professionals who respond quickly to reports of pain.
- State-of-the-art pain management.
- Dedicated pain relief specialists.
- Pain expressions will be believed.

As a patient at Rockford Memorial Hospital, we expect that you will:

- Ask your doctor or nurse what to expect.
- Discuss pain relief options with your doctors and nurses.
- Work with you doctor and nurse to make a pain relief plan.
- Ask for pain relief drugs when pain first begins.
- Help the doctor and nurse measure your pain.
- Tell the doctor or nurse about any pain that will not go away.
- Not worry about getting "hooked" on pain medication."[28]

This may not be the exact statement our institutions choose, but it is a great place to start. Individual and organizational commitment to pain relief is truly powerful. Education, attitude, passion, and compassion will overcome all of the barriers to adequate pain relief at the end of life, fulfilling our promise as concerned healthcare providers. **NCMJ**

> *"Paradoxically, healthcare providers are expecting patients to complain, while patients are waiting for their provider to ask."*

A JOINT STATEMENT FROM 21 HEALTH ORGANIZATIONS AND THE DRUG ENFORCEMENT ADMINISTRATION

Promoting Pain Relief and Preventing Abuse of Pain Medications: A Critical Balancing Act

As representatives of the health care community and law enforcement, we are working together to prevent abuse of prescription pain medications while ensuring that they remain available for patients in need.

Both healthcare professionals, and law enforcement and regulatory personnel, share a responsibility for ensuring that prescription pain medications are available to the patients who need them and for preventing these drugs from becoming a source of harm or abuse. We all must ensure that accurate information about both the legitimate use and the abuse of prescription pain medications is made available. The roles of both health professionals and law enforcement personnel in maintaining this essential balance between patient care and diversion prevention are critical.

Preventing drug abuse is an important societal goal, but there is consensus, by law enforcement agencies, health care practitioners, and patient advocates alike, that it should not hinder patients' ability to receive the care they need and deserve.

This consensus statement is necessary based on the following facts:

◆ Undertreatment of pain is a serious problem in the United States, including pain among patients with chronic conditions and those who are critically ill or near death. Effective pain management is an integral and important aspect of quality medical care, and pain should be treated aggressively.

◆ For many patients, opioid analgesics – when used as recommended by established pain management guidelines – are the most effective way to treat their pain, and often the only treatment option that provides significant relief.

◆ Because opioids are one of several types of controlled substances that have potential for abuse, they are carefully regulated by the Drug Enforcement Administration and other state agencies. For example, a physician must be licensed by State medical authorities and registered with the DEA before prescribing a controlled substance.

◆ In spite of regulatory controls, drug abusers obtain these and other prescription medications by diverting them from legitimate channels in several ways, including fraud, theft, forged prescriptions, and via unscrupulous health professionals.

◆ Drug abuse is a serious problem. Those who legally manufacture, distribute, prescribe and dispense controlled substances must be mindful of and have respect for their inherent abuse potential. Focusing only on the abuse potential of a drug, however, could erroneously lead to the conclusion that these medications should be avoided when medically indicated – generating a sense of fear rather than respect for their legitimate properties.

◆ Helping doctors, nurses, pharmacists, other healthcare professionals, law enforcement personnel and the general public become more aware of both the use and abuse of pain medications will enable all of us to make proper and wise decisions regarding the treatment of pain.

Addressing Pain Management and Palliative Care:

The Official Position of the North Carolina Medical Board

Charles E. Trado, MD, FAPA

Dr. Hanson has addressed the subject of palliative care in end-of-life situations, expertly documenting the definitions, statistics, and strategies for dealing with such care.[1] She has made notable references to these issues as confronted by North Carolinians, references that will prove educational to physicians, nurses, and other healthcare providers in our state. It is comforting to know that we in North Carolina are attending to this important issue with some institutional awareness and program implementation such as the Pain and Symptom Care Program at UNC Hospitals. Obviously more needs to be done by our statewide medical community.

Palliative care is a comprehensive approach to end-of-life issues and all aspects of this care need be addressed as discussed by Dr. Hanson. Alleviation of suffering should be a major goal of healthcare providers and should include not only the physical, but also the psychological, spiritual, emotional, and family suffering that takes place in this difficult life situation.

I would direct your attention to the physical suffering that dying patients more often than not experience. For at least the last 10-to-15 years the medical community has been made aware that adequate pain management in the dying patient has been a continuing problem. It has been reported in several studies over the years that 25-to-30% of cancer patients suffer severe pain and 40-to-50% suffer moderate to severe pain. This despite the fact that 90% of cancer pain can be relieved with current pain management protocols. One such protocol is presented comprehensively in The Clinical Practice Guideline, "Management of Cancer Pain," published by the Agency for Healthcare Research and Quality (AHRQ).[2] This publication is readily available to professionals and to the public alike from AHRQ. This is only one of many resources available to help us address this ongoing problem.

Hospice, introduced to this country in the 1970's, alerted our medical community to the need for sensible pain control in the dying patients and, even in its rudimentary protocols, opened our eyes and minds to the unmet needs of our patients. Palliative care programs will take us another important step in the right direction through its comprehensive approach.

But, as noted above, we are still not doing a good enough job in overall pain management. We can't lay the blame for our shortcomings in this area entirely on the medical community. Patients have every right to refuse adequate pain control even if that refusal is based upon faulty beliefs or assumptions. Many patients see themselves as weak or certainly non-heroic if they "give in" and use medication to control their pain. Others fear that using any kind of pain reliever will identify them as an "addict" to the public and to family members. Others fear that pain relievers have such mysterious power that they will automatically be addicted by the first dose. For patients who think and feel this way, the medical community needs to put more effort into assuaging their fears and improving their understanding of the proper and appropriate use of these medications.

> *"...substance abuse in this country has little or nothing to do with the proper practice of pain management in palliative and end-of-life care. Studies indicate that only approximately one to four percent of patients are addicted iatrogenically."*

Unfortunately, patients are not the only ones either misinformed or under educated about this issue. Too many, but thankfully not a majority, of physicians hold outdated and or prejudicial views about the use of pain relievers. Many of those views mirror those held by patients. As younger physicians who

Charles E. Trado, MD, FAPA, is a retired psychiatrist in Hickory, North Carolina. He is also a past-president of the NC Medical Board. Dr. Trado can be reached at cetrado@charter.net or 828-328-5995.

have more current and focused training in pain management become the majority care givers in our communities, this problem should continue to ameliorate.

Physician pain specialists and formal, structured pain treatment centers have afforded our patients up-to-date, comprehensive approaches to pain management. These highly trained specialists and their treatment teams tend, by necessity, to deal with outpatients who experience a full range of acute and chronic pain symptoms. All modalities of treatment are considered and applied with the goal of adequate pain relief for the patient in the safest and least noxious manner.

However, it is my observation that pain-treatment centers have to be preoccupied with the specific population mentioned above and do not routinely become involved with the dying patient. I mention this not to be critical, but to suggest that those who are taking care of the dying patient not overlook these valuable specialty programs and consultations when appropriate. This, too, in my opinion, should be part of a comprehensive palliative care program for our patients.

If it is true that some of our medical community, specifically physicians, either are improperly trained or inordinately under informed or incomprehensibly prejudiced with regard to appropriate pain management, then what, if anything, can or should be done about the problem? Please note that I said "some" of our physicians, not a majority, fall into this category. Also note that this minority of physicians have charge of the treatment of a significant number of dying patients and thereby influence decisions about their palliative care.

> *"Facilitating a 'good death' is what any humane and civilized society must demand for its citizens."*

What can be done to help these physicians practice pain management according to more currently acceptable guidelines? In the mid-1990s, the North Carolina Medical Board, while trying to deal with "over-prescribing" of pain medication by some physicians, observed that these same medications were being "under-prescribed" by other physicians. There was a heightened awareness of the inadequacy of pain treatment prevalent in the country at that time and the Board examined the findings of several studies of this issue. It discovered that many physicians were afraid to prescribe adequate pain relief, especially opioids, for fear of being sanctioned by the Board. This was the state of affairs at that time, not only in North Carolina but throughout the nation, which led to national debate among licensing and disciplinary boards about what position boards should take in the matter.

The North Carolina Medical Board elected to write and publish a "position statement" on the topic for the purpose of letting physicians know about the problem, to educate physicians about the kind of protocol to follow in using these medications, and hopefully to help alleviate fears of being sanctioned by the Board for prescribing these medications appropriately. Reassurance to physicians was provided in the following paragraph taken from the position statement:

> *"No physician need fear reprisals from the North Carolina Medical Board for appropriately prescribing as described above, even large amounts of controlled substances indefinitely for chronic non-malignant pain."*

The last paragraph of the statement is as follows:

> *"Nothing in this statement should be construed as advocating the imprudent use of controlled substances."*

The entire position statement by the North Carolina Medical Board is meant to address what we felt might be an impediment to proper pain management by North Carolina physicians and is especially applicable to formal palliative care programs and caregivers.

It is generally accepted that we have a drug problem in this country, and that citizens hold strong and varied opinions about what should be done about the problem. These strong and diverse opinions can and, in some instances do, have an impact upon pain management decisions made by caregivers.

In my opinion, substance abuse in this country has little or nothing to do with the proper practice of pain management in palliative and end-of-life care. Studies indicate that only approximately one to four percent of patients are addicted iatrogenically.[1] If caregivers have any role to play in the "drug problem" it is likely to be in the area of diversion of prescription drugs for illicit sale and use by recreational drug users and hardcore addicts. The latter group will find their supply by whatever means possible, and their addictive behavior should not be allowed to compromise quality of care for any of our patients, especially those in a palliative care program.

End-of-life issues have rightfully captured our attention and demand continued study by our profession. We are miles from where we were just a few decades ago and articles such as Dr. Hanson's will help point the way to the future of this important life event. A good life is what we all wish for our loved ones. Facilitating a "good death" is what any humane and civilized society must demand for its citizens. **NCMJ**

North Carolina Medical Board Position Statement on
MANAGEMENT OF CHRONIC NON-MALIGNANT PAIN

It has become increasingly apparent to physicians and their patients that the use of effective pain management has not kept pace with other advances in medical practice. There are several factors that have contributed to this. These include a history of relatively low priority given to pain management in our healthcare system, the incomplete integration of current knowledge in medical education and clinical practice, a scarcity of practitioners specifically trained in pain management, and the fear of legal consequences when controlled substances are used—fear shared by physician and patient. There are three general categories of pain.

Acute Pain is associated with surgery, trauma, and acute illness. It has received its share of attention by physicians. Its treatment by various means is widely accepted by patients, and it has been addressed in guidelines issued by the Agency for Health Care Policy and Research (AHCPR) [now the Agency for Healthcare Research and Quality (AHRQ)] of the United States Department of Health and Human Services.

Cancer Pain has been receiving greater attention and more enlightened treatment by physicians and patients, particularly since development of the hospice movement. It has also been addressed in AHCPR/AHRQ guidelines.

Chronic Non-Malignant Pain is often difficult to diagnose, often intractable, and often under-treated. It is the management of chronic non-malignant pain on which the North Carolina Medical Board wishes to focus attention in this position statement.

The North Carolina Medical Board recognizes that many strategies exist for treating chronic non-malignant pain. Because such pain may have many causes and perpetuating factors, treatment will vary from behavioral and rehabilitation approaches to the use of a number of medications, including opioids. Specialty groups in the field point out that most chronic non-malignant pain is best managed in a coordinated way, using a number of strategies in concert. Inadequate management of such pain is not uncommon, however, despite the availability of safe and effective treatments.

The Board is aware that some physicians avoid prescribing controlled substances such as opioids in treating chronic non-malignant pain. While it does not suggest those physicians abandon their reservations or professional judgment about using opioids in such situations, neither does the Board wish to be an obstacle to proper and effective management of chronic pain by physicians. It should be understood that the Board recognizes opioids can be an appropriate treatment for chronic pain.

It is the position of the North Carolina Medical Board that effective management of chronic pain should include:

- thorough documentation of all aspects of the patient's assessment and care;
- a thorough history and physical examination, including a drug and pain history;
- appropriate studies;
- a working diagnosis and treatment plan;
- a rationale for the treatment selected;
- education of the patient;
- clear understanding by the patient and physician of methods and goals of treatment;
- a specific follow-up protocol, which must be adhered to;
- regular assessment of treatment efficacy;
- consultation with specialists in pain medicine, when warranted; and
- use of a multidisciplinary approach, when indicated.

The Board expects physicians using controlled substances in the management of chronic pain to be familiar with conditions such as:

- physical dependence;
- respiratory depression and other side effects;
- tolerance;
- addiction; and
- pseudo addiction.

There is an abundance of literature available on these topics and on the effective management of pain. The physician's knowledge should be regularly updated in these areas.

No physician need fear reprisals from the Board for appropriately prescribing, as described above, even large amounts of controlled substances indefinitely for chronic non-malignant pain.

Nothing in this statement should be construed as advocating the imprudent use of controlled substances.

(Adopted 9/13/96)

North Carolina Medical Board Position Statement on
END-OF-LIFE RESPONSIBILITIES AND PALLIATIVE CARE

Assuring Patients

Death is part of life. When appropriate processes have determined that the use of life-sustaining or invasive interventions will only prolong the dying process, it is incumbent on physicians to accept death "not as a failure, but the natural culmination of our lives."*

It is the position of the North Carolina Medical Board that patients and their families should be assured of competent, comprehensive palliative care at the end of their lives. Physicians should be knowledgeable regarding effective and compassionate pain relief, and patients and their families should be assured such relief will be provided.

Palliative Care

There is no one definition of palliative care, but the Board accepts that found in the *Oxford Textbook of Palliative Medicine*: "The study and management of patients with active, progressive, far advanced disease for whom the prognosis is limited and the focus of care is the quality of life." This is not intended to exclude remissions and requires that the management of patients be comprehensive, embracing the efforts of medical clinicians and of those who provide psychosocial services, spiritual support, and hospice care.

A physician who provides palliative care, encompassing the full range of comfort care, should assess his or her patient's physical, psychological, and spiritual conditions. Because of the overwhelming concern of patients about pain relief, special attention should be given to the effective assessment of pain. It is particularly important that the physician frankly, but sensitively, discuss with the patient and the family their concerns and choices at the end of life. As part of this discussion, the physician should make clear that, in some cases, there are inherent risks associated with effective pain relief in such situations.

Opioid Use

The Board will assume opioid use in such patients is appropriate if the responsible physician is familiar with and abides by acceptable medical guidelines regarding such use, is knowledgeable about effective and compassionate pain relief, and maintains an appropriate medical record that details a pain management plan. (See the Board's position statement on the Management of Chronic Non-Malignant Pain for an outline of what the Board expects of physicians in the management of pain.) Because the Board is aware of the inherent risks associated with effective pain relief in such situations, it will not interpret their occurrence as subject to discipline by the Board.

Selected Guides

To assist physicians in meeting these responsibilities, the Board recommends *Cancer Pain Relief: With a Guide to Opioid Availability, 2nd ed* (1996), *Cancer Pain Relief and Palliative Care* (1990), *Cancer Pain Relief and Palliative Care in Children* (1999), and *Symptom Relief in Terminal Illness* (1998), (World Health Organization, Geneva); *Management of Cancer Pain* (1994), (Agency for Health Care Policy and Research, Rockville, MD); *Principles of Analgesic Use in the Treatment of Acute Pain and Cancer Pain*, 4th Edition (1999)(American Pain Society, Glenview, IL); *Hospice Care: A Physician's Guide* (1998) (Hospice for the Carolinas, Raleigh); and the *Oxford Textbook of Palliative Medicine* (1993) (Oxford Medical, Oxford).

(Adopted 10/1999)

RELATED STATEMENT

Joint Statement on Pain Management in End-of-Life Care

(Adopted by the North Carolina Medical, Nursing, and Pharmacy Boards)

Through dialogue with members of the healthcare community and consumers, a number of perceived regulatory barriers to adequate pain management in end-of-life care have been expressed to the Boards of Medicine, Nursing, and Pharmacy. The following statement attempts to address these misperceptions by outlining practice expectations for physicians and other healthcare professionals authorized to prescribe medications, as well as nurses and pharmacists involved in this aspect of end-of-life care. The statement is based on:

- the legal scope of practice for each of these licensed health professionals;
- professional collaboration and communication among health professionals providing palliative care; and
- a standard of care that assures on-going pain assessment, a therapeutic plan for pain management interventions; and evidence of adequate symptom management for the dying patient.

It is the position of all three Boards that patients and their families should be assured of competent, comprehensive palliative care at the end of their lives. Physicians, nurses, and pharmacists should be knowledgeable regarding effective and compassionate pain relief, and patients and their families should be assured such relief will be provided.

Because of the overwhelming concern of patients about pain relief, the physician needs to give special attention to the effective assessment of pain. It is particularly important that the physician frankly, but sensitively, discuss with the patient and the family their concerns and choices at the end of life. As part of this discussion, the physician should make clear that, in some end-of-life care situations, there are inherent risks associated with effective pain relief. The Medical Board will assume opioid use in such patients is appropriate if the responsible physician is familiar with, and abides by, acceptable medical guidelines regarding such use, is knowledgeable about effective and compassionate pain relief, and maintains an appropriate medical record that details a pain management plan. Because the Board is aware of the inherent risks associated with effective pain relief in such situations, it will not interpret their occurrence as subject to discipline by the Board.

With regard to pharmacy practice, North Carolina has no quantity restrictions on dispensing controlled substances including those in Schedule II. This is significant when utilizing the federal rule that allows the partial filling of Schedule II prescriptions for up to 60 days. In these situations it would minimize expenses and unnecessary waste of drugs if the prescriber would note on the prescription that the patient is terminally ill and specify the largest anticipated quantity that could be needed for the next two months. The pharmacist could then dispense smaller quantities of the prescription to meet the patient's needs up to the total quantity authorized. Government-approved labeling for dosage level and frequency can be useful as guidance for patient care. Health professionals may, on occasion, determine that higher levels are justified in specific cases. However, these occasions would be exceptions to general practice and would need to be properly documented to establish informed consent of the patient and family.

Federal and state rules also allow the fax transmittal of an original prescription for Schedule II drugs for hospice patients. If the prescriber notes the hospice status of the patient on the faxed document, it serves as the original. Pharmacy rules also allow the emergency refilling of prescriptions in Schedules III, IV, and V. While this does not apply to Schedule II drugs, it can be useful in situations where the patient is using drugs such as Vicodin for pain or Xanax for anxiety.

The nurse is often the health professional most involved in on-going pain assessment, implementing the prescribed pain management plan, evaluating the patient's response to such interventions, and adjusting medication levels based on patient status. In order to achieve adequate pain management, the prescription must provide dosage ranges and frequency parameters within which the nurse may adjust (titrate) medication in order to achieve adequate pain control. Consistent with the licensee's scope of practice, the RN or LPN is accountable for implementing the pain management plan utilizing his/her knowledge base and documented assessment of the patient's needs. The nurse has the authority to adjust medication levels within the dosage and frequency

STATEMENT—continued on page 241

STATEMENT—continued from page 240

ranges stipulated by the prescriber and according to the agency's established protocols. However, the nurse does not have the authority to change the medical pain management plan. When adequate pain management is not achieved under the currently prescribed treatment plan, the nurse is responsible for reporting such findings to the prescriber and documenting this communication. Only the physician or other health professional with authority to prescribe may change the medical pain management plan.

Communication and collaboration between members of the healthcare team, and the patient and family are essential in achieving adequate pain management in end-of-life care. Within this interdisciplinary framework for end-of-life care, effective pain management should include:

- thorough documentation of all aspects of the patient's assessment and care;
- a working diagnosis and therapeutic treatment plan including pharmacologic and non-pharmacologic interventions;
- regular and documented evaluation of response to the interventions and, as appropriate, revisions to the treatment plan;
- evidence of communication among care providers;
- education of the patient and family; and
- a clear understanding by the patient, the family, and healthcare team of the treatment goals.

It is important to remind health professionals that licensing boards hold each licensee accountable for providing safe, effective care. Exercising this standard of care requires the application of knowledge and skills, as well as ethical principles, focused on optimum patient care while taking all appropriate measures to relieve suffering. The healthcare team should give primary importance to the expressed desires of the patient tempered by the judgment and legal responsibilities of each licensed health professional as to what is in the patient's best interest.

(10/1999)

Guiding the Decisions of Physicians and Families in End-of-Life Care:

The Case of Long-Term Feeding Tube Placement

Ethical and Judicial Affairs Committee, North Carolina Medical Society

The issue of long-term feeding tube placement for patients near the end of life who are unable to make decisions with regard to their own care is a complex issue for physicians and families. There is controversy about how appropriate the placement of percutaneous endoscopy gastrostomy (PEG) tubes might be in specific cases, and physicians have felt a need for clearer guidelines for their use. Consequently, the North Carolina Academy of Family Physicians asked that the 2001 House of Delegates of the North Carolina Medical Society (NCMS) undertake efforts to educate policymakers about the inappropriate use of long-term feeding tubes and to seek and support legislative and/or administrative actions supporting the adoption of the following language into law:

"Before placement of any long-term feeding tube, in a mentally incompetent patient, the hospital or nursing home ethics committee (whichever is appropriate) would have to review the case and render a non-binding written opinion. This opinion would have to be presented to the responsible parties. The rationale for this non-binding opinion would have to be explained to the responsible parties in easily understood layman's terms."

Resolution 1-2001 was referred for study to the Ethical and Judicial Affairs Committee of the NCMS, whose members undertook to develop an educational statement for physicians about the efficacy of long-term feeding tubes and then to convene a larger task force that would include representatives from external interest groups to develop a consensus on the statement.

> *"Tube feeding does not necessarily provide medical benefit to the dying patient by enhancing quality of life nor by reducing suffering."*

A subcommittee was appointed and charged with developing a set of guidelines for physicians. The committee members were: Janelle Rhyne, MD, Chair; Darlyne Menscer, MD; Glenn Pickard, MD; Douglas Nelson, MD; Richard Stephenson, MD; and Lance Stell, PhD. The subcommittee met a number of times and produced a draft statement in the summer of 2003.

Given the sensitivity of the subject matter and the central role of patients and their families or loved ones in deciding whether a long-term feeding tube should be placed, the subcommittee also decided to promote the importance of patient and family education.

A task force, which included the subcommittee as well as representatives from nursing homes, hospitals, hospice, home health, elder law, speech pathology, the Medical Directors Association, was convened in September 2003. Members of the task force agreed that educational information was definitely needed on this issue for providers and patients alike. After significant discussion, the task force approved the following draft with some modifications. The task force also agreed that educational pieces for patients and their families should be promoted. The statement was subsequently approved by the House of Delegates of the North Carolina Medical Society in November 2003 and is presented here with the hope that it will be of value to physicians and families struggling with these issues in the care of patients and family members in these complex situations. **NCMJ**

Long-Term Feeding Tubes: Ethical Issues in Physicians' Decision Making

Statement Adopted by the North Carolina Medical Society House of Delegates, November 2001

When a decisionally incapable patient who suffers from a chronic, progressive illness develops swallowing difficulty, physicians, families, nurses, and other care providers have, with increasing frequency, elected non-oral nutritional support. However, recently accumulated outcome data make dubious a reflexive decision in favor of tube feeding in this setting.

- Feeding tube placement is associated with an in-hospital mortality of 15-25%, and a one-year mortality of 60%.
- Co-factors associated with increased risk of mortality include: advanced age, CNS pathology (CVA, advanced dementia), cancer (except early stage head/neck cancer), disorientation, and low albumin.
- Aspiration occurs in up to 50% of patients being tube fed.
- For patients with advanced dementia, feeding tubes have not proven effective in prolonging life, in preventing aspiration, or even in providing adequate nourishment.[1]

David Weissman, MD, has outlined the *tube feeding death spiral*:[2]

1. Hospital admission for complications secondary to brain failure or other predictable end organ failure due to primary illnesses (e.g. Urosepsis in the setting of advanced dementia)
2. Inability to swallow documented and/or direct evidence of aspiration and/or weight loss associated with low or no p-o (by mouth) intake
3. Swallowing evaluation followed by a recommendation for nonoral feeding.
4. Feeding tube placed followed by increasing patient agitation, resulting in feeding tube dislodgement.
5. Re-insertion of feeding tube; restraints placed.
6. Aspiration pneumonia
7. Intravenous antibiotics and pulse oximetry.
8. Repeat steps 4-6 two or more times.
9. Family conference.
10. Death

- The specter of aggressive, over-treatment was a major factor motivating the patients' rights movement.
- Legal and ethical standards have been developed to support an informed decision to withhold or withdraw any medical intervention, including tube feeding.[3]
- North Carolina does not prejudice with unique restrictions the medical decision of whether or not to place a feeding tube.
- There is no ethical or legal warrant for the physician to evaluate differently a decision to withdraw tube feeding from a decision to withhold tube feeding.[4]
- Advance care directives, such as living wills, healthcare powers of attorney, etc., enable decisionally capable patients to anticipate and plan for the contingency of losing their ability to communicate healthcare decisions, including a decision whether to withhold or withdraw tube feeding.
- Persons authorized to give informed consent to feeding tube placement on a patient's behalf may also make an ***informed refusal*** of tube placement.
- In the absence of advance care directives, a surrogate's decisions regarding feeding tube placement or removal should be based, whenever possible, on what the patient would choose in the circumstances. Otherwise, the surrogate's decisions should be guided by considering the patient's best interests.

FEEDING TUBES—continued on page 244

FEEDING TUBES—continued from page 243

The physician should not bias a discussion of the pros and cons of tube feeding with an implicit assumption that nursing home residents would prefer tube feeding in the event they cannot swallow. On the contrary:

- A study of 421 randomly selected, competent persons living in 49 nursing homes found that only one-third would favor feeding tube placement if they were unable to eat because of permanent brain damage. Sixty-one percent opposed tube feeding. Of those who initially favored tube placement, 25% changed their preference when they learned that physical restraints might be necessary to facilitate feeding tube use.[5]
- The desire for tube feeding decreases as the hypothetical degree of cognitive impairment increases.[6]

Tube feeding does not necessarily provide medical benefit to the dying patient by enhancing quality of life nor by reducing suffering.

- Tube feeding is associated with increased agitation and may reduce quality of life and dignity because it increases the need for physical restraints;[7]
- Typically, dying patients do not experience hunger or thirst;
- Malnutrition, a concomitant of the natural dying process, should not be confused with "starvation";
- While dry mouth commonly occurs in dying patients, tube feeding does not relieve it;
- Complete relief from symptoms associated with dry mouth may be achieved with ice chips, moist sponge, sips of liquid, lip moisteners, hard candy, and mouth care."[8]

Recommendations:

- Prior to feeding tube placement in a decisionally incapable patient, it is the physician's ethical responsibility to determine whether the patient has executed an advance directive whose provisions may apply to the placement decision. Otherwise, the physician should take the lead in discussing with the patient's surrogate decision maker the pros and cons of long-term tube feeding.
- The physician should be prepared to address the common tendency to confuse "malnutrition" (a concomitant of the natural dying process) and "starvation."
- The physician should relate decisions about tube feeding +/- to achievable goals of care. A summary of discussions regarding tube feeding should be documented in the medical record.
- The goals of care should be reviewed regularly to determine whether, or to what degree, tube feeding promotes or contradicts them.
- Consultation with hospice or with a palliative care service facilitates setting realistic goals of care.
- Since tube feeding has not proven beneficial in patients with advanced dementia, but on the contrary, is associated with significant increased morbidity, mortality, and indignity, physicians may, in good conscience, recommend that it be withheld or withdrawn in these circumstances.
- In the event a valid decision is made to forego tube feeding, the physician should enter in the patient's medical record an order "Do Not Tube Feed."
- Patients who are genuinely hungry should be allowed to eat anything they please.

This document was written with adult patients in mind; issues facing pediatric patients were not discussed by the authors and are not addressed herein.

Current End-of-life Issues:
A Practicing Physician's View

Phillip A. Sellers, MD

As a third-year internal medicine resident in the 1960s, I visited the small North Carolina Cancer Hospital in Lumberton, NC. To my amazement patients received no blood transfusions or nutritional supplementation; the only medication provided was morphine for pain. With my newly developed and up-to-date scientific knowledge about how to prolong life, I was disturbed by the predominant treatment philosophy in this facility. This was not the standard of care accepted by the medical community at that time, or now. Over the last 40 years, however, a new set of concepts has gradually been accepted by the healthcare delivery system and, more importantly, by most of the public.

End-of-life health policies have been slow to evolve. Living wills, healthcare power of attorney documents, Do-Not-Resuscitate (DNR) orders, as well as the so-called "yellow sheet" DNRs have all been made legal by the North Carolina General Assembly. The use of feeding tubes increased rapidly, but has now receded after studies have shown that feeding tubes used in the chronically ill are not as beneficial as we originally thought.[1] It is now clearly recognized that IV fluids and "hydration" are not indicated at the end of life. Dehydration and malnutrition do not cause symptoms or discomfort. The passing is easy. As the old-time practitioner always knew, pneumonia and infection frequently can be "the dying person's friend." Antibiotics may be contraindicated at the end.

The above changes include both good and bad concepts of care. Hospice care and the rapidly emerging new medical specialty of palliative care have better defined the concepts and how they should be applied. I would like to explore some of these from the perspective of the practicing physician.

Comfort Care

The concept of comfort care has developed over the last several years. The primary goal of comfort care treatment is to make the patient comfortable, which includes relieving the patient's pain and other symptoms. No other treatment is provided to sustain life. Medication such as sleeping pills, tranquilizers, and narcotics, as well as food and fluid by mouth, are appropriate to assure comfort. This is an excellent option for the chronically ill, severely demented, immobile nursing home patient, as well as for the less debilitated terminally ill cancer patient. In addition, for the competent patient who has verbally and unequivocally let it be known—and who has signed the appropriate legal papers such as a living will and a DNR order—comfort care is appropriate. For the incompetent patient who has a healthcare power of attorney who knows the patient's desire for comfort care only, it is also appropriate, especially if the appropriate papers were signed earlier.

"A trusting relationship between a terminally ill patient and her or his physician is the most important basis for realistic and good decision making."

Many have interpreted a living will or a DNR to mean comfort care only. This is not true. The living will is effective only when the patient has lost his or her competency to make her or his own decisions. The same is true for the Health Care Power of Attorney. Competency of the individual is the critical factor. A DNR order is only effective if the patient is not breathing or does not have a heart beat and therefore is not responsive. If there is a heart beat and the patient is breathing, the healthcare providers (emergency medical technicians, hospital and nursing home nurses, emergency room physicians, etc.) are obligated to treat unless the patient is competent and refuses treatment. This policy has resulted in many individuals receiving treatment they did not desire in hospitals, emergency rooms, nursing homes, and at home. An available, effective, and legal comfort care physician's order

Phillip A. Sellers, MD, is Chairman of the Ethics Committee, Pardee Memorial Hospital, Hendersonville, NC. He is also in Private Practice of General Internal Medicine and the Medical Director, Health Center, Carolina Village Retirement Center. He can be reached at sell3982@bellsouth.net or 828-692-2231.

would have averted the unwanted treatment. The patient could stay in the nursing home or at home and receive comfort care treatment without having their wishes exceeded.

Problems

Today some healthcare givers assume the presence of a living will or a DNR order is also a comfort care only order. It clearly is not. Many healthcare providers—including doctors, nurses, patients, and families—are unclear about the difference. At times there is a tendency for the care-giving medical staff to assume it is okay for the patient to die if there is a living will and/or a DNR order. The staff may not be as attentive to that patient's needs and complaints as they would be to patients having no living will or DNR order. Indicated and beneficial treatment may be delayed or not instituted.

Under comfort care orders, the decision not to treat with antibiotics frequently poses a dilemma. Do you treat reversible and easily curable urinary infections or skin infections? Some would argue treatment of an easily curable infection is a component of comfort care. But not all agree. There is no clear-cut answer to this question. A competent patient can make the decision at the time, but the incompetent need better-defined advanced directives.

The care of the patients with ultimately fatal medical illnesses, such as congestive heart failure or chronic obstructive pulmonary disease, is much more difficult to address from a comfort care or palliative care approach. To be comfortable, these patients will continue to need medication for treatment of their disease. Decision making and medication management are much more complicated and require more than the usual palliative or comfort measures. Prognosis is much more difficult to predict and instead of living for months the patient may live for years. I am concerned that the hospice principles will be applied too soon to some now receiving palliative care for chronic, slowly progressive medical illnesses. It may be detrimental to some patients.

Some in our community feel we make dying too easy and, subsequently, resist hospice care. Others believe that earlier application of hospice care services and principles give families of these patients much needed respite and enable them to better cope with the possibly long trajectory of illness and death.

"Recent efforts to involve team members—nurses, chaplains, social workers and psychologists—in educating both the patient and the family about end-of-life issues are very helpful."

Team Care

The expansion of hospice and palliative care to include multiple other caregivers—such as physician's assistants, nurse practitioners, chaplains, nurses, social workers, and counselors—has been necessary and good. The personal doctor or specialist cannot do it all. The team is able to give the patient more comprehensive care.

Problems

My concern is that the personal or primary care physician is frequently left out of the loop. I would argue that the care can be just as good if the primary care doctor is involved and head of the team, so long as he or she functions as a "team member." Consistent attention to the needs of the patient is something the primary care physician can provide. The personal physician should know the patient better than any other care giver. The patient's own "doc" should not abandon the patient in his time of greatest need or as he approaches death. I realize my view is in the minority these days. In fact, many primary doctors are happy to turn their patients over to the hospice or palliative care team. Their view is that terminal care takes too much time for too little reimbursement. I think the reason goes deeper than this. Unfortunately, some physicians do not want to deal with the difficult management and emotional issues associated with dying. This is not good for long-term physician-patient-family relationships. I personally find helping a long-term patient die a good death is one of most beneficial things I do.

Family Relationships

Recent efforts to involve team members—nurses, chaplains, social workers and psychologists—in educating both the patient and the family about end-of-life issues are very helpful.

Problems

Frequently a family's understanding of the process of death and its variability is difficult. Much time must be expended in elucidating the diagnosis, deciding between treatment or non-treatment, and expected course. Families are vastly more knowledgeable about medical illnesses than in the past. But they may not fully understand the jargon in an experienced medical sense. A little knowledge may lead to great expectations both realistic and unrealistic. With their increased Internet-derived medical knowledge, families can reasonably challenge the physician's decision making. This more easily happens if family members have not been around the patient recently and have not experienced the patient's recent physical and mental decline.

Trust

A trusting relationship between a terminally ill patient and her or his physician is the most important basis for realistic and good decision making. It is even better if the trusting relationship extends to the family. A long-time physician-patient-family relationship in which all parties are comfortable and are free to express themselves in a trusting environment makes the care for all much easier. Primarily the patient needs to be comfortable and able to clearly communicate her or his wishes whenever the he or she wants. Compassionate caregivers must communicate with honesty, modified by prudence and fidelity to the patient's wishes.

Recommendations to Improve the Possibilities of a "Good Death"

POST - Physicians Orders for Scope of Treatment

The North Carolina General Assembly should approve the use of the POST form (as developed in West Virginia) as a legal upgrade to the currently approved North Carolina DNR Yellow Sheet. The proposed new "pink-sheet" or POST form has been approved by the West Virginia State Legislature for use in that state. The current North Carolina "yellow-sheet" DNR only addresses the patient with no pulse or who is not breathing. The new POST form addresses the patient with no pulse and not breathing plus offering options for comfort care only, not being hospitalized or moved, as well as decisions on whether or not to receive antibiotics or tube feedings. It fully defines the patient's desires and is reinforced by state law. For terminally ill or severely demented patients, it clearly defines for families, nursing homes, emergency medical technicians, and emergency room physicians, what should be done and not done. The POST forms are physician orders that will stay with the patient all the time and can be changed anytime, but only by a physician's order. You can learn more about POST at the West Virginia Center for End-of-Life Care at http://www.hsc.wvu.edu/chel/wvi/ContactUs.asp.

Patient-Physician Relationships

Physicians who know their patients well should continue to follow and be involved in critical decisions at the end of life. They should participate in the team approach to terminal illness and receive reasonable reimbursement for it.

Trust

For multiple reasons, trust in the healthcare system is becoming more difficult to achieve at the end of life. Physicians must see that patient trust is maintained to the end, and they must not abandon their patients.

So, we have indeed learned a lot from the time I visited the North Carolina Cancer Hospital in the 1960s about the appropriate treatment for those of us who are about to die. But we can always make it better. **NCMJ**

COMMENTARY

Why the Patient Self-Determination Act Has Failed

Dee Leahman

Deciding when and how to cross the bridge from curative to palliative care is both complicated and simple. Complicated by clashes in perspective and values: Opinions differ as to what is best for the patient, how quality of life should be defined, who is best qualified to make these important decisions.

Simple? Sometimes as simple as asking, "What would the patient want?" But what if they can't express themselves?

Over a decade ago the Patient Self-Determination Act (PSDA) was passed. If designed to give patients the right to refuse unwanted treatments before the fact so that tragedies like the family of Nancy Cruzan and Terri Schiavo faced would disappear, then the PSDA has not worked.

> *"Why are we still dying in places we would not choose, in ways we do not want, surrounded by strangers, our wishes undocumented, unknown and, therefore, often not honored?"*

Today, only about 30% of Americans have advance directives. Living Wills are the simplest, most common and least effective type. Healthcare Powers of Attorney require that you appoint a healthcare agent, tell that agent which treatment options you would choose under what circumstances, document your choices and wishes, make sure all the right people have copies of the document... Whoa!! Talk about complicated. Most people respond: "We'll get around to that later—when we need it." Discussion deferred.

As Dr. Laura Hanson points out in this edition's lead article,[1] "Patients and their families say they prefer terminal care at home, but four of five deaths in the United States take place in hospitals and nursing homes." In other words, about 80% of us would rather die in a home-like setting, but that only happens 20% of the time. What we say we want is NOT what we get. Why are we still dying in places we would not choose, in ways we do not want, surrounded by strangers, our wishes undocumented, unknown and, therefore, often not honored?

A cancer patient who was active in her church taught me the answer. Asked if she had talked with her doctor about her disease, she replied: "Oh, no! He's much too busy." I asked, "What about your minister?" "Lord, no," she replied. "This kind of talk makes him really uncomfortable." Her perceptions may not have been accurate but they kept her from helpful information and support she needed.

I agree with Dr. Hanson when she says "patients generally welcome these conversations, and many are willing to record their wishes in some form." I also believe that most patients, physicians, and family members are reluctant to *initiate* the conversation. Once given permission and some coaching, discussion flows freely. But permission to talk about these care options is often implicitly denied.

Most of us know clearly what kind of treatment we want near life's end. Few of us are comfortable and skilled when approaching the subject. Avoiding discomfort now, we invite confusion, conflict, and permanent damage to relationships later. Documented wishes are often too vague to be of much help once patients cannot speak for themselves. The only fail-safe I know is thorough and early conversations about these tough decisions.

We have failed in implementing the Patient Self-Determination Act because we have allowed documents to speak for us, and paper can't talk. We don't say the right things to the right people at the right time in the right place. We have failed both organizationally and personally.

Organizationally

Organizations receiving Medicare funding are mandated to distribute advance care documents and information about them. *Wrong place!*

Information about living wills and healthcare powers of

Dee Leahman is the Director of Education and Program Development and the Director of the Community Partnership for End of Life Care at the Hospice & Palliative CareCenter in Winston-Salem, North Carolina. He can be reached at Dee.Leahman@hospicecarecenter.org or 1100-C South Stratford Road, Winston-Salem, NC 27103. Telephone: 336-768-6157.

attorney is given to patients upon admission to healthcare facilities along with a mix of other material about the facility. ***Wrong time!***

Healthcare facility admissions personnel seldom have time to facilitate in-depth advance care planning discussions and often don't have answers to questions that should be asked. ***Wrong person!***

Admissions staff ask, "Yes or No: Do you have an advance directive?" Most of the time that is translated to the easier default: "Do you have a Living Will?" Healthcare Powers of Attorney are more complicated and confusing. Time is limited. Seldom is the patient asked to identify their healthcare agent. Most patients don't bring a copy of the document with them. Many medical records that have the "yes" box marked do not contain copies of advance care documents that are easy to access and understand. Even completed documents clearly marked on the medical record do not give physicians much direction. They are often vague and open to interpretation. That is not a good thing in the presence of difference of opinion. ***Wrong mechanism!***

Personally

Focus has been on documents rather than on the all-important conversation. Time, skill, and comfort level are in short supply all around when talking about treatment options and end-of-life care decisions. Parents don't want to upset children; children don't like talking to their parents about life's end. Patients expect the physician to bring it up. Physicians hope the patient will. In short, the conversation doesn't happen, at least not in the way it should.

The Carolinas Center for Hospice and End of Life Care, in collaboration with the North Carolina AARP and the Life's End Institute in Missoula, Montana, conducted a survey of North Carolina AARP members that revealed interesting facts about the way they approached (or did not approach) discussions about end-of-life care.

Ninety-two percent of respondents reported they wanted honest answers from their physician; 88% wanted to understand treatment options; 74% feared dying painfully. Even so, only 11% had spoken to their physician about their concerns.

Eighty-three percent said it is very important to be at peace spiritually (this number was 93% among African American respondents); 62% said it is very important to have comfort from spiritual or religious persons. Still, only six percent had talked with their clergy about these issues.

What an Incredible Disconnect!

Instead of using the documents as a catalyst to promote conversation, they have been used as a shield to protect us from having the conversation. The formal documents leave out the personal touch.

Two of my most memorable conversations about advance directives and end-of-life care, one with an aging relative, the other with my closest friend, taught me a lot about how important the details of the conversation can be and how void of meaning and direction the documents alone are.

Mamie was practically blind and deaf. She knew she didn't have much longer to live. She was bed ridden and dependent on others but mentally alert. As we talked about her future, she said, "I can't hear, I can't see. I can hardly move. But I can still smell. Can we get some flowers and scented candles in here?" I couldn't find that request anywhere in her formal documents.

I asked my friend: "What's on your list of the kind of care you'd like near the end of life?" He said quickly and matter-of-factly, "I want my pain controlled. I'd like to be with people I love. And I want music."

"Fine," I said. "I can help make that happen." We changed the subject. A few days later I realized I had failed to ask something important: What ***kind*** of music did he want? I assumed I knew, knowing what he listened to all the time. I asked, "Classic Rock, right?" He replied, "No, Celtic Harp." Lessons learned: it's in the details; ask the right questions.

You would think that healthcare professionals would have protected themselves and those they love by selecting a healthcare agent and documenting their wishes. They will have expressed to their agent and those in their important "inner circle" details about the setting, care, treatment options, and personal details they'd like someone to handle when they can no longer speak or act for themselves. Knowing that such a conversation makes it more likely that their wishes will be honored, they will have recorded their wishes and made them easily accessible to the right people. Not so. A clear majority of most audiences of physicians, nurses, social workers, clergy, and attorneys I speak to have not adequately dealt with these issues.

I maintain that it is difficult, if not hypocritical, to encourage patients to do advance care planning unless we have done it ourselves. It is appalling that so many of us are willing to subject our patients, our families, and ourselves to "pot luck" when it comes to end-of-life care.

So What Can We Do?

1 Normalize the conversation. Talk about the taboos early, prior to diagnosis or crisis. Ask about the kind of care they want. Take enough time or make a referral to someone who can.

I like the familiar model of the "consult." If my primary care physician discovers I have a cardiac problem, she calls for a cardiac consult. If I'm in respiratory distress, she may ask for a pulmonary consult. Why not call for an advance care planning consult if a patient needs assistance discussing and documenting one's end-of-life care wishes?

2 With terminal diagnoses, help the patient and family redefine hope. Rather than avoiding the truth, creating false hope, and delaying the inevitable, help patients and families focus on hope for comfort and maximizing quality of remaining life. As Dr. Hanson points out, identifying the point in time to transition from curative to palliative care and helping the patient and family manage that transition well is one of the central dilemmas of end-of-life care. I like her mention of compassionate communication. She states, *"Absent this skill, physicians will be unable to help patients decide on appropriate treatments, assess physical symptoms, or address emotional and spiritual suffering. Meaningful and compassionate communication is the core skill in end-of-life care. Patients facing the crisis of their own mortality require time to express fears and to seek reassurance of physician attention to their needs, in addition to medical aspects of their care."*

3. Use the documents as a vehicle to foster discussion about treatment options and preferences rather than viewing them as the desired outcome
4. Encourage policy change by sponsoring consumer and physician-friendly statutes such as Oregon's POLST (Physician Orders for Life-Sustaining Treatment) or West Virginia's POST (Physician Orders for Scope of Treatment). Become a process improvement activist in institutions having difficulty with advance directive documentation, tracking, and education. Help create an organization recognized for patients' wishes being known, documented, and honored wherever possible.
5. Spend time talking with patients' families about the whole person, not just the medical components of the disease. An unsolicited, positive outcome of this kind of trust-building dialogue is risk reduction. Well informed families who feel the physician has been caring, compassionate, and open are less likely to litigate.
6. Help "relocate" advance directives. Move them out of the acute care setting and "upstream" to physicians' offices, ministers' studies, estate planning sessions with attorneys, and kitchen table conversations.
7. Break the barrier of silence by bringing the subject of advance care planning into routine intake and assessment appointments. Add questions related to selection of a healthcare proxy to paperwork completed during the initial visit.

Linda Lewis, former hospice chaplain and currently Project Coordinator for *Faith In Action* End of Life Care Ministries at the Hospice & Palliative CareCenter in Winston-Salem, North Carolina, sums it up well:

> *"What used to be the moment of death when life ended fairly abruptly and quickly, has now become, in many cases, the season of death. Ventilators, feeding tubes, artificial hydration, dialysis, and even antibiotics can prolong the inevitable, meaning that the dying process may take weeks or months, or as in Terri Schiavo's case, even years.*

The dialogue has to be more than, "I don't want to live like a vegetable." What is it that makes life meaningful? What would I want my family and other decision-makers to know about me should I be unable to communicate my wishes? Encouraging people to complete Advance Directives is important, but these documents are of little use unless open and reflective conversation has taken place with those who may be faced with making crucial decisions in a time of crisis.

This is not just about "autonomy," the ethical principle that has guided most of the discussion around these issues in recent years. It is not just about "what I want." Who will be the one to speak for me when I cannot speak for myself? What does that person need to know about my values and my feelings about life? How can I have conversations now that will pave the way for wholeness and community when a crisis occurs? Personal wishes need to be discussed in the context of community, recognizing that others will be involved in carrying out wishes and will be affected by decisions that are made. Meaningful conversations with loved ones before a crisis not only help make medical decisions easier down the road; they can also strengthen relationships and create bonds as life values are shared openly and honestly."

Too many people are dying in ways they would not choose simply because they did not talk about it ahead of time. Physicians can only honor patients' wishes if they know what those wishes are. Encourage the conversation.

Deaths Among North Carolinians Age 85 and Older

According to the United States Census Bureau, the nation's population age 85 and older is projected to increase from 4.5 million in 2002 to 9.6 million in 2030. North Carolinians also are living longer and dying later in life than in the past. In 2002, there were 17,739 deaths of North Carolina residents age 85 and older. This represented 25% of all 71,780 deaths of North Carolina residents during 2002. By comparison, deaths to persons age 85 and older were 14% of all deaths in 1980.

In 2002, there were 1,938 deaths of persons at exactly age 85, and the number declined steadily at each single year of age, with 238 deaths of persons age 99. There were 461 deaths of persons age 100 and older in 2002, with the oldest reported age at death being 113 (one death).

Of the deaths of persons age 85 and older, 70% were female and 30% were male. Seventy-four percent were widowed and 19% were married at the time of death. Men age 85 and older who died were much more likely to be married than women: 48% compared to 6%. For deaths of North Carolina residents of all ages, 51% were female and 49% were male; 38% were widowed, 40% were married, 11% were never married, and 10% were divorced. Fifty-eight percent of decedents age 85 and older had less than a high school education, compared to 47% of decedents of all ages.

Persons age 85 and older are much more likely to die in a nursing home. Among deaths of those age 85 and older, 42% occurred in a nursing or rest home, 39% in a hospital, and 16% in the home or not in an institution. For deaths of North Carolina residents of all ages in 2002, the comparable percentages are 20%, 50%, and 23%. Cremation occurred for 15% of the deaths of persons age 85 and older, compared to 19% for North Carolina resident deaths of all ages.

Following are the ten leading causes of death in 2002 for persons age 85 and older:

Cause of Death	Number of Deaths	% of Total Deaths
Heart disease	5,616	32%
Stroke	2,005	11%
Cancer	1,987	11%
Alzheimer's disease	1,124	6%
Pneumonia and influenza	863	5%
Chronic lung disease	711	4%
Diabetes	411	2%
Nephritis and nephrosis	394	2%
Non-motor vehicle unintentional injuries	384	2%
Septicemia	305	2%
All other causes	3,939	22%
TOTAL	17,739	100%

For persons age 85 and older, heart disease and stroke accounted for 43% of the total deaths in 2002, compared to 33% for persons of all ages. Cancer deaths were 11% of the total for persons ages 85 and older, compared to 23% for deaths of persons of all ages. Alzheimer's disease accounted for 6% of deaths of persons age 85 and older, compared to 3% of deaths in the total population.

Infant Mortality in North Carolina

To The Editor:

I have just reviewed the May/June 2004 issue on Infant Mortality. It is very well done. In particular, the article on folic acid by Robert Meyer and Anna Bess Brown was of particular interest. It is nice to know that some of one's efforts pay off. I chaired the Food and Drug Administration (FDA) Food Advisory Committee (FAC) that recommended folic acid fortification of cereal grains. This was a very controversial issue for two reasons. The first concerned the principle of whether the FDA should order the "artificial" modification of "natural" foods. The second was more substantial and was concerned with how much folic acid should be added. The issue was to not increase it so much that Vitamin B12 deficiency was masked in the elderly since the elderly consume more cereal grains than young women. Hence, the final level will not meet the 40mcg. needed in young women. In spite of this final decision, it is clear that folic acid fortification of cereal grains is having an effect.

(The writer was Assistant Secretary for Health, United States Department of Health and Human Services under President Ronald Reagan.)

To The Editor:

I read with interest the article, "Demand for CME Programs on Cancer Care Among Primary Care Physicians in North Carolina," published in the May/June 2004 issue of the *North Carolina Medical Journal.* As a Continuing Medical Education (CME) provider for one of the North Carolina Area Health Education Centers (AHEC) organizations, we survey physicians in the 16-county western region of the state each year, and our survey results support the findings of Dr. Anderson, Dr. Torti, and their research associates and assistants at Wake Forest University School of Medicine.

In response to our regional survey in the fall of 2003, we began last spring to plan a CME conference to address primary care physicians' concerns and the clear need for updated information. I am pleased to report that the Lineberger Comprehensive Cancer Center at UNC-Chapel Hill responded to our need, and the conference is scheduled October 8 and 9 at Fairfield Mountains, Lake Lure, NC.

Dr. Beverly Mitchell, Associate Director of the Lineberger Comprehensive Center, is serving as the medical course director of Early Detection, Screening, and Detection of Malignancies —A Cancer Update for Primary Care Providers. She will be joined by six of her colleagues, and the topics will include updated information on cancer of the breast, colon, lung, prostate, and skin, as well as discussions on hematological and central nervous system malignancies.

I encourage interested primary care physicians who would benefit from the October conference to visit our website www.mtn.ncahec.org for more information.

I extend my thanks to you for highlighting a pressing educational need in your journal.

Sincerely,
Irene D. Jurczyk,
Co-Director Continuing Medical Education
Mountain Area Health Education Center (MAHEC)
Asheville, NC

The North Carolina Institute of Medicine

Since January 2002, Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 when the North Carolina Medical Society reached the decision to cease support for its publication. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

North Carolina Medical Journal: Call for Papers

Herbert G. Garrison, MD, MPH
Scientific Editor, North Carolina Medical Journal

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The *Journal* seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The *Journal* is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

Physician Assistants… *Assisting* is Just a Drop in the Ocean.

Physician assistants are licensed health care professionals who practice medicine with physician supervision. As integral members of the physician-directed team, PAs increase access, enhance quality, and are cost-effective.

Hunter A. Hoover, M.D. (left) and his PA, Ray Brown, PA-C, act as a team to diagnose and treat their patients at Charlotte Eye, Ear, Nose & Throat Associates.

"Having practiced with and without physician assistants, I am impressed by the positive impact they make not only in the quality of life of my patients, but also in my own quality of life."

Hunter A. Hoover, M.D.

Physician Assistants can help you in your practice, too! For more information on what a PA can do for you, your patients, and your practice, or to learn how to hire a PA, please contact the North Carolina Academy of Physician Assistants.

A partnership that's working for eastern North Carolina

Bariatric surgery: Team approach wins national acclaim

Bariatric surgery is offered at Pitt County Memorial Hospital in conjunction with the Surgical Obesity Program at the Brody School of Medicine at East Carolina University and in partnership with private practice physicians in Greenville. Last year, the National Institutes of Health designated our program as one of six centers that will work cooperatively on research into the surgical treatment of obesity. More recently, the surgeons who practice bariatric surgery at PCMH have been recognized as a Center of Excellence by Blue Cross / Blue Shield of North Carolina.

The Brody School of Medicine Obesity Program, which has been offered here for 24 years, has developed a nationally recognized protocol that incorporates extensive preliminary screening and lifetime follow up by a multi-specialty team including psychiatrists, nutritionists and medical counselors. Bariatric surgery has proved particularly effective in reducing the effects of diabetes in morbidly obese patients. The Brody School of Medicine and University Health Systems are working together to make things happen — in the community, in the region and in the state.

your fastest path to payment

Sick of the claims paperwork? Ready for an all-payer web-based solution?

Blue Cross and Blue Shield of North Carolina is always on the lookout for new ways to speed and simplify the claims filing process for our participating physicians and other health care providers.

That's why we're excited to announce that physician practices of all sizes can take advantage of instantaneous, electronic claims submission under an innovation developed by RealMed, a business partner of BCBSNC.

Now, you can "virtually" print and instantly transmit claims to all payers in less time than it takes to stuff envelopes — all with the push of a button.

RealMed's Print Exchange does what its name implies — it changes your workstation's print instructions into electronic claim filings. Using a single, simple process you can instantly transmit claims to all payers — not just to BCBSNC — eliminating posting and handling costs and greatly speeding payment.

Call ReadMed today to find out how easy and affordable it is to submit all claims to all payers, verify eligibility and claim status, automatically check errors, adjudicate claims, receive payment and eliminate your paper — all while being HIPAA compliant.

Find out more at 1-877-REALMED or **www.realmed.com**.

For more than 70 years, our members and providers have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's dependable and reliable health insurer. Learn more at **bcbsnc.com**.

Innovative health care designed around you. | *bcbsnc.com*

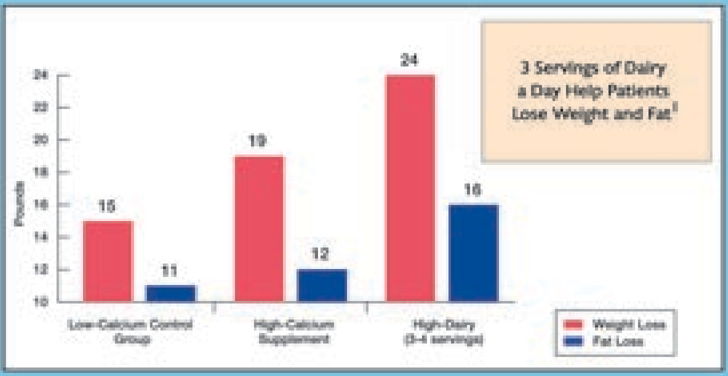
"...we have revolutionized the products of healthcare, ...but we have not changed the fundamental process of providing care."

Milk, Cheese, and Yogurt May Help Your Patients Lose More Weight

Dairy foods, including milk, cheese, and yogurt, do more than build strong bones. Research shows 3 daily servings of dairy foods may actually improve your patients' weight- and fat-loss results when part of a reduced-calorie diet.[1,2]

The mix of essential nutrients found in dairy foods, including calcium and protein, appears to improve the body's ability to mobilize and burn fat.[3] A recent study published in *Obesity Research* showed that people on a reduced-calorie diet who consumed 3 servings of milk, cheese, or yogurt each day lost significantly more weight and more body fat than those who consumed calcium supplements or just cut calories while consuming little or no dairy.[1]



Recommend that your patients include 3 servings of dairy foods a day in their weight-loss plans and advocate a healthy lifestyle that includes ample physical activity. The dairy case has a wide variety of reduced-fat, lowfat, and fat-free products to choose from to fit your patients' reduced-calorie eating plans.

For more information about the important role dairy foods play in weight loss, visit www.3aday.org.

To download a FREE Healthy Weight Education Kit, including materials appropriate for distribution to patients, visit www.nationaldairycouncil.org.

GUEST EDITORS' INTRODUCTION

Quality of Care and Performance Improvement:

An Important New Emphasis Whose Time Has Come

Lawrence M. Cutchin, MD, and Clyde L. Brooks, Jr., MD

Background

In December of 2003, the North Carolina Medical Society (NCMS) appointed a Task Force on Quality of Care and Performance Improvement. The NCMS Task Force, consisting of 13 members and six consultants, is charged with "recommend[ing] actions the NCMS [could] take to expedite the employment of available resources to address documented problems with care quality and patient safety in North Carolina." The Task Force has met on a number of occasions since its initial appointment and has reviewed the literature on quality of care and perfomance improvement, looking at the national experience as well as experience in our own state. The Task Force has discussed the range of actions that the North Carolina Medical Society could take to create a safer and more effective healthcare delivery system for our patients. The Task Force is submitting a white paper with specific recommendations on the subject to the North Carolina Medical Society this fall.

At the invitation of the Editor of the *North Carolina Medical Journal*, the Task Force summarized some of the principal themes developed during its early work. Members of the Task Force are contributing papers to the *North Carolina Medical Journal*—papers designed to share these ideas and themes with a broad spectrum of healthcare professionals, healthcare organizations, and policy makers in our state. We hope that these writings will serve as a basis for further discussion of how North Carolina physicians can work in partnership with others to elevate the safety and effectiveness of care available to the citizens of North Carolina.

A Philosophical Perspective on Quality of Care and Its Improvement

From the outset, the Task Force was concerned with a few central ideas that are well described in various literature:

(1) Insofar as there exists a body of knowledge from which medical decisions should be made, there is a presently a lack of consistent application of this knowledge in clinical practice. This is known as the knowledge-practice gap. Clearly any action recommended by the Task Force must incorporate ways to address this issue.

(2) The Task Force was concerned with national (and state and local) publicity related to the volume of errors occurring in routine medical care (particularly since the publication of the national Institute of Medicine report, *To Err is Human*, in 2000).[1] This has raised feelings of alarm and distain among the general public. The publicity has also spawned expectations that healthcare professionals and provider organizations will take specific steps to ensure that these systematic errors are minimized or eliminated. Task Force members recognized the effort to reduce the frequency of errors as an essential component of overall system performance and care quality and that Task Force recommendations must address this issue.

(3) The Task Force has taken the view that quality of care is a broader concept than simply the issue of errors or adverse events (safety). The effectiveness of healthcare delivery—the extent to which desired patient outcomes are achieved—is the other side of the quality coin. The Task Force's recommendations will address the extent to which the delivery of healthcare in general, and the practice of medicine by physicians in particular, achieve desired outcomes. To that end, the Task Force will recommend some initiatives aimed at improving the decisions and actions of practicing physicians.

(4) The Task Force is aware of recently documented care quality deficiencies in the United States, as well as disappointing efforts to address these deficiencies through interventions

Lawrence M. Cutchin, MD, is President and CEO of Health Care Savings, Inc. in Raleigh, NC. He is also the current president of the North Carolina Medical Society and appointed the Task Force on Quality of Care. He can be reached at lcutchin@healthcaresavings.com and PO Box 27987, Raleigh, NC 27611. Telephone: 919-828-1789.

Clyde L. Brooks, Jr., MD, is the Director of the Office of Quality at Pitt County Memorial Hospital in Greenville, NC. He is also a member of the North Carolina Medical Society and chairs the Task Force on Quality of Care. He can be reached at cbrooks@pcmh.com. Telephone: 252-816-4633.

targeted to either individual practitioners or care delivery systems. For example, McGlynn, et al.[2] recently presented data to show that United States adults receive only about half of the recommended care for a group of common acute and chronic conditions and preventive services (a *process* indicator of care quality). Comparisons of key quality of care indicators delivered in 12 United States metropolitan communities show that for 439 indicators across 30 conditions and types of preventive care (representing 52% of the reasons adults use ambulatory care services in this country and 46% of the reasons for which they are hospitalized), on average, adults in these communities were receiving 50 to 60% of the recommended care. These studies, which found considerable variation among communities studied, indicate that there are significant quality differentials among communities with regard to these indicators of service "omission" for which there is solid evidence of appropriateness. Our own North Carolina Teachers' and State Employees' Comprehensive Major Medical Plan has recently disseminated data showing that there are substantial numbers of North Carolina state employees, dependents, and retirees with diagnosed chronic diseases for whom standard, evidence-supported healthcare services are not being provided. Medical Review of North Carolina (MRNC) has shown similar findings with respect to patients discharged from North Carolina hospitals following a myocardial infarction. Clearly there are reasons to examine the patterns of such services for defined clinical entities. It is important to ascertain the extent to which explicit services covered by standard health insurance plans are not provided, even though there is substantial evidence of their appropriateness and effectiveness in the care of specific patients.

(5) The Task Force recognized that there are arguments with the current emphasis on evidence-based approaches to medical practice, particularly as this movement has led to the promulgation of so-called "clinical guidelines" pertaining to the care of patients with particular conditions or diagnoses by various professional, third-party, and governmental agencies. Even so, few can deny the merit of disease management strategies. These strategies have attempted to encapsulate clinical guidelines in an organized and cost-effective strategy for managing the care of large numbers of individuals who have similar clinical diagnoses/conditions and for whom it is possible to standardize both the patterns of healthcare encounters, related services, and pharmaceutical usage. Despite these advances, the fact remains that there is a substantial lack of evidence, by any criteria used, to evaluate the effectiveness of many of the treatments and strategies for disease management in use today. Hence, there is a continuing need for the development of the clinical evaluation science base of contemporary medical practice. The fact that randomized, placebo-controlled research evidence does not yet exist (or perhaps cannot ever be developed) to support every clinical procedure or maneuver does not mean that clinical decision making has to sit idly by and remain non-responsive to the needs of patients. But, where such evidence is available, or where it can be amassed, it should be used to shape the clinical decisions of those on the frontlines of medical practice.

(6) The Task Force took heart from recent reports from studies in the United Kingdom and elsewhere indicating that for those clinical procedures *actually performed* or prescription medications *actually ordered*, the majority seem to be procedures and prescriptions for which there is evidence from randomized, controlled trials or convincing non-experimental evidence with high consensus among clinicians that these procedures or treatments are actually "evidence-based." for example, Mulligan, et al., reported in *The Lancet* that a *post hoc* analysis of 100 consecutive patients in a single medical ward in Oxford, England found 82% of the patient management interventions "...were based on high quality scientific evidence."[3]

Similar retrospective findings have been reported from internal medicine departments in Canada,[4] for dermatology outpatients in Denmark,[5] hematology-oncology clinics in the United States,[6] and thoracic surgical practice in Buffalo, New York.[7] The literature is rapidly growing in this regard, and these are only illustrative of the range of clinical situations where evidence-based approaches have been shown to be implemented. The point is: though the conduct of randomized clinical trials of every procedure or maneuver in medicine and surgery is a practical impossibility, there is substantial data available to show that not only is there a growing body of literature offering evidence of effectiveness of common medical and surgical procedures, but there are also data to show that the procedures being performed are ones for which there is supporting evidence of effectiveness.

The Value of Quality Improvement

The Task Force grappled with the question of establishing the *economic value* of quality improvement (the so-called "business case" for quality). This question comes up most often in discussions among purchasers of group health insurance (e.g., large employers) or among insurers themselves who ask whether investments in quality improvement programs or initiatives yield a financial benefit to those who either purchase or insure healthcare for defined beneficiary populations.

The Task Force believes that despite the difficulties of establishing the "business case" for quality improvement, the fact that there are usually clearly demonstrated health and economic benefits to those served constitutes a sound reason for the North Carolina Medical Society to lead the way in promoting the improvement of quality of care and the performance of healthcare systems in our state. We plan to do so in the interest of benefiting the health and healthcare available to all North Carolinians.

This special issue of the Journal begins with a two substantial Issue Briefs. The first is prepared by prepared by two colleagues affiliated with Medical Review of North Carolina, the federally-designated Quality Improvement Organization (QIO) serving

North and South Carolina. Drs. Meera Kelley and Ross Simpson have offered a comprehensive overview of key health policy issues surrounding the problems of quality improvement and assurance. The second is by Drs. Sharon Hull, Leila Kahwati, Elizabeth Kanof, and Ms. Jennifer Proko. It offers a detailed discussion of how considerations of quality may be integrated with mainstream clinical practice in primary care. Their reviews are followed by papers on: data and information systems essential to quality improvement by Mr. Robert Weiser and Dr. Christopher Mansfield; evidence-based medicine by Drs. Charles Willson and Hadley Callaway; disease management approaches to quality improvement by Drs. John Mangum and Conrad Flick; educational programs addressing quality of care by Drs. Stephen Willis, Thomas Pulliam, and Thomas Bacon; efforts to make quality of care efforts "patient-centered" by Drs. Allen Dobson and Michelle Jones; and a summary paper on how quality of care and performance improvement efforts are mutually reinforcing by Drs. Noel McDevitt, William Walker, and Gordon DeFriese.

We are grateful to the authors of the papers appearing in this special issue of the *North Carolina Medical Journal*, most of whom are members of the Task Force on Quality of Care and Performance Improvement appointed a year ago. The preparation of these papers, and the deliberations which have led to their collection in this issue of the Journal, reflect the intensity of interest among these Task Force members, but also provide a template and a roadmap for further quality improvement initiatives taking place in our state. **NCMJ**

ISSUE BRIEF

Quality of Care and Health System Performance:

Where Are We Now? Where Should We Be Going? Who Can Take Charge and Lead Us There?

Meera A. Kelley, MD, and Ross J. Simpson, Jr., MD, PhD, MPH

Where Are We Now?

We have observed tremendous advances in healthcare during the past century. Between 1900 and 2000, life expectancy in the United States increased from 46.3 to 73.9 years for a man and from 48.3 to 79.4 years for a woman. Significant developments include vaccines, antibiotics, modern surgery, anesthesia, and treatments for chronic conditions such as diabetes and hypertension—just to name a few.

In the face of these dramatic improvements, however, there is considerable concern about the safety and quality of our current healthcare system. The concerns with healthcare quality focus on medical errors, underuse and overuse of diagnostic tests and therapies, and waste of resources. Medical errors reflect unintended actions, such as the wrong drug being given to a patient. Underuse of therapies, which can also be termed "errors of omission" reflect lack of use of recommended care, such as use of beta-blocker medication for patients with a heart attack. Overuse of certain aspects of care is suggested by the significant geographic variability across the United States in resource utilization (e.g., the cost of care for the average patient), and in rates of certain procedures such as hysterectomy. Finally, waste reflects the all-too-common repetition of tests and services such as x-rays or CT scans when patients receive care at different sites.

Errors

"Medical errors" include events in which an unintended action was performed, an intended action was not performed, or an intended action was performed incorrectly. Not all errors result in a negative outcome for the patient—indeed, most do not. Similarly, not all bad outcomes result from medical errors; "adverse events" are occurrences that are deleterious to the health of the patient and may or may not result from an error. A patient with no history of drug allergy, for example, who develops a severe rash when prescribed an appropriate therapy experienced an "adverse event," but not a "medical error." The focus on medical error reduction is to minimize the opportunity for adverse events that result from medical errors—these are termed "preventable adverse events."

The 1999 national Institute of Medicine's *To Err is Human*[1] reported that 44,000-98,000 people die in United States hospitals each year as a result of medical errors. While the precise number has come under considerable scrutiny, certainly the true number is "too many," and the number of people hurt non-lethally is likely to be much, much greater than the number who actually died. Adverse drug events are common in hospitalized patients, with 2-35% of patients having such events, and cause over 7,000 deaths per year. Over two million nosocomial (hospital-acquired) infections occur per year in United States hospitals. As previously suggested, not all adverse drug events or infections acquired in the hospital are preventable.

Variability

Healthcare delivery varies considerably across our country. Among Medicare beneficiaries, for example, spending per enrollee in 1996 in Miami, Florida was $8,414, while in Lynchburg, Virginia it was $2,829. The chance of being hospitalized when a person dies in Newark, New Jersey was 49%, while in Boulder, Colorado it was 19.9%. The likelihood of spending greater than seven days out of the last six months of life in an intensive care unit in Munster, Indiana was 25.5%, while in Eugene, Oregon it was 2.9%. Finally, the chance of getting aspirin upon discharge from the hospital after a myocardial infarction in Mason City, Iowa was 96%, while in San Luis Obispo, California it was 52%.[2] Interestingly, states with higher

Meera A. Kelley, MD, is a clinical coordinator for Medical Review of North Carolina. She is also a Clinical Associate Professor of Medicine in the Division of Infectious Diseases at the University of North Carolina at Chapel Hill. She can be reached at mkelley@ncqio.sdps.org or CB# 7030, Chapel Hill, NC 27599-7030. Telephone: 919-966-2536.

Ross J. Simpson, Jr., MD, PhD, MPH, is a Principal Clinical Coordinator of Medical Review of North Carolina. He is also a Professor of Medicine in the Division of Cardiology at the University of North Carolina at Chapel Hill. He can be reached at rsimpson@ncqio.sdps.org or CB# 7075, Chapel Hill, NC 27599-7075. Telephone: 919-966-5208.

Medicare spending actually seem to receive lower-quality care. States with more general practitioners use more effective care and have lower spending, where states with a higher proportion of specialists have higher costs and lower quality as measured by specific process of care criteria.[3]

Underuse of Standard Treatments

Overall in the United States, the proportion of patients receiving the recommended care for prevention, acute treatment, and chronic care is approximately 55%.[4] Beta blockers following acute myocardial infarction, testing for hemoglobin A1C in patients with diabetes, administration of vaccines for pneumococcus and influenza, anticoagulants for stroke prevention in patients with atrial fibrillation, mammography screening, and smoking cessation counseling are often not used in appropriate patients.

Overuse

There is a growing consensus that certain diagnostic tests, drug therapies, and surgeries are overused. These include hysterectomies, cardiac catheterizations, cardiac bypass surgery, pacemakers, and the use of sedatives and antibiotics. For example, antibiotic prescriptions for sore throats, which are commonly caused by viral infections that are not responsive to antibiotics, are prescribed in over 60% of encounters. By expert panel review, over 40% of hysterectomies, coronary bypass surgeries, and coronary angioplasties are either inappropriate or of questionable utility.[5]

Waste

Our healthcare system is inefficient. Duplicate history taking, complex billing requirements, incomplete or missing patient records, and unnecessary reports all contribute to added costs and decreased patient satisfaction. In addition, patients seeking care from multiple institutions often face duplication of tests due to lack of availability of prior ones.

Comparison of Consumer Perceptions in the United States with Those of Other Industrialized Nations

The goals for healthcare in the 21st century suggested by the 2001 national Institute of Medicine report, *Crossing the Quality Chasm*,[6] are for healthcare to be: (1) safe, (2) effective, (3) patient-centered, (4) timely, (5) efficient, and (6) equitable. The Commonwealth Fund conducted international health policy surveys measuring these six factors.[7,8] The 2001 International Health Policy Survey sponsored by the Commonwealth Fund included 1,400 adults and the 2002 International Health Policy Survey included a sample of 750 from the United States, United Kingdom, New Zealand, Australia, and Canada. Subsequent comparisons among the countries surveyed in these healthcare quality priority dimensions revealed the following:

(1) ***Safety:*** The United States ranked last. The United States had the highest reports of medication errors (receiving the wrong medication or dose over the past two years), and patients who were most likely to say a medical mistake was made in their treatment.
(2) ***Effectiveness:*** The United States tied for last. The United States had more patients not getting a recommended test, treatment, or follow-up due to cost, and was last in patients not filling a prescription due to cost.
(3) ***Patient-Centered:*** The United States ranked second to last. The United States ranked last (tied with the United Kingdom) on physicians spending enough time with patients and last on physicians listening carefully to patients' health concerns.
(4) ***Timeliness:*** The United States ranked third. The United States was the best on hospital admission waiting times, but next to last on waiting five days or more for a physician appointment when patients last needed medical attention.
(5) ***Efficiency:*** The United States ranked last. The United States was last on being sent for duplicate tests by different healthcare professionals, and worst on not having medical records or test results reach a doctor's office in time for appointment.
(6) ***Equity:*** The United States ranked last for lower-income patients. The United States was worst on patients having problems paying medical bills and worst on patients being unable to get care where they live.

How Did We Get Here?

Despite the dramatic scientific advances we have seen over the past century, the way we deliver care for patients has not changed significantly. In other words, we have revolutionized the *products* of healthcare—medications, interventions, etc., but we have not changed the fundamental *process* of providing care. The physician-patient encounter still remains as the hub of American healthcare, with essentially all care orchestrated by the physician.

In our current environment, this method of delivery poses two serious challenges. For one, in order to provide the best, guideline-based evaluations and therapies at the time of the patient encounter, the sheer volume of information that the physician must have is staggering. As of July 2004, the National

> *"Physicians face numerous interruptions, distractions, and required activities that are not critical to the actual care of the patient."*

Guidelines Clearinghouse contained 1,329 individual guideline summaries.[9] Patients today take significantly more medications than even five years ago, with new drugs developed all the time.

Second, providing care itself is much more hazardous than in the past. Physicians face numerous interruptions, distractions, and required activities that are not critical to the actual care of the patient. Just a few examples include documentation for billing that is not essential to the care of the patient, administrative demands from the practice and hospital, health plan programs with redundant and distinct safeguards, such as prior authorizations and post-payment audits, and inconsistent formularies across plans so that the physician cannot, as a routine, simply write for the medication he or she feels is most appropriate and has experience with. Therefore, the resources needed at the time of the patient-physician encounter have increased, while the time actually available for focused, uninterrupted interaction has decreased.

How Do We Build a Better Health System?

Given how complex our healthcare system is, there will be no single easy solution. One key component that will be essential is the consistent availability of information on how we are doing. Without this ongoing information, attempts to determine effective solutions will be unsuccessful and highly inefficient. How do we know where we are now and how will we know if a change has resulted in improvement? We need a practical way to measure quality that results in data that are meaningful; that is, data which are based on sound scientific evidence and are clinically important.

How Do We Measure Quality?

In order to measure quality, several things need to be in place. Easily available and accurate health data are a necessary requirement as standards for care norms and appropriate or achievable outcomes for patients are agreed upon.

There are three types of quality of care measures: structure, process, and outcome measures. Structural measures include capacities, technologies, and infrastructure, such as telecommunications, a management information system, and staffing, which may affect outcomes. Structural measures may also include the credentials (e.g., board certification) of healthcare providers. Outcome measures include adverse events that happen to patients like death and readmission to a hospital. These events are the ones physicians often find easiest to relate to and understand. Process measures include the procedures to assure the appropriate use of diagnostic tests and therapeutics.

Quality of care can be measured through assessment of appropriate outcomes and by the processes of care delivered to patients. Facility licensing and accreditation, for example, usually rely on structural measures of quality. Requirements range from rooms size and sanitation to fire detection and staffing (both numbers and credentials). Facilities and support systems must be physically adequate to uphold the provision of quality care.

Outcome measures are the end results of particular healthcare practices and interventions that patients feel and recognize. Poor outcomes are obviously events like death or serious complications that might lead to hospital readmissions. Studies of outcome measures can lead to decisions about where a patient can be treated. If the patient has pneumonia and can be treated at home, that could reduce treatment costs. Or, if there is not a cure, outcomes research can provide information that may help improve a patient's quality of life.

Process measures reflect actual care provided to a patient. Examples of a process measure include timely administration of beta blocking drugs to appropriate patients recovering from a myocardial infarction, and regular testing of blood lipid levels and hemoglobin A1C levels in patients with diabetes.

Neither structure, process, nor outcome measures are inherently better for measuring quality as each type has its own advantages and disadvantages, and quality of care projects often include all three types of measures. For example, outcome measures are often influenced by factors outside the healthcare system and are often not amenable to direct improvement. Process measures are most likely to be under the control of the healthcare system and amenable to change. However, their link to improved health may not always be obvious. For example, a hospital's rate for administering a beta-blocking drug to patients who do not have contraindications to these drugs is an important process measure of good care, but it may be difficult to show that improving this single process of care results in an improved outcome of lower death rates following discharge. Quality of care requires efforts in the assessment of multiple processes of care and outcomes that are linked to these processes.

Good measures of healthcare quality share several key attributes. They must be accurately measured; there must be consensus that the measure is important for health; and there must be room for improvement and established approaches to improve the measure. Health information might be in the form of administrative data, such as claims data or information that can be obtained or abstracted from medical records. There must be agreement in the medical community on the type of care that is appropriate for patients with the medical condition under study. Typically, information from randomized trials and expert panels are utilized to identify populations and treatments appropriate for the specific disease. Most importantly, there must be accepted interventions available to improve the measure. The key factor offering the promise for improving care is developing and implementing change. Such interventions often include performance reports in which an individual hospital's or physician's ratings of key care indicators are compared to appropriate normative data. Increasingly, more specific interventions (e.g., care maps or plans, standardized discharge orders, or educational material) are developed and disseminated as part of the program.

What Is Happening on a National Level?

Several national organizations have committed to stimulate the necessary changes in healthcare quality. These key organizations include the Centers for Medicaid and Medicare Services (CMS), the National Quality Forum (NQF), the Agency for Healthcare Research and Quality (AHRQ), the Joint

Commission on Accreditation of Healthcare Organizations (JCAHO), the American Health Quality Association (AHQA), and Quality Improvement Organizations (QIOs).

Making quality of care information available to the public has become an increasing priority among these groups. CMS began a national effort to make information on quality of care in nursing homes public in 2002, home health agencies in 2003, hospitals in 2004, and is expected to release physician-level practice quality data in the next few years.[10] Expectations of accountability and openness about the care provided are likely to expand. In addition, Blue Cross Blue Shield and the Centers for Medicaid and Medicare Services are examples of organizations trying models of "pay for performance"—that is, rewarding providers of better care with increased payment.

How Do We Begin to Develop a Healthcare System that Is Safe, Effective, Patient-Centered, Timely, Efficient, and Equitable?

In order to create a better and higher quality healthcare system, information must be readily accessible at the time of the patient encounter. Communication across healthcare settings—hospitals, offices, nursing homes—will have to be efficient and effective. Giving the patient all his or her own basic health history in a concrete format (written or electronic) is one initial step to assist with knowledge transfer. Finally practice complexity must be minimized through the use of standardized, simplified communication—for exchange with health plans, for sharing of information across different healthcare settings and systems, and for improved education and empowerment of patients in their own care. Many of these goals will be more readily achieved through the widespread incorporation of electronic health records.

Physician Culture

The other major shift that will be required is a change in the culture in which we practice—our way of thinking about how care is best delivered, and who is responsible for the results. Traditionally, physicians have been trained to work and think independently, to maintain knowledge through the use of their memory—to avoid the use of crutches, "cookbooks," or checklists; and to appreciate the variation among patients and the necessity of a tailored approach. Instructions of the physician were expected to be followed by other healthcare workers and even patients, without questioning. In order to change our culture, we as physicians must begin to think of ourselves as members of a healthcare team—a team that involves nurses, pharmacists, social workers, therapists, many other healthcare workers, and, importantly, the patient. We must recognize the limitations of our memory and encourage the reliance on readily available, up-to-date clinical information, and check lists to ensure that each patient receives every step of recommended care and so that medication interactions and errors can be better avoided. We must also encourage input from the various members of the team, including the patients, if these goals are to be achieved.

This new culture does not undermine the physician's role. The physician still performs those critical aspects of care that only he or she as a member of the team is trained to do—assess patients, direct major aspects of therapy, perform procedures or interventions, and communicate with the patients. Indeed, by limiting the roles to those things that only the physician can do, the physician-patient interaction once again can become the center, can be strengthened, and distractions, which include concerns about medical errors, will be minimized.

No longer can we afford to rely solely on the physician to ensure all aspects of care. We must set up systems of care that include the various members of the team—each empowered to do that which he or she is trained to do according to protocols, which are often predetermined. While physicians cannot be solely responsible for each aspect of care, given our clinical training and experience, we must lead the changes—the new systems.

Some Examples of Successes

For the past two decades, many national organizations, led by the Health Care Financing Administration, now the Centers for Medicare and Medicaid Services (CMS), have been actively involved in healthcare quality improvement. Such efforts began with the use of implicit criteria for case review of individual medical records by peer physicians and have progressed to explicit review of quality using standardized epidemiological and educational methods. Specific diseases with specific indicators were identified and compared across providers. The improved use of warfarin in the prevention of stroke in patients with atrial fibrillation, decreasing the delay time in administration of antibiotics in patients with pneumonia, and the administration of ACE inhibitors in patients with heart failure occurred as the result of these efforts.

These data-based activities were effective in improving key processes of care in specific diseases. However these projects were limited by the extensive costs and delays inherent in the collection, analysis, and feedback of this information to providers. Most importantly, the interventions used to improve care were limited by the efforts involved in data collection, and these efforts could not encompass the full range of modern interventions. Current efforts focus less on data collection and more on public reporting and specific educational interventions. Future efforts will focus on use and support for electronic health records, increased focus on outpatient care rather than care provided in the hospitals, and active steps to support and encourage widespread culture change to support quality care. Quality Improvement Organizations (QIOs), like Medical Review of North Carolina, are expected to provide active support for these programs.

First steps

Donald Berwick, MD, likely the most prominent leader in the healthcare quality improvement movement, suggests that in order to change the system, three preconditions seem helpful;

to face reality, to seek new designs, and to involve everyone. Facing reality means looking honestly at the weaknesses in our current system. New designs will be essential for success. We must involve everyone on the healthcare team—including patients—to create the new vision and to develop solutions.

As individual physicians we can take one step, now, to look at weaknesses in our practice settings. For the primary care physician, this may include examining a small proportion of charts of patients with diabetes mellitus and assessing the frequency with which the recommended steps of care were met. For a hospital physician, contacting the quality improvement department will readily generate performance data for some common, significant medical conditions. Nursing homes and home health agencies also have extensive data on care for the current national priority conditions.

We can also empower our patients with knowledge of their health conditions and treatments. We can acknowledge to them that the system is far from perfect. We can encourage them to take an active role in their own care, to ask questions, and to bring a friend or family member with them when they are hospitalized to help gather and process the information and care provided.

Some in healthcare assume that we as individuals can wait for the system to be changed, that somehow there will occur sweeping, broad, systematic changes across the United States. This assumption is incorrect. Past experience reveals that models of success have been developed by small groups of people working together, trying something new. Margaret Mead put it best; "Never doubt that a small group of thoughtful, committed citizens can change the world. Indeed, it is the only thing that ever has." **NCMJ**

ISSUE BRIEF

The Practice of Quality:
Incorporating High-Yield Strategies into the Daily Reality of Medical Practice

Sharon K. Hull, MD, Leila C. Kahwati, MD, MPH, Elizabeth P. Kanof, MD, and Jennifer P. Proko, RN, CHCQM

Introduction

Today's physician is expected to incorporate clinical guidelines, increasing numbers of preventive services, and patient safety concerns into the realities of the day-to-day practice of medicine, regardless of specialty.[1-4] Fifty years ago, the concepts of "utilization review," "best practices," or "patient safety" were virtually unheard of, and the field of preventive medicine was in its infancy (though great strides in sanitation and other public health issues had been made by the early 1900's). As medicine progressed during the latter half of the 20th century, physicians were increasingly asked to be mindful of the costs and effectiveness of healthcare. With the increased oversight of therapeutic interventions, particularly by the Food and Drug Administration (FDA) in the United States, significant emphasis was given to the safety of particular medications and medical devices. As we enter the 21st century, physicians now must to be aware of patient safety and quality issues at both the individual patient and the systems of care levels. Third party payors are increasingly linking quality of care and safety measures to reimbursement and privileging decisions, holding physicians and corporate healthcare systems accountable for their practice in new ways.

> *"Today's physician is expected to incorporate clinical guidelines, increasing numbers of preventive services, and patient safety concerns into the realities of the day-to-day practice of medicine, regardless of specialty."*

It is challenging to incorporate quality improvement into our primary care delivery system. The value of quality care is obvious, but methods for measuring it and for improving it are not so easily determined, nor is it familiar territory to most practicing physicians. A number of difficulties arise in simply measuring quality in healthcare. These include the balancing of stakeholders' perspectives, developing a framework to enforce accountability, development of clinical criteria, choosing the indicators to be reported publicly, addressing the ethical and other conflicts between reimbursement and quality, and development of information systems to support the collection and analysis of quality data.[5] It is also important that measurement of quality take into account outcomes that matter to patients, such as pain relief, improved functional ability, and relief of emotional distress. Despite the challenges, however, the potential exists for this evolving concern about quality to lead to development of a new paradigm of healthcare. The concept of "prospective healthcare," utilizing personalized health plans to determine individual risk for disease, planning for early detection of disease and delivery of preventive or therapeutic interventions early enough to be effective, has been proposed as a model for the future of the United States healthcare system.[6]

Sharon K. Hull, MD, is an NRSA Primary Care Research Fellow in the Cecil G. Sheps Center for Health Services Research and the Department of Family Medicine at the University of North Carolina at Chapel Hill. She can be reached at Sharon_Hull@med.unc.edu or CB 7595 Chapel Hill, NC 27599-7595. Telephone: 919-843-8045.

Leila C. Kahwati, MD, MPH, is a family physician with additional training in preventive medicine/public health. She is an Adjunct Assistant Professor in the Department of Family Medicine, UNC School of Medicine and can be reached at Leila.kahwati@med.va.gov or at the VA National Center for Health Promotion and Disease Prevention, 3022 Croasdaile Rd, Durham, NC 27705, Telephone: 919-383-7874, ext. 251.

Elizabeth P. Kanof, MD, is the President of the North Carolina Medical Society Foundation. She can be reached at ekanof@ncmedsoc.org or PO Box 27167, Raleigh, NC 27611. Telephone: 919-833-3836.

Jennifer P. Proko, RN, CHCQM, is the Manager of Quality Improvement at Health Care Savings. She can be reached at jennyp@health-caresavings.com or 4530 Park Road, Suite 110, Charlotte, NC 28209. Telephone: 704-527-6261.

Moving from our present system to "prospective healthcare" is a lofty goal that will require a major overhaul of our current healthcare system. It will also require changes that extend far beyond any one physician, patient, or medical practice. Such change can only occur through systems-level redesign, taking into account patients, physicians, and the myriad of business entities that comprise our healthcare system. For the practicing physician, success in improving quality of care begins with the actual day-to-day encounters between a patient, a physician, and the medical practice. In this paper we discuss the practicalities of quality improvement (with an emphasis on systems-level considerations) in two commonly targeted areas: clinical preventive services and chronic disease management.

> *"Studies have shown that office organization and staff and provider attitudes are more important than tools such as flow sheets and computerized records."*

Is Quality a Primary Care Issue?

McGlynn, et al., surveyed metropolitan United States residents and found that only 56% receive recommended care for chronic conditions and less than 55% receive recommended preventive care.[7] The increasing burden of chronic illness, time constraints, and practice, as well as healthcare system organization, all contribute to problems delivering high-quality care. Physicians want to "do the right thing," agreeing with the importance of most clinical recommendations,[8,9] but they want the flexibility to form their own opinions about relevant and appropriate guidelines for their patients.[10] Despite their general agreement with such recommendations, physicians may find themselves confronting clinical inertia, defined as "failure of healthcare providers to initiate or intensify therapy when indicated."[10,11] The burden of chronic disease and pressures to increase practice volume and productivity combine to create a "perfect storm" in primary care, making delivery of quality healthcare a significant challenge.

Escalating chronic disease burdens challenge a healthcare delivery system that is already strained by difficulties with access to and payment for care. More than half of patients in primary care clinics have a chronic disease.[12] Over 80% of patients who have cardiovascular disease, stroke, hypertension, diabetes, cancer, chronic obstructive pulmonary disease, asthma or anxiety/depression and who have a physician see a family practitioner, general internist, or general pediatrician on a regular basis.[13] This means that primary care physicians are the front-line providers for people who already have or are at risk to develop one or more chronic illnesses.

Clinical preventive services also lie within the domain of primary care practice and evidence indicates that preventive services recommended by knowledgeable sources are not being delivered. Since the 1980's, the United States Preventive Services Task Force (USPSTF) and other organizations have issued evidence-based recommendations for clinical preventive services.[14] Such recommendations are useful and often form the basis of clinical practice guidelines and performance measures. However, they are often difficult to implement, and uptake rates for many services are low. Among the 15 recommendations from the USPSTF with the greatest likelihood of reducing the burden of disease and the highest degree of cost-effectiveness, eight are being provided to eligible patients less than half the time.[15]

So why is there a gap between the recommendations that work and those that get done in practice? Many barriers have been proposed including lack of time, lack of staff, lack of knowledge, and lack of appropriate levels of reimbursement.[10,16-20] High-volume practices have been shown to deliver preventive services less frequently.[10] Though the average time spent delivering health promotion or health education in a routine family physician's office visit ranges from 0.7 to 1.98 minutes,[10,21] a recent study showed that delivery of the full set of USPSTF recommendations to eligible patients in a typical primary care practice would require 7.4 hours of physician work time per day.[20] Thus, time constraints often force primary care physicians to prioritize between illness care and delivery of preventive services. There is some evidence that physicians and patients do not always make such priority choices in accord with the best evidence available.[19,20,22]

Interventions to Improve Delivery of Quality Care

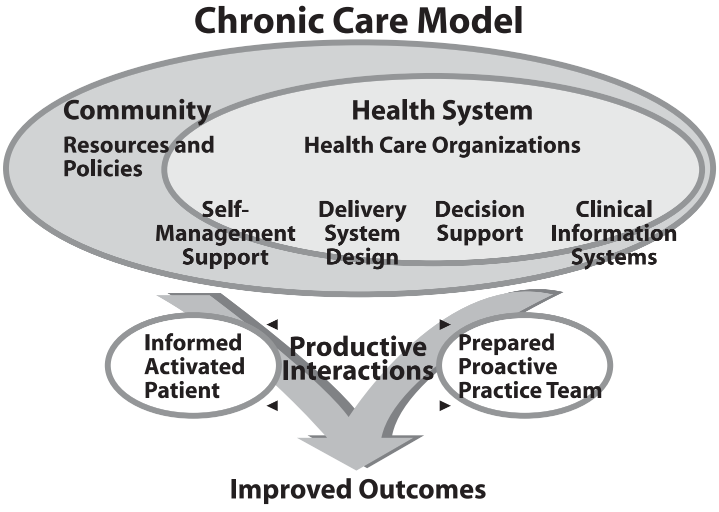
Many strategies have been used to translate research into practice and so we have some ideas about what works and what doesn't work. Passive education about guidelines such as lectures and seminars are not very effective at increasing uptake rates,[16,23] while one-on-one discussions,[16,23,24] reminder systems and other computer information systems[16,23] may be more effective. Multifaceted interventions (i.e., those that combine more than one strategy) appear to be more effective than any one single strategy,[25] and systems that automate or use standing orders fare better than on-demand type systems.

In one of the largest interventions to improve preventive services delivery in community family practice settings (Study to Enhance Prevention by Understanding Practice, or STEP-UP), tailored approaches were developed to increase the delivery of preventive services.[26,27] This program incorporated several systems-level interventions, including a one-day assessment of practice operations by a trained nurse facilitator, analysis of staff relationships and the external environment. Staff and physicians were provided feedback about their rates of preventive service delivery and a toolkit was developed from which practices could choose items most useful to them. Follow-up of this program at 12 and 24 months after the intervention showed that practices participating in the STEP-UP program had a significant and persistent increase in overall preventive service delivery rates, rates of health habit counseling, and screening rates. No significant increase was found in immunization rates.[26,28] It is unclear from the literature how many of the practices that implemented the STEP-UP program were also using electronic medical records.

A study of 44 primary care clinics testing systems-level changes to improve a variety of preventive services cited several barriers to the effectiveness of quality-improvement measures at this level. Some of these barriers included insufficient motivation for change, lack of ability to change on the part of the organizational culture and leadership, lack of evidence for changes that were implemented, processes related to implementation, and lack of sufficient time to make change.[29,30]

In 1994, the United States Department of Health and Human Services began a program called "Put Prevention into Practice" (PPIP) designed to improve delivery rates of preventive services recommended by the USPSTF. The program provides practice workflow and patient education materials for physician practices to use, and is available for purchase through the Agency for Healthcare Research and Quality (AHRQ), with some items available for free download at the PPIP website, http://www.ahrq.gov/clinic/ppipix.htm.[31] These materials appear to be helpful, but implementation without practice-specific assessment and tailored, multifactorial intervention strategies seems to be difficult.[17,18,32-39] Consistent barriers to implementation include clinician issues (time, lack of training, lack of self-efficacy), office systems issues (lack of knowledge, motivation, or support among office staff; inadequate systems to keep and monitor preventive service records), patient issues (lack of knowledge or motivation, anxiety about procedures and results, inconvenience, cost concerns), and systems issues (inadequate reimbursement and excessive time and productivity pressures).[19,20]

Figure 1.
The Chronic Care Model[40]



Used with permission from the American College of Physicians

Management of chronic disease with appropriate screening, treatment, education, and prevention interventions is also a significant challenge. The Chronic Care Model[40-46] has been developed to address the multi-level considerations that should be incorporated into adequate management of long-term illness. The model considers six dimensions of chronic care (community resources and policies, healthcare organization, self-management support, delivery system design, decision support, and clinical information systems)[40-46] in three settings (the community, the healthcare system, and the provider organization) (see Figure 1).[44] This model is complex, and its implementation requires a practicing physician to become a *systems-level thinker*. Where it has been most successfully utilized, this model has been instrumental in improving disease management, particularly in diabetes, congestive heart failure, and asthma.[46-48]

Electronic medical records (EMR) and computer reminder systems are increasingly common in primary care and other health-related settings and have a significant role to play in improving quality. The Veterans Health Administration recently announced plans to allow its computerized medical record system to be available to other public and private sector healthcare organizations at nominal cost beginning in late 2005.[49] This is consistent with a recently announced initiative by the Department of Health and Human Services to create a health information infrastructure that will incorporate nationally standardized electronic medical records.[50,51] These trends indicate that physicians in the future can likely expect increasing pressure to implement such systems. The cost to implement EMR, privacy issues, standardization of file formats, and implementation of "a minimum but affordable set of variables needed to assess quality and outcomes of care"[52] all can be significant barriers to their use. While only about 5% of United States primary care providers currently (in 2003) use EMR,[53] their use has been shown to improve guideline adherence.[54] It has been noted, however, that computer guideline systems can be difficult to implement.[55] Results of some studies show that use of EMR increases the number of tests ordered, but without significant improvement in clinically relevant patient outcomes.[56,57]

Other uses of information technology include direct physician order entry in hospital and clinic settings[58] and prevention of adverse drug effects by computer warning systems.[59,60] These developing technologies bring with them a distinct set of implementation, privacy, and cost concerns that may delay their widespread acceptance.

There are many external pressures to improve quality in healthcare,[61] and physicians must become familiar with the language and culture of quality improvement (QI). Managed care organizations and healthcare payors have been monitoring quality of care for years, mainly through the use of insurance claims information. Increasingly common are chart audits, which allow the capture of relevant clinical information not always available from claims.

Physician performance report cards have yet to appear, but efforts to improve the methods used to sample and calculate accurate physician-level performance measures are in progress. Recently, the American Board of Medical Specialties (ABMS) developed "Maintenance of Certification" (MOC) requirements for board-certified physicians.[62,63] The MOC program is being adopted by most recognized medical specialty boards and requires four basic components, the last of which mandates that physicians be able to document their ability to "assess the quality of care they provide compared to peers and national benchmarks and then apply the best evidence or consensus recommendations to improve that care using follow-up assessments."[62,63] The specialties of pediatrics, internal medicine and family practice all are offering modules for self-study and assessment relevant to common disease processes.[62-64]

Where to Begin

To improve the quality of care, a practice needs (1) evidence-based clinical recommendations, (2) evidence-based system recommendations, and (3) an improvement strategy.[40] The first spells out the clinical content, the second spells out what system changes can influence the delivery of the clinical content, and the third lays out how to bring items (1) and (2) into routine use. Without all three elements, most attempts to improve quality will not be successful or sustainable.

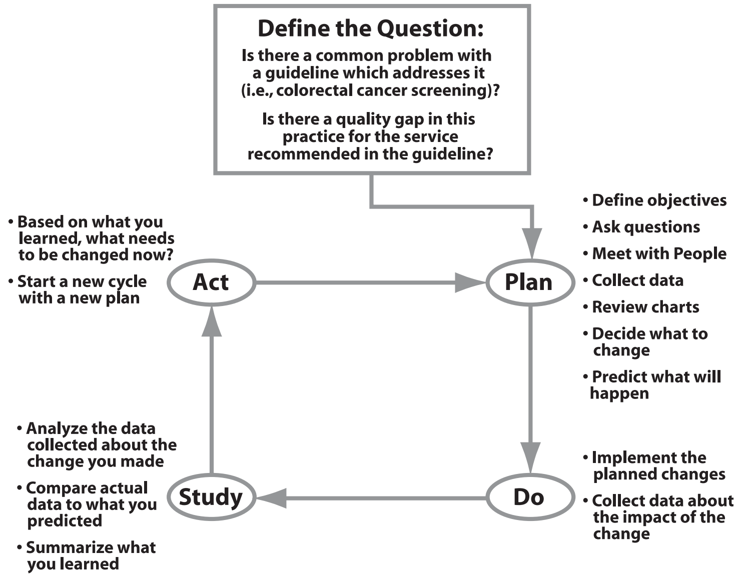
Perhaps the most important suggestion for those who are just starting to introduce quality improvement into their practice is to start with a single medical condition. The selected condition should be prevalent within the practice population and more importantly, it should be one in which current evaluation suggests that patients are not routinely receiving care consistent with clinical practice guidelines and best evidence. To determine whether a quality gap for a particular service exists, a practice can perform a manual chart audit by reviewing ten to 20 charts of patients eligible to receive that service based on age, gender, or risk factors. For offices without EMR, a request to the practice's largest insurance payors can provide a list of patients in the practice with a particular condition such as diabetes or asthma and can provide a raw list from which a manual chart audit can proceed. Chart audits are even easier for offices with EMR. Lastly, the physicians and practice staff should be highly motivated to study the particular condition and act to improve it.

One useful improvement strategy for affecting change is the "Plan-Do-Study-Act" (PDSA) paradigm (Figure 2) used widely by the Institute for Health Care Improvement (IHI)[65,66] and developed by W. Edwards Deming.[66] This systems-oriented approach to problem solving requires that an organization (e.g., a clinical practice) develop an objective and a plan to meet that objective, carry out the plan, study the results within a relatively brief time period, and act on the results of the initial study.[65, 66] We will not attempt to describe this framework in detail here, but those who are interested are encouraged to consult the original references[65,66] or the IHI website.[67] A sample strategy for utilizing the PDSA strategy in a clinical practice setting is provided in the sidebar accompanying this paper.

The process of quality improvement requires the cooperation of everyone who works in the practice, and it requires thinking at the systems and process levels. The importance of systems approaches cannot be overemphasized. Studies have shown that office organization and staff and provider attitudes are more important than tools such as flow sheets and computerized records.[68] It has also been noted that supportive attitudes and high levels of self-efficacy were not sufficient to improve prevention service delivery; over half of medical practices studied were poorly organized to deliver recommended services.[69]

Figure 2.

PDSA Cycle Overview *(Adapted from Deming[66] and Langley[65])*



In summary, the process of quality improvement in private practice can be daunting if one sets out to provide the entire range of best practice recommendations at one time. For the private practitioner who is not part of a larger healthcare system, success is more likely if one improvement process is undertaken at a time. Subsequent efforts will benefit from the experience of earlier improvements, and enthusiasm is more likely if early efforts are successful. The practitioner who begins with one or two small projects is likely to quickly decide that EMR and computer technology would make the task easier.

As more specialties comply with the ABMS guidelines for Maintenance of Certification, and as governmental regulations and reimbursement strategies focus more heavily on quality issues, this process will become more common, and practitioners who start now, even if they start small, will be well-prepared for the future of quality improvement in the real world. **NCMJ**

Dr. Hull's effort on this study was supported by a grant from the Health Resources and Services Administration (#T32-HP14001).

Sample PDSA Cycle Strategy for Colorectal Cancer Screening

The following sample strategy illustrates the use of the PDSA model.

I am general internist in a small town solo practice that does not presently use EMR. I know that colon cancer is among the more common of cancers in older men and women and early detection through screening leads to decreased morbidity and mortality.[70] Annual fecal occult blood testing, periodic sigmoidoscopy or colonoscopy, and periodic double contrast barium enema are all acceptable and effective screening strategies.

QUESTION:
Does my practice have a quality gap for this service?
A manual review of 20 charts from patients 50-70 years in age without terminal illness or obvious medical contraindications to screening reveal the following statistics:

- 65% of charts document that colon cancer screening was offered to the patient
- Of those offered screening:
  - 40% received a recommended test
  - 15% received an inadequate or incomplete screening
  - 25% did not follow through with the screening after intially agreeing to it
  - 20% refused screening
- 100% of those with abnormal screening results had appropriate follow-up arranged in a timely fashion

As my practicing partners and I review these results, we realize that our practice has no systematic way to ensure we offer colon cancer screening to every eligible patient. Furthermore, our practice has no systematic way of facilitating patient decision-making about screening, particularly with regard to choosing from among the various recommended strategies. We seem to do well with ensuring the results are reviewed and appropriate follow-up is arranged.

PLAN:
I meet with my staff to review these findings, and to ask for their input about how to improve our practice performance in this area. We agree that our first objective will be to increase the percentage of eligible patients who are offered a screening test, and we set our target at 90%. We will take the following steps:

(1) A preventive services flow sheet, such as the one obtained for free at the PPIP website, will be placed in every patient chart at their next scheduled visit by the front-office clerk who pulls patient charts prior to appointments.

(2) The nursing assistant (NA) who triages the patient at the appointment will ask the patient about his/her last colon cancer screening and also review the chart to determine the current status. The physician will develop a simple one-page flowchart based on USPSTF recommendations for the NA to use in determining whether a patient is due for this service.

(3) Patients who are overdue for screening will have a "sticky note" placed on the chart by the NA to remind the physician to offer screening.

(4) Physicians will strongly recommend screening to patients and answer any questions they may have. Patients who decline screening will have this noted in their progress note. Patients who accept screening will be referred back to the NA for further arrangements. Either way, the physician will note on the flow sheet the date on which screening was offered.

DO:
The office staff implement these policies and agree to review our progress in six weeks. To facilitate implementation, small adjustments to the policies can be made along the way and do not have to wait until the STUDY phase.

STUDY:
After these policies have been in place for six weeks, we select another set of 20 charts of patients age 50-70 who were seen within the prior six weeks and find the following:

- 80% of charts document that colon cancer screening was offered to the patient
- Of those offered screening:
  - 60% received a recommended test
  - 5% received an inadequate or incomplete screening
  - 20% did not follow through with the screening after initially agreeing to it
  - 15% refused screening

The staff note that several patients had to have their procedures rescheduled because they did not follow any preparation instructions, and others did not return the entire set of hemoccult cards to the office. Staff also report that patients have many questions about the differences in the various screening options available. While our office has certainly improved the percentage of patients offered a screening test, it is still short of the practice goal of 90%.

This completes one PDSA cycle, and a new one begins.

In the new PDSA cycle we begin with the following changes or additions to the PLAN based on our last STUDY results and agree to STUDY again in six weeks:

(1) We will place posters in the waiting and exam rooms encouraging patients to ask their physician or nurse about colon cancer screening.

(2) During triage, when the NA determines if the patient is due for screening, the NA will ask the patient if he/she is interested in screening, and, if "yes," will begin to prepare the necessary paperwork for the physician to order the test.

***Sample PDSA**—continued on page 280*

***Sample PDSA**—continued from page 279*

(3) NAs will give patient education materials about colon cancer screening (including a decision aid to help patients choose from the effective alternatives) to the patient waiting in the exam room. Patients can read the material while waiting for the physician.

(4) Standard written patient preparation instructions for each of the four screening strategies are given to patients who have tests scheduled. We arrange necessary referrals and give them to the patient before he/she leaves the office.

This sample strategy may seem archaic to those who have access to computers or EMR, but it is presented to illustrate that care quality improvements can be made even without access to computers. While EMR and computerized databases would improve efficiency in this process, it is possible to improve without them. In our practice, we have agreed to "start somewhere."

COMMENTARY

Data and Information Requirements for Healthcare Performance Monitoring and Improvement

Robert R. Weiser, and Christopher Mansfield, PhD

Quality improvement requires the ability to measure performance. In healthcare, because of the many variables that can affect outcomes, performance measurement has been difficult. Establishing standardized measures based on valid and reliable clinical data on a state or national scale has proven to be especially challenging. A good deal of effort and resources by several different national groups and many individual physician practice organizations has demonstrated that performance measurement in healthcare is possible, and that, when combined with quality improvement methods, it does produce results.[1,2]

Quality improvement efforts must address two principal objectives. Safety is the first objective of quality, (i.e., "First, do no harm."). And safety, is defined as freedom from accidental injury.[3] Prevention of accidental injury in medical care depends on practicing within rational, evidence-based systems designed to anticipate, avoid, minimize, and learn from error. Such systems rely on algorithms, checklists, and recording and sharing information about the patient's care among the host of health providers likely to be involved. The second objective of quality is that the best care possible is provided within reasonable cost parameters. We can think of "best" care as that which is "safe, effective, patient-centered, timely, efficient, and equitable."[4] If not the best, then at least that which is adequate within conventional standards of care (i.e., "reasonable care"). It is not just that "Healthcare harms too frequently... but that it also...routinely fails to deliver its potential benefits."[4] Things that ought to be done may be left undone.

To achieve these two objectives, there must be commitment, accountability, leadership, systems for review and decision making, performance standards, means to measure performance, and data systems and procedures that allow providers to identify and learn from error. This commentary focuses on the measures, data systems, and procedures (i.e., establishing the information base required for quality improvement) both at a state- or system-wide level and within individual institutions and practice organizations.

> *"The need for better health records and recognition that technology exists to provide them is apparent not just to a few leaders of organized medicine, but to the general public and politicians as well."*

What is the Best Way to Measure Performance?

Performance measurement in healthcare refers to the ability to quantify outcomes, processes, satisfaction, or events in a manner that is objective, valid, and reliable. This means that it must be based on data that are collected accurately and consistently over time and location. The measures should be evidence- or consensus-based and provide a measurement of the care actually being provided against explicit standards. And perhaps most importantly, the measures must be meaningful. This means that the healthcare system has the ability to intervene directly to improve that which is being measured.

While it is not currently possible to measure every nuance of each patient's care, we can measure those parts of care for which there is evidence or wide agreement.[5,6] And this certainly tells us more about the care provided than the limited information in the measures themselves. The fact that only

Robert R. Weiser, is the Director of Healthcare Assessment at Medical Review of North Carolina. He can be reached at bweiser@mrnc.org or 100 Regency Forest Drive, Suite 200, Cary, NC 27511-8598. Telephone: 919-380-9860.

Christopher Mansfield, PhD, is an Associate Professor of Family Medicine and Director of the Center for Health Services Research and Development in the Division of Health Sciences at East Carolina University. He can be reached at mansfiledc@mail.ecu.edu or Physicians Quadrangle, Building N, Greenville, NC 27858-4354. Telephone: 252-816-2785.

64% of Medicare patients admitted to hospitals in North Carolina receive antibiotics within four hours of arrival tells us a great deal beyond the measure. It points to underlying systemic issues. If we can't establish processes that assure that this one well-defined, understood and accepted part of treatment is accomplished, what else is being missed?

The data to drive the measures can be derived from a variety of sources including, payment or claims data, paper or electronic medical records, surveys, and reports such as incident reports. Each of these sources has its pluses and minuses. Claims data are the easiest to obtain, but the accuracy of certain variables, such as diagnoses and comorbidities, is sometimes uncertain. Information abstracted from medical records is the most clinically rich, but is a challenge to abstract reliably when multiple institutions or abstractors are involved. It is also labor-intensive and therefore the most costly means of obtaining data. Widespread adoption of electronic medical records will facilitate access to this information.

While the ultimate aim of quality improvement is to improve *outcomes*, outcome measures are the most difficult to develop. This is because most outcome measures must be risk-adjusted to account for the variations in the patients' condition or severity of illness. Fortunately *process* measures generally do not require risk adjustment and can be far more useful in quality improvement. Process measures address those aspects of treatment for which there is evidence linking them to improved outcomes for a specific diagnosis. Improvement in process measures for the specified population of patients should result in better outcomes. An example of a process measure currently in use is the percentage of eligible acute myocardial infarction (AMI) patients discharged from the hospital on a beta blocker.

Satisfaction measures attempt to quantify the consumers' degree of satisfaction with their encounter with the healthcare system. This is an aspect of quality that has been addressed through commercial surveys that are widely used by hospitals.

Event measures are most commonly associated with patient safety, such as the capture of medication or treatment errors.

Who Is Measuring Performance?

The importance of *performance* measurement is reflected by the number and type of organizations and agencies that have dedicated a significant amount of time and resources to their development. The Joint Commission on Accreditation of Health Care Organizations (JCAHO), the American Medical Association (AMA), the National Committee on Quality Assurance (NCQA), and the National Quality Forum (NQF) have all been deeply involved in the development of quality measures. The JCAHO now requires hospitals to abstract, validate, and submit a set of quality measures covering four clinical topics on a quarterly basis. The AMA in conjunction with several specialty medical societies has published nine sets of physician performance measures. The NCQA developed measures for managed care organizations. The NQF is a non-profit organization that operates a consensus-based process to endorse quality measures. It functions as a standards-setting organization for the healthcare industry. The federal government is obligated to utilize NQF-endorsed measures or must justify why they are utilizing something different.

At the federal level the Agency for Healthcare Research and Quality (AHRQ) and the Centers for Medicare and Medicaid Services (CMS) have worked for several years to develop quality measures. AHRQ has established the National Quality Measures Clearinghouse (www.qualitymeasures.ahrq.gov) that contains more than 400 sets of quality measures. CMS has developed, and now makes public, performance measures for nursing homes and home health agencies. CMS has also indicated it will make hospital performance measures public by the end of this year. All of these measures, plus a set of claims-based quality measures for the outpatient setting, are currently utilized by Medicare Quality Improvement Organizations (QIOs) in their work. Medical Review of North Carolina (MRNC), a private non-profit physician organization, is the QIO for this state.

Using Performance Measures to Improve Care and Ensure Patient Safety

Performance measurement and data collection is difficult, but if it is used constructively it is worth the effort. To utilize it constructively means incorporating it into quality improvement activities rather than using it in a punitive manner. And there are several constructive uses. *Benchmarking* with these measures allows us to determine what an achievable performance level is right now. Benchmarks should represent a demonstrably attainable level of excellence.[7]

For example, if we know that 10% of hospitals in North Carolina can get the proper antibiotic started within four hours of admission for 95% of their pneumonia patients, then we have determined that this is an achievable level. Utilizing systems analysis, we can examine how this was accomplished and construct models of best practice that can be shared with and implemented by other hospitals. Comparisons of performance levels can be done among similar types of institutions and practices.

Utilizing performance data, MRNC has worked with hospitals, nursing homes, and physicians in North Carolina and has seen improvement in several areas. Nursing homes have substantially improved the management of pain in their residents. Physicians have dramatically improved rates of testing for lipids and hemoglobin A1C in patients with diabetes. And hospitals have substantially improved on the number of eligible AMI patients discharged on beta blockers.

Individual physician practices have begun to utilize performance measures and comparative data to improve the care provided their patients. Patient registries, electronic medical records, and manual systems are being used to collect data and assess practice performance. The results are sometimes surprising to physicians who frequently believe that they are performing at a much higher rate. In some instances the ability to identify all of their patients with diabetes and measure practice performance has led to systemic change in the practice.

For individual practice organizations, safety remains the first concern, and systems must be in place to prevent errors of commission. But to provide the best care possible, the systems must also prevent errors of omission. We must make sure that we do the things we ought to do (e.g., not just the proper sequence of steps in a procedure, but acquiring, recording, considering, and sharing information required to prevent, diagnose, prescribe, and treat). For primary care practitioners, patient information systems must be designed to facilitate prevention and management of the most common infectious and chronic diseases. Clinical priority in structuring the patient information system should be preventing the leading diseases associated with mortality (heart, cancer, and stroke) and making sure the leading "actual" causes of death are addressed, (i.e., smoking, diet, and physical activity).[8,9] Does the record system remind, facilitate, perhaps even force, the clinician to consider patient behaviors and discuss them with the patient if appropriate or necessary?

A patient information system should provide a list of the patient's principal problems for the physician at each encounter. A physician, being reminded that Mrs. Jones is a diabetic, should be cued by the system to consider whether her visit should include: an eye exam, hemagolbin A1C test, urine test, foot exam, lipid profile, nutritional assessment, diabetes education, and assessment of blood pressure, weight/body mass index (BMI), and physical activity. For female patients, regardless of the problem list, it should cue to remind about smoking, and, by age standards, for mammograms, cancer screenings, and flu vaccine. The data system should be designed for sharing information with the patient and other providers. If Mrs. Jones is educated and engaged in her care, she should know her "numbers" and encouraged to set goals for those within her control. Sharing data with her may itself reduce the chance of error. Educated and engaged patients may spot potential errors themselves. Sometimes, breakdowns in the clinical-patient relationship are responsible for errors.[10] Breakdowns in communication with other providers are a very common source of error and most error incidents are not single acts, but a chain of events or a cascade.[11,12] An electronic health record, can become a shared communication tool among her providers. The pharmacist can easily know what other medications she is taking and essential information can accompany referrals to other providers.

Error is a condition of being human. The more humans involved, the more error is possible. Indeed, without proper systems the potential for increase in error is exponentially related to the number of people involved a patient's care. Good systems not only allow us to minimize error but to learn from error. Lewis Thomas said "We get along in life this way. We are built to make mistakes, coded for error. We learn, as we say, by 'trial and error.'...Why not 'trial and rightness' or 'trial and triumph'"[13]

Conclusion

"If we want safer, higher-quality care, we will need to have redesigned systems of care, including the use of information technology to support clinical and administrative processes."[4] The need for better health records and recognition that technology exists to provide them is apparent not just to a few leaders of organized medicine, but to the general public and politicians as well. President Bush recently announced an initiative with the goal of an electronic health record (EHR) for most Americans within a decade, proposed doubling federal spending for EHR to $100 million, and challenged the healthcare industry to invest in health information systems.[14] Ultimately that is what performance measurement is about: changing systems to provide better care. Without collecting the data and measuring the system's performance, we don't know what we need to change or the urgency with which we need to change it. **NCMJ**

COMMENTARY

Evidence-Based Medicine:
Ready for Prime Time?

Charles F. Willson, MD, and G. Hadley Callaway, MD

The authors elected to take separate viewpoints

New and Better
Charles F. Willson, MD

"Evidence-based medicine is most recently defined as the integration of the best research evidence with clinical experience and patient values."[1] As a busy clinician for the past 25 years, I've become accustomed to the science of uncertainty and to making timely decisions based on incomplete evidence. But I've yearned for a way to know that my diagnostic and therapeutic approaches reflected state-of-the-art pediatric care at that moment in time. Most textbooks when published are already two years behind current knowledge. Continuing Medical Education (CME) courses certainly helped to update my knowledge base, but often left gaps in how to implement the best approach being described. Hospital or phone consultations with pediatric subspecialists were helpful, but the specialist I needed at that moment may not be available for hours or days. The movement toward a systemized analysis of the research evidence and development of practical care guidelines for common or more rare clinical problems (i.e., evidence-based medicine) has the potential to meet this significant need of busy primary care clinicians.

Under the old medical care paradigm, when an infant presented acutely to my office with a serious, but uncommon, diagnosis such as septic arthritis, I'd arrange admission to the hospital. Hectically trying to remember the teachings on septic arthritis of our pediatric infectious disease experts during my residency years, 1974 through 1980, I'd quickly consult a general textbook of pediatrics published about ten years earlier. I'd hurriedly write orders that included diagnostic studies prior to antibiotics, intravenous antibiotics, orthopedic consultation, and pediatric infectious disease consultation. If I were really uncertain about what to do, such as whether to have the orthopedist tap the joint or have a radiologist tap it under ultrasound guidance, I'd call the consultant for a recommendation. This process might take 20-40 minutes. All the while patients continue to arrive for care at the rate of four to six per hour. As I entered the next exam room, I'd fret about the serious decisions I'd just launched and wondered if I had met "best-practice" standards.

But things are changing. Spurred by the national Institute of Medicine report, *To Err is Human*,[2] reporting that 98,000 deaths occur yearly in our hospitals due to preventable medical errors, our profession has been called to action. We must improve our systems of care. These mortality statistics don't even address how many hospitalized patients might have received substandard care. In the companion report, *Crossing the Quality Chasm*,[3] the Institute of Medicine Recommendation Number 8 calls for the Secretary of the United States Department of Health and Human Services to be given "the responsibility and necessary resources to establish and maintain a comprehensive program aimed at making scientific evidence more useful and accessible to clinicians and patients." Fortunately, the evolution of computer technology and the Internet will make such a massive effort feasible. Our medical school students and residents have also changed. They are computer literate and savvy. We medical school faculty are encouraging them to search the Internet for evidence-based articles relevant to their patients, and many now turn to the computer for help instead of the aging textbooks on the clinic shelf.

> *"The practice of medicine is an art, based on science. Medicine is a science of uncertainty and an art of probability"*
>
> —Sir William Osler

Charles F. Willson, MD, is Clinical Professor of Pediatrics at the Brody School of Medicine, East Carolina University. He can be reached at willsonc@mail.ecu.edu or Brody 3E139, 600 Moye Boulevard, Greenville, NC 27834. Telephone: 252-744-2535.

G. Hadley Callaway, MD, is an orthopedic surgeon in Raleigh, NC. He can be reached at HCallaway@raleighortho.com or Raleigh Orthopaedic Clinic, 3515 Glenwood Avenue, Raleigh, NC 27612. Telephone: 919-781-5600.

Not only will the computer software allow us to access the latest information about a particular clinical problem, I hope the Institute of Medicine will link these sites to a data warehouse that will allow the patient's admission data and eventual outcome to be recorded. That way, we would have an on-going study of the clinical effectiveness on all the patients we treat with a particular diagnosis. Although time-consuming, this feedback on outcomes could be the price we physicians pay for having evidence-based medicine at our fingertips. Of course, in all these activities, patient confidentiality must be maintained. Physician-specific information would be protected under peer-review laws.

Now, when I admit a patient to the hospital, I ask the resident on the pediatric ward to do a quick diagnosis-specific search to see what recent articles may answer our clinically relevant questions. Medication dosages are easily accessed on a personal digital assistant (PDA) linked to the ePocrates®[4] web site. Evidence-based medicine is becoming a reality. I'm left with a few extra, precious minutes to practice the art of medicine, sitting with the parent, holding her hand, and answering her tearful questions.

But, there are bumps in the road. Dr. Onady who authored the chapter on evidence-based medicine in our textbook, *Pediatric Hospital Medicine*,[1] has testified in a malpractice trial where the defendant physician used an evidence-based approach to treat a patient who subsequently suffered a poor outcome. The plaintiff alleged that the physician's care deviated from the community standard and won. Progress is rarely painless.

The future for our physicians in training is truly exciting. Instead of trying to remember what Dr. Willson taught her about managing a 15-month old with fever and a swollen joint, the new physician will turn to her laptop computer. In seconds a pediatric web site will appear that outlines a recently updated algorithm for diagnostic work-up and management of septic arthritis in a child. Perhaps the data will even be age, sex, and ethnically specific. A comprehensive differential diagnosis list may provide much of the value of a specialty consultation. Within seconds, the pediatrician will have ordered a hospital admission, ultrasound-guided arthrocentesis, blood culture, complete blood count (CBC), and pathogen-specific antibiotics. OOPS! The computer screen flashes that the child is allergic to penicillin, and a substitute antibiotic is suggested. The physician then has time to answer the mother's questions and allay fears. The mother knows that her baby's doctor has used the latest medical information in developing the care plan. As the mother carries her child to the hospital, she'll stop first at the radiology suite for the joint tap and the orthopedist consulting will have the fluid analysis when he arrives on the ward to see her. The pediatrician goes into the next exam room with a mind uncluttered by doubts and questions about the crucial decisions she has just made.

Osler would be relieved and proud.

Approach with Caution

G. Hadley Callaway, MD

The new "evidence-based medicine" has a somewhat arrogant name, as though the rest of healthcare is "opinion-based." I would be careful not to throw out the baby with the bathwater.

I hesitate to throw out the "opinions" I was taught in medical school and orthopedic training. My teachers taught from all the evidence that was available, supplemented by their clinical experience. During training we used Medline and critically reviewed the literature. We had lots of evidence, but not randomized controlled studies for every treatment.

In my specialty of orthopedics, the "evidence-based medicine" is surprisingly limited. Very few surgical treatments have been evaluated in randomized controlled studies with comparison to sham surgery or to each other. As an example, consider the difficulty in randomizing a humpback child to scoliosis surgery or not.

If I only used "evidence-based medicine," my scope of practice would be tiny. My standard treatment for back or joint pain might be: "There is evidence that acetaminophen will reduce your pain score, but nothing else to offer." I have ePocrates®, but that is no help in this situation.

I am also wary of sudden changes in the medical "evidence." Witness the Atkins® diet craze. Should my mom have been taking Premarin®? Within orthopedics there are a hundred "scientifically" supported fads that come and go. Many published and unpublished studies are controlled by industry. This is why most doctors do not change their practice based on the newest journal reports.

Finally, most of my life is guided by firmly held opinions based on limited evidence. What to study, whom to marry, which religion, how to raise the children—all are determined by opinion. Why should medicine be so different?

So How Should We Deal with "Evidence-Based Medicine?"

First, tell the public that evidence-based medicine is not new. Physicians have always relied on scientific evaluation of treatment alternatives, but the quality of studies is constantly improving. We have been using computerized literature searches of Medline since the 1980s. We were taught in medical school to critically analyze the literature. Statistics were part of the pre-med and first year curriculum. Most of us update our practice according to monthly journal reports.

Second, let's change the name to "medicine with a constantly updated computer reference." The whole movement owes its existence to the Internet. Either the reference will pop up when I enter orders at the hospital, or I will need to carry it in my pocket. You cannot practice according to the voluminous and changing evidence-based guidelines without an Internet device.

Third, recognize that evidence-based medicine is just the

X-generation reviewing and rewriting the information base. Remember how crude and mistaken the medical evidence was before the baby boom rewrote it last generation? The term "evidence-based medicine" is inflammatory and misleading; it should be abandoned. I would suggest "medicine based on randomized trials," which acknowledges that the rest of medicine has a good foundation in evidence also.

Fourth, tell everyone that updating our information will take a long time. During the transition we must work with a blend of old and new information. Don't let Medicare or insurance companies deny or limit coverage for valuable treatments because they are not yet supported by randomized controlled studies which constitute the best "evidence." Misuse of guidelines by third-party payers may harm more patients than the guidelines help.

Fifth, get familiar with the guidelines. Before they are accepted as dogma, they deserve scrutiny by practicing physicians. Guidelines that conflict with common sense should be reviewed. Areas that need study should be identified. As journal articles are published, their effect on guidelines should be considered. Over time, the guidelines will increasingly restrict our treatment options, so they had better be good. Whoever controls the guidelines will control medical practice.

Finally, use the guidelines as a crutch. I have a hard time keeping up with journal reading. The Cochrane guidelines are like Cliff's (or Spark) Notes, although chapters covering most of my practice are still missing! **NCMJ**

Evidence-Based Medicine: A Clinical Case Scenerio

Charles F. Willson, MD

The first patient of the morning

The young mother is clearly worried as she relates that her nine-month-old daughter, Kaylee, started running a fever last night. She gave an appropriate dose of Tylenol and checked on her throughout the night. The fever waned initially, but is now back with a vengeance: 104.4F. When she changed the diaper this morning, the child cried in pain as she moved the left leg. The left knee was swollen and warm. The Tylenol dose this morning did little to relieve the pain and fever.

As a pediatrician, I know the diagnosis of septic arthritis is fairly certain. But, it has been several years since I initiated care for a child with septic arthritis, and, over a practice lifetime (25 years), I'd probably made the initial diagnosis only a dozen or so times. Thinking back to my resident days, I try to recall the teachings of my honored mentors. ("What would Floyd Denny have done?") Clearly, I'll admit the child to the hospital, get someone to tap the joint for cell count and culture, and begin intravenous antibiotics. But questions begin crowding my thoughts. ***Should I ask the orthopedist to tap the joint or should I have a radiologist tap it under ultrasound guidance?*** In this era of immunization against Hemophilus influenza group B, ***what antibiotics should I start, and at what doses?*** I remember seeing an article from the Centers for Disease Control and Prevention in the *Journal of the American Medical Association* last month that talked about Kingella kingae as an emerging cause of septic arthritis in children. I'd never heard of Kingella kingae and meant to look it up. ***Is it a new pathogen or one of the old ones now renamed?*** I don't even know if it is a gram positive or gram negative bug. ***What antibiotic would cover it? What are the chances that the baby will have a damaged hip, or make a full recovery?*** As the questions come, so do the patients. I need to call the hospital and have the patient admitted. Fortunately, we have pediatric residents who can take over and call radiology, orthopedics, and pediatrics infectious disease. (My colleagues in more rural practices don't have these resources.) I'd like to sound knowledgeable as I instruct the resident, but I don't know the current literature, and the next patient is waiting.

I take the mother's hand, explaining that her daughter has an infection of the knee that can be quite dangerous. Hospitalization, study of the joint fluid, and intravenous antibiotics for many days will be necessary. Tears begin rolling down her face. "We have wonderful specialists who will help us with Kaylee's care," I tried to reassure her, but I was certain that the worry on my face spoke louder. Her questions start to come. ***How long will Kaylee need to stay in the hospital? Will her knee be ok? Is it dangerous to stick a needle in a baby's knee? Do the antibiotics have side effects? How did she get this infection?*** I reassure her that I'll be over to the hospital at lunch time to answer all these good questions, but we needed to get Kaylee over to the hospital now to start treatment. As I enter the next exam room, I hope that I'll be finished with my morning patients in time to get over to the hospital to check on Kaylee.

I feel an irony that the vast fund of medical knowledge is inaccessible when a busy clinician needs it the most. When a baby presents with a septic arthritis or any other major infection, the clock is ticking. The opportunity for an optimal outcome is hanging in the balance. Evidence-based medicine with its guidelines, decision trees, and clinical care paths will bring the state-of-the-art, up-to-date information to the finger tips of the front-line practitioner, even in the remotest of setting.

Not only must we embrace evidence-based medicine, we must go the extra mile and ask that all physicians who use these tools report the outcomes of their patients. Precious information that would strengthen our knowledge base is being lost every day. Am I concerned about losing some autonomy as a practitioner? It's a small price to pay to benefit Kaylee.

COMMENTARY

Disease Management Approaches to Quality Improvement

John R. Mangum, MD, and Conrad L. Flick, MD

Physicians and other healthcare professionals correctly view good medical decision-making as the cornerstone of quality care for our patients. However, no matter how well-constructed a plan of treatment for an individual patient may be, optimal management of that disease may still not be achieved unless other, less obvious factors fall appropriately into place. Unfortunately, the pitfalls are numerous and commonplace. The cost of medication may lead a patient to not fill a prescription. The patient may take the medication less often than prescribed due to real or perceived side effects. The patient may not understand that a chronic asymptomatic disease requires ongoing therapy and periodic medical re-evaluation. These and numerous other cultural, financial, and social factors may strongly impact the management of a patient's disease and that patient's overall health status.

> *"Disease management is a many-faceted process...usually designed for high-cost and/or high-volume diseases, such as diabetes, hypertension, asthma, HIV, and congestive heart failure."*

The number of Americans living with chronic disease is increasing dramatically. It is estimated that the number will reach 120 million in 2010, constituting 40% of the United States population.[1] Within the Medicare program, as much as two-thirds of the expenditures are estimated to go for the care of participants with five or more longstanding medical conditions.[2] Among younger populations, estimates of lost workplace productivity due to chronic disease are remarkably high.[1]

The federal government, groups of employers, and providers of healthcare are all searching for innovative solutions that can improve health outcomes, reduce hospitalization rates, provide cost savings, and reduce workplace absenteeism. More and more frequently they are looking to "disease management" as a key strategy in achieving these goals.

Disease management is a many-faceted process of organizing care with the intention of improving health outcomes for certain disease states and, when possible, lowering overall healthcare costs. Most of the cost reductions are achieved through methods to prevent errors, limit long-term complications of diseases that are not being maximally managed and prevent duplication or overuse of services. It is usually designed for high-cost and/or high-volume diseases, such as diabetes, hypertension, asthma, HIV, and congestive heart failure.

Disease management can be as simple as a patient education handout explaining the disease or as complex as a multidisciplinary team working together to establish a comprehensive plan of care for an individual with multiple chronic conditions.

Medical conditions that seem to be the best candidates for disease management approaches have some or all of the following characteristics:

- High volume or high cost (or both)
- Evidence that wide variations in care approaches exist among practitioners
- Evidence that particular defined care approaches lead to improvements in clinical outcomes

---

John R. Mangum, MD, is a family physician in Sanford, NC. He can be reached at jmangum@wave-net.net or at Sanford Medical Group, 555 Carthage Street, Sanford, NC 27330. Telephone: 919-774-6518.

Conrad L. Flick, MD, is a family physician in Raleigh, NC. Dr. Flick is also the current president of the North Carolina Academy of Family Physicians. He can be reached at clflickmd@aol.com or at Family Medical Associates of Raleigh, 3500 Bush Street, Suite 103, Raleigh, NC 27609. Telephone: 919-875-8150.

Disease Management in Practice

Joe Taylor is a moderately overweight 58-year-old male who has been hypertensive for seven years. His hypertension is controlled with two medications. He presents to his family physician, Dr. Williams, complaining of increased urinary frequency and low energy. He is diagnosed with new-onset type II diabetes mellitus. Dr. Williams discusses with Mr. Taylor many aspects of diabetes—how it is treated, the importance of exercise and weight loss, the vital role diet plays, the potential complications that may arise. She provides written patient education materials. She asks Mr. Taylor to begin home glucose monitoring. Dr. Williams follows appropriate clinical practice guidelines in choosing an oral hypoglycemic agent and re-evaluates his hypertensive regimen in light of the newly diagnosed diabetes.

Through the disease management program already in place, Mr. Taylor is referred to a dietitian and to a local patient education program for diabetics that brings them in for a series of group sessions. A nurse with the disease management program contacts Mr. Taylor by phone two weeks after his diagnosis to ask how he is doing, answer questions he may have about diabetes, see if he is doing the home glucose monitoring, encourage adherence to diet and exercise recommendations, and to reinforce the reasons that long-term control of the diabetes is so important to his health.

A few days before his follow-up appointment with Dr. Williams, Mr. Taylor is contacted by phone reminding him of the day and time of the appointment. At that first follow-up appointment, Dr. Williams has triggered her diabetes software program in the electronic medical record for Mr. Taylor. The program provides for easy tracking over time of blood pressure, weight, hemoglobin A1Cs, annual dilated eye exams, and last flu and pneumococcal immunizations. It provides reminders to Dr. Williams for periodic checking of urine micro-albumin, foot/skin integrity and sensation, and other important aspects of diabetic care. Over the next several months, the pharmaceutical benefit manager monitors medication refill records to see if the patient appears to be taking his medication as prescribed.

Through the combined efforts of the patient and all those involved in his care, Mr. Taylor is given the best possible chance to control his diabetes and reduce the likelihood that he will develop vascular, renal, neurologic or other complications.

- Care by multiple physicians of different medical specialties
- Purchaser interest in reducing treatment variation/cost[3]

Disease management is in its early stages and, thus far, there is little firm evidence regarding outcomes.[1] Over 150 companies in the United States currently offer some form of disease management services or products.[1] Many of these are independent companies, but some have been developed by managed care organizations, e-Health technology companies and pharmacy benefit managers.

Future purchasers of disease management services will require detailed information on the effectiveness of these programs. This is especially important as the medical community strives for a more evidence-based approach to its medical decision-making. The disease management industry has the challenge of providing measurable and accurate data showing improved health outcomes and reduced healthcare costs.

Well-structured disease management programs should incorporate the following characteristics and goals.

- Improve outcomes by promoting the provision of timely and appropriate services.
- Utilize clinical information systems to help identify and track defined patient populations.
- Develop clinical practice guidelines by physicians and other healthcare personnel knowledgeable in treating chronic disease, utilizing evidence-based medicine, where available.
- Promote cooperation between primary care and specialty care physicians, including free flow of clinical information.
- Emphasize educating and empowering patients to successfully manage their own health, use self-monitoring techniques, and intelligently use care resources.
- Allow the choice of pharmaceuticals to be based on clinical judgment and validated outcomes studies rather than forcing strict adherence to program formularies.
- Allow informed and voluntary patient participation in the program.
- Incorporate ancillary medical services to support the physician's treatment plan.
- Allow physicians to deviate from disease management practice guidelines when appropriate, without incurring sanctions or jeopardizing coverage for services.
- Collect, evaluate, and disseminate information on outcomes to physicians and other providers of care.
- Support the primary care physician's authority for decisions to use or not use specialized care and ancillary services for patients.

Physicians have many opportunities within their own offices to establish disease management approaches to the care of their patients with chronic illnesses. Any disease management initiative should make the physician an integral part of the planning and implementation of that system. Without physician involvement and cooperation, the program is far less likely to be effective. A system without physician involvement may, in fact, be counterproductive, since it is the physician who is ultimately responsible for the care plan and health of that patient.

The growing use of electronic medical records should facilitate more and more physicians in utilizing disease management strategies in their offices. Many primary care organizations and, more recently, the Centers for Medicare and Medicaid Services are encouraging the increased use of electronic medical records.[2] They rightly recognize the potential for decreasing errors, making periodic health maintenance (e.g., mammograms, immunizations) easier to track, and improving health outcomes. Current limitations for physician offices include its cost and the difficulties of getting such systems to allow for easy flow of information between all providers of care (primary care physicians, specialty care physicians, hospitals, pharmacies, and others).

Disease management is an evolving concept. Whether it will be successful is highly dependent on a collaborative effort among all members of the healthcare team (patients, physicians, allied health professionals, health insurers, and employers) to bring improved health outcomes. The need for such approaches will only grow with time, as our population ages and as the unfortunate trend of adult and childhood obesity leads to more Americans living with chronic disease states. The potential burden on society and on the healthcare system is great, and the need for innovative and meaningful new approaches is equally great. With a disease management system that is well-constructed, relatively easy to implement, and efficient in its consumption of time and resources, we have a tremendous opportunity to positively impact our patients' health. **NCMJ**

Educating a New Generation of Healthcare Professionals with a Lifelong Commitment to Quality of Care

Stephen E. Willis, MD, Thomas J. Pulliam, MD, and Thomas J. Bacon, DrPH

This is a time of evolution and some turmoil within continuing medical education. Physician continuing professional development is coming under increasing scrutiny by a number of regulatory authorities both within the profession and external to it. A number of areas are receiving especially focused attention. These include the need for continuing professional development to be based on demonstrated needs of the physician and to result in demonstrable positive outcomes. The increased empowerment of the consumer and heightened expectations about quality care and evidence-based practices are also an influencing factor.

> *"...new entrants into the healthcare professions are being trained in paradigms that differ somewhat from the training received by those currently in practice."*

Increased physician accountability is expected to ensure positive outcomes. The influence of commercial entities on continuing professional development is closely monitored and scrutinized. Physicians and educators are challenged to successfully incorporate technology and electronic resources into healthcare and continuing education. Educators throughout the continuum of medical education are challenged to include training designed to augment the skills of learners in interacting effectively with patients.

Furthermore, new entrants into healthcare professions are being trained in paradigms that differ somewhat from the training received by those currently in practice. These new methods emphasize the use of interdisciplinary teams in healthcare, evidence-based practice and best practices, quality improvement initiatives, and the use of medical informatics as a tool for healthcare performance improvement. These are recent developments that will substantially impact the care rendered by new providers entering practice. They may bring a set of skills that may not be entirely congruous with traditions of practice developed by more seasoned and experienced clinicians. One of the challenges for educators involved in continuing professional development will be the need to incorporate training in these newer methods into their offerings. Continuous learning and development are important, first and foremost, to improve the healthcare rendered to, and the health of, those patients we serve.

We must embrace a system of practice-based continuing professional development that encourages physicians to: extract data from their practice, understand how these data relate to evidence-based best practices, design a system for conscious evolution of medical practice that is relevant to the community of patients served, incorporate technology and interdisciplinary healthcare teams into the provision of patient care, and finally, to assess the outcome of appropriate interventions and changes in patient care. Physicians must be both supported in and rewarded for such practice-based, patient-centered, and community-focused educational and practice initiatives. In the near future, it seems likely that physicians will be responsible for accounting for more than just "seat time" at continuing medical education (CME) events as they demonstrate their commitment to the ongoing maintenance of certification and continued competence.

Stephen E. Willis, MD, is Associate Dean of Continuing Medical Education and Professor of Family Medicine at the East Carolina University Brody School of Medicine. He is also the Executive Director of the Eastern AHEC. He can be reached at williss@mail.ecu.edu or PO Box 7224, Greenville, NC 27835. Telephone: 252-744-5221.

Thomas J. Pulliam, MD, is Vice President for Professional Affairs at the Wake Forest University Baptist Medical Center. He can be reached at tpulliam@wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157. Telephone: 336-716-6860.

Thomas J. Bacon, DrPH, is Executive Associate Dean University of North Carolina School of Medicine and Director of the NC AHEC Program. He can be reached at tom_bacon@med.unc.edu or CB# 7165, Chapel Hill, NC 27599-7165. Telephone: 919-966-8981.

We are fortunate in North Carolina to have a number of organizations committed to the education of our healthcare professionals. These include, but are certainly not limited to, the North Carolina Medical Society, various specialty and sub-specialty associations and societies, regulatory authorities, third-party payors, the academic health centers, and the North Carolina Area Health Education Centers (AHEC) Program. There are a large number of important initiatives, frequently involving collaborative efforts among these various organizations, currently underway. Many of these initiatives could impact medical practice in very fundamental ways. All of these initiatives require that physicians be skilled in the precepts of lifelong learning and committed to making changes in practice. Lifelong learning and continuing professional development must start with the physician being focused on enhancing the health of those we serve, and never end.

When Does Lifelong Learning Begin?

All clinical professionals evolve in their depth of understanding and knowledge in their areas of expertise. Ideally, the evolution of a professional's learning would begin while a student and continue throughout his or her professional life. Medical educators at the four medical schools in North Carolina continue to modify and refocus programs in the areas of interdisciplinary practice, computer-based learning, and evidence-based standards of care.

As examples:

- The Wake Forest University School of Medicine (WFUSM) provides a problem-based medical education. The medical curriculum is called the "Prescription for Excellence: A Physician's Pathway to Lifelong Learning." The curriculum initiates the learning process of the medical student by integrating the basic and clinical knowledge of medicine with current technology while building upon a foundation of ethical professional behaviors. The curriculum is organized to meet the five specific goals: (1) proficiency in self-directed learning and lifelong learning skills; (2) appropriate core biomedical science knowledge, clinical problem solving, and reasoning skills; (3) interviewing and communication skills; (4) information management skills; and (5) professional attitudes and behaviors. Across the five phases of their four-year curriculum WFUSM students study the basics of clinical sciences in an integrated fashion utilizing a variety of educational methods including small groups and problem-based learning. Community-based clinical experiences begin in the first year and focus on general population health. Issues of professionalism and humanism in medicine are addressed longitudinally throughout the four years. Information technology is integrated with a laptop computer issued early on and a Personal Digital Assistant (PDA) provided during their clinical rotations.

  Students are held accountable for embracing lifelong learning. The emphasis is upon the student gathering information and learning to think rather than simply memorizing factual information. The testing process also enhances the learning process with a focus on critical thinking skills rather than simply recalling factual knowledge. Thus far, the product of the Prescription for Excellence curriculum has been a well-rounded, generalist clinician who is prepared to embrace the evolving changes in medical practice with a focus on learning and self-assessment.

"Physicians must be both supported in and rewarded for such practice-based, patient-centered, and community-focused educational and practice initiatives."

- The East Carolina University Division of Health Sciences, collaborating with Eastern AHEC, has a nationally renowned program for training new entrants into healthcare professions in the nuances of effective interdisciplinary practice. Students are challenged to develop and demonstrate the ability to work together as members of teams aimed at providing comprehensive, cost-effective, efficient, and compassionate care for patients with chronic medical conditions. They utilize the unique skills and knowledge of providers from a large variety of disciplines while simultaneously minimizing repetition, enhancing communication, and capitalizing on the synergy inherent in truly interdisciplinary care. Learners who participate in these programs have skills heretofore not taught in the educational programs in medicine.

- Medical and other health profession students at most, or all, of our universities in North Carolina are now required to utilize computers and electronic resources as an integral mechanism for learning. Real-time and "point-of-care" resources are being utilized by an increasing number of health professionals. It will not be long before physicians emerging from residency will be dependent upon electronic resources in the day-to-day provision of patient care. Many of these practitioners will also use electronic media as a primary learning tool. In our opinion, electronic media will never entirely supplant, nor should they, traditional face-to-face professional development. These events provide critical networking and socialization functions in addition to serving as many practitioners' preferred mechanism of learning. At the same time, these events need to be much more data-driven and tied to changes in practice by the participating physicians.

A project funded by The Duke Endowment is currently getting underway in Charlotte and Southern Regional AHECs, in collaboration with the North Carolina Child Health Improvement Initiative at the University of North Carolina at Chapel Hill, to improve asthma care among all pediatric and family medicine practices in those two regions. Ultimately, some 330 practices will be involved in the project. Participating practices will receive data on their practices, take part in learning collaboratives, and implement evidence-based practices to achieve better outcomes of care.

- The United States Medical Licensing Examination (USMLE) has recently incorporated a clinical skills test utilizing standardized patients. As of June 2005, all potential licensees within the United States will be required to take, as a part of the USMLE Step 2, an examination that challenges them to demonstrate an ability to interact effectively with a patient in the context of an authentic, realistic clinical encounter.

As evidenced by the American Board of Medical Specialties (ABMS) maintenance of certification initiative, certifying boards are likely to expect practicing healthcare providers to demonstrate proficiency in some of these evolving skills to maintain their certification. It will take a sustained commitment among the many entities committed to improving patient health to effectively integrate new initiatives in continuing professional development. These organizations must work effectively and efficiently with physicians and other healthcare professionals to maximize the rational utilization of these new initiatives.

Equally important is the need for academic health centers, the North Carolina AHEC Program, Medical Review of North Carolina, third-party payers, and individual healthcare providers to accumulate and analyze data that will inform decision-making regarding the appropriate and effective utilization of emerging initiatives in healthcare and continuing professional development. While these critically important challenges are great, they are not insoluble. By capitalizing on the synergy of effective collaboration, we can meet these challenges and insure that the evolution in healthcare and continuing professional development results in improved health for those we serve. **NCMJ**

Making Healthcare 'Patient-Centered':
The Centerpiece of Quality Improvement

L. Allen Dobson, Jr., MD, FAAFP, and Michelle F. Jones, MD

In a time when the bottom line drives healthcare delivery, including access to care, diagnostic interventions, and therapeutic plans, we are left with a system that is in need of fundamental change. The system is inefficient, redundant, confusing for patients and providers. It is increasingly fragmented and is not meeting the needs of its recipients. Instead of treating patients, caregivers treat the threat of malpractice law suits as well as concerns of evoking the wrath of payers over the costs of tests ordered and medications prescribed. Despite the best efforts of those involved in caring for patients, our systems have failed both the patients and the caregiver.

The current attention to the need for quality improvement identified in the 2001 national Institute of Medicine report[1] and the subject of this Journal has sparked significant discussion in the medical, government, and business communities. Future models of healthcare must focus on patients' needs and preferences, quality of services, and a reduction in variability of care. Care coordination and integration, the transfer of information, and communication with the patient must be addressed in any emerging system that adequately meets patients' expectations.

> *"...all patients in the healthcare system deserve a medical home."*

Patient-Centered Care

Patient-centered care has been identified as a key attribute of a new system. It has the needs and preferences of each patient as its central focus. The cornerstone of this care is a patient-physician relationship that is satisfying to the patient and humanizing to both the patient and physician.[2] The interaction should be sensitive to the patient's physical and emotional needs and wants and should be culturally competent. These needs are likely to change over time and with different disease states; therefore, an established relationship will augment decisions and help ensure patient satisfaction. This should ideally be a long-term relationship and should be a partnership for the good of the patient. To-date, there is limited research to identify the most important aspects of patient-centered care or how to best deliver such care. The Cochrane Collaborative[3] performed a systematic review of the literature to determine whether patient-centered communication improves patient health outcomes and patient satisfaction. Although there was evidence of positive impact on patient satisfaction, the evidence was insufficient to draw conclusions about the impact on the patient's health status. Yet, intuitively, care that is patient-centered is what we all want for our own families and represents an obvious system goal in the move toward quality improvement. Clearly more research is required.

Unfortunately the quality of care and evidenced-based decision making provided alone may do little to make up for the shortcomings in the quality of service patients receive, and therefore their perception regarding the quality of our healthcare system. A study by the Picker/Commonwealth Program for Patient-Centered Care[4] suggests that patients often define quality care in terms of "service." Among the measures of quality patients identified in the study were: (1) respect for patient's preferences and values, (2) timely access to care, (3) information and education, and (4) continuity. Similarly, a recent study found that medical errors reported by patients are more likely to directly involve the breakdowns in the physician-patient relationship and the access to clinicians than the technical errors that are the focus of the most current patient safety initiatives.[5]

A Medical Home for All Patients

There is clearly a need for the healthcare system to refocus on better coordination and integration of patient care. This coordination and integration of care should focus on better

L. Allen Dobson, Jr., MD, FAAFP, is the Director of Graduate Medical Education at the Cabarrus Family Medicine Residency Program. He can be reached at adobson@northeastmedical.org or 270 Copperfield Blvd., Suite 201, Concord, NC 28025. Telephone: 704-721-2060.

Michelle F. Jones, MD, is the Treasurer of the North Carolina Academy of Family Physicians and in private practice in Wilmington, NC. She can be reached at drsjones@charter.net or at Wilmington Health Associates, 8108-B Market St., Wilmington, NC 28401. Telephone: 910-686-8775.

service and begin with a personal physician and a personal medical home. The recommendation of a medical home was initially adopted by the American Academy of Pediatrics for children, but all patients in the healthcare system deserve a medical home. A medical home would serve as a point though which all individuals regardless of age, sex, race, or socioeconomic status enter into the healthcare system. It would ensure access to comprehensive and integrated care through physicians, nurses, therapists, and educators. Information and educational materials for patients could be easily accessed by patients. Barriers to access can be minimized with flexible office hours, open-access scheduling, and asynchronous communication such as voice mail and e-mail. Consultation and referral services would be coordinated through this model and would be smooth with a timely and reliable exchange of information to and from the consultant. The electronic medical record has great potential for improving this vital communication exchange. Many patients depend on those who provide care to coordinate seamless transitions from one setting to another and from a healthcare to a self-care setting.[6]

Patient Inclusion Improves Care

In the current system, timely access to information belongs only to the caregivers. Patients may only obtain information after permission is obtained, the appropriate paperwork is completed, and the two-week waiting period during which the charts are copied by contracting agencies has passed. Donald Berwick has introduced a concept of nurturing “transparency” in the healthcare system. By this he means that all information should be available to anyone involved in the system and in the care of the patient, including, and most importantly, the patient. Healthcare should certainly be confidential, but the healthcare industry is not entitled to secrecy.[7]

A quote from Diane Plamping, a public health researcher from the United Kingdom. says, “Nothing about me, without me.”[8] Transparency in the system will allow patients to make informed choices and allow access to facts that may be relevant to the patient’s decision making. Naturally, there is a concern about increased liability risk, and tort reform would be a desirable change, but improvement in the system cannot wait for such change. Healthcare systems with transparency will be more patient-centered and safer because patients may recognize information that is outdated or incorrect, which may affect their care.

Information on disease states may be obtained through many peer-reviewed and non-peer reviewed sources with varying degrees of accuracy. No longer is the physician the major source of medical information for patients. In a 1998 survey of Internet users, 42% said they accessed medical information weekly or daily on the Internet.[9] It is becoming well known through growing scientific literature that informed patients participating actively in their care have better outcomes, lower costs, and higher functional status than those held to more passive roles. Guadagnoli and Ward have found in a recent review of the literature that most patients want to be involved in the treatment decisions and to know about available alternatives.[10] Patients should not be forced to share decision making, but should be able to exercise the degree of control they wish. Arora and McHorney found that the majority of patients with chronic diseases, such as hypertension, diabetes, congestive heart failure and depression, preferred to delegate their medical decisions to their physicians.[11] Currently, two-thirds of United States healthcare expenditures are related to such chronic illnesses. Providing systems that support a continuous ongoing relationship between patient and physician, collaborative multi-provider models that support patient needs, and reliable information exchange with patients and clinical decision support systems for physicians are critical in adjusting the healthcare system from an acute care model to one capable of handling the burden of chronic illness.

> *“Healthcare systems with transparency will be more patient-centered and safer because patients may recognize information that is outdated or incorrect, which may affect their care.”*

The Internet Extends Care Beyond the Office

Traditionally, the doctor-patient interaction is only reimbursed with a face-to-face meeting. Often times this interaction is needed for evaluation of a patient’s condition, but for many this meeting is neither needed by the provider nor wanted by the patient. Twenty-first century technology through the Internet and e-mail communication allows for care in the comfort of a patient’s own home. The Internet may offer providers a way to interact more frequently with patients, to monitor progress, and provide education and reminders.

The Internet will likely be able to support a substantial portion of healthcare services, which will require new payment policies to compensate providers as the face-to-face patient visits cease to be the single method of patient care. In the past, payers have resisted paying for these services, citing this was part of the coordination of care and difficulties in adequately documenting time and effort spent on such services. However, primary care practice involves much more time spent in answering calls and messages and in coordinating care. A new healthcare system must keep the patient and the patient-physician relationship as its central focus and must also compensate providers adequately for such services. As pointed out in a recent commentary by Paul Ginsburg, “mechanisms of payment for primary care services can be a substantial impediment to achieving the vision of the primary care of the future. Fee-for service payment is not evolving in the same way that the practice of medicine is."[12]

Conclusion

Major reform in the system clearly is needed, including new payment methods to support needed changes. However providers should not wait until the system is reformed, tort reform is enacted, or new payment methods are aligned to begin the work at-hand. We must begin the discussions necessary between specialties to re-establish a degree of coordination in care. We must make sure all patients have a medical home. We must innovate and share successes in better service delivery for patients. Insurers must be willing to be flexible in looking at funding innovation. We all must engage our patients in this discussion—becoming patient-centered begins there. **NCMJ**

COMMENTARY

Quality of Care and Performance Improvement:
Two Ideas that Go Hand-in-Hand

Noel B. McDevitt, MD, William A. Walker, MD, FACS, FASCRS, and Gordon H. DeFriese, PhD

Americans have become accustomed to hearing the statement that "the United States has the highest quality healthcare in the world!" There is little doubt that the best and most advanced medical care exists in this country. But, the term "quality of care" encompasses both *qualitative* and *quantitative* aspects of care. As Shuster, et al.,[1] have pointed out, "poor quality" can refer to too much, too little, or the wrong care. Assuring access to appropriate and needed basic healthcare services is an integral part of what we mean by quality care. We also recognize that some receive far more care and services than is really necessary, effective, or safe. Moreover, receiving the appropriate procedure or therapeutic intervention does not mean that such services were provided correctly, or in a timely manner. Hence, quality of care, as an implied standard or goal of the healthcare industry or of healthcare professionals, is a multifaceted and complex concept. Achieving this goal or standard of care requires concerted action on the part of all who provide, organize, regulate, pay for, and receive healthcare services.

The Paradox of Quality Improvement

Physicians are confronted by a number of seemingly paradoxical dimensions of the increasing emphasis on quality of care. On one hand, there is the claim that we have the best medical care on the planet, but, on the other, there is the crescendo of claims that American healthcare suffers from serious problems of overuse, omissions, and lack of access and errors that have led to serious compromises in patient safety. Physicians and other healthcare providers are admonished to provide *all* appropriate clinical and preventive services appropriate to the age and gender of their patients, while at the same time healthcare insurers, purchasers, and policy makers seem to impose ever more stringent criteria for both performance and payment as part of so-called "utilization-management" programs. Quality of care, as defined by scientific evidence of benefit and considerations of accessibility and equity among all population subgroups, can seem to be an elusive goal.

Systems of Care: The Focal Point for Performance Improvement

So, what does (or should) an increased emphasis on quality of healthcare mean for the individual healthcare professional? There is no question that any attempt to improve the overall quality of care within any defined population will depend on the day-to-day attention to standards of care, clinical guidelines, and available scientific evidence on the part of individual practitioners. However, nearly all physicians and other healthcare professionals practice in some relationship to organized "systems" of care—most of which have specified (and often legal) responsibility for the provision of medical services to defined populations. Hence, quality of care improvement efforts are conventionally defined and developed within these systems of care and in consideration of patterns of health conditions and healthcare needs within the target populations being served. Insurance and managed care companies often consider even unaffiliated physicians to be participants in qualified "panels" of providers approved to participate in the care of patients who share a common employer or insurance carrier. It is within these formal and informal "systems of care" that organized efforts toward the improvement of care quality have received most attention in recent years, and it is within such systems of care that the potential for the greatest overall public benefit may lie.

Within defined populations served by care systems, patterns and categories of health conditions that represent the predominant burden of illness in a given population may be identified, and therefore the greatest proportion of overall healthcare costs.

Noel B. McDevitt, MD, is a plastic surgeon in Pinehurst, North Carolina. He can be reached at drmcdevitt@earthlink.net or PO Box 3550, Pinehurst, NC 27374. Telephone: 910-295-1917.

William A. Walker, MD, FACS, FASCRS, is the Chair of the Surgical Peer Review Committee at Presbyterian Hospital in Charlotte, NC. He can be reached at wwalker@charlottecolorectal.com.

Gordon H. DeFriese, PhD, is President and CEO of the North Carolina Institute of Medicine. He is also Editor-in-Chief and Publisher of the *North Carolina Medical Journal*. He can be reached at gordon_defriese@nciom.org or 5501 Fortunes Ridge Dr., Suite E, Durham, NC 27713. Telephone: 919-401-6599, ext. 27.

Although simultaneously addressing quality of care across the full spectrum of health and illness conditions encountered in a conventional practice situation may be daunting, it is important to agree to "start somewhere." That "somewhere" should be with a focus on health conditions or diseases demanding the most time and resources.

> *"Quality of care, as defined by scientific evidence of benefit and considerations of accessibility and equity among all population subgroups, can seem to be an elusive goal in the imperfect world of mainstream healthcare practice."*

As an illustration of this incremental approach, assume that every fifth patient seen in a primary care practice is a person of middle-age or older with hypertension. In such a practice, systematic steps to assure that all clinical screening and monitoring of this condition—as well as a consideration of recommended pharmaceutical interventions to control blood pressure and counseling for smoking cessation, diet, and physical activity, take place *as a matter of routine* with every hypertensive patient encounter—is a starting point. Data and information from the practice summarizing the extent to which the blood pressures of *all* diagnosed hypertensive patients are being monitored regularly and under control is an essential element of any approach to internal practice (or system) evaluation of care quality. Similar approaches are appropriate for other categories of patients representing significant proportions of overall practice volume (e.g., numbers and proportion of diabetic patients needing hemoglobin A1C testing, having regular ocular and foot examinations, etc.).

This approach, which is increasingly a matter of routine in physician practices of all sizes and complexity, is an integral part of healthcare system *performance improvement*. Having clinical epidemiological information from one's practice can be a source of lifelong intellectual interest in one's major career activities, and serve as a means of self-evaluation.

Utilization Management Should Encompass Quality of Care

Physicians and other healthcare professionals for a number of years have complained bitterly with justification about the increasing burden of bureaucratic procedures associated with patient care. As utilization management systems have been promulgated by third parties (insurance carriers, health plans, employers, and managed care organizations) to reduce costs and rationalize clinical care, the reporting requirements of nearly every aspect of care have increased. Yet, it is time that these utilization management approaches be integrated with efforts to improve the overall quality of care.[2] Instead of a complete focus on cost-containment and the prevention of the overuse of care, utilization management efforts should be enlarged to include a consideration of "...the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge."[3]

Moreover, Wickizer and Lessler[2] have argued that utilization management efforts should give emphasis to areas of care where there is strong evidence of both appropriateness and clinical need in addition to identifying those categories of care where services and procedures are underused and under-prescribed. The emphasis should be on monitoring defined categories of patients, not total populations of the insured, to ensure that those in these defined categories (e.g., all diabetics) receive all appropriate preventive services and acute medical care.

The special Task Force of the North Carolina Medical Society on Quality of Care and Performance Improvement has recommended that the Society identify evidence-based protocols for managing patients diagnosed with diabetes, asthma, and heart failure. Clinical screening and preventive interventions are appropriate and recommended for obesity, smoking cessation, immunizations, alcohol and substance abuse counseling or other intervention, mammography, colorectal cancer screening, and elevated blood pressure. To ensure these services are provided once protocols are identified, the North Carolina Medical Society should provide physicians with tools that are applicable to office-based practice. The North Carolina Medical Society hopes this will help the general public to understand these conditions and the need for clinical screening and other preventive services.

What about Medical Errors and Patient Safety?

All segments of the healthcare industry are placing greater emphasis on reducing medical errors and assuring patient safety. Since the publication of the 1999 landmark report of the national Institute of Medicine, *To Err is Human: Building a Safer Health System*,[4] there has been widespread concern among the general public, the news media, and policy makers over both the enormity of these problems and over the apparent reluctance of professional and healthcare industry groups to address these issues.[5]

As an important part of the overall movement to improve quality and performance in American healthcare, efforts to stem the tide of medical errors and assure the safety of patient care are often too little and too late. As Millenson[5] argues, healthcare professionals have always maintained that, by virtue of their commitment and training, they are motivated to "do the right thing." Yet, professionalism alone often is not enough to address some of the systemic problems in healthcare that require concerted and forceful action. When the common routines of practice allow the possibility of inadvertent error (such as in surgically amputating the wrong limb, or hanging the wrong bottle of fluid on an IV pole, or dispensing the wrong medication), and when these errors occur repeatedly, everyone should be incensed. Such errors are both preventable (through proper labeling and computerized ordering) and also unacceptable. Patient safety should be an integral part of any quality of care or safety improvement initiative.

> *"...it is important to agree to start somewhere."*

As with quality concerns over the provision of clinical preventive services, errors of omission and commission can result in significant harm to patients. If patients recovering from myocardial ischemic events are allowed to leave a hospital without receiving beta-blockers, despite compelling evidence of beneficial effect and mortality reduction, a serious problem of quality with important implications for patient safety exists. Efforts to improve the quality of care and system performance must include steps that assure that all healthcare professionals are aware of life-saving interventions and are provided reminders that ensure that they will not be overlooked.

What about the Incentives for Quality Improvement?

The United States healthcare system does not recognize the quality of care provided at any level and reward those providers who diligently assure the highest standards of care for their patients. Moreover, there is very little easily accessible data by which patients or the purchasers of healthcare insurance can evaluate the quality of care routinely provided by either individual professionals or by healthcare organizations. As methods for the systematic measurement of care quality (and evidence-based strategies for it's provision) are developed, it will be important that healthcare insurers and policy makers find ways to compensate those who consistently provide the highest quality care for their patients. The so-called "pay-for-performance" movement is controversial largely because of past experience with record-based approaches to physician reimbursement by insurance agencies and by governmental regulatory bodies. But, without such systems, there will remain only the incentive of professionalism as a primary motivator of change toward these higher standards of quality and system performance. Much more can and should be done to reward healthcare professionals who uphold the highest quality of care for their patients. **NCMJ**

SPECIAL ARTICLE

Remembering Cecil*

Donald L. Madison, MD

An accounting of what Cecil Sheps managed to accomplish during his working life might be possible, but it would be less interesting—for the accountant at least—than attempting to understand how and why he did what he did. And so, alongside an admittedly superficial chronicling of his career, I have made that attempt, relying both on the historical record and my own observations.

I begin with the question: Who was Cecil Sheps, MD, MPH, professionally? It is a question that naturally incorporates two others—Where did he come from? And, as importantly, When did he arrive on the scene?

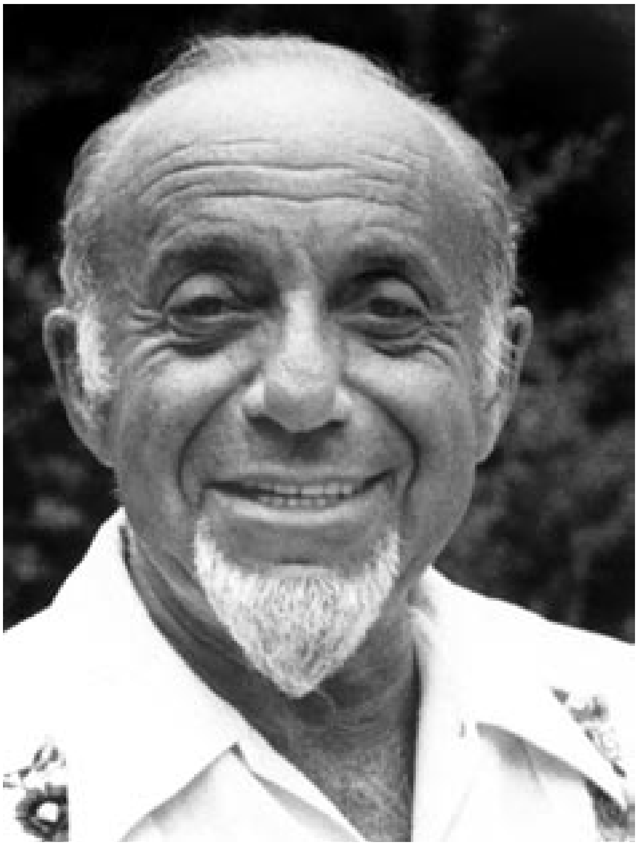
Cecil was one of a small group of "medical careniks" who became active at the end of World War II. They called themselves medical careniks partly in jest; yet one would suppose that the Russian genesis of the word also matched their favorable view of socialist health systems, as well as their view of themselves as young revolutionaries in public health.

The suffix, *nik*, is both Russian and Yiddish. It means something "associated with or characterized by," as in the Russian *Sputnik* (meaning associated with or, literally, traveling with the earth), and two familiar nikwords of American slanguage—beatnik and peacenik, or the Yiddish word *nudnik:* a bothersome boor or pest, which is how some of the old-line public health officers in the late 1940s must have viewed the medical careniks who were urging change on the public health establishment.[1]

What set the medical careniks apart, besides their youth (young for the most part, although the leaders were veterans of earlier campaigns), was their wish to turn both the American Public Health Association and the United States Public Health Service in a direction that would enlarge public health's concern to include medical care.

They called it "medical care," not "healthcare"—which, so far as I can tell, is a recent singleword invention of "publicrelations" consultants to the hospital industry, a term generated out of concern that "medical care" might point too narrowly to the medical profession and thereby exclude the new hospital CEOs and their various underling Os, along with their corporate bosses. Certainly, the medical careniks did not envision, much less embrace, the corporate genesis of so much of today's health services sector. In their day the term "medical care" stood for medical programs for populations—starting with the practice of medicine to be sure, but moving from there in a public health rather than a private practice direction—and certainly never toward a corporate destination.

Almost all in the group of whom I speak were physicians. Virtually all were male. Most were veterans of World War II. Most were Jews. In intellect they ranged from superior to brilliant. And they shared the same commitment to public health and social justice. They were also of about the same age; those I



*Based on remarks by the author at the Memorial Service for Cecil G. Sheps, MD, MPH (1913-2004), Chapel Hill, NC, May 21, 2004.

Donald L. Madison, MD, is a professor of Social Medicine in the UNC School of Medicine and Contributing Editor for the North Carolina Medical Journal. He can be reached at donmad@med.unc.edu or at the Department of Social Medicine, UNC School of Medicine, CB# 7240, Chapel Hill, NC 27500-7240. Telephone: 919-962-1140.

knew best (the group mentioned below) were all born between 1912 and 1917.

I should name some names here. Nearly all of these people are gone now. The oldest—Sy Axelrod, and the youngest—Dick Weinerman, plus Milt Roemer and Les Falk had become close friends while working together in the Farm Labor Health Program (the original migrant health program) just after World War II. Others included Milton Terris, Leonard Rosenfeld, Paul Cornely, and my two mentors, George Silver and Cecil Sheps. Those were probably the core, although there were several others. They all seemed to know each other, either through the Public Health Service or the American Public Health Association (APHA), from earlier association as medical students, or through their common mentor—because all would have considered themselves disciples of the medical historian, internationalist, and public gadfly (where medical care was concerned), Dr. Henry Sigerist of Johns Hopkins.

In the years before email and cheap long-distance telephone service they also wrote to each other. That correspondence probably exists in several places, but a good deal of it can be found in the Richard Weinerman papers at Yale. (Weinerman was a faculty member at Yale at the time of his premature death, so his papers were catalogued before those of the others, most of whom, by the way, also gave their papers to the Contemporary Medical Care and Health Policy Collection at the Yale University Library.[2])

Their letters to each other between 1945 and about 1949 voice concerns that were common among veterans: finding a job, entering graduate school, fathering children. These young men, however, also wrote about politics, especially their hopes for the next Wagner-Murray-Dingell Bill, and, often, of the prospect of seeing each other, and of visits to or lectures by or letters from Henry Sigerist.

In the Weinerman correspondence from those years, there are only one or two exchanges between Dick Weinerman and Cecil, but in letters from the others to Dick, Cecil is mentioned several times in ways that make it clear that he is a member of the group, even though in one respect he was an outsider.

Cecil was a Canadian. But not just *any* Canadian; because he had been a "carpetbagger" to Saskatchewan. That was what they called themselves—those who came from outside that mainly rural Canadian Province to help plant the first North American instance of social insurance for hospital care. Mindel Sheps, Cecil's wife and medical school classmate at the University of Manitoba, was also a carpetbagger; and so, later, was Len Rosenfeld. The carpetbaggers would have been automatically welcomed into the group of medical careniks because the Saskatchewan development was so profoundly important to them. Besides, the most famous carpetbagger of all had been Henry Sigerist, who came to Regina at Cecil and Mindel's invitation to direct the preliminary survey for the Provincial health plan.[3] And more than anyone else, it was Sigerist who united the younger medical careniks and articulated their cause.

All the members of this group would distinguish themselves later. By another 20 years, in the mid- to late-1960s, they had become the mentors for a new generation of medical careniks. Sy Axelrod, Milt Roemer, and Milton Terris became teachers—primarily (although they were researchers, too). Len Rosenfeld and Les Falk became administrators, but were teachers and researchers, as well. Paul Cornely, Dick Weinerman, George Silver, and Cecil Sheps did it all.[4]

I met George Silver in September 1964. I was a fourth-year medical student from California and had come east to do a two-month elective with him in Social Medicine at Montefiore Hospital in the Bronx. The American Public Health Association just happened to be meeting in New York City that fall, and so I heard, and even met, some of the medical careniks—those who spoke at the meeting or chaired sessions. But although I'm quite sure he was on the program someplace, I didn't lay eyes on Cecil. I knew his name, though.

A little over a year later—after Silver had become Phil Lee's[5] Deputy in charge of stirring things up in Washington, DC, after he helped me find a job in the Public Health Service, and after my new bosses had accepted my suggestion that I be assigned to Cecil Sheps at Beth Israel Medical Center in New York—after all that had been arranged, I made an appointment to meet him, finally. (I started to write, "to finally meet him," but splitting an infinitive when writing about Cecil is something you can't do—not if he once corrected your prose.)

The night before our scheduled meeting, my wife and I were driving from Staten Island, where we lived, to see a movie in Manhattan. Somewhere in Brooklyn I turned the radio on and, quite by chance, heard two people engaged in a polite but vigorous debate about Medicare, which Congress had enacted nearly a year earlier and which was just about to be implemented, as a matter of fact, by my division of the Public Health Service. In essence, their argument was over whether Medicare had been a bad idea all along and was therefore doomed to fail—as organized medicine was still predicting in the spring of 1966—or whether it was necessary and would succeed. Both debaters were in command of the points they wanted to make, but I had no idea who they were. We were coming off the Brooklyn Bridge when the host identified his guests. One was president of one of the borough medical societies; the other was the General Director of Beth Israel Medical Center, Dr. Cecil Sheps.

The next morning I showed up at Beth Israel and was ushered into the inner sanctum of the office of the General Director. I had already heard him speak, and now, there he was, puffing his cigar in a holder, attired in a bow tie, shorter than I'd imagined. He didn't have the goatee yet, and I remember thinking that he looked like Jacob Javits, who was then the senior Senator from New York. Dr. Sheps accepted my congratulations on his previous night's radio performance and then quickly got to the business at hand. He had only been at Beth Israel a few months, yet he was full of ideas about what projects I might work on—virtually every project, it sounded like, and there were a lot of them.

The Public Health Service's idea (and mine) was that I was there to learn how to be a medical care administrator so that I might be of some use to my unit, which was called, by the way, the Division of Medical Care Administration. Cecil would be my teacher. I was enthusiastic, not having realized yet that my aptitudes, whatever they may have been, did not include administration. But I was still ignorant of that and eager to learn.

Cecil was presiding over at least ten—possibly twice that many—community medical care programs or related projects from Beth Israel: the Gouverneur Ambulatory Care Program, the "I Spy" Children and Youth Project, the Methadone Maintenance Demonstration at Manhattan General, the community medicine curriculum at Mt. Sinai Medical School, the Judson Memorial Church project, nursing home affiliations, the national neighborhood health centers evaluation project for the War on Poverty, the *Guide to Medical Care Administration* project for the APHA. Those are the ones I can remember him mentioning that I might work on.

In 1966 he was 53 years old and at the peak of his professional career. In the office he was a dynamo. Three secretaries stationed just outside the door worked on his dictation. He wrote letters constantly (he followed up on everything). After editing each dictated draft quickly, he gave it back for typing, then read the final version carefully before signing it; and always, in those pre-Xerox days, he initialed every carbon copy. He once told me the reason he did that. I've forgotten what it was, but since he did it, I did it, too, for as long as there were carbon copies. Then the phone calls, one after another, placed by one of those secretaries. And the small blue slips that he habitually attached—perhaps at home the night before, or on an airplane the previous day—to documents that he had already perused and wanted one or several of his colleagues to know about. The notes on the blue slips were sometimes dictated, too, but were more often scribed in his illegible scrawl. At the bottom of each blue slip was a check mark either on the "please return" line or the "need not be returned" line. To an impressionable and wholly inexperienced young person like me, watching him work was an indelible adventure. If I were casting a film about Cecil in New York, I would look for a young Edward G. Robinson.

He had many interests and talents. First, of course, he was interested in—and knowledgeable of—all developments in medical care. That's a lot right there. Beyond that he was keenly interested in politics and history, theatre and art—and travel. Also in all jokes that started with the line, "Two old Jews were talking." He collected those.

But he was no Renaissance man; there were things he didn't know, and things he couldn't do so well. He could barely drive a car. And despite his love of travel, his sense of direction lacked a great deal. As a writer and editor he was a stickler more than a stylist. And he didn't understand sports at all; this would turn out to be a disadvantage later, when he became Vice Chancellor of a major state university and was obliged to sit in the Chancellor's box at football games, and converse at halftime with other, more observant fans who also happened to be trustees and important alumni.

Cecil's first listed publication, in *Canadian Advance*, was on a medical care topic: it was titled "The Municipal Doctor System." The article appeared in 1939, three years after his graduation from medical school, perhaps when he was working in general practice in Manitoba, which he did for a time. I say "perhaps" because he omitted those early experiences from his *curriculum vitae*, including only this entry: "Health Administration, Health Professions Education, Health Policy, Preventive Medicine and Public Health, 48 years." Presumably that would cover everything. World War II also began in 1939, and Cecil entered the Canadian Army—although his military service doesn't appear on his vita either. However, from the end of the war forward, one can follow his major professional interests pretty well from reading the titles of his 154 publications.

The first thing I notice is an impressive series of articles on the subject of venereal disease control, beginning in Saskatchewan. The venereal disease papers are interrupted by a second publication on a medical care topic, "Health Regions—(the) Essential First Step in (the) Saskatchewan Health Program," and one on general public health, "Mortality in Socio-Economic Districts of New Haven" (written while he was getting his master's degree in public health at Yale). The venereal desease papers then continue, but now from the School of Public Health at the University of North Carolina at Chapel Hill (UNC-CH).

To explain this odd trajectory—Winnipeg to Regina to New Haven to Chapel Hill—I should amplify something I mentioned earlier. Near the end of the war, the people of the Province of Saskatchewan elected a socialist government headed by Premier Tommy Douglas, leader of a political party called the Cooperative Commonwealth Federation (CCF). The CCF was the first socialist government in North America—if one discounts municipal governments. In Great Britain, at nearly the same time, the socialists (Clement Atlee's Labor Party) defeated Winston Churchill's Conservatives, and a few years later Britain put in place the National Health Service. How heady a time those immediate post-war years must have been for young socialists like Cecil and Mindel!

In Saskatchewan Cecil held the title of Acting Chairman of the Health Services Planning Commission and the political title of Assistant Deputy Minister. He was 31 years old then. By some accounts—but not his—he aggravated the medical profession of the province, and the government acceded to the doctors' wish that he be relieved.

Enter the Rockefeller Foundation. In the immediate post-war years, Alan Gregg, who ran the medical sciences program at Rockefeller, made a few small grants in medical care. He had been doing this for a number of years, but strictly on the side, so to speak, because the Rockefeller Foundation had no formal program in medical care; it was merely one of Dr. Gregg's hobbies. At the end of the war he proposed that the Foundation launch such a program, which it did, bringing in John Grant, who had been a long-time field officer—in China primarily, but also in India and elsewhere—to head it up.

During the 1940s, first Gregg and then Grant invested in a few young men (I'm reasonably certain they were all men) by giving them stipends and sending them off for a year to a school of public health—either Hopkins, Harvard, Yale, or Michigan—to study medical care and get a degree. Several of those I named earlier received such Rockefeller stipends; and that is how Cecil was able to attend Yale during the 1946-47 school year. His medical care teacher was Franz Goldmann, who authored one of the first American texts on the topic.[6]

At the end of his year at Yale, Cecil needed a job and found a temporary one—in North Carolina. The School of Public Health at Chapel Hill needed someone to teach biostatistics in summer school. On his way south he stopped in New York to see Dr. Grant, who made an entry in his diary (all Rockefeller Foundation officers kept diaries): "Sheps is certainly bright, and one judges (he) will make an excellent and enthusiastic teacher."

Later on, Cecil and Dr. Grant would come to know each other well. Cecil used to say that of all the people he knew professionally—and he seemed to know everyone—the two he most admired, whom he considered his mentors, were Henry Sigerist and John Grant.

Assistant Professor of Public Health, 1947

At the end of that summer session, someone—it was probably John Wright, who was then the chair of the Department of Public Health Administration and the co-author on several of those early articles on venereal disease control—asked Cecil to stay on at the School of Public Health.

After a couple of years, Cecil's interest in venereal disease gave way to an altogether different theme—planning. Rockefeller awarded a major grant to UNC-CH to plan to become a statewide medical center. John Grant considered the UNC-CH grant one of the most significant investments of his burgeoning medical care program. A teaching hospital was due to open in Chapel Hill in 1952, and with it what Abraham Flexner had called a "half medical school" (in his 1910 report, *Medical Education in the United States and Canada*) would expand at last to a full four years. Further, the University promised its constituents that the new hospital's mission would be "to serve the people of North Carolina." These events were the stimuli for the Rockefeller grant. Cecil was put in charge—John Grant more or less insisted on this—and given the title, Director of Program Planning in the Division of Health Affairs.

But soon his publications began to shift again, to the subject of the hospital. In fact, Cecil ended his six-year sojourn in Chapel Hill in 1953 to become General Director of the Beth Israel Hospital in Boston.

I notice that during the early and middle 1950s, some of his titles began to sound less like scholarship and research and more like mild exhortations or at least wise musings, which suggests that they were probably speeches edited for publication —for example, "Community Hospital: The Future Health Center" and "We Must Use Hospitals More Effectively."

During both of Cecil's two main administrative jobs—as head of two major urban medical centers—he published articles, not just occasionally but regularly. In fact, when I worked with him in New York, he reported in print, promptly, on whatever it was that he was doing or thinking. From his example I assumed that writing for publication must be part of a medical care administrator's job. It never occurred to me until years later, after I had met many important administrators, some of whom could hardly draft a press release, that Cecil's example was not the standard; that the *sine qua non* quality for an institutional administrator was not an eagerness to lead by communicating ideas—to one's staff, professional peers, and the public—so much as good conduct in the board room.

At the Beth Israel in Boston Cecil also began medical care research. (We now call it health services research.) He received a grant from the Public Health Service, found two outstanding colleagues, Jerry Solon and Sidney Lee, and they began their pioneering investigations—intellectually and methodologically important studies of hospital-based ambulatory care. For the first time, an important teaching hospital, used by thousands of people as their major source of medical care, was actually tracking its community of patients, finding out who they were, understanding the reasons why they used the outpatient department as their primary source of care, and learning what finally happened to them. This was research focused on the modern teaching hospital, where by the mid-1950s, biomedical research and house staff training ruled. Furthermore, it was non-biomedical patient care research designed to uncover information that any administrator would want to know, should want to know, and Cecil did want to know.

Most of his publications during the Boston years reflect or report on these studies of outpatient care. But he was also interested in the larger environment of the teaching hospital, for example, on how it related to the medical school. With a group of colleagues that included Dean Clark, the General Director of the Massachusetts General Hospital (who would later join Cecil at the University of Pittsburgh), he undertook a national survey of teaching hospitals, concentrating on the nature of their affiliations with medical schools. He wrote about the hospital's responsibility for home care and community health education. And along with his old professor Franz Goldmann and a couple of fellow medical careniks, Sy Axelrod and Milton Terris, he co-edited a book for teaching medical and public health students, titled *Readings in Medical Care*.

In 1960, Cecil became a full-time academic for the second time when he moved to the University of Pittsburgh to chair the Department of Health and Hospital Administration in the School of Public Health. During his five years at Pittsburgh, the topics of his publications broadened further. Much of his writing was still about the hospital, but now he was writing also about medical schools, schools of public health, expenditures for health and medical care, and on the general topic of research in medical care and community health. One notices, too, that some of his publications reported the results of some outside committee and consulting assignments, for example, emergency medical care in Allegheny County, and the adequacy of health resources in Idaho, Montana, Nevada, and Wyoming. In addition, he was engaged in community medical care research, with articles about families and their regular doctors, how the citizens of an industrial town that the authors called "Aluminum City" made use of medical specialists, and the office practices of 500 internists in New York State.

I had always assumed that Cecil's move to New York City in 1965 was explained by the lure of Beth Israel Medical Center, which to my mind was already becoming the Montefiore of Manhattan in terms of its strong social medicine orientation. I assumed that the general directorship of this institution was simply too attractive an offer to turn down. I assumed wrong. Much later, Cecil told me that the reason he had moved to Chapel Hill (the first time) and then to Boston, and to Pittsburgh, had been because of the professional opportunity each of those positions offered. Mindel had gone along, had followed him, so to speak, as the "less-qualified" member of the couple. But while they were in Boston, she had earned her graduate degree in biostatistics, and in Pittsburgh she became a member of the faculty of the Graduate School of Public Health. After a time, however, she found herself in a fundamental disagreement with her superior over some basic matters of academic behavior. The disagreement was important enough so that Cecil told her that they would leave Pittsburgh, and that it was now her turn to take the lead; she should find her best opportunity, and wherever it was he would follow. She picked Columbia University, and he then applied at Beth Israel. He would have found some other job in New York had the position at Beth Israel not been open.

In New York several of Cecil's publications began to reflect some of the federal health legislation that was part of President Johnson's Great Society, and the general theme of "serving the community." His pieces of that period had titles like "The Medical School—Community Expectations" and "The Role of the Teaching Hospital in Community Service" and "Evaluation of Neighborhood Health Centers" and "Relating a Neighborhood Health Center to a General Hospital."

The return to Chapel Hill in 1969 seems to have been a perfect fit for both Cecil and the University. The ideal candidate to head a new federally funded health services research center, he had, after all, been a pioneer in that field—well-recognized for his own work and highly regarded as an advisor to the Washington, DC, funding agencies.

But for Cecil the opportunity must have seemed fortuitous for personal reasons. One day in New York, I think it was in the spring of 1967, he told me that he and Mindel were going to Chapel Hill the following day to close on the purchase of a lot on which they intended to build their retirement home. I asked him when that would be. "Probably a long time from now," he said. The opportunity to move to Chapel Hill earlier—for Cecil to launch a new research center, for Mindel, who was just then emerging as a world-class demographer, to join Bernie Greenberg's department of Biostatistics, for the couple to go where they intended to move eventually—must have been something both were enthusiastic about.

Many of Cecil's Chapel Hill writings—numbers 90 through 154 on his publications list—were becoming even more hortatory. The titles suggest this, but since he sent most of them to me, I can also bear witness. Once he asked me whether I thought one of his offerings, I believe it was a commencement address, was "too opinionated" for publication, not well enough supported by "data." I said that at his age and career standing he was entitled to speak his mind in print. "That's what I was thinking," he said, "but I'm glad to hear you say it." By this time he was being invited frequently to comment, for publication, on topics that concerned him; and by this time those topics were many. Again, he was writing about medical schools, schools of public health, hospitals and academic medical centers, consumer sponsorship of medical services, and regionalization, plus four new topics—the Health Maintenance Organization (HMO), the Area Health Education Center (AHEC), the family nurse practitioner, and something called "primary care." And as he had done in Pittsburgh, he was accepting consulting assignments when they suited his interests, which were now turning increasingly international. There were papers on Puerto Rico and Beer Sheva, Israel, and an edited volume, *Primary Health Care in Industrialized Nations*.

Early in the history of the UNC-CH Health Services Research Center—it might have appeared in the first annual report—Cecil announced a motto for the Center: "turning services into programs." I knew what it meant, but I wasn't sure exactly how or where research fit into that phrase. Cecil *was* sure. "Turning services into programs" had been the theme of his entire career. And it was what the Health Services Research Center was going to do. Sometimes research would come first—as it had at Beth Israel Hospital in Boston. But just as often, the meaning of that phrase would be realized through direct action, by organizing programs, with only an implied promise that research would, might, someday follow. The promise was enough for Cecil. As a result, some of his research associates organized health centers, others worked on plans for a local HMO, some worked at developing an AHEC program, and a few actually did research.

It is clear to me that Cecil wielded considerable influence. He was responsible for a few policies and many programs. In some cases he was directly responsible, in more, indirectly responsible—through a remark he made to someone, through someone he appointed or suggested for an assignment or job, or by his continuous coaxing, and because he always followed up.

I started to draw up a list of programs and institutions that Cecil might have been responsible for, at least where one can fairly ask the question: Would this have existed if it hadn't been for Cecil? Often, of course, we don't know. But even that element of doubt is a measure of his influence. I began my list locally, but soon realized that I just don't know enough to go very far with it. Beyond the health services research center that now bears his name, I thought first of the Orange-Chatham Comprehensive Health Service Program (now Piedmont Health Services), probably because it was the first thing he suggested I work on when I arrived in Chapel Hill. Then there was the Lincoln Community Health Center in Durham; HealthCo in Warren County; the North Carolina Office of Rural Health (and by extension all of the many local initiatives throughout the state that this office has been responsible for, as well as similar rural health offices in other states that so admired the one in Raleigh that they copied it); UNC-CH's family nurse practitioner program (and by extension, because it was one of the earliest and most influential, other such programs throughout the nation); the distinctive community orientation of the medical school at Ben Gurion University of the Negev in Beer Sheva, Israel; and countless other programs—federal, state, and local, on which he "gave advice."

During his time in New York, Cecil was often in Washington, DC, for a day. During those years, the federal government was launching a host of new medical care programs. When Cecil would return from one of his day trips to Washington, DC, and someone asked what he had been doing there, he would usually say, "I was giving advice." His advice was frequently sought and often followed.

Vice Chancellor, mid-1970s

I could never quite understand exactly why he was so influential, but I acknowledge that he was. Sometimes when I heard him pressing some point in a group, I would think that what he was saying could not possibly make a difference because it was too familiar; I'd heard it many times, even said it myself, and I imagined his other listeners were responding in the same way. But he *was* effective. I remember, for example, hearing him speak at a retreat to the group of idealistic young physicians and administrators who were organizing their own community health centers through the Rural Practice Project.[7] He was talking with them as colleagues, informally, but he seemed again to be repeating the obvious, and I thought his words would be of little value to this group. That wasn't their reaction. They listened closely, and several of them came up to me afterward, or the next day, or in some cases months later, to say how much they'd learned from Cecil, how clear he had made everything, and how much his words meant to them. They were stimulated—intellectually and, I think now, even emotionally—by what he had to say. I'm not sure why, but I think it wasn't as much the content of what he said as the conviction with which he said it; he was telling them what he stood for. They must have realized that all of that experience, passion, and commitment were authentic, and that they were hearing The Word from a genuine medical carenik. **NCMJ**

NOTES & REFERENCES

1 The story of this battle is told by Arthur Viseltear in Emergence of the Medical Care Section of the American Public Health Association, 1926-1948: A Chapter in the History of Medical Care in the United States. Washington, DC: American Public Health Association, 1972.

2 The exceptions are Axelrod and Cornely. The Solomon J. Axelrod papers are at the University of Michigan, the Paul B. Cornely papers at the National Library of Medicine.

3 There are several published accounts of Sigerist's mission to Regina. Probably the best is: Duffin J, Falk LA. Sigerist in Saskatchewan: The Quest for Balance in Social and Technical Medicine, Bulletin of the History of Medicine 1996;70(4)658-693. See also various chapters in: Fee E, Brown T (Editors). Making Medical History: The Life and Times of Henry E. Sigerist. Baltimore: Johns Hopkins University Press, 1997.

4 Axelrod spent most of his career at the University of Michigan; Roemer was at Cornell and then UCLA; and Terris at the New York College of Medicine. Rosenfeld held several administrative positions—in Nicaragua, Saskatchewan, Rochester, Detroit, and New York—before he finished his career at UNC-Chapel Hill. Falk worked for the United Mine Workers in Pittsburgh and then as a professor at Meharry Medical College in Nashville. Cornely was at Freedman's Hospital in Washington, but spent most of his career at Howard University; Weinerman was at the University of California at Berkeley, Kaiser-Permanente in Oakland, and at Yale; Silver was at Johns Hopkins, Montefiore Hospital in the Bronx, and then Washington, DC; he finished his career at Yale.

5 Lee was twice Assistant Secretary for Health and Scientific Affairs: first in the Johnson Administration (under Secretary of Health, Education, and Welfare Wilbur Cohen) and again in the Clinton Administration (under Health and Human Services Secretary Donna Shalala).

Potentially Avoidable Hospitalizations in North Carolina

While many inpatient hospitalizations are for trauma emergencies or elective procedures, some hospitalizations might be avoided if satisfactory primary care were used or if the conditions were diagnosed earlier. Research suggests that certain hospital diagnoses in particular are often associated with problems in access to or use of primary care. Using diagnostic criteria established in previous research,[1,2] we examine potentially avoidable inpatient hospital discharges in North Carolina (sometimes called ambulatory sensitive conditions) based on selected principal or first-listed diagnoses.

We used the principal ICD-9-CM (International Classification of Diseases, 9th Revision, Clinical Modification) diagnosis codes from the 2002 North Carolina hospital discharge data base to identify potentially avoidable hospitalizations. Discharges for newborns and deliveries were excluded from the analysis, as were records for residents of other states. North Carolina residents discharged from out-of-state hospitals are not included in the North Carolina hospital discharge data base.

The following table presents potentially avoidable hospitalizations in 2002 by diagnostic category, showing the total number of discharges, the average length of stay, total hospital charges, and average charges per hospital stay.

Potentially Avoidable Hospitalizations in North Carolina, 2002

Primary Diagnosis	Total Discharges	Avg. Length of Stay (days)	Total Hospital Charges	Average Charges Per Stay
Pneumonia	32,900	6.0	$423,612,729	$12,876
Congestive heart failure	29,193	5.4	$395,333,009	$13,542
Asthma	11,280	3.4	$74,265,930	$6,584
Cellulitis	8,186	5.1	$71,943,189	$8,789
Diabetes with ketoacidosis or coma	4,560	3.8	$39,720,703	$8,711
Pyelonephritis	3,652	3.9	$27,182,354	$7,443
Perforated or bleeding ulcer	3,584	5.1	$51,015,899	$14,234
Ruptured appendix	1,874	5.9	$33,267,109	$17,752
Malignant hypertension	1,458	4.2	$16,442,232	$11,277
Hypokalemia	743	4.3	$6,357,782	$8,557
Gangrene	163	7.2	$2,608,125	$16,001
Immunizable conditions	39	6.6	$423,887	$10,869
Total	**97,632**	**5.2**	**$1,142,172,948**	**$11,699**

These 97,632 discharges represent 11% of the total of 855,268 hospital discharges in North Carolina in 2002 (with the exclusions mentioned above). These hospitalizations accounted for $1.14 billion in hospital charges. Charges indicate the amount billed by the hospital to the patient or the patient's insurance company, not what was actually paid to the hospital. Pneumonia and congestive heart failure were the most common primary diagnoses, accounting for 64% of all potentially avoidable hospitalizations. The rate of potentially avoidable hospitalization was 1172.6 per 100,000 North Carolina resident population, which is only a slight decline from the 1997 rate of 1182.5.

RUNNING THE NUMBERS—continued on page 310

RUNNING THE NUMBERS—continued from page 309

Persons on Medicare accounted for 57% of all potentially avoidable hospitalizations (data not shown in table). Rural counties and counties with the lowest per capita income levels have potentially avoidable hospitalization rates (per 100,000 population) substantially higher than the state average.

There could be some debate about exactly which diagnoses are used to indicate "potentially avoidable" hospitalizations, and certainly not all hospitalizations for conditions such as pneumonia and congestive heart failure can be prevented, especially among older persons. Nevertheless, the results here indicate that many hospitalizations in North Carolina could be prevented if the seriousness of the diseases were reduced through better primary care services.

An earlier report of the State Center for Health Statistics on this topic by Kathleen Jones-Vessey can be accessed at http://www.schs.state.nc.us/SCHS/pdf/schs118.pdf.

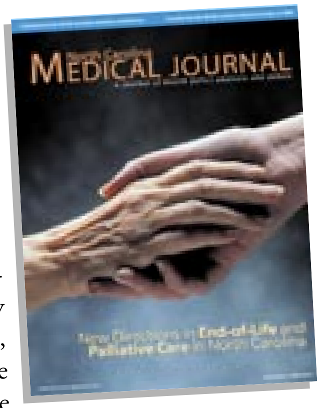
Letters to the Editor

New Directions in End-of-Life and Palliative Care in North Carolina



To The Editor:

I just finished reading Dr. Keith Meador's article on Spirituality and I for one want to sound out an enthusiastic Hurrah! Finally, an article from a physician that seems to understand the complexities of contextual and content issues in spirituality and medicine.

Calling a chaplain early in the process of end-of-life care is absolutely essential. He is absolutely correct that not all institutions have chaplains, but some medical professionals out there are working very hard to get institutions to see the value of paid professional chaplains. And he is also correct when he says that standards for spiritual care have not been developed. However, some chaplains are writing about the need for standards, the Association of Professional Chaplains (www.professionalchaplains.org) and the Association of Clinical Pastoral Education (www.acpe.edu) have study documents on their web sites that would offer a first set of universal standards for spirituality. Unfortunately, they are conceived of by professional chaplains for professional chaplains, and as of yet we have not seen any secular accreditation organization take the risk to affirm or deny the importance of such standards.

I applaud Dr. Meador's insight. I hope that articles such as his and others written by informed and committed physicians and chaplains will be used as stepping stones for opportunities to sit down together and discuss context and content of spirituality and medicine.

North Carolina Medical Journal: Call for Papers

Herbert G. Garrison, MD, MPH
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

The North Carolina Institute of Medicine

Since January 2002, Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

DOCTORS MAKING HOUSECALLS is an exciting, innovative group serving the Raleigh/Durham/ Chapel Hill area. We have immediate openings for BC internists who love patient care but also want a life outside medicine. Full-time and flexible part-time positions, outpatient only. Please contact Alan Kronhaus, MD: 919-932-5700, or kronhaus@bellsouth.net.

EMERGENCY MEDICINE MEDICAL DIRECTOR POSITION available in Brevard just south of Asheville. We are in search of an experienced ED Medical Director board certified in emergency medicine. An excellent hourly rate as well as generous stipend is offered in addition to paid malpractice (including tail coverage). Contact Deanna Maloney at EDCare Management, Inc. Call toll free (866) 625-6639 or fax your CV to (972) 562-7991; Email dmaloney@edcaremgt.com.

NC STATE UNIVERSITY STUDENT HEALTH SERVICES seeks BC physician (prefer IM or FP) for permanent 9 month academic year position. NC Medical License. Join physicians, extenders, lab/x-ray, pharmacy, PT in delivering quality ambulatory care to 29,000 students. Send letter of interest and CV to: Director, Student Health Services, Box 7304, Raleigh NC 27695, or fax 919-513-1994, or email Jerry_Barker@ncsu.edu EO/AA Employer. NCSU welcomes all persons without regard to sexual orientation. For ADA accommodations contact the address/fax above. http://www.ncsu.edu/provost/offices/affirm_action/epa_vacancies/tepa.html.

GREAT CAREERS! GREAT BENEFITS! GREAT THINGS ARE HAPPENING AT THE FAST GROWING VA MEDICAL CENTER, FAYETTEVILLE, NC! EXCELLENT PHYSICIAN OPPORTUNITIES exist at the VA Medical Center, Fayetteville, NC, for a Board Certified or Board Ready UROLOGIST, GASTROENTEROLOGIST, PSYCHIATRIST, EMERGENCY MEDICINE, INTERNAL MEDICINE, NEUROLOGIST, and RADIOLOGIST. Applicants must have a current, full, and unrestricted valid medical license to practice medicine or surgery in a state, Territory or Commonwealth of the US or in the District of Columbia. Proficiency in the English language required. Must be a US or naturalized US citizen, or meet the requirements for federal employment. These are permanent, full-time positions with career-conditional appointment. EXCEPTIONAL BENEFITS include competitive salary with additional physicians special pay, health and life insurance, a great retirement program, contributions to tax-sheltered savings plan, malpractice insurance, annual leave, sick leave and holidays. Fayetteville, NC, is a large diverse metropolitan city located in Southeastern NC along the I-95 corridor. It is two hours to superb Atlantic beaches and 3-4 hours to scenic mountains. The area boasts of numerous parks, lakes, cultural activities, sports events, excellent restaurants, museums, theatres, affordable housing and excellent schools. For details of these EXCELLENT OPPORTUNITIES, respond to ad#VA565JAMA with a curriculum vitae, along with three references, to Department of Veterans Affairs, ATTN: Jim Turner (11), 2300 Ramsey Street, Fayetteville, NC, 28301, 910-822-7077, e-mail: jim.turner2@med.va.gov., or Fax: 910-822-7982. Equal Opportunity Employer.

BOARD CERTIFIED GI PHYSICIAN wanted for large Family Practice in Raleigh. For information call 919-424-3824. Fax CV to 919-882-9722 or E Mail willmchenry@healthcarecounsel.com.

NC, LAURINBURG: EPA, a Team Health affiliate, has ED staff opportunities available in Laurinburg. Annual ED volume is 24k. This region offers exceptional activities with easy access to Charlotte, Myrtle Beach and Raleigh. Must be BC/BP EM or BC PC with ED experience. For more information, call Donna Conte at 800-848-3721 or email: donna_conte@teamhealth.com. Sorry, no visa sponsorships available.

BD. CERT. PHYSICIAN IN IM, FP, OR ONC for part-time position in hospice and palliative care. Prior experience desirable. Call or email Ned Yellig, MD, FACP, Medical Director, Hospice of Wake County, 919-828-1998 or eyellig@hospiceofwake.org.

North Carolina MEDICAL JOURNAL

NORTH CAROLINA:
Board Certified **Primary Care** and **Hospitalist/Emergency** physician opportunities at the Salisbury VA Medical Center, located in Salisbury, North Carolina. Affiliated with Wake Forest University School of Medicine. Liberal benefits with generous 401K, 30 days paid vacation and paid federal holidays; 40-hour workweek. Candidate may be eligible for school loan repayment program. Some subspecialty positions available in Medicine. U.S. citizenship required.

Salisbury is a lovely, historic city in the Piedmont area of North Carolina, less than one hour from Charlotte and Winston-Salem. Enjoy a mild year-round climate; within easy driving distance from the Blue Ridge Mountains and beautiful Carolina beaches.

Call or forward a current CV to:

CROSS INTO THE BLUE

NO ONE GOES THROUGH
MEDICAL SCHOOL
TO PRACTICE INSURANCE.

Remember graduating from college and passing your MCATs, then spending the next four years of your life getting through classes like clinical epidemiology, neurology and radiology so you could practice medicine? Today's financially driven managed care environments make having a practice difficult. Hurrying patients in and out of the office to make a quota and going into negotiations to prescribe treatments that don't coincide with a patient's policy aren't practicing medicine. We'd like to prescribe a solution: Move your profession to the United States Air Force. Get back to what's important — practicing medicine. To request more information, please visit our website at AIRFORCE.COM or give us a call at 1-800-423-USAF.

We heard you. And we're doing something about it.

Blue Cross and Blue Shield of North Carolina asked doctors across the state: How can we support you on the front lines in a battle against our epidemic of obesity?

Doctors in North Carolina told us they want to address excess weight and obesity with their patients. But you also told us there simply isn't enough time to squeeze one more health condition into an office visit.

We heard you. Blue Cross and Blue Shield of North Carolina will pay for four visits to a doctor each year specifically for the evaluation and treatment of obesity.

It's part of our new obesity initiative called Healthy Lifestyle Choices℠.

Obesity shortens lives and increases health care costs. The first step toward a healthier, more active life can start in the doctor's office – where we are encouraging a hard look at how excess weight can impact people's health.

Healthy Lifestyle Choices is a broad program that extends from online support for members trying to maintain a healthy weight or lose a few pounds – to coverage of doctor visits and prescription weight-loss drugs when medically necessary – to establishing Bariatric Surgery Centers of Excellence to identify providers of superior results in obesity surgery.

For more information about the Healthy Lifestyle Choices program or to request educational materials for your patients, e-mail your request to **quality@bcbsnc.com**.

For more than 70 years, our members and doctors have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's stable, reliable and largest health insurer.

Innovative health care designed around you.℠ | *bcbsnc.com*

Call for Papers

Herbert G. Garrison, MD, MPH
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

Instructions for Authors

Manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All manuscripts submitted for review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter with the article [via e-mail or a disk (3-1/2" floppy, zip, or CD)] containing the double-spaced text, preferably in Microsoft Word for DOS. The letter should indicate that the article is not under consideration for publication elsewhere.

For more information visit our web site: http://www.ncmedicaljournal.com/guideline.shtml

Influenza Vaccination of Healthcare Workers:

Institutional Strategies for Improving Rates

Kristina Simeonsson, MD, MSPH, Chris Summers-Bean, MS, RN, and Allison Connolly, MA, MPH

Abstract

The nosocomial transmission of influenza has been well documented since the 1970s with both direct and indirect effects of outbreaks in healthcare settings. Outbreaks can directly increase morbidity among patients and residents of long-term care facilities. Indirect effects include disruption of normal operations of healthcare institutions, shortages of healthcare workers (HCWs), fewer elective admissions, and income loss due to absenteeism. Influenza vaccination of United States HCWs remains below 40% despite the availability of a safe, effective vaccine and a long-standing recommendation for vaccination of HCWs. New strategies to improve the rate of influenza vaccination among HCWs are needed as the percentage of those receiving yearly vaccination has changed little in the past 20 years. Increasing HCW influenza vaccination coverage calls for a paradigm shift; institutions should view vaccination of HCWs as a crucial part of a comprehensive infection control program designed to protect patients and staff. Administrators of hospitals, long-term care facilities, and other health agencies should respond to this challenge by developing programs to improve yearly influenza vaccination of their staff. Such efforts would put these employees into compliance with national recommendations and also benefit the institution by reducing absenteeism, nosocomial influenza transmission, and the associated economic losses and disruption of routine operations.

Introduction

Influenza epidemics occur each year in the United States; however, the impact of the disease on morbidity, mortality, and the economy is underestimated both by healthcare workers (HCWs) and the general public. An average of 200,000 people are hospitalized and 36,000 die due to influenza or its complications each year in the United States.[1,2] The healthcare costs related to these episodes as well as the time lost from work and school have a significant economic impact. In the United States, it is estimated that the economic cost associated with influenza epidemics exceeds $12 billion annually.[3]

Influenza is easily spread from person-to-person by respiratory droplets, particularly in enclosed areas. Infected adults can transmit influenza virus even in the absence of symptoms.[4] Therefore, infected HCWs can unknowingly serve as vectors of the virus even if they avoid contact with patients after the onset of illness.

Vaccination is the most effective means of preventing influenza illness. HCWs are among the target groups to receive influenza vaccine each year, yet their compliance with vaccination remains low. Institutions should promote influenza vaccination of HCWs as a necessary step to ensure the health of employees and patients.

Nosocomial Transmission of Influenza

Nosocomial transmission of influenza has been well documented since the 1970s. Outbreaks have been identified even during times when influenza activity was not documented in the surrounding community.[5,6] The effects of these outbreaks can be far reaching. They can increase morbidity among hospitalized patients and residents of long-term care facilities, who are at risk for complications from influenza illness. Outbreaks of influenza can also have the indirect effects of disrupting the normal operations of healthcare settings (if there are shortages of staff), decreasing elective admissions, and loss of worker income due to absenteeism.

Numerous outbreaks of nosocomial influenza, with effects

Kristina Simeonsson, MD, MSPH, is a Medical Epidemiologist in the General Communicable Disease Control Branch in the Division of Public Health, NC Department of Health and Human Services. She can be reached at kristina.simeonsson@ncmail.net or 1902 Mail Service Center, Raleigh, NC 27699-1902. Telephone: (919)733-3419.

Chris Summers-Bean, MS, RN, is a CDC Public Health Advisor in the Immunization Branch in the Division of Public Health, NC Department of Health and Human Services.

Allison Connolly, MA, MPH, is an Epidemiologist in the General Communicable Disease Control Branch in the Division of Public Health, NC Department of Health and Human Services.

on staff, institutions, and patients, have been documented in the infection control literature. A descriptive example by Sartor of an outbreak on an internal medicine ward is illustrative: Five of the 22 staff members became ill with influenza.[7] These five cases resulted in 14 person-days of sick leave during the two-week outbreak. Because of the staff shortage, eight scheduled admissions to this ward were postponed, and all admissions to the ward from the emergency department were suspended for 11 days. In this same study, nine of the 22 susceptible patients developed influenza illness, and three of the nine had prolonged hospitalizations.[7]

Outbreaks of influenza in high-risk settings like neonatal intensive care units, transplant units, and specialty care units, have resulted in increased morbidity or mortality for patients.[5,6,8-10] For example, Munoz and colleagues describe an outbreak of influenza A in a 20-bed neonatal intensive care unit (NICU).[8] This outbreak resulted in four infants developing influenza-like illness. Laboratory results confirmed influenza A in three of these infants. One of the infants subsequently died. Although no definite source for this outbreak was identified, four NICU staff members had been sick with influenza-like illness when the first infant manifested symptoms.

Cunney and colleagues describe an outbreak of influenza in a 34-bed NICU in which 19 infants became infected with influenza virus, six showed symptoms, and one died.[9] In both of the outbreaks described (by Munoz and Cunney), a very low percentage of NICU staff had been vaccinated for influenza. In the first instance, 45% of NICU physicians and 5% of NICU nurses had been vaccinated; in the second instance, only 15% of the NICU staff were vaccinated.[8,9]

The Effect of Vaccination

Research demonstrates that vaccination is effective in reducing morbidity and mortality due to influenza. In healthy persons under 65 years of age, the efficacy of influenza vaccination exceeds 80% when there is a good match between the vaccine strain and the circulating strain of influenza virus.[11,12] While the vaccine is not as effective in preventing illness in those over 65, it has been shown to significantly reduce severe complications and deaths in this age group.[13,14]

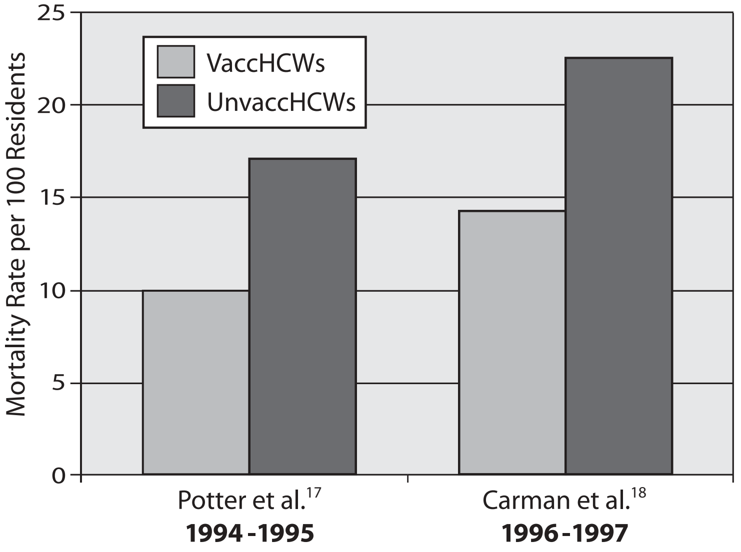
Further, vaccination has been shown to be effective in reducing absenteeism among healthy working adults.[11,12,15] In the largest study of healthy working adults (randomized and placebo-controlled), influenza vaccination reduced absenteeism due to upper respiratory infections from any cause by 43%.[15] In a study looking specifically at healthcare workers, influenza vaccination resulted in a 28% reduction of absenteeism due to respiratory infections during the influenza season.[16]

Vaccination of HCWs against influenza has also been associated with a reduction in patient mortality, as shown by two studies that examined the effect of vaccination of HCWs on patient mortality rates in long-term care facilities.[17,18] The first study, by Potter and colleagues, was conducted during the 1994-1995 influenza season in 12 long-term care facilities (LTCFs) in Scotland.[17] The investigators stratified the LTCFs according to their policy regarding vaccination of patients for influenza. The study then randomized the LTCFs into two groups—those in which HCWs were routinely offered influenza vaccination and those in which HCWs were not offered vaccination. In the LTCFs in which influenza vaccination was routinely offered to the workers, 61% of HCWs received the vaccine. Although the authors did not determine how many HCWs may have received vaccine at the LTCFs that did not offer the vaccine, they believed that the percentage of vaccinated HCWs in these facilities would be negligible.

A follow-up study was conducted by Carman and colleagues during the 1996-1997 influenza season in 20 LTCFs in Scotland.[18] LTCFs were again stratified according to their policy on influenza vaccination of patients and also by size of the facility. As in the study by Potter et al., the sites were then randomized into two groups. In one group, HCWs were routinely offered influenza vaccine, while in the other group of sites they were not. In those facilities where influenza vaccine was routinely offered to HCWs, 51% received the vaccine; in facilities where vaccine was not routinely offered, only 5% were vaccinated.

Both of these studies showed an association between vaccination of HCWs and decreased patient mortality (See Figure 1). In the study by Potter et al., patient mortality in facilities where HCWs were not routinely offered influenza vaccine was 17%, and in facilities where HCWs were offered the vaccine, patient mortality was 10%.[17] (The difference in patient mortality remained statistically significant after controlling for patient characteristics such as age, sex, influenza vaccination status, and

Figure 1.
Association of Long-term Care Resident Mortality and Healthcare Worker (HCW) Vaccination



degree of disability). The study by Carman et al. showed an unadjusted rate of mortality of 14% for residents in facilities where vaccine was offered to HCWs, compared to 22% in the facilities where vaccine had not been offered. A significant difference was still observed after adjusting for patient characteristics.[18]

Influenza Immunization of Healthcare Workers

Every year the Advisory Committee for Immunization Practices (ACIP) issues recommendations regarding which population subgroups should be targeted to receive influenza vaccination; the most recent recommendations are summarized in Box 1.[4] Although the ACIP has recommended for over 20 years that HCWs receive annual influenza vaccination, only 36% of HCWs (estimated) actually receive the vaccine each year.[19] The HCWs who receive influenza vaccine tend to be older, more likely in their work to be caring for children or the elderly, more likely to have received influenza vaccine in the past, and more likely to be physicians.[20,21]

Reasons for Acceptance

Compared to HCWs who are not vaccinated, those who are vaccinated are more likely to acknowledge the seriousness of influenza illness and its complications, recognize the efficacy of the vaccine, and understand their increased risk of contracting influenza.[20] In a study by Martinello et al., HCWs who responded correctly to a set of five basic knowledge questions pertaining to influenza vaccine were more likely to have been vaccinated compared to those who responded incorrectly to any one of the questions. [22]

Self-protection and personal health are the most common reasons that HCWs give for why they accept the influenza vaccine.[20,21,23-25] Beyond the wish to avoid illness, HCWs may accept vaccination in order to decrease the chance that they might miss work because of illness. In one survey of house staff physicians, one-third of the respondents said they got the vaccine to help avoid absenteeism.[26]

The desire to protect patients from influenza is another reason why HCWs decide to receive influenza vaccine. In some studies over half of vaccinated HCWs listed protection of patients as a major reason to receive the vaccine.[21,25]

Finally, the wish to serve as a role model may factor into a HCW's decision to receive influenza vaccine. Setting an example to other HCWs and patients was mentioned by 46% of hospital physicians surveyed in one study.[24] Twenty-four percent gave this as their most important reason for being vaccinated.

Reasons for Nonacceptance

Why are the majority of healthcare workers not receiving influenza vaccine? Surprisingly, the reasons are the same ones given by the general public. For instance, unvaccinated HCWs share the public's perceptions about the vaccine's side effects and its efficacy. The literature suggests that 20-44% of unvaccinated HCWs decline the influenza vaccine because they are concerned about side effects.[20-25] The most frequently mentioned side effect is the possibility of getting influenza or an influenza-like illness from the vaccine itself.[21,23,24,27] HCWs also fear allergic reactions or contracting Guillain-Barré syndrome following

Box 1: 2004 ACIP Recommendations: Target Groups for Annual Influenza Vaccination[4]

Persons at risk for complications

- persons aged ≥65 years;
- residents of nursing homes and other chronic-care facilities that house persons of any age who have chronic medical conditions;
- adults and children who have chronic disorders of the pulmonary or cardiovascular systems, including asthma;
- adults and children who have required regular medical follow-up or hospitalization during the preceding year because of chronic metabolic diseases (including diabetes mellitus), renal dysfunction, hemoglobinopathies, or immunosuppression (including immunosuppression caused by medications or by human immunodeficiency virus [HIV]);
- children and adolescents (aged six months-18 years) who are receiving long-term aspirin therapy and, therefore, might be at risk for experiencing Reye syndrome after influenza infection;
- women who will be pregnant during the influenza season; and
- children aged six-23 months.

Persons Aged 50-64 Years

- recommended because this age group has an increased prevalence of persons with high-risk medical conditions

Persons Who Can Transmit Influenza to Those at High Risk

- physicians, nurses, and other personnel in both hospital and outpatient-care settings, including medical emergency response workers (e.g., paramedics and emergency medical technicians);
- employees of nursing homes and chronic-care facilities who have contact with patients or residents;
- employees of assisted living and other residences for persons in groups at high risk;
- persons who provide home care to persons in groups at high risk; and
- household contacts (including children) of persons in groups at high risk.

influenza vaccination, although these side effects are mentioned less often.[20,25] Unvaccinated HCWs may also have doubts about the efficacy of the influenza vaccine.[23,24,28] A study of pediatricians in a Swiss hospital revealed that nearly half of those who remained unvaccinated gave doubt of the vaccine's efficacy as the primary reason.[24]

Even though HCWs may know that they can transmit influenza to others and also recognize the potential severity of the influenza illness in their high-risk patients, they may still choose not to receive the vaccine. A study at one United States institution documented a vaccination rate among HCWs of only 16.2%, this despite the finding that over 90% of the physicians and nurses surveyed recognized that HCWs could transmit influenza to patients and that the patients could die from the illness.[29] Although knowledge of the severity of influenza illness and the efficacy and safety of the vaccine does not insure a HCW's acceptance of it, misperceptions about influenza illness and the vaccine can be significant barriers to being vaccinated.[22,26,29]

Many HCWs are unaware of ACIP's recommendations regarding which population subgroups should be vaccinated for influenza.[20-23,26,29] In some instances, this may influence their decision to be vaccinated. For example, Nichol and colleagues found that 8% of unvaccinated HCWs said that the most important reason for not being vaccinated against influenza was that they did not think they were in a target group for receiving it.[20] In addition, four studies discovered that between 2% and 15% of unvaccinated HCWs declined the vaccine because they were pregnant or breastfeeding,[21-23,29] although neither pregnancy nor breastfeeding is a contraindication to influenza vaccination.[4] In fact, the ACIP recommends that women who will be pregnant during the influenza season receive vaccine because they are at risk for complications from influenza illness.[4]

Finally, some unvaccinated HCWs simply believe that they are not at risk for influenza infection. [21-23,28] Harbarth and colleagues found that over half of the unvaccinated HCWs cited either their strong host defense or a low risk of getting sick from influenza as the primary reason not to be vaccinated.[28]

The belief of some HCWs that they are not at risk may stem from confidence in their host defense mechanisms or an ability to avoid influenza through personal prevention strategies.[21,28,30] For example, Manuel and colleagues found that the 81% of never-vaccinated HCWs believed that hand washing was more important for preventing illness from influenza than the vaccine.[30] In comparison, 67% of vaccinated HCWs held the same opinion. In the same study, 73% of never-vaccinated HCWs and 48% of vaccinated HCWs believed that a healthy diet and regular exercise were more important for preventing influenza than vaccination.

Improving HCW Immunization Rates

Influenza vaccination among HCWs in the United States remains below 40% despite continued nosocomial outbreaks of influenza, the availability of a safe and effective vaccine, and a long-standing recommendation by the nation's leading committee on vaccination guidelines that HCWs be vaccinated. Administrators of hospitals, long-term care facilities, and home-health agencies, among others, need to respond to this situation by developing programs to improve yearly influenza vaccination coverage among their staff. Such programs would not only put these employees into compliance with ACIP recommendations, it would also benefit the institutions by reducing absenteeism, nosocomial influenza transmission, and the associated economic losses and disruption of routine hospital operations.

Healthcare institutions should design their influenza immunization programs around the inactivated, injectable vaccine. Although an intranasally-administered influenza vaccine became available in 2003, it is a live, attenuated influenza vaccine (LAIV) with several limitations that make it impractical to use in an institution-wide campaign. For instance, it is only approved for young, healthy persons (between five and 49

Box 2: Keys to Increasing Healthcare Worker Vaccination Rates

1. Top management and administration need to become strong advocates to ensure healthcare workers get vaccinated to accomplish:
    a. better infection control
    b. reduced absenteeism
    c. cost savings
2. Make vaccination convenient
3. Reduce or remove cost barriers
4. Remind healthcare workers that CDC recommends influenza vaccination annually
5. Educate healthcare workers that:
    a. Injectable influenza vaccine cannot cause influenza
    b. Influenza virus is easily transmitted between healthcare workers and patients, putting already ill patients at risk for influenza illness and its complications

From the National Foundation for Infectious Diseases. Call to action: influenza immunization among health-care workers 2003. Bethesda, MD: National Foundation for Infectious Diseases, 2003. Available at http://www.nfid.org years);[4] people with an array of chronic conditions, including diabetes and heart disease, should not receive LAIV. In addition, LAIV is not recommended for HCWs who care for severely immunosuppressed patients.[4] Further, from an institutional perspective, the cost and the storage and handling procedures make LAIV undesirable compared to the injectable vaccine.

The National Foundation for Infectious Diseases (NFID) recently issued a call to action for employers to improve HCW influenza vaccination rates.[31] The key elements of the NFID's action plan (See Box 2) provide a solid foundation from which to develop a comprehensive influenza vaccination program. NFID recommends that top management become strong advocates of HCW influenza vaccination and that cost and access barriers be removed. The Foundation also suggests educating healthcare workers about the ACIP's recommendations and about nosocomial transmission of influenza, as well as debunking the common myths and misperceptions regarding the virus and the vaccine itself.

The educational component of an immunization campaign will likely require the most extensive planning and implementation. According to the NFID, increasing awareness among healthcare workers of the ACIP recommendation regarding them as a target group to receive the vaccine should be directed at all healthcare workers—those who already know the ACIP recommendation and those who do not. Some who know the recommendation may disagree with it.[20] Therefore, the rationale behind the recommendation must be included in the educational messages. HCWs should be made to understand that they can spread influenza to their patients, even in the absence of symptoms. When it is appropriate, documentation of nosocomial outbreaks can be used to illustrate this point.

Knowledge of ACIP recommendations and the ramifications of nosocomial influenza will not be enough to convince some HCWs to participate in a vaccination program. As discussed in the previous section, the fear of side effects or doubts about efficacy are often the principal factors in the decision to not receive the influenza vaccine. Therefore, educational campaigns should also highlight the low risk of side effects from influenza vaccine as well as its proven efficacy.

Influenza Vaccination of Healthcare Workers Remains a Priority

Kristina Simeonsson, MD, MSPH

On October 5, 2004, one of the two manufacturers of inactivated influenza vaccine for the United States announced that it would be unable to deliver any of its vaccine because of contamination problems. This loss of more than 40 million doses of influenza vaccine has significantly reduced the projected supply for the United States, creating a severe shortage of vaccine for the current influenza season. In response, the Advisory Committee on Immunization Practices (ACIP) amended its list of recommendations for vaccination groups in an attempt to target the remaining supply to reduce the risk of influenza complications for those at highest risk.[1] These interim recommendations define eight groups of equal priority to receive influenza vaccine:

- all children aged six-23 months;
- adults aged 65 years and older;
- persons aged two-64 years with underlying chronic medical conditions;
- all women who will be pregnant during the influenza season;
- residents of nursing homes and long-term care facilities;
- children aged six months-18 years on chronic aspirin therapy;
- healthcare workers involved in direct patient care; and
- out-of-home caregivers and household contacts of children aged less than six months.

Individuals who are not in one of these priority groups have been asked to forego or defer vaccination for the 2004-2005 influenza season. These interim recommendations no longer include persons 50-64 years or household contacts of high-risk individuals as groups for which influenza vaccine is recommended.

Despite the change in vaccination recommendations due to this season's shortage, the ACIP still includes healthcare workers (HCWs) as a priority. The decision to include HCWs in the priority groups underscores that HCW-vaccination is essential to control the spread of influenza to high-risk patients.

Even for individuals in the eight priority groups, gaining access to vaccination this season may continue to pose significant challenges. HCWs who are not offered vaccination at their workplace should make every effort to get vaccinated on their own. Certain categories of HCWs have two options for influenza vaccination: (1) They can receive either the injectable influenza vaccine or (2) the intranasal, live attenuated form of influenza vaccine (FluMist). FluMist is indicated for healthy individuals five-49 years of age. According to the ACIP, HCWs who meet these criteria and do not care for severely immunosuppressed patients can receive the intranasal form of vaccine.[2] Healthcare facilities may choose to develop institutional policies pertaining to the use of FluMist for their HCWs. Regardless of whether HCWs are successful in finding influenza vaccination this year, the message about HCW vaccination is clear. Annual influenza vaccination of HCWs remains a top priority.

2 Centers for Disease Control and Prevention. Prevention and control of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP). MMWR 2004;53(No. RR-6):1-40.

Access to influenza vaccination must also be ensured. Several studies document that the location and schedule of vaccination administration influence whether HCWs will participate.[20,22,26,28] Access, however, includes not only logistical issues such as locations and times for vaccine administration, but also the cost to the worker of being vaccinated. One study found that one-third of vaccinated HCWs at one institution would not accept influenza vaccine if they had to pay for it themselves.[21] A recent position statement of the Association for Professionals in Infection Control and Epidemiology urged institutions to provide their employees with influenza vaccination at no charge—just as these institutions provide masks, gloves, gowns, and hand-washing products to employees at no charge.[32]

In short, the educational and access components of vaccine programs will likely be multi-faceted. Thus, assessing the employees' knowledge and concerns about the influenza vaccine, and therefore their willingness to be vaccinated, and removing the barriers to gaining access to vaccination, are both critical steps in planning a campaign. HCWs are a heterogeneous group who vary greatly in terms of their healthcare knowledge, educational level, and primary work environment, as well as race and culture. These variations may influence both the workers' educational needs and their ability to surmount the access barriers with respect to receiving influenza vaccination.[22-26,28]

Begue and colleagues found that addressing all of the issues expressed by HCWs during the educational component of the campaign increased their vaccination rate by 50%.[23] Other studies have demonstrated that some HCWs—attending and resident physicians, for example—are more likely than others to cite time and convenience as important reasons behind their failure to be vaccinated.[22,25,26]

One successful strategy to improve access is linking the vaccination campaign to a required activity. At one institution, a HCW vaccination rate of 62% was achieved for the 1999-2000 influenza season when vaccine was offered to HCWs during their mandatory tuberculosis screening, which was scheduled for a one-week period in October.[21] Offering the vaccine in a setting where employees are screened for other occupational health issues may also provide an opportunity to address individual concerns about the vaccine in a private manner. Other institutions have noted that offering the vaccine to the HCWs in the units where they work has proven to be an effective strategy.[20,22,28]

The ACIP recommendation that HCWs receive influenza vaccination every year is not a new one. However, new strategies to improve vaccination coverage of HCWs are necessary because the rate of vaccination has not changed significantly in the past 20 years. The challenge of increasing HCW influenza vaccination calls for a paradigm shift. Institutions should view influenza vaccination of HCWs as an integral part of a comprehensive infection control program designed to protect both patients and staff.[33] Vaccination remains the most effective way to prevent influenza illness, and vaccination of HCWs is essential to preventing the spread of influenza in healthcare settings. **NCMJ**

ARTICLE

Racial Disparities in Health between White and African American Family Practice Patients:

Clinical Implications

Remy R. Coeytaux, MD, PhD, Heather M. Gillespie, MD, MPH, Leigh F. Callahan, PhD, Jay S. Kaufman, PhD, Marcus Plescia, MD, MPH, Christianna Williams, PhD, and Philip D. Sloane, MD, MPH

Abstract

Objective: *To identify differences in self-reported health status and prevalence of chronic disease between African American and white patients.*

Study Design: *A representative sample of African American and white adult patients from a stratified sample of family practices in North Carolina completed a questionnaire that included self-reported racial status, certain sociodemographic data, health risk factors, chronic conditions, and health status measures.*

Data Source: *The North Carolina Health Project, a practice-based cohort of adult patients from a representative sample of family practice offices in North Carolina.*

Principal Findings: *African Americans report poorer general health status than whites. Obesity, insufficient exercise, high blood pressure, and diabetes are more prevalent among African American than white family practice patients, even after adjusting for age, gender, and educational attainment.*

Conclusions: *This study complements previous evidence of disparities in chronic disease and health risk factors between African Americans and whites, and it highlights specific factors that may be important in the primary care setting.*

Relevance: *By focusing clinical attention on the prevention or treatment of specific factors that are known to be more prevalent among certain racial groups, primary care providers may help to reduce racial differences in healthcare.*

Key words: *Health Disparities, Race, Ethnicity, Family Practice Network, Risk Factors, Health Conditions, Health Status*

Introduction

Compared with other ethnic groups, African Americans have a disproportionately high prevalence of many risk factors and diseases, and these are associated with increased morbidity and mortality. For clinicians to better serve African American patients, they must understand the disparities that exist, their causes, and practical means of intervening. African Americans have historically had less access to and use of ambulatory care services, and there appear to be potentially important differences in the ways that African Americans and whites perceive their health status.[1-4] African Americans may also differ from whites

in how they perceive benefits or harms that they associate with certain medical or surgical interventions.[5,6] It is unclear to what extent race contributes directly to disparities in perceived health status, as opposed to serving as a proxy for other, more directly pertinent factors such as socioeconomic status. Race, however, is a salient attribute for many individuals, either in how they identify themselves, or how they are identified by others, including healthcare providers. It is useful and informative, therefore, to assess the extent to which actual and perceived health status differs between members of different races who reside in the same community and who receive medical care from the same provider.

The primary care physician's office practice constitutes an important site for both prevention and treatment of health problems. Therefore, it is important for primary care physicians to be sensitive to race and ethnicity-related issues in their patients, to be aware of the care their patients receive, and to provide complete and accurate information about healthcare options to all of their patients.

This study compared general health status, health risk factors, and chronic disease rates between African American and white patients in a representative sample of family practices in North Carolina. The study aimed to identify how perceived health status, as well as healthcare needs and access, differ by race, so as to better inform the delivery of health interventions that are appropriate to African American and white patients in the primary care setting.

Methods

Data for this study are from the North Carolina Health Project (NCHP), a network of 13 family practices with 16 location sites in North Carolina. The study selected practices by a purposive sampling method that ensured representation of rural and urban sites in each of the state's three geographic regions (west, central, and east), and that preferentially selected practices serving high proportions of racial/ethnic minorities. Rural and urban status was designated based on the United States Department of Agriculture's (USDA) rural-urban county codes for the county in which the practice was located.[7] All selected practices agreed to participate in data collection.

The study placed research assistants at each participating site for a four-week data collection period. The research assistants offered a four-page, self-report questionnaire, available in English or Spanish, to each non-emergency adult patient who presented for an office visit. As needed, the research assistants explained the questionnaires and consent forms, answered participants' questions, and assisted them with questionnaire completion, which took place in the healthcare provider's office at the time of the visit.

The questionnaire included the following measures:

- **Sociodemographic data:** age, race, gender, marital status, work status, education level.
- **Physical measures:** weight and height. Body mass index (BMI) was calculated from the reported weight and height.
- **Health risk behaviors:** exercise habits and smoking status.
- **Chronic health conditions:** high blood pressure, heart disease, osteoarthritis, depression, chronic back pain, and diabetes.

Table 1.

Selected Characteristics of African American and White Adult Patients in North Carolina Family Practice Settings

	African Americans (N=900) % or Mean	Whites (N=3,481) % or Mean	p Value*
Female Gender	75.9%	69.5%	0.018
Age in Years	46.0	48.0	0.342
Residence in Rural County	48.1%	53.1	0.781
Educational Attainment			
Less than high school	29.6%	16.5%	
High school diploma	31.7%	30.1%	
Beyond high school	38.7%	53.4%	0.031
Marital Status			
Married	32.7%	65.4%	
Widowed	12.1%	8.4%	
Living w/ partner	5.3%	2.7%	
Separated/divorced	22.6%	13.4%	
Never married	27.3%	10.3%	0.016
Currently Working	49.2%	58.7%	0.062
Health Risk Factors			
Smoking now	24.2%	25.4%	0.482
No exercise	56.3%	41.6%	0.001
Obese (BMI > 30)	53.4%	35.5%	< 0.001
Chronic Conditions			
High blood pressure	48.6%	31.9%	0.004
Heart disease	9.8%	11.4%	0.295
Osteoarthritis	24.7%	23.8%	0.763
Depression	23.7%	26.4%	0.185
Chronic back pain	24.1%	25.1%	0.503
Diabetes	21.6%	12.0%	0.006
General Health Status			
"Fair" or "poor" health	36.6%	24.3%	0.009

** Significance tests for comparisons were calculated using Pearson's chi-square test for categorical variables and the 2-sample t-test for continuous variables, adjusted for stratified sampling design using SUDAAN 8.1*

- **Health status:** self-rated health status as assessed by the question, "In general, would you say that your health is: excellent, very good, good, fair, poor?"

Research assistants mailed completed and incomplete questionnaires to the principal investigators on a weekly basis. All data were then entered into an Access database.

The investigators stratified the subjects' demographic and clinical characteristics by race (African American vs. white) and excluded data from subjects who did not identify themselves as either African American or white from these analyses. We used Pearson chi-square analyses and 2-sample t-tests to measure the significance of differences between the two study groups, and we dichotomized the five-point scale for general health status into two categories: fair/poor *versus* excellent/very good/good. We analyzed educational attainment in three categories: less than a high school diploma, high school diploma, and more than a high school diploma. In calculating odds ratios between African Americans and whites, we used logistic regression, with health habits, risk factors, chronic conditions, and health status as dependent variables, and age, gender, and education level as co-variates. All statistical tests were two-sided (alpha=0.05) and were adjusted for the clustering of residents within clinics using Taylor series expansion methods,[8] as implemented in SUDAAN software.[9]

Results

Response rate

In the 16 practice sites, we found 7,680 eligible patients, of whom 4,760 consented to participate, yielding a recruitment rate of 62%. Approximately 10% of respondents required support from study research assistants to complete the self-report questionnaires. Sixty-nine (1%) respondents identified themselves as belonging to more than one racial group (mixed race), and 310 (7%) checked neither "black" nor "white." Of these, 95 (31%) identified themselves as either "Mexican, Mexican-American, or Chicano" or "Other Spanish, Hispanic, or Latino." We omitted these respondents from the analyses. The total analysis sample consisted of 4,381 respondents, 3,481 (79%) of whom identified themselves as white and 900 (21%) who identified themselves as black. In this paper, we use the term African American to refer to the participants who checked "black" in accordance with convention in the medical literature, even though the African ancestry may be distant for many of the individuals in this sample. All of the respondents included in this study completed the English version of the study questionnaire.

Demographics

Demographic data for the study sample, stratified by race, appear in Table 1. Within the study sample, 76% of African Americans and 70% of whites were female (p=0.018). The mean ages in years for African Americans and whites were 46 and 48, respectively (p=0.342). Approximately half of the sample of both African Americans and whites resided in a rural county. Whites tended to have higher educational levels, with a greater percentage of whites having had more than a high school education than African Americans (p=0.031). More whites (65%) than African Americans (33%) reported being married (p=0.016). More whites (59%) than African Americans (49%) also reported being currently employed, either full-time or part-time (p=0.062).

Health risk factors

We found no significant difference in smoking status between African Americans and whites; approximately one-quarter of both groups were smokers. There was, however, a significant racial difference in the percentage of the population whom we defined as obese (BMI > 30), with 54% of African Americans *versus* 36% of whites meeting this criterion (p<0.001). African Americans also tended to be more sedentary; 56% of African Americans compared to 42% of whites reported getting no exercise on a typical day (p<0.001).

We report the odds ratios for selected risk factors and conditions among African Americans and whites, adjusted for age, gender, and education level, in Table 2. Compared to white patients, the adjusted odds for African Americans are lower for current smoking status (OR 0.76, 95% CI 0.61-0.94) and higher for reporting no exercise on a typical day (OR 1.63; 95% CI 1.29-2.05) and for being obese (OR 1.92; 95% CI 1.61-2.30).

Chronic conditions

Of the self-reported chronic conditions selected for analysis, we found that the frequency of heart disease, osteoarthritis, depression, or chronic back pain did not differ by race. However, African Americans did report more high blood pressure (49% vs. 32%, p=0.004) and diabetes (22% vs. 12%, p=0.006) than did whites (See Table 1). After adjusting for age, gender, and education, this difference still held: African Americans were more likely than whites to report high blood pressure (OR=2.44; 95% CI 2.05-2.91) and diabetes (OR=2.16; 95% CI 1.66-2.78) and less likely to report depression (OR=0.74; 95% CI 0.58-0.95) and chronic back pain (OR=0.81; 95% CI 0.71-0.94). The adjusted odds of reporting heart disease or arthritis were not statistically different from 1.00, when controlling for age, gender, and education (See Table 2, Model 1). However, after controlling for the additional variables of current smoking, exercise status, and obesity, the odds of African Americans reporting heart disease were significantly lower than for whites (See Table 2, Model II; OR=0.73; 95% CI 0.60-0.88).

Health status

More African Americans rated their general health as "poor" or "fair" than whites (37% vs. 24%, p=0.009) (See Table 1). This difference remained significant even after controlling for age, gender, education, current smoking, exercise status, and obesity (OR=1.47; CI 1.06-2.04) (Table 2).

Discussion

The United States is becomingly increasingly diverse racially and ethnically. Racial disparities in health and in the receipt of healthcare in the United States are well documented.

Table 2.
Adjusted Odds Ratio of Selected Health Indicators among African American Patients Compared to Whites in Family Practice Settings

	Odds Ratios (95% CI)	
Dependent Variables	Model I[a]	Model II[b]
Health Risk Factors		
Smoke now	0.76 (0.61, 0.94)	—
No exercise	1.63 (1.29, 2.05)	—
Obese (BMI > 30)	1.92 (1.61, 2.30)	—
Chronic Conditions		
High blood pressure	2.44 (2.05, 2.91)	2.11 (1.67, 2.67)
Heart disease	0.88 (0.71, 1.08)	0.73 (0.60, 0.88)
Osteoarthritis	1.10 (0.86, 1.39)	0.97 (0.75, 1.25)
Depression	0.74 (0.58, 0.95)	0.65 (0.53, 0.78)
Chronic back pain	0.81 (0.71, 0.94)	0.72 (0.60, 0.85)
Diabetes	2.16 (1.66, 2.82)	1.83 (1.37, 2.45)
General Health Status		
"Fair" or "poor" health	1.59 (1.23, 2.06)	1.47 (1.06, 2.04)

Odds ratios calculated using logistic regression with race as the explanatory variable, and adjusted for stratified sampling design using SUDAAN 8.1.

[a] Model I: adjusted for subject age, gender, and education.
[b] Model II: adjusted for subject age, gender, education, current smoking, exercise status, and obesity.

Maintaining and improving the nation's health will, therefore, be dependent in part on reducing the factors that lead to health status disparities between minority groups and whites.[10] This study confirms that African American patients report poorer health status and greater prevalence of certain risk factors for poor health, particularly obesity, sedentary lifestyle, and high blood pressure, compared to their white counterparts in the primary care setting of North Carolina. The purpose of this study was to confirm and measure these health disparities in the family practice setting in order to illustrate the challenges that face primary care providers in North Carolina. Because the offices of primary care physicians are common sites of medical care for persons with risk factors who have not yet developed overt disease, primary care physicians could play an important role in decreasing the observed disparities in health outcomes.

Data for this study were obtained only from individuals who received medical care from family practice providers in the state of North Carolina. Our findings may therefore not be readily generalized to other regions of the United States, or to other medical practice settings. An additional limitation is that the data were obtained by patient self-report, which makes the health risk factors and chronic condition reports subject to bias or inaccuracies due to misunderstanding of medical diagnoses by some respondents. On the other hand, the study has a unique strength: it is the first to examine health risk factors, chronic conditions, and self-reported health status among a representative sample of family practice patients across an entire state.

There are many plausible explanations for observed disparities in health, including potential differences in socioeconomic status, educational attainment, access to healthcare, health-related behavior, discrimination, and racism. In our study, disparities in risk factors and chronic conditions persisted after adjusting for educational attainment (See Table 2). Furthermore, every study participant had at least some access to primary care, although we did not assess the quality or quantity of healthcare services available to individual patients. It therefore seems unlikely that access to healthcare is a major contributor to the race-related differences observed in this study. Other explanations must be considered, including the possibility that some forms of discrimination or racism occur in the community or in the healthcare setting. Evidence that suggests that a patient's race may influence providers' decisions or actions has been found in studies that reveal that physicians may sometimes perceive African Americans as less intelligent and less likely to adhere to medical advice compared to white patients,[11] that medical students judge black patients to have a lower quality of life than white patients with similar symptoms,[12] and that the race and sex of patients may independently influence the way a physician elects to manage chest pain.[13]

Strong evidence exists to suggest that a primary care office may be an appropriate setting to bring about change in health-related behaviors. A meta-analysis of primary-care-based intervention studies revealed that physical activity counseling is often effective, with stronger results obtained from interventions that are brief (3-10 minutes), tailored to the patients' characteristics and preferences, and that include supplemental written materials.[14] Physician intervention can also lead to smoking cessation.[15,16] Moreover, achieving a healthy weight tends to improve patients' subjective well-being.[17] It is has also been shown that minority and economically disadvantaged patients are less likely to receive screening[18] and behavioral interventions[19] from their physicians. Finally, steps to increase cultural competency among healthcare providers may help to reduce the tendency toward racial and ethnic bias in the provision of care. Elements of cultural competency within the practice setting include: a culturally diverse staff that reflects the community served; bilingual providers and/or translators when significant language barriers exist; providers who are knowledgeable about different health beliefs, cultural practices, or values among their patients; patient education materials that are culturally and linguistically appropriate; and a practice that engages in community outreach activities.[20] **NCMJ**

Acknowledgements

The North Carolina Health Project (NCHP) is a practice-based cohort of adult patients who were enrolled in a representative sample of Family Practice Offices in North Carolina. The project is jointly conducted by the Department of Family Medicine and the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill, in collaboration with the North Carolina Academy of Family Physicians. The project co-directors are Leigh Callahan, PhD, and Philip Sloane, MD, MPH. Participating Family Practices: Biddle Point Health Center, Charlotte; Bladen Medical Associates, Elizabethtown; Blair Family Medicine, Wallace; Chatham Primary Care, Siler City; Community Family Practice, Asheville; Dayspring Family Medicine, Eden; Goldsboro Family Physicians, Goldsboro; Henderson Family Health Center, Hendersonville; North Park Medical Center, Charlotte; Orange Family Medical Center, Hillsborough (pilot site); Person Family Medical Center, Roxboro; Robbins Family Practice, Robbins; South Cabarrus Family Physicians, Harrisburg, Concord, Mt. Pleasant & Kannapolis; and Summerfield Family Practice, Summerfield. Funding for the NCHP has been provided by a grant from the Centers for Disease Control and Prevention through the University of North Carolina Center for Health Promotion and Disease Prevention, and by a pilot grant from the University of North Carolina Project on Health Outcomes' Population Research Advisory Committee.

ARTICLE

Diabetes Awareness among African Americans in Rural North Carolina

Angela K. Antony and Walid A. Baaklini, MD, FCCP

Abstract

Objective: *To evaluate the extent of diabetes unawareness in rural North Carolina.*

Methods: *Randomly administered an eight-question survey to African Americans age 15-74 living in Halifax County, North Carolina.*

Results: *Ninety-five out of 116 eligible participants completed the survey (82% response rate). Most (67%) of the participants reported having two or more major risk factors for Type II diabetes (diabetes mellitus). More than half (51.6%) of the participants were obese. Most (96.8%) of the participants reported having been tested for diabetes at some point in their lives (10% tested positive, only 8.4% of the remaining 90% reported ever having a second test).*

Conclusion: *Diabetes mellitus is a very prevalent problem among the African American population of Halifax County, North Carolina. Our study underscores the fact that patients are not systematically screened and followed-up for diabetes mellitus. More healthcare and commnity programs need to be adapted to fight this serious public health problem.*

Introduction

Diabetes mellitus is one of the most serious health problems facing the more than 35 million African Americans living in the United States—1.8 million of whom live in North Carolina.[9] Diabetes mellitus, a condition in which the body produces little or no insulin or is unable to utilize insulin properly, results in dangerously high blood sugar levels; this can lead to coma, death, or a myriad of other health complications including blindness, kidney failure, foot or leg amputations, stroke, and heart disease. Diabetes impairs lives of countless African Americans is the seventh leading cause of death of African Americans in the United States.[8]

There are two major categories of diabetes, Type I and Type II. With Type I diabetes, the body produces almost no insulin at all so the afflicted individual must take exogenous insulin to survive. In Type II diabetes, also known as adult onset diabetes mellitus (AODM), the body either produces insufficient amounts of insulin or experiences insulin resistance, a condition in which the body cannot properly utilize insulin. Type II diabetes accounts for 90-95% of all diabetes cases.

Over the last 30 years, the number of African Americans diagnosed with diabetes nationwide has more than tripled. Presently, over 2.8 million African Americans are plagued with this serious disease.[1] Studies show that in North Carolina, African Americans are three times more likely to develop diabetes than whites of a similar age. Compared to white Americans, African Americans experience higher rates of three serious diabetes complications: blindness, kidney failure, and amputations. In addition, African Americans also experience greater disabilities from these complications.[9] However, despite the staggering statistics, diabetes awareness within the African American communities of North Carolina is alarmingly low. In fact, diabetes awareness is such a problem that more than half of African Americans with diabetes are totally unaware of their medical condition. This means that for every African American diagnosed with diabetes, there is at least one undiagnosed case.[3]

This study was conducted to investigate the level of diabetes awareness within the African American population of rural North Carolina. In this study, the targeted population was that of Halifax County where African Americans comprise over 53% of the total population.[9] Research found that many of the African Americans in Halifax County fell into the high-risk category and exhibited several of the genetic, medical, and lifestyle risk factors characteristic of diabetes.[5] However, many of these individuals had not been tested for diabetes, and of the few who had been tested, the majority had not gone back for a second testing. This study was conducted in Halifax County with the hope that it would encourage similar studies elsewhere in rural North Carolina, thereby aiding in the imperative task

Figure 1.
Diabetes Survey

1. **Please specify your age group:**
   ☐0-20 ☐20-39 ☐40-49 ☐50-59 ☐60-74 ☐75+
2. **What is your sex?** ☐Male ☐Female
3. **What is your race/origin?**
   ☐Caucasian ☐African American ☐Hispanic
   ☐Asian/Pacific Islander ☐Other: _______________
4. **Do you visit a doctor regularly?**
   ☐Yes ☐No
5. **When was the last time you visited a doctor?**
   ☐last week ☐last month ☐last year ☐1-2 years ago
   ☐more than 2 years ago
6. **What is your height and weight?**
   Height: ___feet ___inches Weight: ___lbs
7. **Which of the following describe you?** *(please mark all that apply):*
   ☐ I have been diagnosed with obesity.
   ☐ I have an immediate family member with diabetes.
   ☐ I exercise regularly. (at least three times a week)
   ☐ I am a woman who has delivered a baby weighing over 9 pounds.
   ☐ I have high blood pressure or hypertension.
8. **Have you ever been tested for diabetes?** If yes, please circle your test result.
   ☐Yes (positive / negative) ☐No
   If you answered yes and positive, are you being treated for diabetes? ☐Yes ☐No
   If you answered yes and negative, have you been tested again for diabetes since? ☐Yes ☐No

of increasing diabetes awareness throughout the African American population of North Carolina.

A questionnaire was developed to evaluate how much the rural African American population understood about the various risk factors of Type II diabetes mellitus. We categorized the risk factors of Type II diabetes into three groups: genetic, medical, and lifestyle. Genetic risk factors include inherited traits and family ancestry; medical risk factors include obesity, hyperinsulinemia, insulin resistance, and impaired glucose tolerance; lifestyle risk factors include diet and physical activity. Included in the questionnaire was a survey (See Figure 1), which assessed the risk level of each individual and inquired whether the individual had been tested or treated for diabetes. Our survey responses were analyzed to determine the number of people unaware that they were at high risk for diabetes. A presentation and lecture on diabetes risk factors and prevention was given to the participants after they completed the survey. Our study was aimed at evaluating the severity of diabetes unawareness in rural North Carolina, which would ideally generate interest in how to deal with this issue and increase awareness in the African American community.

Methods

Before embarking on our campaign to research diabetes awareness, we first assessed the current diabetes knowledge of the African American population in question. The five members of the survey research team were Dr. Walid Baaklini; North Carolina School for Science and Mathematics Senior Angela Antony; registered nurse and diabetes educator Susan Liverman; and two local volunteers. We devised a survey (See Figure 1) on diabetes awareness and risk factors and distributed it randomly to citizens in several African American concentrated areas of Halifax County, North Carolina. Out of 116 eligible participants, 95 individuals participated in the study yielding a response rate of about 82%. The survey included questions that identified the individual risk factors of diabetes such as age, physical activity level, family history, and other genetic, medical, and lifestyle factors. Individuals who were at high risk for diabetes based on their answers to the risk factor questions were then asked additional questions assessing their awareness of this high-risk condition. In addition, we asked individuals if they had ever been tested for diabetes. If they had and were found to be non-diabetic, we inquired whether they had gone back for a second testing. Finally, we requested the height and weight of each person surveyed and used a Body Mass Index Chart to assess whether these individuals could be at risk because of their weight since obesity is another major risk factor for diabetes.

Results

African Americans between the ages of 15 and 74 completed the survey. Upon analysis of the data, we found that 67% of the studied population had two or more of the major risk factors for Type II diabetes, which classified them as “high risk.” However, only three of these high-risk individuals had visited a doctor within the last year. Fortunately, the findings also showed that 96.8% of the surveyed population had been tested for diabetes at some point in their lives, and 10% of those tested were found positive for the disease and were given treatment. However, of the 90% that had tested negative, only 8.4% had gone back for a second testing. This is unfortunate, given Halifax County’s high-risk reputation and the wide range of ages in which diabetes can develop.

Another of the major risk factors of diabetes is heredity, and the survey found that 10% of the population had an immediate family member with Type II diabetes. Those taking the survey were also asked whether they exercised regularly, because research has proven that exercising at least three times a week can significantly reduce the risk of developing diabetes.[3] Unfortunately, only 3.3% of the surveyed population reported regular exercise—a group that included less than 6.7% of the female population. One other major risk factor of diabetes is obesity, which was also inquired about in the survey. Using the Body Mass Index (BMI) chart, we found an alarming 51.6% of the population to be obese, meaning they had scored over 29 on the BMI scale. In several extreme but common cases, the obesity in question had become especially dangerous. One male in the over-75 age group stood at 5'2" and 189 pounds, scoring a 34.5 on the BMI scale. Another male in the 50-60 age group, measured 5'3" tall but weighed 200 pounds, scoring a 36 on the BMI chart. One of the most alarming cases observed, however, was that of a female in the 60-74 age groups. Standing at 4'5", a normal height for a schoolchild, the woman in question weighed 175 pounds, putting her off the charts on the BMI scale. We estimated her score to be roughly 38 or 39.

Unfortunately, although over half of the randomly chosen participants in our study were obese, only 6.45% of these cases had been diagnosed. Even more alarming, a full 71.1% of the undiagnosed obesity cases claimed to visit a doctor on a regular basis.

Conclusion

Diabetes, once relatively uncommon among African Americans, is now the third leading cause of death from disease among this population.[2] Studies have found that African Americans, both in North Carolina and throughout the United States, are more prone to this disorder for numerous reasons. African Americans have a higher prevalence of obesity, a fact also observed in this study, which is a major risk factor for Type II diabetes. In addition, African Americans are known to have a higher occurrence of hypertension, a disorder strongly associated with diabetic complications such as eye, kidney, and heart disease. Lastly, African Americans tend to have less access to financial, social, health, and educational resources that would otherwise improve their current health status and level of diabetes awareness.[10]

Still, there are many ways to alleviate this problem and to improve the present health situation of our state and nation's African American population. First, obese individuals, through proper diabetes education and instruction, can effectively manage or prevent diabetes through diet, weight control, and exercise if they act early. With more advanced obesity cases, treatment with oral hypoglycemic agents or insulin can make a difference. In addition, proper diabetes education and management can reduce the risk of suffering from the major diabetes complications such as blindness, kidney failure, heart attack, stroke, and amputations. The factors that aggravate these complications include delay in diabetes diagnosis, delay in treatment, denial of diabetes, abnormal blood lipids, high blood pressure, and cigarette smoking, all of which can be avoided or alleviated through increased diabetes awareness.

Ultimately, the key is spreading the word. This study was intended to motivate clinics, hospitals, and medical professionals to aid in the crucial task of increasing diabetes awareness. Already throughout Halifax County, the word is beginning to spread: diabetes support groups, fundraisers, and public presentations are becoming increasingly more common. Awareness is paramount if we want to see more favorable diabetes statistics for the African Americans of Halifax County, North Carolina, and the entire United States. **NCMJ**

Angela Antony was senior in high school at the North Carolina School for Science and Mathematics when she completed her study and this article. She is now a freshman pre-med student at Harvard University. Her work here is remarkable at this early stage in her career. We are proud to produce young students like Ms. Antony in North Carolina and hope that she will return to North Carolina to practice.

POLICY FORUM
Eliminating Racial and Ethnic Health Disparities

> ***"The fundamental need for eliminating health disparities is to preserve the health of the nation. Health is not just the absence of disease, but rather the presence of both physical and mental well-being."***

COMMENTARIES

INTRODUCTION

Policy Forum:
Eliminating Racial and Ethnic Health Disparities

In our continuing effort to present clear and broad-spectrum coverage of key health and healthcare issues facing North Carolinians, this issue of the *North Carolina Medical Journal* focuses on a national policy agenda having significant implications for our state. When former President Clinton and Surgeon General Dr. David Satcher announced a major new initiative to decrease or eliminate the disparities that exist in the United States affecting groups defined by racial/ethnic, socio-economic/income, gender, geographic, age, disablement, or sexual orientation characteristics, they were calling to our attention some of the most pervasive and embarrassing realities of American health status and healthcare. Not only are these disparities in the incidence, prevalence, and burden of illness associated with common health conditions huge in many cases, but addressing these issues is made all the more difficult by the sheer complexity of these disparities and the factors that may have contributed to them.

Although disparities exist when comparisons are made between the health status and healthcare accessibility experienced by most middle- and upper-class American whites and persons in several minority population categories, the predominant emphasis in discussions of health disparities has been on those related to race and ethnic status. These discussions often are more narrowly focused on differences between whites and African Americans. In this issue of the Journal, we bring attention to the broader set of problems under the rubric of "health disparities," but our focus, like that of others, is limited, for the most part, to racial/ethnic disparities. We have tried to expand the discussion to include minority groups other than African Americans.

We have invited Anissa I. Vines, PhD, MS, and Paul A. Godley, MD, PhD, of the University of North Carolina, Co-Directors of the Program on Ethnicity, Culture, and Health Outcomes (ECHO), to write an Issue Brief on this theme. In their Issue Brief, these authors provide a conceptual overview of the topic, as well as illustrations of many dimensions of the broader set of problems along which attempts have be made to address these issues. Vines and Godley raise questions about the utility of the concept (and labels) of "race" and "ethnicity" in assessing the health significance of disparities. Even though they do not deal with disparities beyond those involving race or ethnicity, Vines and Godley clearly demonstrate the reasons why this area of public policy development has been very difficult and a substantial challenge to those who work in the healthcare field.

We have invited a number of commentaries from persons and organizations who are working in our state to address these issues, including information on the extent of these problems among the state's American Indian and Latino populations; the extent to which healthcare access differs among racial and ethnic populations; the adequacy of numbers of healthcare professionals from racial/ethnic groups; the efforts of state governmental agencies, community health centers, and local public health departments to address the health and healthcare needs of the state's minority populations; the role of faith-based voluntary organizations in meeting the challenge of health disparities; and the importance of minority group participation in health and medical research. In addition, we have included recently received scientific papers addressing these issues in the front of this issue.

Despite the narrower focus on racial and ethnic group disparities in this issue of the Journal, we hope that we have presented a set of ideas and supporting information through which these issues may be elevated on our state's public policy agenda for the future. We continue to invite comments from our readers on these and other topics addressed in the Journal.

ISSUE BRIEF

The Challenges of Eliminating Racial and Ethnic Health Disparities:

Inescapable Realities? Perplexing Science? Ineffective Policy?

Anissa I. Vines, MS, PhD and Paul A. Godley, MD, PhD

One of the most important new foci of American health policy deliberations since the late 1990s has been widespread concern over racial and ethnic disparities-that is, the disproportionate burden of diseases and other adverse health conditions among specific populations. Serious discussions about inequity in access to care and the epidemiological patterns of illness, disability, and mortality began during the Clinton Administration and through the personal efforts of former Surgeon General Dr. David Satcher. Wide variations in the provision of health and medical care and in health outcomes among racial, ethnic, and other social groups have been viewed as inseparable from issues of social justice and equity in our country.

As health disparities have been examined in the United States or in North Carolina, the predominant emphasis has been on disparities that exist for particular race and ethnic groups (also referred to as persons of color), especially those whose race or ethnicity is identified as African American, Latino/Hispanic, American Indian or Alaskan Native, or Native Hawaiian or other Pacific Islander. These groups collectively represent nearly a third of the nation's and North Carolina's populations and are expected to grow. Latinos now represent our nation's largest minority group (12.5%), with African Americans comprising 12% of the population. North Carolina has experienced one of the most rapid increases in its Latino population among all states, with Latinos now representing 4.7% of the state's population, increasing from 1.04% in 1990.[1] African Americans are now 21% of the state's population and remain as North Carolina's largest minority population group. Recent reports from the North Carolina State Center for Health Statistics show that African Americans, American Indians, and Latinos are more likely to have poorer health than whites in North Carolina. Given the predicted growth of minority populations—populations experiencing poorer health—our ability to successfully identify and address health disparities will significantly influence the health of our state and nation.

Racial and ethnic health disparities are intricately woven with socio-economic status and the ability to access other educational and social supports. Indeed social and environmental factors, such as having a low income, living in poor housing, having limited education, living with violence in communities, and the limited access to recreational facilities, are important to consider in health disparities research. But, health disparities cannot be fully explained by differences in socio-economic status alone. Health disparities are due to a complex interaction of many factors,

> *"The promise and potential of the American healthcare system is often beyond the reach of persons of color or is culturally inadequate when accessed. The continuance of health disparities lowers our nation's overall health status and poses social, environmental, and financial risks for everyone."*

Anissa I. Vines, MS, PhD, is a Research Assistant Professor in the Department of Epidemiology in the University of North Carolina at Chapel Hill School of Public Health and the Associate Director for the ECHO program. She can be reached at avines@email.unc.edu or at CB#7400, Chapel Hill, NC 27599-7400. Telephone: (919) 843-3539.

Paul A. Godley, MD, PhD, is an Associate Professor in the Division of Hematology/Oncology at the School of Medicine; is an adjunct associate professor in the Department of Epidemiology in the University of North Carolina School of Medicine Public Health as well as in the Department of Biostatistics; and the Director of the Program on Ethnicity, Culture, and Health Outcomes (ECHO). He can be reached at pgodley@med.unc.edu.

including: individual behaviors and preferences, cultural beliefs, biological factors, environmental factors, differential health interventions, potential bias among treating providers, public and private health policies, and differential access to healthcare services, in addition to socio-economic factors.[2]

Latinos, for example are relatively healthy compared to whites or African Americans despite their low incomes and poor working and living conditions. This may be due to their recent immigration to the United States (e.g., the so-called "healthy migrant effect") and relatively young age. Latina birth outcomes are much better—with lower rates of infant mortality and low-birth weight—than other racial or ethnic groups.[3] Yet, Latinas tend to delay or omit prenatal care more often than other groups. Unfortunately, studies from states with more mature Latino communities suggest that, over successive generations, the favorable birth outcomes among Latinos will rapidly disappear.[4] Culturally and linguistically appropriate interventions need to be developed before these recent immigrants become acculturated to the diet and lifestyle prevalent in the United States. Health literacy issues must also be addressed for this population. Not only do many Latinos have trouble understanding our healthcare system, but many Latinos are faced with a healthcare system that does not understand their culture and providers who cannot assess their health needs and preferences because of language barriers. These problems/differences present a number of health policy dilemmas. To achieve health equity, the priority in all areas of health policy should be to address health differences among population groups.

A nation that boasts as having the world's best medical care cannot overlook differential healthcare and health status outcomes where the system's performance, in some cases, is among the world's least equitable. The *promise* and *potential* of the American healthcare system is often beyond the reach of persons of color or is culturally inadequate when accessed. The continuance of health disparities lowers our nation's overall health status and poses social, environmental, and financial risks for everyone. A focus on health and healthcare disparities offers the opportunity to re-examine all that we do (and say) in regard to our highest ideals in American healthcare policy and practice. In addition, it gives us the opportunity to identify programs and policies that need strengthening and to better target resources so that we may attain these important national health goals and objectives.

Measures of Health Disparities

Five principal measures of health disparities are of greatest salience with respect to national and state health policy. First, there are issues related to the epidemiologic distribution and variation among population subgroups in the *incidence/prevalence* of specific health conditions. Second, there are issues related to *accessing* basic healthcare services when the need arises. Third, there are issues related to the *types of treatment* provided when services are obtained. Fourth are issues related to the *quality* of those services that are provided. Finally, there are issues related to the *outcomes* (or the *effectiveness*) of the services for which access has been possible. Though these five dimensions are interrelated, the measurement of health disparities has often given emphasis to one or the other of these dimensions individually, without consideration of their interrelationship.

Typically, most discussions (occurring prior to the late

Table 3.
Summary Health Indicators for White and Non-White Minority Populations in North Carolina by Gender, 2002[8]

	Years of Healthy Life	Years of Poor Health	Life Expectancy
White Men	62.4	10.6	73
White Women	66.6	13	79.6
Minority Men	53.3	14.7	68
Minority Women	59.3	16.5	75.8

1990s) of health disparities have focused on the differences in the incidence or prevalence of specific health conditions. Key indicators of health disparities among racial and ethnic groups include such rates as infant mortality, life expectancy at birth, cardiovascular disease morbidity and mortality, diabetes incidence and prevalence, and musculoskeletal morbidity (including arthritis and other related conditions). For example, African Americans have higher death rates for stroke, diabetes, septicemia, nephritis, homicide, and AIDS; and lower death rates for chronic lung disease and suicide.[5] American Indians have high death rates for diabetes, motor vehicle injuries, and homicide. Latinos also have high death rates for motor vehicle injuries and homicide. The incidence and prevalence of different health problems do not affect all racial and ethnic groups equally. For example, Latinos have high death rates for AIDS, but low death rates for chronic diseases. Asians have low death rates for every cause.[5] The data in Table 1 depict mortality rates attributable to these conditions among racial and ethnic populations in North Carolina. Table 2 provides indicators of the impact of health disparities among racial/ethnic groups in North Carolina. The data in Table 3 summarize more general indices of health status for white and non-white populations, by gender, in North Carolina.

Several gaps in the health of minorities are much wider in North Carolina than they are in the nation as a whole. For example, African American North Carolinians shoulder a disproportionate burden from prostate cancer than their counterparts in other states.[9] Although the incidence rate for prostate cancer is lower for North Carolina African Americans than African Americans nationally, the mortality rate for prostate cancer is greater and more than three times that of white North Carolinians. Pockets of extraordinarily wide health disparities, such as those found in our state among prostate cancer patients, will be particularly challenging for healthcare practitioners and researchers alike. This is an area that needs basic etiologic research to understand the factors that account for the differential incidence of prostate cancer and the poorer health outcomes for some minority populations.

Over the past 50 years in the United States, health status has improved in many areas, such as infant mortality, cardiovascular mortality and morbidity and in reductions in musculoskeletal morbidity through joint replacement. These improvements have occurred among many ethnic groups, yet the gap in health outcomes between black and white, between Latino and non-Latinos, persist even after differences in socio-economic status have been taken into account. Rates of heart disease among adults illustrate the point; black men ages 25 to 64 years have higher death rates from heart disease than those for whites regardless of income. Only at older ages do the rates converge.[8]

Racial and Ethnic Minorities are More Likely to be Uninsured

Racial and ethnic minorities are more likely to be uninsured than whites. In North Carolina, 14% of non-Hispanic whites are uninsured, compared to 19.9% of African Americans, and

55.7% of Latinos.[10] Latinos are least likely to have health insurance coverage because many of the Latinos in North Carolina are recent immigrants, and recent immigrants have a much harder time obtaining public health insurance coverage, regardless of their income,[a] and many are employed in jobs offering little or no health insurance coverage.

Individuals who lack health insurance coverage face financial barriers which make it difficult for them to access health care services. For example, 41% of the uninsured respondents from the 2003 North Carolina Behavioral Risk Factor Surveillance Survey reported that there was a time, in the last 12 months, when they needed to see a doctor, but were unable to obtain such care because of the costs (as compared to only 9.5% of people with insurance coverage).[11] This differential insurance coverage, coupled with lower socio-economic status, makes it difficult for some racial and ethnic minorities to access needed services.

Disparities with the Utilization of Lifesaving Treatments

Disparities in healthcare are more easily measured as differences in the *use* of services than as differences in the quality of those services actually used or provided. Differences in insurance coverage do not address all the differences in use of health services. Cardiac catheterization in patients with chest pain, kidney transplants in dialysis patients, thoracic surgery in lung cancer patients, and acute reperfusion therapy for myocardial infarction are illustrations of areas where inequitable utilization (or provision) of life-saving or life-improving therapeutic procedures have been documented, even after controlling for insurance status. Some of these studies are briefly noted here.

One of the most striking health disparity studies used Medicare data to examine surgery rates among 10,984 black and white early-stage lung cancer patients.[12] Bach and his colleagues compared the surgery rates of black and white Medicare patients with stage I or stage II small cell lung cancer (for which surgical resection has been shown to be beneficial). Compared to the white patients, black patients underwent lung cancer surgery less frequently than whites (64.0% vs. 76.7%, $p<0.001$). Black patients who underwent thoracotomy had mortality rates that were at least equivalent to those of white patients, but overall, blacks had a lower five-year survival rate than whites (26.4% vs. 34.1%, $p<0.001$). The study attempted to control for socio-economic factors as well as comorbidities that might preclude surgery. Even after controlling for these factors, the authors were unable to determine why black patients had a lower rate of resection than white patients, whether this difference was due to patient preferences in treatment options, or whether black patients are offered this procedure less frequently.

Investigators at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill plan to conduct a follow-up study that surveys both physicians and lung cancer patients to determine why some patients eligible for potentially life-saving surgery do not undergo the procedure. In their preliminary analysis of data from patients treated in Chapel Hill and Greensboro, these investigators have found that a surprisingly high proportion of North Carolina lung cancer patients refused to believe their diagnosis or declined surgery and chose to seek non-medical or alternative medical treatments.[13]

Godley et al. used Medicare reimbursement data merged with Surveillance Epidemiology and End Results (SEER) files from the National Cancer Institute to examine racial differences in prostate cancer treatment outcomes among 43,989 patients with clinically localized disease.[14] The investigators found that unlike the lung cancer study, black patients who received the same treatment as whites (whether surgery, radiation or watchful waiting) continued to experience poorer survival, particularly among the surgery patients (median survival after surgery was 1.8 years less for blacks than for whites). Black patients tended to choose surgery less often, watchful waiting more, and radiation at about the same rates as white patients. The challenge that this study posed is not necessarily why treatment is different, but why mortality differs significantly when treatment is similar, and potential confounders are taken into account. In contradistinction to lung cancer, prostate cancer patients tend to live for many years after diagnosis, even without treatment, allowing non-prostate cancer causes of death to account for a substantial proportion of the racial differences in overall mortality.

A study by Bradley et al.[15] of 70,030 patients with ST-segment elevation myocardial infarction or left bundle branch block, used data from the National Registry of Myocardial Infarction to find that non-white patients, as identified by healthcare workers, had significantly longer waiting times before receiving emergency coronary intervention. African Americans waited 41.1 minutes in door-to-drug times (fibrinolytic therapy) and 122.3 minutes in door-to-balloon (percutaneous coronary intervention), Hispanics waited 36.1 and 114.8 minutes, respectively, compared to whites, who waited on average 33.8 and 103.4 minutes. All of the differences were statistically significant. A third of the difference for blacks and 75% of the difference for Hispanics were accounted for by the differences in the hospitals to which the patients were admitted. However, significant

---

[a] The Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (PRWORA) significantly changed the eligibility of non-citizens for Federal means-tested public benefits, including Medicaid and the State Children's Health Insurance Program (SCHIP). As a general rule, only citizens or legally documented immigrants may be eligible for coverage. Most immigrants cannot be eligible for coverage for five years from the date they enter the country as a legally documented and qualified immigrant. In North Carolina, there are several different groups of individuals who qualify for Medicaid benefits. All have income limits and some have resource limits. To be eligible for Medicaid one must meet the income restrictions and be among one of the following groups: older adults (65 and older), blind, or disabled persons; a person in need of long-term care, a pregnant woman, a child (age 18 or younger), age 65 or older, a caretaker/relative of (living with and caring for) a child under age 19 who receives Medicaid.

differences remained even after adjusting for socio-economic characteristics, insurance status, and clinical and hospital characteristics. The disparity in this case is at least partially due to healthcare access, if not quality of care.

Another article by Bach et al.[16] also emphasizes the importance of hospital resources in health disparities. The study used data from 150,391 Medicare patient visits linked to 4,355 primary care physicians who completed the 2000-2001 Physician Survey component of the Community Tracking Study. The authors concluded that black Medicare patients received their medical care from a small group of physicians who, when compared to their colleagues practicing in other settings, were less likely to be board-certified (77.4% vs. 86.1%), less likely to be able to provide high-quality care to all of their patients (19.3% vs. 27.8%), and more likely to "not always" be able to access high-quality sub-specialists for their patients (24.0% vs. 17.9%) or not able to arrange non-emergency hospital admissions (48.5% vs. 37.0%). All of the differences were statistically significant. These findings reinforce the observation by Bradley et al. that black patients not only receive care from physicians with different training, but also receive their care in hospitals that have diminished capacity to access needed healthcare resources.

The findings by Bach et al. suggest that disparities in the allocation of healthcare resources may be due to more than a lack of patient education or bias on the part of healthcare providers. The findings project an image of a "shadow healthcare system" that is largely separate and unequal, often offering blacks suboptimal services from less-credentialed physicians who work at relatively resource-poor hospitals and clinics. If this dual system of healthcare is corroborated by subsequent investigations, alternatives to the usual solutions based on interventions with healthcare professionals and patients, will need to be explored.

One possible area to investigate is the efficacy of increased resources for the subset of physicians caring for minority patients. Equalizing access to specialist referrals and expensive procedures for these physicians may help equalize the disparities documented for their patient populations—a kind of "trickle-down" approach to solving the problem of disparities in healthcare. An editorial accompanying the article by Bach et al. suggests that longstanding societal discrimination plays a role in blunting opportunities for patients to obtain high-quality healthcare. Some problems, such as facilitating the granting of admitting privileges to local well-equipped hospitals, may be easy to address, especially in urban areas. Other issues may be more difficult, particularly in more rural areas of the country like North Carolina, where minority patients and their physicians may be geographically isolated from well-equipped medical facilities and sub-specialist physicians. It is also not clear whether the deficit in board certification among the physicians predominantly caring for black patients contributes to health disparities, or if differential access to healthcare resources alone would explain the differences in utilization of medical services.

Are Disparities Caused by Structural Inequalities or Biological Differences?

If available evidence (as just cited) indicates that minority populations (African Americans in particular) are served by *different* healthcare providers (who differ by their training and credentials; their ability [not their desire] to arrange for sub-specialty referrals, diagnostic studies, or non-emergency hospital admissions; and by the quality of the hospitals with which they are affiliated), then are these *structural* facts of American healthcare sufficient to explain the wide variations in the health status outcomes that exist among racial and ethnic groups when they experience similar diseases or health conditions as the majority populations? Are there studies that have been conducted in closed healthcare systems in this country that presumably assure access to the same services for all patients, regardless of racial and ethnic status? It turns out that there *are* such studies conducted within the United States Veterans Health System and in large staff-model managed care systems. These studies have documented that patients served in systems that purport to provide the same services to every eligible patient in fact *do* show patterns of lower quality care for persons of color.[17,18,19] It should be noted that while a number of Veterans Affairs hospitals have demonstrated disparities, a number of them have not found disparities. Thus, the differences in the structural systems of care provided to racial and ethnic minorities and the interpersonal bias of health professionals and patients contribute to health disparities. It is essential that in our search for policies to address health disparities that we take *both of these explanations* (or factors) into account and develop approaches that will deal with each.

One of the inescapable conclusions from the existing research in this area is that the socio-economic status of patients has much to do with *where* care is received, *what* care they receive, and of what quality, from *which* healthcare providers. The study by Bach et al., mentioned previously, attempted to adjust statistically for the socio-economic status of patients through the use of postal ZIP Codes of both the physician's practice and the patient's residence. Neither adjustment procedure altered the results of their research, although they point out (in a response to letters to the editor of the *New England Journal of Medicine*)[20] that "ZIP Code-based estimates (of socio-economic status) are imperfect surrogates for measures at the individual level." In the final analysis, the significance of the study by Bach et al. is that it clearly indicates the importance of inequality and race as contributing factors to what we now collectively define as "health disparities."

Recent information has surfaced that has raised the question of whether some of the disparities now seen in outcomes (or the effectiveness) of medical therapeutics are a result of the way (or systems within which) those therapies were delivered, or whether an explanation may lie in the biological differences among racial and ethnic groups that may moderate the effects of pharmaceuticals and other therapies. The November 11, 2004 issue of the *New England Journal of Medicine* included a controversial report,[21] which described a single-race clinical trial of a fixed-dose combination of two drugs previously approved by the United States Food and Drug Administration (FDA), isosorbide dinitrate[b] and hydralazine[c] for the treatment of heart failure among blacks (a condition from which mortality for blacks has been argued to be disproportionately higher than for whites, although the evidence for these differences is now questionable, as noted below). The combination pill carries the commercial name "BiDill®" and the trial of its use was co-sponsored by the Association of Black Cardiologists. Irrespective of the controversies raised by this publication over granting patents for race-based formulations of therapeutic agents, or the way in which the FDA approval of this new combined regimen may have been assured, there are serious questions about the way racial status is defined (or self-identified by study subjects) and the appropriate interpretation of the results of such trials.

This study, the African American Heart Failure Trial (A-HeFT) study, found that the drug combination being evaluated, when combined with conventional therapy, reduced relative one-year mortality for blacks by 43%, a truly remarkable finding. Bloche,[22] in an editorial accompanying the trial's publication, points out problems relying on single-race studies or self-identified race as a crude proxy for clinically-relevant genetic differences among people. First, studies that focus exclusively on the evaluation of therapeutics in a single race or ethnic group are not able to discern whether there are differential effects of these therapies among groups that are attributable to race alone. Second, when research subjects are asked to self-identify their racial and ethnic status, it is likely that such categorizations are influenced by the social and cultural definitions of race, not an index of the genetic or biologic variables that may determine one's response to illness or therapies. Racial groups originating from Africa, as well as other racial groups, are genetically heterogeneous. Focusing exclusively on race as a proxy for genetic predispositions may also mask the psychological, economic, cultural, environmental, and social factors that are known to influence human physiology.

The day after the results of the A-HeFT findings were published, the significance of these controversial findings was underscored by an editorial in the *New York Times*,[23] which offered these observations:

> "...there are reasons to go slow in moving toward race-based medicine. The chief drawback is that race is too superficial and subjective a concept, mostly based on skin color, to match up well with any underlying genetic or physiological differences that may affect how an individual responds to a disease or a drug treatment. Medical scientists are using race as a crude surrogate for what they assume are genetic differences yet to be identified.
>
> But there is considerable genetic variability within any racial group, so it is likely that the new pill may fail some black patients, while white patients who could benefit may not get it because they don't fit the racial profile. The ultimate goal, still years or decades away, is to develop medical treatments based on an individual's genes and life experiences, not on membership in some poorly defined racial or ethnic category. Race-based prescribing makes sense only as a temporary measure."

There are substantial questions about the scientific veracity of statements about the variability of response to treatment among groups defined by self-identified sociologic/cultural criteria, which overlook the genetic variability within "racial/ethnicity" categories.

The controversy over the BiDil® trial did not start with the publication of the trial's results. Nearly two years prior to publication of these findings there were numerous papers in the medical, ethics, and social policy journals questioning the inherent logic and rationale for the study. Kahn[24] demonstrated the fallacy of arguing a clear disadvantage of blacks in regard to mortality associated with heart failure. The 2:1 mortality ratio advanced by so many to justify the search for a race-based therapy has been shown not to be supported by available epidemiological evidence at the time. The ratio established by the Centers for Disease Control and Prevention (CDC) is approximately 1.1:1, but the 2:1 ratio has been repeated in numerous publications without attribution as a rationale for further clinical trials to address this problem.

The real worry about such efforts to find race-specific therapies is that the investment in these endeavors, and the controversies over the meaning and measurement of "race," may deflect attention from the basic problem of inequities in American healthcare—allowing those who may deny the existence or extent of these disparities to advocate for further delays in addressing these issues.[25]

Steps toward the Elimination of Health Disparities

One of the first steps being recommended by the National Research Council of the National Academies (NRC/NAS) is to strengthen the national informational technology infrastructure through which the data pertinent to health disparities may be documented and tracked for future progress. A recent report of the NRC entitled *Eliminating Health Disparities: Measurement and Data Needs*[26] has called attention to the need for individual-level data on race, ethnicity, socio-economic position, and acculturation (e.g., language use, place of birth, generational status), which are essential to documenting the nature of disparities in healthcare and to developing strategies for intervention. Not only are individual-level data severely limited, but the data that are available suffer from limited accuracy, completeness, and detail. State governmental data collection in programs like Medicaid, the State Children's Health Insurance Program (S-CHIP), and various registry systems, are potentially valuable for tracking health disparities, but data from these programs are collected in non-standardized ways. Hence, the NRC report

---

[b] Isosorbide dinitrate is used primarily to prevent and treat angina, and in the treatment of acute heart attacks and heart failure.

[c] Hydralazine is used to treat high blood pressure.

The University of North Carolina at Chapel Hill Launches ECHO Program to Address Health Disparities in North Carolina

The Program on Ethnicity, Culture, and Health Outcomes (ECHO) has been created at the University of North Carolina at Chapel Hill (UNC-CH) to support and strengthen existing health disparity research, training, and education activities and to develop additional initiatives within the university. Recognizing the importance of an interdisciplinary focus, the deans of the UNC Schools of Public Health and Medicine, as well as the deans of the UNC Schools of Dentistry, Nursing, and Pharmacy and the College of Arts and Sciences, provide the executive oversight for the program.

Directed by Paul A. Godley, MD, PhD, Timothy S. Carey, MD, MPH, and Anissa I. Vines, MS, PhD, the program has employed multiple approaches to address health disparities in North Carolina. The program has helped to sponsor research by UNC-CH faculty on an intervention study of obesity prevention among Latino children, the effects of massage therapy on diabetes control among African Americans, laboratory-based experiments of genetic polymorphisms related to prostate cancer; pilot awards, designed to fund innovative health disparity research and to enhance the careers of young health disparity investigators who are faculty members at North Carolina's historically black educational institutions; a 10-credit hour Inter-disciplinary Certificate Program in Health Disparities open to all UNC-CH graduate, professional, and continuing education students.

One of ECHO's primary goals is to help communities identify and solve community health problems through facilitation of increased student and faculty involvement in community-oriented research. One of the most innovative ECHO initiatives has been to establish Centers for Community Research to facilitate constructive communication between community groups and researchers, and to provide an enduring UNC presence in communities across the state. ECHO's mission is to work with communities to identify and develop resources in the community to meet healthcare challenges and to build strong relationships with community groups. The Centers are based at two of the 13 Area Health Education Centers (AHECs), covering 13 North Carolina counties, and provide continuing education and related services to health professionals in all 100 North Carolina counties. Locating the Centers within the AHECs allows the ECHO program to establish relationships with local healthcare providers as well as faith-based organizations and not-for-profit agencies within the AHEC's catchment area. These relationships will be critical to the success of the Program's community research efforts.

ECHO also provided the administrative and organizational structure for the, "Carolina-Shaw Partnership for the Elimination of Health Disparities," a National Institutes of Health, National Center for Minority Health and Health Disparities (Project EXPORT) center grant. This Center provides $6 million to UNC-CH and Shaw University over a period of five years to address health disparities in North Carolina using novel faith-based interventions. The most innovative Carolina-Shaw Project EXPORT center components include: a recruitment core tasked with building a database of minority candidates who have an expressed an interest in participating in clinical trials; a community outreach core that will connect to the internet 25 African American churches in five regions in eastern and central North Carolina to form a network of congregations interested in participating in health promotion research, and a new survey research unit created at Shaw University that will have specific expertise in surveying minority populations.

The ECHO program is an initial step to develop concentrated research efforts that will build on decades of minority research at UNC-CH. The challenge of eliminating health disparities lies with all of us—health professionals, policy makers, researchers, and citizens. We must move from merely reconfirming the documented disparities to documenting the social inequities that perpetuate these differences. This is necessary in order to disentangle issues of racism, access to care, and mistrust.

makes a number of suggestions for how these informational resources could be made more useful for documenting the extent of current disparities as well as for monitoring the success of efforts to reduce or eliminate disparities.

Administrative data such as those collected through the operations of health service delivery programs often are limited in scope to records of service use, costs incurred, and expenses covered. They rarely give any information about the processes of care (including the range of healthcare professionals with whom a patient may interact, the clinical decision-making processes involved in rendering care, and the types and results of diagnostic studies carried out in making such decisions). If race, or the more obvious race and ethnic characteristics of patients, is but a shorthand index or "place marker"[22] for a much more complex social and cultural set of phenomena, there is a need to know far more about how these shorthand indices lead healthcare providers to presume certain characteristics of patients and then factor these categorical notions into their recommended treatment strategies. There is a need for a much better understanding of the roles of stereotyping, uncertainty, and bias in clinical decision-making by all types of healthcare providers, as well as evaluated demonstration efforts designed to offset the potential influence of these factors in the care of patients.

Because so much of biomedical research in this nation has, until recently, been conducted exclusively among majority populations, the National Institutes of Health mandated, in 1993, following passage of the NIH Revitalization Act, that research funded by any of the National Institutes of Health should include adequate numbers of both women and minorities, or provide substantial justification for their lack of inclusion. This has been an important development in the American health science community. Yet, there remain substantial problems in encouraging minority participation as subjects in health research, for reasons explained by Dr. Giselle Corbie-Smith elsewhere in this special issue of the *North Carolina Medical Journal*.[27] Until there is evidence to clarify the presence/absence of differential effects of clinical interventions among minority populations, we are unable to ascertain the extent to which biological disparities exist, or, if they do, to what extent they matter.

Low Health Literacy Levels Contribute to the Health Disparity Problem

As previously mentioned, there is growing awareness of the problem of patient "health literacy" in this country that deserves serious attention in any attempt to address issues of disparities in either health status or healthcare access and outcomes. Though language-related problems for non-English speaking population subgroups are significant, issues of health literacy go beyond language facility. There is now substantial evidence to suggest that large segments of the United States population (regardless of native language) simply cannot comprehend, and thereby comply with, disease-related information and other instructions offered by healthcare providers. Even for native English language speakers, there are substantial numbers of United States adults who lack the basic skills to read and understand the information contained on a conventional prescription bottle or in a drug package insert.[28] This is a huge problem that will require broad-sweeping efforts on the part of public education *and* healthcare systems. Efforts currently underway at the University of North Carolina School of Medicine dealing with the health literacy of patients with diagnoses such as diabetes have shown remarkable levels of success in achieving critical clinical outcomes.[29]

Cultural Differences

Some racial and ethnic groups, especially those who are more recent immigrants to the United States, will require intensive and more focused efforts that offer healthcare services in a manner consistent with cultural patterns to which these populations have been accustomed in their native countries. For example, it appears that Latinos do not experience (and therefore do not interpret) the symptoms of ill health in ways similar to the majority white or African American populations. The matter of Latino culture and belief systems would not be major concerns if we were dealing with the health and medical care needs of this population in their native countries. There, both the patients and their healthcare providers would share the same culture and spoken language. But this lack of a common understanding of the etiology of health—exacerbated by language barriers—may lessen the potential effectiveness of healthcare services and interventions offered by healthcare professionals to the growing Latino population. Language and cultural differences, along with lower education levels, make it difficult for Latinos to access and use the United States healthcare system and may lead them to seek care in inappropriate places (tiendas, emergency departments, etc).These healthcare challenges faced by the Latino population are ripe for more intensive investigation by health disparity investigators. Moreover, the lessons to be learned from these studies may lead to interventions applicable to other racial and ethnic groups in the United States who are not recent immigrants, and for whom teasing apart the cultural, lifestyle, and dietary contributors to health disparities from issues of racism, healthcare access, and mistrust of the medical system may be more difficult.

The Role of Institutional Racism

Racism also has links to disparities in health due to race and ethnicity.[30] Racism leads to many stress-related reactions such as changes in eating patterns, a lack of sleep, high blood pressure, and an increased reliance on alcohol and other substances.[31] Institutionalized racism is another factor that impedes the narrowing of the health gap between whites and non-whites. Despite legislation to end segregation and other blatantly racist practices, many structures and policies that shape the health of this nation are racially and culturally biased. In a recent study by Vines et al., 23% of African American women in metropolitan Washington, DC perceived experiences of racism in the medical care setting.[32] The persistence of racism and its manifestation in the built environment are contributors to both physical and mental health problems as well as the persistent racial profiling in medical care.

Summary

Despite the accomplishments of American medical science and the impressive array of healthcare facilities and service delivery models available in this country, the existence of significant health disparities is a matter of urgent national and state health policy priority. Policies to address these issues should address fundamental problems having to do with access to care (such as health insurance coverage and the availability and the geographic and culturally-appropriate accessibility of personal health services), the educational preparation of healthcare professionals for the challenge of caring for the increasing diversity of patients in a truly "patient-centered" healthcare system of the future, efforts to deal with widespread problems of health literacy that reduce the likely impact and effectiveness of healthcare, and a more aggressive effort to assure that future medial science continues to include minorities and women (and they continue to participate) as subjects in clinical trials of innovative therapeutic interventions.

The policy agenda to address these issues is both broad and demanding, as would be expected of any set of problems which is so widespread and complex. But, America is no stranger to challenges, and few are more worthy of the effort than this. **NCMJ**

COMMENTARY

Perceptions of Racial and Ethnic Differences in Access to Healthcare

Damon M. Seils, MA, and Kevin A. Schulman, MD

Interest in racial and ethnic differences in health and healthcare during the past 15 years has tended to focus, with growing sophistication, on differences in procedure use, referrals, and health outcomes. This research has been accompanied by studies of communication in provider-patient relationships and, more recently, an increasing interest in patients' and physicians' perceptions of barriers to high-quality healthcare for different racial and ethnic groups. In this commentary, we briefly review some recent studies of perceptions of barriers to care. We focus especially on our group's recent research in Durham County as a way of highlighting the importance of focusing on the experiences of local communities in studies of barriers to care.

Public Perceptions

The Henry J. Kaiser Family Foundation (KFF) conducted a survey in 1999 of a nationally representative sample of 3,884 adults in the United States.[1] The survey explored public perceptions of associations between race/ethnicity and healthcare and found that these perceptions varied by race and ethnicity. Black and Latino respondents perceived greater unfairness in the nation's healthcare system and expressed greater concern about financial barriers to healthcare than did white respondents. Following on the KFF national survey, our group collaborated with The Duke Endowment, El Centro Latino, and North Carolina Central University to conduct a similar survey in Durham County. Friedman et al.[2] sought to understand perceived barriers to care in the Durham County healthcare system and how those local perceptions compared to the national findings of the KFF survey.

The Durham County survey has provided data for several analyses. Van Houtven et al.[3] found that residents of Durham County who perceive that they are treated unfairly in the healthcare system have greater odds of delaying or forgoing medical tests and treatments, controlling for economic constraints such as unemployment and lack of health insurance. Hong et al.[4] examined associations between self-rated health status and barriers to healthcare (i.e., lack of health insurance, lack of a usual source of care, problems with transportation, limited English-language ability, and perceived scarcity of physicians in the area). Greater barriers or perceived barriers on all but the variable for usual source of care were associated with lower self-rated health status. Voils et al. examined levels of concern among respondents that their health would be harmed by disease, diet, lack of exercise, and inability to follow physicians' recommendations.[24] Latino and black respondents in Durham County tended to be more concerned than white respondents about their ability to follow physicians' recommendations.

According to another study by Voils et al.,[5] racial and ethnic groups in Durham County also have differing levels of trust in health institutions, and perceived trustworthiness differs by type of institution. For example, Latinos in Durham County were more trusting overall than white and black respondents. Also, whereas Latinos tended to trust various types of health institutions equally, white and black respondents were less trusting of insurance companies and state and federal governments and were more trusting of physicians, public hospitals, and county health services. Williams et al. recently completed an analysis of respondents' trust in sources of health information in Durham County.[25] They found that black and Latino respondents were more likely than white respondents to trust the health department, ministers and churches, and television and radio as sources of health information. Trust in physicians, nurses, friends, and relatives was similar across racial and ethnic groups; however, Latinos were less likely to trust pharmacies as sources of information.

Physician Perceptions

Research on physicians' perceptions of racial/ethnic disparities and barriers to healthcare is limited. A study by Schulman et al.,[6] using identical case descriptions presented by patient-actors of

different races and genders, identified a race-gender interaction term as a significant predictor of referral for cardiac catheterization. The investigators also found racial differences in physicians' perceptions of patients' personality characteristics and socioeconomic status. These secondary outcomes pointed to some additional areas of potential concern.

In a series of reports, researchers examined physicians' and patients' beliefs regarding access to kidney transplantation. They found racial differences in patients' preferences and expectations, but these did not account for differences in referral for transplantation.[7] Epstein et al.[8] found that racial differences in kidney transplantation could be explained both by differences in clinical characteristics and by underuse among black patients and overuse among white patients. The investigators also found that physicians were more likely to believe that black patients would not experience a survival benefit from kidney transplantation.[9] Many physicians also viewed donor availability, patient adherence, and patient preferences as explanations for why black patients are less likely to be evaluated for kidney transplantation.[9]

> *"Latino populations in Charlotte, Greensboro-Winston-Salem, and Raleigh-Durham have experienced 'hypergrowth'—increases of more than 300% (i.e., twice the national average) in the 20-year period from 1980 to 2000."*

Another recent study by Bach et al.,[10] using the 2000-2001 Community Tracking Study Physician Survey, found that primary care visits by black Medicare beneficiaries were concentrated in a small subgroup of physicians and that visits by black patients tended to be with physicians who were not board-certified. Moreover, visits by black patients were more often with physicians who reported limited access to high-quality medical services. In other words, physicians in the study who were most likely to see black patients reported having less training and restricted access to high-quality specialist, hospital, and ancillary services.[10]

Preparatory work for our group's Durham County survey provided some information about physicians' views of racial/ethnic disparities in healthcare. In a small survey of physicians practicing in Durham County, our group asked respondents to identify the "special challenges" they faced in treating patients from different cultures.[11] Three quarters of the physicians identified language barriers as a problem, ranging from some patients' lack of English-language ability to physicians' difficulty understanding regional English-language dialects. Several physicians noted problems obtaining access to translators for Spanish-speaking patients, and others emphasized the lack of Spanish-speaking physicians and other providers.

Local Research for Local Circumstances

Accompanying the report of the KFF national study in *Medical Care Research and Review*,[1] Waidmann and Rajan[12] reported racial and ethnic differences in access to and use of healthcare resources both nationally and in individual states. They concluded that "efforts to eliminate disparities in access to quality healthcare may need to be tailored to the specific needs of states." Strategies for one racial or ethnic group in one location will not necessarily be successful for other racial and ethnic groups in other locations. For example, the Latino populations of Florida, New York, and Texas differ considerably in their ethnic and cultural characteristics (e.g., national origin). Not surprisingly, their experiences with and demands on the healthcare system also vary.[12]

From 1990 to 2000, for example, the Latino population of the Raleigh-Durham metropolitan area increased by 631% as a proportion of the overall population.[13] Latino populations in Charlotte, Greensboro-Winston-Salem, and Raleigh-Durham have experienced "hypergrowth"-increases of more than 300% (i.e., twice the national average) in the 20-year period from 1980 to 2000.[13] Growth in Latino populations has also been accompanied by growth in Asian-Pacific Islander communities. In Durham County, for example, the proportion of Asian-Pacific Islander residents increased twofold, a trend mirrored in neighboring Orange and Wake Counties.[14]

Because the large majority of Latinos in Durham County were born outside of the United States, compared to only about half of Latinos nationwide, it is reasonable to expect that Durham Latinos have unique attitudes, concerns, and patterns of behavior about health and healthcare. In their effort to identify concerns unique to Durham County, Friedman et al.[2] compared findings from their survey of Durham County residents to findings from the KFF national sample. They found a number of important differences in the perceptions and experiences of respondents from Durham County, as compared to the national survey. These included substantial differences among Latinos with respect to demographic characteristics, English-language ability, and health insurance status. Durham Latinos were relatively young, and a much greater proportion of them were men, compared to the national sample. Latinos in the Durham County survey also expressed greater concern than those in the national survey about their clinical encounters, including perceptions of being treated unfairly because of their ethnicity.

Several studies have documented the unique experiences of Latinos in North Carolina. For example, Buescher[15] describes how the major health problems of North Carolina Latinos can be tied to the population's relative youth and limited access to healthcare services. Many of the recommendations of the

Latino Health Task Force[16] emphasize the need for more bilingual healthcare providers, and several studies have pointed to links between North Carolina Latinos' health needs and the large number of recent immigrants and migrant workers in the population.[15-19]

Heterogeneity at regional, state, and local levels—in racial/ethnic composition, socio-economic status, health infrastructure and resources, and any number of other community characteristics—has important implications for the ways researchers, providers, and policy makers approach public health issues. As readers of the *North Carolina Medical Journal* know, collaborations between community organizations, foundations, academic institutions, and local and state governments can foster important research in these areas. They will also lead to the development of innovative, sophisticated methods for targeted public health interventions.[20-22]

Concern about health disparities in local communities leads to a broader question about meeting the needs of patients in a complex healthcare system. Barriers to high-quality healthcare may reflect, in part, individual encounters with individual providers. However, it is more likely that barriers arise in a series of complicated steps in the medical decision-making process. For example, Einbinder and Schulman[23] described eight steps in the referral process for invasive cardiac procedures—from the patients' recognition of symptoms through the physician's referral for a procedure—and discussed the evidence for racial/ethnic differences and disparities in each step. Healthcare is a process, not a single encounter, and at each step in that process the most vulnerable patients are the least likely to successfully navigate the system and receive the healthcare they need. Efforts to understand racial and ethnic differences and reduce disparities will have to take an account of a broader range of clinical, socio-economic, and structural variables than have been considered to-date. **NCMJ**

COMMENTARY

Health Issues Facing the State's American Indian Populations

Ronny A. Bell, PhD, MS

According to 2003 Census estimates, approximately 108,000 North Carolina residents identify themselves as American Indians/Alaska Natives, representing about 1.2% of the state's population.[1] The state's American Indian population is largely represented by eight recognized tribal groups (Coharie, Eastern Band of Cherokee, Haliwa Saponi, Lumbee, Meherrin, Occaneechi Band of Saponi Nation, Sappony, Waccamaw Siouan) and four American Indian Urban Centers (Cumberland County Association for Indian People, Guilford Native American Association, Metrolina Native American Association, Triangle Native American Society).[2] North Carolina represents the largest state concentration of American Indians east of the Mississippi River.

Limited information available from research studies and publicly available data sources indicate that significant disparities exist for many health conditions in American Indian communities. For example, the prevalence of diabetes and other cardiovascular disease risk factors are substantially higher for North Carolina American Indians compared to whites.[3-5] Diabetes-related complications, such as lower-extremity amputation and end-stage renal disease, have been reported to be three and six times higher, respectively, among the Eastern Band of Cherokee Indians compared to the rate for United State whites.[6-7] The diabetes death rate for North Carolina American Indians is three times higher, and the death rates for stroke and heart disease are at least 25% higher, than the rates for non-Hispanic whites.[8] Other health concerns, such as unintentional injuries and homicides, are dramatically higher for American Indians compared to whites.[8] These conditions lead to higher rates of premature mortality; the average years of potential life lost per death (YPLL) in North Carolina is 22.2 for American Indians, compared to 15.2 for whites and 20.5 for African Americans.[9]

> *"The diabetes death rate for North Carolina American Indians is three times higher, and the death rates for stroke and heart disease are at least 25% higher, than the rates for non-Hispanic whites."*

Disparities in Health Are Linked to Socio-economic Status

These disparities are believed to be reflective to a large extent of the significant socio-economic burden in many American Indian communities. Nearly one-quarter of North Carolina American Indians live below the poverty level, and rates of unemployment are at least two to three times higher in this population compared to whites.[10] About three-quarters of American Indians in the state have a high school education or less, compared to 56% of whites.[8]

Access to healthcare is a major concern in American Indian communities. Only one of the eight tribal groups in the state, the Eastern Band of Cherokee Indians, is authorized to provide healthcare through the Indian Health Service (IHS). However, barriers such as limited resources and inadequate transportation for many tribal members still exist that limit effective appropriation of healthcare. Statewide, American Indians are twice as likely to report that they have no healthcare coverage, and to report they

Ronny A. Bell, PhD, MS, is a member of the Lumbee Indian Tribe, and is an Associate Professor in the Department of Public Health Sciences, Wake Forest University Health Sciences. He can be reached at rbell@wfubmc.edu or the Department of Public Health Sciences, Wake Forest University School of Medicine, Medical Center Boulevard, Winston-Salem, NC 27157-1063. Telephone: 336-716-9736.

were unable to see a doctor in the past year due to costs. Approximately 38% of pregnant American Indian women do not access prenatal care during the first trimester, compared to 18.4% for whites and 21.8% overall.[11] Inadequate healthcare among North Carolina American Indians is likely due, in addition to the high rates of poverty in these communities, to other barriers. For example, nearly 70% of North Carolina American Indians live in rural communities.[8] where access to high-quality healthcare may be difficult. Cultural factors may also contribute to reluctance by American Indians to access the available healthcare system.

Limited Data

Much is still unknown about the health and healthcare of American Indians in North Carolina. One of the more significant gaps in our understanding is the limited information on the health of American Indian children. Maternal risk factors are very high among American Indian mothers, and the infant mortality rate for American Indian children is higher that the state rate. The asthma hospitalization rate for American Indian children in 1997 was reported to be nearly three times the rate for white children.[8] There is no information currently available on Type II diabetes among American Indian adolescents. This condition is documented as being on the increase among ethnic minority adolescents in general, and among American Indian adolescents in particular.[12] Data on chronic disease risk factors among American Indian children, such as obesity, physical inactivity, harmful tobacco use, and inadequate diet, are not readily available.

Another gap in our understanding of American Indian health in North Carolina is the lack of tribal-specific data. The eight recognized tribal groups in the state are divided not only by geography, but also by unique elements in culture and history. Much of the data on health and healthcare among North Carolina American Indians comes from one tribe, or is not segmented by tribal group, which limits our ability to interpret this information for every tribe. Some tribes are relatively small, and some do not have organized tribal rolls, making research efforts difficult in these communities.

Cultural Differences

Culture is a significant but often overlooked contributor to health and healthcare in the United States. Culture can influence lifestyle behaviors, attitudes toward health, living arrangements, and receipt of healthcare. The extent to which culture, relative to other factors, such as socio-economic status, contributes to the observed disparities among American Indians in North Carolina is not well understood. Similarly, little is known about whether racism influences health, health behaviors, and healthcare for North Carolina American Indians.

North Carolina Commission on Indian Affairs

The North Carolina Commission on Indian Affairs, created in 1971 by the North Carolina General Assembly, has been instrumental in advocating for issues related to American Indian health. The Commission was instrumental in organizing three statewide American Indian Summits since 2001. The goals of these conferences have been to raise awareness of the health needs of American Indians, develop and implement healthcare best practices guidelines, and to develop networking opportunities for healthcare providers and organizations interested in healthcare. The Health Committee of the Commission has also been instrumental in identifying and participating in research and health priorities for American Indian communities. These priorities include an initiative to provide diabetes education in American Indian churches and anti-smoking cessation efforts targeting American Indian youth.[13]

American Indian Health Task Force

The American Indian Health Task Force has been developed as a collaboration between the North Carolina Department of Health and Human Services, the Office of Minority Health and Health Disparities, and the North Carolina Commission on Indian Affairs. The Task Force was initially convened in July 2004. The Task Force is represented by a diverse group of healthcare providers, administrators, and academicians from across the state and from various American Indian tribes. This Task Force is charged with developing recommendations to address the health disparities of North Carolina's American Indian population. This Task Force is examining issues related to the availability of health-related data, sovereignty and governmental issues, and access to prevention and care services.

Conclusion

Despite substantial gaps in our understanding, the existing information available point to significant health disparities for North Carolina American Indians. Chronic diseases such as diabetes and cardiovascular diseases, and other concerns such as unintentional injury and homicide, contribute substantially to these disparities. The causes of these disparities are more than likely multi-faceted, but our understanding of these factors is limited. On-going efforts in the state involving numerous agencies will hopefully address these gaps and reduce the health burden in this population. **NCMJ**

COMMENTARY

Health Disparities among North Carolina's Latinos:

Our Point of View

H. Nolo Martínez, EdD, and Andrea Bazán Manson, MSW, MPH

The fact that Latinos are a growing presence in North Carolina is well known among the public health community and other sectors. From 1990 to 2000, the state experienced the fastest growing Latino population of any state in the nation. Today, at least 5% of the state's residents are of Hispanic origin. And due to undercounts and the fast growth of the community, it is estimated that the proportion is much higher. The United States Bureau of the Census announced last year that Latinos are now the largest minority group in the country. Latinos are today a vital part of the North Carolina economy, having initially been recruited to work in low-skill jobs and industries, and now settling in with young families in every county of North Carolina.

North Carolina initially began addressing Latino health disparities during the 1990s, at the time when the state began experiencing a large influx in Latinos. The term 'health disparities' had then gained national and local attention, and public health leaders were charged with getting a better sense of the disparities that existed in our own state. But, little was known about the newly arrived population, and basic questions needed to be answered first: Who were they? Why were they coming in such numbers? And what was public health's role in this? Indeed, the state of North Carolina was confronting the health disparities of a community it did not fully understand. Information on ethnicity was not generally collected in the health data systems, so the state did not have an accurate picture of Latino health. To address this gap in knowledge, some initial studies were conducted by the North Carolina Center for Public Policy Research, the then-called Office of Minority Health and the State Center for Health Statistics within the North Carolina Department of Health and Human Services, and other groups. As a state and a public health community, we began to learn more about our new neighbors.

> *"...North Carolina does not yet have the infrastructure, including bilingual personnel and culturally appropriate policies, to fully tackle disparities among Hispanics in the state."*

Indeed, the work of the early to mid-1990s contributed significantly to our understanding of health disparities among Latinos. It is disappointing, however, that although some progress has been made in translating this knowledge into practice, North Carolina does not yet have the infrastructure, including bilingual personnel and culturally appropriate policies, to fully tackle disparities among Hispanics in the state. Latino health disparities in most cases have been addressed independent of policy change. North Carolina Latinos are at a disadvantage when it comes to sound healthcare policies that address their unique health and healthcare needs.

And the disparities persist. Latino children are more likely to be obese than other children. They are more likely than whites and other minorities to have asthma. National data indicate that Latino children and adults are more likely to have dental caries than those from other races or ethnic groups. Latinos are more likely to die in car crashes than any other group. Although not much concrete data exist to support it, we are aware that mental health issues are becoming increasingly serious among Latinos—and that they are largely untreated. Latinas in North Carolina have the highest rate of adolescent pregnancy in the country. Of concern, too, is the number of Latino adolescents

Andrea Bazan Manson, MSW, MPH, is the Executive Director for El Pueblo and a Member of the Institute of Medicine. She can be reached at andrea@elpueblo.org or at 4 North Blount Street, 2nd Floor, Raleigh, NC 27601. Telephone: 919-835-1526.

who are reporting depression to their peers and teachers. And among the North Carolina Latino worker population, there are disproportionate rates of injuries and deaths.

These are serious differences. But beyond specific healthcare issues, we see language barriers as the principal healthcare 'problem,' as defined by both the provider and the Latino community. Until the language differences are addressed, we will make no progress in addressing health disparities for the North Carolina Latino population.

And, in order to fully address the healthcare challenges among Latinos, not just the healthcare access problem, it is critical to recognize that policy plays an increasingly vital part.

Federal Laws Complicate the Provision of Healthcare to Latinos and Other Immigrants

Although Latinos have lived in North Carolina for generations, the 'core' of the community is a newly arriving one. The large immigration wave that occurred over the past ten years is due to the need for low-skilled workers in industries such as poultry plants, construction, restaurants, and agriculture. Many of these workers are not documented. An increasing number of them have young children who were born in North Carolina, and who make up 'mixed-status families.' Some workers may be here on temporary visas and may stay beyond their allotted time. The legal status of a family is crucial, and influences every aspect of a person's life in this country—including access to healthcare.

Immigration policy, however, is mainly an issue that is addressed at the federal level. It is one of the most controversial and complicated issues to tackle. It is also capricious—often influenced by politics, campaigns, and money. Immigration policies impact on the ability of Latinos to access healthcare services.

For example, undocumented immigrants, and other lawful permanent residents who recently arrived in this country, are generally ineligible for publicly funded health insurance coverage, such as Medicaid or NC Health Choice. Medicaid will pay for emergency services provided in a hospital for these immigrants. In addition, the Medicare Modernization Act has funding to pay for emergency services for other undocumented immigrants (who would not otherwise qualify for Medicaid). The Centers for Medicare and Medicaid Services (CMS) earlier this year initially proposed rules that would require hospitals to ask immigrants about their immigration status in order to qualify for these new funds. While this policy may appear innocuous on its face, it would have discouraged immigrants from seeking hospital services for fear that their status would be reported to the Office of Homeland Security (formerly known as Immigration and Naturalization Service). It would put healthcare providers in the role of immigration agents. This policy also could have created public health hazards if people with communicable diseases failed to obtain needed healthcare services. And, it could have cost states more in the long run if emergency healthcare issues were not treated immediately.

Hospitals, providers, and advocates criticized this proposal, and CMS eventually backed down. The proposal, however, re-ignited the debate of uncompensated care for immigrants.

The state did recently receive some good news. A Medicaid family planning waiver to expand Medicaid income eligibility for family planning services to 185% of the federal poverty level was approved on November 5, 2004. This expansion will provide Medicaid funding to cover family planning services to Latinos who would otherwise be eligible for Medicaid. It also addresses a vital need among the young population—family planning.

Title VI of the Civil Rights Act Requires that Healthcare Providers Make Their Services Linguistically Accessible

Title VI of the Civil Rights Act of 1964 states that organizations or providers that receive any amount of federal funds cannot discriminate against people because of race, ethnicity, or national origin. The federal government has interpreted this "national origin" provision to mean that individuals have a right to receive services in a language they understand. This means that patients who go to such facilities should be able to communicate effectively with their providers, and should be able to comprehend the written instructions as they walk out with their prescribed medicines.

In 2001, the Office of Civil Rights within the United States Department of Health and Human Services reviewed North Carolina for its compliance under Title VI, and the state did not receive a good grade. Under the leadership of the Secretary of the North Carolina Department of Health and Human Services, North Carolina has been working hard to ensure that local plans are in place to meet the language needs of both providers and the community. In addition, the Department is also exploring ways to pay for interpreter services for individuals with limited English proficiency who receive Medicaid services. However, more work is needed to make sure that language barriers are removed so that individuals with limited English proficiency can communicate effectively with health and human services providers.

A State Plan

North Carolina has done some groundbreaking work in establishing priorities for the Latino population. *The 2003 Task Force on Latino Health Report*,[1] produced by the North Carolina Institute of Medicine in collaboration with El Pueblo, Inc., is perhaps the most comprehensive summary of Latino health status produced to-date. It also contains specific recommendations on how to improve that health status. The most important premise of the report is that, if North Carolina adopts the recommendations of this comprehensive plan, Latino health disparities will be significantly reduced and/or removed. The report answers the following questions. What are some challenges and opportunities that Latinos face? How can we change the challenges into opportunities? What are some actions and activities (e.g., policy, legislative, and administrative) that can be implemented to improve the health of Latinos? Which agencies and organizations are responsible for making these recommendations happen?

The report provides a thorough explanation of the gaps between services and programs provided by local health departments, community health centers and migrant clinics, other state programs, and the current local Hispanic community. The strong collaboration, inclusion, and partnership built and maintained by those involved in the Task Force guaranteed that North Carolina healthcare professionals, advocates, and policy makers would be aware of the wide range of health issues facing Latinos. On November 10, 2004, the North Carolina Institute of Medicine and El Pueblo re-convened the Task Force to review progress since the Report's publication. Positive steps have been taken to begin implementation on more than three-quarters of the recommendations. It is commendable work for such a diverse group of agencies, policy makers, and advocates.

However, the General Assembly has not made the level of commitment needed to ameliorate the access barriers and healthcare disparities faced by the growing North Carolina Latino population. While the General Assembly did recently enact legislation to expand the availability of services offered to the uninsured through community health centers, health departments and rural health clinics (many of whom are Latino), these funds are not sufficient to meet the growing needs. For example, there are some estimates that health departments are providing more than $10 million in uncompensated prenatal care, largely to Latinos; yet only $1 million was allocated to health departments to meet the primary care needs of the uninsured. Further, no funds were allocated to train interpreters or to assist in recruiting bilingual providers.

There are some local programs that exemplify collaborations among sectors that have been implemented, thanks to private funding. The most promising are the lay health advisor programs. They utilize models that take into account Latinos' native language as well as their strong sense of community and family. Lay health advisor programs do this by training local volunteers to become advocates for health. El Pueblo began such an initiative in March 2004 with funding from The John Rex Endowment. The initiative has trained a group of "promotoras," or health promoters, to work directly with families at the community level. Promotoras become formal leaders in Latino communities across the state. They receive needed up-to-date health information and develop connections with existing health services, which were once unfamiliar to them. The Chatham Hospital Immigrant Health Initiative has been implementing a lay health promoter program for several years. It has been able to establish a positive and effective collaboration among the hospital, local churches, two local poultry factories, and the University of North Carolina Department of Family Medicine.

In language training, too, there are some promising efforts. "A Su Salud," a recently-launched program at the University of North Carolina at Chapel Hill, provides hands-on Spanish-language training for healthcare providers and students. Area Health Education Centers across the state continue to offer an array of courses for providers who are interested in improving their knowledge about the Latino culture and learning the Spanish language, as well as training programs for interpreter services.

A Commitment to System Change Is Needed

There is a lot of activity from the North Carolina Latino community itself. English classes are offered by various centers and volunteer groups and church-sponsored English classes are usually filled to capacity. Latino non-profit organizations are creating innovative programs to help engage the community in state affairs related to health and human services. The Spanish-language media has emerged as a crucial source for information and is actively utilized by Latino leaders and providers.

Some of the efforts described here are promising, but they are not enough. We have a plan to ensure that all North Carolinians have the same chances. A set of policy recommendations that can take care of our disparities has been developed. We have been challenged by the report, the initial collaborations, and the groundbreaking work of many organizations across the state.

The reduction of Latino health disparities will require North Carolina leaders, elected officials, business and healthcare administrators to commit themselves to system changes. Any efforts will have to take federal immigration policies into account.

Latinos represent more than demographic changes. Latinos represent an important part of North Carolina, contributing significantly to its economic development and culture. It is due time that the Latino community be recognized for this, and that we continue the initial work that has begun. **NCMJ**

COMMENTARY

North Carolina's Response to the Challenge of Health Disparities

Barbara Pullen Smith

The North Carolina Department of Health and Human Services has embraced the national public policy agenda to eliminate health disparities by the year 2010. Key state and national policy decisions have played a pivotal role in elevating the issue of eliminating health disparities in our state.

History

North Carolina has a long history of defining and addressing these issues. Focused attention on the disproportionate burden of disease among racial/ethnic minorities has been gaining momentum since the first minority health report was published in 1987, "The Health of Minorities in North Carolina."[1] That report initiated a response by the former State Health Director, Ronald H. Levine, MD, MPH, who established a workgroup to study the issues surrounding minority health in North Carolina and make recommendations for action. As a result of this early work, two entities were created by the North Carolina General Assembly in 1992: House Bill 1340, part 24, Section 165-166 led to the establishment of the Office of Minority Health and Health Disparities (OMHHD) and the Minority Health Advisory Council (MHAC). The fifteen member advisory council is charged with advising the Governor and cabinet Secretary of Health and Human Services on minority health issues. The mission of the OMHHD and MHAC is to "promote and advocate for the elimination of health disparities among all racial and ethnic minorities and other underserved populations in North Carolina." Both entities provide leadership to increase resources for addressing health disparities, advocate for policies to improve minorities' access to prevention and care services, identify promising practices in target communities, improve the collection of health data by race/ethnicity, inform leaders and policymakers about the issues, and engage minority leaders in new ways of promoting health.

> *"The mission of the OMHHD and MHAC is to "promote and advocate for the elimination of health disparities among all racial and ethnic minorities and other underserved populations in North Carolina."*

In 1998 the elimination of health disparities became a national priority. That year, President Bill Clinton and his Surgeon General, Dr. David Satcher, articulated the goal of eliminating disparities in six key health categories by 2010.[2] This important public policy challenged states to increase efforts to address the persistent disparities in health between racial/ethnic minorities and whites. The national initiative focused on cardiovascular disease, cancer screening and management, infant mortality, diabetes, HIV/AIDS, and immunizations. These six health areas were selected for emphasis because they reflect areas of disparity that are known to affect multiple racial and ethnic minority groups at all life stages. Resources were allocated to invest in disparate communities and seek solutions to the nation's growing disparities. Addressing "health disparities" is the cutting edge of public health practice.

The year 2001 marked an important milestone in North Carolina's efforts to address the health challenges facing racial/ethnic minority populations. With the appointment of Carmen Hooker Odom as Secretary of the North Carolina Department of Health and Human Services (DHHS) came a heightened focus on eliminating health disparities. Secretary Hooker Odom included eliminating health disparities as one of her top four priorities, along

Barbara Pullen Smith, is the Director of the North Carolina Office of Minority Health and Health Disparities in the North Carolina Department of Health and Human Services. She can be reached at barbara.pullen-smith@ncmail.net or at 1906 Mail Service Center, Raleigh, NC 27699-2009. Telephone: 919-715-0992.

with early childhood development, mental health, and long-term care further emphasizing the fact that the cutting edge of public health practice includes addressing health disparities.

The vision guiding the Department's work is for "all North Carolinians to enjoy good health regardless of their race and ethnicity, disability, or socio-economic status." In order to achieve that vision, the Department recognizes that all state sectors will have to embrace and invest in efforts to address and eliminate health disparities. The solutions are local. All sectors including individuals, families, the professional medical community, academic institutions, business/industry, faith-based, and other community leaders must play an active role. Although one department cannot do it alone, the Department of Health and Human Services has assumed a key leadership role in addressing these issues and serves as a model for other state Departments. Leadership and commitment are key elements to systems change.

Secretary Hooker Odom challenged all Divisions/Offices in the Department of Health and Human Services to participate in efforts to identify service gaps and come up with creative solutions to increase access to programs and services for racial/ethnic minorities and other underserved populations. The OMHHD was directed to lead the Department in the systems change process. An integrated, comprehensive, and coordinated approach has been outlined to identify and reduce service barriers throughout the Department's programs and services. The approach is driven by the concept that eliminating health disparities is not another "special initiative," but must be incorporated as an integral part of good business and public health practice for Department of Health and Human Services. Three overarching principles guide the systems change process: integration, investment, and accountability. The process has been implemented in three phases.

Phase I. Internal Capacity-Building/ Team-Building

The Eliminating Health Disparities (EHD) Steering Committee was organized and includes representatives from 14 Divisions and Offices of the Department. This internal team has been mobilized to build the capacity of the Department to identify and address access and service disparities. The mission is to use health disparities data to guide program and funding decisions and to establish priorities for effective outreach to diverse communities, with a major emphasis on creating culturally competent services and programs, workforce diversity, and investments in community strategies.

During the initial phase, considerable time and effort was spent to build the capacity of staff within the Department through in-service training sessions on health disparities, Healthy People 2010 goals/objectives, promising practices, and organizing disparity teams within each organization. Building the capacity of the Department was a critical first step to ensure that the staff, programs, and services are effective in reaching and engaging racial/ethnic minority communities throughout the state. The training was effective in demonstrating the importance of integrating health disparity intervention programs and services of the Divisions and Offices of DHHS.

To establish baseline information, the selected Divisions and Offices completed a Disparity Assessment Tool that provided an internal perspective of the Department's existing strategies to identify and address disparities within each program area. Divisions/Offices were directed to assess current data, resources, and programs focused on reaching underserved and minority populations; identify gaps in services/programs/resources; identify issues around workforce diversity and current processes for making funding decisions.

Phase II. Plan Development

Developing a comprehensive, coordinated, Department-wide action plan with a systematic approach was the goal. A strategic process was implemented to ensure broad-based input into the Department's action plan. Community leaders, service providers, researchers, policy makers, administrators, educators, and faith leaders were engaged using multiple strategies, including, but not limited to, two focus group sessions and three regional forums. Minority health experts consisting of community leaders, researchers, service providers, and agency administrators were invited to participate in the focus group sessions. The focus group participants provided insights on recommended state and local strategies for addressing the ongoing health challenges experienced by racial/ethnic minorities in our state.

The Healthy Carolinians Program sponsored three regional forums with support from the OMHHD to hear directly from communities impacted by health disparities. Forum participants included local public health departments, human service agencies, medical clinic/hospitals, educators, and faith leaders as well as other community leaders. Local solutions to eliminate health disparities were documented. The forums increased awareness about health disparity issues and generated recommendations for action at the local and state levels.

Information collected by the Disparity Assessment Tool, focus groups, and regional forums was incorporated in the Department's action plan. The resulting document is entitled, "From Disparity to Parity in Health: Eliminating Health Disparities Call to Action."[3] The plan serves as the operational framework for the North Carolina DHHS Division/Offices. The nine recommendations contained in the plan focus on increasing awareness, championing best practices, enhancing community capacity, monitoring progress, promoting customer-friendly services, investing in eliminating the gaps, building a diverse workforce, advocating for key public policies, and ensuring accountability. Using the nine recommendations as a guide, each Division/Office developed an implementation plan that includes action steps tailored to their programs and services. Priority areas have been determined; internal/external resources identified and timelines/evaluation measures are included.

Phase III. Implementation/Accountability

Keeping the issue of eliminating health disparities in the forefront is key to continued progress. The EHD Steering Committee meets monthly to learn about each other's programs/services, discuss progress, talk about challenges, solicit suggestions, share innovative strategies, and identify opportunities to share resources and develop joint projects. To ensure accountability, Division/Office progress reports are submitted every six months to the OMHHD. Regular meetings are held to brief the Secretary on progress.

Moving in the Right Direction: State Progress

The North Carolina DHHS Divisions/Offices continue to operate at different stages in this systems change process. However, Divisions/Offices have demonstrated progress in building the Department's internal capacity to identify and address disparities and to engage minority communities as evidenced by the following short-term impacts:

- Improved data on the health status of racial/ethnic minorities continues to be a priority. Strategies are in place to increase access to health information for all minority populations. The State Center for Health Statistics and OMHHD published two reports, "Racial and Ethnic Disparities in North Carolina: Report Card 2003" and "Racial and Ethnic Differences in Health in North Carolina: 2004 Update."[4,5]
- Programs have completed internal assessments of their service history. The resulting reports document current gaps in data, existing disparities, and service gaps. For example, the Division of Mental Health, Developmental Disabilities, and Substance Abuse Services' (MH/DD/SAS) report in 2003 documents racial and ethnic disparities in the delivery of mental health services in North Carolina. The draft report is entitled "Health Disparities by Race and Ethnicity: Access to Care, Expenditures and Consumer Satisfaction."
- Disparity issues are incorporated in policies, program guidance, and contract language with local agency partners. For example, Title VI of the Civil Rights Act of 1964 requires that language services be provided for limited English Proficient (LEP) clients. This requirement is included in the service contracts for local public health departments. The Governor's Healthy Carolinians Task Force has incorporated a focus on eliminating health disparities in their standards for certification and re-certification for local Partnerships.
- Workshops on minority health, cultural competence, and health disparity issues are included in conferences/forums on an ongoing basis. The result has been increased awareness among audiences outside of the traditional public health and healthcare arenas. An increased understanding of the impact of all health and human services on the health of the people in our state is a fundamental first step in the systems change process.
- The Department has established key policy initiatives around the provision of language services for Limited English Proficient Clients. A team, lead by the Division of Medical Assistance is in the process of establishing protocols for Medicaid reimbursement for language services.
- Health disparities data are included in grant proposals to leverage additional funds. Additional funds have enabled Divisions/Offices to invest in disparity issues in new ways. For example, the OMHHD was awarded an AmeriCorps grant from the North Carolina Commission on Volunteerism and Community Services. The grant will support 21 full-time AmeriCorps members. The majority of the members, called "Health Disparity Fellows," are placed in local health and human service agencies, community-based organizations, and faith-based organizations throughout the state. These new partnerships will expand our efforts to identify promising practices to eliminate health disparities.
- DHHS Division/Offices have established internal teams to organize their systems change process and discuss strategies across programs/services. The Disparity teams have been instrumental in keeping disparity issues in the forefront of Department of Health and Human Service program planning and operations.
- Disparity issues have become a part of the routine work of program managers and a part of regular discussions by management teams. DHHS Divisions/Offices have incorporated eliminating health disparities activities in staff work plans and in job descriptions. This level of accountability has been key to ensure that Divisions/Offices maintain eliminating health disparities as a priority issue for staff.
- New partnerships have been formed between Divisions/Offices around health disparity issues and joint projects are underway. For example, a regional health disparities elimination project focusing on diabetes prevention and control among African Americans received a grant from Bristol Myers Squibb. Partners in this demonstration project include the Office of Rural Health, OMHHD, Division of Public Health, and the Old North State Medical Society (the professional organization of African American physicians in North Carolina).
- Department of Health and Human Services divisions are implementing cultural competence training and minority recruitment strategies to increase the availability of culturally and linguistically appropriate programs and services. The Division of Mental Health, Developmental Disabilities, and Substance Abuse Services has enhanced its efforts to reduce barriers to services and improve access for diverse communities through cultural competence training and skill development of staff in all levels of the organization.

Progress has also been made at the community level. The network of minority, community-based, and faith-based organizations have expanded tremendously throughout the state. More and more minority leaders are taking on the health challenges in their communities. Their focus is on prevention, early detection, linking to existing resources, forming new partnerships with health providers, reducing access barriers, and holding local healthcare and human service providers accountable for the community's health. These community groups have created effective avenues for engaging and reaching racial/ethnic minority groups included among the targeted populations of the Department.

North Carolina DHHS Divisions/Offices have demonstrated success in working more closely with communities across the state, with increased funding going directly to support minority community-based and faith-based projects. The many promising practices funded throughout North Carolina focus on a variety of health disparity issues, including increased access to prevention and early detection services for diabetes, HIV/AIDS, cancer, and infant mortality to name a few. The ongoing challenge continues to be the fact that many of the projects can demonstrate improved health outcomes among the population reached, but the projects are often limited in duration, funding, and scope. As a result, good projects are not able to affect county-level health status data over time. However, without these community-based efforts, the health disparities data would be even worse.

While there is significant work to do to reduce and eliminate health disparities, North Carolina is moving in the right direction. We are challenged to mobilize all sectors of our state around these issues. We are challenged to engage racial/ethnic minority communities in new ways. We are challenged to invest in closing the gaps. **NCMJ**

3 NC Department of Health and Human Services: From disparity to parity in health: eliminating health disparities call to action 2003. Available at http://www.ncminorityhealth.org
Recommendations from this Call to Action:
(1) Increase awareness of health and service disparities, especially disparities related to race/ethnicity, disability, and socio-economic status.
(2) Communicate, document, and champion best practices in eliminating health disparities.
(3) Promote, develop, and enhance communities' capacity to engage in healthy living and elimination of disparities in health status.
(4) Monitor progress towards the elimination of health disparities.
(5) Promote customer-friendly services that meet the needs of underserved populations (i.e., the poor and minority groups).
(6) Increase resources and investments to eliminate health status gaps.
(7) Build, support, and fully utilize a diverse workforce capable of working in cross-cultural settings.
(8) Identify and advocate for public policies that aid in closing the health status gap.
(9) Demonstrate accountability and ownership for health outcomes.

COMMENTARY

Community Health Centers and Their Role in Reducing Healthcare Disparities in North Carolina

D. Alden Smith, MBA, CEO, and E. Benjamin Money, Jr, MPH

INTRODUCTION

One of the most effective national strategies for reducing health disparities in the United States has been the development of community health centers. Community health centers are not-for-profit organizations partially funded by the federal government and have local boards of directors, the majority of whose members must be users of the center's services. Community Health Centers, also known as "Federally Qualified Health Centers (FQHCs)," base their fees on locally prevailing rates. Community Health Centers (CHCs) use a sliding-fee schedule to discount their charges to patients with incomes of 200% of Federal Poverty Guidelines and below. There were 890 community health centers in the United States with over 3,400 sites in calendar year 2003 providing a medical home for 15 million Americans.[2] North Carolina has 23 community health centers with over 73 sites serving more than 260,000 North Carolinians every year; about 50% of these patients have no insurance.[3]

Community health centers were born in the crucible of the 1960s to serve Americans regardless of race, religion, insurance status, or ability to pay. The first centers were the migrant health centers created by the federal government in the aftermath of Edward R. Murrow's documentary "Harvest of Shame." Shortly thereafter, the Office of Economic Opportunity created neighborhood health centers. Rural health centers were soon developed under a federal rural health initiative. One of the earliest documentaries showing the impact of these centers on rural communities was Dr. Jack Geiger's "Out in the Rural." These unique public-private partnerships have been studied extensively since their inception. A recent paper by the National Health Policy Forum described CHCs as the "dominant model of federal grant funding for primary care in the healthcare safety net" and reviewed the background, services provided, people served, financing, and high quality care provided by community health centers.[4]

Community health centers serve the most vulnerable populations. The national patient population of CHCs in 2003 was represented by 64% from racial and ethnic minorities. About 90% of this patient population had household incomes under 200% of the federal poverty level.[5]

A 2000 study showed that health centers provided 4.2% of the total primary care visits in the United States. However, they provided 14.6% of the visits by ethnic minorities and 28.7% of the visits by ethnic minorities with Medicaid or no insurance (See Figure 1).[6] Since this study used 1994 data, and given that the number of uninsured patients at CHCs has grown from 3.5 million in 1998 to 5.9 million in 2003, we would expect that these percentages are even more dramatic now.[7]

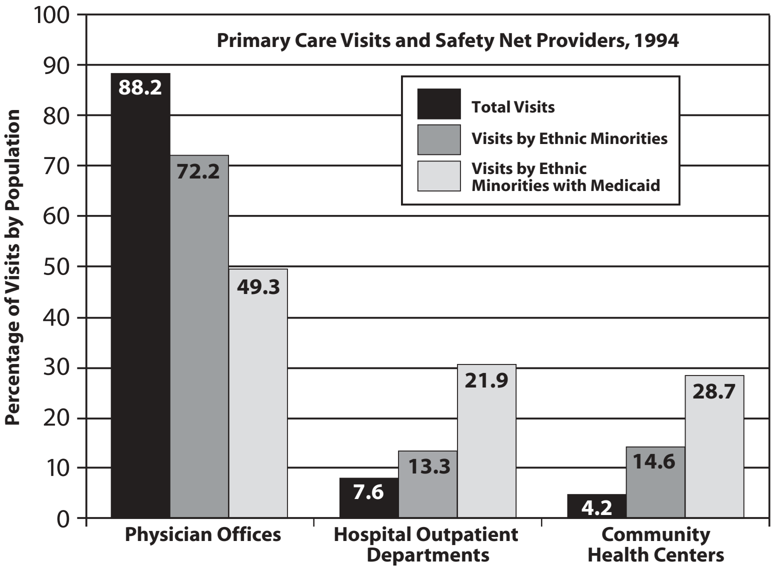
> *"One of the most effective national strategies for reducing health disparities in the United States has been the development of community health centers."*

At community health centers, 74% of the patient population is uninsured or covered by Medicaid. In private medical practices only 19% of the patients are uninsured or on Medicaid.[8]

D. Alden Smith, MBA, is the CEO of Greene County Health Care and the CEO/CIO of Community Partners HealthNet. He is also an Adjunct Professor in the Department of Family Medicine at the Brody School of Medicine, East Carolina University; and Chair of the Data Workgroup at Bureau of Primary Health Care in the Health Resources and Services Administration.

E. Benjamin Money, Jr., MPH, is the Associate Director for the North Carolina Community Health Center Association. He can be reached at moneyb@ncphca.org or 975 Walnut Street, Suite 363, Cary, NC 27511. Telephone: 919-297-0012.

Figure 1.
Health Centers Serve a Greater Proportion of Racial/Ethnic Minorities and Those on Medicaid and Uninsured than Other Providers.[6]



Numerous studies have examined the quality of care provided by community health centers. One study in 2001 showed that community health centers exceeded the national average for providing appropriate pap smear screenings.[9] Another study showed that racial/ethnic disparities in the provision of digital rectal examinations seen in other primary care practices were not evident in community health centers (See Figure 2).[10]

A 1996 study by the Office of Data Evaluation and Research (ODEAR) in the Bureau of Primary Health Care, Health Resources and Services Administration, United States Department of Health and Human Services showed that diabetics receiving care at community health centers were more than twice as likely to receive appropriate glycohemoglobin testing than a United States comparison group.[11] Another study by ODEAR showed that African American and Hispanic hypertensive patients at CHCs were three times as likely to report controlled blood pressure than a United States comparison group.[12]

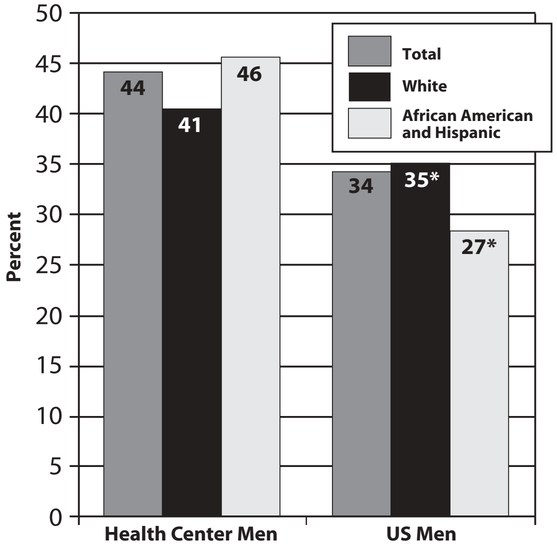
Community health centers were shown to provide better continuity of care than other providers in a 2000 study. A CHC patient is nearly twice as likely to return to the CHC for a new problem than they are likely to return to private physician or a hospital outpatient department (See Figure 3).[13]

Numerous studies of community health centers have documented their role in improving the health of the communities that they serve.[14] A recent study by George Washington University School of Public Health and Health Services showed that greater levels of health center penetration in a given market "were associated with significant and positive reductions in minority health disparities."[15]

Community health centers have shown significant success in improving prenatal care and infant health outcomes.[16,17] Communities served by a CHC have infant mortality rates between 10 and 40% lower than communities that do not have a CHC.[18-21] Community health center patients have also been shown to have higher immunization rates than the general population.[22]

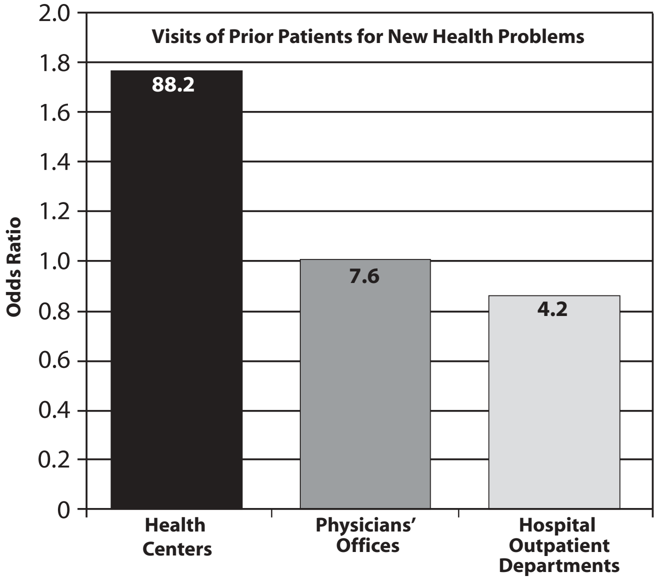
In addition to increasing access to primary and preventive care services, community health centers have been designated

Figure 2.
Health Centers Do Not Show Racial/Ethnic Disparities in Digital Rectal Examination Rates.[10]



**Statistically signifigant at p<0.05*

Figure 3.
Health Centers Provide More Continuity of Care Than Other Safety-Net Providers.[13]



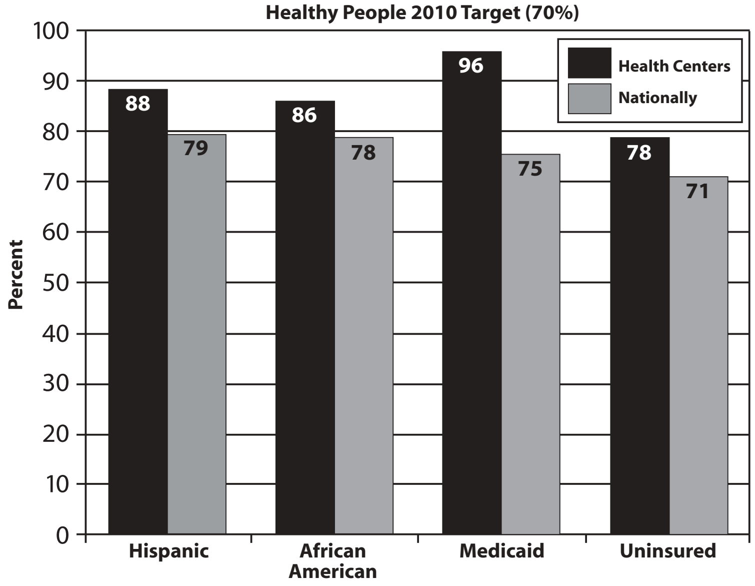
by the federal Office of Management and Budget as one of government's ten most successful and cost-effective programs.[23] In fact, the same study ranked the community health center program as the most effective program in the federal Department of Health and Human Services. These centers also have been recognized as a very effective vehicle to reduce health disparities by the federal General Accounting Office.[24-25]

In fact, these health centers have been called the "most important in the country for serving underserved populations... CHCs run the best primary care delivery systems in the United States."[26] The reasons for these successes are varied and include community boards, culturally-appropriate services, outreach, case management, eligibility assistance, partnerships with other local and faith-based organizations, and other health and human services located in one comprehensive system.

In the late 1990s, health centers refocused their efforts on health disparities through the development of the chronic care collaboratives. The Institute for Healthcare Improvement (IHI) trained the community health centers in the chronic care model with the support of the Bureau of Primary Health Care, Health Resources and Services Administration, a division of the United States Department of Health and Human Services. Clinical foci have included diabetes, asthma, cardiovascular disease, depression, and cancer. In each collaborative, appropriate clinical outcome measures are tracked and reported back to the health center providers. Some of the data from individual health centers around the country have been remarkable, for example:

- Grace Hill, Neighborhood Health Centers in St. Louis, Missouri has achieved an average decrease of HbA1c levels from 10.76 to 8.23.
- La Clinica Campesina in Lafayette, Colorado reduced average HbA1c levels from 10.5 to 8.5.[27]

Figure 4.
Percent of Women Receiving Mammograms at Health Centers vs. Nationally[29]



These collaboratives have both formalized and provided the theoretical underpinning for the system of care long provided by CHCs. The results from the collaboratives initiative show further improvement in quality over the earlier studies. More than half of the CHCs participated in these collaboratives as of 2003.

A study published in the *Journal of the American Medical Association* in 2002 showed that community health center patients with chronic disease were more likely to be healthier than white, insured patients with chronic disease in the private sector because of the prevalence of collaborative care and self-management education in community health centers versus the traditional care model used in most private practices.[28]

A 2002 study compared the percentages of CHC women over 40 receiving mammograms to all women under 200% of federal poverty level. The study showed that CHCs exceeded both the national averages and the Healthy People 2010 targets for both minorities and Medicaid uninsured populations (See Figure 4).[29]

METHODS

Since racial and ethnic health disparities remain a major problem in the United States, particularly in the southeast, we designed this study to present preliminary data from individual community health centers in North Carolina in order to investigate whether there were improvements in the state that mirrored the national data. Health Centers in North Carolina in 2003 served a patient population that was 40% African American, 27% white, 25% Hispanic, and 8% other.[30] Through clinical work groups in the 1990s, health centers began tracking clinical indicators. In recent years, health centers participating in the various federal and state chronic disease collaboratives have entered data into clinical tracking and reporting systems called Cardiovascular and Diabetes Electronic Management System (CVDEMS) or Patient Electronic Care System (PECS). These systems generate reports on a quarterly basis. CHCs in North Carolina were asked to submit copies of these reports to the North Carolina Community Health Center Association. These reports were submitted by five of 11 (45% response rate) community health centers in North Carolina.

In addition, the North Carolina Community Health Center Association and the North Carolina Diabetes Prevention and Control program have partnered to implement the models of the national Health Disparities Collaboratives (HDC) in a state-based collaborative. University health systems, integrated delivery systems, health departments, rural health clinics, free clinics, health education centers, and other settings involved in healthcare delivery are also able to participate and learn the Chronic Care Model[31] and the rapid cycle improvement model. For Community Health Centers, the state-based initiative serves as a mechanism to support North Carolina CHCs in ramping up for HDC participation; it also serves as a vehicle to sustain and spread after participating in the initial year of learning with the HDC.

RESULTS

The results as of September 2004 are presented in numbered form below:

1. Greene County Health Care in Snow Hill reported a diabetic patient population that was 70% minority with an average HbA1c level of 7.8.
2. Person Community Health Center in Roxboro reported that over the two years in the collaborative, the average HbA1c rate dropped from 12 to 7.8 and that blood pressures dropped from 140/110 to 120/70's to mid 80s.
3. Tri-County Community Health Center in Newton Grove reported that they joined the diabetic collaborative in November 2000 with an average HbA1c level of 9.5. By the end of September 2004, the average had dropped to 8.3.
4. Robeson Health Care Corporation in Robeson County reported lowered HbA1c levels from 9.1 to 7.9 with 1,763 patients in the registry.
5. Robeson Health Care Corporation also reported that among cardiovascular patients, 50% of 2,304 cardiovascular patients had blood pressures under 140/90.
6. Lincoln Community Health Center in Durham reported its diabetic patient population of 2,354 patients (76% minority) had an average HbA1c rate of 8.2, down from 8.5, last year and from over 9.0 five years ago.

These results mirror large studies including the one that showed a lowering of the HbA1c level from 9.0 to 8.0 in 23 health centers with 8,000 diabetes patients and a January 2004 article, which analyzed a diabetes quality improvement initiative in 19 midwestern health centers and found that the collaboratives dramatically improved diabetes care in one year using a variety of outcome and process measures.[32,33]

Also, the North Carolina Diabetes Collaborative, the pilot state-based collaborative, was able to mirror the successes of the national Health Disparities Collaborative. With 13 participating centers during the 2003-2004 year, 1,379 patients were entered into the registry. The aggregate HbA1c declined from 7.96 to 7.81, with the number of patients receiving two HbA1cs annually increasing from 4.4% to 24.7%. Significant strides were made in the following measures: annual foot exam rates increased from 15.1% to 48.8% and annual dilated eye exams increased from 6.2% to 24.2%.[34]

DISCUSSION

CHCs clearly play a major role in reducing or eliminating health disparities, as the numerous examples already cited have shown. Some of the reasons for this include: the CHC mission; federal grant requirements; frequent location in areas with large minority populations; provision of culturally-sensitive care; federal mandate to serve all regardless of race, religion, country of origin, or ability to pay; community involvement; and diversity in staffing.

The improvements in the control of chronic disease at North Carolina CHCs measured by specific clinical outcome measures mirror the improvements shown in the national literature. More formal studies need to be conducted. Longitudinal studies would be particularly useful in tracking improved clinical outcomes over time. Data from the North Carolina CHCs participating in federal and state collaboratives should be published as soon as it becomes available.

A major research opportunity has been created by five community health centers in Eastern North Carolina. Beginning in 2001, these centers began to implement a common electronic health record system and build a clinical data warehouse to track clinical outcome measures using sophisticated report writing software. The record systems for three CHCs are currently operational and two more will be operational within the next six months. As more patients are enrolled in this system, the data will be both readily accessible and comprehensive. By 2006, there will be data on nearly 75,000 patients. These data present a major research opportunity to improve and disseminate outcome documentation among all community health centers serving these highly diverse, and underserved, populations in North Carolina. **NCMJ**

Churches, Academic Institutions, and Public Health:

Partnerships to Eliminate Health Disparities

Moses V. Goldmon, EdD, and James T. Roberson, Jr., PhD

Introduction

The disproportionate burden of preventable illness and death suffered by racial and ethnic minorities and/or other persons from low-socio-economic status backgrounds—health disparities —came into focus with the release of the 1986 landmark document titled the Report of the United States Secretary's Task Force on Black and Minority Health (the Heckler Report). This report, along with *Healthy People 2000 and 2010*, has spurned a number of research, education, and service initiatives aimed at eliminating health disparities. Despite many efforts to address these disparities, health professionals continue to experience difficulty reaching minority populations with sustainable research, education, and service initiatives. Obstacles include, but are not limited to, mistrust due to past misuse and abuse, culturally insensitive methods and materials, and one-way research and intervention efforts that benefit academic and public health institutions, but fail to provide tangible benefits to church and community members.[1] These obstacles hinder progress in addressing health disparities. African American and other racial and ethnic minority populations continue to suffer a disproportionate burden of preventable disease and death.[2]

Broad partnerships between community-based, academic and public health institutions have emerged as a plausible solution to overcoming the obstacles to engaging hard-to-reach populations in efforts to eliminate health disparities. Interdisciplinary and/or inter-institutional partnerships (involving pastors, physicians, parish nurses, lay health advisors, chaplains, community leaders, theological educators, health educators, researchers, and other stakeholders) engage a diverse group of people in the discovery and transfer of new knowledge that could provide solutions to the complex issues that cause health disparities. More specifically, research suggests that engaging the black church in health disparities partnerships is an effective way to develop sustainable culturally-appropriate research, education, and service projects that are acceptable to African Americans.[3,4,5]

Drawing upon current literature and our experiences as pastors, health and theological educators, and practitioner-researchers[6] who are actively engaged in several health disparities partnerships, this commentary explores the development of sustainable partnerships between African American churches and academic and public health institutions.

> *"churches are uniquely situated to facilitate participation of people from hard-to-reach populations."*

Why Churches?

Community members, universities, and government agencies see churches as institutions that should be included in public health partnerships.[7,8,9,10] Reasons include: (1) churches share a mutual concern with public health institutions about the issues that impact the health knowledge, attitudes, behavior, access, and outcomes of racial and ethnic minority, low-income, and other underserved populations, (2) the faith tenets of most churches encourage the promotion of holistic health, healing, and living, (3) churches are the historical center of comfort, guidance, and inspiration, particularly in African American communities, (4) churches offer a variety of resources (human, intellectual, capital, social, and spiritual), and (5) churches are uniquely situated to facilitate participation of people from hard-to-reach populations.

Moses V. Goldmon, EdD, is Director of the Action Research in Ministry Institute and Assistant Professor of Field Education of the Shaw University Divinity School. He also serves as Pastor of the Faucette Memorial Christian Methodist Episcopal Church in Durham, North Carolina. He can be reached at mgoldmon@shawu.edu or at PO Box 2090, Raleigh, NC 27602. Telephone: 919-405-2267.

James T. Roberson, Jr., PhD, is Dean of the Shaw University Divinity School, Director of the Carolina-Shaw Partnership Community Outreach Core and pastor of the New Bethel Baptist Church, Macon, NC. He can be reached at jtrob@shawu.edu or at PO Box 2090, Raleigh, NC 27602. Telephone: 919-546-8569.

Increasing Emphasis on Church Involvement in Health Initiatives

Recently, the number of health research, education, and service initiatives implemented by or including churches has increased. For example, the number of "faith and health" initiatives in North Carolina that have some connection to the North Carolina Office of Minority Health and Health Disparities has increased by 78% (from 11 to 48 over the past five years).[11] Health disparities partnerships that include churches are encouraged and participated in by state and local governments, universities, corporations, hospitals, professional associations, and community groups.[1,7,12,13,14,15]

The increased emphasis on partnerships in general, and the engagement of churches specifically, as a mechanism to effectively address health disparities is encouraging. However, concerns about the difficulty associated with effectively engaging and sustaining African American churches has been expressed by church, community, university, public health, and government representatives. These concerns highlight the need for a strategic approach to the development of broad partnerships that include churches. Below is a set of principles that could help to address these concerns.

Principles for Engaging African American Churches in Health Disparities Partnerships[i]

These principles are informed by the current literature and our experiences as pastors, health and theological educators, and practitioner-researchers.[10,16,17,18,19,20]

Principle Number 1: Identify and Prioritize Potential Partner Churches

Identification of churches begins with a deliberate choice to prioritize churches that will comprise a pool of *potential* participants. A common mistake associated with efforts to engage the "the church" is a failure to recognize the diversity that exists among churches. This diversity stems from the fundamental beliefs that people of faith have about "their god" and the corresponding doctrine, polity, and denominational structure employed to guide their understanding, devotion, worship, and service. There is also a great deal of diversity within and among churches that share the same doctrine and to a lesser degree polity and denominational affiliation. For example, there are eight different *historical* denominations categorized as African American Protestant churches.[ii] In recent years, we have also experienced a boom in the growth of other denominations as well as "Non-Denominational" Protestant Churches. A working understanding of the basic doctrinal beliefs, polity, and organizational structures of the various churches that are potential partners is a pre-requisite to recruiting and forming trusting relationships with churches.

Principle Number 2: Develop Trusting Relationships that Lead to Sustainable Partnerships

Sustainable or "true partnerships" include trusting relationships, mutually beneficial collaborations, participatory processes and shared governance. The people who are sent to interact with representatives of the potential partners are key to establishing trusting relationships. Identifying the "right representative(s)" is not merely a matter of race and ethnicity. The primary factor is a willingness to understand and develop an appreciation for the perspectives of others. When seeking to engage churches, it helps to have a translator—persons with knowledge of and experience working with both churches and public health institutions.

Previously, we mentioned the doctrinal, political, and denominational diversity within "the black church." Attempts to establish partnerships with churches without an appreciation for these fundamental tenets increase the risk that something might breech church polity. Such activities, although often unspoken, tend to deepen the mistrust that pastors and other church leaders have of "secular organizations." Mistrust stifles the reflective dialog that is essential for sorting through the inter-institutional (churches, universities, healthcare and government agencies) and interdisciplinary (public health, medicine, theology, and religion) differences and similarities. Identifying the similarities coupled with efforts to understand and appreciate the differences precede the identification and

---

[i] (a) The principles are designed to assist public health representatives as they engage faith-based organizations in sustainable health disparities research, education, and service partnerships. While the premise of the principles discussed in this commentary represent a framework for engaging "the faith community," they are most applicable to collaborations that include historically African American Protestant churches. The emphasis on African American Protestant churches does not insinuate that this or any other particular faith tradition is inherently more applicable for involvement in health disparities partnerships than others. However, since our knowledge and experiences are centered in African American Protestant church and theological education traditions, we are most qualified to adequately represent this perspective.

(b) We use the term "faith community" to refer to a diverse group of people who believe and trust in a god or a religious system whose existence cannot necessarily be proven with tangible evidence. Further, we emphasize our view that African American churches are part of the larger "faith community." Similarly, we use the term churches generically to refer to organized religious fellowships. The term is inclusive of synagogues, mosques, and parishes and other fellowships.

(c) While this discussion is limited to broad principles, we distinguish *principles* from *practices*. Principles are fundamental presuppositions designed to guide the process of identifying, recruiting, and selecting churches (as well as church leaders) as partner participants. Principles are used to promote reflective dialog among a diverse group of partner participants that will lead to the establishment of mutually beneficial practices. Thus, practices are mutually agreed upon activities derived by the principles.

[ii] African Methodist Episcopal (AME); African Methodist Episcopal Zion (AMEZ); Christian Methodist Episcopal (CME); Church of God in Christ (COGIC) National Baptist Convention of America, Inc. (NBCA); National Baptist Convention, USA, Inc (NBCUSA); National Missionary Baptist Convention of America (NMBCA); and the Progressive National Baptist Convention, Inc. (PNBC)

prioritization of areas of mutual concern, which enable partnerships to build upon the strengths and minimize the weaknesses of each partner organization. Partnerships established without cultivating trusting relationships and mutually agreed upon policies and practices simply transfer traditional models of health disparities research and interventions from academic, government, and healthcare settings to churches.

Sustainable partnerships founded on trusting relationships reduce the likelihood that this will occur by ensuring that pastors and other church leaders are engaged as equal partners with other professionals.[21] This provides pastors and other church representatives an opportunity to influence and be influenced by the policy and practices of public health institutions and vice versa. Ultimately, true partnerships produce changes in the policy and procedures of all participating institutions that will lead to culturally relevant health disparities research, education, information dissemination, and service/ministries.

When engaging churches in partnerships, it is important to involve pastors from the outset. Pastor "buy in" legitimizes church and community involvement in a manner that facilitates adoption, participant recruitment, and decision-making.[22] As respected leaders in the community, pastors can help to: (1) design and plan culturally-appropriate research and interventions; (2) serve as advocates that will bridge the communication gap between health professionals, church, and community members; (3) develop comprehensive sustainable ministries of health; and (4) help to ensure a more culturally diverse healthcare workforce by encouraging church and community youth to pursue careers in the health professions.

Principle Number 3: Identify and Respect Institutional Priorities, Traditions, and Boundaries

Churches and public health institutions, particularly research-intensive universities, have divergent perspectives of how to effectively address an issue of mutual concern—health disparities. These perspectives grow out of the priorities, traditions, and boundaries (professional, intellectual, and ethical) of the respective institutions. They are rooted in the central differences between theology and science, particularly epidemiology.

Epidemiology is *the systematic, objective study of the natural history of disease within populations and the factors that determine its spread.*[23] *The core functions of public health agencies... are assessment, policy development and assurance.*[24] These functions are carried out in order to promote health and prevent disease. Theology is the science of God, and of the relations between God, *[humans]*, and the universe.[25] In African American churches, theological constructs are applied in ways that are sensitive to the language, concepts, and issues of the folk [in the African American community] in a manner that leads to edification and liberation.[26] An emphasis is placed on ministry (the provision of service) that liberates destitute, oppressed, and marginalized people.

Interestingly, the desired outcomes of both institutions focus on eradicating *dis-ease*. However, the priorities and traditions that undergird the practices appear disparate. For example, churches tend to measure the success of projects by how they helped to provide immediate solutions to "felt needs." To this end, churches desire the provision of tangible and sustainable service. Unlike the scientific process, the measures employed to determine success are sometimes "discernable," but not necessarily quantifiable. On the other hand, public health institutions (particularly research-intensive universities) often measure success by the discovery of new knowledge, theories, models, policies, and/or procedures that may not necessarily help the participants of an existing study, but will be of benefit to others in the future. Therefore, efforts can be considered successful in the public health arena without the provision of direct service that provides "immediate" solutions to the felt needs of the prioritized populations.

These divergent perspectives must be reconciled if sustainable partnerships are to be developed. A failure to recognize or respect the institutional priorities, traditions, and professional boundaries of other partnership participants hinders reconciliation. For example, health disparities research, education, and service interventions that involve churches often focus on assessment and planning. Many pastors and church leaders have often expressed concern, if not frustration, over the fact that their involvement in health projects has resulted in their "being assessed to death." However, both assessment and service are necessary if innovative ways to reduce health disparities are to be developed and sustained.

Principle Number 4: Promote the Transfer and Local Control of Tangible Power

Power refers to the knowledge, privilege, force, influence, authority and strength to accomplish a desired action. Power comes in various forms including social, mental, physical, spiritual, moral, political, and economic. These forms can be categorized as tangible and intangible. Tangible power is easy to recognize and measure, while intangible power is often invisible and difficult to measure. However, both forms are essential to the elimination of health disparities. Generally those possessing tangible power (money, budgetary authority, decision-making —particularly with respect to personnel and project goals, facilities, fund-raising ability, organized networks, the ability to determine legitimate and valid forms of knowledge, etc.) exert the greatest influence on the policies and practices that govern partnerships. In order to overcome the barriers to sustainability and to foster participation of persons from hard-to-reach populations, some tangible power should be transferred to church and community leaders where feasible.

Summary and Conclusion

The four principles represent a framework for improving the process of establishing sustainable partnerships between research, public health, and faith-based institutions that seek to eliminate health disparities. To improve the efficacy of partnerships with churches identification of potential partner churches must be deliberate, trusting relationships must be built, divergent perspectives must be communicated and reconciled, and some tangible power should be transferred to church and community leaders where feasible.

We applaud the National Institutes of Health, through the National Center on Minority Health and Health Disparities', efforts to "promote coordination and collaboration among the agencies conducting or supporting minority health or other health disparities research."[15] We recommend that the North Carolina Office of Minority Health and Health Disparities be charged with and provided adequate resources to facilitate this type of coordination and collaboration among North Carolina Department of Health and Human Services agencies that are conducting or supporting minority health and health disparities research. A special emphasis should be placed on partnerships that seek to engage communities of faith.

Acknowledgements: Thanks to Mr. Carlton Boyd for assistance with literature review and comments on manuscript drafts.

The Data Collection/Data Distribution Center $(DC)^2$ Model of Engagement

The Data Collection/Data Distribution Center $(DC)^2$ is a network of 25 churches located in five prioritized regions of North Carolina. The regions and associated counties are: Northeast (Warren, Vance, Granville, and Franklin Counties); Eastern (Northampton, Bertie, Halifax, and Hertford Counties); Central (Wake, Durham, Orange, Chatham, and Johnston Counties); South Central (Duplin, Sampson, Cumberland, Bladen, and Robeson Counties) and Southwest (Mecklenburg, Gaston, Anson, and Scotland Counties). The network includes pastors and other church leaders, educators, researchers, and healthcare administrators representing various disciplines. Academic and governmental partners include Shaw University (a historically black liberal arts university), the University of North Carolina at Chapel Hill (a research-intensive majority institution), and the North Carolina Office of Minority Health and Health Disparities (established by the NC General Assembly to promote and advocate for the elimination of health disparities).

Spearheaded by the Shaw University Divinity School, $(DC)^2$ engages African American churches as an integral part of the Excellence in Partnerships for Community Outreach and Research on Health Disparities and Training (EXPORT) partnership. Funded by the National Center for Minority Health and Health Disparities, (grant #R24/P20/P60), the Carolina-Shaw Partnership seeks to eliminate health disparities between racial-ethnic minority and majority populations in a variety of ways. $(DC)^2$ is the hub of the partnerships community outreach activities. The primary goal is to investigate whether church-based information technology is an effective way for educators and researchers to communicate health issues to and receive feedback from communities about their health that could help make research, education, and service/ministry efforts more relevant. The network emphasizes a two-way flow of information where: (1) the health concerns and priorities of African American church and community members are communicated to educators, researchers, health policy makers, funding agencies, and healthcare providers to inform and influence their practices; and (2) practically useful health information is developed and disseminated to church and community members. The network also provides a mechanism for recruiting church and community members into health disparities research studies as partner-participants rather than as mere subjects. This ensures that a voice representing African American churches is included in academic research, education, information dissemination, and service projects that seek to identify solutions to African American health disparities in North Carolina.

COMMENTARY

Health Disparities, the Faith Agenda, and Health Promotion/Disease Prevention:
The General Baptist State Convention of North Carolina Model

M. Anita P. Holmes, JD, MPH

Faith and Health and the African American Experience

As increased emphasis has been given to holistic health and lifestyle issues in American health and healthcare policy, faith-based entities are more frequently viewed, or acknowledged, as one of the "players." The intersection of faith and health to address societal "ills" has a rich history. This health and healing agenda is strongly rooted in the African American experience. Historically, "the black church" has been on the forefront of this movement as advocate for education, health, and justice. C. Eric Lincoln, a noted theologian and historian of the black church in America stated: "To understand the power of the Black Church, it must first be understood that there is no disjunction between the Black Church and the Black community. The Church is the spiritual face of the Black subculture, and whether one is a 'church member' or not is beside the point."[1]

> *"To efficiently and effectively engage 'the black church' as a partner in health promotion, requires an understanding of organizational leadership, structure, demographics, and faith orientation."*

Prior to the more formally organized black church, religious ceremonies and worship services provided a mechanism for African Americans to come together in a setting that not only facilitated worship, but enabled "messengers" to carry out human rights and freedom agendas.[2] This agenda continued as the church emerged as a leading societal institution and is well documented during the Civil Rights Movement.

Self-help movements were encouraged since resources to address emerging health and social needs were always in short supply. Various auxiliaries were established to facilitate the church's health and social ministries. For instance, nurse aide groups consisted of women appointed to help the elderly and others coping with disabilities. At a time when many insurance companies considered African Americans a poor risk for life insurance, church affiliated mutual benefit and burial societies filled this void for service immediately after slavery and gave rise to the emergence of African American insurance companies. Services were not limited to church members, but were provided to every community member as acts of goodwill and good citizenship.

Today, the need for grassroots church and community activism continues. The gains the science community has made in health knowledge are not matched with successful modes of application. Faith-based initiatives, with several notable exceptions (e.g., the Seventh-Day Adventist and Mormon churches have focused on health promotion over many years), are at the pioneering level. To address today's concerns and the greater emphasis on lifestyle issues will require mobilizing diverse community partners and resources and shifting focus from sick care to "well care" or health promotion.

Morbidity and mortality data reveal the African American population is one of the leading disparate groups. While it is increasingly common for health service organizations to enlist the support of "the black church" in attempts to reach the African American community, most are limited in scope and frequently ineffective. These efforts generally do not meet the

M. Anita P. Holmes, JD, MPH, is the Executive Director of the General Baptist State Convention of North Carolina Office of Health and Human Services. She can be reached at anita.holmes@c4hh.org or 200 Meredith Drive, Suite 103, Durham, NC 27713. Telephone: 919-572-6374, ext. 1.

definition of partnership. For instance, churches may be requested to provide assistance by announcing the availability of important health and human services, displaying exhibits and/or distributing educational materials, participating in research, and/or conducting presentations on health-related topics. There may be beneficial outcomes from these activities; however, the impact usually falls far short of need and potential. Too often, services are provided in a manner that diminishes the possibility for participation in the planning and decision-making processes and do not enable sustainability, capacity building, and/or empowerment.

More appropriate use of faith-based resources will require changing the rules of engagement. To efficiently and effectively engage "the black church" as a partner in health promotion, requires an understanding of organizational leadership, structure, demographics, and faith orientation. There must also be a conscious awareness of past history and a willingness to accommodate. Partnerships should be based on cooperation, communication, commitment, clear understandings, trust, and caring.[3] This model enables the development of working relationships that best use the strengths and resources of both churches and health advocacy organizations.

Early Scientifically-Designed Faith-Based Health Promotion Initiatives in North Carolina

One of the first scientifically-designed and evaluated health promotion initiatives utilizing black churches was a North Carolina project targeting diabetes, hypertension, and maternal and child health. Through the use of lay health educators, the project was designed to raise the level of technical understanding and to encourage beneficial lifestyle changes. This initiative, based in the Department of Health Behavior and Health Education of the University of North Carolina School of Public Health (UNC-SPH), led to discussions with the leadership of the General Baptist State Convention of North Carolina, Inc. (GBSC) and the founding of the Convention's Health and Human Services (HHS) Program.[4]

Health professionals provided technical knowledge during church-based training. Learning took place at two levels: (1) the lay leaders and (2) the health professionals. Lay leaders gained increased understanding of diabetes and hypertension, including current information regarding disease prevention and control and available disease-related resources. Healthcare providers met community leaders and learned about community perceptions of healthcare issues and concerns.[4-6]

GBSC is a voluntary association of approximately 2,000 churches and 600,000 congregation members. Sixty-two geographically dispersed Associations facilitate the work of this statewide organization. It is estimated that, on any given Sunday, approximately half of the African American worshippers in North Carolina attend a GBSC church. In addressing health promotion issues within the African American community, GBSC and its churches build on an organizational structure that formally started in 1867. For instance, one of the lay health advocates presently involved with a Faith and Health Initiative, is from the family of deacons that are direct descendents of her church's founder. The founder was a slave who gained permission to organize a church in 1838.

The first GBSC health promotion project was funded by Z. Smith Reynolds Foundation and focused on enabling selected church members/leaders to serve as lay health educators and health advocates within their respective congregations and the broader community. The GBSC Office of Health and Human Services (HHS) was established to facilitate the development of this demonstration project. Staff from HHS, with technical support from UNC-SPH, designed training programs and recruited health professionals to teach volunteers about the causes, prevention, and management of selected health problems (e.g., hypertension, diabetes, and infant mortality).

The Convention created the Health and Human Services Advisory Committee to provide oversight and guide the overall development of this evolving ministry. A Technical Advisory Committee was also formed. The Technical Advisory Committee included among its members clergy, lay leaders, health professionals from local universities (North Carolina Central University, Duke University Medical Center, Shaw University Divinity School, UNC-SPH and UNC School of Medicine), North Carolina State Division of Public Health, and civic leaders. The Committee, which included persons of other faith and ethnic backgrounds, was very helpful in identifying resources and allies from within the broader community. Through this process, learning took place at several levels. The professionals learned about church style, protocol, and church members' values. Church leadership learned the value of critical review, evaluation, and the overall assets health professionals could bring to the table.

The GBSC Model

The GBSC-HHS ministry is grounded in an awareness that many African Americans do not fully benefit from pioneering gains in health that new knowledge, medical technology, and research have made possible. The ministry is designed to build on the strengths present within the Convention and its member congregations through a strategy that draws on the combined resources, talent, and leadership of clergy, laity, and health professionals. The key methodology employed is training church-based volunteers to inform others about the causes of selected health problems, and then helping them to change behavior and gain access to necessary resources for prevention and control.

The role of the pastor is pivotal in this process.[7] GBSC-HHS programs seek the counsel and advice of clergy in determining the overall course of implementation for local and regional activities. Pastors offer sanctioning and best ways to define, refine, and reshape faith-based health models. The life experience of the pastor and lay leaders is very influential in determining interest and support. Of the six pastors responding to a local diabetes initiative, five either had diabetes or had a spouse with the disease.

Most of the work of the Convention's health ministry is carried out by volunteers and is premised on theories, research, and best practices developed in other settings.[8] These volunteers are trusted and respected persons that others come to for advice. They are a part of the web of support systems in their communities. Most have resided in their community for over 20 years.

An essential factor to the long-term success of faith-based models is the education and empowerment of clergy and lay leaders.

"The church can serve a role in bringing about a much better lifestyle, a much better health condition for all concerned. But, it has to be a situation where the ministry and the key laity in churches are educated and empowered with all the information about particular diseases and all the things that the health community would like to impart so that they might play the ambassadorial role that you [the public health community] seek."[9]

Orientation and training congruent with project goals and objectives are provided for staff and volunteers. Sessions usually take place on Saturdays or evenings, when the majority of congregation members are available. In addition to technical health information, education sessions integrate faith and theological understandings to support the technical teachings. Hours of training vary by project with initial training generally averaging about 15 hours. Following the initial orientation and training, lay health advisors provide education and social support to the congregation and other community members. Continuing education and programmatic support are provided by GBSC-HHS staff and local and area healthcare professionals throughout the project.

Lay health advisors are asked to serve a minimum of two years. However, the majority continue for the duration of the project (generally three-to-five years). Most importantly, these volunteers remain health promotion advocates within their congregation once the formal funding period has ended.

An essential role for GBSC-HHS is to serve as a support to projects after outside funding has ceased. HHS maintains contact with prior externally-funded GBSC projects in an effort to continue services. Some groups have established support systems with local resources to enable continuation.

Faith-based models provide a unique opportunity for team building between congregation members and healthcare providers. Individuals have an opportunity to learn from and support each other as they share their experiences. Healthcare providers who assist with the training gain increased understanding of community concerns and priorities and an enhanced ability to involve community leaders. During training sessions, providers come on the "turf" of congregations in a setting controlled by members. This facilitates discussion that is more open and enables the building of trust.

Successes

Evaluation has been a continuous component of GBSC-HHS projects. Many noteworthy accomplishments have been made since the ministry's inception. These have included (1) increased knowledge and understanding of beneficial health information, (2) identification of knowledge transmission patterns, (3) diffusion across faith, race, and neighborhood boundaries, (4) lifestyle and policy changes at the congregation level, and (5) increased awareness and use of healthcare resources. The basic elements identified with the importance and success of the first GBSC project funded by the Z. Smith Reynolds Foundation,[10] continue to be reflected in Convention initiatives.

There are many anecdotal stories that relay changes in behavior, lifestyle, access to healthcare resources, and effective healthcare utilization. In 1997, on a Saturday morning in Creedmoor, North Carolina, approximately 200 persons representing 20 or more churches attended a diabetes awareness session. Attendees told personal stories about what led to their diabetes diagnosis and encouraged others to be checked. A substantial number of the persons telling their story indicated that it was another individual in their network that recognized they had the symptoms of diabetes (not a physician) and encouraged them to be tested. The following Monday, in response to a significantly increased diabetes screening load, a health department staff member questioned one of the diabetes awareness session participants/screenees about the unusually large number of people coming in for testing.[11]

It is well documented that education and income make a difference in health status. During two fatherhood projects in economically deprived areas, pastors, male congregants, and other supporters mentored unemployed fathers and fathers without a high-school degree. Six months following project initiation, 100% of 25 previously unemployed fathers were employed and 100% of 18 fathers previously without a high school diploma were enrolled in a GED program.

The Convention's Health Ministry continues to sponsor health promotion programs to: (1) reduce health risks, (2) promote health, (3) improve disease states through increased knowledge, improved practices, and improved access and utilization of healthcare services, (4) increase community involvement/participation in the healthcare delivery system, (5) build and expand the helping and social support role of the church, and (6) increase community capacity to initiate and sustain health promotion programs. These goals are carried out through programs reaching congregation members and the communities they serve.

In addition to focusing on specific diseases, lifestyle modifications, and service delivery concerns, special seminars/summits have been held with GBSC leadership to address current and cutting edge issues, such as stress in ministry and end-of-life decision-making. The Office has also served as an information and referral source for congregation and community members.

Since the inception of the program, GBSC has provided about 20% direct and lots of in-kind support. The Convention has continued to seek the support of a broader range of donors from both the public and private sectors. Following the Z. Smith Reynolds funding, the W. K. Kellogg Foundation funded two major projects. In more recent years, the Convention has received funding from the Kate B. Reynolds Charitable Trust, the North Carolina Hospital Foundation, the State of North Carolina (including the North Carolina Division of Public

Health, North Carolina Health and Wellness Trust Fund, and federal funds received through state-funded projects), direct church contributions, and private donations.

Sustainability

The HHS program has gone through several stages of development, from demonstration project to permanent program. In 2002, the Center for Health and Healing, a 501(c)(3) IRS-recognized nonprofit entity, took on the health and human services agenda of the Convention. This legally independent and structurally autonomous organization is similar in character to the relationship between the Catholic Church and the Catholic Relief Society and the relationship between the Unitarian Church and the Unitarian Universalist Service Committee. Advantages include access to a broader funding base and reduced liability for the Convention.

Capacity to sustain health promotion initiatives is essential to health status change. We believe the church in the African American community can play a major supportive role in the nation's effort to encourage and sustain healthy lifestyles. This must include all the prerequisites necessary to assure the institutionalization (e.g., ownership, commitment, and resources) of faith-based health promotion initiatives. Dr. John Hatch, a UNC-Chapel Hill professor of health behavior and health education at the time, has stated that he believes the project would not have survived had resources not been placed with the Convention.[12] Evidence of sustainability at the Association and local church level is evident in several GBSC models (e.g., Faith and Wellness Auxiliaries as part of formal Associations; inclusion of the health ministry in some Association and church budgets; inclusion of ministry functions on church, Association, and Convention agendas).

In addition to building the internal capacity of communities, faith-based health programs enable the provision of community healthcare promotion programs at a time when resources are limited. A partnership with a local agency was compromised when the agency experienced the loss of a staff person that would have been able to assist with GBSC lay training. The agency director suggested a local community member to serve as a resource person. The individual she recommended was a GBSC grassroots Facilitator trained by GBSC-HHS.

Conclusion

The continued survival and growth of faith-based health initiatives will likely be dependent on a number of factors, including interest, financial, and programmatic support available from the faith-based organization, government, and private philanthropy. These ministries may vary in scope (e.g., lifestyle modification, advocacy and policy development, education, social support, self-help, information and referral, environmental change [inclusive of the church environment], demonstration/research, and career development) as a reflection of interest and resources.

However, as faith-based and other organizations continue an agenda of pursuing reductions in health disparities, partnerships between faith-based groups and health-interest organizations (public and private) are likely to continue. **NCMJ**

COMMENTARY

Northeastern North Carolina Partnership for Public Health and Health Disparities in Northeastern North Carolina

Curtis W. Dickson, MEd, Janet G. Alexander, MSPH, Barbara H. Earley, RN, MSN, and Erin K. Riddle, MPH

The Northeastern North Carolina Partnership for Public Health (Partnership) is a collaboration of public health agencies formed in 1999 to improve the health of people in the northeastern region of the state. The Partnership's specific goal is maximizing the available resources and service potential of local health departments through cooperation with each other on public health issues. Economic and health disparities in this region provided the impetus leading ten health departments to form this collaboration and continue to guide the activities of the Partnership. The Partnership hopes that these disparities will now become the motivation for the adoption of healthy behaviors by community members and for policy and environmental changes by decision makers that will improve the health status of northeastern North Carolina.

> *"These disparity gap coordinators help to link the Partnership to community coalitions in each of the counties, such as Healthy Carolinians partnerships."*

The Northeastern North Carolina Partnership was formed when health directors in the region recognized that each of their agencies faced similar challenges in their work to protect the health of their constituents. Specifically, how could these health departments improve the health of a region that is entirely non-metropolitan, has a high rate of poverty, and a high rate of medically uninsured? How could a health department maximize its impact, given its limited resources? In 2000, 13 of the 19 counties included in the partnership were designated as *Tier One* counties by the North Carolina Department of Commerce, meaning that they are among the most economically depressed counties in the state.[1] Nineteen percent of the population in northeastern North Carolina is living in poverty,[2] between 16 and 24% do not have health insurance,[3] and 29% of adults do not have at least a high school education.[4] It has long been recognized that there is a positive correlation between economic health and physical health. These demographics became the starting point for the health departments in northeastern North Carolina to discuss innovative ways to collaborate and improve the health status of the region.

These discussions evolved into the creation of a well-structured partnership. The Partnership is currently guided by a governing board that consists of now 11 local health directors (Pamlico County recently joined) and of representatives from both the North Carolina Division of Public Health and the North Carolina Institute for Public Health at the University for North Carolina at Chapel Hill (NCIPH). The Partnership region covers 19 counties: Bertie, Beaufort, Camden, Chowan, Currituck, Dare, Edgecombe, Gates, Halifax, Hertford, Hyde, Martin, Northampton, Pamlico, Pasquotank, Perquimans, Tyrell, Warren, and Washington. The partnership has demonstrated how health departments can share some resources, such as staff, and therefore increase the capacity of all the health departments. In 2002, the partnership received a federal grant that allowed them to hire a regional epidemiologist, a regional health educator

(regional health disparity coordinator), and eventually a paid, half-time project director. Annual membership dues for each participating agency help augment the partnership's activities. In addition, each of the health departments has allocated an existing health department staff member (a health educator) to serve as their department's disparity gap coordinator. These disparity gap coordinators help to link the Partnership to community coalitions in each of the counties, such as Healthy Carolinians partnerships. The disparity gap coordinators are also the target audience for regional training focused on cultural competencies and public health practice.

Health disparities data have continued to guide the activities of the Partnership. In 2003 the Partnership published, "Health in Northeastern North Carolina: Assessing Health Disparities of an 18-County Region," that was researched and developed by the Partnership's regional epidemiologist, the regional health disparities coordinator, and University of North Carolina School of Public Health graduate students (only 18 counties were in the Partnership at the time). The Partnership governing board used this report to help them identify priority public health problems that the partnership is now moving to address through the development of regional public health programs. This regional health report highlighted health conditions where geographic or race and gender disparities exist. Health disparities were evaluated by comparing overall disease rates for northeastern North Carolina to the state rate (geographic disparity), and by comparing rates for race and gender groups within the region to their respective state rates (race/gender disparity). Health conditions examined included: accidents, perinatal mortality, heart disease, stroke, HIV disease, diabetes mellitus, lung cancer, breast cancer, colorectal cancer, prostate cancer, chlamydia, gonorrhea, teen pregnancy, low-birth weight infants, asthma, child obesity, untreated tooth decay among kindergartners, and untreated tooth decay among fifth-graders. This regional assessment for 18 key health indicators found geographic disparities for northeastern North Carolina in relation to state rates in general in 17 of the indicators, and race/gender disparities in 13 of the indicators (See Table 1).

"Diabetes is one of the leading causes of death and disability in northeastern North Carolina. Each year there are 640 deaths due to diabetes as a primary or a contributing cause of death in these counties."

After studying these and other data for the northeast region (including county health assessments, focus groups' results, and key informant interviews), the governing board of the Partnership determined three strategic priorities for further studies and activities: (1) diabetes, (2) heart disease and stroke, and (3) AIDS and HIV.

The Partnership has just completed an intensive analysis of the first chosen priority—diabetes—and a similar process will be used to investigate the two other priority health issues. The purpose of the diabetes investigation was to assess the strengths and gaps of current public health efforts to reduce the burden of diabetes in northeastern North Carolina. This synthesis has been helpful to the Partnership as it plans regional diabetes prevention efforts.

Diabetes in Northeastern North Carolina

In its analysis of diabetes, the Partnership first reviewed, in-depth, the diabetes data that are currently available for the region. Since 2003, the Partnership has been participating in the Behavioral Risk Factor Surveillance System conducted by the North Carolina State Center for Health Statistics. This has proven to be an asset to the Partnership in its ability to monitor the burden of diabetes in the region. Because the Partnership paid for the northeastern North Carolina counties to be over-sampled in the survey, region-specific prevalence data on diabetes and its related lifestyle risk factors are available. Results of the 2003 survey showed that 12.5% of adults (39,205 people) in northeastern North Carolina reported that they have been told they have diabetes. Because about one-third of diabetes cases are undiagnosed, the true number of adults with diabetes in northeastern North Carolina is most likely higher. Diabetes is more prevalent in northeastern North Carolina than in any other region of the state (12.5% in northeastern North Carolina versus 7.9% in western North Carolina, and 7.5% in the piedmont region), and is 67% higher than the overall national rate (7.5% of adults in the United States).[5]

Region-specific diabetes mortality and hospitalization data are also available. Diabetes is one of the leading causes of death and disability in northeastern North Carolina. Each year there are 640 deaths due to diabetes as a primary or a contributing cause of death in these counties. The overall age-adjusted mortality rate for northeastern North Carolina is 1.4 times the state rate (132.2 compared to 95.1 deaths per 100,000 people). In northeastern North Carolina each year there are more than 11,000 hospitalizations, and more than 250 amputations related to diabetes, with costs totaling $126,295,426 and $5,530,115, respectively. African Americans and other minority groups are disproportionately affected by diabetes. The age-adjusted mortality rate for African Americans, Native Americans, and other non-white races combined was 1.9 times higher than for whites (189.7 compared to 98.9 deaths per 100,000).[6]

After examining the existing health data, the Partnership assessed the current diabetes programs in each of the region's

Table 1.
Health Disparities Summary Table, Northeastern Region, North Carolina, 2004.

Condition	Number Affected	Comparison of Rates

KEY to COMPARISON OF RATES

1.1 - 1.3	Slightly Elevated Rate compared to NC
1.4 - 1.7	Modestly Elevated Rate compared to NC
1.8 to 3.0	Moderately Elevated Rate compared to NC
3.1 to 8.0	Highly Elevated Rate compared to NC

public health departments. Six of the ten health departments in the region have primary prevention programs to increase awareness about diabetes (health communication). Many of these take place in various community settings, such as health fairs, senior centers, schools, civic groups, or at the health department. However, none of the health departments described a multimedia approach using radio, newspapers, and/or television, or a social marketing approach to determine elements or messages that could bring about behavior change within our region. As a result, the Partnership is preparing to launch a major social marketing campaign aimed at diabetes prevention utilizing funds recently appropriated by the state legislature to the NCIPH to establish "public health incubators" across the state. Social marketing campaigns aimed at heart disease, stroke, and AIDS/HIV prevention will be developed in subsequent years.

The Partnership strengths and gaps assessment of diabetes programs also determined that five of the ten health departments have primary prevention programs that are intended to increase physical activity and improve nutrition in the community (community intervention). All health departments reported they provide screening or testing for diabetes. Eight of the ten health departments have tertiary prevention programs or diabetes self-management and education programs to prevent the incidence of diabetic complications.

Correcting the Problem Will Take a Financial Commitment from the State

It is clear that while these 11 local health departments are mounting community responses to tackle the overall diabetes problem in their respective communities and the disparity issue among people of color, the resources available to them are not adequate to deal with a health problem of this magnitude. Public health departments in the northeastern North Carolina region have come together to find creative solutions to tackle these tough issues across jurisdictional lines with limited resources. The major social marketing campaign aimed at diabetes has the potential for great impact with a limited amount of new resources. Much more must be done. The health disparities data can now serve as an advocacy tool. While knowledge of a problem alone may not be sufficient for change to happen, information on health inequalities is a good place to begin the discussion with community members and decision makers about what can be done to improve the health of northeastern North Carolina. The Partnership is attempting to convince state legislators and state public health leaders to make an ongoing commitment of funding resources to this impoverished area of the state to tackle not only the diabetes, heart disease, stroke, and AIDS/HIV health issues of pressing concern, but also strengthening the local public health infrastructure and its ability to assess, address, and assure the public's health.

The northeastern North Carolina region has been innovative in its collaborative approach to health concerns and health disparities in this hard-impacted area of the state and has a significant capability to impact health disparities in northeastern North Carolina. **NCMJ**

Numbers of Minority Health Professionals:
Where Do We Stand?

Thomas C. Ricketts, III, MPH, PhD, and Katie Gaul, MA

Should race and ethnicity matter in the supply of health professionals? Given that we know there are demonstrated differences in patterns of care and outcomes for racial and ethnic minorities in the United States,[1] the answer is yes. But what should be our workforce goals in eliminating these differences? The simple answer to this question is that there should be equal representation among health professionals according to the race and ethnicity of the population to be served. By that standard, we have failed by a large margin.[2,3] All health professions fall well short of "population parity" measured against the proportion of under-represented minorities (URMs) in the overall United States population. According to 2000 United States Census data, African Americans, Latinos, and American Indians are 26% of the United States population. URMs constitute 20% and 16%, respectively, of the students in public health schools and baccalaureate nursing programs, with URMs constituting less than 15% of students in all other health professions. The late 1990s through 2002 saw a reversal in promising trends in increasing minority enrollment in United States medical schools, but that seems to have abated to some degree. In its review of applications for the fall of 2004, the Association of American Medical Colleges noted a second consecutive year of increase in minority applications to medical schools. The number of black and Hispanic applicants was up 2.3% and 2.5%, respectively, and actual enrollment increased by 2.5% for blacks and 8% for Hispanics, reversing decreases in first-year enrollment in 2003. This change may reflect admissions policy changes or the re-application of existing policies in the wake of the June 2003 United States Supreme Court decision on affirmative action.[4]

Underrepresented minorities comprise 25% of the nation's population, but only 10% of all health professionals. Only 3% of medical school faculty, 17% of all city and county health officials, and 2% of senior leaders in healthcare management are minorities.[5] Table 1 provides an overview of the national racial and ethnic distribution of selected health professions compared to the United States population. Among blacks and Hispanics, the two largest minority groups, only in nursing is there close to parity with the population distribution, with

Figure 1.
Race and Ethnicity of North Carolina Population Compared to North Carolina Health Professionals[7]

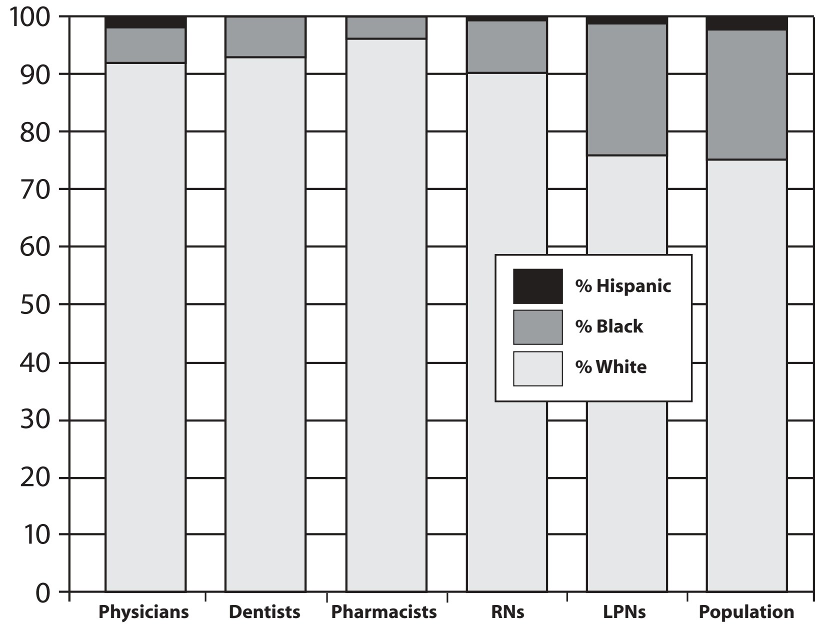

Figure 2.
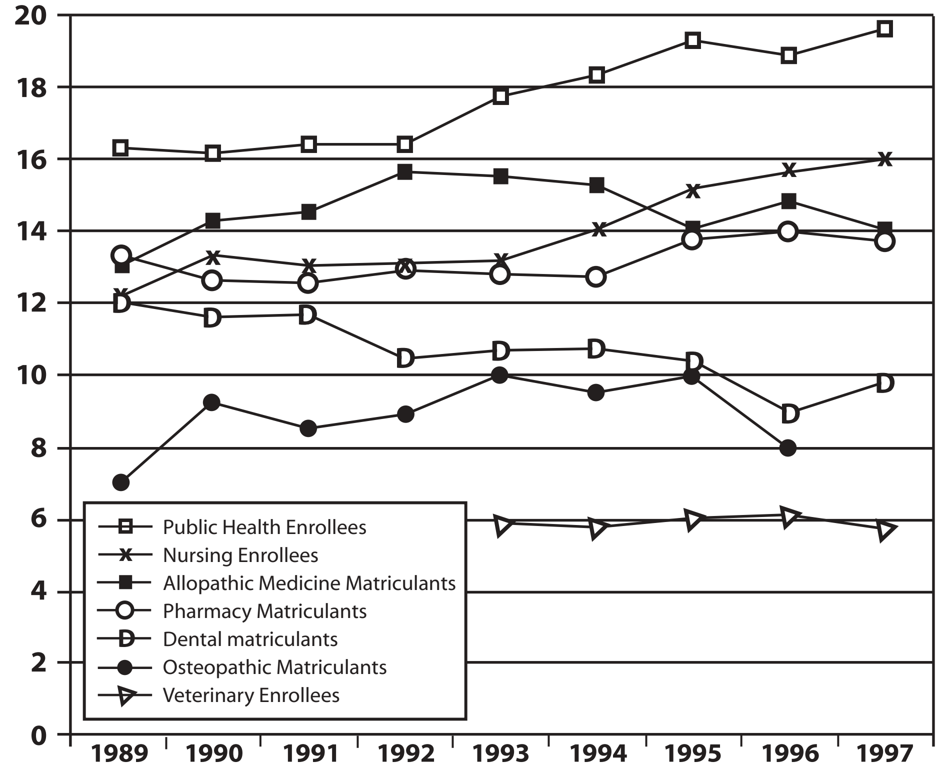
Underrepresented Minorities as a Percentage of Enrollees and Matriculants in Health Professionals Schools, United States, 1989-1997[8]



Recently reported data on enrollments (see Table 2) indicate that the percentages in Figure 2 have not changed substantially over the most recent five years.

licensed practical nurses (LPNs) exceeding their overall population representation among blacks. Asians/Pacific Islanders are often "over-represented" among health professions, reflecting the more complex nature of their immigration patterns.[6]

In North Carolina, minority representation in the health professions matches national rates despite higher proportions of minorities in the population. For example, in 2002, 21% of the state's population was black, but only 5.5% of active physicians in the state were black. The 2002 estimate for the Hispanic population in North Carolina is 4.7%, and Hispanics make up 1.5% of the North Carolina physician supply. In contrast, 22.8% of the state's licensed practical nurses (LPNs) are black, but only 9% of registered nurses (RNs) and 6.9% of dentists are black. The data displayed in Figure 1 graphically compare these proportions to the state's population for selected professions. These proportions are likely to remain at their current levels due to a leveling off of minority applications and enrollments in health professional education programs.[7] Figure 2 tracks numbers of enrolled and matriculated students in selected health disciplines in North Carolina. Only public health has shown a sustained pattern of increase in the numbers of minority students and trainees.[8]

Minority Representation Enhancement Programs in the United States and North Carolina

There have been efforts on the part of the state's health professional associations and health professional schools to reduce these disparities in minority representation. Since the 1970s, the federal government, through its Title VII and VIII programs that support medical, dental, and nursing training, has given priority funding to programs that increase minority representation. These programs support a full range of interventions intended to modify the "pipeline" into the health professions. The pipeline (See Figure 3) is the metaphor used for the process of career preparation, education, and training that starts at birth and continues through

Table 2.
Medical School Graduates by Race/Ethnicity, North Carolina and United States, 2003[9]

	NC	US
White	249 (66.4%)	9880 (63.7%)

early exposure to health professionals and science courses, through counseling, scholarship, placement, recruitment, and retention in careers and practice in underserved areas. These programs have, for the last several years, been the targets of both Congressional and Administration efforts to reduce federal outlays. Each year, however, the Congress has voted to restore funds roughly at the levels established in the late 1990s. For North Carolina, these programs are important because they support family medicine residencies, the statewide Area Health Education Centers Program (AHEC), basic and advanced nursing education, and the Health Careers Opportunity Program (HCOP) that focuses on minority recruitment into health careers.

A range of "best practice" programs have been highlighted in a report recently released by the Sullivan Commission (www.sullivancommission.org/). That report describes the multiple ways in which educational institutions can increase minority presence in health professions and provides a comprehensive guide to funding sources and currently active programs and initiatives.[10]

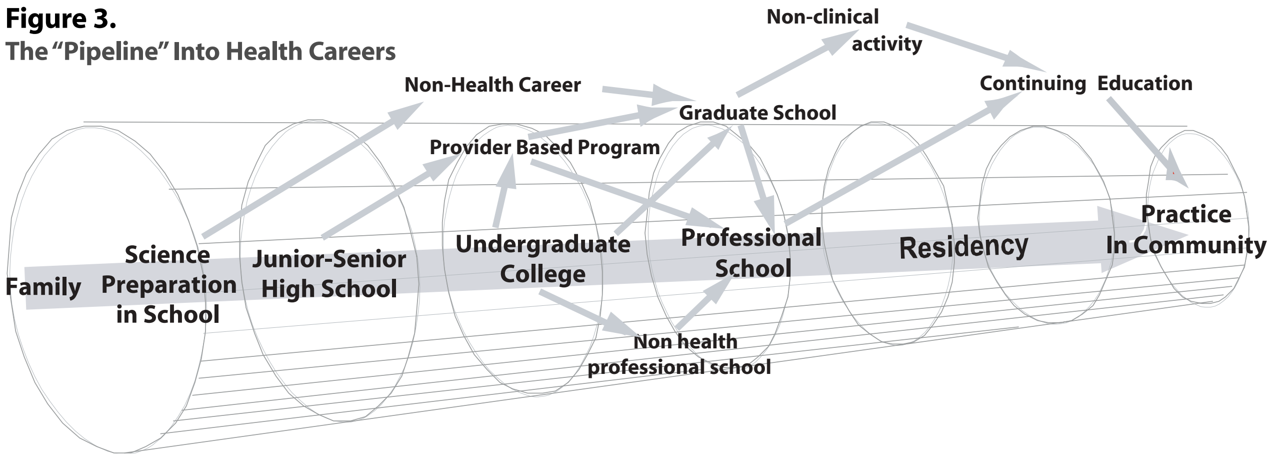

Figure 3.
The "Pipeline" Into Health Careers

One section of that report describes professional school involvement in "pipeline" programs. These efforts attempt to modify individuals' perceptions of their career options early in their schooling and help them prepare to move toward health careers sometime in the future. Nationally, 92.9% of medical schools and 100% of dental and nursing schools report doing some form of "pipeline" programming.[10] In medical schools, more of that effort is targeted to grades nine through 12, 78.6% of medical schools, 40% of dental schools, and 100% of nursing schools report programs for those grades with only 42.9% of medical schools, 40% of dental schools, and 80% of nursing schools reporting working with grades six through eight.

The University of North Carolina sponsors a multi-campus collaborative effort that supports pipeline programs under its HCOP funding. The North Carolina Health Careers Access Program (NC-HCAP) brings together the University of North Carolina at Chapel Hill (UNC-CH) School of Dentistry; the North Carolina Health Careers Access Program; the Student National Medical Association chapters in North Carolina; East Carolina University; Fayetteville State University; North Carolina Central University; North Carolina Agricultural and Technical State University; University of North Carolina at Pembroke; the school systems of Chapel Hill-Carrboro, Durham, and Orange Counties; and the state's nine regional Area Health Education Centers. In 2002-2003, through programs supported or affiliated with the North Carolina AHEC Program, 39,000 individuals participated in Health Careers and Workforce Diversity activities. These projects included shadowing and mentoring activities, summer work experiences and placements, health careers fairs, and cultural sensitivity training.

Individual schools also sponsor focused minority health career development projects. East Carolina University sponsors the Ventures into Health Careers Institute that provides two-week experiences for minority students from eastern North Carolina to observe practicing and in-training physicians, nurses, therapists, and technicians. The Pathways to Health Careers and Health Careers Awareness Programs also support local schools in developing curricula and learning modules to improve the chances of minority and rural youth to enter health careers. Wake Forest University Medical School and the Northwest AHEC sponsor several similar programs under a "Health Careers Pipeline" program. An elementary school program called "Drew Academy" works with young minority males students to develop lifestyle and learning skills; the program is held at the Rowan Regional Medical Center and Winston-Salem State University. Programs for middle school and high school students focus on the development of science and mathematics skills, SAT preparation, and financial aid.

The Wake AHEC program supports a Health Careers Academy that provides educational experiences for students from elementary through and beyond high school. The interventions are mostly workshops or involve specific health professions-related experiences including skills-building, CPR and first-aid certification, job shadowing, and recruitment fairs. The Wake AHEC also sponsors a Summer Youth Enrichment Internship and the Carolina Visions Health Careers Summer Camp, both of which offer structured exposure to health careers for young people.

North Carolina is also home to a statewide Spanish Language & Cultural Competency and Training Program funded by The Duke Endowment. This project brings together the North Carolina Department of Health and Human Services (DHHS) Office of Minority Health, the UNC-CH School of Public Health, the UNC-CH Health Sciences Library, and the North Carolina AHEC system into a coordinated approach to teach Spanish language to practitioners and increase cultural awareness and sensitivity among professionals. This program includes an online translation facility supported by the Duke University AHEC (www.hhcc.arealahec.dst.nc.us/).

At UNC-CH, the Health Professions Partnership Initiative and the Research Apprenticeship Program are designed for pre-college students to support and direct them into health careers. Established in 1996 with start-up funding from the Robert Wood Johnson Foundation and the UNC-CH Schools of Dentistry, Medicine, and Nursing, the Health Professions Partnership Initiative works with local school systems to offer information, experiences, and skills development for middle and high school minority students to better prepare them for health professions education programs. Students with the potential to pursue health careers come to UNC-CH for summer programs.

Federal efforts are supplemented by national, state, and local programs sponsored by professional associations and societies, foundations, and state government. In North Carolina The Duke Endowment and The Kate B. Reynolds Health Care Trust have been actively supporting diversity and recruitment projects. A national collaboration among the Association of American Medical Colleges, the W.K. Kellogg Foundation, and the Robert Wood Johnson Foundation has set a goal of increasing minority enrollments and minorities in practice in medicine and other health professions through its Health Professions Partnerships Initiative (HPPI). The Association of American Medical Colleges also sponsors the Herbert W. Nickens Scholarships and Faculty Awards, along with other recruitment and retention programs sharing the support with foundations and individuals schools.

Summary

This overview has pointed to a continuing racial and ethnic imbalance in the health professions that applies to North Carolina as well as the nation. Great strides have been made early in the development of programs to enhance racial and ethnic representation, but they have generally reached a plateau in terms of growth and progress. Resistance to affirmative action programs and subsequent uncertainty over their legal standing can be cited as one factor thwarting progress, but that issue has been resolved and schools, professions, and the North Carolina General Assembly can move forward with a clear understanding of how to proceed.

A full generation has matured with the benefit of positive emphasis on increasing the proportion of minorities in the health professions. The coming generations must build and expand on the programs and initiatives that brought the nation and the state to where we are now. But these goals must be re-stated, and intensified efforts are required if any reasonable parity in representation of minorities among the health professions is to be achieved. **NCMJ**

COMMENTARY

Minority Recruitment and Participation in Health Research

Giselle M. Corbie-Smith, MD, MSc

Since 1993, all investigators funded by the National Institutes of Health (NIH) to conduct clinical research have been expected to demonstrate appropriate inclusion of racial and ethnic minorities and women in their research or clearly demonstrate why they should be excluded in order to pursue a specific research objective. This mandate, the NIH Revitalization Act, was a response to the realization that women and minorities were underrepresented in clinical research. These guidelines have mandated the inclusion of minorities in clinical research in an effort to better understand disparities in health and to improve the generalizability of research findings. While few would argue with the goals of this mandate, investigators have been challenged in its implementation. This article gives an overview of some of the challenges raised by minority participation in research and describes some of the consequences of a lack of minority involvement in research.

Challenges Raised by Mandated Inclusion of Minorities

Most of the scientific literature on minority participation in research has focused on the barriers to minority participation. The factors that impede the participation of minorities in research can be specific to the participant, the investigator, or the study. For example, since African Americans are over-represented in lower socio-economic strata; race, as a commonly measured variable, may be a proxy for other socio-demographic factors. Socio-economic status can influence the decision to participate in a number of other ways. For example, access to transportation[1] and the location of study sites significantly impact the recruitment and retention of patients in clinical trials.[2] Educational level,[3] age,[4] and marital status all have been shown to be associated with various aspects of decision making.[5,6] Among the economically disadvantaged, competing subsistence needs may outweigh any anticipated benefits of participation. Psychosocial factors such as perceived stress, community involvement, and social isolation may be powerful factors in a patient's decision to participate in a clinical trial and ability to maintain adherence to a research protocol, particularly in an older population.

In addition, trust or lack of trust is an important factor when deciding to participate in research. Fear, mistrust, and lack of knowledge were cited by minority respondents as the main reasons they didn't participate in oncology research.[7] The history of clinical experimentation on blacks during slavery laid the foundation of distrust among blacks toward medical research.[8] Yet, it is the Tuskegee Syphilis Study (1932-1972) that has become the contemporary metaphor of research that violates human rights of vulnerable groups. Several medical historians have asserted that this study, where 400 poor black men with syphilis were left untreated for 40 years, validated suspicions about ethical treatment in the context of research.[9-11] Awareness of the Tuskegee Syphilis Study among minority and other underserved groups contributes to pervasive distrust of physicians and the medical research establishment.[8,12-14] The dissemination of oral histories about the Tuskegee Study and fictional dramas may reinforce distortions in the historical record and provide moral justification for refusal to participate in any clinical research.

> *"Fear, mistrust, and lack of knowledge were cited by minority respondents as the main reasons they didn't participate in oncology research."*

The influence of culture on health-seeking behavior is

Giselle M. Corbie-Smith, MD, MSc, is Associate Professor of Social Medicine and Medicine at the University of North Carolina at Chapel-Hill. She can be reached at gcorbie@med.unc.edu or CB# 7240, Chapel Hill, NC 27599-7240. Telephone: 919-962-1136.

another important influence on minority participation as research subjects. Health-seeking behavior influences where, when, and how one accesses the healthcare system. Bailey describes six culturally-based steps in health seeking behavior among African Americans.[15] He noted that patients are active participants in their health, from the perception of symptoms to eventually seeking formal medical care (whether or not their actions are considered appropriate to the biomedical model of disease). Other authors have demonstrated that the combination of socio-economic factors and culture can account for racial differences in the stage of presentation of disease.[16] Cultural differences in how the healthcare system is accessed and utilized can impact the availability and opportunities to participate in medical research.[17] In addition, expectations of medical roles and responsibilities, explanatory models of disease, and verbal and non-verbal communication patterns are all influenced by the culture framework of patients.[17,18] Investigators' cultural competency, not just their ability to speak another language or dialect, but their desire to respectfully address the patient's needs within the framework of that person's health beliefs, religious background, cultural philosophy, and social customs will ease the transition in recruiting individuals that may hold beliefs and attitudes toward health that are discordant with those of clinical researchers.

However, empirical data are lacking on how well investigators understand and are able to negotiate these cultural differences. There have been no studies of investigators' knowledge of the barriers to minority participation in clinical trials or how these recommendations have been translated into successful recruitment strategies. At the introduction of the NIH mandate, researchers were quite vocal about their concerns. Editorialists likened the mandate to include minorities and women in clinical research trials to affirmative action[19] and quota systems.[20] Investigators raised concerns about the potential added costs to recruiting more diverse study samples.[19-21] Investigators also described the ethical consideration of mandating the inclusion of women and minorities. Some authors described the potential to give minorities the "hard-sell" and therefore not fully respecting an autonomous decision not to participate in a trial.[22]

In the research community there is a general belief that minority groups may be more difficult to recruit into clinical trials,[18,23] less likely to adhere to study protocols, and more difficult to retain in clinical studies.[23] While there is some evidence that race alone is not a predictor of recruitment success,[24] the belief that minority groups are hard to reach may affect some investigator's willingness to recruit minority participants. In fact, when investigators take more innovative approaches to recruitment, these efforts have been more successful.[25-30] Community-based strategies can elicit and address differing cultural beliefs while informing the design of recruitment strategies that lead to successful minority enrollment and improved investigator-participant relationships.

Consequences of Lack of Minority Involvement in Research

While investigators have been conducting clinical research for a decade under this mandate, minorities are still under-represented in areas of known disparities in health research relative to the prevalence of disease in minority communities.[31-33] Underrepresentation of minorities as subjects in research and lack of minority involvement in research partnerships may adversely affect minority communities in a number of ways.

Clinical research is the basis of advances in all areas of medical knowledge and clinical care. The lack of minority participation in research limits the generalizability of study results to those groups that are included in research. More diverse research populations allow the generation and testing of research hypotheses that may enhance our understanding of disparities in health by race and ethnicity and the development of interventions to address these disparities.

Minority participation in research also increases the likelihood that research results are more relevant to the needs of minority communities. If minority communities are not involved in the process of research, as participants, staff, or as community advisors, interventions are less likely to be culturally-relevant and therefore less likely to be sustainable once the study has ended. Research that actively engages target communities leads to interventions that are more likely to be successful and sustained[34,35] and, more likely to lead to program institutionalization.[35,36] In addition, involvement of the target communities also enhances the relevance and usefulness of the data, as well as data quality and validity.[35,37,38] Finally, community involvement in research can also strengthen the research and program development capacity of the individuals and organizations in undeserved communities. The lack of active engagement of minority communities in research severely limits the potential of improving the health and well-being of minority communities, either directly through examining and addressing disparities in health, or indirectly through increasing the power and influence of minorities over the research process affecting the health and healthcare they receive.[35,37,38] **NCMJ**

The Health of American Indians in North Carolina

North Carolina has the eighth largest American Indian population among all states. The 2000 Census counted 99,600 residents of North Carolina who reported their race as American Indian alone, and also more than 20,000 who reported American Indian in combination with another race. More than one-half of the American Indians in North Carolina are of the Lumbee Tribe. American Indians in North Carolina experience a relatively high rate of poverty, which is associated with more health problems. The percentage of American Indian families in North Carolina living below the federal poverty level in 1999 was 21.0, compared to 22.9 for African Americans and 8.4 for whites.

American Indians in North Carolina experience worse outcomes for many health measures, compared to other racial groups. Two recent publications are available that profile the health of American Indians in our state: *Racial and Ethnic*

	American Indian	African American	White
AIDS deaths per 100,000 population	4.0	21.5	1.5
Homicide deaths per 100,000 population	18.1	17.0	4.6
Motor vehicle deaths per 100,000 population	41.6	20.7	19.2
Diabetes deaths per 100,000 population	52.7	55.6	21.5
Kidney disease deaths per 100,000 population	20.7	34.9	13.4
% of mothers with a live birth who smoked during pregnancy	25.3	11.0	15.2
% of mothers with a live birth reporting an unintended pregnancy	65.2	66.8	36.7
% of live births with no prenatal care or where prenatal care started late	23.5	24.1	12.1
Infant deaths per 1,000 live births	11.2	15.4	6.3
Deaths ages 1-17 per 100,000 population	53.8	37.5	30.0
Pregnancies per 1,000 teens ages 15-17	63.2	72.4	38.0
% of adults with arthritis	36.3	29.5	29.1
% of adults with diabetes	14.1	12.6	6.8
% of adults ever having asthma	16.4	12.9	11.1
% of adults with high blood pressure	40.2	38.6	26.6
% of adults who are obese	33.2	37.2	20.9
% of adults reporting no leisure time physical activity	32.4	33.8	23.7
% of adults with no health insurance	19.2	19.0	13.4
% of adults reporting a disability	38.5	29.7	24.9
% of adults reporting fair or poor health	25.9	25.1	17.5

Disparities in North Carolina: Report Card 2003 (available at http://www.schs.state.nc.us/SCHS/pdf/FinalReportCard.pdf) and *Racial and Ethnic Differences in Health in North Carolina: 2004 Update* (available at http://www.schs.state.nc.us/SCHS/pdf/RaceEthnicRpt.pdf). We briefly summarize here some of the results from these publications, emphasizing areas where health disparities are the largest. See the publications for a more complete definition of the indicators, including time periods for the data. We also use selected 2002-2003 age-adjusted percentages from the North Carolina Behavioral Risk Factor Surveillance System (BRFSS), a statewide random telephone survey of adults in North Carolina.

American Indians in North Carolina experience outcomes on many chronic disease measures (such as rates for heart disease, stroke, cancer, and chronic liver disease) similar to or only slightly higher than those for whites, and therefore these measures do not appear in the table above since the apparent disparities are not large. But these measures often rely on death certificate data, where there is probably substantial under-reporting of American Indian as the race of the decedent.

The North Carolina American Indian Health Task Force was created in 2004 by the North Carolina Commission of Indian Affairs and the Secretary of the North Carolina Department of Health and Human Services. The purpose of this Task Force is to identify and study Indian health issues in North Carolina and to evaluate and strengthen programs and services for American Indians in the state. The Task Force will be issuing a final report with recommendations for action in the Spring of 2005.

Quality Care and Performance Improvement

To The Editor:

I am writing in reference to the fine special article "Remembering Cecil" that appeared in the September/October 2004 issue of the *North Carolina Medical Journal.* I was one of the young physicians participating in the Rural Practice Project to whom the author, Donald Madison, MD, referred in the last paragraph of his remembrance to Dr. Cecil Sheps.

After I graduated from Duke Medical School and completed my family medicine residency, I joined a public health service practice in Tooele, Utah with little appreciation of what I would confront. I had the good fortune to work with a terrific team of dedicated people in our small practice, and together we learned many important lessons about how to provide healthcare to the people we served in our rural community.

We applied for a grant from the Robert Wood Johnson Foundation (RWJF) in 1975 and were fortunate to be selected as one of the 13 grant recipients. Donald Madison was the director of this national program called the Rural Practice Project. It was established to help improve the ability of rural practices to survive in the face of some of the significant challenges that they faced at the time. Our participation as a member of the Rural Practice Project resulted in our having visitors on occasion who might not otherwise have found their way to Tooele. Cecil Sheps was one of those visitors and, in fact, one of the most memorable and notable.

I fondly recall Cecil's visit and believe it was 1978. He was stopping at several rural practices as part of a study he was conducting. He sat in my office as I was speaking with a consultant in Salt Lake City about a dying hospitalized patient I wanted the consultant to evaluate to make sure I was not overlooking a potentially reversible cause for her illness. She was an older woman and did not want to leave Tooele, but she was willing to do so at my request provided she did not have to remain in the Salt Lake City hospital for more than two days. I told the consultant over the phone what I was seeking from him both from my and from the patient's perspective. Cecil reflected after hearing the conversation that it would certainly help introduce more sanity into our healthcare system if those in primary care could "call the shots" on a more consistent basis as advocates for their patients and their patients' families.

It was inspiring for me to see Cecil's passion and observation skills. Although his time in our community was short, and although our paths crossed subsequently for only brief periods, I still remember the validation I felt as a result of his positive comments. Needless to say, we certainly could benefit from more leaders like Cecil Sheps in our world today.

To The Editor:

I was amused at the frequency with which the authors in the current issue of the *North Carolina Medical Journal* bemoan unnecessary and duplicative paperwork as a detriment to the delivery of quality medical care and the improvement thereof. As a perpetrator and victim of quality improvement efforts in my own practice and hospital since such became fashionable in the late 1980s, I can report from experience that most of the unnecessary and duplicative documentation and reporting is a result of poorly conceived quality improvement efforts imposed on those at the bedside by governmental agencies and their surrogates like JCAHO. Such requirements are usually not supported by clinical science, but "seem like things we ought to be doing" by bureaucrats or the residents of think tanks and their accomplices at the local hospital. Thus, as those of us at the bedside continue to cope with the increasing demands of an older, fatter, sicker population, ever more belligerent attorneys, stingier paymasters, and fewer physicians in practice, we can look forward to more forms, checklists, signatures, meetings, and ever more imaginative intrusions all in the name of quality. Sadly, I have seen nothing in the last 22 years of practice to assure me that efforts at quality improvement in medicine, as laudable as they may be, can produce anything more than that.

I hope I am wrong.

Randy A. Peters, MD
Winston-Salem, NC

The North Carolina Institute of Medicine

Since January 2002, Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

Physician Assistants… *Assisting* is Just a Drop in the Ocean.

Physician assistants are licensed health care professionals who practice medicine with physician supervision. As integral members of the physician-directed team, PAs increase access, enhance quality, and are cost-effective.

Jeff Anderson, M.D., and W. Graham Evans, Jr, PA-C, review a patient's x-ray at BeachCare Urgent Care Centers of Morehead City and Havelock.

In looking for a PA to staff the office in Havelock, NC, I was looking for a mature and experienced PA. Graham had worked on Ocracoke Island as the only year-round health care provider for eight years before joining me at BeachCare.

Graham's contribution to the practice was so strong that I offered him equal partnership in the practice. Without Graham's commitment to the practice and our patients, the practice would not be as successful.

Jeff Anderson, M.D.
BeachCare Urgent Care Centers of
Morehead City and Havelock

Physician Assistants can help you in your practice too! For more information on what a PA can do for you, your patients, and your practice, or to learn how to hire a PA, please contact the North Carolina Academy of Physician Assistants.

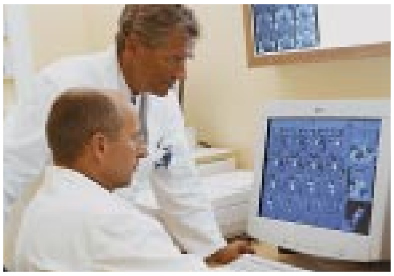
A partnership that's working for eastern North Carolina



Better tools mean better care

Cooperation and vision are bringing leading-edge technology to help patients in eastern North Carolina who are diagnosed with brain lesions. Pitt County Memorial Hospital has received state approval to buy and install a Leksell Gamma Knife, one of medicine's newest and most powerful tools for the treatment of brain tumors and other neurological conditions. The Leksell Gamma Knife is the most recent addition to the hospital's growing armamentarium of leading-edge diagnostic and treatment technology.

The project, which is expected to be operational in the fall of this year, is the result of careful collaboration and planning involving the hospital, the Leo W. Jenkins Cancer Center, the Brody School of Medicine Department of Radiation Oncology and private physician practices including Eastern Neurosurgical and Spine Associates, Eastern Radiologists and Carolina Radiation Medicine.

The Brody School of Medicine, University Health Systems and private physicians are working together to make things happen — in the community, in the region and in the state.

We heard you.
And we're doing something about it.

Blue Cross and Blue Shield of North Carolina asked doctors across the state: How can we support you on the front lines in a battle against our epidemic of obesity?

Doctors in North Carolina told us they want to address excess weight and obesity with their patients. But you also told us there simply isn't enough time to squeeze one more health condition into an office visit.

We heard you. Blue Cross and Blue Shield of North Carolina will pay for four visits to a doctor each year specifically for the evaluation and treatment of obesity.

It's part of our new obesity initiative called Healthy Lifestyle Choices℠.

Obesity shortens lives and increases health care costs. The first step toward a healthier, more active life can start in the doctor's office – where we are encouraging a hard look at how excess weight can impact people's health.

Healthy Lifestyle Choices is a broad program that extends from online support for members trying to maintain a healthy weight or lose a few pounds – to coverage of doctor visits and prescription weight-loss drugs when medically necessary – to establishing Bariatric Surgery Centers of Excellence to identify providers of superior results in obesity surgery.

For more information about the Healthy Lifestyle Choices program or to request educational materials for your patients, e-mail your request to **quality@bcbsnc.com**.

For more than 70 years, our members and doctors have come to expect innovation from Blue Cross and Blue Shield of North Carolina, our state's stable, reliable and largest health insurer.

Innovative health care designed around you.℠ | *bcbsnc.com*

maintain your brain™

alzheimer's association

changing how we think about brain health in north carolina

Alzheimer's disease was first identified by Dr. Alois Alzheimer in 1906, but 95 percent of what we know has been discovered in the last 15 years. Now, for the first time, research tells us that you can manage your lifestyle to help reduce your risk of Alzheimer's and we can anticipate major breakthroughs toward prevention over the next decade.

Today 4.5 million Americans have Alzheimer's disease; unless something is done to prevent it, that number will increase by 70 percent to 7 million Americans by 2025. Simple lifestyle modifications, if adopted by everyone would have an enormous impact on our nation's public health and the cost of health care.

When we think about staying fit, we generally think about our bodies and not our minds. But brain health plays a critical role in almost everything we do: thinking, feeling, remembering, working, playing and even sleeping. The good news is we now know there are things we can do to keep our brains healthier as we age and these steps might reduce our risk of Alzheimer's disease or other dementias.

10 ways to maintain your brain

1. Head first
Good health starts with your brain. It's one of the most vital body organs, and it needs care and maintenance.

2. Take brain health to heart
What's good for the heart is good for the brain. Do something every day to prevent heart disease, high blood pressure, diabetes and stroke – all of which can increase your risk for Alzheimer's.

3. Your numbers count
Keep your body weight, blood pressure, cholesterol and blood sugar levels within recommended ranges.

4. Feed your brain
Eat less fat and more antioxidant-rich foods.

5. Work your body
Physical exercise keeps the blood flowing and may encourage new brain cells. Do what you can – like walking 30 minutes a day – to keep both body and mind active.

6. Jog your mind
Keeping your brain active and engaged increases its vitality and builds reserves of brain cells and connections. Read, write, play board games, learn new languages or skills, do crossword puzzles or brain teasers.

7. Connect with others
Leisure activities that combine physical, mental and social elements may be most likely to prevent dementia. Be social, converse, volunteer, join a club or take a class.

8. Heads up! Protect your brain
Take precautions against head injuries. Use your car seat belts, unclutter your house to avoid falls; and wear a helmet when cycling or rollerblading.

9. Use your head
Avoid unhealthy habits. Don't smoke, drink alcohol excessively, or use street drugs.

10. Think ahead – Start today!
You can do something today to protect your tomorrow.

An estimated 150,000 North Carolinians suffer from the devastating effects of Alzheimer's disease. From the mountains to the coast, individuals, families, health care professionals and the general public receive information and assistance from the Eastern North Carolina Chapter in Raleigh, the Western Carolina Chapter in Charlotte and their satellite offices. Programs and services include 800 Helplines, support groups, information and referral services, educational programs, counseling, newsletters, lending libraries of books and videos and collaborative programs with other non-profits and local, state and federal agencies.

Be an advocate for those who can no longer speak for themselves. Support the programs and services of the North Carolina Chapters and help make Alzheimer's a distant memory through research for a cause, prevention and cure.

For information about programs and services, please contact the office nearest you.

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

Instructions for Authors

Manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All manuscripts submitted for review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

Stroke Prevention in Atrial Fibrillation:
Are We Following the Guidelines?

Benjamin E. Pusser, DO, Sandy L. Robertson, PharmD, Mark D. Robinson, MD, Cole Barton, PhD, and L. Allen Dobson, MD

Abstract

Background: *Warfarin therapy substantially reduces stroke in atrial fibrillation (AF), yet medical literature reports it is only prescribed in 15-60% of eligible patients. No current national benchmarks for warfarin use in AF patients exist, and it is unclear whether the reported poor compliance represents current rates within primary care practices. The primary study objective was to measure the rate of warfarin use in eligible, high-risk AF patients in a large southeastern group family practice. Secondary objectives were to report the demographics, stroke-risk profiles, contraindications, and reasons for discontinuation of warfarin therapy.*

Methods: *A retrospective chart review was performed on all active patients with documented AF in a large southeastern group family practice/residency between July 1, 2000 and June 30, 2002. Data was abstracted on warfarin use, contraindications, stroke risk, and reasons for discontinuation.*

Results: *Four hundred ninety-one (491) patients were identified from the electronic billing system as potential study subjects. Two hundred eighty-three (283) patients met study criteria, with 210 patients considered to be at high-risk of stroke without contraindications to warfarin therapy. Ninety-four percent (198/210) of these patients were prescribed warfarin during the study period, and 87% (172/198) continued warfarin throughout the study period.*

Conclusions: *Family physicians in this practice prescribe warfarin in AF more frequently than published rates, demonstrating that high rates of physician adherence to standards are achievable in primary care. Most patients in this setting were considered high-risk for stroke.*

Key words: *anticoagulation, atrial fibrillation, warfarin, stroke, family medicine*

INTRODUCTION

Atrial fibrillation (AF) is the most common sustained arrhythmia affecting 0.9% of the United States population.[1] The incidence of AF increases sharply with age affecting 5.9% of people over 65 years and 10% of those greater than 80, with a median age of 75 years.[1] AF is associated with a six-fold increase in the risk of stroke, with 50% of strokes occurring in patients greater than 75 years.[2] The annual stroke rate is 6-12% in patients older than 70 years with any high-risk factor for stroke.[3-5]

AF patients on antithrombotic therapy for stroke prevention have a relative risk reduction of 70% with warfarin vs. placebo, and a 20% reduction with aspirin vs. placebo.[3-5] Given the high incidence of stroke in AF patients and the efficacy of warfarin in preventing stroke, the American College of Chest Physicians (ACCP) published grade A recommendations via the Fourth ACCP Consensus Conference on Antithrombotic Therapy in 1995.[6] These recommendations were based on level 1 evidence, and remain largely unchanged in the most recent ACCP guidelines from the Sixth ACCP Consensus Conference on Antithrombotic Therapy.[7] In these guidelines, patients are stratified into risk categories to guide appropriate antithrombotic therapy (see Table 1). AF patients are categorized as high-,

Mark D. Robinson, MD, is the Director of the Cabarrus Family Medicine Residency Program at NorthEast Medical Center and Vice President of Education at Cabarrus Family Medicine, PA.

Cole Barton, PhD, is Professor of Psychology at Davidson College and Director of the Clinical Research Institute at Northeast Medical Center.

L. Allen Dobson, MD, is President and Chief Executive Officer of Cabarrus Family Medicine, PA, and the Director of Graduate Medical Education at the Cabarrus Family Medicine Residency Program at Northeast Medical Center.

Table 1.
ACCP Stroke Prevention Guidelines 2001[7]

Atrial Fibrillation Stroke Profile	Risk Factors	Treatment Guidelines
High Risk	One or more of the following: ■ Age ≥ 75 years ■ History of hypertension ■ Prior cerebrovascular accident/ transient ischemic attack ■ Prior arterial thromboembolism ■ Poor left ventricular systolic dysfunction (ef<40%) ■ Rheumatic mitral valve disease or prosthetic heart valve ■ Two or more moderate-risk factors	Warfarin (INR 2.5, range 2-3)
Moderate Risk	No high-risk factors and one of the following: ■ Age 65-74 years ■ Diabetes ■ Coronary Artery Disease	Warfarin (INR 2.5, range 2-3) or Aspirin 325 mg/day
Low Risk	No high- or moderate-risk factors and: ■ Age <65 years	Aspirin 325 mg/day

moderate-, and low-risk for stroke based on age, hypertension, previous cerebral embolic event, poor left ventricular systolic function, the presence of valvular disease or a mechanical valve, diabetes, or coronary artery disease. Patients in the high-risk category should receive warfarin therapy unless contraindicated, whereas patients in the low-risk category should be maintained on aspirin therapy. Patients in the moderate-risk category can be maintained on either warfarin or aspirin therapy. Despite these nationally accepted guidelines, published studies report only 15-60% of eligible AF patients are prescribed warfarin, with family physicians reported as having the lowest use rates in AF.[8-15] We do not believe these low rates reported for family physicians are accurate.

Our primary study objective was to measure the current rate of warfarin use in eligible high-risk AF patients in a large southeastern group family practice. Secondary objectives were to report the demographics, stroke risk profiles of patients with AF, and the contraindications and reasons for discontinuation of warfarin therapy.

METHODS

A retrospective chart review was conducted from the 57,912 active patients, defined as seen in the clinic within two years of start of study, receiving care through Cabarrus Family Medicine Residency Program (CFMR) at Cabarrus Family Medicine, PA, (CFM) clinics. CFM operates five family practice clinics in five municipalities in North Carolina (Concord, Kannapolis, Harrisburg, Mt. Pleasant, and Richfield). These clinics function as residency training and practice sites for CFMR, within a large multi-office community practice. The 28 attending physicians and 24 resident physicians utilize NorthEast Medical Center (NEMC), the only hospital in Cabarrus County, nearly exclusively for all admissions.

The study period was defined as July 1, 2000 to June 30, 2002. Patients were included in the study if they visited a CFM clinic during the study period and AF was documented by electrocardiogram or medical records including AF as a diagnosis. For study purposes, AF included atrial flutter and any subtype of AF (e.g., paroxysmal, chronic). AF was considered remote if a patient remained in sinus rhythm throughout the study period but records indicated a history of AF.

In order to ensure that we captured as many patients as possible with AF, we searched CFM's electronic billing database (Medical Manager™) to identify patients seen in the study period and who had an ICD-9 diagnosis of atrial fibrillation or atrial flutter (427.31-427.32) any time during the preceding seven-year period. As an additional search, we used the hospital's (NEMC) electronic billing database to identify additional hospitalized patients with the same ICD-9 codes discharged during the study period with a CFM attending physician or a CFM primary care provider.

A data collection tool was developed and piloted with ten medical records. Direct, on-site abstraction was conducted by a single resident physician (BEP) utilizing a computer database on a laptop and Windows based PDA. Hospital records were utilized as needed to complete data abstraction.

Risk factor variables were recorded for the purpose of stratifying patients into high, moderate, and low stroke risk categories (see Table 1). If a patient received warfarin anytime during the study period warfarin use was recorded as positive. Contraindications and acceptable reasons to not prescribe warfarin were based on Medical Review of North Carolina, Inc.'s *National Stroke Medicare Quality Improvement Project*[16] (See Table 2) and were recorded when patients were not started or continued on warfarin.

SPSS software was used to analyze standard descriptive statistics and p values for categorical variables were calculated using nonparametric χ2 tests. Categorical variables of risk were tabled with whether or not warfarin was prescribed. Chi-square statistics were computed which compared measured rates of prescribing to recommended guidelines, or whether or not patient categories exceeded base rate expectations as supported by the literature.

RESULTS

A total of 491 potential study patients were identified by CFM and NEMC billing systems, with 490 patient charts located and abstracted. Two hundred seven patients were excluded after detailed chart reviews revealed 117 of them had

Table 2.
Contraindications to and Acceptable Reasons Not to Prescribe or to Discontinue Warfarin Therapy[11]

Contraindications/acceptable reasons patients not on warfarin therapy	
■ Syncope ■ Multiple falls/risk of falls ■ Advanced dementia ■ Hemorrhagic cerebrovascular accident ■ Patient noncompliance/refusal ■ Warfarin allergy ■ Prior serious gastrointestinal bleeding and/or untreated or unresponsive peptic ulcer disease ■ Predisposition to bleeding (thrombocytopenia, end-stage renal disease, cirrhosis, hemophilia)	■ Major bleeding (requiring hospitalization or transfusion) ■ AF lasting <48 hours and did not recur or secondary to medical condition ■ Seizure disorder ■ At risk of falls ■ Prior bleeding with anticoagulants ■ Alcohol abuse ■ Terminal/comfort care ■ Extensive, metastatic cancer

Contraindications to Warfarin Therapy in Study	**# (% high-risk patients, n=257)**
One episode <48 hours or AF secondary to medical condition	9 (3.5%)
Prior/predisposition to major bleeding	9 (3.5%)
Syncope, seizures, multiple falls	8 (3.1%)
Advanced dementia	7 (2.7%)
Prior bleeding with anticoagulants	5 (1.9%)
Patient declined warfarin	5 (1.9%)
Alcohol abuse, prior noncompliance	3 (1.2%)
Metastatic cancer, comfort care only	1 (0.4%)

remote AF only, 60 were without a diagnosis of AF, and 30 patients were not seen in the study period. AF was prevalent in 6.1% of patients age 75 and older and 0.69% of all patients (see Table 3, Figure 1). These prevalence rates are consistent with the published literature. The types of AF documented were evenly distributed between paroxysmal, chronic, and unspecified (see Table 3).

Of the 283 patients who met study criteria, 257 (91%) were categorized as high-risk for stroke by having at least one high-risk factor, or at least 2 moderate-risk factors listed in Table 1. Of these 257 patients, 47 (18%) were considered not to be warfarin candidates (see Table 2), leaving 210 patients eligible to receive warfarin therapy for stroke prevention. The most common acceptable reasons not to prescribe warfarin were: transient AF secondary to medical condition/1 episode lasting less than 48 hours, prior/predisposition to major bleeding, syncope, seizure, or multiple falls, and advanced dementia.

Ninety-four percent (198/210) of eligible high-risk AF patients were prescribed warfarin during the study period. Results were unchanged when moderate-risk patients (n=7), who are recommended warfarin or aspirin, were included in the analysis. Likewise, 87% (172/198) of active patients continued warfarin throughout the study period. Warfarin was discontinued during the study period in 26 patients; 14 patients had valid reasons documented, including major bleeding (2.5%), patient refusal (1.5%), and AF secondary to medical condition/1 episode lasting <48hrs (1.5%), whereas 12 patients did not have documentation of an acceptable reason.

The majority (11/15) of female patients not started or maintained on warfarin were noted to have the paroxysmal subtype of AF. There was no such difference in AF subtypes among males. Age and clinic location had no correlation with warfarin use.

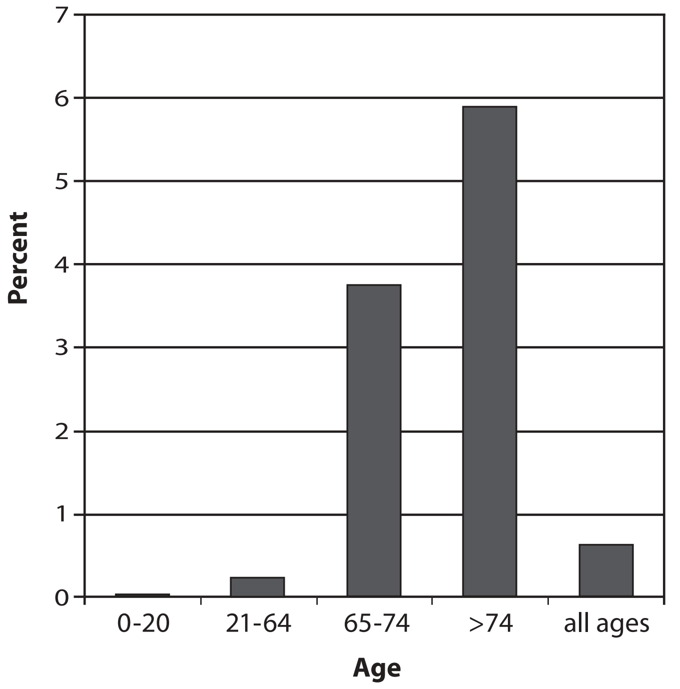
DISCUSSION

This retrospective study of warfarin use in high-risk AF patients in a large primary care setting demonstrates a high rate of compliance with national guidelines set forth by the American College of Chest Physicians and challenges the previously low compliance rates for Family Practitioners.[7] Currently, there are no published national benchmarks for achievable warfarin use in AF. CFM's 94% prescription rate is significantly higher than all other rates found in the literature ($\chi^2 = 39.00$, $P<0.001$).[8-15] We located eight publications investigating warfarin use in AF patients with most of the data collected in the early 1990's. Three of these trials investigated warfarin use in hospitalized patients admitted with AF with or without stroke,[8,10,15] while three trials reported warfarin use in long-term care facilities (LTCF).[9,13,14] The remaining two trials described warfarin use in outpatient settings over a period of time.[11-12] Each trial considered contraindications to warfarin therapy in calculating the number of patients on warfarin, and five of these trials reported the number of ideal candidates on warfarin.[8-10,12,14] The acceptable contraindications were similar to each other and to our study. Valid contraindications shared by these investigations included fall risk, bleeding history, peptic ulcer disease, and terminal illness. Our study reports 18% of patients with contraindications (see Table 2), while the other trials varied from 1% to 81%, with LTCF patients gleaning the highest proportion of ineligibility.

Table 3.
Patient Demographic Data and Prevalence of AF within Clinic System

Patient Demographics (n=283)	
Female	137 (48%)
Median age	74 years (range 21.8 - 106.2)
Age ≥ 75 years	140 (49.1%)
Age 65-74 years	70 (24.7%)
Age < 65 years	73 (26.1%)
Paroxysmal AF	32.5%
Chronic AF	28.6%
Unspecified AF	38.9%

Figure 1.
Prevalence of Atrial Fibrillation at CFMR Clinics (n=57,912)
*includes patients with remote AF documented between 1995-2000



The percentage of eligible patients on warfarin was 38% and 69% in hospitalized patients,[8,10] 25% and 53% in LTCF patients,[9,14] and 35% in the clinic setting.[12] The remaining three trials did not report eligible patients, but rather the total number of patients on warfarin. Stafford et al[11] compared warfarin use among cardiology, internal medicine, and family practice clinics from 1980 to 1993, with internal medicine having the highest portion of patients on warfarin at 40%, cardiology at 32%, and family practice at 15%. In a report by Jencks et al,[15] Medicare patients with AF in North Carolina between 1998 and 1999 had a 60% warfarin prescription rate at hospital discharge. No definite trend of improved warfarin use can be detected by these studies, despite the growing body of evidence supporting its use. It is unclear whether the quoted rates could be low due to study design, period of study compared to date of new guidelines, or whether rates in those studies represent lower compliance. A recent review of the literature describes numerous potential reasons for noncompliance with warfarin use.[17] Increasing age, perceived hemorrhage risk, and perceived noncompliance are consistent physician barriers to prescribing warfarin. Other barriers identified were difficulty in monitoring and unfamiliarity with the clinical guidelines. Physicians were found to be more enthusiastic about warfarin in patients with a history of cardioembolic stroke.

The significantly higher rates found in this study population suggest that very high compliance rates are achievable in a primary care practice. Factors which may have influenced this high compliance rate include (1) focus on education and current standards of care within a residency program, (2) close working relationship with local cardiologists, or (3) hospital disease management protocols initiated near the end of the study period. Currently at NEMC, patients admitted for AF are flagged with an anticoagulation form in which providers are asked if the patient will be discharged on appropriate anticoagulation. A summary of the guidelines are included on this form with acceptable contraindications to warfarin therapy. These strategies will continue to educate and remind providers of the importance of warfarin therapy in the treatment of AF.

There was no specific practice-based disease management system in place in the clinics during the study period. Further evaluation and study of compliance rates with current guidelines in other clinic settings is needed, including evaluation of the most effective method in achieving compliance. The authors believe that practice-based disease management systems in primary care will be key to improving care for patients in the future.

Unlike studies that focus on warfarin prescribing at hospital discharge, our study followed patients throughout a two-year period and documented an 87% continuous warfarin use rate in this population, suggesting good continuity of care and practice-based disease management. Also, our study did not differentiate between chronic AF and paroxysmal AF with regard to eligibility for warfarin therapy, despite the common belief that patients maintaining normal sinus rhythm for a period of time can safely stop anticoagulation. In the recently published AFFIRM trial,[18] the majority of strokes in both groups (rate control group versus rhythm control group) occurred in patients who had either stopped warfarin therapy or had an INR <2.0. Of the 77 patients in the rate control group with stroke, 32% had discontinued warfarin compared to 55% (44 of 80) in the rhythm control group. We posit that clinicians make the decision to stop warfarin more often in AF patients on antiarrhythmic agents assuming normal sinus rhythm will be maintained. The decision to anticoagulate a high-risk AF patient is more likely to improve outcomes than antiarrhythmic therapy. In the AFFIRM trial, antiarrhythmic therapy had no effect on mortality (trend toward increased mortality, p=0.08) and had significantly increased rates of hospitalizations, torsades de pointes, and bradycardic cardiac arrest as compared to rate control and anticoagulation alone. Moreover, AF patients are at risk of stroke whether or not they are in normal sinus rhythm (NSR) or AF. In another recently published trial of rate control vs rhythm control, 17% of strokes in the rhythm control group occurred after cessation of warfarin therapy. In all but one of these six cases, the patient was still in NSR at the time of stroke.[19]

Future analysis measuring compliance with warfarin monitoring and maintenance of INR goals is needed. Management of stroke prevention with warfarin therapy in AF patients can be effectively performed by family physicians. **NCMJ**

INTRODUCTION

Policy Forum:
Alzheimer's Disease and Family Caregiving

The growth of North Carolina's older adult population (in size and proportion) has serious implications for families and for the state's health and human services programs. Public policy deliberations about the impending challenges associated with the growth of this population segment often begin with concern for how we will provide care for the increasing numbers of older adults who will suffer from various forms of dementia, including Alzheimer's disease. In this issue of the *North Carolina Medical Journal*, we have collected a number of perspectives on this large and looming set of issues.

We are fortunate to begin our discussion with an extensive Issue Brief prepared by Donald H. Taylor, Jr., PhD, a health policy specialist at Duke University. Dr. Taylor describes the demographic and epidemiologic trends related to dementia and Alzheimer's disease. He also directs our attention to some of the key public policy issues in need of immediate consideration (hopefully, before these issues overwhelm existing service delivery systems) and to the tremendous burden these issues pose for the families of those affected by Alzheimer's disease. Next, Bonnie Hogue Duffy, national policy specialist for the Alzheimer's Association in Washington, DC, provides an explanation of the Association's national legislative agenda. Their papers help to underscore the scope of the problem and make it clear that early diagnosis can be beneficial in a number of ways. They also emphasize the substantial public as well as personal benefit that could be gained from badly needed clinical therapeutics designed to delay disease onset. Being able to delay onset for even five years could dramatically lessen the personal and societal burden of this disease.

We are also pleased to include a substantial interview with caregiver, Myron H. Green of Durham, North Carolina, by our Contributing Editor, Donald L. Madison, MD. Dr. Madison brings the everyday burden and frustration of spousal care for a loved one with Alzheimer's disease to our attention. We are grateful to Myron Green for sharing his personal experiences with us. No one who reads Mr. Green's story will come away without deep respect and admiration for a caregiver or without an understanding of how important respite care and other helpful services can be to "round-the-clock" caregivers. Following this interview, we include several papers by well-known specialists in North Carolina who have either developed programs for the benefit of caregivers or who administer statewide programs offering such services. The hopeful message in these commentaries is that reliable sources of caregiver support exist, but they are often stretched thin, and their ability to meet the increasing need is in doubt. In addition, we include brief commentaries by specialists who have devoted careers to serving older adults through: primary care medicine and nursing, the provision of respite and bereavement services to caregivers, a variety of faith-based services, and/or long-term care facilities.

The concerns discussed in this issue of the Journal are ones that can have a major impact on the lives of all North Carolinians, regardless of social or economic status. Any time dementia or Alzheimer's disease threatens a close friend or family member, the effects of this diagnosis are likely to be all encompassing. Initially, families nearly always try to manage the care of a loved one in the home or community setting, but the burden of this decision often leaves the caregiver isolated; over-burdened physically, mentally, and economically; and with his/her own health at risk. It is apparent that family caregivers provide an enormous service to their ailing loved ones and to the state. We hope that organizing and presenting this information will generate thoughtful discussions among healthcare providers, patients, and policy makers that will ultimately enhance our family caregivers' ability to provide this important care and, in turn, enhance the state's long-term care capacity.

We invite our readers to share their reaction to these papers, and to these issues in general, in our Readers' Forum over the coming months.

ISSUE BRIEF

Alzheimer's Disease and the Family Caregiver:
The Cost and Who Pays?

Donald H. Taylor, Jr, PhD

What Is It?

Alzheimer's disease (AD) is an acquired, progressive neurodegenerative disorder that is the most common cause of dementia in older adults in the United States, constituting 50-60% of all cases of dementia.[1,2] Dementia is a syndrome characterized by progressive decline in memory and other intellectual abilities, and typically results in a need for complete caregiving for the patient. Contemporary diagnostic criteria for AD were published in 1987.[3] The Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) identifies the following three criteria as being necessary for a diagnosis of dementia: (1) memory impairment, (2) cognitive dysfunction in at least one other area of cognitive functioning (aphasia, apraxia, agnosia, or inability to carry out executive functions), and (3) cognitive impairments severe enough to limit social or occupational functioning. Alzheimer's disease has a societal significance that is greater than simply being the leading cause of dementia. AD has come to symbolize worries about how the United States will deal with the aging of society.

How Common Is It?

There have been a variety of prevalence studies conducted over the past decade, with wide variance in the estimates.[4-14] The most recent published estimate is that 4.5 million persons had AD at the 2000 Census.[4] Comparing estimates is difficult because of differences in methods, settings, timing, and definitions of AD used across studies. There are four key points with respect to the prevalence of AD. (1) The true prevalence of the disease is unknown, and there are conflicting estimates. (2) All published prevalence estimates are based on geographically-based samples that are not representative of the entire United States. (3) All published estimates agree that prevalence increases with older age, and a general rule of thumb is that prevalence roughly doubles per decade of age with around half of those age 85 and older likely afflicted with AD.[10] (4) The number of persons living with AD will dramatically increase given the rapid increase in the number of Americans who are age 85 and older, and who, all studies agree, have the highest prevalence rates.

A recent study using Medicare claims records to track diagnosed prevalence of AD recorded in claims data found large increases across the 1990s using the same diagnosis method in all years.[15] Such a study provides an opportunity to see how identification of AD is changing over time, but the case definition being based on ICD-9-CM codes in claims data produces a serious undercount of the overall true prevalence of the disease. There is no obvious reason to expect that the true prevalence of AD should have risen so sharply during this time frame, so the observed increases are most likely due to an increase in the probability of being diagnosed with AD, given the presence of the disease, particularly for persons with mild symptoms over time.

In addition to age, race and gender have been shown to be related to the prevalence of AD. Women have higher rates of AD than men. There is some epidemiological evidence that AD rates are higher among African Americans compared to whites.[16-23] For example, Folstein et al.[19] found the AD rate for blacks to be 7.2% compared to 3.8% for whites. Other studies have not found differences in the prevalence of AD between African Americans and whites.[24-25] Plausible explanations for a higher rate of AD among blacks are the community-based samples in studies finding differences (e.g., blacks are less likely to be institutionalized where rates of AD are much higher) as well as lower sensitivity of cognitive tests for identifying AD in blacks.[26] The study cited earlier showing an increase in prevalence of AD identified in Medicare claims records showed that the rate of increase was faster for blacks compared to whites.[15] This may suggest an increase in awareness of AD in the African American community, an increase in access to care, changes in coding rules that allow a diagnosis of AD with a history of stroke, or all of these.

What Treatment Options Are Available?

AD is non-reversible, and the current therapy available to directly address the disease is limited to: (1) pharmaceuticals

---

Donald H. Taylor, Jr, PhD, is an Assistant Professor of Public Policy Studies and Community and Family Medicine, Center for Health Policy, Law and Management, in the Terry Sanford Institute of Public Policy at Duke University. He can be reached at detaylor@duke.edu or Box 90253, Duke University, Durham, NC 27708. Telephone: 919-684-2361.

that may slow the decline of cognitive function and (2) the development of approaches to best care for persons with AD who suffer from extreme cognitive decline and disability. Developing methods for early diagnosis of AD are of critical importance to provide maximum opportunities for both existing and any future therapies to have the best chance of success.

A recent review outlines the present pharmaceutical treatment options for AD that are currently in use.[1] These drugs are commonly used to treat the signs and symptoms of AD: Donepezil, Rivastigmine, and Galantamine (all Choinesterase inhibitors), and Memantine (a NMDA-receptor antagonist). Such treatment is currently the standard of care for the disease. Other pharmaceuticals are used to treat neuophychiatric symptoms and behavioral disturbances of the disease, such as depression, psychosis, and anxiety.[1] Development of new pharmaceutical agents is an area of intense interest for all parties—for physicians, patients, and families who want an effective therapy to address the underlying mechanisms of the disease or to better treat symptoms, and for pharmaceutical companies who understand the large market for persons with AD and dementia, generally. In short, there are few therapies available to address AD, and most efforts are spent trying to best manage symptoms, treat comorbid illness, and help families deal with the disability of their loved one.

"Twenty-five years from now, 35% of the state's population will be age 50 or older; hence dealing with AD will become an increasingly important issue in North Carolina."

There are hopes that future therapies will be more effective at either forestalling cognitive decline or perhaps even reversing dementia. For existing pharmaceutical therapies, as well as future ones, early diagnosis of AD seems to be a key to maximizing the benefit of both current and potential approaches. Conclusive diagnosis of AD is only possible through a post-mortem autopsy. Prospectively, the diagnosis of AD is made when persons meet standard criteria for the diagnosis and have no other plausible explanations for their observed dementia.[1] The primary advances in diagnosis over the past two decades have been (1) the adoption of standard criteria for diagnosis, (2) an understanding by the medical community and the population in general that dementia, and AD in particular, is a disease and not a normal part of the aging process, and (3) the development of more advanced imaging techniques that are useful for diagnosis. In particular, the decision of the Medicare program to finance the use of Magnetic Resonance Imaging (MRI) scans for diagnosing AD, and more recently covering PET Positron Emission Tomography (PET) scanning for the same purpose, may yield more precise and potentially earlier diagnoses of AD. However, it is important to note that the use of a PET scan is not generally considered to be necessary for the diagnosis of AD, and Medicare will only cover PET scans in complex cases where a cognitive decline is noted, but a diagnosis of AD can not otherwise be easily made. The development of new pharmaceuticals or other therapeutic approaches to either slow or reverse dementia associated with AD will increase pressure to diagnose the disease as early as possible, so new therapies and diagnostic procedures are likely to develop hand-in-hand.

There are non-medical treatment options designed to aid in the care of persons with AD, including placement of individuals in dementia care units that are long-term care facilities designed specifically to provide care for those suffering from AD and other dementias. This treatment is probably best understood as a means of dealing with the effects of AD in the most efficacious manner possible and doing so in a way that helps reduce the caregiving stress and burden on spouses and/or families of loved ones with AD. In reality, most persons with AD are living and being cared for in community settings. Families tend to seek institutional settings such as nursing homes/dementia care units for the care of their loved ones with AD when the difficulty, strain, and burden of caring for the patient in a community setting becomes too difficult. There are a variety of negative effects of caregiving for persons with AD that have been well-documented in the literature. A clearer understanding of these negative effects as well as the aging of the population with respect to the number of working-age persons for each person age 65 and over should lead to a societal discussion about the most appropriate manner in which to care for persons with AD and other sources of age-related disability.

Extent of Alzheimer's Disease in North Carolina

The population of North Carolina is rapidly growing, with tremendous increases among both working age persons as well as retirees. The state is getting older, like the rest of the United States; the North Carolina median age rose from 33.0 in 1990 to 35.3 in 2000, and will increase to 38 by the year 2030.[27] During the 1990s, the proportion of the North Carolina population at highest risk of AD, those 85 and older, increased by 53% (from 69,000 to 105,000 persons).[27] At present, 28% of North Carolinians are age 50 or older, which means that they are either at substantial risk of developing AD or will be at-risk within 10-15 years. Twenty-five years from now, 35% of the state's population will be age 50 or older; hence dealing with AD will become an increasingly important issue in North Carolina.[27] AD is the seventh leading cause of death in North Carolina at 27.7 per 100,000 (age-adjusted) population,[28] and was the primary cause of death in 4,996 deaths from 1999-2001.[27] The state's number of nursing home residents (all ages) per 1,000 persons age 85 and older in 2001 was 322.6, compared to 317.5 for the United States as a whole.[27]

Similarly, nursing home occupancy rates for North Carolina were 88% compared to 82.4% nationally.[27] As noted earlier, over half of nursing home residents suffer from AD or other dementias, but most persons with AD live in community settings.

Conceptualizing the Cost of Alzheimer's Disease

AD has a broad effect on American society, and discussion of the disease has ceased being only a clinical topic and become a part of the cultural dialogue of the United States. It is useful to distinguish three distinct perspectives of cost and burden when considering AD. Cost need not imply monetized cost estimates, but could. The first cost perspective is the private or individual level that encompasses the cost experienced by the person with AD. The second level is what can be called quasi-external costs, notably the costs borne by spouses and/or other family members who are engaged in caring for a person with AD. Taken together, the individual and the quasi-external costs could be viewed as a unified household perspective, but they are separately identified here because the preferences, potential costs, and wellbeing of all members of the household are not likely to be identical when choosing a particular way to care for a person with AD. Finally, there is the purely external cost, or the cost of AD to persons outside of the household. This perspective is largely comprised by the effect of AD on programs, such as Medicare and Medicaid, and any additional costs borne by others outside of the household experiencing AD, such as lost work productivity for companies whose employees are caring for a parent with AD. It is necessary to consider the private, quasi-external, and external perspectives to fully understand the social cost of AD on the larger society. Considering these different perspectives is useful because it illustrates that using one to the exclusion of the others provides an incomplete understanding of the cost of AD and may lead to suboptimal policy.

Private Costs of Alzheimer's Disease

AD most directly and profoundly affects persons who are stricken with the disease. Such persons have their lifespan shortened. Prior to death they suffer from a tremendous morbidity burden that greatly diminishes their quality of life. After onset of the disease, persons generally suffer from impaired memory, lose the ability to communicate via spoken language and otherwise, and become unable to complete executive functions. As the disease progresses they may suffer from sensory problems, lose their ability to walk normally, and may suffer from seizures later in the course of the disease. Higher-level functioning is lost as the clinical symptoms progress, resulting in the inability to complete Instrumental Activities of Daily Living (IADLs) such as driving, shopping, cooking, maintaining personal records, and the ability to appropriately take medicines. Further decline results in the loss of ability to complete Basic Activities of Daily Living (BADLs), such as dressing, bathing, going to the toilet, and eating. Behavioral disturbances, such as wandering, outbursts of anger, or an increase in socially inappropriate actions (e.g, disrobing in public places), can onset across different phases of the disease progression, and psychotic behavior and extreme agitation often come during later phases of the disease. The private costs of AD are profound, and the development of therapies, such as pharmaceuticals, aim to ease the burden of the disease on persons afflicted with AD.

Quasi-External Cost of Alzheimer's Disease

Quasi-external costs are those borne by persons other than the patient in either the immediate (spouse) or inter-generational household (e.g., adult children, siblings of the afflicted). The primary cost is the magnitude of informal caregiving that persons are likely to provide to a family member with AD. This care is not static, but increases steadily throughout the disease course. A past estimate of the cost of informal caregiving in the United States found that their costs ranged from $117-$292 billion (1998 dollars), depending upon the assumptions about the hourly price used in the calculation.[29] This estimate showed the cost of informal caregiving to be larger than the total spent on nursing homes in the same year, in spite of the fact that it represented a replacement-cost estimate (how much it would cost to replace informal care with paid care) and assigned a value of zero to the well-known negative effects of caregiving on the health, emotional, and financial status of caregivers. In short, the quasi-external costs of AD are staggering.

The informal caregiving cost estimate noted above was for all caregiving, not only that provided to persons with Alzheimer's disease. However, there is reason to expect that caring for persons with AD and other dementias is a large contributor to this total and is more burdensome on a per-case basis than caregiving for persons with other diseases and ailments. Most persons with AD are being cared for in non-institutional settings in the community. A recent annual estimate of the cost of providing care for a person with dementia was $18,395 in 1998.[30] The two largest sources of cost were caregiver time ($6,295/year) and lost earnings ($10,709/year) due to reductions in market work in order to provide care. A recent paper illustrated that Medicare-financed care represented less than half of the total cost of dementia care,[31] illustrating that ignoring the quasi-external perspective in favor of the external perspective only (e.g., cost to the Medicare program) gives a skewed view of the burden of the disease on society as a whole (i.e., the social cost of the disease).

The other major source of quasi-external costs are the physical, emotional, and financial harm that befalls caregivers of persons with AD. Caregiving for a person with dementia has been found to be more deleterious to the caregivers' health than is caregiving for a family member with cancer across a variety of domains, including stress, depression, isolation, and delay in the seeking of medical care by the caregiver him/herself.[32] More recent work has shown that dementia caregivers provide more care and suffer great self-reported strain, mental and physical problems, and family conflict linked to the care of their loved one than do persons caring for persons afflicted with other diseases.[30] Caregiving and perceived stress in this role has even been found to increase mortality among caregivers.[33] Such costs need not be monetized to demonstrate that the quasi-external cost of AD is immense.

Spouses and adult children typically suffer financial strain due to caregiving. This is shown through the reduction of market work, out-of-pocket payments for house modifications to aid with caregiving, and interruptions of the retirement savings of adult children. While some studies document the lost wages associated with caregiving as a cost of AD,[30] this review did not identify estimates of the effect of reduced contributions to retirement plans, and what effect such a reduction could ultimately have on either retirement decisions (timing) or the amount of retirement savings. This effect would most likely be seen through reduced private savings through vehicles such as 401-K or 403-B retirement plans. This issue could be of great consequence, since caregiving may interrupt the retirement savings of persons who are likely to be in their highest wage-earning years (50-somethings caring for their 70- and 80-something parents). Interruptions or decreases in retirement savings are not easily made up, even through accelerated contributions at a later date, given the effect of the compounding interest principle. Reduced retirement savings could also be viewed as an external cost to the Medicaid program as a person with reduced savings could be expected to "spend down" to Medicaid eligibility levels sooner than would a person with more retirement assets (see below).

Other quasi-external effects of AD are not as tangible, nor are they easily monetized. For example, the loss of grandchildren being able to interact with and learn from their grandparent with dementia is easily understood as a "cost" in the most general sense, but assigning an economic value to such a cost is difficult. AD robs younger members of the inter-generational household from being able to learn from the wisdom and experience of the older members.

External Costs of Alzheimer's Disease

External costs are those costs that are neither private nor quasi-external. These are costs borne by society, defined as persons outside of the inter-generational household. A very common perspective when considering the external cost of AD, is the impact of the disease on a program such as Medicare. Recent work shows that persons who are diagnosed with AD cost the Medicare program around 60% more per year compared to a similar beneficiary (in terms of age, gender, and disability level) who does not have such as diagnosis.[34] However, the time path of the cost effect is complex. Costs increase in the year that AD is first noted in Medicare claims. As the disease progresses, the cost effect reduces, eventually falling below average per-beneficiary costs, suggesting a reduced propensity to use Medicare-financed healthcare services at more advanced stages of the disease. Further, there is some evidence that the presence of AD may influence the manner in which an acute medical condition may be treated. For example, a heart attack may be treated less aggressively for a person with AD compared to one who does not have AD. Thus, a precise estimate of the effect of AD on the Medicare program would need to account for several types of effects: the costs of diagnosis that would be expected to increase costs; the morbidity burden associated with AD that would be expected to increase costs; the effect of disease stage on the propensity to use formal medical care, which likely declines as the disease progresses; and the fact that some illnesses may be treated less aggressively given the presence of AD, which would be expected to reduce costs. While it seems certain that the presence of AD results in higher Medicare program costs, the mechanisms underlying such increases are more difficult to measure precisely, and are best considered longitudinally and not in cross-section, as is most easily done. A future issue with respect to Medicare costs is the impact of the prescription drug plans developed through the Medicare Modernization Act of 2003, which will be in place in 2006. It is not clear if existing or future drugs designed to treat AD and/or symptoms of AD will be routinely included in plan formularies.

The Medicaid program serves as a de facto nursing home insurance scheme for the entire United States, with the deductible essentially being non-housing wealth. The Medicaid program pays for approximately 40% of the national nursing home bill.[35] And given that over half the persons living in nursing homes suffer from AD or a related form of dementia, it is clear that the effect of AD on state Medicaid programs is large. The Medicaid program is also involved in financing acute medical services, but for persons age 65 and over who are both Medicare and Medicaid beneficiaries ("dual eligibles"), the Medicare program is the primary payor for acute care. For this reason, the burden of AD on the acute-care expenditures of state Medicaid programs would be expected to be modest.

The effect of AD on Social Security is more ambiguous. Social Security is an inherently more simple program than Medicare in that it simply provides cash payments to a person age 65 and over and therefore doesn't have the uncertainty of medical innovations, the propensity to seek medical care, and the unit price of services that Medicare faces. A recent book on the cost of smoking to society points out that smokers actually cross-subsidize non-smokers with respect to Social Security in that they contribute through the payroll tax over the course of their life at similar rates to non-smokers, but die substantially earlier.[36] This means they take out less than they put into the Social Security system. A similar analysis could be undertaken for persons who later develop AD—comparing what those with AD contribute versus what they receive in benefits. But it seems that persons living to an older age and developing AD prior to death are precisely the type of persons who are being cross-subsidized by smokers and others who die either prior to retirement age or relatively soon after the receipt of Social Security retirement benefits (age 62 or 65 depending upon the choice of the individual). Thus, it seems that persons with AD are likely to be among the persons who will cost the Social Security program relatively more over the course of their lifetimes.

Social Cost and Next Steps

The social cost perspective takes account of all aspects of cost and burden of AD—private, quasi-external, and external. Excluding one type of cost will result in an incomplete understanding of the cost of AD to society and may result in an under-investment in strategies to address the cost of AD. A complete understanding of social costs can also help identify areas in which policy attention is warranted, but which may not often garner much attention. The point of this Issue Brief is not to produce an estimate of the social cost of AD, but instead to identify the different types of costs and policy considerations that emerge from doing so.

In the case of AD, both the private and external cost perspectives have generated much (warranted) attention. The burden suffered by individuals with AD is immense, and it is clearly a societal priority to develop improved means of treating AD and/or symptoms of the disease. Pharmaceutical companies and clinical researchers will continue to seek new treatments and more effective ways to diagnose AD earlier, which is likely a precursor to any effective treatment.

Likewise, the external cost perspective has received a great deal of attention in recent years as researchers and policy makers worry about the effect of AD on the future solvency of programs such as Medicare and Medicaid. Identifying the cost burden of AD on such programs is a legitimate endeavor, but it is not clear what such estimates can do other than underscore the seriousness of AD and its current and potential impact on the system. It is not clear that there are many left who need to be convinced. However, there is a need for conceptual clarity about what is being measured in such work. Are the costs of persons *with AD* of interest? Obviously, some of them also have heart disease and cancer as well. Or, is it more important to focus on the cost of *AD per se*? In other words, are we measuring the cost of treating a person with AD compared to what it would have been otherwise? While related, these two external cost perspectives are not identical, and they should be kept separate. The answer may not be that important, given that the Medicare program will have to finance acute care for such persons in any event.

The area in which there is too little policy concern is in identifying and responding to the quasi-external costs associated with AD. A body of research literature exists that documents the physical, emotional, and economic effects on a family caring for a person with AD, but there has not been a serious national or state discussion around what to do about it. This is an area needing focused discussion around the issue of how will persons with AD be cared for and whose responsibility will it be? While the hope for future pharmaceutical agents to address the processes of the disease itself is real, so is the fact that several million people are likely to live through and die with or from AD before such therapies are developed. Their families will be left primarily to deal with the effects of the disease on their loved ones. Therefore, a top priority should be to directly address the issue of informal caregiving and determine how society views it. Currently, we have made the policy decision by not addressing the issue head-on. As life expectancy has continued to rise and the proportion of the population that is retired compared to those who are working is also rising, we can no longer afford to avoid directly addressing this issue.

Policy Options: The Case of Germany and Japan

Two nations (Germany and Japan) have recently adopted long-term care financing strategies that are instructive for outlining some of the key issues related to how to care for persons with AD in the absence of any pharmaceutical or other therapy that drastically slows cognitive decline and/or improves functioning. It is important to note that the magnitude of the aging of the population is greater in both Germany and Japan than in the United States, so the situation we face is not unique. While the need to address population aging issues and long-term care is similar in Germany and Japan, their respective approaches are fairly different. Their differences provide food-for-thought for considering how AD might best be cared for in the United States context.

Germany[37] has developed a voucher-based approach whereby persons are eligible for a fixed subsidy based on their level of disability, regardless of age. The voucher amount is not expected to pay for the full cost of market-provided long-term care (such as a nursing home or home health), and families are responsible for the rest unless they are totally impoverished. The most innovative aspect of the German system is the ability for families to continue providing long-term care services in the community and to "cash out" their voucher for money to be used to defray the cost of caring for their loved one. The cash-out value is approximately two-thirds of the voucher amount, providing a cost-savings for government when families choose to provide care informally. The German approach to determining eligibility has been criticized as being too simplistic (it places people in very broad categories based on ADL limitations) and does not take direct account of the extent of cognition/dementia. It has generally been affirmed for identifying family-provided care as the preference of large segments of German society and moving through policy to make such care more sustainable—basically by identifying quasi-external costs as worthy of policy action.

The Japanese approach is quite different.[38] Whereas Germany has sought to continue giving emphasis to a system based on family-provided long-term care, Japan has moved to aggressively increase the supply of formally-provided long-term care services with the explicit purpose of reducing the reliance upon informal care. The political discussion of the Japanese long-term care system was euphemistically known as "the daughter-in-law bill." This highlights concern among political elites that gender equity issues were particularly acute in the area of long-term care, in the nation with the longest life expectancy in the world. The Japanese approach also differs from Germany in having a very detailed disability assessment approach that categorizes persons on numerous metrics, including the extent of dementia/cognition. Further, age is an explicit aspect of benefit determination, with those age 65+ presumed to qualify, but those age 40-64 are also able to qualify if they suffer disability due to an "age-related" condition.

The Policy Questions Ahead

These two approaches raise a series of questions that are useful for considering how to appropriately care for persons with AD. The questions are important even though it is unlikely that the United States would seriously consider a social insurance response to the provision of long-term care at any point in the foreseeable future.

First, given that family-provided care in the community is likely to remain the preference for many, is public policy intervention (e.g., public money) acceptable to defray the costs of such care?

Second, in determining eligibility of services/subsidies for long-term care for persons with AD, how will eligibility for services be determined? There is generally a trade-off between simple assessment (Germany), which is relatively cheap, and more precise assessment (Japan) that includes more data on a larger proportion of program costs on administration.

Third, what is of paramount importance in determining the best setting in which to care for a person with AD—the patient with AD or the caregiver(s)? This is another way of asking whether it is the role of the family to care for persons with AD or the family in conjunction with society as a whole.

There are certainly other questions that can be asked, but these are key ones to discuss and answer if the United States is going to more directly consider the quasi-external costs of AD.

What Policy Options Are Available for North Carolina?

Answering the questions posed above with respect to how to conceptualize the cost of AD and how such costs should be borne are prerequisites for good policy. A national discussion and approach are needed to prepare the United States for the coming increases in persons with AD, but this is likely to require a long-term discussion. At present, most acute care is financed by the Medicare program, and families provide most of the caregiving, with the Medicaid program financing nursing home stays of persons with AD after the point of personal spend down. Large-scale changes in this mix seem unlikely, and the development of a long-term care financing scheme based on social insurance principles similar to Germany or Japan's is not likely in the near future. Given this backdrop, North Carolina has two primary means of addressing the AD situation, long-term care insurance regulation and alterations of the state Medicaid program with respect to eligibility for nursing home and other services for persons with AD. Expanding Medicaid, while a possibility, seems unlikely given the fiscal situation of the state, so the remainder of this Issue Brief discusses long-term care insurance in North Carolina.

Long-term care insurance is often noted as a key to preparing for the aging of society and dealing with increased numbers of persons with AD and fewer workers to help support same. If North Carolina could develop policies that would lead to the expanded purchase of such insurance it would be helpful in dealing with AD. However, determining how to expand such coverage is not clear. Private long-term care insurance enrollment rates are very low, around 5% of the population.*

Insurance is commonly used to spread the risk of potentially large and catastrophic losses when the occurrence of loss is unpredictable, but plausible. If a potential loss is very small, individuals don't bother with insurance. If the likelihood of a loss is extremely small, then likewise, they do not bother with

---

* Note: Among North Carolina's state employees and teachers, only 2,700 State Health Plan members subscribed to a long-term care group insurance plan offered to more than 550,000 plan members in 2004.

insurance. When potential losses are large and the likelihood of occurrence is more common, then a market for insurance is more likely to develop. Long-term care clearly fits the description of a potentially catastrophic cost that is fairly common, yet the market for private insurance is very small. Why is this the case? There are several possibilities.

The public may fully understand the risks associated with needing long-term care due to AD, and most may choose to self-insure via family caregiving, turning to Medicaid via spend down if necessary. Arguing against this conclusion is the myopia of many persons in thinking about long-term care.

Long-term care insurance may simply be too expensive for many persons, hence the low rates of coverage. It is also possible that many North Carolinians have not thought clearly about long-term care insurance (myopia), but would choose not to purchase it even if they did because of its cost. For example, the median wealth of households headed by persons age 70 and older across the nation in 1998 was around $35,000 according to the Asset and Health Dynamics among the Oldest Old (AHEAD) database, a nationally representative survey of elders. At such low rates of wealth (less than the cost of one year in a nursing home), long-term care insurance is neither affordable, nor reasonable, from a wealth-protection perspective. The North Carolina Department of Insurance consumer guidelines for the purchase of long-term care insurance advises persons with less than $100,000 of wealth (excluding their house, which is generally exempt from Medicaid spend down rules) against the purchase of such insurance. According to the AHEAD survey, persons at the 80th percentile of overall wealth had just $60,000 of non-housing wealth, on average, meaning that no more than 15% of the population might be expected to reasonably purchase long-term care insurance using the North Carolina Department of Insurance's conservative guidelines. Long-term care insurance can offer protection against catastrophic costs and can provide some control in where and how a person with AD receives care, but the vast majority of North Carolinians can't afford such coverage.

Long-term care insurance premiums are cheaper if purchased at a younger age. Persons who begin thinking about their need for long-term care in their 40s and 50s will therefore get a lower premium than will persons who purchase policies in later years. However, there is a subtle risk in purchasing long-term care insurance at younger ages due to the nature of the insurance products that are currently offered in the state of North Carolina (and in other states). Long-term care benefits are denominated in dollars per day, as opposed to care required, as is the case with major medical insurance. A 40-year-old purchasing a policy will most likely not use a long-term care insurance benefit for 30+ years. Even with a 5% annual inflation rider on a policy, which is the most common inflation protection chosen by consumers (policies sold in North Carolina must offer one of three types of inflation protection), the purchasing value of a policy will be substantially less than when enrollment occured if long-term care costs rise at just 5.1% annually for 30 or 40 years. Paradoxically, long-term care insurance purchased at younger ages provides lower premiums, more uncertainty with respect to what you are actually purchasing given the age at which most persons with AD need care, and perhaps a sense of unwarranted security.

There are at least two other motivations other than asset protection for purchasing long-term care insurance—control over some aspect of future care needs uncertainty and protecting family members from having to provide care. Long-term care insurance provides control over where long-term care is received and affords an individual the maximum amount of choice in receiving such care. In addition, long-term care insurance can prevent family members from having to provide care if needed. While many families may prefer to provide long-term care informally, others may explicitly not want to take this route for a variety of reasons, including the negative effect that caregiving has been shown to have on many caregivers. However, in order to act upon such motivations, an individual or family must have the financial resources necessary to afford such policies.

In the end, it is likely that only 15% or less of middle-aged or elderly persons in North Carolina might conceivably purchase long-term care insurance, based on wealth and income levels necessary to afford such a policy. The state Department of Insurance has some excellent materials on its Website, www.ncshiip.com, to guide consumers in considering whether or not to purchase long-term care insurance. The biggest advancement would be for more long-term care insurance policies to be denominated in terms of care provided, instead of dollars per day. In this way, the time/risk uncertainty involved with purchasing policies at younger ages when premiums are lower would be reduced.

AD is a large and growing concern for the people of North Carolina and the nation as the cost of this disease for society is enormous. Future advances in diagnosis and treatment are hoped for, but the fruition of same is uncertain. In the meantime, society must more clearly understand the costs of AD, and particularly the degree to which a large portion is borne by the intergenerational household of those affected with the disease. A societal discussion is needed to determine whether we will continue to let the epidemiology of the disease spread this part of the burden or whether society would be better served to develop a direct means of spreading these costs in a more systematic manner. Such discussions are needed every bit as much as research designed to develop new treatments for AD. State-level experimentation is often the preferred approach to tackling difficult policy issues. What will North Carolina do? **NCMJ**

The Alzheimer's Association National Policy Agenda

Bonnie Hogue Duffy, MA

The evidence presented in Donald Taylor's Issue Brief is a compelling call for action.[1] The Alzheimer's Association has a plan that includes a major mobilization of people and significant new resources. The Association is prepared to lead the fight, but the nation needs the leadership of the President and the Congress as well. We call upon Congress and the Administration to take action in three key areas:

(1) Increase funding for Alzheimer's research at the National Institutes of Health (NIH) to $1 billion annually as quickly as possible;
(2) Protect Medicaid funding levels and improve quality of long-term care; and,
(3) Implement the new Medicare Modernization Act in ways that meet the needs of people with Alzheimer's disease and improve the Medicare program so that it better meets the needs of people with dementia and other chronic conditions.

Research Funding

In 1983, when President Ronald Reagan first designated November as National Alzheimer's Disease Month, the extent of the disease was not widely known. At that time, a definitive diagnosis could be confirmed only via an autopsy and there was no infrastructure for Alzheimer's research. Twenty years of investment in research through NIH has resulted in steady scientific progress and advances no one would have imagined in 1983. We are well into an era of discovery that has already brought us tangible benefits.

It is now possible to diagnose Alzheimer's with more than 90% accuracy. Understanding of the fundamental neurobiology of the disease and its impact on the brain is developing rapidly. Identification of potential points of therapeutic intervention has accelerated the search for new treatments. Several animal models mimicking some aspects of the disease are available to researchers, enabling scientists to narrow the targets for prevention and speed effective drugs to market. Five prescription medicines specifically approved to treat Alzheimer's are available in pharmacies. Three genes that cause rare, early-onset forms of the disease, and one risk gene for the more common, late-onset form, have been identified.

Current research is focused on the importance of identifying and treating Alzheimer's disease at much earlier stages, before the symptoms of the disease emerge. Additional strategies for slowing the progression of the disease process—to postpone onset of and hopefully prevent full-blown Alzheimer's—are under investigation. Advanced technologies, including neuroimaging techniques such as magnetic resonance imaging (MRI), functional MRI, and positron emission tomography (PET) are expanding possibilities for early detection and intervention.

The best treatment, for individuals, for the healthcare system and for the public health system, is prevention. If science could delay the onset of Alzheimer's by even five years, the number of individuals with the disease could be reduced by as much as 50% over time. The key to realizing a future without Alzheimer's disease is finding a way to prevent the disease. Scientists are closing in on this goal because of the past investment in research by the federal government, private funders like the Alzheimer's Association, and the pharmaceutical industry.

To ensure that rapid progress continues, additional resources are needed in all sectors, but especially at the NIH. If current federal funding for Alzheimer's research were increased to $1 billion annually, substantial progress could be made on the most promising leads in basic science, risk factors, early markers, and clinical trials to develop new treatments and prevention.

> *"If science could delay the onset of Alzheimer's by even five years, the number of individuals with the disease could be reduced by as much as 50% over time."*

Bonnie Hogue Duffy, MA is the Director of Federal Policy for the national Alzheimer's Association. She can be reached at Bonnie.Duffy@alz.org or 1319 F Street NW, Suite 710, Washington, DC 20004. Telephone: 202.393.7737.

The National Institute on Aging (NIA) has undertaken two promising efforts, among many others, on genetics and imaging. While we maintain hope about our ability to slow the progression of and one day prevent Alzheimer's disease, we must also invest in research that will speed the discovery of risk-factor genes for late-onset Alzheimer's, the most common form of the disease. Discovery of risk-factor genes will help illuminate the underlying processes of Alzheimer's disease, open up novel areas of research, and identify new targets for drug therapy. NIA and the Alzheimer's Association are in the process of recruiting at least 1,000 families over the next three years to create the nation's largest repository of genetic material from families affected by late-onset Alzheimer's disease.

NIA, in partnership with the pharmaceutical industry, the Alzheimer's Association and the Food and Drug Administration (FDA), is also engaged in a new initiative using imaging technologies to monitor changes in the brain that indicate progression of Alzheimer's disease and to provide accurate, early diagnosis. We are hopeful that this initiative will lead to better diagnostic techniques. More importantly, the imaging initiative may help speed up the process of discovering new, more effective treatments and preventive agents for Alzheimer's disease by allowing scientists to detect the effects of interventions on brain function much more quickly than traditional clinical trials without the use of imaging.

> *"Twenty years of investment in research through NIH has resulted in steady scientific progress and advances no one would have imagined in 1983. We are well into an era of discovery that has already brought us tangible benefits."*

A significant, immediate investment in Alzheimer's research could save lives and money. Increasing funding for Alzheimer's research will increase the pace of discoveries that can delay the onset of the disease and slow its progression. If annual research funding of $1 billion for the next five years resulted in modest delays in onset and slowing of progression of AD by 2010, the return on investment in 2015 could be as high as $13 for each federal dollar spent on research. By 2025 the return could be as high as $28 to $1 and by 2050 it could be $100 to $1. Under this scenario, annual Medicare savings could reach $51 billion and saving in Medicaid spending on nursing home care could be $10 billion by 2015.[2]

Only Congress and the President, through a significant addition of new funding, can assure that we realize the opportunities in Alzheimer's research. Minimal increases in funding for the NIH are not enough to support additional clinical trials and maintain the momentum of basic scientific discovery. Inadequate funding increases mean that less money will be available to support new research grants and clinical trials, delaying scientific discoveries, and resulting in lost opportunities.

Medicare

Because of their impaired memory, judgment, and reasoning ability, Medicare beneficiaries with advanced Alzheimer's disease or other dementias cannot completely manage or direct their own care. As Alzheimer's progresses, individuals with the disease cannot follow the medication instructions or nutritional regimes prescribed by their doctors, nor can they recognize symptoms that their condition may be getting out of control. Individuals with dementia need ongoing care management to monitor their health status and prevent the acute care crises that are driving up Medicare costs today.

Alzheimer's disease is a major contributor to rising Medicare costs. Ninety-five percent of all beneficiaries with dementia have at least one other chronic health condition common in the elderly —30% have coronary heart disease, 28% have congestive heart failure, and 21% have diabetes. Medicare costs for beneficiaries with dementia and other chronic conditions such as coronary heart disease, congestive heart failure, or diabetes are twice as high as costs for beneficiaries with chronic conditions who do not have dementia.

One of the most effective ways to restructure Medicare in the short term is to establish a care coordination benefit targeted to individuals with complex chronic conditions, including Alzheimer's or other dementia. A Medicare chronic care benefit should include: payments to the beneficiary's primary healthcare provider for an initial assessment of health status; development of a coordinated care plan; and care management activities including coordination of clinical care across providers, medication management, multidisciplinary care conferences, and ongoing consultation with the beneficiary and his/her caregivers.

Care coordination is very different from disease management programs that focus on managing only one aspect of an individual's overall health status at a time. Care coordination focuses on managing an individual's care needs across various healthcare settings and among different providers to avoid adverse medical events exacerbated by the presence of multiple chronic conditions.

Passage of the *Medicare Prescription Drug & Modernization Act* will, for the first time, provide Medicare beneficiaries with Alzheimer's disease critically needed coverage for prescription drugs. This is an historic accomplishment that provides both up-front and catastrophic coverage of prescription drugs and offers subsidies to help protect low-income Medicare beneficiaries. The Alzheimer's Association believes that the addition of the prescription drug benefit moves the Medicare program in the right direction. The Alzheimer's Association, however, will be vigilant in overseeing the implementation of this new benefit in an effort to make sure this benefit meets the needs of people with Alzheimer's disease.

Medicaid

Medicaid is the single largest public payer for long-term care services in the United States and a last resort for persons with Alzheimer's who have no other way to pay for the help they need. Half of all Medicare beneficiaries with Alzheimer's also received Medicaid to help pay for long-term care, prescription drugs and other medical care because they have exhausted their own resources and qualify for assistance. In 2000, Medicaid spent an estimated $19 billion on nursing home care for people with Alzheimer's. Medicaid nursing home expenditures for persons with Alzheimer's are projected to rise to $118 billion by 2050—a more than six-fold increase over current spending.[2]

In the absence of a better national long-term care program, Congress and the President must preserve the long-term care safety net that Medicaid provides. This includes maintaining or improving the federal entitlement to benefits, and preserving existing nursing home quality standards as well as protections against spousal impoverishment. Reform proposals that cap Medicaid funding as a method of giving states more flexibility regarding benefits and services will leave many of society's most vulnerable citizens in jeopardy.

Conclusion

Without a cure, the number of Americans with Alzheimer's—4.5 million today—will increase to between 11.2 million and 16 million by 2050. Without a cure, the incalculable human costs will continue to rise—the pain of seeing loved ones suffer and the lost contributions of millions of older Americans who would otherwise enrich us as a people. The time to act is now.

There is real hope for a future without Alzheimer's disease. Greater understanding of the disease, improved care and treatment, and unprecedented scientific opportunities for delaying onset and preventing the disease can all lead to a future where Alzheimer's is just a memory. By investing in Alzheimer's research, President Bush and Congress can ensure that the scientific opportunities that lie before us are realized. And by improving the Medicare and Medicaid programs, Congress will help the 4.5 million people living with Alzheimer's get the care they need. **NCMJ**

SPECIAL INTERVIEW

Alzheimer's and the Caregiver

Donald L. Madison, MD (with Myron H. Green)

Sadie Green's eyes are closed. She chews, swallows, and opens her mouth when her husband brings another forkful of syrup-soaked pancake near it. She chews each mouthful eagerly, the way anyone who likes pancakes and syrup would. But she doesn't otherwise respond; and her eyes stay closed, as they have for the better part of the past year.

She is 72 and has Alzheimer's disease, a malady named for the German psychiatrist, Alois Alzheimer, who in 1906 first described the characteristic changes in the brain tissue of a woman who had died of an unusual kind of mental illness.

Sadie also has Parkinson's disease, another "named for" malady, this one after the English general practitioner (and social reformer and political activist) James Parkinson. Parkinson described the disease in his "Essay on the Shaking Palsy" (1817), which is a model of the kind of detailed clinical description that made up so much of the medical literature of his time (and would for another 100 years).

Unlike Alzheimer, who observed a single patient's clinical course and later correlated it with the morbid anatomy of her brain, Parkinson relied on the clarity of his description of six clinical cases. And because his description seemed fresh and new to the medical profession, it commanded their attention. Sixty years later, the French neurologist Jean-Martin Charcot applied the name *la maladie de Parkinson*. And that is what we call it still today.

Parkinson said that the disease leaves the "senses and intellect... uninjured," even though some of his case histories revealed mental disturbance. (It is now believed that up to one-half of Parkinson's disease patients show mild to moderate dementia.) Perhaps Parkinson allowed this discrepancy to stand because he wished to emphasize that the dominant characteristic of the "Shaking Palsy" was the impairment of an involuntary function. Both Alzheimer's and Parkinson's result from degeneration of the brain—the cortex (the outermost region) and the sub-cortex. Alzheimer's is thought to affect the cortex primarily, and Parkinson's the sub-cortex primarily. But, since both diseases may affect both areas, it is usually presumed that the patient has Alzheimer's when the dominant symptoms represent defects of cognition; and when the dominant symptoms refer mainly to involuntary functions (but the patient at the same time shows defects of cognition), the diagnosis is Parkinson's Dementia.

"Presumed" is the key verb here; because both Alzheimer's and Parkinson's are presumptive diagnoses, which are confirmed only by examining the brain tissue in much the same way Dr. Alzheimer did in his laboratory in Munich. The recognizable behavior and clinical course of Alzheimer's are presumed to be accompanied by—and caused by—the characteristic amyloid plaques and neurofibrillary tangles in the cortex of the brain. But if they are not, it matters little to those who must provide the care. The criteria set down by those who first describe a disease, name it, or alter the understanding of it from later experience and investigation, are not so important to the "consumers" of the disease. Their experiences consist mainly of a gradual loss of function in the case of the patient, or in the case of the caregiver, of the work—the daily mundane routine—of nursing. Therefore, while the question of whether Sadie Green has Alzheimer's Disease or Parkinson's Dementia may be important to sticklers for correct clinical nomenclature and pathological criteria, it isn't nearly so important to Pete Green, her husband and caregiver. For once it is known that her illness is chronic, and that it is some variety of what used to be called "senile dementia" or "organic brain syndrome"—it doesn't matter much which variety it is—not to Pete, whose goal is to give comfort, not to cure.

Myron "Pete" Green grew up on the north side of Pittsburgh, the next to youngest of six children in a working class family. His parents did not name him "Pete." That familiar name was the result of a mispronunciation (by a toddler sibling) that stuck. Pete's mother kept house; his father worked for Jones and Laughlin Steel as a locomotive engineer on the company-owned "short line" that hauled steel between mills. (J&L operated on both sides of the Monongahela River in the south Pittsburgh area and a company railroad bridge spanned the River.) Following high school, Pete enrolled in the local north side college—Duquesne University—intending to

---

Donald L. Madison, MD, is a professor of Social Medicine in the University of North Carolina (UNC) School of Medicine and Contributing Editor for the North Carolina Medical Journal. He can be reached at donmad@med.unc.edu or at the Department of Social Medicine, UNC School of Medicine, CB# 7240, Chapel Hill, NC 27500-7240. Telephone: 919-962-1140.

work toward a business degree. Sadie also grew up on Pittsburgh's north side. The two met one rainy night in a north side restaurant, where Sadie's sister was working as a waitress. Pete remembers:

> I knew her sister well, because most of us guys loafed in this restaurant. And I just happened to come in that evening. And her sister said that she was glad that I'd showed up because her daughter had been out shopping with her sister (Sadie) when it started to rain very hard, and they were stuck in the restaurant and needed a ride home. That would have been in 1953. We were married two years later, in February of '55. She's two years older than I am.

After they married, Pete dropped out of school.

> I had to get a job. After the first child came I got a second job, working part-time. And then when the second child came, I was able to get a job with an insurance firm; and they would help pay for my education as an insurance sales agent if I would take advantage of it, which I did. Eventually, I went back to Duquesne, and it took me another year and a half, while at the same time working full-time selling insurance. I graduated from Duquesne, then, in 1964—finally. It took a while.

He continued in insurance sales, completed all of the training programs offered by the Underwriting Training Council, and spent the next 33 years with Western-Southern Life, a company headquartered in Cincinnati. At first, Pete sold what was called "industrial insurance-weekly premium" life insurance. This was a product designed mainly for lower-wage, working class families. It was, in fact, the principal product of the life insurance industry in both North America and Great Britain from the latter half of the nineteenth century, continuing up until World War II. Brigades of insurance salesmen once plied the streets of working class urban neighborhoods selling life insurance and collecting the weekly premium. Pete tells how he did it:

> I was out every day. They would supply you with an area that they called a 'debit.'

And this was an area you could draw on a map?

> Exactly. And they would give you a 'debit book' that was 'routed,' so that you would be able to go through it without doubling back too much.

Like a paper route?

> Yes, except that everybody's insurance premiums were not due at the same time. Some people paid weekly. 'Weekly premium' means that you could pay by the week if you wanted to. If I could convince them to pay by the month I could cut down on my travel time. One of the commissions on that was that if you sold one dollar of weekly premium you would make twenty dollars. So it looked quite enticing. You'd get out there and if you wrote five dollars of weekly premium in a day, you're making some money. But now, the company that I was with, they haven't exactly done away with the industrial insurance—they still carry it—but they don't market it any more. They honor the ones that are in force, but they don't collect at your house. They don't do that any more. And if you fail to pay your premium, well...

Pete was soon promoted to assistant manager at the same Pittsburgh office where he had begun as a salesman, with seven sales reps assigned to him. In 1966 he was promoted again, to district sales manager in Reston, Virginia; and in 1974 he was transferred, laterally, to be the district sales manager at one of the largest offices in the company, in Royal Oak, Michigan, just north of Detroit. Pete and Sadie lived in Michigan for 18 years; they raised their five children there. Then, in 1990, Pete took early retirement.

> ...for a couple of reasons. I had a little mini-stroke. What is that called? A TI or what is it?

TIA-transient ischemic attack.

> Yes. And that kind of bothered me. And then Sadie was having some problems at the time, not knowing what they were. And she was diagnosed wrong. When I would go to their help groups and I would hear what was going on, it wasn't at all like her. And I would tell her doctor that, and he would get mad at me and tell me that he was the doctor and he knew what he was doing. And so I listened to what he had to say.

As a young woman in Pittsburgh, Sadie did occasional modeling work. This portrait hangs in the Greens' living room.

After Pete retired the Greens stayed in Michigan two more years before moving to North Carolina. Some time earlier they had purchased a town house in Durham (near where Pete's brother was living) and rented it out. The plan was that when Pete retired they would move into that town house. They did so in 1992. None of the Greens' five children and 12 grandchildren live nearby. The children are all in Michigan or California. So after Pete and Sadie retired to North Carolina, they were alone and together, for better or worse. The couple didn't stay long in the town house.

> By the time we moved in Sadie was starting to get really ill. And it was a two-story town house, and a small one, and she would just not go upstairs. Well, one day we decided to take a little ride and drove down the road and came down through here. And the young couple that owned this house—they were the original owners—he was putting a sign out on the front lawn, 'For Sale by Owner.' So we came in, and my wife stood at the doorway—she didn't even go into the back or anywhere. She said, 'I want this house.' So she went out and took the sign out of the lawn and put it in the car. I said, 'I guess I've got a house.' That was 11 years ago. And I'm glad we bought this house, because it's all on one floor. It's a lot easier.

Newlyweds, 1955

I'm wondering... You said earlier that Sadie was having some problems back in Michigan, and that she saw a doctor. What was the reason she went to see the doctor then?

> She was having convulsions. She would get short of breath and start shaking, and sweating, and her pulse would race. And I took her to several doctors. And of course they would send her to another doctor. And we wound up with this one who said that he knew what was happening. He said she was manic-depressive. But I didn't think it was that. And he had her on some drugs; one was Paxil®—I think that's the name. Does that sound right?

Yes, it's a drug used to treat depression and anxiety attacks.

> But they had her on these drugs, and she was way out in left field. You would talk to her and she just wasn't there... just wasn't there. And she was like that for quite a while, until we moved down here. And I didn't know where to go, and so we went to Duke. And they had done all kinds of tests on her—sleep disorder, everything. And then she finally wound up at the Memory Disorder Clinic, with Dr. Donald Schmechel (Professor of Medicine and Neurology and Director of the Clinic). And he discovered through... It wasn't an X-ray; they put you through that machine?

MRI? (magnetic resonance imaging)

> MRI, that's it. And he showed me the picture of the back of her head. And there was a hole that had developed. And he said that she has Alzheimer's. He said, 'We can diagnose it as Alzheimer's, but we really don't know, because the only way we can find out for sure is... if and when she becomes deceased, if you donate the brain, we can dissect it and tell.' But he said that in his professional opinion she has it.

So she is presumably Alzheimer's.

> Exactly. And she has developed some Parkinson's now, too. That's the diagnosis that she has.

Pete says that after the move to Durham, when Sadie was taken off the earlier drugs:

> She could laugh, she could carry on a little bit of conversation with you, she would watch television, where before she'd be watching it but not really. And by this time she was losing her memory. That was already happening when we were in Michigan. She would forget where she put things.

I'm wondering if the convulsions stopped—either back in Michigan when she took that first drug, or after that?

> No, they never stopped. In fact, they were more severe. That's one reason why her doctor up there in Michigan and I... why I'd get a little upset with him. Because nothing was happening with that. But, Dr. Schmechel put her on Neurontin® (gabapentin) and then the convulsions subsided. They didn't stop right away, but they were less severe and less frequent. And now, the last convulsion she had was probably about three years ago.

And that's the only medication she's on now except for a beta-blocker—those two.

But since she doesn't talk anymore, I don't know when she's having pain. I called Dr. Sheline (Barbara Sheline, family physician on the Duke faculty) a few weeks ago because she was crying out in pain. Usually, I have no idea if she's in pain. But I've learned how to read her face. I look right here between her eyes, and if that forehead's kind of squished up, she's thinking something that's bothering her, or she's having some pain.

So now, you rely on yourself. And Dr. Sheline may call once in a while. How often?

Only when I call her. When I need her she'll come. When hospice discharged Sadie, Dr. Sheline told me to call her—a long time ago. She said, "Call me at home." She only lives ten minutes from here. But I always hesitated to do that, because I didn't want to take advantage of her. I just didn't feel that was proper for me to do.

Well, that's the straw she chose—to be called. She could have gone into dermatology. No one would call her then.

She could have. But, anyhow, I didn't want to call her. And things were going fine until several weeks ago, when Sadie was in pain, terrible pain, and I had no idea where it was at or anything. So I called Dr. Sheline. She came over Saturday morning. And she spent quite a while here. And she checked her all out. She said she had a slight bit of pneumonia in her right lung. And then we came in the living room here and talked for a while, and she said that her heart is relatively strong and her blood pressure is pretty good. And she said that when she does pass away it will probably be pneumonia. Because she's inactive.

How would you describe Sadie's condition at the time you bought this house, 11 years ago? I'm wondering if she required any care then?

She was able to walk, but she was very forgetful. Although if you had known her 11 years ago, you wouldn't know, unless you spent time here and then you would be able to detect some of the things that were going on... She looked normal, and walked normal, and talked to you. But, then she would forget something she had done 15 minutes before. Not always, but often. And she needed to be watched.

What do you mean?

To make sure that if she was going to the bathroom... I had to make sure that when she walked down the hall that she went to the bathroom, because if this chair was setting there, as she walked past the chair, she would sit down and go to the bathroom. So I had to keep my eye on her as to what she was doing and where she was going. And that would happen quite often. But as long as she was parked, she was fine.

What if you needed to go somewhere—to run an errand? Did you leave her here?

No, I'd take her with me. Well, she could be left here for a short period of time and not have too much of a problem. But then I'd have to stop and think: What if she lit the stove? And what if she did this, and what if she did that? So I'd take her with me.

Were there any times when you left her alone a little while, thinking she would be all right, but it turned out badly?

Sadie in the mid-1970s

Yes, once. I had a medical appointment over at Duke, and I had nobody to be with her. So I went over to get my X-ray or whatever they were going to do. And she stayed home. That's probably been nine years ago. I came home, and she wasn't here. I had been gone an hour, less than an hour. I looked in the showers; I looked under the beds; I looked everywhere. I couldn't find her. So I called the Sheriff. And the Sheriff said, 'Well, before you get really excited, take a walk through your subdivision while we get a car over there. See if you can find her.' Well, I was going to go that way, but I went this way, and I went around the back, to the town houses. And she was standing in the middle of the road. And all the neighbors were out working, so nobody was there to see her. And she was as red as fire. She was crying. She had wet herself. So I brought her back home, and changed her clothes for her, put her in bed, and put a cold washcloth on her head. What happened was she went out and sat on the front porch. And the door was not all the way open; it was

> halfway open. And a UPS truck came up the street for a delivery next door. And he seen her sitting on the porch, because nobody was home next door, and he asked her if she would take this package for them, which she did. And she told me this. She went to come back in the house, and when she opened the storm door the vacuum pulled the wooden door shut, and it was locked. But the back door was open. And she said, 'I just wanted to find you, so I went to look for you.' So I'm very fortunate that she turned this way into the cul-de-sac area, because if she had gone straight ahead that way, she would have been down on the main road where there is traffic. She may have been in trouble then. So that was about the last time she's been out of my sight.

And that is the only time she's been lost?

> Yes. But she's been confused many times. I had to put a rope... had to rope off the bedroom so that she wouldn't go past that rope, because she would sit on the edge of the bed and go to the bathroom. She wouldn't know where she was at.

As Sadie's condition deteriorated to the point where she was no longer responding, she was admitted to hospice. But hospice care comes with a term limit that is based on the expectation that the patient will die within a short time. Sadie did not die, however, and she was discharged last May. I asked Pete to describe the range of services that hospice provided.

> A nurse would come once a week to check the vitals. A nurse's aide would come once a day to give her a bath, even on the weekends. And the social worker would come maybe every six or seven weeks.

And since she's been discharged, have you done all of that yourself?

> Yes. Except that the two male nurses who are neighbors come in once and a while to check her blood pressure for me, and listen to her heart, when I ask them to. I keep charts on her—on everything I do, every day. I keep track of everything, and I can tell you... Here's where one of the nurses was over on July the fourth. Her blood pressure was 142 over 68. Her pulse was 60. 'Lung sounds...' I don't know what he put down here— 'coarse crackles.' So I keep track of everything. And I started doing that because when hospice came in the nurse would ask me some things. I'd have so many things going on... And I have so many things about Alzheimer's on my computer. Every time I find something new I put it in my favorite ones, and then I read all about it. I read how to turn her in bed and how to change the bedclothes and how to do all that. I read it and then I go in there and refresh my memory on a lot of that stuff. Of course, when hospice was in I watched them and what they did, too. So it taught me quite a bit.

But 11 years ago the care you were giving Sadie amounted mostly to keeping an eye out, watching when she got up to make sure she was headed to the right place, and so on. At some point the amount of care she required increased. I'm wondering what came next?

> Her inability to walk properly. She would trip over things... and fall. Finally, I got her one of those aluminum walkers. And she would walk with that. But then she would have difficulty with it because she would lean backwards instead of forwards, and she would fall backwards. And then, of course, after that I bought a wheelchair. That walking problem started maybe six, eight years ago, and she kept getting progressively worse. And so about five years ago I bought what they call a transport chair, with the smaller wheels on it—lightweight. I bought that. And then three years ago I had a ramp put out there on my back deck. I didn't want it in the front. And then I had a sidewalk put in.

So, up until five years ago she could still walk, although with difficulty. After that she could no longer walk and had to be transported in the chair. Could she tell you then when she needed to go to the bathroom?

> Yes, she would tell me, or I would know it was time. And I would take her in the back. In fact, I had the bathroom—the one in the room she's in, which is our master bedroom—it's her room now... the bathroom in there had a tub and a commode, and it was small. I had the wall knocked out and had the bathroom enlarged, had the tub ripped out, and put a shower in. And I bought a sliding bath chair. And I would set her in it, and I'd slide her into the shower, and then I'd get in the shower and wash her hair, and then slide her back out, dry her, and then bring her out here and put her in the chair, and she would sit there and either sleep or watch TV. But now I bathe her in bed. She doesn't get out of bed now. I stopped using the shower with her when I had my surgery (coronary bypass) two years ago, because they said I couldn't pick up anything over 30 pounds. I didn't have anybody here. Our youngest daughter came down and stayed for three months. She works at Home Depot, and she transferred down to this Home Depot in order to take care of Sadie. But she couldn't get her out of bed to put her into the shower.

Who would be here when you were in the hospital, or recuperating later, and your daughter was at work?

> When I was having my surgery I had my family down here. But it was when I was recuperating, after everybody left, and I hadn't reached room temperature... But

hospice was here then, and I was here, and I was able to call if I needed any help. I was able to feed her, and I was able to do little things—most things, except pick up heavy things. I was able to make her lunch and make her dinner, and my daughter was within calling distance at Home Depot. If I needed her she would come home.

But now, since May of this year (2004), when hospice discharged Sadie, you have been her sole caretaker?

Yes. I bathe her; I feed her; I change her clothes; I change the bed clothing on the bed. Everything that hospice did, I do now. Before that, when hospice came, I didn't bathe her in bed. Before she had to be bathed in bed I did bathe her, though.

Of all the caretaking tasks that you perform on a regular basis, which is your biggest challenge?

Bathing.

How long does it take?

Well, when I started I think it took all day.

Literally? All day?

No, I'm exaggerating. But it took quite a while, because I never did it before—at least an hour and a half, maybe two hours. And why it took so long was that she would become rigid, hold her arms down. And I would try to pull her arms up, and she would get mad, and then she'd holler. And I'm thinking, I'm hurting her. And it just became a hassle. But then, as I kept doing it and trying to schedule, I figured I didn't have to bathe her every day because she's not getting dirty. Hospice was doing it, and different ladies would come, and they were experienced in what they were doing. So I had to figure out what I was going to do, because I can't bathe her every day or I would have become a basket case myself. So I scheduled that I would bathe her every other day. But that wasn't working out either. I was falling short on laundry and... It just wasn't working for me. Now I have it down to where I bathe her on Monday morning and Saturday morning. That's when I bathe her. And I change the bed clothing—unless they get soiled—once a week. Because she sleeps on waterproof pads. I put them over the sheet, so the sheet does not get soiled, unless there's a leakage or something when I'm changing her and I happen to get some on her. Then I'll change the bed. I learned how to take a fitted sheet and hook the corner on the top, and hook the corner on the bottom, roll her over and stuff it under, roll her back and hook the other side. I'm an expert. And I haven't even been in the Army! I'm an expert at it. I can bathe her in bed. I can change the bed

clothing in bed. I can shampoo her hair in bed. Once every three weeks I put...she gets that cradle cap—like little babies do—and I put the cradle cap conditioning on, and I comb all the flakes out. So... I need care! I take good care of her, though.

When you were observing the hospice people bathe her, did she get rigid and cry out then during the bath?

I never really noticed that. But after I'd bathe her I would often sit down and think: How did they do it? I'm sure they had problems, though, because she still does that. I have to figure out how to get her arms and slowly move them down to her side, while I talk to her. 'I'm going to wash your tummy now, so you've got to keep your arms down here.' And as soon as I get them down and I turn around to get the washcloth, I see that arm coming back up again. She hears. And she understands. But it takes a while for a lot of things to register. I don't say it just once. I have to keep reminding her. And I have to say, 'OK, now, the washcloth is going to be warm, not hot.' This morning when I was bathing her I put a waterproof pad under her legs, and then I would take the pillow, flatten the bed, take the pillow out, and then I take another waterproof pad and roll the corner, roll it towards her. And she starts screaming. I don't know why. And her arm was up. She just got frightened, I think. I had to keep talking to her, and tell her, 'I'm not going to hurt you. I'm not hurting you. Everything's fine.' But that doesn't happen every time. But she does hear. That's why I refrain from talking about anything in reference to her in the bedroom. And when people are over, when neighbors are over, if they ask me a question that I think is not right for me to answer in front of her, I won't answer it then. I'll tell them in the other room.

When do you feed her?

> She has her breakfast in the morning. Then she has a snack in the afternoon. Then her dinner is about 5:30. Then in the evening about 8:30 I give her a Creamsicle. She loves Creamsicle. Then she's good for the night. I change her underwear first thing in the morning. Cause I don't want her lying in it until I get her breakfast, so I change her first thing in the morning. And then after I feed her breakfast, probably about an hour later, I go in and check her. And most of the time she needs to be changed then. Then I change her at dinnertime before I go to bed. And then every other day I have to give her a suppository. She'll have a bowel movement that'll be just a smudge. I buy the overnight fitted, throwaway underwear with the tapes on the sides. They're diapers. And that's what she wears. And, of course, she's on a waterproof pad, too, in case they leak. And I'm an expert at that, too. I can line it and roll her, and everything is exactly where I need it.

If you needed to go out for an hour or so this afternoon, what sort of arrangement could you make?

> I have a schedule. Mondays, I don't have nothing scheduled to do. It's a bath day. And I also have things to do around the house, maybe cut the grass or whatever. But today (Monday) I did go out. My neighbor, the nurse, came over and sat while I ran to the bank. And then I went to the drugstore to pick up her prescription and came right back. But that's only because my neighbor was home, and I was able to do that. Most Mondays I'm here all day doing what I have to do around the house. On Tuesday I have a sitter that comes in from 1:00 to 3:00 or maybe 3:30. And I run my errands at that time; and even if I don't have no errands, at least I can get out for a little while. I'm on the executive board of the Helping Hand of Chapel Hill, and this lady, she's been coming over here for the last two years on Tuesdays, she's like a member of the family, a very nice lady. And then on Wednesday I have the hospice volunteer from before hospice discharged Sadie. He's a retired professor from Duke, a wonderful elderly gentleman. But we knew him before, when we lived over in the town house. And it was amazing that he was with hospice when Sadie was in there. But he said that he wasn't going to stop coming here (after hospice discharged her); he was going to come on Wednesdays, because he just wants to do that. So he comes on Wednesday, gets here about 12:30, and I'm back here by 3:00 or 3:30. And Wednesday is doing some errands that I didn't have a chance to get to on Tuesday. And then Thursday is the most delightful day of the whole week. And that's grocery shopping—with all these elderly old ladies—at Harris Teeter. So I do my grocery shopping on Thursday. I have a sitter from UNC, a young lady who volunteers through the Helping Hand to sit while I go grocery shopping. And, of course, Friday I'm home all day, Saturday I'm home all day. Sunday I'm home all day—unless one of the neighbors stops in, and I may run down to the drugstore or something. Now, Sunday... there was a lady who was a nanny here in the neighborhood, and now she's... well, she's still a nanny. She's in her 70s, and she's been a very good friend of mine, and Sadie's, for about the last three or four years. She came here this past Sunday, and she fed Sadie for me while I went to the Wal-Mart—I had to pick up more diapers. So things like that will work out when I don't have anything scheduled. Somebody might stop by and tell me, 'If you have something to do, I have about an hour or so and...' We have a lot of friends here in the neighborhood. I was president of the homeowners' association here for seven years, so I know everybody.

Your past involvement in the neighborhood must make it easier for you to arrange this kind of help than it would for someone who wasn't that involved.

> That's true. And there's not a day that goes by that I don't have one or two neighbors who stop by.

Since May, when you've had to do all the bathing and bed changing and diaper changing and feeding—all of it yourself—have you noticed whether Sadie's condition has deteriorated further?

> It has. She shows more signs of something bothering her. And her eating habits have slowed way down. She doesn't eat as much. Although since Dr. Sheline was here a few weeks ago and put Sadie on some antibiotics for that pneumonia, her eating has picked up a wee bit. She's eating a little bit more than she did.
>
> This is a very difficult thing in life to do, to take care of somebody. And when this really got to the nitty-gritty of taking care of her, when I go back and think of the many developing problems that she's had over the years, it's a strange... I don't know whether it's strange, that's not the right word, but you find out that, number one, family backs away. Everybody wants to disappear. You might have one or two... But everybody backs away; they don't want the problem. And you get mad. You get mad at yourself. You get mad at God. You get mad at her. You know: 'Why are you doing this?' And I became confused. I didn't know what to do. I didn't know how to handle things. At least I thought I didn't. But when you finally accept—I'm just speaking for myself—when I finally accepted that this is the way she is, and she's going to need a lot of my help and attention; once I accepted that, what I do doesn't seem like nothing. Prior to that it was a lot of work. But I guess that's the way life is. Once you accept something it becomes a lot easier. **NCMJ**

COMMENTARY

Grieving the Living!

Linda E. Jordan, DMin, CT

Although the word "grief" is seldom used in the stories of families affected by Alzheimer's Disease (AD), it surely is woven into the entire fabric of the experience. Grief related to on-going AD is grief for the living, and it is often a disenfranchised grief. Our culture tends to devalue persons who grow to be nonproductive and dependent as is the case in AD; they are often stigmatized socially and marginalized relationally. The person who feels the pain of that devaluation and limbo status is the caregiver. In addition, the person with AD sometimes manifests unpredictable, inappropriate, and even indecent behaviors. These can be embarrassing to family members and intensify their pain and loss. Moreover, as long as the person with AD is alive, caregiver grief, though appropriate, is generally not recognized or sanctioned. The community is more likely to associate grief with a physical death. Yet, grieving the living is real; it is constant and complex; and it is important that caregivers receive help in managing it.

> *"...grieving the living is real; it is constant and complex; and it is important that caregivers receive help in managing it."*

When grief is acknowledged in AD, the concept most often used is *anticipatory grief*. Although this term has value, the losses incurred with AD are not just future; they are actual and profound in the present. Each pre-death loss in this progressive disease is compounded by all previous losses and introduces new tangible losses, as well as potential losses in the future.

In *Treatment of Complicated Grief* (1993), Therese Rando describes six grief processes that must be accomplished when loss occurs in order to integrate the loss successfully.[1] These processes are not linear, but are necessary tasks for the person in grief, and they can be useful to caregivers who experience pre-death losses. Being informed about these processes can assist healthcare providers in their care for family caregivers.

Acknowledging the Reality of the Loss

The goals of this process are to comprehend that the loss is permanent and irreversible and to understand the implications of that reality. For persons with AD, changes are often gradual, variable, and intermittent with good days and even lucid moments throughout, enabling caregivers to deny that loss is really happening. As the disorder progresses, it is natural for caregivers to want to believe that the deterioration is temporary and reversible, and it is complicated by the fact that the person is very present physically and frequently otherwise healthy. The death is psychological and is one which society does not tend to validate. Caregivers lose not only the person as they were prior to the disease, but also lose who they were with them. These secondary and symbolic losses, in addition to the physical ones, fluctuate and are re-experienced over and over again. Professionals can help by encouraging caregivers to identify the layers of loss, by confirming their grief, and by providing information that will help the caregiver assimilate the fact that the changes are real and permanent.

Experiencing the Pain

Healing can be accomplished only by contending with the emotional pain of a loss. Often caregivers of a person with AD are so consumed with the ever-growing list of caregiving tasks that they suppress their pain or do not take time to attend to it. Feelings such as anger, anxiety, and fatigue often go unexpressed when caregivers feel that they must maintain an atmosphere that is cheerful, calm, and optimistic. Unfortunately, our culture confuses care of self with selfishness, a position detrimental both to the caregiver and the person with AD.

Healthcare providers often try to rescue caregivers by trying to take away their pain instead of authenticating the gamut of strong and sometimes contradictory emotions. Providers will do well to remember that all emotions are energy in motion

and can work for caregivers instead of against them. In addition, prescribing regular self-care for caregivers needs to be considered part of every treatment plan in AD. Most caregivers find family support programs reduce their isolation while enhancing their personal self-care strategies.

Reviewing and Remembering the Person and the Relationship Realistically

The goals of this process are to identify unfinished business, enable a good goodbye, and alter the bonds of the relationship. AD makes this, at best, a challenge, especially in the moderate and severe stages of the disease when the mental faculties needed for resolution are often missing. Yet, caregivers can accomplish the process independently of the person with AD, because it is about caregivers doing their own work—making their peace, finding forgiveness, and marking the significance of the relationship. It is important that caregivers be encouraged to tell the stories of the person and of the relationship—positive and negative. And it is important to recognize that conflicted relationships are nonetheless significant. Allan Gurganas, a North Carolina author, once told me, "Always remember that the story knows more than the storyteller." To tell the stories of the relationship can restore wholeness in the midst of brokenness. To tell the stories of the past informs the present and the future. In telling the stories, caregivers can find ways to alter the bonds of the relationship in ways that simultaneously allow them to stay connected and to let go.

Adjusting to the Environment Where the Person Is Missing

The usual goal of this process is to learn how to be in the world without a person who has died. However, the caregiver of a person with AD has to adjust to a new environment while the person is physically present and in need of emotional and physical care. Persons with AD never will be their "old selves" again; neither will the family unit. Caregivers are forced into additional roles and stresses that they did not choose and do not want. They have to revise their own identity, find different ways to define self-worth and pleasure, and learn new ways of thinking and relating to the person with AD. Adjusting to a new reality and relearning the world can be stressful; providers can patiently instill confidence in caregivers as they take these most difficult steps.

While counseling a husband whose wife had AD, I encouraged him to adjust to her new reality rather than trying to force her back into his reality—being with her mentally wherever she was. As he began to adjust to the new reality, he was able to sell their home of 40 years and move to a retirement facility where she had 24-hour care and he could still be near her while also having additional support for himself.

Revising the Assumptive World

Each of us has expectations of how things should be and should happen. When we adamantly declare that life is not fair, there is an assumption of what constitutes fairness, i.e., good things happen to good people. However, the goal of this process is to make sense of things NOW, not as we think they should be. When caregivers watch a vibrant personality disappear before their eyes, be unable to recall a rich life, and no longer recognize the familiar, they experience moments that do try their souls. Reeve Lindbergh, daughter of Ann Morrow Lindbergh, recounts a time when she shouted to her mother, who had AD, "Stop it. Don't abandon your principles... Don't be strange. Don't be weak..."[2]

This process of grief propels caregivers to re-define the values and core beliefs on which they can still base their lives. If they are religious, their faith can be a source of comfort and guidance as they encounter the mysteries of life and death. The essential movement is from "Why me?" to "What now?" Providers, without imposing their own values, can be instrumental in this transition. Again, Reeve Lindbergh's words are appropriate, "What we have is a day...We cannot make plans. We must live a border life and make concessions to both sides—a little life here, a little death there."[3]

Integrating the Loss and Reinvesting in a Meaningful Future

Throughout life, we are always integrating our losses—small and large. How we integrate these losses determines whether we move through life in despair or with gratitude. In the instance of AD, reinvestment means integrating not only what is lost, but also exploring what is still possible in the relationship. One woman with AD had played the piano for the children's department in her church for many years. When I entered her room one day she was singing a hymn so I joined her. She never changed her blank stare, but began singing in perfect alto harmony all the words of the hymn. I told her four adult daughters about this experience, and when they next visited, they spent almost an hour singing with their mother. In that brief time, they had part of their mother back and meaningful memories to recall in later years.

Additional Recommendations for Caregivers

Although the grief process in AD is complex, there are additional things that healthcare professionals can do to support caregivers of persons with AD and nurture their own emotional health and wellbeing.

One is *utilizing the health perspective*. It can be tempting to treat caregivers much like the person with AD—to foster dependency and to try to rescue them from pain. However, the health perspective recognizes that most people have the internal and external resources needed to integrate their losses into a meaningful future. Inherent health principles in framing this experience are: (1) pain and loss are normal, and grieving is a healthy way of taking care of ourselves; (2) each person has a unique style of doing grief work, and people have the right to interpret their loss and make choices that are right for them; (3) grief is a long process where small steps and partial accomplishments are enormous and should be affirmed; (4) grief is a healing process, not a disease. People have tremendous inner strengths to heal themselves if they are provided good information, a safe place to grieve, support for their journey, and reinforcement for their self-reliance.

Secondly, *creating a ritual* can be therapeutic. Society has not created rituals for pre-death grief, yet throughout history, rituals have helped families and nations mark numerous special events and sacred time. Rituals need not be equated with funerals and do not mean that the family is abandoning the person with AD. Instead, a family ceremony can be an intentional time designated for sharing present grief, remembering past joys, and strategizing future plans. Such an occasion can help family members address all of the six processes of grief discussed earlier and provide the momentum to reinvest in a new reality. Healthcare professionals can institute this practice as a standard of care and assist caregivers in designing an event that fits their needs. Families have an amazing capacity for creativity if given permission, assistance, and encouragement.

Finally, family caregivers can benefit from healthcare professionals directing them to *post-death bereavement services*. When physical death does occur in AD, often the grief reactions of survivors are again discounted because the disease has been so measured and the demands of caregiving have been considerable. Although death is frequently accompanied by a sense of relief, healthcare professionals tend to assume that the grief of AD is completed when the person dies; hence post-death grief is inadvertently disenfranchized. Not only is there the physical death of the person with AD to be dealt with, but there also can be the cumulative effects of a long-term and strenuous illness. Being knowledgeable about and supplying the family with information about specialized bereavement resources such as Duke Community Bereavement Services will be important in legitimizing post-death grief. In most communities, local hospices offer bereavement support to survivors whether or not they have been served by hospice.

Families are incredible. Ordinary people can face extraordinary hardships, and resilience is a more common outcome than defeat. Caregivers of persons with AD can be and have been examples of such invincible courage. **NCMJ**

Family Care and Alzheimer's Disease

What Do We Know? What Can We Do?

Lisa P. Gwyther, MSW, LCSW

Alzheimer's Family Care: What Do We Know?

Alzheimer's family care is intense, personal, and unrelenting. It has been compared to running a marathon without ever seeing the finish line. Alzheimer's has forced long-term care services and policy to move from a narrow "aging" focus to a "family" focus that is more inclusive of the person with dementia as well. National public awareness campaigns have accelerated recent consumer trends. Families as consumers and surrogate decision makers for their impaired relatives are demanding earlier and more comprehensive diagnosis and treatment of Alzheimer's or a related disorder. This growing family recognition of Alzheimer's costs to multiple generations is becoming clear to the public in advance of business and policy recognition.

Family care definitions have also moved beyond blood and co-residence to be more inclusive of other informal or faith-based community support programs and working family members who frequently become long-distance care decision-makers and care managers.

> *"Not only do Alzheimer's families face personal fears and risks of heritability, but they also face documented risks to their physical and emotional health from providing care."*

Research estimates suggest that 30% of persons with moderate to severe dementia live alone in the community, often relying upon close supervision and direct help from family members, neighbors, or friends who live close-by.[1] Primary, secondary, and even tertiary family caregivers have been identified in studies of diverse ethnic and racial groups caring for persons with Alzheimer's.[2] In contrast to persistent myths of family abandonment, research consistently finds more Alzheimer's family care in hospitals and nursing homes than at any time in our history, with persistent documented negative effects on family caregiver mental health even after nursing home placement or death of the person with dementia[3,4] Although persons with Alzheimer's disease living alone or in nursing homes are more likely to be older women who have literally outlived all family support, 70% of nursing home residents have involved family caregivers and the majority of these residents have some form of dementia.

Even in the best of families, for whom Alzheimer's care is knowledgeably and willingly undertaken, and when there are personal testimonials about meaningful gratification in providing such care,[5] the "wear and tear" and prolonged strain of constant supervision have been shown to have negative consequences on health, family relationships, and future financial security of surviving family members. Research on Alzheimer's family care was the first to document the significant proportion of male (primarily husband caregivers) often overlooked in general studies of family caregiving as a predominantly women's issue.

We have long known that there is increased risk of late-onset Alzheimer's disease when one has two or more first degree relatives with Alzheimer's. Not only do Alzheimer's families face personal fears and risks of heritability, but they also face documented risks to their physical and emotional health from providing care. Providing more than nine hours of care per week for a relative with Alzheimer's disease has been associated with a two-fold increased risk relative to non-caregivers of coronary heart disease (CHD), hypertension, poor immune function, slow wound

She can be reached at lpg@geri.duke.edu or 3600 DUMC, Durham, NC 27710. Telephone: 919-660-7510 or toll-free at 800-646-2028.

healing, low perceived health, depression and anxiety, exacerbation of chronic illness, and even premature death.[6]

Physicians also hear from anguished family members fretting from afar about relatives with dementia. One son laments,

> How can I know what's really going on? When I call, they say "we're fine," but I see changes. When I make suggestions to my sister, she reacts with "why don't you take them?" Crisis calls tear me up. I'm helpless, trapped, grieving. I catch myself relieved to be 3,000 miles away... and guilty about it.

Even families who have resources for extensive medical treatment and personalized home care still wonder, as Reeve Lindbergh did in caring for her mother, Anne Morrow Lindbergh, when she was dying with dementia,

> No matter how good the medical care, attention or money lavished on our beloved mother... we feel guilty because our presence doesn't seem to help... it is never enough.[7]

The Duke Aging Center's research on Alzheimer's family care documents that families make decisions about use of paid or voluntary services based on subjective perceptions of whether help from other family members or friends is "dependable, sufficient, or enough." Older spouses often "wait" for physician "prescriptions" for outside help, and they are frequently disappointed by cavalier recommendations to "look for nursing homes," which many families perceive as medical abandonment. Each family member has his/her own definition of what constitutes "dependable and sufficient quality care." This variability and complexity among family caregivers limits the effectiveness of Alzheimer's "disease management protocols" applied outside the context of family assessment. Practice guidelines for Alzheimer's disease management must consider care context as well as patient variables.

Alzheimer's Family Care Is Complex

Although no two family care situations will necessarily respond to a single, linear disease management algorithm or protocol, each family caregiver at some point will have to:

- Define and negotiate complex situations and decisions: Whose needs? How much help is adequate or enough? How long can we provide this level of help? How can we evaluate quality, safety, risks, cost, and benefit?
- Perform physically intimate tasks made more difficult because of resistance, fear, or misunderstanding by the person with dementia.
- Manage emotions and communication as the person with dementia becomes less able to manage his or her emotions and communication.
- Modify expectations of one's family, oneself as caregiver, the person with dementia, physician, and social support services.
- Capitalize on the person with dementia's intact remaining skills and abilities.

In the process of providing family care, individual family members may become the person with dementia's confidante, protector, enemy, constant companion, information seeker, care manager, consumer advocate, surrogate decision maker, and healthcare provider in no particular order.

High-Risk Family Care Profiles

There are known high-risk profiles for Alzheimer's family care that are not amenable to health or social interventions. Family caregivers who co-reside and provide a high or intense level of direct care or supervision, especially low-income or low-education female caregivers over 50 years old who perceive no choice in a decision to care, or frail older wives, are most vulnerable to negative outcomes from providing Alzheimer's family care. Studies further confirm modifiable risks associated with negative outcomes of Alzheimer's family care that are amenable to health and social support interventions: high depression and anxiety, impaired self-care and health behaviors, safety issues, inadequate social support (social isolation vs. engagement), and the challenging behaviors, personality, and communication changes of the person with Alzheimer's. Adult children who provide care out of financial necessity pose additional risks for the person with Alzheimer's from fraud, exploitation, abuse, or neglect. Often families providing care are at risk simply because they lack health literacy, knowledge of or access to information and support, or because they have personal health/mental health conditions that limit their capacity to provide quality care.

Box 1.
Just for Families: *Ten Things to Know*

1 The desire to avoid thinking about what you are facing is normal, but you can get beyond it.

2 The process of the disease is not completely predictable. Other things happen. Your family member will need more help over time, and you may be forced to make decisions that he/she will not like.

3 The person with AD can still, and needs to, do many things for you.

4 The person with AD is doing the best he/she can. Trying harder is frustrating and doesn't work.

5 You, not your relative, will have to change.

6 Your emotional relationship with each other will change despite your continued love and willingness to help.

7 Grief comes with this process of loss.

8 There is no single right or wrong place or time to care or care plan.

9 This is the rainy day for which you saved.

10 There is life beyond and after Alzheimer's care.

Personal and Social Costs of Alzheimer's Family Care

The most commonly cited personal costs of Alzheimer's care are feelings of being overwhelmed, alone, fatigued, depressed, anxious, angry, and suffering from exacerbated chronic conditions or stress-related illnesses. Often, families report the premature death of the primary spouse caregiver necessitates a sudden change in both the care location and primary caregiver, disrupting entire families. Further, families report social costs of Alzheimer's disease care as loss of valued friendships and community activities; family conflict and guilt; less personal time and privacy; and prolonged bereavement, loss, and sadness.

Box 2.
Nine Strategies for Alzheimer's Families

1 Being reasonable, rational, and logical will just get you into trouble.
2 People with dementia do not need to be grounded in reality.
3 You cannot be a perfect caregiver.
4 Making agreements with the person with dementia doesn't work.
5 Doctors need your input on what's really going on and what works.
6 You can't do it all. It's okay to get help before you are desperate.
7 It is easy to both overestimate and underestimate what your relative can do.
8 Tell, don't ask.
9 It is perfectly normal to wonder about the diagnosis when the person has moments of lucidity, insight, and good judgment.

Adapted from Family Caregiver Alliance Update, 21 (3):1. 2004.

Successful Coping with Alzheimer's Family Care

The Duke Aging Center's Alzheimer's caregiver studies provided early evidence of successful coping strategies of North Carolina families. The majority of North Carolina families reported reliance on a strong religious faith, belief system, or practice. In addition, caregivers who successfully modify expectations and re-appraise their efficacy ("good enough for now" solutions) report success in adapting over the disease trajectory. Other successful coping strategies include enhanced self-care and health behaviors, reducing rigid or inflexible behaviors, using humor, dependable family support, respite options, energy economies, forgiveness strategies, ingenuity, problem-solving, expressive, and advocacy outlets.

Key Decision Points for Physician Intervention: Transitions in Care

Transitions in illness symptoms and care are especially vulnerable times for persons with dementia and their family decision-makers. It is at these times that families are most likely to turn to physicians as gatekeepers. These transitions (see column to the right) in care highlight common hazards in family decision-making around Alzheimer's disease.

Families are often forced to make decisions in the face of an unrelenting series of crises without time to sort through conflicting perceptions and expectations. We know stressed individuals are at a disadvantage in decision-making and, for many families, Alzheimer's care is only one of a number of pressing family crises. Families may rigidly adhere to old promises that are no longer situationally relevant. Families may wait for the person with dementia to ask for help, chasing the ghost of the person as someone with intact judgment and executive function. Family decisions may await direction from a physician and often that direction is not framed in a way to facilitate a choice between equally unattractive options. Families may also delay acting on safety issues for fear of losing control of their relative's care to public or agency services. Finally, we know from clinical experience that families may delay decisions based solely on cost, on preserving assets for future generations, or from fear of the stigma and loss of privacy associated with the overwhelming disclosure required for eligibility and service determinations.

The following are examples of transition times where physicians can help families make difficult decisions and find ways to sustain their caregiving capacity:

- Diagnosis (reluctance to seek or accept early diagnosis by the person with dementia or family)
- Changes in driving (getting lost), handling money, taking medications, or alcohol use
- Decisions about the safety of living alone (fraud, neglect, exploitation—see Box 3)
- Decisions about hospitalization, surgery, diagnosis, and treatment of co-morbid conditions (Are symptoms and/or injuries attributable to dementia or signs of another acute illness, medical emergency, or delirium?)
- Decisions about the use of antipsychotics, antidepressants, anxiolytics, sedative hypnotics, and other psychiatric medications
- Changes in primary caregiver
- Need for constant supervision (respite options, in-home help, or day services).[8] See Box 3 for suggestions on how to determine need for constant supervision.
- Residential/assisted living care
- Skilled nursing facility care
- Palliative care and/or hospice care options

Physicians may use these transitions or decision points in care as opportunities to focus education on the most pressing family issues. The timing and "dosing" of information in a way that will not overwhelm patients and families may be just as important as the timing and dosing of medications.[9] Selecting educational strategies—brochures, websites, verbal directions, or referral to an Alzheimer's Association Helpline—should be done with sensitivity to literacy, culture, and capacity of the family caregiver. See examples of brief family caregiver reminders in Box 1 and Box 2. The geriatric prescribing axiom of "start low, go slow, and repeat often" is relevant to communication and family education around transitions in Alzheimer's care.

Box 3.
Considerations in Determining if a Relative is Safe Living Alone

1. Can the person use the telephone, read and send mail, manage their medication and money? Do they drink alcohol?
2. Is the person vulnerable to telephone, mail, or in-person fraud, scams, exploitation, neglect?
3. Can the person travel safely and at appropriate times outside home without getting lost?
4. Can the person maintain personal hygiene? Is the person continent?
5. Could the person be at risk for falls or other injuries. Are there guns or power tools, etc. in their home that might pose a risk?
6. Is the person at risk in their kitchen? Can they operate a stove safely, store food properly, recognize inedible food, etc.?
7. Is the person experiencing any weight loss or sleep disturbances?
8. Is discrete surveillance available from neighbors?

Key Messages for Alzheimer's Family Caregivers

- Be willing to listen to your relative, but understand that you cannot fix or do everything he or she may want or need. Know that it will not necessarily get easier, but things will change, and the experience will change your family forever.
- You are living with a situation you didn't create, and your relative doesn't like it any better than you do. Your choices may be limited by circumstances beyond your control. Seek options that are good enough for now.
- You can only do what seems best at the time. Identify what you can and will tolerate, set limits, and call in reinforcements. Doubts are inevitable.
- Find someone or a support group with whom you can be brutally honest, express your feelings to them, and move on.
- Solving problems is much easier than living with the solutions. It is tempting for distant relatives to second-guess or criticize. Hope for the best, but have contingency plans for the worst.
- It is not always possible to compare how one person handles things to how another relative would handle it if the positions were reversed.
- Your relative is not always unhappy or upset because of what you have done. He or she is living with unwanted dependency. Sick people often take out their frustration on close family members.
- Considering what is best for your family involves compromise among competing needs, loyalties, and commitments. Everyone may get some of what he or she needs. Think twice before giving up that job, club, or church group. Make realistic commitments and avoid making promises that include the words *always*, *forever*, or *never*.
- Find ways to let your relative help or give to you. He or she needs to feel purposeful, appreciated, and loved.
- Take time to celebrate small victories when things go well.

Primary Care and Family-Centered Dementia Care Models

The Alzheimer's Association has tested and disseminated family-centered models and tools for primary care diagnosis and management of persons with Alzheimer's, including guidelines for hospitalization and management of nursing home residents.[10] These collaborative models among physician group practices and Alzheimer's Association chapter services could be replicated in North Carolina.[11] North Carolina Alzheimer's Association chapters also have a national program workshop package available to help families communicate more effectively with physicians around dementia care. Linking health, aging, and social support services makes sense to consumers and health professionals, but the physician or healthcare provider is the lynchpin that makes or breaks seamless care delivery.

REACH (Resources for Enhancing Alzheimer's Caregiver Health)

A series of collaborative National Institute on Aging studies provides evidence-based direction for interventions to enhance Alzheimer's family care capacity and reduce negative consequences for caregiver health.[12] REACH tested interventions in settings ranging from primary care offices to telephone-based to in-home and group settings.

Original interventions targeted challenging behaviors, caregiver distress, delayed nursing home placement, and death. Interventions included cognitive and environmental strategies to reduce negative family appraisals of demands while enhancing the adaptive capacity of family caregivers. Other strategies targeted emotions or affective states of caregivers like depression, anger, and frustration. At six months, the studies reported clinically meaningful, site-specific positive outcomes such as decreases in depression, caregiver strain, and burden (especially among spousal caregivers); and increases in self care, social support, and efficacy in responding to challenging behaviors. When compared to the control group, persons with Alzheimer's whose caregivers received research interventions had significantly delayed nursing home placement, and their family caregivers suffered significantly less major depression.

REACH studies confirm the efficacy of multi-component interventions matched to individual caregiver risks. Multi-component interventions include a range of treatment modalities (like individual and family counseling, psychoeducational support

Duke University and Alzheimer's Families

"The docs back home don't know about this."

North Carolina responded to Alzheimer's families long before national attention focused on the public health and epidemic consequences of memory disorders on individuals, families and communities. Duke's Aging Center began its Alzheimer's Family Support Program in 1979 in response to urgent requests from families of persons with rare early-onset (i.e., before age 65) dementias taking part in the first federally-funded case control studies of Alzheimer's disease led by Duke University professor of neurology, Dr. Albert Heyman.[1] These families rarely knew of others their age in their communities coping with what was then commonly attributed to "senility or old age." These primarily middle-aged, well-educated couples were eager to meet and learn from each other and from "experts" while the national Alzheimer's Association was initiating its public awareness and support programs.

From Duke to Mobilizing Communities throughout North Carolina

These research subject families began attending a monthly "support group" at Duke in 1980. They connected with others at the monthly meetings, by writing letters or getting together socially outside of meetings. They urged Duke's Aging Center to publish a newsletter sharing their stories and tips, which the families named *The Caregiver*. Duke's *Caregiver* newsletter is now one of the oldest continuing newsletters for families and professionals caring for persons with Alzheimer's or a related dementia available by free subscription to North Carolina residents. The first-person narratives and tips in this newsletter addressed the isolation of these primarily rural families who lived at a distance from each other and Duke before there was e-mail, the Internet, cell phones or affordable long-distance telephone access. The original Duke support group has continued to meet monthly since 1979, now under the sponsorship of the Eastern North Carolina Alzheimer's Association.

In the early 1980s, North Carolina's Z. Smith Reynolds Foundation and Levi Strauss Foundation funded Duke's Aging Center to mobilize local informal support groups as sources of information and help closer to home. These groups are now part of two North Carolina Alzheimer's Associations sponsoring support groups across the entire state. Original subscribers to *The Caregiver* newsletter became mail survey research subjects for one of the first and most cited studies of Alzheimer's family care in the community.[2]

In 1984, the North Carolina Division of Aging (now the Division of Aging and Adult Services) contracted with Duke's Family Support Program to provide a toll-free telephone and mail clearinghouse for families and professionals caring for persons with memory disorders. The Duke contract covered state-level technical assistance, training, consultation, a newsletter and toll-free individualized telephone assistance. This annually renewed Program contract continues to serve as a state barometer of family needs, preferences, and gaps in health and social support services.

Subsequent studies at Duke and other universities have replicated and expanded original family care research findings. Duke Alzheimer's family care studies moved, along with federally funded cooperative studies, from measuring family stress and burden to interventions to mitigate negative consequences of caregiving on families. North Carolina now benefits from multi-site research findings offering an evidence base for clinically meaningful outcomes of family support strategies aimed at enhanced quality of family and community care for persons with Alzheimer's and related disorders.

groups, self-care programs, and respite care) along with behavioral and skill-building techniques, which are available in standardized reproducible protocols and can be customized to caregiver risk profiles.

Future Responses to Alzheimer's Family Care

Evidence-based interventions for family caregivers are being translated into intervention protocols and packaged training materials that can be tested or evaluated in community settings. However, there remains a significant need to improve the quality of care in family settings through integration of health and social support services. This seamless, systematic, and more comprehensive support for families must focus on the vulnerable transition points in Alzheimer's care identified previously in this commentary.

Plans are in place to link this evidence-based research on family caregiver interventions to service delivery systems change in states (like North Carolina) that are participating in the Administration on Aging's Alzheimer's Disease Demonstration Grant to States Program (see Derence article on Project CARE).[13]

While we wait for state policy and service systems change, much can be done to assist physicians and community agencies to collaborate effectively in offering dementia-capable, family-centered care. **NCMJ**

COMMENTARY

North Carolina's Support of Family Caregivers

Christine Urso, MSW

A significant number of adult North Carolinians are family caregivers. Many try to juggle the demands of children, grandchildren, and jobs, while taking care of their older relatives. By doing this, they often put their own health in jeopardy. According to the 2003 Behavioral Risk Factor Surveillance System Survey, one of every four adults in North Carolina provided regular care for an older adult within the past month.[1] Close to half reported that the person for whom they are caring has memory loss, confusion, or a disorder such as Alzheimer's disease (AD).

Although caregiving is a normative experience for families and plays an integral role in our long-term care system, it does not come without a price. Families providing care to a person with AD usually face a longer and much more difficult journey. As Dr. Taylor asserts in his issue brief,[2] our society must recognize the staggering quasi-external costs of caregiving (i.e., the deleterious effect on caregivers' immediate and retirement finances, physical and emotional health, family relationships, etc.) and examine the merits of using public dollars to help families care for loved ones at home. Taylor suggested that our inaction in support of caregivers speaks volumes.

The 2001 Report of the North Carolina Institute of Medicine's Task Force on Long-Term Care also called for action:

> The Office of Long-Term Care, within the Department of Health and Human Services, should assure that all policy and program development activities consider and respect the importance of family caregiving and examine how to further strengthen the capacity of families to perform their caregiving function.[3]

While North Carolina has begun to recognize and support the value of family caregivers, we are still in our infancy in developing the array of supports they need.

Because caregivers' needs change as the condition of their loved ones changes, a wide variety of supports must be available through the various stages and circumstances of the caregiving career. More importantly, there must be flexibility in the provision of these supports.

"While North Carolina has begun to recognize and support the value of family caregivers, we are still in our infancy in developing the array of supports they need."

What Is North Carolina Doing to Support Caregivers?

North Carolina first officially recognized the need to *support* caregivers of older adults in 1985[4] when the General Assembly passed respite care legislation and provided some funds to be administered through the (then) state Division of Aging. The statute identified the importance of counseling, support groups, training, access to services, assessment and care planning, and respite for the caregiver through in-home assistance and temporary out-of-home placement. This legislation targeted caregivers of persons age 60 and older, but was later revised to serve also people aged 60 and older who are providing care for an adult of any age. Although these funds helped raise awareness of caregivers' special needs, no concentrated, coordinated effort was implemented on behalf of family caregivers until the creation of the National Family Caregiver Support Program (NFCSP) in 2000.

Christine Urso, MSW, is the Caregiver Program Consultant for the North Carolina Division of Aging and Adult Services, NC Department of Health and Human Services. She can be reached at chris.urso@ncmail.net or 2101 Mail Service Center, Raleigh, NC 27699-2101. Telephone: 919-733-3983.

Figure 1.
North Carolina's Family Caregiver Support Program

Vision

Families will enter into caregiving with the knowledge and assurance that they can call upon the business, faith, and health and human service communities to assist with information, counseling, problem solving, respite, and formal services when needed.

Care Recipient and Caregiver Characteristics

- The average age of the person receiving care is 80, while more than half (53%) of caregivers are between ages 40 and 59.
- Nearly half of care recipients are cognitively impaired (44%).
- Seven in ten caregivers live with the care recipient.
- More than three-quarters of the caregivers are women (76%).
- Nearly half of the participants are caring for their parents (45%) and about a third (32%) for their spouse.
- Half of caregivers report their own health as 'fair' or 'poor,' as opposed to 'well.'

With the 2000 enactment of the Older Americans Act (OAA) Amendments, the NFCSP became the first federal program with a required focus on the caregiver. The NFCSP, Title III-E of the OAA, is intended to offer a "multifaceted system" of caregiver supports. The NFCSP must contribute to a seamless service delivery system, building on effective services, and developing new services where needed. The legislation allows five broad categories of supports, which correspond closely to those of North Carolina's 1985 Respite Act:

- Information
- Assistance with access to services
- Individual counseling, support groups, and caregiver training
- Respite care
- Supplemental services (on a limited basis) to complement the care provided by eligible caregivers[5]

The primary population served by the NFCSP are the family caregivers of persons aged 60 and older. Family is defined very broadly and includes adults in the immediate family as well as caregivers in the community who provide informal assistance. In many instances, these families are caring for older persons with AD or related dementia. The NFCSP also recognizes and supports grandparents and other relatives age 60 and older who are primary caregivers of minor children. See Figure 1 for further information on North Carolina's Family Caregiver Support Program (FCSP).

The OAA services, including the NFCSP, and state funds to serve community dwelling older adults are administered by the Division of Aging and Adult Services, within the North Carolina Department of Health and Human Services, through a network of 17 Area Agencies on Aging and hundreds of local providers. The services under its Home and Community Care Block Grant services include home-delivered meals, in-home aide, adult day services, and transportation. These services are available to any person aged 60 and older, although special effort is made to reach seniors who are socially and economically needy. Many of these services provide relief to family caregivers. At the end of 2004, more than 7,500 seniors were on a waiting list for services. In addition, services to at-risk adults of all ages are administered by Division of Aging and Adult Services through the county departments of social services. One of these services—Adult Protective Services—sheds additional light on the importance and stresses of caregiving. Among the Adult Protective Services-confirmed cases handled in 2003-2004, more than half (54%) involved self-neglect, 26% caregiver neglect, 12% exploitation, and 7% abuse.[6]

Challenges to Implementing a Caregiver Support Program

In implementing the NFCSP, the Division of Aging and Adult Services and the Area Agencies on Aging have had to tackle significant challenges. First, families providing care do not typically identify themselves as being "caregivers." They are just doing what comes naturally as a part of their familial responsibility. Their interest in the use of services is directly related to how their loved one will benefit.

From the program's inception in 2001, North Caroilina's version of the NFCSP has emphasized public awareness. Specifically, the program has attempted to reach caregivers and

Figure 2.
How Healthcare Professionals Can Assist Caregivers

Identify and recognize family caregivers.	25% of adult North Carolinians are caregivers of adults 60 and older.
Assess how the caregiver is coping.	Caregiver assessment forms in English or Spanish can be be downloaded at http://www.ama-assn.org/ama/upload/mm/36/caregivertooleng.pdf.
Provide information and education on the patient's disease process.	In addition to information that healthcare practitioners provide, caregivers can also refer to the Western and Eastern Alzheimer's Chapters and the Duke Family Support Program.
Encourage caregivers to be a partner in care.	Barring safety concerns, support families' decisions for where care will be provided, whether in an institution or at home.
Refer caregiver for support and further information.	Connect with the Family Caregiver Specialist at the Area Agency on Aging or contact the local Council or Department on Aging.

those who touch their lives, including employers, the faith community, and health and human service professionals. Because caregivers often do not self-identify, public awareness efforts remain critical. Caregivers need to know that they are not alone and that support services are available. Not only is public awareness key to reaching isolated caregivers, it also helps build partnerships and leverage resources.

The healthcare community has a vital role in this outreach and is viewed by the program as an important partner. Figure 2 outlines a view of some of the significant roles that healthcare professionals can assume in the lives of caregivers.

Caregivers often turn to healthcare professionals for information, and not surprisingly, this increases as the caregiver burden grows. Information is cited as the chief unmet need of caregivers in several surveys. The 2004 Caregiving in the United States Survey found that two-thirds of caregivers need more information on a variety of topics.[7] This figure jumps to three-fourths for those caring for persons with AD. Alzheimer's caregivers report a need for information on resources, help in navigating the system, and managing special behavioral challenges presented by their loved ones.

One successful effort that is helping physicians to better assist caregivers is *Making the Link: Connecting Caregivers with Services through Physicians*. This is a program of the National Association of Area Agencies on Aging and the United States Administration on Aging. Several of North Carolina's Area Agencies on Aging are using the tools of this program to raise awareness within the medical community about how caregiving can present its own health risks and to help physicians connect caregivers to local services when appropriate. In endorsing the program, the American Medical Association asserts, "an effective relationship model acknowledges the key linkage role of the primary care physician and recognizes that caregivers and patients form interdependent units. It also considers the caregiver as a partner with the physician in the care of the patient. The physician demonstrates concern for and carries out periodic assessment of the caregiver as well as the patient and validates the role of the caregiver."[8]

Hopefully soon, physicians and their patients will be better able to access information about community supports throughout North Carolina. A new initiative of the North Carolina Department of Health and Human Services will connect various community resource databases from across the state. This statewide database will be made available on the Internet to aid the location of supports for near-by or long-distance caregivers. Because of the myriad of services provided through a variety of public and private for-profit and not-for-profit agencies, caregivers need easier access to information about these services in making decisions about the care of their family members.

A second barrier to the program's implementation has been the limited federal funding made available, especially relative to need. North Carolina received $2.9 million in 2001 to start the Family Caregiver Support Program, and this increased to $3.7 million in 2004. These funds are minimal in comparison to the more than $868 million spent in North Carolina under Medicaid for nursing home care in 2003.[9] Without the ongoing support of families, the need and cost of facility care would surely rise. In introducing the NFCSP to states in early 2001, Edwin Walker, Director of Program Operations and Development at the United States Administration on Aging (AoA), offered these words of advice:

- The Caregiver program offers a chance to change the long-term care paradigm and correspondingly, the long-term care delivery system, to acknowledge the role of informal, unpaid services by caregivers.
- The focus is on the needs of the caregiver as opposed to the care recipient.
- We want to develop and implement multifaceted and coordinated systems of supports, not just services. The focus is on responding to diverse needs of today and building for tomorrow.
- Exercise caution—strategically plan a system of services, assess needs of caregivers, prioritize these needs, find and incorporate research and best practice—integrate, build on and enhance what exists when possible, including use of non-traditional partners as well as the current home and community-based care programs.
- Don't rush to provide services. Avoid the temptation to dump the money into existing respite services just to get it spent.
- AoA is going easy on regulations for the Caregiver program, preferring to allow flexible, innovative implementation at the local level. Don't push AoA to regulate or define things too quickly.
- Build broad-based coalitions that include non-traditional partners and find ways to maximize resources in comparison to need.
- Produce and document desired outcomes—build a foundation to justify the caregiver funding and advocate for additional funds.

Creating Partnerships

North Carolina heeded this advice and saw the need first to address a third challenge to the program's implementation, namely, the absence of a community infrastructure to focus on caregiver needs. The Division responded by creating the position of Family Caregiver Resource Specialist in each of the 17 Area Agencies on Aging located within regional Councils of Government across the state. These Resource Specialists are charged with building the multifaceted and well-coordinated system of supports that caregivers need. With limited public funds available, the specialists work to create partners and leverage resources whenever possible. Their success in this regard, along with the increasing number of local specialists, is largely responsible for the program's effectiveness to-date. With input from many different community agencies and groups and from caregivers themselves, these specialists have seeded numerous new and unique partnerships.

Strong partnerships with statewide organizations [i.e., North Carolina Cooperative Extension, Duke Family Support Program, AARP-NC, and The Carolinas Center for Hospice and End-of-Life Care] have provided significant support in the development and implementation of the Family Caregiver Support Program. For example, the North Carolina Cooperative Extension Aging Specialist and a social worker from the Duke Family Support Program became master trainers for a highly acclaimed caregiver curriculum the "Taking Care of You: Powerful Tools for Caregivers." With the assistance and financial support of AARP-NC, class leader workshops for this and other caregiving curricula were held across the state. Locally the Area Agencies on Aging, Cooperative Extension, AARP Health Specialists, and others now partner to deliver these workshops directly to caregivers across the state.

AARP-NC has further demonstrated its strong commitment to caregiving with two publications: the *Family Caregiving in North Carolina* guidebook and a *Grandparents Raising Grandchildren Guide*. These publications were developed with input from many participating partners. AARP-NC has also sponsored surveys and conferences aimed at helping businesses support caregivers in the workplace.

North Carolina is fortunate to have very strong professional and consumer resources focused specifically on AD. These resources have been instrumental to the implementation of the FCSP.

Since 1994, the General Assembly has invested in services for families affected by AD by helping fund programs of the Eastern North Carolina and Western North Carolina Chapters of the Alzheimer's Association. Their programs include support groups, caregiver workshops, maintaining a library of educational materials, toll-free help-lines, and many other services. Caregivers are learning first-hand about AD and strategies for managing challenging behaviors, and their association with others in similar situations helps reduce feelings of isolation. A calendar of events for the Eastern Chapter is found at http://www.alznc.org and for the Western Chapter at http://www.alz-nc.org. Since 2001, each of the two Chapters has received $75,000 in state funds, which has been critical to their operation.

Duke's Family Support Program, with an emphasis on dementia-specific supports, also receives state funds. Since 1984, the program has used its $50,000 to serve as a one-stop clearinghouse, crisis hotline, and technical assistance center for families and professionals caring for people with memory disorders. The state funding of the Alzheimer's Chapters and the Duke Family Support Program also has enabled North Carolina to leverage other resources. For example, it is helping provide the required matching funds for the federal Alzheimer's Demonstration Grant that the Division of Aging and Adult Services is currently administering and that is described in the commentary by Karisa Derence.[10]

The fact that North Carolina has chosen to support Alzheimer's-specific services is admirable among states. The fact that these funds have been stagnant is cause for reflection and concern. The number of family caregivers, including those of persons with AD, is growing dramatically with the aging of our state's population.

How Is the State Addressing Policy Issues?

Our nation, state, and local communities face a monumental challenge in meeting the long-term care needs of the aging population. As the state continues to move forward to meet the requirements of the United States Supreme Court's Olmstead decision for promoting the least restrictive care environment, family caregiving will inevitably play an even more critical role.

The North Carolina Department of Health and Human Services is the recipient of several grants through President Bush's *New Freedom Initiative*. These "systems change" grants through the Center for Medicare and Medicaid Services are charged with improving the infrastructure, availability, and

Division of Vocational Rehabilitation

North Carolina Assistive Technology Program quality of community services available to adults with disabilities. As envisioned, informed consumers will increasingly have the opportunity to direct their own plan and delivery of service supports. While these grants enhance work on systems change, demand for community services continues to exceed availability.

As society hears increasingly about the value of quality care in the setting of choice, government struggles with how to pay for this care for many of its citizens whose resources are inadequate or quickly diminish with the high cost of care. Government must operate under a responsive long-term care system where the caregiving contributions of families are valued and supported. Just as businesses are realizing the economic sense of responding to the interests and needs of working caregivers, support of caregivers is sound public policy.

This year (2005) the NFCSP comes up for reauthorization under the Older Americans Act. Also this year, the fifth White House Conference on Aging is scheduled, October 23-26, 2005. The previous conferences, held in 1961, 1971, 1981, and 1995, were significant in their policy recommendations to the President and Congress. They also assisted the public and private sectors in identifying emerging trends and preparing for current and future generations of older persons. One of many important issue areas will surely be health and long-term care and within this discussion, the importance of investing in family caregiving.

North Carolina's delegates to the White House Conference will be able to voice their opinions on the NFCSP and other public policy considerations, such as the proposed Ronald Reagan Alzheimer's Breakthrough Act of 2004. This bill would double funding for AD research at the National Institutes of Health (from $700 million to $1.4 billion); support a National Summit on Alzheimer's Disease; and increase the availability of services, such as respite care, home healthcare, counseling, and training. The bill also proposes to double funds for the NFCSP (from $125 million to $250 million) and the Alzheimer's Demonstration Grant Program (from $12 million to $25 million).

Both nationally and in North Carolina, we must follow the lead of the Task Force on Long-Term Care of the North Carolina Institute of Medicine, in finding "ways to invest in family caregiving so that it can be sustained as a primary resource for long-term care, reducing the risk for needing formal, publicly-financed services." **NCMJ**

COMMENTARY

Dementia-Specific Respite:
The Key to Effective Caregiver Support

Karisa Derence, MA

Value of Informal Dementia Care

Most older adults, including those with dementia, prefer to remain at home and in the community for as long as possible. More than 70% of the 4.5 million Americans currently diagnosed with Alzheimer's disease live at home and are cared for by family and friends.[1] In order to ensure that individuals with dementia receive quality care in the environment of their choice, the support of informal caregiving is critical.[+] Extending the duration of home care is also an important health and quality of life issue. Adjusting to a new environment is particularly difficult for a person with Alzheimer's disease. The comfort and security of familiar surroundings and a stable routine can help alleviate the fear and anxiety often associated with progressive memory loss.

The value of informal caregiving extends beyond ensuring quality of life and freedom of choice. It has become "an essential element of our health and long-term care system."[2] The national cost of caring for people with Alzheimer's disease has reached at least $100 billion.[3] Unless an intervention or cure is found soon, Alzheimer's could bankrupt Medicare and Medicaid.[3] Even a one-month delay in nursing home placement is estimated to save the healthcare system $1 billion a year.[4] The contributions of family caregivers, worth $257 billion in unpaid services and support, are more than double the annual cost of home care ($32 billion) and nursing home care ($92 billion) combined.[1] This level of assistance simply cannot be replaced. The need to support and sustain family care at home will only intensify as our population ages.

> *"Unless an intervention or cure is found soon, Alzheimer's could bankrupt Medicare and Medicaid."*

Burden of Dementia Caregiving

The progressive and unpredictable nature of Alzheimer's disease poses enormous challenges to caregivers. People with Alzheimer's disease live an average of eight years after diagnosis but may survive for up to 20 years. They need help with most activities of daily living such as bathing, dressing, eating, and dealing with incontinence. Their level of care and ability to communicate can fluctuate from one day to the next and they may be resistant to personal care assistance. Behaviors such as wandering, hoarding, and perseveration further complicate care needs and create serious safety issues. Eventually, most individuals with Alzheimer's disease will need full-time care and continuous supervision.

A recent survey reported that among all caregivers, those caring for people with dementia experience a disproportionately heavy burden.[5] They spend more hours providing care over longer periods of time. More than half feel as if they are "on call" 24 hours a day and have to reduce or end employment to fulfill the demands of caregiving.[6-8] Dementia caregivers encounter more family conflict, personal stress, serious health problems, and a shorter life expectancy.[6,8,9] Many of these caregivers cope with immense grief and feelings of guilt, anxiety, and anger. Nearly half (43%) are clinically depressed.[10] The unique behavioral and communication challenges associated with dementia require specialized skills and make it even more difficult for the caregiver to get rest or help providing care.

Dementia caregivers are particularly vulnerable to severe burnout. Reaching this level of stress and fatigue places both the caregiver and the person with dementia at risk and is one of the most cited reasons for early institution-

---

[+] In this commentary, the term "informal caregiver" is used interchangeably with "family caregiver" to include all types of unpaid primary caregivers: family members, friends, and/or neighbors. The term "Alzheimer's" is used interchangeably with "dementia" to include all types of progressive memory impairment or mental confusion.

Karisa Derence, MA, is the Alzheimer's Specialist at the Division of Aging and Adult Services, NC Department of Health and Human Services. She is also the Director for the NC Alzheimer's Demonstration Grant Program (Project CARE). She can be reached at karisa.derence@ncmail.net or 2101 Mail Service Center, Raleigh, NC 27699. Telephone: 919-733-0440.

alization.[11] Caregivers need to adequately manage stress and have effective ways to relieve the tremendous burden of providing constant care. In doing so, family caregivers strengthen their ability to provide quality long-term care at home.

Respite* Options

Family caregivers identify respite care as one of their greatest needs.[12] Respite care offers relief for family, friends, and other informal caregivers so they can take a much needed break from their daily responsibilities while knowing their loved ones are in good care. Respite represents a continuum of services based on the individual needs of the caregiver and the person with dementia. There are many different ways respite can be provided (see Table 1):*

- In a home, community organization, or residential facility;
- For part of the day, evening, or overnight;
- By paid staff, volunteers, family, or friends;
- Occasionally or on a regular basis.

Dementia caregivers desperately need sufficient and regular amounts of respite, more than just temporary or short-term intervals. Respite support should be ongoing and is most helpful before the caregiver becomes exhausted, isolated, and overwhelmed. Families need to consider respite care before reaching a point of crisis. The unique circumstances of each family will help determine what type of support is most appropriate. The most successful and effective respite programs promote flexibility and consumer control, allowing caregivers to direct their own care.

Benefits of Respite Care

Respite care benefits both the primary caregiver and the individual with dementia. The person with dementia is provided with social stimulation and the opportunity to live in the community longer. Respite enhances quality of life, promotes better psychological health, and preserves family and caregiving relationships.

Respite care also mitigates the distress of caregiving and delays costly out-of-home placement.[12] Caregivers receive the kind of help that reduces the burden of dementia care and the likelihood of abuse and neglect. Without adequate support and timely respite, families often suffer economically and emotionally, and caregivers themselves face serious health and social consequences.

> *"Respite care also mitigates the distress of caregiving and delays costly out-of-home placement."*

Comprehensive Interventions

Respite care is most effective when enhanced with other caregiver-focused services such as individualized counseling, education, and ongoing support. Though essential, these services should not be used in isolation.[13] Flexible and comprehensive support programs maximize the benefits of caregiver interventions by effectively relieving caregiver depression and care-related stress over a long period of time.[10,13,14]

For many caregivers, respite is a gateway to more comprehensive care including training and emotional support.[15,16] Respite relief helps caregivers gain further perspective and make better decisions. Caregivers begin to take steps toward maintaining personal health and are often more willing to connect with peers and explore additional resource opportunities.

A Model Program

The North Carolina Alzheimer's Demonstration Program, Project CARE (Caregiver Alternatives to Running on Empty), uses a consumer-directed, family consultant model to provide comprehensive respite support to dementia caregivers. The goal of the program is to increase access, choice, use, and quality of respite care to underserved rural and minority communities. Through the integration of dementia-specific services, Project CARE intends to create a seamless, coordinated delivery system that is responsive to the needs, values, and preferences of Alzheimer's families.

Project CARE is funded through the federal Administration on Aging Alzheimer's Disease Demonstration Grants to States Program (ADDGS). The program is administered by the North Carolina Division of Aging and Adult Services and receives technical assistance from the Duke Aging Center Family Support Program. Operating within the community-based contexts of the Western Carolina Alzheimer's Association and the Mecklenburg County Department of Social Services, Project CARE Family Consultants visit the homes of referred Alzheimer's caregivers in crises. The consultants offer timely, individualized guidance, counseling, support, advocacy, and education for family caregivers. Their aim is to match families with the most appropriate and preferred local respite and community services tailored to the unique context of care and family needs. Families are able to choose among a full continuum of consumer-directed care options, including adult day services, group respite, private or agency in-home care, and overnight residential respite. There are three pilot sites set up to serve the following ten counties: Winston-Salem (Forsyth, Surry, and Stokes Counties); Asheville (Polk, Henderson, Transylvania, Rutherford, Madison, and McDowell Counties); and Charlotte (Mecklenburg County).

Project CARE Family Consultants employ a family-centered, home-based intervention. The North Carolina demonstration program emphasizes the use of home visits to accommodate caregiver time and energy limits. During home visits, the consultant:

---

* Respite (res' pit) n. 1. a delay or postponement 2. an interval of temporary relief or rest.

Table 1.
Respite Options

Types	Provider	Services	Benefits/Cost
In-home Care	Employed privately, through a home health agency, or as part of a government program	1 Companion: help with supervision, recreational activities, and visiting. 2 Personal Care: assistance with bathing, dressing, incontinence care, and other activities of daily living. 3 Homemaker: help with housekeeping, shopping, and meal preparation. 4 Skilled nursing care: help with medication and other medical needs.	Person with dementia receives one-on-one attention within the comfort of their own home. Caregiver does not have to provide or arrange for transportation. Variety of service options and types of assistance. Moderate cost—dependent on level of care.
Adult Day Programs (or "community-based service")	State Certified Adult Day Care or Day Health Centers; Group Respite Programs	Daily activities may include music, exercise, social stimulation, and peer support. Staff are often highly interactive and, in some centers, consist of a social worker and recreation therapist. Adult Day Health Centers offer medical services administered by a registered or licensed nurse. Some centers have specialized Alzheimer's programs.	Participants have the opportunity to interact with others while being part of a structured environment. Most programs provide a meal and/or snacks. State certified centers are open a minimum of six hours per day for at least five days a week. Group respite programs are open a maximum of five hours per day, four days a week. Allows caregivers to continue working outside the home. More respite time available at a lower annual cost.
Residential Respite (or "institutional respite")	Nursing Homes, Residential Care Facilities, and Assisted Living Facilities	Provides overnight or short-term respite stays ranging from a few days to several weeks. Services include personal care assistance, meals, laundry, and therapeutic activities. Some facilities have special care units or programs for people with dementia.	Allows caregivers to take an extended break or vacation while the person with dementia stays in a safe, secure environment. Option for emergency situations such as an accident, illness, surgery, or long-distance trip. May be needed for crisis situations where there is a risk of abuse or neglect. High cost. Person with dementia may have difficulty adjusting to the new environment.
Informal Respite	Involves the help of family, friends, neighbors, church groups, or other volunteers who can share the responsibility of caregiving.	Range from companion services to personal care or household assistance. Some communities have organizations or support team networks that provide a stable source of volunteer caregiving services (e.g., Center for Volunteer Caregiving: www.volunteercaregiving.org; The Support Team Network: www.supportteam.org)	Provides emotional support for the caregiver and helps the person with dementia maintain a healthy level of social and recreational activity. Receive same benefits as non-medical in-home care at no cost. Not available in all communities. May not be as dependable as professional care. Some families feel they have less quality control when services are free. Can also be used to supplement formal care.

For more information, see the Respite Care Guide: How to Find What's Right for You (National Alzheimer's Association: www.alz.org), Community Care Options (Family Caregiver Alliance: www.caregiver.org) or Respite for Persons with Alzheimer's Disease or Related Disorders (ARCH National Respite Network and Resource Center: www.archrespite.com)

- assesses the family care environment,
- identifies the needs of both the caregiver and the person with dementia,
- facilitates discussion and mutual understanding among family members,
- connects the family with community resources, and
- ensures the provision of quality services.

The personalized approach of the Family Consultant fosters family trust, instills a variety of skills, and promotes self-care. Project CARE families learn the value of respite and are empowered to make self-directed, informed decisions about care.

Project CARE builds upon, enhances, and sustains existing home and community-based services. The Family Consultant uses local providers to deliver respite care and serves as a direct link to the expertise and resources of the Alzheimer's Association. Project CARE also opens doors to the Family Caregiver Support Program and other caregiver-focused initiatives creating a strong network of community support for Alzheimer's families. This comprehensive system builds the family's capacity to manage all the challenges inherent in caring for individuals with dementia.

Future Direction

Within the next ten years, as the first wave of baby boomers reach the age of greatest risk, the numbers of people affected by Alzheimer's disease will increase dramatically. In 2000, an estimated 132,329 older adults in North Carolina had mild, moderate, or severe Alzheimer's disease. This number is projected to rise to 253,176 by 2025—an increase of 91%.[17] It is critical that we prepare for this upcoming healthcare crisis by creating a sustainable, dementia-capable system of respite support for Alzheimer's families across the entire state.

The future of respite care in North Carolina is at a crossroads. The state Family Caregiver Support Program (FCSP) has insufficient funds to adequately serve all types of caregivers, and it does not contain a dementia-specific component. As we look to the future, federal and state policy makers would be well advised to build on the success of the FCSP and the Alzheimer's Disease Demonstration Project. North Carolina must integrate and fund dementia-specific respite as part of all future caregiver support programs. **NCMJ**

COMMENTARY

Managing the Patient with Dementia in Primary Care

Sindy McCrystle, ANP-C, MSN, and Darlyne Menscer, MD

The primary healthcare provider can play an especially important role in the early detection, patient and family counseling, and medical care of the older adult with dementia or Alzheimer's disease (AD). The patient with such a diagnosis presents a unique set of challenges for the healthcare professional, whether physician, dentist, nurse practitioner, or physician assistant. Early on after such a diagnosis, the focal "client" becomes more than the patient alone, but must include consideration of the family or caregiver role(s) and the context within which the patient lives and receives care from loved ones or friends. Few of us, regardless of professional background, have received adequate training and experience in the management of the many dimensions of Alzheimer's disease and its manifestations to feel completely comfortable delving into the issues likely to be brought to our attention by family, friends, and even Alzheimer's patients themselves.

> *"Having an early definitive diagnosis and some understanding of the probable course of this disease can help families maximize quality time with loved ones and share periods of better health and lucidity with children, grandchildren and others."*

Establishing a Diagnosis of Alzheimer's Disease

It is important to diagnose AD as early as possible. Medications are available that can slow the progression of the disease, giving patients and their families precious time to make necessary adjustments and plans, as well as to forestall the urgency of nursing facility placement. Most importantly, as the disease progresses, there are important safety precautions that families with this information can use to lessen the likelihood of unfortunate circumstances or accidents in the home or in the larger community. Having an early definitive diagnosis and some understanding of the probable course of this disease can help families maximize quality time with loved ones and share periods of better health and lucidity with children, grandchildren, and others.

Despite the advantages of early diagnosis, it is quite common for clinicians to miss or misinterpret the signs of this disease and therefore be unable to assist with a more accurate and useful diagnosis early in the progression of the disease. Diagnosis is made even more complex by the fact that patients often work hard to disguise the symptoms that might signify the early stages of this disease. We have been made aware in our own practice of the extent to which some patients actually "rehearse" their likely interactions with their primary care physicians (such as reviewing the date, month, county of residence, names of the United States President and Vice President, and their own children) so as not to appear "forgetful" and to be judged to be as "normal" and "independent" as possible. Stories circulating among older adults about some who have come away from visits to their physicians with the admonition to give up their driver licenses and automobiles make many fear these visits. Whether imagined or real, any limitations on independence or any suggestion of the needs to live in a more dependant environment can be intimidating for a person with AD.

One strategy for minimizing the likelihood of obfuscation

Sindy McCrystle ANP-C, MSN, is the Coordinator of Geriatric Medical Education for the Family Practice Residency Program at Carolinas Medical Center in Charlotte, NC. She can be reached at sindy.mccrystle@carolinashealthcare.org or PO Box 32861 A, Charlotte, NC 28232-2861. Telephone: 704-446-7706.

Darlyne Menscer, MD, Director of Geriatric Education for the Family Practice Residency Program at Carolinas Medical Center in Charlotte, NC. She can be reached at darlyne.menscer@carolinashealthcare.org or PO Box 32861 A, Charlotte, NC 28232-2861. Telephone: 704-446-7707

of these basic signs of dementia that has proven helpful to many clinicians is to ask that older patients be accompanied by family members (or close friends familiar with their everyday routines and living situations). Patients who naturally want to maintain their independence, dignity, and self-respect are uncomfortable with the discussion of problems with memory or functional activities of daily living. Even discussion of these issues with other family members in the presence of the patient can produce tensions between family members. But, every visit with a healthcare provider can be a valuable opportunity to note changes in one's physical, emotional, and functional status, as well as a chance to ask questions that might unveil new problems. Unusual scenarios recounted in these encounters can reveal patterns of behavior that signal the need for more careful diagnostic exploration (such as missed appointments, electricity or telephone service being cut off unexpectedly, problems with one's checking account and encounters with a local bank, repeated episodes of familiar cooking recipes not turning out well, leaving the burner of a stove on, or failure to remove a pot from the stove, etc.) are all valuable pieces of information that take a few minutes to garner in these visits, but are rarely shared by the patient visiting a clinic alone for a regular periodic encounter.

One of the most helpful aspects of medical care delivery systems for assuring that conditions of dementia or Alzheimer's disease are identified early is having every older adult served by a singular primary care provider who can follow the patient (and know the patient's family and living situation) over a sustained period of time. When multiple specialists are involved in the care of a single patient, each may be so focused on the specific clinical problem for which the patient has sought their care, and each may assume that the patient is being managed in a more comprehensive way by someone else, that no one actually "connects the dots" or synthesizes a complete picture of the individual's state of health. Diagnoses of dementia or Alzheimer's disease can take far longer when there is no single provider responsible for coordinating the care of the older adult. It is also important to use one pharmacy so that medications can be managed safely, even if multiple prescribers are involved. The pharmacist can be invaluable in detecting problems with multiple medications of the same class, too frequent refill requests, allergies, and identifying duplicate medications if generics and brand names are being used by different providers. Eliminating unnecassary polypharmacy is helpful.

Once the Diagnosis is Made: What Next?

At the point that a diagnosis can be established, the Alzheimer's patient and his/her family have a number of issues and challenges that require deliberate attention and often require the assistance of professionals in fields other than medicine or the health professions. Though it may not appear necessary at the time of an "early" diagnosis, care options for the future should be thought about and planned as early as possible. If the decision is made to continue living in one's residence, as is often the case for those whose diagnosis is made earlier, the presence of others who can offer social support is a consideration. The ability to drive, shop, cook, maintain household cleanliness and personal grooming, and participate in various aspects of social life (such as church attendance) become issues of importance to those with this diagnosis. Financial and legal planning are also important considerations. The management of personal banking and other financial matters is something that most families find difficult to discuss with a loved one who has an early diagnosis of dementia or Alzheimer's disease, but these matters become progressively more important as the disease develops. Advanced directives and healthcare power of attorney documents are the most important legal considerations, both of which need to be arranged while the individual is cognitively able to speak for him/herself, although these documents only become operative when the individual no longer has this cognitive capacity.

Physicians and other healthcare providers often do not see their role as very "direct" with regard to these issues, but asking the right questions and directing patients and their family members to appropriate community resources can be invaluable (many of whom are identified elsewhere in this issue of the *North Carolina Medical Journal*).

As the Disease Progresses, Caregiving Becomes Increasingly Important

In the United States, many families are smaller or more geographically distant with many more women working outside the home than in past generations. This can make caregiving options more difficult than in other countries or cultures. Adult grandchildren seem to be emerging as caregivers of AD patients. Their ability to drive and shop and cook can often be exchanged for free housing and other financial benefits. Late-life relocation can rob seniors of informal support systems such as a faith community, neighbors, civic clubs, and extended families. Long-distance caregiving can result in feelings of guilt among caregivers, especially family members. This is particularly relevant if the person with AD has been successfully hiding cognitive impairments. Many primary care practitioners have had several patients who have fallen and been unable to get up for several days, resulting in decubiti, fractures, and dehydration. Substance abuse, incontinence, or throw rugs are common causes. Simple solutions like Lifeline, telephone reassurance, or a neighbor checking on the individual can be helpful. Adding homemaking and personal care services, as the need becomes apparent, is also very useful and can extend the period of successful "aging in place."

The Importance of Routine Primary Care Visits

The routine clinical encounter with an older adult who has been diagnosed with AD should include consideration of changes in a number of dimensions of the illness experience and general life situation. It is important to assess patient function, safety, pain/comfort, and patient/caregiver coping at each of these visits. Changes involving incontinence, wandering, agitation, violence toward staff or caregiver, insomnia, active smoking, cooking, driving, guns in the home, or caregiving to young children or elder spouses when cognition in the AD person is moderately impaired can each trigger serious problems. Identifying problems in these areas and developing care plans can prevent untoward outcomes.

Unfortunately, aging in the later years often involves many losses. Loss of spouse, job, friends, driving, vision, or hearing are a few, and these can affect loss of pleasurable activities. Clinical depression is more pronounced than natural loss and is often missed in the ongoing assessment of the older adult with AD. These patients rarely present as sad or crying, but more commonly there is weight loss, isolation, and reports of "no energy" or "feeling empty." Treatment can be very effective, and patients often agree to try medications to increase appetite or boost their energy if not specifically identified as treatment for "depression."

Treating the Caregiver

For the caregiver, the first challenge is to accept that someone you care about has an incurable, progressive illness that is likely to last many years and make them very dependent with different personality traits. Role reversal is demanded with spouses becoming the parent and adult children "parenting" their parents as they become increasingly childlike and dependent.

> *"One of the most helpful aspects of medical care delivery systems for assuring that conditions of dementia or Alzheimer's disease are identified early is having every older adult served by a singular primary care provider who can follow the patient (and know the patient's family and living situation) over a sustained period of time."*

It can be uncomfortable and sometimes daunting to assume the role of disciplinarian, personal care attendant, and financial and legal planner. Decisions need to be made about how tasks that the person with AD can no longer handle will be managed by the caregiver. These include shopping, cooking, laundry, paying bills, preparing taxes, maintaining property, transportation, bathing, toileting, refilling prescriptions, making physician appointments and accompanying the person with AD, and offering socialization and religious fulfillment. Many families choose to take on these new responsibilities and assist the person with AD in their own home or have them move in with other family members. This often requires redistribution of other responsibilities to make time (i.e., part-time work rather than full-time work). Cost is also a consideration, as there is often an increased financial expense for food, gas, and prescriptions. According to the national Alzheimer's Association, more than seven out of ten people with AD live at home where family members and provide almost 75% of the care they receive. The average lifetime cost of care for an individual with Alzheimer's disease is $174,000. The average life expectancy after diagnosis of AD is eight years, but some individuals live as many as 20 years after initial symptoms occur.

Generational equity comes into play for many families. The tug of time and money being directed toward children and grandchildren versus aging parents and grandparents is a difficult one, especially for working families or those with multiple members with special needs. The allocation of resources is a personal one reflecting family and cultural values. Sometimes overlooked are the benefits that a person with AD can add to a family. Short-term memory may be impaired, but storytelling and reminiscence are often preserved until late stages. Physical abilities are also often quite intact, and there is usually absence of pain unless co-morbid conditions exist. There is time to reflect, to make wishes known, and to enjoy the love of family. If there has been a history of commitment to faith, it can often bring peace and contentment. Pets, children, and bright colors can bring joy. Simple tasks like folding laundry, setting the table, and watering plants can be helpful and add meaning to life. Since memory is impaired, individuals who previously suffered from anxiety are often quite calm and content as AD progresses.

The Decision about Institutional Care

For some families the choice of institutional placement and relocation is the optimal choice. This most often occurs at the point when family members are convinced that the patient can no longer be left alone. But, even when that choice is made, there are many necessary decisions that can be confusing to families and healthcare professionals. Nursing homes tend to embrace a "medical model" and allow persons with AD to have on-site assessment by professionals, including physicians. Assisted living facilities reflect more of a "hospitality model" and typically require that new residents be able to live with independence in most activities of daily living, but add on costs for additional services that might be required. Residents of assisted living facilities usually go to the physician's office for assessment, or, if urgent care is required after hours, to the emergency room. Retirement homes provide some transportation and food options, but no direct nursing or medical care. Continuing care retirement communities have the entire continuum from independent living to skilled nursing home care, making it possible for the individual resident to "age in place." The cost of this often includes a substantial up-front entrance fee, as well as an ongoing monthly charge. Dementia units are also available at some assisted living facilities and nursing homes. They vary widely and careful scrutiny of staffing, programs, and policies should be reviewed. Annual costs for these options vary from $15,000-$60,000 or more per year.

As healthcare providers, we often see how these choices bring out both the best and the worst in family relationships. While one family may benefit from the homecoming of a child who is temporarily out of work and unemployable as a primary caregiver for a parent with AD, another may experience considerable sibling disagreement over the decision to use what might otherwise be the children's inheritance as the source of funding for long-term institutional care. In our experience, the options available to Alzheimer's patients often reflect the resources, both personal and financial, they have "banked" before they became ill. The quality of the relationships they have with their children often affects how willing the children are, as adults, to sacrifice in their own lives in order to assist a parent.

There are no right or wrong decisions, but one's cultural, religious, and family values and background should be taken into account. Ideally the primary healthcare provider should work with the patient and family to connect with the many health and social services relevant to the patient's changing needs and enlist community and/or facility support systems as appropriate. If this is done, dignity, comfort, and quality of life can be preserved to the maximum extent possible, without the practice of futile medicine or caregiver burnout. Until reliable preventive measures or treatments for Alzheimer's disease are available, the provision of ongoing primary healthcare to patients and families experiencing the impact of this disease will remain a challenging problem for patients, their families, and their doctors. **NCMJ**

Alzheimer's Disease:
A Nursing Home Perspective

Ted W. Goins, Jr, and Lori R. Reid, BSW, CSW

Few would argue with Dorothy, "There's no place like home." We are all comfortable in our homes and lives, and want to keep it that way. Unfortunately, the ideal and the reality are often dissimilar. A person with Alzheimer's disease (AD) or dementia may no longer be safe living alone. Cooking, hygiene, and safety concerns collide with the desire to stay at home. A spouse or child may spend years caring for an Alzheimer's patient, often to their own detriment.

The sadness associated with caring for AD patients is overwhelming. Alzheimer's support groups are a necessity in providing caregivers the support and encouragement to continue. Family members constantly worry about early stage sufferers living alone. When will I receive a call that there has been a fire or an accident? How many times did mother get confused and call me in the middle of the night? Caregivers are exhausted from being awakened, worrying, chasing, cleaning, holding, and providing for every need.

> *"There comes a time when your local community nursing home is the best option. Your nursing home is salvation for the AD patient, caregiver, and the wider family."*

Professional Care

There comes a time when your local community nursing home is the best option. Your nursing home is salvation for the AD patient, caregiver, and the wider family. Many of North Carolina's 420[1] nursing homes are equipped to care for Alzheimer's patients, and some specialize in AD care. Most facilities are equipped to care for early stage residents, especially those who are not apt to wander. Wandering is as dangerous to the AD patient in a nursing home as it is to one at home. It is difficult to constantly watch any person in any setting.

Some nursing homes have specialized in AD care by creating special wings or units. An AD unit is usually a locked unit with programming specifically designed for AD residents, and has specially trained staff. Programming is important. AD residents need specialized approaches, care, and activities. Inviting an AD resident to sit and watch a movie for two hours or to work on a craft for an hour is counterproductive.

Successful programming may be unusual, but effective. After a retired mechanic was found under an overturned couch, he informed the staff he was changing the oil. The facility installed part of the front end of a car to keep the mechanic busy. Musical programs are well received. Residents may not remember many things, but they can belt out every word of "Amazing Grace." A resident may be quite confused, but that mouth pops open when the chaplain offers Communion, and they never seem to forget the Lord's Prayer.

Some facilities have created a "Snoozelin" room. Snoozelin, or Snoezelen, is a Dutch concept used with mentally disturbed children, and adapted for use with AD patients. A Snoozelin room contains light and sensory stimulation to improve the quality of life of residents. It might contain multi-color fiber optics, aromatherapy, music, cascading water,

Ted W. Goins, Jr., is President and CEO of Lutheran Services for the Aging, Inc. LSA is a faith-based, nonprofit ministry that operates nursing homes, retirement centers, adult day care, and other elder services in North Carolina. Ted is an active advocate for North Carolina's elders and nursing homes. He can be reached at tgoins@lsanc.net or PO Box 947, Salisbury, NC 28145. Telephone: 704-637-2870.

Lori R. Reid, BSW, CSW, was employed at Lutheran Home of Hickory from August 1992 until October 2004 and is now employed at Hospice of Burke County. She serves on the Western Carolina Alzheimer's Association Board. Lori has also been a facilitator for the Catawba County Alzheimer's Support Group since 1993 and serves on various other Alzheimer's Association committees. She can be reached at reidscape@charter.net or 1721 Enon Road, Valdese, NC 28690. Telephone: 828-879-1601.

and more. Residents are encouraged to look, touch, and participate. The room is stimulating, satisfying, and tiring, thus reducing the tendency to wander.

"A 'dementia capable' staff is essential and should be the distinctive characteristic of an Alzheimer's care program."[2]

There must be appropriate numbers of staff who are appropriately trained to provide the best care to our loved ones. AD residents cannot be approached or cared for in the same way as other elders. The answer to the question, "Do you want a bath?" is always "no." The alternative may be, "How about helping me get cleaned up for dinner?" Leaning into the face of a combative resident can easily result in staff injury. It's important to know when and how to approach AD residents.

Special Alzheimer's units are becoming more prevalent. Many of these are wings of existing facilities that have been designed or converted for AD residents. While there are differing opinions on whether to lock a unit, or whether to admit AD residents into the general nursing home population, the prevailing opinion seems to be in favor of a locked unit specifically for AD. By the time AD residents are admitted to a nursing home, wandering is often a significant problem. Elopement, a resident wandering away, is a serious problem for a nursing home. The safety of the resident is at risk. Elopement is a major liability event. Elopement, even without harm, will result in serious punitive action due to the zero tolerance, perfection-based federal regulatory system. Locked units provide resident rooms, dining areas, activity space, and room to wander, while keeping the resident and the facility safe.

The use of physical and chemical restraints is a concern of residents, families, and healthcare facilities. Professional standards and federal requirements dictate that if residents must be restrained, that they be restrained in the least restrictive manner. Nursing home residents will fall. Helen Lach points out that healthcare facilities want to prevent falls, but this goal is not realistic. One-third of older adults living at home fall each year.[3]

Restraints can cause more harm than good. Residents can, and have, become entangled or even hung by their restraints or bed rails. Restraints can cause residents to become more agitated, combative, and likely to fall. Chemical restraints (drugs) can have serious side-effects including weakness and dizziness and can interact negatively with other medications.

Some nursing facilities have designated themselves as "restraint-free." All facilities are required to restrain in the least restrictive manner. Residents/families should discuss the issue with the nursing home to ensure a clear understanding. A proactive nursing home will be taking steps to minimize restraints and fall hazards. Restraints and falls can be minimized by proper exercise, supportive and nonskid shoes, elimination of tripping hazards, clean floors, appropriate medications, etc.

Choosing a Nursing Home

People should not wait to engage in the nursing home search until they need one. Your local nursing home is a wonderful community resource. Active involvement in its life and activities will help ensure the kind of place where you would want to live. If the local nursing home doesn't have an Alzheimer's unit, you may be able to assist in the creation of a unit, or expand the search to the nearest quality Alzheimer's facility. Choosing a facility is easy if it has been an ongoing part of your life. While there are various Internet and other resources to assist in selecting a nursing home, they are based on snapshots and subjective criteria. In the absence of active involvement, selecting a nursing home is best based on personal visits, interviews with staff, residents and families, and references from residents and their families. Residents and their families should expect:

- a safe, clean, and comfortable environment,
- friendly and well-trained staff with a customer service mentality,
- an attentive attending physician who visits when necessary and required,
- attractive and tasty meals,
- a home environment, even if the building is institutional in nature,
- regular involvement in the plan of care and care of the resident,
- stimulating activities, and
- appropriate medications.

Herb Shore was a founding member of the American Association of Homes and Services for the Aging. Mr. Shore was quoted during his eulogy as saying that "nursing home quality could be defined as a dry bed, warm toast, and a gracious 'Good Morning'." While this may appear simplistic, Mr. Shore covered the gamut in his definition of quality.

Residents and families must be realistic about long-term care, a subject that should be discussed at length on admission. The resident is being admitted to the nursing home because the family was not able to continue to keep the person at home, even with one or more caregivers involved, even with one-on-one care. Nursing homes are able to take advantage of economies of scale while making healthcare professionals directly available to residents. One-on-one care at home (or in a nursing home) could easily cost $87,600 per year, while the average annual cost of nursing home care in the United States is $42,000. Open and honest communication between facility and family will result in realistic expectations for everyone concerned.

The nursing home profession faces significant challenges for the future. The aging of America and the corresponding increase in the number of people suffering from Alzheimer's disease will overwhelm the current healthcare system in the United States. It is estimated that 4.5 million Americans have Alzheimer's disease. By 2050, the number of individuals with Alzheimer's disease could range from 11.3 to 16 million.[4]

The Challenge for Nursing Homes

The great "truth," "It's always about the money," has never been truer. We get what we pay for. Our society has shunned elders. Youth and beauty are in; aging is out. Many don't want to face the aging process, and society doesn't want to pay for it. As a result, Medicaid reimbursement, which pays for approximately 73% of nursing home care, is an under-funded and broken system. Twelve percent of North Carolina's nursing home residents are covered by Medicare.[1]

According to a recent Brown University study, 40% of African American nursing home residents live in low-tier facilities, compared to only 9% of whites.[5] Low-tier is defined as employing less staff, a high proportion of Medicaid-paid care, and having financial and management problems. Institutional racism pervades the Medicaid program. Different states fund Medicaid in different ways and at different levels, often poorly. The federal government must repair the Medicaid system to provide for today's and tomorrow's elders and to correct injustices against minorities and elders. Re-creation of the nursing home Medicaid program, similar to the federally-administered Medicare program, seems the most reasonable method of correcting inequities between states, institutional racism, and inadequate funding.

While the reimbursement system pays for "mediocrity," the regulatory system is based on criteria of "perfection." The federal system of regulation is expensive, punitive, and largely dysfunctional. Anything less than perfection during surprise nursing home inspections may be subject to severe penalty. A reasonable system of inspections and collaboration between residents, providers, and regulators could create a situation that provides a better home for every nursing home resident.

Nursing home financing cannot be left strictly to government. Every North Carolinian has the obligation to prepare for their own future, including healthcare. In light of the cost of long-term care and the likelihood of needing some form of care, long-term care insurance may be one of the soundest investments a person can make.

There is already a shortage of qualified, dedicated nurses, nursing assistants, and other workers in the nursing home profession. There is a projected shortage of almost 18,000 nurses by 2020.[6] The North Carolina Institute of Medicine Task Force on the North Carolina Nursing Workforce outlined a number of recommendations to combat the shortage, which should be addressed immediately.[6]

Future Models

Society's attitudes about nursing homes must change. Negativity about nursing homes hurts today's residents, and perpetuates negative stereotypes for future generations of people who may have to live there whether they want to or not. Our society has gotten even more mobile. Who will take care of you?

Nursing homes have to change too. The old institutional, hierarchical nursing home will not survive. Today's nursing homes are adopting quality improvement and innovation as their strategies. Nursing homes are adopting the quality of life improvements of the Eden Alternative and similar programs. Eden fights the old nursing home's ills of loneliness, helplessness, and boredom through resident-centered care, a team culture among staff, and even children, plants, and animals. Leaders are turning their facilities into homes!

Another quality improvement initiative, Wellspring, is to quality of care what Eden has been to quality of life. Using many of the same culture-changing techniques along with massive education at all levels, Wellspring improves the clinical care provided in nursing homes. Wellspring and Eden have seen the advantages of working together and have adopted the term "New Pathways" to reflect their work together. The five Lutheran Homes in North Carolina and the four Lutheran Homes in South Carolina have joined together to bring only the third Wellspring collaborative in the United States to the southeast. Medical Review of North Carolina is piloting a similar collaborative effort at this same time.

Culture change breeds more new ideas. The Eden Alternative and others have moved their emphasis from culture to physical facilities. Innovators are looking at new, less institutional buildings. The long, cinderblock hallways are being replaced with more homelike surroundings. Eden's Green House philosophy suggests six-to-ten-person (nursing) homes on the same campus or in the same neighborhood, using technology, and visiting nurses to perform needed functions.

There is no place like home, but for victims of Alzheimer's disease and many other elders, nursing homes are essential. Each of us should take the responsibility for creating a healthcare system that honors our elders. **NCMJ**

Preparing Families to Make Informed Decisions about Long-Term Care

Sharon C. Wilder and Kathryn A. Lanier, MS

One of the roles of the Long-Term Care Ombudsman Program is to provide helpful information, make referrals to appropriate resources, and guide families through the process of locating a nursing facility that provides the services and care that meets their loved one's needs. In addition, once an individual becomes a resident in a long-term care facility, long-term care ombudsmen provide assistance to families experiencing difficulty either in communicating or problem-solving with the staff of a long-term care facility on behalf of their relative with Alzheimer's disease.

> *"Persons with Alzheimer's disease or a related dementia should always be included in the discussions about their future care to the extent they are able to participate."*

Families most often express concerns about protection of individual dignity, sufficient staff time to attend to personal hygiene, incontinence care, and adequate assistance with activities of daily living. Occasionally families share concerns when they think a facility staff member has failed to take the time to adequately assess why a resident with Alzheimer's disease may be exhibiting certain behaviors, particularly if the behaviors reflect aggressiveness or resistance to "hands-on" care.

Family members contact long-term care ombudsmen frequently for assistance when their loved one has experienced some type of acute episode that has resulted in their being advised to find placement in a skilled nursing facility. This article focuses on important issues families must work through to prepare themselves and their loved one for a smooth transition into the long-term care setting.

Where to Begin

For some families or spouses, there comes a time when they realize they can no longer adequately manage all of their relative's medical needs and activities of daily living in the home setting. Usually this awareness is triggered by rapidly escalating behavioral problems or medical emergencies that are occurring much too frequently. In such a situation, it would not be unusual for the family physician to be the one who first suggests that it may be time to begin planning for transitioning their loved one with Alzheimer's disease into a long-term care facility. It is very common for family members who are the primary caregivers to undertake this often daunting task during a time when they are emotionally and physically exhausted and don't know what steps to take to begin the process.

As the discussion is begun, family members need to obtain information about several important issues before they actively seek admission for their loved one. In some instances, there will be little or no time for planning because the older relative may already be in the hospital, and recommendations have been made by the physician for the hospital discharge planner to work with the family to find appropriate placement in a long-term care facility right away. In other situations, some advance planning can provide valuable information for a family or spouse beginning their search for a long-term care facility. Key planning issues include designation of a legal spokesperson for the older relative, consultation with the attending physician to obtain important information about the person's current medical status, and collection of information about the family member's assets and income that could be made available to pay for the costs of care in a long-term care facility. Persons with Alzheimer's disease or a related dementia should always be included in the discussions about their future care to the extent they are able to participate.

Kathryn A. Lanier, MS, is the Ombudsman Program Specialist at the North Carolina Division of Aging and Adult Services. She can be reached at: kathryn.lanier@ncmail.net or (919) 733-8395.

Sharon C. Wilder is the State Long-Term Care Ombudsman at the North Carolina Division of Aging and Adult Services. She can be reached at sharon.wilder@ncmail.net or (919) 733-8395.

Selecting a Spokesperson

Establishing legal authority is an important issue for many reasons, including the federal Health Insurance Portability and Accountability Act of 1996, Public Law 104-191, known as HIPAA. HIPAA laws have enhanced healthcare information security protections that prohibit healthcare providers from sharing any personal or medical information with others without appropriate written authorization from the individual or their legal representative.

When persons have Alzheimer's disease or a related dementia, it is important for their family caregivers to determine if their family member has chosen someone, usually an adult child or spouse, as the legal representative to act on their behalf, when they are no longer able to express their preferences or make decisions. If there is no legal representative, then an attorney experienced in elder law issues can be consulted to determine whether necessary legal documents, such as a durable power of attorney or a healthcare power of attorney, can be drawn up to reflect the relative's wishes. In situations where a family member has already experienced substantial declines in cognitive status without having designated a legal representative, the remaining option is for the family to petition the local Clerk of Superior Court to appoint a family member as the person's legal guardian.

Talking with the Physician

Physicians have an opportunity to empower the primary caregiver to assume a positive supportive role for the person with Alzheimer's disease, particularly as their relative gradually loses cognitive and verbal skills. In order to represent their loved one's wishes in care decisions, family members, or legal representatives need clear information about their relative's current medical condition, general medical history, currently prescribed medications, history of allergies, and the expected prognosis for each illness explained to them in laymen's terms. Accompanying their relative on a visit to their physician provides an opportunity for the family member and the physician to discuss recently observed changes in mental status, new safety issues in the home, or deteriorating health conditions. This thorough review of the loved one's current status will aid the physician in determining specific care needs and the care setting that can most appropriately provide the services needed. In some situations there may be an opportunity for the physician and family member to explore whether additional community resources, such as in-home services through the Community Alternatives Program for Disabled Adults (CAP-DA)* or respite services offered through the North Carolina Family Caregiver Program are options that may make it possible for their relative to continue living at home a little longer.

If the evaluation process results in a recommendation by the physician that the person with Alzheimer's disease has medical needs that require placement in a nursing facility, then the family member should ask whether the physician will continue to be the relative's attending physician after the move. If the community physician does not visit nursing facilities to treat patients, families need to know that they must find a new physician. Each long-term care facility can usually provide a list of physicians that a family may use to arrange coverage by a new attending physician for their relative's medical care while in the nursing facility.

Paying for Nursing Care

As stated earlier, primary caregivers or spouses will also need to collect and review financial documents and health insurance policies so that they have a clear understanding of their relative's assets, income, and any third-party health insurance, such as long-term care insurance, that may be available as a resource to pay for care provided by a nursing facility. Most people are not aware that Medicare Part A provides only a short-term skilled nursing benefit following a minimum three-day hospital stay. Often Medicare Part A coverage ends within two-to-three weeks or as soon as individuals achieve their maximum rehabilitation potential. At that point, long-term care expenses must either be covered by a person's personal assets, long-term care insurance benefits, other third-party insurance, or by applying for public financial assistance.

The state Medicaid Program is the primary provider of public financial assistance for nursing home care. The State County Special Assistance Program for Disabled Adults provides financial assistance to pay for assisted living level of care (also known as adult care). Both public programs are administered locally through county departments of social services and have stringent eligibility requirements. Some assisted living facilities and a few skilled nursing facilities admit only individuals who can pay privately for care. If a family member knows that it will be necessary to apply for Medicaid assistance in the near future, then he/she will need to investigate facilities that accept a mix of payment sources. This is important because, in a private facility, once their loved one becomes eligible for public assistance, they may be asked to move to another nursing home, which can be extremely traumatic for someone with Alzheimer's disease or a related dementia.

Looking for a Nursing Facility

When searching for a long-term care facility, geographic location is an important consideration for many families. A nursing facility close to work or home affords families opportunities to visit their loved one and ease in responding to situations as they arise. A second important consideration for families is selecting a facility that has a good performance record and can

---

* The State County Special Assistance Program for Disabled Adults is administered locally through county departments of social services. In many counties there is a waiting list for these services.

meet their family member's medical and safety needs. Once several potential facilities have been identified, family members should obtain as much information as possible about each facility under consideration. Families can then compare the strengths and weaknesses of each facility before making a final decision. Important resources for specific information include:

- each nursing facility's most recent survey records and quality indicator scores are posted on the Medicare web site at www.medicare.gov/NHCompare/home.asp,
- public survey information is available through the North Carolina Division of Facility Services, Licensure and Certification Section,[2]
- other information is available through the local Regional Long-Term Care Ombudsman's Office,[3]
- personal visits to facilities under consideration are recommended, and
- each county department of social services collects public monitoring records, which are available for each licensed adult care home in that county.

Asking Important Questions

The placement process often triggers intensely mixed emotions for family members and can be a difficult period of transition for everyone. Because this situation is unlike anything that a family, particularly adult children, has ever experienced, they may have difficulty identifying the questions that need to be asked when meeting with the admissions staff in the facilities under consideration. Some of the crucial questions that need descriptive answers are:

> *"It is very common for family members who are the primary caregivers to undertake this often daunting task during a time when they are emotionally and physically exhausted and don't know what steps to take to begin the process."*

- What is the organization's philosophy regarding the treatment and care of individuals with dementia?
- Does your facility have a Special Care Unit?
- What factors determine whether someone should be placed in a Special Care Unit?
- What services are provided?
- How is the Special Care Unit staffed?
- What is the background and training of the individuals who work in the Unit?
- What steps are taken by the facility to ensure the autonomy of each resident?
- What happens when the type of care needed or payment sources change?
- What are the facility's visitation policies?
- How does the facility ensure good communication with family members about service provision issues?
- How are individual resident or family concerns and grievances handled internally by facility staff?
- Is this information provided in writing?

Additional resources for guidance about important questions that need to be asked or assistance in developing a checklist that can be used during facility visits are available on numerous web sites such as www.aarp.org, www.medicare.gov, and www.myziva.net.

After the Move

After moving a loved one into a nursing facility, it is not uncommon for family caregivers to experience an array of mixed feelings such as guilt and relief. They may experience lingering concerns that facility staff will not be able to care for their loved one like they did at home. Sometimes a family member or spouse may worry that their loved one will be frightened because he/she cannot understand where he/she is and will not recognize the staff as caregivers. Other family members may be uncomfortable initially with the idea that their loved one is confined behind locked doors or wearing a monitoring device.

Daily routines in a long-term care setting are very different from those one is accustomed to in a private home. Such a change in setting can be very disconcerting, especially for the person with Alzheimer's disease. The most significant changes in the daily routine generally will revolve around the new resident's wake/sleep cycles, eating habits, and bathing routines. It is important for both family members and facility staff to allow the newly admitted resident some time to adjust from having been the center of attention in the home, to now being one of several people depending on staff for care and personal attention. Another important adjustment that may surface is the issue of sharing personal living accommodations with a stranger in a space much smaller than their bedroom at home. In terms of new residents becoming more comfortable in their new surroundings, it is essential that families make an effort to provide staff with personal information about their family member. They can also informally share information with the direct care staff, such as the best way to approach the person, the name their relative responds to, situations that are frightening to them, favorite foods, foods they will not eat, allergies, activities that interest their relative, and a host of other intrinsic characteristics that make their loved one "unique."

This transitional phase is also an ideal time for families to explain to the facility staff, including the resident's new attending physician, how they can be contacted and what types of information or notifications they wish to receive regarding changes in their loved one's health status or problems encountered during daily care. The legal representative for the resident should provide neatly printed or typed instructions including all telephone numbers to be placed in the front of their relative's medical chart along with a copy of their durable power of attorney, healthcare power of attorney or guardianship documents. This information should also be placed on file with the facility social worker and passed on verbally to nursing staff on duty during visits with the resident.

It is important that residents and family members quickly learn to whom questions or issues of concern should be addressed. Once they have identified the appropriate staff members, the next step would be to determine the best way of conveying information. The most effective method is to speak directly with staff about a specific issue or concern and then follow up the conversation in writing. Communication should always be courteous and respectful and focused on specific issues in order to achieve a satisfactory outcome. Many times, situations that initially need minimal attention or intervention turn into matters of seemingly great magnitude as a result of poor communication. It is crucial for residents and family members to know about the facility's internal grievance procedures and the process by which concerns that have been expressed are addressed by facility management. All long-term care facilities have a responsibility to ensure staff familiarity with the facility's policies and procedures for communicating with a resident, resident's family or legal representative, especially in the event of acute changes in condition, accidents, or injuries. When all parties use this frame of reference, then the lines of communication will remain open. Well established communication systems within the facility can help alleviate misunderstandings and reduce a family's anxiety about their loved one's care.

If/when these channels do not produce the desired results, then other avenues of assistance should be sought out to address the issues, such as contacting an objective third-party, like a local long-term care ombudsman. The Long-Term Care Ombudsman Program's mission is to protect residents' rights, welfare, safety, and improve the quality of care and life for residents in long-term care facilities. When complaints are received by or on behalf of residents, long-term care ombudsmen offer an informal grievance resolution process as a tool to resolve issues in a manner that is mutually acceptable to the involved parties.

The North Carolina Division of Aging and Adult Services has several resources available to families on its web site at http://www.dhhs.state.nc.us/aging/ombud/ombtools.htm.

One document "Nursing Home Concerns" details which staff member(s) to direct questions or concerns to based on the nature of the issue(s). A second document "Puzzle Solved" gives suggestions on steps to take to ensure messages are conveyed effectively. **NCMJ**

Dementia Care:
An Outpatient, Community-based, Multi-Disciplinary Approach

Virginia H. Templeton, MD

Many believe our ability to remember is a fundamental part of what makes us human and consider with dread the thought of dementia. Thomas Jefferson said, "Bodily decay is gloomy in prospect, but of all human contemplations, the most abhorrent is body without mind." When I first decided to work in the field of dementia, most of my peers did not understand. Dementia is a devastating disease with no cure and few viable treatment options at this point in history. My training as a family physician emphasizes prevention and health, but with dementia the terms of care change dramatically. Besides the bleak state of medical interventions, the issues are largely social and the reimbursement minimal. I was asked, "Won't you be depressed?" "How can you make a living?" "What can you actually do to help these families?" It was a big personal gamble in many ways, but I have always been interested in neurology and in how illness affects families and thought: what more family-centered disease is there than dementia? When I was offered a position at the Memory Assessment Clinic and Eldercare Resource Center in Asheville, I didn't exactly jump at the opportunity, but I decided to take the risk.

History of the Program

The Memory Assessment Clinic (MAC) was established by Margaret A. Noel, MD, a fellowship-trained geriatrician, who has worked in western North Carolina for the past 15 years. When first in practice, she set up a general geriatric care clinic ensconced within the hospital system in Asheville, North Carolina, and found that the majority of patients came with their families for evaluations of cognitive impairment. Initially, the hospital was able to underwrite the expense of the program, but when re-imbursement changed in the 1990s and funding was limited, the program was unable to sustain its cost and had to close. Because of her work, Dr. Noel knew the extensive needs of the geriatric community in the region and, with the support of a local retirement community that provided space at minimal cost, she established MAC as a nonprofit, charitable organization. By collaborating with the Alzheimer's Association and other community agencies, MAC became a part of Asheville's medical community and is now a valuable community resource for dementia care.

The Need

After joining MAC in 2002, I learned more fully about the impact of aging in our community and began to understand the array of issues that comes with a diagnosis of dementia. As is true for the rest of the country, the aging population in North Carolina is on the rise. According to the United States Bureau of the Census, close to 35 million Americans are now more than 65 years of age (up by 12% from 1990) of whom nearly one million live in North Carolina (up by 20.5% from 1990).[1] While this increase in life span is a huge success for public health efforts, healthier living, and medical advances, it also contributes to the creation of a population at great risk for developing dementia. It is thought that approximately 50% of those who reach 85 years of age will show signs of dementia,[2] so as our population ages, there is a concomitant increase in the incidence of dementia. In North Carolina, the Alzheimer's Association estimates that 132,329 residents have Alzheimer's disease, of whom 77,023 (58.2%) live in one of the 49 counties in the western portion of the state,[3] making it a major health issue for our region.

Dementia is a disease that not only affects the patient, but those around them as well. Caregivers for people with dementia learn to handle finances, manage medications, cook, clean, and provide transportation. Eventually they may also help with bathing, toileting, and feeding, and monitor for wandering. Individuals are often stretched far beyond what they thought they could do. In an editorial in the *Annals of Internal Medicine*, Kenneth Covinsky aptly states that "...a diagnosis of dementia is a sentinel event that signifies progressive loss of independence and increasing demands on caregivers."[4] Families struggle with taking a car from their loved one who relies on it for groceries, medications, and attending church. Removing guns from the home of a paranoid spouse or parent may protect lives, but may

---

Virginia H. Templeton, MD, is the Associate Director of the Memory Assessment Clinic in Asheville, NC. She can be reached at templeton@memorycare.org or 2360 Sweeten Creek Road, Asheville, NC 28803. Telephone: 828-771-2219.

also trigger angry outbursts and affect relationships. Taking responsibility for these important safety issues is necessary, but for many caregivers is done at the expense of their own careers and educations and causes substantial financial and personal loss. As Covinsky points out, because those with dementia are not eligible for palliative services through Medicare until much later in their disease course, the burden of care at earlier stages falls on families.[4] It is no surprise that in a recent report released by the Alzheimer's Association and the National Alliance for Caregiving, "Americans are as afraid of becoming an Alzheimer's caregiver as they are of getting the disease itself."[5]

> *"In caring for people with dementia, I feel I have found a truly family-centered practice very much in keeping with the goals I had going into medicine."*

Our Model

The model of care utilized by MAC attempts to respond to the needs of patients and caregivers by providing the time necessary for accurate medical assessment and treatment, support and care management, and education about the disease process. There is also a commitment to educating the lay and professional communities in the region about healthy aging, dementia prevention, and dementia care.

In the clinic, each team has a physician and a care manager who is trained in nursing or social work. The model is similar to those in memory clinics established in academic centers, but is unusual and challenging outside such a system. In essence, MAC is a community-based, family support program integrated within a medical practice. Patients come to MAC by physician referral at a variety of stages of illness. For those who request enrollment, but have no primary care physician, a list of local physicians accepting new patients is provided so they can undergo initial evaluation and laboratory tests to ensure referral to the program is appropriate. Collaboration with primary care physicians is essential to facilitate routine monitoring and treatment of health problems that may impact cognitive function, such as diabetes, hypertension, hyperlipidemia, and others. MAC physicians serve in a consultative role and focus on the dementia, alone, and are often involved for the duration of the disease process, depending on family needs. Because those with dementia cannot always provide an accurate history and caregivers may not feel comfortable contradicting them, primary care physicians face a task that is not always feasible in a 15-minute office visit; HIPAA rules may limit their interactions with caregivers unless explicit permission is obtained from the patient. MAC is structured so that caregivers and patients each have time alone with the physician to discuss concerns; initial evaluations last from three to four hours with follow-up visits taking an hour. The time MAC has dedicated for physicians to spend with caregivers provides additional history that helps facilitate an accurate diagnosis, opportunity for developing realistic management plans, and a chance to educate caregivers about dementia and its expected progression. The time also allows physicians to address complicated emotional issues that can arise with care-giving. Some find themselves in the position of caring for a previously abusive parent; others are losing a treasured partner and need help finding appropriate ways of dealing with complex feelings. While to some providers, the time may seem luxurious or inefficient, in practice, it feels like a vital part of providing the best care for those suffering with dementia.

In addition to physician services, MAC employs nursing and social work staff who are the program's care managers and provide a wide range of information needed by caregivers. This interdisciplinary approach is a basic necessity for any dementia program to help families deal with such issues as incontinence, insomnia, paranoia, wandering, grief, and more. It may extend the time patients can be cared for in their homes and, if placement becomes necessary, ease the transition. Collaboration with other local service organizations such as the Alzheimer's Association, adult daycare programs, Mountain Area Health Education Center, the Council on Aging, and others is also a fundamental part of care provided.

Funding

The model of care utilized at MAC is costly and could not exist without substantial community support. While insurance companies pay for physician-patient time, they do not cover staff time spent with families for counseling, education, or creation of management plans. To deal with this dilemma, MAC asks each family to pay a yearly enrollment fee ($385), which covers caregiver time spent with the physician, care management, and other support services. The fee is waived for those unable to pay and charitable funds are raised to pay for the remaining expenses of the program. While this is an unusual arrangement for a medical office, extensive efforts are put into explaining the fees to those enrolling, and to-date the organization has been well-received. In our 2003 Caregiver Survey, 87% of responding caregivers (N=121 of 194 surveys sent) felt the caregiver fee was reasonable for the time and service provided through the program; 99% of caregivers and 98% of responding physicians (N=37 of 114 surveys sent) either agreed or strongly agreed that the program should continue to provide these services.[6]

With a commitment to prioritizing time with families, MAC has the challenge of achieving sustainability, which is difficult for all nonprofit organizations. Alternative approaches to funding have been explored, but all have substantial drawbacks. One option would be to house the program under the umbrella of a larger institution such as a university, medical school, or hospital that could cover the financial gap, but if there came a time when the institution could no longer underwrite the expense of the program, it could be dropped or demands made that the model of care be compromised. Families may also be willing to pay in full for the services provided; however, this limits care provision to the wealthy and leaves out a large number who need and deserve the services as well.

Conclusion

During medical training, I learned to maximize the 10-15 minutes I had with each patient. I often found myself choosing which problems to discuss, knowing important issues were being postponed, but hoping we could address them at the next visit. With dementia, this approach is not only inadequate, it is dangerous. Particularly at early stages of disease when diagnosis is difficult, vulnerability is at a peak—medications may be missed or overtaken, dangerous drivers remain on the road, and life savings may be spent or squandered. Without a diagnosis, it may be unclear to families that intervention is necessary. Experience has shown that good care for people with dementia needs to include extensive education, counseling, and support of caregivers and partnerships with community organizations. Time with caregivers is an essential part of providing this care and requires a medical system that values interactions with caregivers, not just in theory, but in practice. MAC is a difficult program to replicate because its structure is not financially viable without considerable community support. The model is an excellent one to provide the best possible care to those with dementia and their caregivers, but it requires community investment and the commitment of individuals who believe in its worth. In our part of the state, where many older adults choose to retire, the degree of community support for MAC has been remarkable and speaks to the need for such a program in this area.

In caring for people with dementia, I feel I have found a truly family-centered practice very much in keeping with the goals I had going into medicine. While a cure remains elusive, the science around this disease is exploding and exciting to be a part of. I confess I occasionally moonlight in an emergency room and relish the moments of actually fixing a problem, but at this point would not trade the complexity of dealing with dementia as a professional focus of my practice. For me, in addition to the joy I find in learning ever more about our brains and how they work, there is great satisfaction in seeing families rise to the challenge of dementia, reach in their hearts and find creative solutions to complicated dilemmas. In a most unexpected way, I have found my path as a true family physician through care of those with dementia. As Jane Austin wrote, "There seems something more speakingly incomprehensible in the powers, the failures, the inequalities of memory, than in any other of our intelligences." **NCMJ**

Acknowledgements

In addition to community support, MAC is indebted to The Duke Endowment, The Kate B. Reynolds Charitable Trust, The Janirve Foundation, and The Fullerton Foundation for their significant support for the initiation and expansion of our program. I am very grateful to Steve Plever and Margaret A. Noel, MD, for their contributions to this article and to Dr. Noel for her commitment to healthy aging.

COMMENTARY

Alzheimer's Disease, Family Caregivers, and *Faith in Action* in North Carolina

Catherine O. Ahrendsen and Teepa Snow, MS, OTR/L, FAOTA

More than 70% of all dementia care is provided by a family member in the home setting, according to a survey conducted by the national office of the Alzheimer's Association. For many caregivers, the journey is an isolated one, particularly when there are no local relatives to take a shift or lend a hand. The call to duty rings seven days a week and caregivers have little or no time to tend to their own needs. Many are unaware that programs such as *Faith in Action* can offer respite and emotional support to those caring for loved ones.

Faith in Action, a national initiative of The Robert Wood Johnson Foundation, was launched in 1984, and there are 804 local programs across the United States including Puerto Rico and Guam; 355 serve Alzheimer's patients. Twelve of the 32 *Faith in Action* programs in North Carolina provide non-medical assistance to Alzheimer's patients and respite for their caregivers. *Faith in Action* programs organize volunteers from faith congregations and the community-at-large to provide non-medical assistance to their neighbors in need. While programs vary geographically, they share the commonality of the five building blocks that define a *Faith in Action* program. The programs must be (1) interfaith, (2) volunteer, (3) focus on caregiving, (4) provide assistance in the care receiver's home, and (5) serve individuals who have long-term healthcare needs. *Faith in Action* programs operate under the slogan, "A Neighbor's Independence Depends on You."

> "*Faith in Action programs operate under the slogan, 'A Neighbor's Independence Depends on You.'*"

According to Larry Weisberg, the director of communications at the *Faith in Action* national office (affiliated with Wake Forest University School of Medicine in Winston-Salem, North Carolina), programs receive start-up grants from the Robert Wood Johnson Foundation. After the initial funding of $150,000 to 25 grantees in 1984 and $25,000-$35,000 to grantees funded since 1994, *Faith in Action* programs depend on donations from individuals, businesses, and other organizations, and grants to continue to provide services. Programs unable to continue operations beyond the 30-month grant period cited lack of funding as the principal reason for closing, rather than lack of need or lack of volunteer participation.

A survey commissioned by The Robert Wood Johnson Foundation in 2001 profiled *Faith in Action* programs receiving grants from 1993 to 1999. The typical *Faith in Action* program operates with a $70,000 annual budget. Eighty percent of coalition members are faith congregations, and the remaining are from the community-at-large and include civic organizations, businesses, and healthcare agencies. More than 90% of programs provide basic services, such as home visits, telephone reassurance calls, transportation, shopping, and help with household chores. More than 70% care for ill and disabled care receivers, providing respite and hospice care. Volunteers typically serve two to three hours per week and 60% of *Faith in Action* volunteers stay with the program more than 12 months.

One role of the *Faith in Action* national office is to help the programs "share best practices," according to Weisberg. Technical assistance is provided on volunteer recruitment, coalition building, fund raising and other aspects of organizational development. Volunteer screening and training is the responsibility of the individual programs.

On a national level, *Faith in Action* has established a partnership with the American Association for Retired Persons (AARP). As part of its community service initiative in North Carolina,

Teepa Snow, MS, OTR/L, FAOTA, is the Director for Educational Programs at the Eastern North Carolina Chapter of the Alzheimer's Association. She can be reached at tsnow@alznc.org or 400 Oberlin Rd., Suite 220, Raleigh, NC 27605-1351. Telephone: 919-832-3732 or toll free 800-228-8738.

Box 1. Why Do They Do That? – Cursing and Swearing

Two major causes

Language and speech destruction and preservation

- Alzheimers' patients have trouble finding the right words, saying what they mean, understanding exactly what you mean, and making you understand. As the disease progresses the person has more and more trouble using words. The speech gets vague and lacks specifics, making it very difficult to understand. Eventually the person may be able to use only one or two phrases or words for all communication. Ultimately, very few words are available. He or she may either speak very little or speak in a 'word salad' making 'no sense,' but keeping some of the rhythms and patterns of speech.
- While the formal language center is damaged early, there are other parts of the brain that are preserved. The first is singing and music. This is why the person can sing all the verses of familiar hymns, or songs, but can't complete a sentence. The second skill is automatic social language and phrases. Things like, "How are you?" "Fine." The third preserved 'skill' has to do with forbidden words and phrases. Swear words are ones that you learned early in life and then stored in the 'don't use these!' areas of your brain, and you learned to use other substitute words. Phrases such as "shoot," "gosh," and "darn" became your substituted words when you felt the need to use the spontaneous 'forbidden words.'

Loss of impulse control

- The front of your brain allows you to control your impulses. It causes you to consider the consequences of your words or actions before acting and deciding whether to say it or not based on the possible or probable outcomes. In a healthy person, this part of the brain keeps you from saying something you might regret and from using the words you are not supposed to use in polite company.
- With the start of Alzheimer's disease, the frontal part of the brain is damaged and then destroyed. The person with Alzheimer's lacks impulse control. If he/she thinks it, he/she will say or act on it. Therefore, Alzheimer's patients may swear and use words that make us uncomfortable or may be completely out of character for that individual. It is critical to realize and remember that persons with Alzheimer's are doing the best they can. They have dementia; it is not a choice they are making.

What Should We Do?

- Always use the positive physical approach when you are helping a person with Alzheimer's disease. Make sure the person is aware of your presence before you begin speaking.
- If a swear word or forbidden word is used, recognize that the person may be frustrated or upset about something.
- If possible, back off a little and give some extra space and time.
- Use empathy and make one of the following statements...
  - "(Name), it looks like you are getting frustrated with this..." (then wait for a response or agreement or disagreement from the person)
  - "It sounds like you are not very happy right now..."
  - "It seems like you are having some trouble..."
- Always remember: You are not this person's 'mother' and you cannot teach impulse control. The brain is dying, and the person is doing his or her best under the circumstances.
- Stop and take stock. Maybe you both need a break before you continue.

AARP recruits members to serve as volunteers with selected *Faith in Action* programs. Eight North Carolina programs are involved in the partnership: A Helping Hand in Chapel Hill, Care Partners in Greensboro, Center for Volunteer Caregiving in Cary/Raleigh, *Faith in Action* at Work in Burlington, Greene County Interfaith Volunteers in Snow Hill, Care Partners of Mountain Area Hospice in Asheville, Project Compassion in Chapel Hill, and Shepherd's Center of Kernersville. Other *Faith in Action* sites include the following Hospice programs: Center of Living Home Health & Hospice in Asheboro, Hospice of Mitchell County, Hospice of Rutherford County, and Lower Cape Fear Hospice, and LifeCare Center in New Hanover County.

AARP training available to *Faith in Action* sites includes community service programs such as End-of-Life issues, Caregiving, Health and Wellness, Benefits Check-up, Driver Safety, Tax Aide, pharmaceutical affordability, Social Security, and Safe Mobility for at-risk drivers. Some *Faith in Action* program directors have become certified class leaders to conduct "AARP Powerful Tools of Caregiving" workshops. The six-week course focuses on self-care for the primary caregivers of persons with severe progressive and chronic illnesses, such as Alzheimer's, Parkinson's, and stroke. Caregivers learn coping strategies/techniques and are provided with a 'tool box' of resources including publications and information on support groups.

Some *Faith in Action* programs partner with the local Area Agency on Aging to provide in-home respite care. A provision of the Older Americans Act, amended in 2000, provides funding for the National Family Caregiver Support Program in North Carolina. This program offers family caregivers a source of information about local resources and offerings, including respite, which may help them provide care for a loved one.

Working with people who have any form of dementia, especially Alzheimer's disease, requires specialized training for the provision of safe and effective service. *Faith in Action* programs and other nonprofit agencies serving the elderly recognize the need to offer additional training to these special volunteers. A

Box 2. Positive Physical Approach

- Approach from the FRONT - let the person know you are coming
- Go SLOW - reaction times slow as we age - it takes longer for information to register
- Get to the SIDE - be supportive NOT confrontational
- Get LOW - don't use your height to intimidate
- Offer HAND - let the person with Alzheimer's start the interaction
- Call NAME - the name that person PREFERS
- THEN wait.

- Start Message
    - Give basic information - "It's time to..."
    - Give simple choices - this or that (orange juice or milk) (eat or go to the bathroom first)
    - Give single step directions - break down the task (to get up, lean forward, pull your feet in)
    - Ask the person to HELP you - it feels better to give than to receive!
    - Ask the person if he or she will at least TRY. Sometimes people will try, even if they don't think they can.
    - DON'T Ask, "Are you ready?" or "Do you want to...?"

- WAIT for a response (silently count to 10)
  IF **NO** response, ask again

  IF Responding...
    - Give positive STROKES - Feedback
    - "Good job!"
    - "Yes!"
    - "That's it"
    - Smile, nod
    - Hug, stroke, or rub

basic understanding of typical behaviors, common symptoms, and realistic expectations for responses and abilities is critical when developing relationships and offering help and support in these situations. Providing respite volunteers with the essential skills needed to interact and respond to Alzheimer's patients can mean the difference between a valuable, long-term, reliable resource for a caregiver and a one-time disaster for everyone involved. One recommended volunteer training program has been developed by and is provided by the Alzheimer's Association-Eastern North Carolina Chapter. This workshop averages four or five hours and provides the latest information about the various dementias as well as addressing misconceptions and myths associated with Alzheimer's disease. Volunteers are given tools to respond to challenging behaviors by learning more about the disease and participating in hands-on demonstrations and role playing. Faith community volunteers learn that they have the potential to be the bridge between the patient and the family, as well as a vital connector to the larger community.

Role playing and demonstration of behaviors and responses is used extensively in the Eastern Chapter's training of *Faith in Action* volunteers in North Carolina. These interactive and experiential techniques are particularly helpful in teaching volunteers how to cope with challenging behaviors. Lead trainers demonstrate characteristics and behaviors of a person with dementia. As the trainer approaches, showing impaired speech, memory, understanding, and impulse control, volunteers in training initially watch and react with nervousness, discomfort, and ineffective but typical responses. A very common issue and concern of potential volunteers is the frequent and unexpected use of profanity and vulgar phrases or words by the patients. Many *Faith in Action* volunteers benefit from a clear and simple explanation of this phenomenon, moving it from a 'bad behavior' to one of the very frustrating yet typical symptoms of this disease (see Box 1 for more information). As training progresses, volunteers begin to use the strategies provided and gain skill and confidence in their abilities to make a difference in interactions and client outcomes. By the end of the session, volunteers are able to approach (see Box 2), interact with, respond to, and meet the needs of the person with dementia in a more effective and consistent manner. Long-term feedback from volunteers and family members has indicated that this preparation makes a great difference in the ability of the volunteers to help both the person with Alzheimer's disease and the caregiver.

Weary caregivers need respite. Medicare and private insurance providers rarely fund such services, yet the use of respite can delay or prevent institutional placement for many elders with cognitive losses. *Faith in Action* programs can provide a valuable resource to community-based dementia patients and their families. These volunteers offer an expanded 'labor pool' that is committed to service. Dementia-specific training and education supports these volunteers and promotes the safety and well-being of all parties involved. Healthcare providers, physicians, physician assistants, nurse practitioners, and other providers can be valuable advocates and information sources for family members and people with dementia. They can encourage the use of respite and reinforce the need for primary caregivers of dementia patients to seek out respite volunteers, which allow them to rest, de-stress, and take care of themselves. A referral to one of the cited resources can show caregivers where to turn for assistance. Increasing public awareness of local resources and supporting these volunteer-based programs will help create an expanding network essential to baby-boomers who become part of the care pool. **NCMJ**

COMMENTARY

Dementia-Responsive Acute Care at Mission Hospitals in Asheville, North Carolina

Nancy Smith-Hunnicutt

In 2002, Mission Hospitals and the Western Carolina Chapter of the Alzheimer's Association received a grant from The Duke Endowment to develop an education-based program to improve care for hospitalized elders with dementia. The grant funds have supported an ongoing hospital initiative called "Dementia Responsive Care." This commentary describes the problem the hospital and chapter are trying to address through the initiative and the specific interventions that have been put in place.

Overview of the Problem

At-risk elders are the greatest consumers of healthcare. This is particularly true in western North Carolina, which is one of the fastest growing retirement areas in the country. Estimates provided by the National Alzheimer's Association indicate that 10% of the population over the age of 65, and almost 50% of the population over 85, have Alzheimer's disease, the most common type of dementia. People with Alzheimer's disease live three to 20 years from the time of diagnosis and often have concurrent chronic diseases that require hospitalization.

Currently, the overall hospital experience presents significant health risks for the patient with dementia. Lack of information regarding cognitive impairment and behavioral issues create serious problems for accurate patient assessment and treatment. Dementia is rarely a primary or even secondary diagnosis upon admission to the hospital. These already-compromised patients, often with multiple chronic conditions, physiologic impairments, numerous medications, and decreased functional reserve, are particularly vulnerable to the adverse affects of hospitalization common to geriatric patients. The hospital experience itself, with unfamiliar environments, changing caregivers, and invasive medical interventions, compromises patients with dementia even further. Research has shown that persons with dementia leave the hospital with more functional limitations than they had prior to admission, have a longer than average stay in the hospital (approximately four days longer), and are more frequently readmitted within 31 days of discharge.[1] Staff difficulty in understanding challenging patient behaviors and limited communication with both patient and family exacerbates complications such as delirium, malnourishment, skin breakdown, decreased mobility, and falling.

Mission Hospitals

Mission Hospitals is an 735-bed regional referral center and Level II Trauma Center for the western North Carolina region and sections of several surrounding states. Because of its location in a rapidly growing retirement area, the hospital has a high proportion of elder patients, including patients living with dementia. Although Mission Hospitals is not a teaching hospital, it does have family practice residents from the local Area Health

> *"Research has shown that persons with dementia leave the hospital with more functional limitations than they had prior to admission, have a longer than average stay in the hospital (approximately four days longer), and are more frequently readmitted within 31 days of discharge."[1]*

Nancy Smith-Hunnicutt is coordinator of Dementia Responsive Care at Mission Hospitals in Asheville, NC. She can be reached at jnsnsh@msj.org or Mission Hospitals, 509 Biltmore Ave. Asheville, North Carolina 28801. Telephone: 828 213-4542.

Education Center completing rotations within the health system. Currently, specialized geriatric efforts within the hospital include: the Geriatric Resource Nurse Program based on the Nursing Improving Care for Health System Elders (NICHE)[*] Geriatric Trained Providers, Geriatric Clinical Nurse Specialist Consult Services, Palliative Care Consultation Team,[+] Senior Medications Assistance Program, and a community-based Elder Clinic. The Dementia Responsive Care initiative builds on these geriatric programs and services.

Objectives of the Dementia Responsive Care Initiative

The problems and issues to be addressed by the Dementia Responsive Care initiative are encountered in three distinct groups: the patients, the hospital staff, and the family caregivers. Objectives are to:

- identify patients with dementia at the time of admission;
- increase staff knowledge of acute care for persons with dementia, including assessing for delirium, dementia, depression, pain and common geriatric syndromes;
- preserve function: prevent/reduce functional and cognitive decline during hospitalization;
- implement interdisciplinary best practices in care of patients with dementia, including nonpharmacologic and environmental interventions; and
- increase involvement and support of family caregivers.

Many of Mission Hospitals' existing programs and services have helped to improve care for patients with dementia and especially to increase family caregiver participation in care activities. In addition to the aforementioned geriatric efforts, there are targeted initiatives on pain management, restraints, falls, patient and family-centered care, an Ethics Committee focus on older adult issues, and a study on artificial nutrition and hydration in end-stage dementia. The chronic and terminal nature of dementia requires staff and caregivers to join together as partners in care planning and delivery.

Interventions

Utilize the expertise of Geriatric Resource Nurses as a resource for bedside nurses and other disciplines caring for patients with dementia. Dementia Responsive Care (DRC) builds on a successful geriatric nursing initiative already in place at Mission Hospitals and other hospitals in the country, the Geriatric Resource Nurse Model. The Geriatric Resource Nurse model (GRN) develops unit-based nurses to provide excellent bedside geriatric nursing care and to be a resource to other staff on the unit. Mission Hospitals currently has 50 Geriatric Resource Nurses practicing on 14 units throughout the hospital. GRNs carry a usual caseload of patients while serving as a unit resource on geriatric best practices. Like the Geriatric Resource Nurse model, Dementia Responsive Care relies on assessment, education, and resource identification to help provide comprehensive care to patients with dementia.

Educate staff on the unique needs of patients with dementia. The curriculum for the multidisciplinary education and training is built around the following assumptions:

- It is essential to address common geriatric syndromes in addition to treating admitting diagnoses. Modules were developed to define a process that looks at the person in terms of risk stratification based on their signs and symptoms, admitting diagnosis, chronic illness profile, and history for the presence of common geriatric syndromes.
- The best history gathering and assessment is holistic and reflects a consistent framework for driving the plan of care.
- Elders are best compared to their own baseline when developing a plan of care for hospitalization. Central to the design of the initiative is the tenet that family caregivers be directly involved in care planning for the patient.
- To assess functional status only is not enough. Effective care planning addresses safety and risk factors while promoting and preserving independence and social function.
- It is critical for persons with dementia to be given the opportunity to practice preserved function while hospitalized. This requires interdisciplinary communication and care planning.
- Patient comfort and avoidance/easing of suffering is of paramount importance.
- Preferences regarding intensity of care, palliative care, and end-of-life considerations are appropriate items for discussion during each hospitalization and should build on earlier dialogues.

Provide a system for addressing the individual needs of each patient with dementia and involve family caregivers in the hospital care of their loved one.

Information about patients with dementia for the hospital team. Upon admission, caregivers are given the brochure *Hospitalization Happens—a Guide to Hospital Visits for Your Loved One with Memory Disorders* (http://www.dhhs.state.nc.us/aging/alzbroch.htm)[#] and are asked to complete a short form that provides a snapshot of the patient just prior to the onset of the acute episode. Caregivers are asked to provide vital information and insight into the patient by

---

[*] NICHE - Nurses Improving Care for Health System Elders, a national initiative funded by John A. Hartford Foundation, a program of the Hartford Institute for Geriatric Nursing at New York University.

[+] Palliative Care Consultative Team, a collaborative program of Care Partners Mountain Area Hospice and Mission Hospitals.

[#] This brochure was supported by a grant from the Administration on Aging to the North Carolina Division of Aging as a product of the federal/state Alzheimer's Services Demonstration. Available at: www.dhhs.state.nc.us/aging.

identifying the patient's strengths, interests, habits, daily routines, nonverbal communications regarding pain and other needs, and non-pharmacologic methods for addressing anxiety and agitation. This form, *Personalized Care for Our Elder Patients*, is returned to the nurse at the time of admission, and the information is incorporated into the patient's plan of care and becomes a part of the medical record. Caregiver input and ongoing involvement are critical to providing dementia-responsive care. Persons with dementia must be given the opportunity to practice preserved function while hospitalized, and hospital staff need information from family caregivers to provide optimum care. Physical, functional, and psychosocial deterioration is best minimized through an awareness of the common risks of hospitalization for elders with dementia.

Information about dementia for family caregivers. Caregivers are provided information and education regarding dementia, community resources and support, and a referral to the Alzheimer's Association early in the hospitalization. Discussions with family members regarding disease progression, tube feeding in patients with dementia, advance care directives, palliative care, and end-of-life care are held during every admission. Caregivers are given additional information and the hospital referrals necessary to make informed decisions.

Information about patients from nursing homes. Nursing homes are provided with *Personalized Care for Our Elder Patients* forms and asked to fax completed forms to the hospital following transfer of a patient. Hospital staff are encouraged to talk with the long-term care provider to establish functional status prior to the acute episode and to receive patient-specific information pertinent to caring for the patient.

Information about dementia via Mission Hospital's Intranet-patient/family education literature. Educational materials written at sixth grade reading level are available for downloading on all units throughout the hospital. Additional materials are available from case managers and discharge planners on each unit.

Education and training for family caregivers. Education and training can enhance caregiver confidence in providing care. The caregiver is given strategies for communication, personal care assistance, and preventing and understanding difficult behaviors. Confidence and enhanced caregiving skills strengthen the caregiver's ability to provide care for the person with dementia.

Partner with the Alzheimer's Association to educate and support family caregivers regarding dementia and community resources.

When a loved one is hospitalized, the heavily stressed caregiver must cope with new and often complex medical challenges. The caregiver may be required to make critical decisions based on limited information with little support. The caregiver also suffers the added burden of the patient's increased confusion. Upon discharge, a new challenge arises, as the patient, most likely, will have declined considerably during hospitalization and is now more dependent on the caregiver for care. Family members often have become isolated during the course of their caregiving and have little knowledge of available community resources or how to go about accessing resources.

Caregivers of patients with dementia are given information on services available through the local chapter of the Alzheimer's Association, such as Safe Return, caregiver support and education, and respite coordination, as well as other resources available in the community. Additional resources in the community include the Memory Assessment Clinic & Eldercare Resource Center, adult day programs, legal services, in-home aid, respite care, and meal delivery. Connection with community resources can enhance quality of life for both the caregiver and the person being cared for, and provide appropriate supports as the disease progresses.

Evaluation Plans

This is an interim report, provided pre-evaluation. Dementia Responsive Care was piloted on two adult medicine units and is currently being implemented throughout the hospital. Evaluation of clinical, educational, and system outcomes is underway and will be completed in summer 2005. **NCMJ**

Remembering “Bud” Busse

(1917-2004)

Dan G. Blazer MD, PhD

Ewald W. “Bud” Busse, MD, DSc, died on Sunday, March 7, 2004, and North Carolina lost a quadruple threat—an outstanding investigator, administrator, teacher, and clinician. The JP Gibbons Professor of Psychiatry Emeritus at Duke University Medical Center, Dr. Busse was 86 years old at the time of his death. Bud Busse held many positions of importance at Duke and in North Carolina, serving from 1953-1974 as Chair of the Department of Psychiatry and from 1974-1982 as Associate Provost and Dean of Medical Education. He served as the President and Chief Executive Officer of the North Carolina Institute of Medicine from 1987-1994. Yet, the offices do not define the man. Bud defined each position with his unique style and creativity.

Bud was a gracious yet intimidating man. Quadruple threats are intimidating in large part because they innovate—weave their talents together in ways that people more narrowly focused cannot conceive. The metaphor derives from triple threat football players some years back, specifically single-wing tailbacks. These players could run, pass, and kick (and I suppose they were quadruple threats because they played defense as well). When I was growing up in Nashville, Tennessee, a diehard Vanderbilt fan, I dreaded the annual game with Tennessee. The Vols were a hated rival, and they always featured a player in their single wing formation (few teams were using the single wing after the mid 1950s) who possessed a collection of talents that seemed inevitably to coalesce into a unique and game winning play I had not seen before. For example, one year Vandy had Tennessee pinned at their own ten-yard line on third down. The tailback ran back, faked a pass, and quick kicked the ball 80 yards. I could not imagine that play before I saw it, a play both innovative and intimidating. Vandy (as usual) could not recover and Tennessee won the game. Bud frequently won victories in ways most could not imagine.

Bud was first and foremost a scientist. During his early research career, he discovered a distinctive spike on electroencephalographic (EEG) tracings in the temporal lobe associated with aging.[1] Though he never established the origin of that spike, nor its physiological relevance to aging, this finding lead Bud down two paths that ran counter to prevailing trends in American medicine, especially psychiatry—biological psychiatry and gerontology. At a time that psychiatry was dominated by psychoanalysis, except in the most backward of state hospitals, Bud grounded his understanding of human behavior in the basic biology of the brain. To put it another way, Bud was a pioneer neuroscientist in psychiatry. At a time when aging was considered closely linked (if not identical) to disease, Bud pursued an understanding of aging as a normal part of the life cycle.[2]

To investigate this “radical” view, he established the Center for the Study of Aging and Human Development at Duke in 1954. The core research project at the center was a biopsychosocial[3] study of elderly community volunteers evaluated on a regular basis for 20 years. The initial and follow-up evaluations included biological measures (such as blood studies and encephalographic studies), psychological tests (such as portions of classic intelligence tests), and extensive exploration of the social environment in which these elders lived (such as family structure and community involvement). This longitudinal, biopsychosocial exploration of normal aging, intuitive today, was a far-reaching paradigm shift and remains the pillar of modern gerontology. Much of the current excitement about “successful aging” is built on the foundation of aging as normal, not a disease state.[4]

Bud asked questions. He never stopped asking questions! Over the decades that I knew him, I never ceased to be amazed at the questions he asked. He would call my office. After a few pleasantries, he asked if I had seen a recent article (I answered

Dan G. Blazer MD, PhD, is JP Gibbons Professor of Psychiatry at the Duke University School of Medicine. He can be reached at blaze001@mc.duke.edu or DUMC Box 3003, Durham, NC 27710. Telephone: 919-684-4128.

in the negative more often than not because he was on top of the literature like a leopard pouncing on a zebra, devouring it as soon as it was in sight). What did I think about…? About two weeks prior to his death I visited him. He pointed to two books at his bedside. The first was *The Da Vinci Code* by Dan Brown,[5] a novel that raises many questions about something most of us have taken for granted—the Last Supper painting by Da Vinci. The second was *Doubt: A History* by Jennifer Hecht,[6] a book documenting the importance of doubt, not a vindictive and overly critical debunking of established truths, but rather an honest questioning of what we all-too-often take for granted. I have no idea if he read *Doubt*. If he did, he would have liked it.

Bud's administrative style was also unique for his era. At a time when the disciplines of medicine were differentiating and dividing themselves, we never quite knew whether Bud was a psychiatrist or a neurologist (of course, he was both). At a time when the chair of a clinical department was "the Professor," establishing his (at the time they were virtually all men) reputation by pronouncing an answer to every clinical question, Bud asked questions. At a time when clinical departments exemplified a particular ideological bent (Freud, Sullivan, Kaplan, Kraepelin), Duke's department was eclectic (the first time I ever heard the word eclectic was during my interviews for residency at Duke). The department had ties to a psychoanalytic institute, supported a strong program in social psychiatry, and was engaged in basic neurobiological research. At a time when investigators tended to work in isolation, either with their case reports or their test tubes, Duke investigators worked in interdisciplinary teams. Therefore we should not be surprised that Bud founded the longest standing aging center in North America, if not the world, established the first fellowship training in geriatric psychiatry in the United States, facilitated a clinical faculty that was so integrated into the medical center that at one time fully one third of all patients admitted to Duke Hospital were seen by psychiatry in consultation, and grew a department whose budget exceeded the budget of entire medical schools in the south.

Bud took that style of leadership worldwide in his service to the scientific and professional community during his professional career. His various positions of leadership include: President, American Psychiatric Association (1971-1972); President, Gerontological Society of America (1967-1968); President, American Geriatrics Society (1975-1976); President, Southern Psychiatric Association (1975-1976); President, International Association of Gerontology (1983-1984); and President, North Carolina Neuropsychiatric Association (1957). He also served as Chairman of the Veterans's Administration Committee of Geriatrics and Gerontology (1981-1985); Secretary-Treasurer of the American Board of Psychiatry and Neurology (1967-1969); Chairman of the Residency Review Committee for Psychiatry and Neurology of the American Medical Association (1968-1969); Member of the National Council on Aging at the National Institute on Aging (1979-1983); and member of the President's Biomedical Research Panel (1975-1976).

Bud was an excellent lecturer, yet, I believe he saw less value in such public dissertations of one's knowledge than from a well-written book. He learned from books and he taught by writing books. Bud and his colleagues authored or edited many books, including *Behavior and Adaptation in Later Life*[7] and *The Handbook of Geriatric Psychiatry*.[8] These two volumes exemplify Bud's philosophy of teaching. He believed in a well-written, carefully reasoned, exhaustively researched presentation of a topic. The lecture format did not permit filling in all the gaps. Every argument must be complete. All arguments must eventually come together. He especially admired the work of EO Wilson, who presented such a comprehensive argument in *Consilience: The Unity of Knowledge*.[9]

Bud's clinical talents were well exhibited in his willingness to pragmatically tackle some of the most difficult clinical problems. At a time when psychiatrists theorized about "hypochondriacs," yet provided virtually no practical advice to primary care physicians who encountered these very difficult patients, he provided practical guidance for treating patients with multiple physical complaints of unknown origin, such as: (1) never try to explain to the patient that his or her symptoms are not caused by an illness; (2) limit time seen with patients to 15-20 minutes; (3) do not venture a diagnosis or prognosis; and (4) do something that assures the patient that an effort is being made.[10] These practical suggestions hold today as much as they did 50 years ago and busy practitioners would do well to follow Bud's keen clinical insights.

Prior to his long tenure at Duke, Bud received his bachelor's degree from Westminster College in Fulton Missouri, which awarded him an honorary DSc degree in 1960. He received his MD degree from Washington University in St. Louis in 1942 and interned at the St. Louis City Hospital and his training in psychiatry at the University of Colorado from 1946-1948. During his medical school and internship, Bud acquired an expertise in electroencephalography. Between his internship and residency he served as a Major, MC, AUS in the United States Army and this expertise (rare at the time) was utilized during his military career.

While at the University of Colorado, Bud nourished his interest in aging. He came from a long-lived and healthy family, so a fascination with longevity came naturally. Upon arrival at Duke, he immediately set out to create an interdisciplinary center for aging studies and became the founding director of the Duke Center on Aging and Human Development in 1957. The university received a grant from National Institutes of Health that supported the building of research facilities (a building that today carries Bud's name). Yet, the Aging Center was far more than simply a building. Bud gathered a group of scientists that ranged from the most basic biologists to economists. That interdisciplinary team designed the Duke longitudinal studies. For many years, these investigators met at Bud's home, sharing their findings and discussing this new horizon. These were halcyon days for aging research.

Bud received many honors during his career, including election to the Institute of Medicine of the National Academies; The Edward Allen Award from the American Geriatrics Society; the William Menninger Award from the American College of

Physicians; the Brookdale Foundation Award from the Gerontological Society of America; the Salmon Award from the New York Academy of Medicine; and the Jack Weinberg Award from the American Psychiatric Association. He was a member of the Rotary Club in Durham during most of his career in North Carolina, serving as president in 1972-73.

I was a psychiatric resident at Duke in 1973, the 20th year of Bud's tenure as chair of the Department of Psychiatry. Dignitaries throughout the country attended a symposium in his honor, including eight sitting chairs of psychiatry directly mentored by Bud. After listening to accolade after accolade, Bud rose to speak and he said something that startled me! "You may have noticed that I have rather large ears." Yes, I had noticed, yet Bud was an intimidating man. I never dared to mention it to anyone and had never heard anyone say a word about his ears. "I have been conscious of my ears since I was a child, and that is why I was intrigued by Rudyard Kipling's story 'The Elephant's Child' in *Just So Stories*.[11] As we may remember from our own childhood reading, the elephant child was brimming with curiosity, and never stopped asking questions. One question that was avoided by parents and friends alike was, "What does the crocodile eat for dinner?" "Don't ask," was the answer. Finally the elephant child approached the crocodile and asked his question. The crocodile answered by reaching out and grabbing the elephant child's nose, trying to pull the child into the water for dinner. The child survived, but with a greatly extended nose, and perhaps less curiosity.

Bud then quoted the poem that follows the story:

I keep six honest serving men
(They taught me all I knew);
Their names are What and Why and When
And How and Where and Who.
I send them over land and sea,
I send them east and west;
But after they have worked for me,
I give them all a rest…
I know a person small —
She keeps ten million serving-men,
Who get no rest at all!
She send 'em abroad on her own affairs,
From the second she opens her eyes —
One million Hows, two million Wheres,
And seven million Whys!

Bud Busse was a man of seven million Whys! **NCMJ**

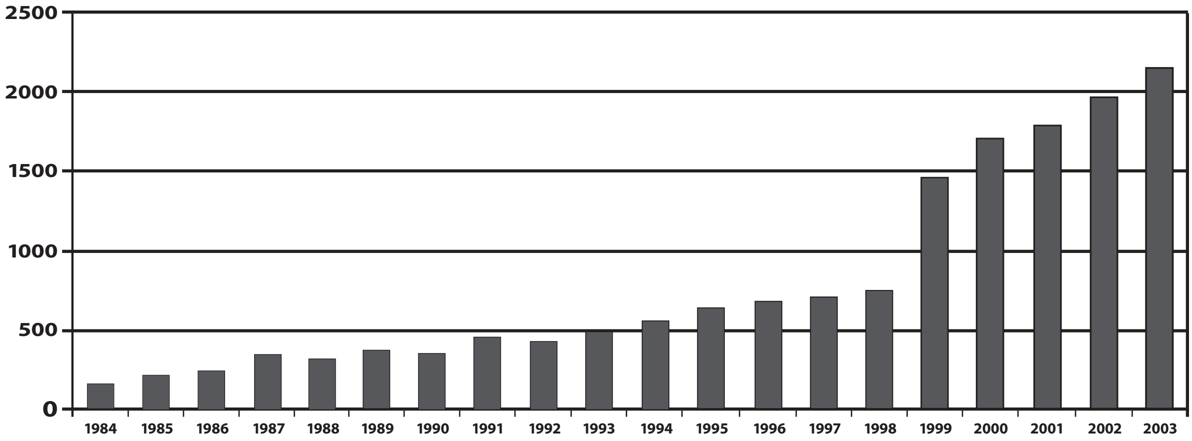
Deaths and Hospitalizations from Alzheimer's Disease in North Carolina

Alzheimer's disease was the seventh leading cause of death in North Carolina in 2003, ranking behind heart disease, cancer, stroke, chronic lung disease, diabetes, and non-motor-vehicle injuries. In 2003, 2,143 death certificates of North Carolina residents showed Alzheimer's disease as the primary cause of death. Alzheimer's disease was the fifth leading cause of death in 2003 among persons ages 65 and older (all but 19 of the total Alzheimer's deaths occurred in this age group) and the fifth leading cause of death among females (1,557 deaths compared to 586 for males). In addition to the 2,143 deaths in 2003 with Alzheimer's disease as the primary cause of death, there were 1,110 deaths with another primary cause, but with Alzheimer's disease listed as a condition contributing to the death.

Over the past 20 years, there has been a large increase in the number of deaths in North Carolina from Alzheimer's disease. The chart below shows the trend, based on primary cause of death. There is a large jump in the number of Alzheimer's disease deaths in1999, due mainly to the change from the ninth to the tenth revision of the International Classification of Diseases (ICD) mortality coding system. Nearly all deaths that were attributed to "pre-senile dementia" under the ninth revision of the ICD were coded as Alzheimer's disease under ICD-10. In 1998 (the year before implementation of ICD-10) there were 748 deaths attributed to Alzheimer's disease and 481 more attributed to pre-senile dementia.

Number of Deaths from Alzheimer's Disease in North Carolina, 1984-2003



In 2002, there were 1,481 hospitalizations of North Carolina residents with Alzheimer's disease listed as the primary cause of admission. Of these hospitalizations, 906 were for females and 575 for males; 39 were for persons under age 65, 236 ages 65-74, 743 ages 75-84, and 463 ages 85 and older. The total hospital charges for these 1,481 hospitalizations were $15,628,000, or $10,552 per hospitalization. The North Carolina hospitalization database still uses the ICD-9 for diagnosis coding, but only another 21 hospitalizations in 2002 had pre-senile dementia listed as the primary cause of admission.

State Center for Health Statistics, North Carolina Division of Public Health

Reader's Forum

A Letter *from* The Editor:

To Our Readers:

In a January 27, 2005 *New York Times* article remarking on an exchange among residents of a Bronx neighborhood, which was previously published in a community newspaper, Alan Feuer had this to say:

> In the great combustion engine of democracy, the letter to the editor is probably the smallest working part.
>
> There is the vote, which sparks the pistons, and the campaign contribution, which greases sticky gears. Then there is the letter to the editor, which acts much like a valve. It allows a citizen to pour out powerful emotions and, often, to vent spleen.

While the Editors of the *North Carolina Medical Journal* have not gone seeking "spleen venting" letters or commentaries from our readers, we have constantly invited letters and other communications addressing the themes covered in the Journal. Like the situation in the Bronx, we consider our "Readers Forum" to be an important part of the Journal and hope that more of you will offer (publishable) comments in response to the issue coverage we are working hard to provide to interested healthcare professionals and other stakeholders every other month.

We hope you will let us know what you think and add to the conversation that we hope will enliven these pages.

Gordon H. DeFriese, PhD
Editor-in-Chief and Publisher
Durham, NC

Quality of Care and Performance Improvement

To The Editor:

I enjoyed your recent issue of the *North Carolina Medical Journal* on "Quality of Care and Performance Improvement." It reminded me of our experience developing and implementing the American College of Radiology (ACR) Mammography Accreditation Program (MAP).[1] This ultimately led to federal legislation and the Mammography Quality Standards Act (MQSA) in 1992. Congress then charged the Food and Drug Administration (FDA) to develop and implement regulations, and there have been additions and amendments on several occasions since that time.

More than 20 years ago I chaired the Mammography Committee of the ACR. We became progressively concerned regarding the uneven quality and accuracy of mammography throughout the United States. We developed the ACR/MAP, which officially began in August, 1987. It was voluntary and directly addressed image quality and radiation dose by means of a four-phased process:

- First, there was a comprehensive questionnaire concerning personnel (radiologists, technologists, and medical physicists); equipment; technique; quality control practices; patient information; and reporting and follow-up procedures. If any part of this survey did not meet acceptable standards, it must be corrected before proceeding to the next phase.
- Second, there was actual testing of the entire mammography imaging process (equipment, technique, receptors, processing, image quality, and radiation dose). Again, any failure must be corrected before proceeding.
- Third, there was peer review and evaluation of clinical mammograms. Again, failure required correction.
- Finally, quality control practices and records for the immediate previous 30-day period were evaluated.

Each site received a detailed report including a pass or fail result and suggestions, especially for correction of the latter. Accreditation was for three years and required annual updates.

The MAP only indirectly addressed the quality and accuracy of interpretation of the mammograms by assessing the radiologist's training, American Board of Radiology certification, experience, and continuing medical education. It recognized the need for a patient tracking system for data collection including follow-up information for results and accuracy determinations.

Some measures of the MAP's success are its endorsement and support by the American Cancer Society, the Center for Disease Control, the National Cancer Institute, and others. It led to the Mammography Quality Standards Act (MQSA) with oversight by the FDA and is mandated by law with potential penalties.

It has resulted in significant improvement in image quality. But there are some things we did not foresee. Mammography has become the most regulated and is one of the most litigious procedures in all of medicine. MQSA/FDA has increased costs significantly without appropriate increased reimbursement, especially for screening mammography, which may have led to a "loss-leader" mentality. It has not directly addressed the accuracy of interpretation issue, and comparisons with results in Europe (United Kingdom and Sweden), where mammography is done at centralized specialized facilities, suggest a need for this.

The ACR Mammography Accreditation Program is a success story as far as it goes. But there are lessons to be learned within the program and by those who entertain similar ideas.

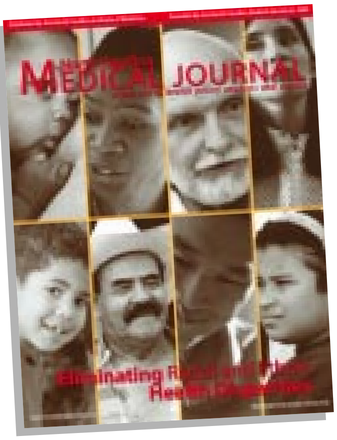
Eliminating Racial and Ethnic Health Diparities



To The Editor:

Kudos to you and your contributing authors for your November/December 2004 issue on "eliminating racial and ethnic health disparities." The issue should serve as a model for other states as they consider and confront the issue of health disparities. It serves as a challenge and a guide for action. Thank you for continuing to identify and discuss the important question of "who is left out?"—a question that should drive our priorities and our actions.

William L. Beery, MPH
Vice President
Group Health Community Foundation
Seattle, WA

To The Editor:

Today I enjoyed another copy of the *North Carolina Medical Journal*; as usual, several items stick with the reader. I shall mention a few.

I always enjoy reading a "grass roots" letter, as written by Dr. Peters of Winston-Salem, North Carolina. His view point is as he reports, from the "trenches." He mentions a number of the burdens that the clinician encounters daily-all true. One of his items is: "fewer physicians in practice;" so, in spite of the increasing numbers of visas being issued to foreign physicians, I assume he's relating to North Carolina's population growth of approximately two million souls since the days the East Carolina University (ECU) Medical School was conceived. I also understand (although I don't know the numbers) that the other three North Carolina medical schools have reduced their admissions in the intervening time. I recall the struggles encountered in trying to get the ECU medical school (the Brody School of Medicine) through the North Carolina General Assembly—most of it due to the vigorous opposition of our state's then three existing medical schools. Now, considering the increase in North Carolina's population and the strong movement toward specialization in our state, we are experiencing a shortage, perhaps as serious as was being experienced then. This is especially true if it is a member of your family facing the difficulties experienced by persons who are unable to get an appointment (and even less likely, a prompt appointment) and the difficulty physicians have in obtaining prompt referrals. Of course, the emergency department is not the panacea of all these problems; although, it appears that many want to hide the problem behind that veil.

I was particularly taken with the page called "Running the Numbers." This information is somewhat startling in its revelation of data on the health (in certain situations, not all) of North Carolinians. It starts out to tell the health story of North Carolina's American Indians, but it ends up relating a more telling story in its comparisons with "white" and "African American" groups. It is something every person, not just physicians, should be aware of.

John R. Gamble, Jr., MD
Lincolnton, NC

(Editorial note: Dr. Gamble is a former member of the NC House of Representatives)

The North Carolina Institute of Medicine

Since January 2002,
Publisher of The *North Carolina Medical Journal*

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Members of the North Carolina Institute of Medicine are appointed for five-year terms by the Governor, and each task force convened by the Institute typically includes at least one-third of its membership from among the appointed members. Topics to be addressed through task force efforts are chosen following requests from the Governor, the General Assembly or agencies of state government. In some cases, topics are selected on the basis of requests from a number of stakeholder organizations across the state where this type of analytical process is considered to have potential value.

The North Carolina Institute of Medicine assumed the role of publisher of the *North Carolina Medical Journal* in January 2002 through an agreement with the North Carolina Medical Society, which founded the Journal in 1845. The Institute views the *North Carolina Medical Journal* as an extension of its mission. The Journal provides a forum for stakeholders, healthcare professionals, and policy makers and shapers to study and discuss the most salient health policy issues facing our state. Like many states, North Carolina is grappling with issues such as an increasing number of uninsured, the unmet health needs of the growing Latino population, a critical shortage of nursing personnel, the health risks of tobacco and obesity, rising prescription drugs costs, mental health system reform, the increasing societal burden of chronic illness care, the threat of bioterrorism and the necessity of assuring adequate public health preparedness—all in the midst of an economic downturn. Each of these issues presents unique challenges to healthcare providers and state policy makers. Yet, a fully implemented task force to consider each of these sets of issues is not feasible. The Journal makes it possible to present an organized and balanced overview of some of these issues, six times per year, and allows interested persons the opportunity to engage in the ongoing discussion of these issues throughout the year. The Institute hopes that our readers of the *Journal* will, in this way, become involved in the continuing debate about the most promising avenues for assuring the highest standards of health and healthcare for all North Carolinians.

PHYSICIANS. Seeking full-time and part-time physicians to perform Independent Medical Evaluations in one or more of our offices in North Carolina or multiple locations throughout the United States. Prefer training in Internal Medicine, Family Practice, IM/Peds or Emergency Medicine. Will provide referrals, scheduling, billing, transcription, office assistant, logistical support and training. No call. No emergencies. No managed care. No weekends or holidays. Call Susan Gladys, Human Resources Director, 866-929-8766 or fax CV to: 304-525-4231. Tri-State Occupational Medicine. www.tsom.com.

CLINIC FOR LEASE. Highly visible location, beautiful building, in upscale community bordering Winston-Salem. Ideal demographics. 6 exam rooms and new X-ray suite. Already set up for Urgent Care, FP, Orthopedics, OB, Dental and Surgical Specialists; can be modified. Contact Karen 336-971-9558.

MEDICAL DIRECTOR POSITION: The Private Diagnostic Clinic, PLLC, Duke's faculty practice plan, seeks a Medical Director for the Duke Health Center Raleigh, its multi-specialty group practice on the campus of Duke Health Raleigh Hospital. This 30+ member group practice will be the flagship of a Duke physician network for greater Wake County. The Medical Director, who will maintain a half-time clinical practice, will be responsible for providing leadership for the following: clinical oversight and leadership of the practice, financial management of practice operations, physician recruitment and retention, strategic planning, regulatory compliance, quality improvement, patient safety, and clinical performance improvement. The Medical Director will report directly to the PDC Executive Medical Director and the PDC Executive Director, and will serve as a liaison between the practice and the PDC, Duke University Health System, and Duke Health Raleigh Hospital administration. Interested candidates should contact: Theodore Pappas, MD, PDC Executive Medical Director, 3100 Tower Blvd, Suite 600, Box 80, Durham, NC 27707, email: donna.ecclestone@duke.edu.

Helping your patients with prescription drug options

Blue Cross and Blue Shield of North Carolina (BCBSNC) would like to thank physicians for helping our members take advantage of cost-effective prescription drug options.

During the last three months of 2004, we waived generic drug copayments for members who have prescription coverage through BCBSNC. Hundreds of thousands of our members took the opportunity to talk to their doctors about whether a generic drug might be right for them.

Because of this informed decision, our members will directly save millions of dollars in out-of-pocket health care costs.

We've launched yet another new initiative for 2005 to encourage members to consider generic drugs. We are waiving the first copayment for a new prescription for a variety of generic maintenance drugs. These include prescribed drugs for the treatment of high blood pressure, diabetes, depression and high cholesterol.

Because these drugs are typically taken daily, members stand to save significantly by using these generics, when appropriate. Typically, our members directly save $10 to $30 per month by switching from a brand-name drug to the corresponding generic.

We are grateful for the care and education North Carolina physicians provide as our members work to make the best choices about their health.

Innovative health care designed around you.℠ | *bcbsnc.com*

PHYSICIAN
LEADERSHIP
INSTITUTE

Advancing Excellence
in Healthcare

THE PHYSICIAN LEADERSHIP INSTITUTE IS NOW ACCEPTING CANDIDATES.

The University of North Carolina at Chapel Hill's Kenan-Flagler Business School and Medical Review of North Carolina, Inc., introduce a new educational program in the Carolinas exclusively for physicians. Designed to empower physicians to meet the challenges of our rapidly evolving healthcare system, the Institute offers eight different modules over four weekend sessions. All classes will be taught by both university faculty and nationally recognized experts. The first session begins the weekend of September 30th, 2005, at the Paul J. Rizzo Center, conveniently located in Chapel Hill.

SESSION DATES

SEP 30 – OCT 2, 2005 | DEC 2 – 4th, 2005 | JAN 13 –15, 2006 | MAR 31 – APR 2, 2006

MODULE 1 - Welcome, Program Orientation and Understanding the Changing Role of Physician Leadership in the 21st Century

MODULE 2 - Self-Awareness and Communication Skills

MODULE 3 - Systems Thinking and Tools for Problem Solving

MODULE 4 - Leading Change and Influencing People

MODULE 5 - Negotiations and Consensus Building

MODULE 6 - Conflict Management

MODULE 7 - Quality and Financial Management

MODULE 8 - Strategic Leadership for Creating a Vision Focused Future

To nominate a physician, or to learn more about applying for this program, please contact Jill Blalock, MPH, at jblalock@ncqio.sdps.org or call toll-free (800) 682-2650, ext. 2004.

Enrollment is limited to 50 physicians. Please contact us to reserve your space.

MEDICAL JOURNAL

SPECIAL ARTICLE

This paper is derived from the author's keynote presentation to the "Patient Safety Symposium" sponsored by the North Carolina Foundation for Nursing Excellence. January 20-21, 2005

Patient Safety:
Rejecting the Status Quo

Arthur A. Levin, MPH

A little over five years ago, the National Academy of Science's Institute of Medicine (IOM) released its groundbreaking report on medical errors *To Err Is Human.*[1] The report, a product of more than a year's work by the Committee on the Quality of Health Care in America—on which I had the privilege to serve—was a startling indictment of the unsafe state of hospital care prevalent in the United States.

As this report was released there was an enormous media response, especially to the body count of patients that the IOM attributed to safety lapses (44,000 to 98,000 deaths in America's hospitals each year). The range of estimated fatalities meant that medical error was the fourth or eighth leading cause of death in the United States, and even more alarmingly, many of these deaths were said to be preventable.

Reaction to the IOM's *To Err Is Human*

To Err Is Human caused a firestorm of reaction, some of which was highly critical of specific conclusions or recommendations made by the committee. While few denied that there were safety problems, many took issue with either the IOM's assessment of the dimension of the problem or to its specific recommendations—especially those that proposed mandated changes in the ways that hospitals and health professionals went about providing care and how they were held accountable for the safety of patients.

There was, in general, an expression of gratitude for the IOM's leadership in bringing the problem to the forefront of national consciousness, and while many went back to business as usual, many other providers, professionals, and policy makers rolled up their sleeves to try to do something about the safety problem.

President Clinton pulled together an interagency task force to tackle safety within the federal healthcare system. Congress, heeding one of the IOM's principal recommendations, budgeted an extra $50 million to the Agency for Health Care Research and Quality (AHRQ) to be used to improve patient safety throughout the healthcare system.

That same year, a group of large employers formed the Leapfrog Group to discuss how they could work collectively to influence healthcare quality and affordability. The group promised (and threatened) to use their combined financial leverage to drive the system toward improved safety and better quality outcomes.

Hospitals began to plan for computerized physician-order entry systems (CPOE), bar coding, and the use of clinical pharmacists on rounds to reduce medication errors. Operative sites were to be marked for identification (or, was it the "non-operative" site that was to be marked?), and operating room "time-outs" were instituted to ensure that the right patient was getting the right operation for the right site. Three decades or more of plans for converting from paper to electronic medical records, digitizing films and test results, and other ways of sharing critical patient information in real time were dusted off. Joint Commission on Accreditation of Healthcare Organizations (JCAHO) quickly developed accreditation standards that focused on patient safety, and the American Medical Association (AMA) founded the National Patient Safety Foundation. Legislatures in more than a dozen states began considering legislation aimed at attacking the patient safety crisis.

So, from early 2000, it appeared, at least to some observers, that patient safety was an issue whose time had come, and that perhaps the IOM's challenge to healthcare providers and professionals—to work toward a 50% reduction in medical errors by the end of 2004—was a real possibility.

Quagmire

But, there were some divisions that had begun to erode any unified sense of purpose and almost immediately began to slow forward motion. For example, there was a lot of push-back on the estimates of 44,000-98,000 patient deaths each year that the IOM said were linked to medical errors in hospitals. These estimates, which were based on two different studies by Harvard researchers,[2,3] were being challenged as vastly overblown. Critics agreed that there was a patient safety problem,

Arthur A. Levin, MPH, is the director of the Center for Medical Consumers. Mr. Levin was a member of the Institute of Medicine panel that authored the 1999 report *To Err Is Human*. He can be reached at medconsumers@earthlink.net or 130 Macdougal Street, New York, NY 10012-5030. Telephone: 212-674-7105.

but it was far less lethal than *To Err Is Human* claimed. And, they argued, "error" was a subjective, imprecise event that defied simple definition (i.e., many deaths attributed to error were more likely due to other factors outside of the control of providers and professionals). Thus, a protracted debate ensued about the lethality of medical errors in hospitals and, of course, some provider and professional associations (perhaps embarrassed by the sorry state of patient safety) seized on these critiques to argue that patients were not nearly as much in harm's way as the IOM report claimed, and that they (providers and professionals) had the situation well in hand.

I would have hoped that the numbers distraction would have evaporated more quickly, but it did not. As recently as last year the medical society of my home state, New York, characterized the IOM estimate as having been "discredited" by critics such as Troy Brennan, MD, JD, MPH, a physician, health services researcher, and lawyer from Harvard who is also, paradoxically, a co-author of both of the large studies of hospital patient errors that the IOM relied upon in its report. Brennan, however, while preaching caution, still believes the human toll of medical error is substantial:

> "Whenever you extrapolate from relatively small samples, you have concerns about the statistical precision of the estimates… although we don't know exactly how many people die from medical errors, there is no doubt it's at least 50,000 per year in hospitals and many additional outpatients."[4]

Focusing on Systems and Assuring Professional Compentency

One very key IOM recommendation disappeared from the radar screen almost instantly. It was a recommendation for establishing state-based, mandatory reporting systems for medical errors that caused serious patient harm. Even more contentious was the committee's belief that some of the information collected by states should be publicly disclosable. The IOM committee actually had the temerity to suggest that the healthcare system should be held publicly accountable for its safety performance.

In my mind this was not a radical suggestion. After all, industrial plants post the days without an employee work-related accident in plain view—why shouldn't hospitals and doctors? I debated two successive presidents of the AMA over this issue, and, arguably, their position against mandated reporting of serious harm and any public disclosure of that harm, has for the most part carried the day.

A good part of the IOM's message was that, even more important than individual behavior, there is a lack of effective systems to prevent the epidemic of medical mistakes. The very title of the report, *To Err Is Human*, was, after all, recognition that human error is almost inevitable, especially in complex, constantly evolving environments like healthcare. And so, the essential task, the IOM concluded, is to build systems that are sensitive enough to recognize the conditions that are antecedent to error and that are adept at preventing patient harm from actually occurring. This "de-individualized" approach was seen as transformational—a turning away from a tradition of blame and shame and mostly punitive approaches to error prevention that had so clearly failed in the past. Needless to say this move from a focus on individual provider or professional responsibility to a "systems approach" was *welcomed* by the "players" in hospital care—perhaps *embraced* would be a better description. For the most part, I agree that a systems approach has great merit (the recommendations of an IOM committee are the result of a consensus process), but I worry about the wisdom of a too enthusiastic rush to dismiss the importance of a professional's competency in the patient safety equation.

Ironically, it was the "it's the system approach" permeating the IOM report that may have helped doom the recommendation that there be mandatory reporting of serious error accompanied by some public disclosure. That theme was fodder for critics of an error-reporting mandate to characterize it as antithetical to a non-punitive, systems-based approach to safety improvement. This partly explains why that essential IOM recommendation dropped off the table. Another reason for the disappearance of reporting mandates from ensuing discussion was that many who wanted meaningful improvement in safety and quality to move forward rapidly worried that such efforts would fail to gain traction if there was a fractious break with providers and professionals over a requirement to report harm.

The airline industry's approach to error became the role model for the patient safety movement. Of course, the fact that pilots happen to be the first to hit the ground when serious errors are committed in the cockpit, does not detract from the industry's seriousness of purpose in its safety efforts. Nor that serious harm to pilots and crew, their passengers, and their aircraft is always announced in a very public manner. It is also well-established public policy to invest almost unlimited resources in a painstaking forensic analysis of the causes of any flight failure that is performed by an independent, highly skilled agency. And the lessons learned from the root cause analysis often are used to mandate airline safety improvements. This is not at all analogous to how attempts to understand what went wrong play out in a highly secretive, mutually protective healthcare system, a system that is comfortable with having mistakes remain ambiguous in origin and that historically lacks a culture of safety. The airline analogy also fails to consider that, unlike healthcare professionals (who are more often than not licensed in perpetuity), cockpit crew licensees are tested for competency routinely throughout their careers and in addition, are required to prove competency as they take any different responsibilities, either as to aircraft or crew position.

In healthcare, except for the hit-or-miss, often misdirected employee firing, loss or reduction of credential or privileges, monetary fine, lawsuit or action against a license, there is really no program in place that demands understanding and accountability for unsafe practices.

I did then, and still, take issue with two reasons often used to bolster the benefits of voluntarism and anonymity in reporting: that it produces more and better quality reporting. I think there is little or no evidence to support these claims and, in fact, we seem to have some evidence quite to the contrary. For example, New York State's hospital incident reporting system, known as NYPORTS, which was cited as an example of mandated reporting by the IOM, receives many times more reports of events that meet a sentinel event definition than the total number reported to JCAHO by hospitals across the country. And, the Food and Drug Administration's (FDA) MedWatch system for collecting adverse drug reactions (ADRs) is estimated to receive only from one-to-ten percent of the number of ADRs that actually occur. Even though the FDA has no interest in or any authority to punish those professionals or organizations that report an ADR, there is still vast under-reporting.

Providers have less of a problem with the other half of the IOM reporting recommendation—one that called for a national *voluntary* system of *anonymous* reports of so-called near misses that occur in hospitals. The model for this system has usually been the NASA-run "incident" reporting system used in the airline industry. That system collects anonymous narrative reports of "incidents," which, in airline talk, are "near misses." The reports are reviewed by retired pilots and controllers to spot important lessons to be learned; and these, in turn, are published so as to improve performance.

But, to-date no such voluntary system exists. Bills purportedly addressing this omission passed in both the houses of Congress last session, but failed to reach a conference to settle differences between them. These bills miss the mark and would mainly serve only to protect hospital patient errors, even those causing serious harm, from any outside discovery. The proposals, rather than build on existing organizations such as the federally funded Quality Improvement Organizations (QIOs), would create a new type of entity, Patient Safety Organizations (PSO), to collect, protect and analyze the safety information that hospitals voluntarily submit. The bills set no data standards, no criteria for judging the success of the PSOs in improving patient safety, allow hospitals to opt out of reporting safety data, and add yet even more expense to a healthcare system steadily marching toward 1.8 trillion dollars in annual costs.

Another key IOM recommendation, one that addressed new responsibilities for licensing and credentialing agencies and organizations in assuring professional competency and knowledge of patient safety practices, went almost unnoticed. But, the concept of periodic, routine competency assessment is gaining traction, especially among medical specialty societies.

This encouraging development can inform the work of other health professions and those providers that credential or privilege professionals. It would seem logical to assume that routine assessment of professional competency could have a substantial positive impact on patient safety and healthcare quality. And by making it routine, it becomes a *systems approach*, not a punitive one.

Why am I spending so much time on the past when what's really important is to understand where we are today? An appreciation of the history of professional and provider reactions to the IOM errors report (what was accepted and what was not) helps us understand how we arrived where we are today.

The Situation Today

Three years after the IOM report was published, author and journalist Michael Millenson had this to say in the March/April 2003 issue of *Health Affairs*:

"…the silence within much of the healthcare community about the true dimensions of the crisis caused by poor quality has changed only modestly over time. Many continue to avert their eyes."[5] Millenson, author of *Demanding Medical Excellence; Doctors and Accountability in the Information Age* went on to say:

"There is a world of difference between calling for a revolution and actually leading one. (And, yes, the latter is far riskier to one's professional well-being.) That difference is why the quality improvement movement, it pains me to say, remains essentially a sideshow for most providers and most of the public."[5]

Millenson's words ring as true today as they did in 2003. There is a profoundly disappointing lack of urgency and unified sense of national purpose to support immediate, forceful steps to significantly reduce and eventually eliminate preventable patient harm.

Consider this: if medical errors kill approximately 50,000 patients each year in hospitals alone, then as many as 250,000 patients may have died since the IOM report was published—a greater toll of human lives than that of the recent tragic December 20, 2004 tsunami. One essential difference, however, is that lethal patient error is not a natural disaster for which we have had little or no warning and no way to prevent.

According to a Kaiser Family Foundation poll released in November 2004, four in ten people surveyed believe the quality of care has gotten worse in the last five years.[6] One in three report that they, or a family member, have experienced a medical error at some point in their lives, and for one in five Americans, the error had "serious health consequences" such as death (8%), long-term disability (11%), or severe pain (16%).[6] Remember the immediate, visceral provider and professional opposition to IOM's recommendation of mandatory, publicly reported error tracking systems? Perhaps not surprisingly, nine out of ten of those surveyed said that reporting of serious medical errors should be required, and two out of three wanted this information to be public.

Patient Body Counts Move Public Policy

Patient "body counts" make providers and professionals uncomfortable, but they are necessary to move public policy in the right direction and to have it stay the course. Talking about preventable death puts a face on what is otherwise a "wonkish" debate and is a necessary element in convincing policy makers and the public that improvements in patient safety are critically needed.

Remember the $50-60 million dollars that Congress was providing to AHRQ for patient safety? Without commenting on whether it was money well spent or the miserliness of allocating only $50 million for safety in a 1.5 trillion dollar healthcare economy, the fact is that the money now competes with other needs [e.g., health information technology initiatives (IT)]. The shift of AHRQ funding from "safety" to "IT" tells me that without a body count to vividly remind us of the magnitude of havoc created by unsafe healthcare; adequate, sustained support for improvement is unlikely.

Upon discovering the lack of attention paid to the considerable human costs of preventable harm that occurs in our healthcare system, Millenson describes himself as at first stunned, then depressed, and finally outraged. That outrage is the appropriate response to the lack of progress toward saving lives evident at the five year anniversary of *To Err Is Human*.

The fall 2004 issue of *Health Affairs* published an article by Robert Wachter,[7] which was commissioned by the Commonwealth Fund for a quality improvement colloquium and marked the fifth anniversary of *To Err Is Human* in November 2004. Dr. Watcher's assessment is that the healthcare system deserves only a "C+" over-all grade for the progress it has stimulated in addressing patient safety. That's not great news, considering the costs of not getting an "A." As if a C+ grade is not bad enough, this report card's grading is highly subjective. The reality is—a reality confirmed by all those attending the November quality colloquium—that we do not have an effective safety data collection system to track medical errors (beyond internal systems in place in many hospitals) and; therefore, cannot say whether things are better, the same, or worse than five years ago. How is this state of affairs acceptable when tens of thousands of lives are at stake, and how did it happen? Remember that the IOM recommendation about tracking medical errors causing serious harm was abandoned not very long after it was made.

For the record, it has not been abandoned everywhere. Some states have subsequently legislated reporting and public disclosure. Minnesota, for example, has just published a report on hospital errors that is the result of a law passed in 2003.[8] Because we have no baseline medical error rate and no way to count errors across systems, we cannot measure the progress made overall in meeting the IOM's error reduction challenge.

In *his* answer to the question "Are we making progress?" Wachter writes: "after hearing of yet another sentinel event in their institutions, every patient safety leader I know laments how little headway we've made in the last five years." He goes on to say "… signs of progress are unmistakable." He illustrates this assessment by telling us that when he asked 400 hospitalists (i.e., physicians who spend the bulk of their practice caring for inpatients) for their views about progress in improving patient safety, 45% of them said things were better than five years ago, 38% said they were the same, and 17% said things had gotten worse.[6] Wachter admits this is only anecdotal evidence, but, inexplicably, he finds it "instructive and reassuring." My problem is two fold: (1) it is not credible evidence because we do not have a valid tracking system; and (2) even anecdotally, more than half of those asked said there has been no progress.

These anecdotal responses of the hospitalists are alarmingly *instructive* and certainly not reassuring. Consider the apparent disconnect of the majority of the hospitalists' somewhat-rosy view that things were better, or at least no worse, with the considerably more pessimistic view of the public surveyed by the Kaiser Family Foundation—that the system is no safer or less safe than five years ago.

Bob Wachter is certainly one of the best in the patient safety and quality improvement movement, but he, like most healthcare professionals, is probably troubled by the truth—that tens of thousands of patients continue to die because healthcare, and all its constituent parts and players, have not applied forceful enough pressure to stop the bleeding caused by safety lapses.

That said, it would be unfair not to point out the hard work that is being done by many around the country to make patients safer every day and the great successes in improving safety that have been achieved through dedicated hard work in individual hospitals, clinics, delivery systems, and other settings. That's the "good news." Patient safety does not have to be an intractable or inevitable problem in healthcare. Providers and professionals do care, and they are able to substantially reduce patient harm if and when they put their shoulders to it. On the other hand, the fact that the healthcare field often knows what to do, what will work (either gleaned from first-hand experience or the lessons provided by others) and still it isn't done consistently or at all (think: hand washing) adds to the frustration of those who believe patient safety has not been made the national priority it should be.

The failure of the healthcare system and policy makers to squarely address the crisis in patient safety and, thus, to allow tens of thousands of preventable deaths each year should be viewed as morally unacceptable public policy. It must be a violation of the ethical standards of every healing profession to be knowingly involved in the delivery of substandard, dangerous care. This should not imply that healthcare workers, as individuals, make conscious decisions to harm patients. Rather, the point is that considerable threat to patient well-being occurs in everyday practice, and these dangers are well known to all the players.

The timidity with which we (those who make public policy or, like myself, try to influence it) have approached providers and professionals alike, to beg, cajole, and entice a meaningful, unwavering devotion to fixing our patient safety crisis must change. Keeping patients safe can no longer be just one more request made of a healthcare provider or professional to improve care. It must become the pass/fail condition of continuing to practice and to serve patients.

A Positive Step

I would be remiss if I did not end on a more positive note. It is my opportunity to issue you a challenge to make things better—to provide a "how to do better" along with my outrage about what has not happened five years after *To Err Is Human*. So, I would like to call to your attention to a courageous and critically important initiative just begun by Dr. Donald Berwick and the Institute for Healthcare Improvement (IHI) —the campaign to save 100,000 lives.

I call it "courageous" because, for the first time, someone of great influence in the safety and quality movement is willing to mention the body count, albeit in a positive framework of prospectively saving lives. I call the campaign critically important because, if successful, it could actually save tens of thousands of lives in a relatively short period of time, and wouldn't that be a wonderful turn of events? It's also important because, by joining, healthcare providers and professionals admit both ownership of the tragic error problem and the ownership of working toward hopeful solutions.

The campaign aims to enlist at least 1,500 hospitals across the United States to commit to six key evidence-based, safety and quality improvements that have the potential to save 100,000 lives over the next 18 months—and beyond. These key improvements are:

(1) *Rapid response teams* (RRTs). These are teams that can respond, assess, and take action quickly at the first sign of a patient's decline. RRTs were pioneered in Australia, and studies have reported they can reduce hospital mortality rates by 27%.

(2) *Prevention of central line-associated bloodstream infections*. While not rocket science, this safety intervention can be almost 100% effective. The bundle consists of five steps; hand hygiene, barrier precautions, proper skin antisepsis, proper site care, and no routine replacement. All five, the "bundle," must be delivered to be optimally effective.

(3) *Prevention of surgical site infections*. Again, there is emphasis on the use of well-understood processes of good care, which include the appropriate selection, timing, and duration of antimicrobial prophylaxis; glucose control; proper surgical site hair removal technique; and other basic prevention strategies. These strategies can cut surgical site infections in half.

(4) *Prevention of adverse drug events*. Implementation of proven safety measures (e.g., standardizing and implementing core medication processes in high-risk areas) and learning from many successful examples of what works from innovating hospitals around the country prove it is possible to reduce fatal adverse drug events and even to eliminate them.

(5) *Improved care for acute myocardial infarction (AMI) patients*. The so-called AMI "bundle" of five specific interventions: beta blockers at admission, aspirin at admission, an ACE inhibitor, reperfusion, and beta-blockers at discharge has been shown to reduce AMI mortality by 40%.

(6) *Prevention of ventilator-associated pneumonia* (VAP). The ventilator "bundle:" elevation of the patient's head by 30 degrees, peptic ulcer prophylaxis, deep venous thrombosis (DVT) prophylaxis, "sedation vacations," and strict hand-washing can eliminate cases of VAP altogether.

I think this initiative is worth your careful consideration as a very public way to show that your organization or your profession: (1) recognizes that there has been and will continue to be a significant loss of life as long as healthcare is not safe care; (2) recognizes that much has been learned about how to do things safer and better and these procedures have been tested in settings not unlike your own; (3) makes a public commitment to refocusing current work on patient safety in ways that will demonstrably and almost immediately begin to save lives; and (4) willingly agrees to having progress tracked and fed back to your organization or profession for comparative purposes (although at this point not publicly disclosed).

Berwick concluded his announcement of the 100,000 lives campaign in December 2004 with these words:

"…the patients whose lives we save can never be known, and though they are unknown, we will know that mothers and fathers are at graduations and weddings they would have missed, and that grandchildren will know grandparents they might never have known, and holidays will be taken, and work completed, and books read, and symphonies heard and gardens tended, that without our work, would have never have been….the point is, lets get started…"

I hope that Berwick's words help to inspire you to make patient safety the priority that those who come to you for care deserve. As we remarked in *To Err Is Human*: "The status quo is no longer acceptable and cannot be tolerated any longer." **NCMJ**

Improving Diabetes Care among Low-Income North Carolinians:

Project IDEAL

Ronny A. Bell, PhD, MS, Fabian Camacho, MS, Vanessa T. Duren-Winfield, MS, Denise E. Bonds, MD, Roger T. Anderson, PhD, Joseph C. Konen, MD, MSPH, and David C. Goff, Jr., MD, PhD

Abstract

Objectives: *Many barriers exist in implementing evidence-based guidelines for diabetes care, particularly for low-income patients. To address this, the North Carolina Project IDEAL (Improving Diabetes Education, Access to Care, and Living) Diabetes Initiative was created.*

Study Design/Setting: *Fourteen programs representing different types of agencies and intervention strategies across the state participated in the initiative.*

Data Collection: *Separate random samples of medical charts of participating patients were reviewed at baseline (n=429) and three-year follow-up (n=656) to assess changes in six process (assessment of hemoglobin A1c, cholesterol, blood pressure, and urinary protein; conduction of foot and retina examination) and three outcome (glycemia, blood pressure, and lipid control) measures. Four national guidelines (DQIP, HEDIS, NCEP and ADA) were used as benchmarks.*

Results: *Large increases were observed for some measures (hemoglobin A1c control and testing, LDL-cholesterol testing), while modest increases were observed for others (dilated eye exam, blood pressure testing, and control).*

Conclusions/Relevance: *Project IDEAL was successful in improving access to high-quality diabetes care for low-income patients. Additional effort is needed to address specific areas of concern, particularly retinopathy screening.*

Key Words: *Quality of care, DQIP, HEDIS, NCEP, low-socioeconomic status.*

Introduction

As with the rest of the nation, diabetes mellitus is a tremendous public health burden in North Carolina. Over 500,000 North Carolinians have diabetes, and about one-third of them have not been diagnosed. Diabetes is the seventh leading cause of death in the state and accounts for about 14% of all hospitalizations at a cost of about $1.5 billion.[1] Persons with diabetes in North Carolina have an 80% greater rate of death from stroke, more than twice the rate of death from coronary heart disease, and three times the rate of death from hypertensive heart disease, compared to those without diabetes.[2] North Carolina ranks in the top 25% of all states in diabetes mortality. The burden of diabetes in North Carolina is highest or higher, whichever is true, among the state's sizeable population of older adults, ethnic minorities, and persons of lower-socioeconomic status.

Evidence clearly suggests that the implementation of evidence-based guidelines for treatment of persons with diabetes can greatly reduce the risk of chronic complications associated with diabetes,[3,4] and these guidelines are readily available. However, across a number of different patient populations, there is low adherence to these guidelines, generally as a result of patient- and

Fabian Camacho, MS, is with in the Department of Public Health Sciences at Wake Forest University School of Medicine.

Vanessa T. Duren-Winfield, MS, is with the Maya Angelou Research Center on Minority Health at Wake Forest University School of Medicine.

Denise E. Bonds, MD, is with Department of Public Health Sciences and the Department of Medicine, Section on General Internal Medicine, Wake Forest University School of Medicine.

Roger T. Anderson, PhD, is with Department of Public Health Sciences, Wake Forest University School of Medicine.

Joseph C. Konen, MD, MSPH, is with Pfizer, Inc.

David C. Goff, Jr., MD, PhD, is with Department of Public Health Sciences and the Department of Medicine, Section on General Internal Medicine, Wake Forest University School of Medicine.

provider-oriented barriers.[5] Patients may have limited time or transportation to visit their doctor, while providers may be constrained by time or by challenges in communicating prevention strategies to patients. Thus, there is a need to implement unique and creative approaches to address these barriers to reduce the burden of diabetes.

This report describes a unique community-based initiative implemented in North Carolina designed to improve the quality of care and quality of life of many of the state's vulnerable diabetes population. Included in this report are results that describe improvements in the quality of care provided to patients of programs participating in the initiative.
