Carolinas Medical Center has also served as a primary regional training site for medical students since the inception of UNC-SOM. Initially, UNC students received clinical experience in internal medicine at CMC. That program was soon expanded to include obstetrics and gynecology and pediatrics. The list of established clinical rotations has since expanded to include general surgery, family medicine, emergency medicine, physical medicine and rehabilitation, orthopedics, plastic surgery, and psychiatry. Although most of the student rotations at CMC are filled by UNC students, clinical rotations are also offered to medical students nationally. During the 2004-2005 academic year, approximately 444 undergraduate student months were provided through CHS facilities and physicians.

Supplementing its role in physician education, CHS also trains allied health professionals. The Carolinas College of Health Sciences (CCHS), located on CMC's main campus in Charlotte, educates nursing students and other personnel. The school was initially established as the Charlotte Memorial Hospital Authority School of Nursing in the late 1980s after a comprehensive feasibility study supported the need for more nurses, both locally and statewide. The school's name was changed to CCHS in 1996 when programs expanded to include disciplines other than nursing. Carolinas College of Health Sciences is fully accredited by the Commission on Colleges of the Southern Association of Colleges and Schools and currently has an enrollment of 450 students. Academic programs and courses are offered for prenursing; nursing; emergency medical sciences; radiologic, surgical, and medical technology; general education (ie, liberal arts); and nurse aide training.

Carolinas Medical Center also has a long history of involvement in continuing education. In 1972, CMC was invited by UNC-SOM to become one of 9 Area Health Education Centers (AHECs) in North Carolina. Area Health Education Centers act as regional extensions of universities and teaching hospitals, providing educational programs to physicians, health care professionals, and other students. The Charlotte AHEC serves an 8-county area. The AHEC programs reached approximately 27 000 care practitioners during the 2005-2006 academic year alone.

Charlotte AHEC also offers a variety of ancillary programs. For example, training opportunities in diversity management, foreign languages, and cultural immersion are offered to improve services to underserved populations. The AHEC digital library has facilitated the delivery of certain courses, educational materials, and literature online. This level of accessibility has vastly expanded the opportunities available for community-wide involvement. Finally, CHS and Charlotte AHEC have developed a program called Health Career Education—Reaching Out to Excellent Students (HEROES). This program is designed to educate precollege students, especially underrepresented minorities and disadvantaged populations, about health careers.

Carolinas HealthCare System has also invested heavily in medical research. The James G. Cannon Research Center, which opened in 1991, attracts clinical and basic science researchers to CMC. Cannon currently houses active laboratory research programs in general surgery, urology, emergency medicine, orthopedic biology/engineering, obstetrics-gynecology, internal medicine, and pediatrics. Additionally, it houses the McColl-Lockwood Laboratory for Muscular Dystrophy Research and the Heineman Medical Research Laboratories for cardiovascular disease research. More research laboratories are located in the Blumenthal Cancer Center.

Carolinas Medical Center-based investigators have contributed to expanded knowledge and successful outcomes in medicine. For example, recent work helped to develop a new technique to transplant insulin-producing cells into Type I (insulin-dependent) diabetics.[4-6] The first pancreatic islet transplantation in North or South Carolina was performed in Charlotte, and follow-up studies showed the recipient to be free from exogenous insulin injections 2 years postsurgery. The patient requires minimal immunosuppression.

Additionally, novel use of antisense oligonucleotide mediated therapy was used to improve Duchenne muscular dystrophy in an animal model.[7] Yet another CMC laboratory has identified an array of genes implicated in the progression of ovarian cancer.[8] These genetic markers may potentially serve as the basis for novel treatment strategies and/or the development of more sensitive and earlier screening tests. NIH funding has been utilized at CMC to support the development of a Carboximeter.™[9] The purpose of the device is to detect pulmonary emboli quickly and easily by means of a bedside test. Another NIH-funded study is focused on identifying oral cavity pathogens that may correlate strongly with ventilator associated pneumonia.

The R. Stuart Dickson Institute for Health Studies is a program of applied research and public health studies that is geared toward facilitating improvements in the quality of care and the effectiveness of clinical practice. Dickson staff members include epidemiologists, biostatisticians, health services researchers, database analysts, and database developers.

As this article goes to press, the feasibility of starting a Charlotte Campus of UNC-SOM is still being analyzed. If the initiative does come to fruition, however, the new campus will not need to be built from scratch. The proposed expansion will capitalize upon a long established and mature relationship between UNC-SOM and CMC. A large part of the infrastructure necessary to support expanded medical educational opportunities is already in place. Additionally, a tradition of high educational standards, in conjunction with top-quality patient care and cutting-edge research, is well established. Therefore, the main questions under review tend to revolve around funding, logistics, timing, and capacity.

The medical school expansion concept proposed by UNC-SOM builds upon existing strengths of two organizations with a long-standing commitment to educating tomorrow's physicians. Assurance of an adequate supply of accessible physicians is an issue of seminal importance to the public today and for years to come. The UNC proposal represents a means of increasing the state's production of physicians in a rapid and cost effective manner. **NCMJ**

The Potential for Medical School Expansion:
A Western North Carolina Perspective

Gary Bowers; Teck Penland, PhD; Joseph F. Damore

The North Carolina Institute of Medicine (NC IOM) 2007 Primary Care and Specialty Supply Task Force report indicates that the overall supply of practitioners in North Carolina may currently be adequate, but escalating trends in the environment threaten a substantial future shortage. The overall population growth, combined with the aging of native residents and the influx of retirees from other states, presents a serious threat to quality health services in Western North Carolina (WNC), which is experiencing both of these phenomena at an accelerated rate.

The region's population is projected to increase by 21% over the next 18 years.[1] Of the 15 counties in North Carolina with the highest percent of older adults, 10 are in WNC, and, based on 2000 data, the population aged 65 years and older in WNC is proportionately greater than for North Carolina and the US (17.8%, 12.0%, and 12.4%, respectively).[2] Already, the ratio of physicians to population in WNC is substantially below the statewide average (14.8% and 20.7%, respectively),[3] and as the population ages, they require more health care services.[4,5]

The State Needs to Consider New Options and Alternatives for Training Medical Students

The NC IOM task force has recommended that North Carolina medical schools expand their enrollment by 30% in order to meet the future shortages. An increase of this magnitude would push existing schools well beyond their facility and faculty capacity, leading to potential quality concerns. A more reasonable approach would be to consider off-campus teaching sites in WNC hospitals and private practices for up to a total of 100 third-year and fourth-year students. With additional resources, these sites could utilize existing faculty from community hospitals, including the 750-bed Mission Hospitals regional referral center, and Mountain Area Health Education Center (MAHEC) residency programs. These types of rotations would be new to the region but have proven successful in other states such as Michigan, Indiana,

> *"The region is relatively compact but offers a wide range of characteristics including metropolitan areas and relatively isolated rural communities, a growing elderly population, a strong tradition of collaboration, a sophisticated and high quality medical community, and recognized successful residency programs."*

Gary Bowers is executive director of Western North Carolina Health Network. He can be reached at gary.bowers@wnchn.org or 501 Biltmore Avenue, Asheville, NC 28801.

Teck Penland, PhD, is president and CEO of the Mountain Area Health Education Center. He can be reached at teck.penland@mahec.net or 501 Biltmore Avenue, Asheville, NC 28801.

Joseph F. Damore is president and CEO of Mission Health and Hospitals. He can be reached at joe.damore@msj.org or 509 Biltmore Avenue, Asheville, NC 28801.

and South Carolina. It is believed that this method would be a more economically feasible approach to increasing practitioner supply because existing community hospitals and MAHEC resources could reduce program costs to the state.

Why Utilize Western North Carolina for Training Medical Students?

Western North Carolina possesses assets that make the region ideal for training medical students. The region is relatively compact but offers a wide range of characteristics including metropolitan areas and relatively isolated rural communities, a growing elderly population, a strong tradition of collaboration, a sophisticated and high quality medical community, and recognized successful residency programs. The region can stand apart in offering programs for training practitioners for a variety of settings and environments.

Much of the region is nestled in areas somewhat isolated by the topography of the southern Appalachian mountains. The area is composed of many close-knit communities and residents depend on their local hospital and health care providers for their primary care needs. This setting exposes medical students to genuine rural practice with reasonable access to a large major tertiary care hospital. As more students are exposed to this environment and become integrated into the community, more may decide to practice in the rural settings,[6] which often have the greatest demand for physicians.

The quality of health care in WNC has received national recognition. Mission Hospitals has been ranked as a "Top 50" and "Top 100" hospital in several clinical areas such as cardiology, cardiovascular surgery, and orthopedic surgery. Several other WNC hospitals have been recognized nationally for their quality health care services. In addition, the utilization and cost data in WNC is also perceived as low cost, as demonstrated by the Dartmouth Atlas database. The region has every major specialty covered and provides all 3 levels of care.

The region also has a very successful history of collaboration among health care providers. The 16 WNC hospitals, MAHEC, and 14 public health departments work together closely through the WNC Health Network with the goal of improving access, enhancing quality, and reducing the costs of health care throughout the region. The hospitals formed one of the first initiatives in the country, the WNC Data Link project, to access and exchange electronic patient data across the region to facilitate care and treatment of patients. Western North Carolina community colleges and universities have a cohesive bond with the hospitals and MAHEC to project future demand for health care services and provide adequate training for professionals offering these services.

The region also has experience developing and maintaining very successful residency programs. Led by MAHEC, Mission Hospitals, and Margaret R. Pardee Memorial Hospital, with the cooperation and support of other regional hospitals, these programs have proven successful in attracting and maintaining health care practitioners in WNC. The residency programs boast a retention rate of 56% since their first graduating classes in 1978.[7]

Similar to other areas of the state, WNC has experienced a steep decline in the number of furniture, textile, and other manufacturing jobs over the past decade. The hospitals have partnered with AdvantageWest, the regional economic development team, to enhance and promote the region's strong health care services in order to attract more business and industry. A medical student training program could boost those efforts and help the economic development of the region.

Through the resources and attributes noted above, Western North Carolina can provide a high quality educational experience for third-year and fourth-year medical students. We are prepared to explore the feasibility of this program to ensure an adequate supply of physicians for our future. **NCMJ**

The Roles and Supply of Nurse-Midwives, Nurse Practitioners, and Physician Assistants in North Carolina

Justine Strand, MPH, PA-C; Nancy M. Short, DrPH, MBA, RN; Elizabeth G. Korb, CNM, MSN

Certified nurse-midwives (CNMs), nurse practitioners (NPs), and physician assistants (PAs) play a significant role in health care delivery in North Carolina. Within their scopes of practice, these health care professionals provide quality care with high levels of patient satisfaction.[1] Studies in many settings and specialties demonstrate the quality of care provided,[2-7] cost-effectiveness,[8-12] and patient satisfaction.[13-19] The PA and NP professions have been in existence for just over 40 years and CNMs for 50; but the impact of these clinicians on access to quality care is significant. Over half of the 464 primary care practitioners gained in rural North Carolina from 1998 to 2003 were NPs or PAs, and they comprise 35% of all primary care practitioners in whole county persistent health professional shortage areas.[20] In 2002, it was estimated there was one PA and NP practicing for every 10 practicing physicians.[21] As policy makers and health care leaders consider strategies to confront the impending physician shortage, it is appropriate that the positive impact of CNMs, NPs, and PAs be considered.

Certified Nurse-Midwives

There are 202 CNMs approved to practice in North Carolina. The first nurse-midwives were approved to practice in the state in 1976, and they practiced in major cities throughout the state where more physicians were early adopters of the CNM concept. Their utilization was limited until 1989 when North Carolina's rank of 49th in the nation in infant mortality prompted the Division of Maternal Child Health to conduct a feasibility study for creating a nurse-midwifery education program and the Office of Rural Health to increase its efforts to place CNMs in underserved areas. The CNM degree program was established at East Carolina University and admitted its first class in 1992.

"North Carolina is the birthplace of the PA profession, with the first PA education program established at Duke University in 1965."

Nurse-midwives are trained as women's health care practitioners specializing in care of women throughout their lives. Nurse-midwives regard the North Carolina practice environment as tenuous—North Carolina is one of only 6 states with supervisory language in statutes regulating nurse-midwives.[22] This legislative barrier prohibits CNMs from hospital admitting privileges. This results in an inability to statistically quantify their contributions to health care in the state because patients must be admitted under the supervising physician's name. The supervisory requirements force many nurse-midwives to work in labor and delivery units as nurses, which limits their impact on women's health. Many more CNMs could be trained and utilized in rural and underserved areas if the regulatory environment were improved.[23,24]

Nurse Practitioners

In North Carolina, 8 universities graduate about 190 master degree prepared nurse practitioners annually. In 2005 there

---

Justine Strand, MPH, PA-C, is chief of the Physician Assistant Division and associate professor in the Department of Community and Family Medicine at Duke University Medical Center. She can be reached at justine.strand@duke.edu or DUMC 3848, Durham, NC 27710.

Nancy M. Short, DrPH, MBA, RN, is an assistant professor in the School of Nursing, a Robert Wood Johnson Foundation Health Policy Fellow, and a senior research fellow in the Health Inequalities Program at The Terry Sanford Institute of Public Policy at Duke University. She can be reached at short008@mc.duke.edu or DUMC 3322, Durham, NC 27710.

Elizabeth G. Korb, CNM, MSN, is a perinatal clinical coordinator and senior nurse-midwife at MAHEC Regional OB/GYN Associates. She can be reached at egracek@bellsouth.net or 900 Hendersonville Road, Suite 206, Asheville, NC 28803.

were 2440 nurse practitioners approved to practice in North Carolina. The last decade has seen substantial growth in the numbers of NPs with North Carolina growing faster than the national average. The potential to expand existing NP programs in North Carolina is limited by access to clinical sites and preceptors. Another challenge is the worsening nurse faculty shortage. The major factors driving the faculty shortage are insufficient funds to hire new faculty, inability to recruit qualified faculty, lack of qualified applicants, noncompetitive salaries, and high faculty workload.[25] Recommendations to relieve the faculty shortage include developing and implementing nontraditional methods of instruction to educate future instructors, increasing public and private funding to expand nursing education programs and improve the profession's image, creating a work environment conducive to recruiting and retaining nurse faculty, increasing formal partnerships between schools of nursing and clinical facilities, and engaging retired nursing faculty in support of current faculty.

Physician Assistants

There were 2674 physician assistants in practice in North Carolina in 2005.[26] North Carolina is the birthplace of the PA profession with the first PA education program established at Duke University in 1965. For many years there were two PA programs in the state, at Wake Forest University and Duke, graduating fewer than 80 PAs a year. East Carolina University and Methodist College established PA programs in the mid 1990s, and the annual output of PAs in the state is now greater than 150. The number of PAs in the state has increased 140% since 1990. The practice environment for PAs in North Carolina has been rated the best in the nation, and this serves as a powerful incentive to in-migration.[27] Physician assistants are all trained as generalists, and thus they can provide primary care or be deployed in a variety of surgical and medical specialties. The Bureau of Labor Statistics ranks PA the 4th fastest growing occupation from 2004 to 2010,[28] and the applicant pool to PA programs nationally remains robust. Barriers to expansion of PA programs, nationally and in North Carolina, include adequate financial aid, expanded clinical rotation sites, and local constraints on facilities and resources within institutions.

Recommendations

The North Carolina Institute of Medicine Primary Care and Specialty Supply Task Force recommendations recognize the contributions of nurse-midwives, nurse practitioners, and physician assistants to access to high quality health care for North Carolinians. One option identified to address the practitioner shortage is to increase the production of CNMs, NPs, and PAs by 30%. Although the challenges to such an expansion vary by discipline, there are some overarching themes: the need for adequate faculty and educational resources (including clinical rotation sites and financial aid for students) and the impact of the practice environment on retention of clinicians trained in the state.

A shortage of nursing faculty is an ongoing concern because many educators are approaching retirement. Strategies for increasing the number of faculty in nursing programs include improved salaries, faculty development opportunities, and improved work environment. While the number of physician assistant faculty is currently adequate, expansion of PA programs would likely engender similar difficulties.

Adequate funding for education programs is critical, as is access to clinical training sites. Clinical rotation availability is often cited as a reason not to expand medical school class sizes, and the situation is no different for CNM, NP, and PA educational expansion. In North Carolina, adequate funding of the Area Health Education Centers (AHECs) to expand the stipend for primary care preceptors will be a key factor in assuring adequate clinical training sites.

Underrepresented minorities and disadvantaged candidates for health professions programs face greater barriers to affording education, yet they are more likely to care for the medically underserved. Adequate financial aid packages, including scholarships and loan forgiveness programs, are central to enhanced diversity and deployment of clinicians to where they are needed most.

The foundation for recruitment of CNMs, NPs, and PAs from other states and retention of those educated here once they graduate is the regulatory environment. From the physician assistant perspective, North Carolina's environment is ideal, and it is ranked first in the nation for PA practice.[27] Nurse practitioners and nurse-midwives see the need for improvement in the practice environment to better align regulation with appropriate scope of practice and utilization.[24] For all three disciplines, legislated authority should coincide with clinical ability as precisely as possible. This requires an appropriate balance between assuring protection of the public and enhancing the ability of these clinicians to deliver care within their scopes of practice. **NCMJ**

COMMENTARY

Recruitment and Retention of Physicians and Primary Care Practitioners for North Carolina:

A Partnership Approach

Torlen Wade; Margaret L. Sauer, MS, MHA; Christine Kushner

Population growth, the aging of the population, and an increase in chronic disease—all are expected to increase North Carolina's demand for physicians, physician assistants, nurse practitioners, and other practitioners. Overall in North Carolina, the ratio of all practitioners-to-population is expected to drop between 2% and 13% by 2030.[1]

This will continue to strain counties and communities that historically have had practitioner shortages. In 2005, all or parts of 38 counties in North Carolina remained persistently medically underserved.[2] Without targeted strategies to recruit medical practitioners, access to health care in underserved areas of North Carolina will likely be more difficult than ever. In an effort to defray the effects of these trends, the NC Office of Rural Health and Community Care (ORH, formerly the Office of Rural Health Services) and the NC Medical Society Foundation's Community Practitioner Program (CPP) work as allies to offer loan repayment, financial incentives, and expert technical assistance to support primary care medical practitioners serving medically underserved patients in rural communities. Together, and with other key partners in the state, these organizations have created additional medical access points in rural North Carolina and powerful tools to attract and retain primary medical care services in our state. These partnerships have created one of the strongest recruitment and retention systems in the nation. Yet, while North Carolina is still seen as a leader, many other states are catching up, providing community development, comprehensive and compatible matching in recruitment, and other longer-term support for rural and underserved practices. Now, more than ever, the partnership is critical to meeting the state's growing need for primary care practitioners.

> *"In order for North Carolina to maintain its competitive advantage, collaboration among all the stakeholders is critical and funding is essential to meet the present and future demands on our health care system."*

Recruiting Health Care Practitioners to North Carolina

In 1973, the NC ORH began its mission of establishing community-based primary care medical centers in rural and underserved parts of North Carolina. The staff soon found they needed the capacity to recruit physicians, physician assistants, nurse practitioners, and other practitioners to these sites, so in 1975 the ORH began its Medical Placement Services (MPS) program. In the mid-1990s, the NC General Assembly recognized the severe shortage of general dentists in many parts of North Carolina, and recruiting dentists and dental hygienists was added to the mission of the ORH Medical Placement Services.

Torlen Wade is director of the Office of Rural Health and Community Care in the North Carolina Department of Health and Human Services. He can be reached at torlen.wade@ncmail.net or 2009 Mail Service Center, Raleigh, NC 27699-2009.

Margaret L. Sauer, MS, MHA, is director of the Community Practitioner Program at the North Carolina Medical Society Foundation and consulting associate in Community and Family Medicine at the Duke University School of Medicine.

Christine Kushner is a consultant with the North Carolina Foundation for Advanced Health Programs.

Accompanying the move toward recent mental health reform, in 2005 the legislature provided $1 million annually to ORH to expand the recruitment of psychiatrists to rural and underserved communities that had a shortage or absence of mental health professionals.

Since its inception, MPS has recruited more than 3000 primary care physicians, dentists, nurse practitioners, physician assistants, psychiatrists, and other practitioners to the state.[3] More than half of those placements have been at sites federally designated as health professional shortage areas (HPSAs). Over the course of its history, MPS has contracted with more than 300 communities across the state and at any given time has 350 to 450 different opportunities to offer, including private practice, health departments, federal community and migrant health centers, and state rural health centers.[3] Each year, the staff recruits approximately 140 practitioners to the state, almost all of them serving in medically needy communities, most of them rural towns and counties.

As incentives to placement, physicians, psychiatrists, and dentists locating in medically underserved communities are eligible for up to $70 000 in State Loan Repayment funds for a 4-year commitment. Physician assistants, nurse practitioners, and dental hygienists are eligible for up to $30 000 in State Loan Repayment for a 3-year commitment. MPS receives about $1.4 million each year for primary care and dental loan repayment incentives. One month into the state's fiscal year, most of the funds are obligated to practitioners waiting to receive the funds and relocate to North Carolina.[4] The MPS staff also coordinates applications for Federal Loan Repayment funds and offers state-sponsored High Needs Bonuses, providing greater flexibility in responding to each recruited practitioner's financial needs.

The ORH programs make a critical difference for both new and established practices across the state. Jo Hudson, an administrator with Benson Area Medical Center in Johnston County, said the health center has used ORH services for the past 28 years. "As a community-owned nonprofit rural health center, we often struggle to offer a salary and benefits package that can compete with those offered both in the private sector and in the federally-funded centers," she said. "The State Loan Repayment Program has made the difference for us."

Over the years, ORH staff members have developed strong and ongoing relationships with the state's primary care residency programs, the University of North Carolina at Chapel Hill School of Dentistry, and the 9 Area Health Education Center (AHEC) programs. ORH staff work to build an individualized and trusting relationship with each potential candidate, conducting in-depth interviews and creating an ongoing relationship to gather information on each candidate's professional qualifications, personal and professional goals, and specific individual needs. This one-on-one attention is continued throughout the recruitment process.

The success of the MPS staff hinges on its detailed knowledge of the communities it recruits for. ORH has helped establish numerous practices across the state, which enables staff to give prospective candidates unique details about each site. In addition, MPS staff regularly confers with ORH consultants, community representatives, business leaders, as well as hospital and other health care administrators to accurately assess local health personnel needs and develop effective recruitment strategies.

Adding Resources to Recruitment and Retention Efforts

In the late 1980s, state leaders recognized that the ORH alone was not able to fulfill all the state's recruitment needs. In particular, the state office had few options to help private practitioners who worked outside a community-based or publicly-financed medical system, yet many private physicians were struggling to enter or maintain a rural practice in high-needs communities—communities that needed primary care practitioners.

In 1989, the NC Medical Society Foundation (NCMSF), ORH, the NC AHEC Program, and the Kate B. Reynolds Charitable Trust conducted a needs assessment to determine new strategies, and a $4.5 million grant from Kate B. Reynolds Charitable Trust created the Community Practitioner Program. A program of the NCMSF, CPP was created to assist practitioners and sites not eligible for ORH incentives. The Community Practitioner Program uses its funds to provide loan repayment and financial incentives to physicians, physician assistants, and family nurse practitioners in return for 5 years of service in a targeted medically underserved community. The program typically pays up to half of a practitioner's educational loans and provides practice management assistance through its PractEssentials program to participants and their practice sites. Currently, 103 health care professionals participate in CPP in nearly half of North Carolina's 100 counties. Since its inception, 365 practitioners in 136 communities have been served by the program in 77 counties. About three-fourths of the participating practitioners remain in rural or economically distressed counties beyond their 5-year commitment, and 85% remain in North Carolina.

Beth Hodges, MD, said the chronic shortage of physicians was evident when she and her husband began their family practice in Asheboro with CPP help. "When we opened our practice, we acquired many patients who had not seen a doctor in more than 20 years," she said. "Now, 6 years later, hardly a day goes by that we do not receive thanks from someone for making such a difference in their mother's, father's, or grandparent's life."

From the initial grant provided by Kate B. Reynolds Charitable Trust, $10 million in program expenditures have been leveraged producing $226 million in health care to uninsured North Carolinians through CPP. In 2006, the Blue Cross and Blue Shield of North Carolina Foundation entered into a $10 million, 5-year partnership to sustain CPP; the grant requires a $5 million match from other sources. To date, some of the matching funds have been obtained from the NC Medical Society, Medical Mutual Insurance Co., the Physicians Foundation for Health Systems Excellence, individual physicians, and philanthropists. As a result, by 2010, CPP is projected to increase the number of practitioners assisted on an annual basis

Table 1.
North Carolina Loan Repayment Program Attributes

	NC Office of Rural Health-Medical Placement Services Program	NC Medical Society Foundation-Community Practitioner Program
Budget	$1.4 million primary care annually $1 million psychiatric care annually	$700 000 annually
Funding source	State of North Carolina	Grants from Kate B. Reynolds Charitable Trust, Blue Cross/Blue Shield of North Carolina Foundation, The Duke Endowment, Golden Leaf Foundation
Loan repayment limit	Maximum $70 000	At least half of medical school loan debt
Obligation	Up to 4 years	Up to 5 years
Eligibility	Must practice in community-based nonprofit in a health professional shortage area (HPSA)	Prioritize those practicing in HPSA designated regions, open to private practices treating patients and with a Medicaid, Medicare, and indigent care population constituting at least 30% of their practice
Provider eligibility	Primary care physicians, psychiatrists, dentists, dental hygienists, nurse practitioners, physician assistants, and nurse midwives	Primary care physicians, nurse practitioners, and physician assistants
Application process	Conducted through the Office of Rural Health staff	Application is completed for initial determination, followed by interview with the participant, practice manager, and supervising physician
Coordination of federal loan program resources	Yes	Applicant is ineligible if qualified for federal/state loan repayment programs
Practice management resources	Office of Rural Health and Community Care staff	PractEssentials through NC Medical Society Foundation
Flexible funding	Yes	Yes
Communities served	More than 400	More than 136
Counties served	100	77
Program participants 2006	198 (loan repayment and placements)	103 (loan repayment and placements)

from 103 to 160, increasing annual patient visits from 2 310 000 to 3 696 000.

Primary Care Recruitment: The Changing Landscape

The 1990s saw increased interest nationally in state-based recruitment programs. By 1996, there were 82 different programs in 41 states working to recruit health professionals to underserved communities.[5] Programs in other states include loan repayment, scholarship programs, financial incentives, and residency support. There continues to be greater national competition for practitioners interested in serving rural and remote communities.

With increased pressure on supply, in the 1990s greater emphasis was placed on retaining existing practitioners. Retention in rural North Carolina improved when the federal National Health Service Corps moved from obligating scholars to fixed years of service based on front-end medical school scholarships to loan repayment that recruited medical residents who had been through training and recognized a desire and willingness to practice in a rural or medically underserved area, according to Tom Tucker, a veteran recruiter with ORH. Practitioners who signed up as scholars to pay for medical school had low retention rates and usually left their NHSC site when their obligation was completed. Those recruited after residency through loan repayment have higher retention rates, he said.

In recent years, as the legislature expanded ORH's responsibilities to include recruiting psychiatrists, mental health professionals, and dentists, funding has not been commensurate with the increased demands to recruit practitioners. The 2007-2008 proposed budget allocates an additional $500 000 for loan repayment, funds that will increase the ORH's current resources of $1.2 million for primary care and $1 million for mental health. The proposed increase will help North Carolina stay competitive in the national recruitment process, but it does not return the ORH to the peak of $1.8 million it had in 2002 for primary care incentives. North Carolina remains unique with its extensive and varied resources for recruitment. Other states recognize the value of the programs piloted in North Carolina to meet critical access needs of their residents. In order for North Carolina to maintain its competitive advantage, collaboration among all the stakeholders is critical and funding is essential to meet the present and future demands on our health care system.

Working Together

Leaders from the Office of Rural Health and the Community Practitioner Program have coordinated efforts from the beginning. Staff members from ORH and CPP meet regularly to discuss candidates, look over opportunities, and discuss overall workforce needs and strategies. They also continue to meet regularly with key partners including the NC AHEC Program, the NC Hospital Association's Rural Health Center, the NC Division of Public Health, granting organizations, and other state agencies to analyze trends and strategies concerning health professional supply, workforce issues, and opportunities for collaboration.

"If it weren't for the close collaboration between the Office of Rural Health and the CPP, I would not have found Sampson County," said Art Apolinario, MD, who practices in Harrells and Newton Grove. "It just never really occurred to me that my perfect practice experience could come from one of the most rural counties in the state. Knowing they were behind me and my potential success in the communities of Newton Grove and Harrells made me that much more confident that a lifestyle and practice in Sampson County could work for me and my family. They worked hard to make sure I would match with these communities, and that has made the biggest difference in ensuring I would stay in the community."

North Carolina's ORH and CPP, together with their partners, give the state a national competitive advantage to recruit for medically underserved communities. By working together, they also maximize their resources and partner to recruit high-quality health professionals who will remain in North Carolina's rural and underserved communities. **NCMJ**

Rural Hospitals and Rural Physicians:

Understanding the Physician Workforce Challenges that Affect Rural Communities and Providers

Larry H. Chewning, MHA, FACHE; Jeff Spade, CHE

Rural communities across North Carolina are constantly and increasingly facing significant challenges to their fragile health care systems. The health of rural North Carolina citizens depends on a delicate balance between health care providers; health system resources, facilities, and service development; community, public health, and social support structures; and the underlying health status of the community. Unfortunately, practitioner shortages have a significant potential to unbalance North Carolina's effective but fragile rural health care system.

Rural hospitals and their associated physicians and medical staff are particularly critical aspects of rural health care networks. As a consequence, rural hospitals and physicians are highly dependent upon each other to create services, resources, and access points that ultimately support community health improvements, prevention of disease, and treatment for chronic and acute illness and injury. In order to understand the community-wide impact of the availability of trained, reliable physician resources for rural North Carolina communities and hospitals, please consider the following North Carolina case studies.

> *"Physician recruitment and retention are among the most, if not, the most important issues faced by hospitals today. For rural hospitals, the success of the recruitment process is often termed as a "life and death" objective.*

Vulnerability to Specialty Practitioner Shortages

A 150-bed rural community hospital in eastern North Carolina has provided urology services for 80 000 citizens in the county and local communities for the past 40 years. Recently, one of the two urology physicians practicing in the community and providing care at the hospital decided to terminate his relationship with the practice and move out of state. The decision was based on family decisions as well as lifestyle issues. The physician was beleaguered by a call schedule that required 7 days on, then 7 days off, to provide coverage for the two physician practice.

The rural hospital and the urologist remaining in the practice developed a strategy to successfully restore full physician coverage to the urology practice, including amendments to the hospital medical staff bylaws to create a maximum call exposure of 10 days per month for any physician specialist. The rural hospital and the urologist then began an extensive recruitment process to replace the departing physician partner. Three months after the departure of the first urologist, the remaining urologist decided to depart the practice, leaving the rural hospital and the community as well. Thus, in just 6 months, a vibrant, thriving, and strong urology practice serving a significant rural community had completely collapsed. The consequences for patients in the rural community were devastating, requiring patients and families to seek care and physician relationships across county lines, further from home.

Larry H. Chewning, MHA, FACHE, is CEO of Sampson Regional Medical Center. He can be reached at lchewning@sampsonrmc.org or 607 Beaman Street, Clinton, NC 28328.

Jeff Spade, CHE, is executive director of the NC Rural Health Center at the North Carolina Hospital Association.

For the rural community hospital, losing the urology practice led to an immediate loss of hospitalized patients, causing urology patients to bypass the rural hospital to receive basic outpatient services elsewhere and, ultimately, resulting in substantial decreases in surgical and diagnostic procedures and an estimated net revenue loss of $2 million annually.

Subsequently, the rural hospital worked diligently to negotiate a partnership with a multi-physician urology practice affiliated with a larger urban hospital more than 60 miles away for one day per week of urology coverage in the rural community. Eventually, a full-time urologist was recruited to join the group practice and encouraged to develop a satellite clinic. The rural hospital estimates that the 6-month disruption in urology services will require nearly 3 years of persistent effort to bring services and volume back to where it was prior to the departure of the physicians. Reflecting on the difficult and untimely situation, the rural hospital CEO confirmed, "Recruiting another urologist to suburban North Carolina really doesn't matter. However, one urologist at our community hospital means the difference between 80 000 people receiving care locally or patients having to leave their local community to seek care."

Case Study of Successful Rural Hospital Physician Recruitment

A rural hospital in eastern North Carolina successfully operates a family medicine clinic in a remote rural community of approximately 4000 people located 10 or more miles from the rural hospital. The physician practice served as the only full service primary care clinic in the area. The practicing physicians held hospital privileges and were supported by the rural hospital's existing medical staff structure. After many years of practice, both the physician and family nurse practitioner announced their intent to leave the hospital-supported clinic. The decision left the rural community without immediate access to primary care. The rural hospital immediately began a search to replace the physician and primary care providers.

While the rural hospital is located within an hour and a half drive of 4 major North Carolina physician training programs that focus on primary care, North Carolina's training programs are not the usual resource for recruiting and locating new primary care physicians in this rural community. Of the 10 most recently recruited primary care physicians, only one physician had completed primary care training at a North Carolina-based physician residency program.

The rural hospital was successful in recruiting a husband and wife physician team from Ohio. The key success factors that achieved this recruitment opportunity included:

- Physician interest in the small town setting.
- The appeal of North Carolina as a place to both practice medicine and develop an attractive lifestyle.
- Recruitment support packages offered by the hospital including income guarantees for the practice and assistance with relocation expenses.
- An existing practice with active patient files, well-designed facilities, and readily available office staff.
- Access to a supportive community hospital with a full service compliment of diagnostic capabilities and physician specialists.
- The availability of a weekend hospitalist service, which allows the primary care physicians time off as they develop their practice.

The rural primary care practice is a striking success story. The community has been extremely receptive to the new physicians and their commitment to expand their base of patients. The financial incentives provided by the rural hospital served the practice well during their initial start-up. Financial assistance from the North Carolina Medical Society Foundation proved beneficial to the initial success of the practice as well.

Physician Recruitment and Retention

Virtually all North Carolina rural hospitals are actively and constantly recruiting physicians across many specialties to meet critical physician shortages. Recent surveys from state hospital associations and the American Hospital Association document the recruitment of new physicians to hospitals' medical staffs for small, medium, and large rural community hospitals. Physician recruitment and retention are among the most, if not the most, important issues faced by hospitals today. For rural hospitals, the success of the recruitment process is often termed as a "life and death" objective. The strategic value of the appropriate composition and continued development of the medical staff is critical due to the following factors:

- Each new physician generates incremental, new revenue for the hospital. Physicians with surgical specialties are particularly valuable in creating revenue opportunities for rural hospitals.
- Each new physician expands the market share of the hospital, allowing patients to receive health care services in their rural community.
- Success breeds success. Each new physician recruited to the medical staff improves the image of the rural hospital and the community and, in turn, helps attract more new physicians.

General Lessons Learned

Rural hospitals tend to serve communities whose demographic profiles are more difficult from a health standpoint than the urban hospital counterparts. Typically, communities served by rural hospitals are more elderly and have higher proportions of uninsured residents. Rural community residents also have higher incidence of chronic disease and lower per capita incomes. Recent studies published by the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill document Duplin County and Sampson County in eastern North Carolina as experiencing the highest uninsured vulnerability rate (approximately 25% of the population) throughout North Carolina. Duplin and Sampson are excellent examples of typical rural North Carolina counties served by rural community hospitals based within the county.

In addition, the specialty mix of physicians and services do not reward rural community hospitals. On average, the hospital service lines that feature tertiary services in cardiology, oncology, and surgical subspecialties are able to generate significantly higher operating margins than the primary and secondary care services characteristically offered at rural community hospitals. Obviously, the key to offering specialty services is linked to the availability of specialty physicians. Unfortunately, many of the medical and surgical specialty physicians tend to be in short supply in rural community hospitals.

Obstacles to recruitment of new physicians to serve communities and rural community hospitals are numerous. Many of the critical issues that impact rural physician recruitment and retention are summarized below.

- Lifestyle—Many physicians and their families prefer the amenities available in larger, more metropolitan or suburban areas. Recruitment to a rural community is particularly difficult when neither the physician nor his/her family has any experience living or practicing outside of an urban area.
- Unintentional medical school bias—Many physicians that choose to practice in rural communities relate that there is an informal, but visible, bias communicated in their medical school and residency training against practicing in rural areas. Most of this subtle bias focuses on the absence of medical technology, lack of research, professional isolation, and fewer continuing education opportunities available in rural areas.
- Call coverage—Call coverage for both the practice and the rural hospital can be a particularly thorny issue for specialty physicians practicing in rural areas. Typically, surgical subspecialties may be solo practitioners or small group practices. It is essential that rural hospitals establish a reasonable call schedule for physicians practicing in specialties with only a few physicians on the call panel.
- Payor mix—As demonstrated earlier, payor mix issues can present a significant financial barrier for both rural physicians and rural hospitals. There is a tendency for well-insured patients to seek care in urban or suburban environments. These patients have the ability to travel easily and bypass their local hospital and physician, leaving behind uninsured patients and poor citizens who are dependent on government insurance to receive adequate health care.

Potential Solutions

Physician recruitment to rural communities is not always a frustrating process. There are certain attractive features for a rural community that the astute physician can understand and may often prefer. For example, there tends to be little or no managed care in rural North Carolina communities due to low population densities. Most rural community hospitals are underserved for physician supply in nearly every specialty, thus, there is very little competition between groups or physicians. In addition, physician productivity is better awarded through seeing and treating a larger number of patients.

Furthermore, the cost of living is usually more reasonable and affordable in rural communities. This is particularly noticeable in the cost of housing and land. The camaraderie of the medical staff tends to be a reinforcing factor in rural community hospitals. There is a great sense that “we are all in this together.” Perhaps the greatest physician recruitment advantage rural community hospitals have is the ability to use financial incentives to attract new physicians to rural communities. Federal and state regulatory guidelines governing inducements offered to new physicians permit hospitals in rural underserved areas to offer financial incentives to attract new physicians in return for their service to the community and hospital. The approved financial inducements may include a start-up bonus, income guarantees, medical school loan repayment, and the marketing of the new physician’s practice in the service area of the hospital. Successful rural hospitals will have to build upon these advantages and work closely with programs throughout the state that offer recruitment and retention assistance. **NCMJ**

COMMENTARY

Location, Location, Location:
North Carolina Faces a Shortage of Primary Care and Specialty Practitioners in Rural and Underserved Counties

---

Erin P. Fraher, MPP

It was a downturn in the overall supply of physicians per 10 000 population that prompted the North Carolina Institute of Medicine (NC IOM) to examine the emerging physician shortage in North Carolina. However, what will ultimately matter, and what presents the most pressing policy challenge, is whether we will be able to get the right mix of practitioners in the right places to meet the health care needs of North Carolina's citizens.

Health workforce researchers have long debated how to define a workforce shortage (ie, how many practitioners are too few?), what constitutes the right mix of primary care and specialist physicians to meet population needs, and what is the ideal balance of physician and nonphysician practitioners such as physician assistants, nurse practitioners, and certified nurse midwives in a particular health care setting. While these are important topics to discuss and debate, we must make policy decisions now based on our best understanding of the information currently available. The objective of this commentary is to use data from the North Carolina Health Professions Data System (HPDS) to summarize what we know about the supply and distribution of primary care practitioners, practitioners who deliver babies, general surgeons, and psychiatrists and to suggest what might be done to address shortages and maldistribution of practitioners in these specialties.[a]

> *"Rural counties that have traditionally fared poorly in the competition for practitioners appear to be worse off now than in the past and the existing maldistribution will be exacerbated as the overall physician supply tightens."*

Primary Care Practitioners

Primary care practitioners (PCPs)[b] are those providers who see patients with the most common medical problems. Primary care practitioners serve as the entry point into the medical system for most patients, and they coordinate care for patients requiring specialty services. While there is some evidence that fewer practitioners are selecting primary care specialties,[1] North Carolina continues to have more primary care physicians relative

---

a Undoubtedly shortages of other specialty providers exist but data and resource limitations prevent a fuller examination of all specialty areas. For example, although we know that North Carolina's rapidly aging population has increased the demand for geriatric care, in 2005 only 293 physicians reported a primary or secondary specialty in geriatrics or family practice, geriatrics. Physicians in other specialties (ie, internal medicine) are providing geriatric care, but without information on the physician's patient panel there is no way to assess the adequacy of supply.

b Primary care practitioners are defined as physicians, nurse practitioners, and physician assistants who indicate a primary specialty in general practice, family practice, internal medicine, obstetrics and gynecology, or pediatrics. All certified nurse midwives are considered to be in primary care.

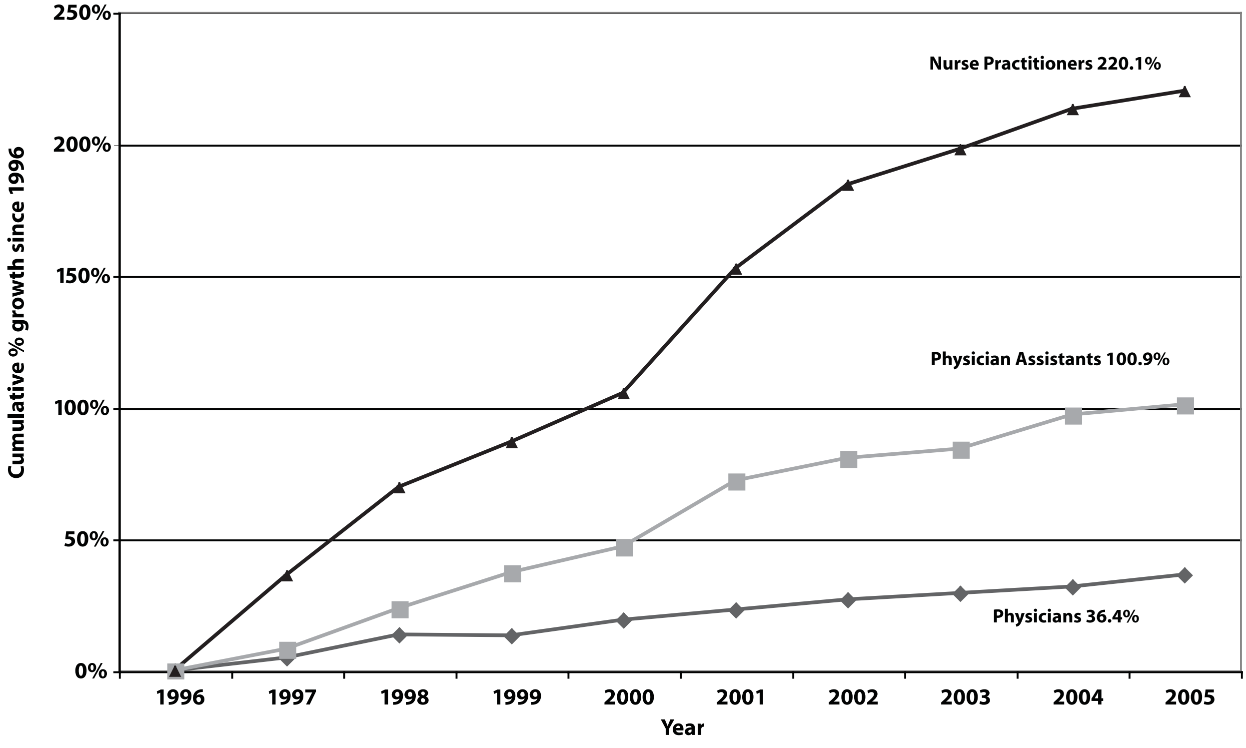
Erin P. Fraher, MPP, is director of the NC Health Professions Data System at the Cecil G. Sheps Center for Health Services Research. She can be reached at erin_fraher@unc.edu or 725 Martin L. King Jr Blvd, Campus Box 7590, Chapel Hill, NC 27699-7590.

to population size than the United States average.[2] Nurse practitioners (NPs) and physician assistants (PAs) make up an increasingly important component of North Carolina's primary care workforce. Over the past decade, the supply of primary care NPs and PAs outstripped physician growth. While physician supply grew by 36.4% between 1996 and 2005, NPs increased by 220.1% and PAs grew by 100.9%. (See Figure 1.) The rapid growth of PA and NP supply has been especially important in rural areas of the state. Between 2001 and 2005, almost half (47%) of the 264 primary care practitioners gained in rural counties were either NPs or PAs. Despite these gains, North Carolina has faced an increasing shortage of primary care practitioners in the state's most underserved counties. Between 2001 and 2005, 30 counties experienced a decrease in primary care practitioners to population ratios compared to 11 counties between 1996 and 2001. Fourteen of the 30 counties where supply declined relative to population have been designated as primary care health professional shortage areas in 6 of the past 7 years.[1] The net result of these trends is that while the overall supply of primary care practitioners is not yet problematic, there is a maldistribution of practitioners across the state.

Practitioners Who Deliver Babies

An important component of primary care is access to obstetric care services. Despite significant anecdotal evidence that fewer providers are delivering babies in North Carolina due to rising malpractice rates, the number of obstetricians/gynecologists and family physicians who reported delivering babies rose between 2000 and 2005. Concomitantly, the number of births per delivering physician declined from 139.3 in 2000 to 125.7 in 2005.[c] The supply of certified nurse midwives also increased over the period from 167 in 2000 to 195 in 2004. An important caveat to this generally good news about the supply of obstetric care practitioners is that between 2003 and 2004 there was a 12% decline in the number of family physicians (FPs) delivering babies, and of the 101 physicians who stopped providing deliveries between 2003 and 2004, 56 (56%) were FPs. This represents a disproportionate share since family physicians comprise just 10% of total physicians delivering babies. This trend does not bode well for the distribution of obstetric care in rural areas because family physicians provide 26% of delivery services in rural counties. If their numbers continue to decline at such a rapid rate or action is taken on the

Figure 1.
Cumulative Percent Growth in Primary Care Physicians, Physician Assistants, Nurse Practitioners, and Certified Nurse Midwives, Relative to 1996



---

[c] There was a slight decrease in the supply of physicians delivering babies between 2004 and 2005, but it is unclear whether this decrease reflects a true trend or a data aberration caused by a change in the way the Medical Board collects this information from physicians.

currently debated question of removing obstetrical training from FP training programs, the supply of practitioners who deliver babies in rural areas may be further compromised. As it is, there are 19 counties in North Carolina without a physician who delivers babies;[d] 12 of these counties have not had a physician deliver a baby in the last 5 years. While there is evidence that the average distance traveled by women delivering babies has not increased,[3] it is not known whether birth outcomes are worse for mothers in counties with no or limited access to obstetrical care.

General Surgeons

Workforce patterns for surgeons echo that of other specialties with an adequate, but poorly distributed, supply. With 0.75 general surgeons per 10 000 population, North Carolina has more general surgeons than the US average (0.60) or other southern states (0.64), but between 2000 and 2005 more than half (53) of North Carolina counties experienced a decrease in the supply of surgeons relative to population, and 5 counties lost all their general surgeons. Seventeen counties had no general surgeons in either 2000 or 2005. General surgeons are a difficult specialty to study from a workforce planning perspective because although they are trained to provide a wide range of surgical services, general surgeons tend to narrow their scope of practice over time in response to the demands exerted by the rapid growth of medical knowledge, patients in their practice, and personal factors.[4] More research is needed to better understand and monitor the supply of general surgery services in the state.

Psychiatrists[5]

North Carolina is currently in the process of redesigning the way mental health services are delivered. As the provision of mental health services is divested from centralized agencies to community settings, it is crucial to know whether there will be practitioners to care for patients at the community level. While a broad range of professionals treat individuals with mental health disorders, a subset of patients requires consultation and pharmacological treatment by psychiatrists. The overall supply of psychiatrists in the state has been keeping pace with population, and North Carolina ranks 20th in the nation with a ratio of 1.05 psychiatrists per 10 000 population. However, two-thirds of North Carolina counties lost psychiatrists relative to population growth or had no psychiatrists between 1999 and 2004.

Examining the supply of psychiatrists relative to primary care physicians is another important perspective from which to examine the issue because in the absence of psychiatrists the burden of diagnosing and managing mental illness will likely fall on primary care physicians who may also be in shortage. In 2004, 19 counties in North Carolina faced a persistent shortage of primary care physicians; 11 of these 19 counties also had a psychiatrist shortage.

Of more concern than the overall supply of psychiatrists is the shortage of child psychiatrists in the state. A recent study of North Carolina pediatricians found that about 15% of children had a behavioral disorder such as attention deficit disorder, anxiety, or depression.[6] While PCPs can diagnose and treat many common childhood mental illnesses, a child psychiatrist is needed for more complex cases. In 1995, the state had 102 physicians reporting a primary specialty in child psychiatry, but this number dropped to 91 in 2005. During the same period, the population 18 years and younger grew by 21%. The net effect of these trends was that the ratio of child psychiatrists per 10 000 population aged 18 years and younger dropped 26% (from 0.55 to 0.41). Distribution is also a problem—in 2004, 43 counties had no child psychiatrists and another 42 counties had fewer than one full-time-equivalent.[e]

So What? Crafting Policies to Address Shortage Issues

The shortage of child psychiatrists is acute and action needs to be taken to increase supply and improve distribution. The long-term ramifications of not taking action will be deleterious for North Carolina's health care system. As children who receive suboptimal or no psychiatric care mature, they are likely to require even more mental health services than if they had been treated earlier. Lack of access to mental health services will also have personal costs that are borne by children and their parents and societal costs if children are not able to reach their potential due to a lack of access to mental health services. Options include increasing the number of child psychiatry positions in North Carolina residency training programs and placing these positions in community-based teaching sites in rural and underserved communities. The thorny issue of reimbursement must also be addressed. Given that many North Carolina rural communities face both a shortage of primary care and psychiatric physicians, private and public payers need to reimburse for face-to-face and telemedicine consultations between the two practitioner groups. Resources also need to be devoted to developing innovative models of interdisciplinary care that do a better job incorporating nurse practitioners and physician assistants with mental health competencies into the psychiatric workforce team.

With the exception of child psychiatrists, North Carolina's current supply of primary care and specialty practitioners is adequate to meet population needs, but there is a maldistribution of practitioners across the state. Rural counties that have traditionally fared poorly in the competition for practitioners appear to be worse off now than in the past, and the existing maldistribution will be exacerbated as the overall physician supply tightens. To reverse this trend, decision makers must focus attention not only on high visibility options such as developing new or satellite medical schools, but must also

---

[d] These data include physicians' reported primary, secondary, and tertiary practice locations.

[e] Data include primary, secondary and tertiary practice locations for physicians reporting a primary specialty in psychiatry.

consider a broad range of policy interventions to encourage and support rural practice. Strategies that address the maldistribution by increasing overall supply rely on a “trickle down” assumption that practitioners will diffuse across geographic areas. Although research supports a general diffusion of practitioners from urban to rural areas,[7,8] past experience has shown that more direct policy action is needed to locate practitioners in underserved areas. Resources need to be invested in placing training programs and clinical rotations in underserved areas of the state because practitioners are more likely to settle near where they train. Financial incentives need to be crafted that not only encourage physicians to move to rural areas but to remain there as well. Loan repayment has proven an effective tool in recruiting physicians to rural areas,[9] but longer-term strategies to reduce professional isolation and workload need to be implemented to address rural physician retention. North Carolina has a well-established history of collaborative action between health workforce stakeholders that makes it well positioned to both digest, and act upon, shortages of primary care and specialty practitioners. **NCMJ**

Increasing Minority Representation in the Health Professions:
One Student at a Time

Patrena N. Benton, MS

Beyond sporadic trips to the clinic for immunization shots, they have limited opportunity to communicate with a physician. A majority of these individuals have never crossed the threshold of a dental office, and they may not understand what the man behind the counter at the local drug store really does. Who are "they" you ask? "They" are the many minority and disadvantaged students who have had limited contact with adequate health care and little to no exposure to any health care practitioners who mirror their image. It is important to understand some of the contributing factors to this harsh reality.

Health Disparities

Many Americans are living longer, and their overall health is improving. However, despite a steady improvement in the overall health of the US population, racial and ethnic minorities, with few exceptions, experience higher rates of morbidity and mortality than nonminorities.[1] This holds true for the citizens of North Carolina. Over the past few decades, enormous strides have been made to enhance the health status and quality of life of all North Carolinians. However, in spite of these gains, a large segment of the state's racial and ethnic minorities, particularly African Americans, American Indians, and Hispanics, continue to experience a disproportionate burden of poor health and premature mortality compared to their white counterparts.[2] Several studies have shown that even with equivalent levels of access to care, racial and ethnic minorities experience a lower quality of health services and are less likely to receive even routine medical procedures than white Americans.[1]

> *"To a great extent, efforts to diversify health care fields have been hampered by gross inequalities in educational opportunities for students of minority racial and ethnic groups."*

In addition to examining this epidemic through national discourse, states are addressing the impact of health disparities on their local home fronts. North Carolina has a long-standing tradition of caring for the health of its citizens. Since 1968, the North Carolina Area Health Education Centers Program (AHEC) Medical Air Operations has transported health science faculty, medical residents, health science students, and university officials to the most remote areas of the state in dire need of health services.[3] In 2001, shortly after Governor Mike Easley appointed her as Secretary of the Department of Health and Human Services (DHHS), Carmen Hooker Odom declared eliminating health disparities a priority for the department. The Secretary charged the Office of Minority Health and Health Disparities (OMHHD) with lead responsibility for developing the DHHS Call to Action to Eliminate Health Disparities.[2] NC OMHHD and the State Center for Health Statistics released the Racial and Ethnic Disparities in North Carolina Report Card 2006. This document reveals some leading health indicators for broad racial and ethnic population groups for the state, provides supporting data for those health indicators, and assigns a letter grade that ranks the health status of those groups. For instance, the 2000-2004 prostate cancer death rate shown for African Americans (73.0) was divided by the prostate cancer death rate for whites (25.1): 73.0 ÷ 25.1= 2.9. This ratio shows that the prostate cancer death rate for African Americans was 2.9 times as high as the rate for the white population. According to the disparity ratio grading scale, this 2.9 receives a grade of "D."[4]

Patrena N. Benton, MS, is interim executive director of the North Carolina Health Careers Access Program at the University of North Carolina at Chapel Hill. She can be reached at pbenton@unc.edu or Campus Box 8010, Chapel Hill, North Carolina 27599-8010.

As the state continues to aggressively focus on this health dilemma, it must also address the shortage of health care practitioners with specific emphasis on increasing the percentage of minority practitioners. Empirical evidence is mounting that compared to whites minorities are more likely to serve the underserved.[8]

Underrepresented Minorities (URMs) Missing from Health Careers

America is experiencing a "browning effect."[5] Due to the rapid increase in minority populations, the country is becoming increasingly more diverse. Unfortunately, the same cannot be said for the diversification of the health care professions. To a great extent, efforts to diversify health care fields have been hampered by gross inequalities in educational opportunities for students of minority racial and ethnic groups. The supply of URM students who are well-prepared for higher education and advanced study in health professions fields has thus suffered.[6] As stated in the Sullivan Commission's Missing Person's Report, increasing diversity in the health care professions will improve health care access and quality for minority patients and assure a sound health care system for all of our nation's citizens. It will also strengthen health care delivery systems at multiple levels, enhance educational experiences for all health professions students, promote relevant research and needed changes in health policy, and prepare our nation for the emerging and culturally dynamic health care challenges of tomorrow.[7] Therefore it is not difficult to surmise that increasing the diversity of our health care professionals is of immense benefit to all citizens. Consequently, health preparation programs are vital vehicles for developing this pool of future practitioners.

Over the years, various academic and enrichment programs have been established at universities across the country to address the shortage of minority and disadvantaged students entering into graduate and health professional programs. These programs have mainly focused on preparing students at the undergraduate and postgraduate levels. However, in order to increase the percentage of matriculants to a more significant level, students must be exposed to health careers at an earlier age.

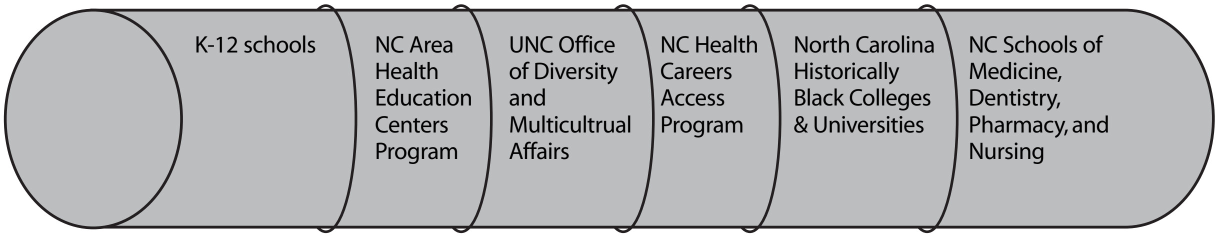
A North Carolina Comprehensive Pipeline Approach

In theory, a pipeline from primary to secondary to postsecondary education and finally to professional training channels the flow of a diverse and talented stream of individuals into the nation's health care workforce. However, in reality, not all students flow equally through the pipeline to the health care professions. Instead, race and ethnicity often substantially influence an individual's forward motion at every stage of the pipeline.[7]

Through years of effective collaboration, many North Carolina institutional partners have worked to create seamless pipeline approaches to increasing opportunities for minority and disadvantaged students pursuing health careers. Collaborators from various sectors of the state such as the K-12 public schools, statewide centers, historically black college and universities, and private and public higher educational schools have created a notable comprehensive pipeline approach.

Over the last three decades, several North Carolina programs were created to address the underrepresentation of minority and disadvantaged students in the health professions. Founded by Dr. Cecil G. Sheps in 1971, the North Carolina Health Careers Access Program (NC-HCAP) is one such program. Together with the North Carolina AHEC Program, NC-HCAP's 4 campus-based centers have exposed thousands of North Carolina's K-12 students to health career offerings. Precollege students also benefit from additional structured programs that AHEC offers throughout the year. As students progress through their undergraduate careers, strong recruitment support is rendered by the University of North Carolina (UNC) Office of Diversity and Multicultural Affairs as well as health science advisors at minority serving institutions within the state. Undergraduate students with interests in various health professions apply for entry into NC-HCAP's Science Enrichment Preparation (SEP) Program. SEP is an 8-week, honors-level academic enrichment program for disadvantaged undergraduate students seeking to increase their level of competitiveness for admissions into graduate/health professional programs. Since its inception in 1979, 834 students have completed the SEP Program. Of that number, currently 86% of these participants are either practicing in a health care field, enrolled in health professions training programs, or completing undergraduate prerequisites for these programs.[9] Freshman and sophomore

Figure 1.
A Comprehensive North Carolina Pipeline Approach



college students interested in medicine or dentistry can apply to the Summer Medical Dental Education Program (SMDEP) at Duke University School of Medicine. For rising seniors and postgraduates with an interest in medicine or dentistry, the natural choice is the Medical Education Development (MED) Program sponsored by the UNC Schools of Medicine and Dentistry. MED offers a structured summer curriculum at the level of professional education to increase the ability of advanced preprofessional candidates, especially those who are disadvantaged, to compete successfully for admission to health professional schools. Since 1974, 88% of the 1886 students who have attended the MED summer program decided to apply to health profession schools. Ninety percent gained admission with 80% matriculating into medical or dental school; the remainder entered other health professional schools.[10] Clearly, this approach has successfully assisted many in becoming the health practitioners they are today. Yet, despite this history of success, the majority of these programs are in constant jeopardy of being eliminated.

Federal Budget Cuts

In addition to the support received by their host institutions, pipeline programs have existed due to the support of federal funding. However, when the federal administration's priorities shift so does the funding. Such a shift occurred in 2006 when the Bush administration enacted drastic cuts to the Health Resources and Services Administration's Title VII Health Professions Education Programs, which supports facilities, initiatives, and individuals engaged in health professions training with an emphasis on recruiting practitioners for rural and other medically underserved areas.[11] The President's 2008 budget has proposed a complete elimination of Title VII and nearly a 30% reduction in Title VIII Nursing Education Programs. This action has dire implications for the future workforce supply. These two funding streams are the only federal programs designed to train practitioners in multidisciplinary settings to meet the needs of special and underserved populations as well as increase the minority representation in the health care workforce. Graduates of these programs are 3 to 10 times more likely to practice in underserved areas and are 2 to 5 times more likely to be minorities.[12]

This federal action has in fact reduced and/or eliminated numerous health professional preparation programs across the country despite their long-standing successes. These programs must recognize their vulnerabilities and the need to validate their continued existence.

Future Direction: Data, Development, Discourse

Pipeline programs have been the saving grace for many minority and disadvantaged students aspiring to be health care practitioners. In light of funding woes, many of these pipeline programs forge ahead, recognizing that in order to create sustainability three areas must become a priority: (1) data collection, (2) development initiatives, and (3) discourse.

Institutional and policy-level strategies for increasing diversity in health professions, however, have been relatively understudied. This lack of emphasis may lead to a void of strategies should future policy changes erode efforts to increase diversity.[6] These programs are attempting to validate their existence through increased efforts to collect data on program graduates. This data collection will assist in demonstrating how many of their program participants completed additional pipeline programs, gained admissions into graduate or health professional programs, and ultimately graduated from these degree programs. Additionally, many of the above programs are striving to evaluate the total impact made not only on increasing the percentage of minority practitioners nationwide but also on how many have remained in North Carolina to serve the people of the state.

With the cyclical nature of federal funding and the economic reality of sparse institutional support, pipeline programs are forced to look in new directions for fiscal resources. One such direction is from their alumni base. The successful impact these pipeline programs have made on the lives of these individuals is evidenced by their willingness to give back. Alumni are demonstrating commitment of support through the development of scholarships and assisting in the creation and funding of program endowments. Additionally, foundations' attention to addressing health disparities and workforce shortages has been unwavering. Historically, they have allocated major funding to support efforts in these areas. As these health disparities and workforce shortages remain on the agenda of the state and nation, philanthropic institutions' interest and dedication to these pressing issues will not dissipate.

Pipeline program accomplishments must no longer be confined within their program walls but shared with the community at large. The disclosing of program outcomes through publications and presentations will assist in creating sustainability and the sharing of best practices and successful models for replication throughout the country.

As North Carolinians, we must continue to recognize that work still remains to be done and continue to be diligent in our commitment to the health of all of our citizens. It is imperative that the pathway to becoming a health professional is open to every student of our great state. Ultimately, we all benefit from a future health care workforce that is reflective of the growing diversity of our society.

COMMENTARY

The Area Health Education Center's Role in North Carolina's Health Workforce Development

Thomas J. Bacon, DrPH; Samuel Cykert, MD

The North Carolina Area Health Education Centers (AHEC) Program was founded in the early 1970s to address critical shortages of health professionals, with a particular focus on the primary care needs of rural communities in the state. From the outset, AHEC was designed as a comprehensive workforce development program to augment the work of the academic health centers in preparing health professionals to meet the needs of these underserved communities. The AHEC Program was created under the premise that the state would only successfully improve the supply and distribution of health practitioners if it put in place a comprehensive, multidisciplinary set of regionally-based programs to influence all stages of the health professions education and practice pipeline. As a result, AHEC's core services include:

- Programs to recruit young people into health careers, with a special focus on underrepresented and disadvantaged students.
- Comprehensive community-based experiences for health professions students in communities across North Carolina.
- Primary care residencies to prepare physicians to meet the needs of underserved communities in the state.
- Continuing education programs for all types of health professionals to improve the environment for practice and strengthen the quality of health care.
- Library and information services to provide the latest health information for students, residents, and health professionals.

In order to increase the supply of primary care physicians in the state, primary care residency programs were established in 5 AHECs in the state in the 1970s. They were developed in collaboration with the large community teaching hospitals in Charlotte, Greensboro, Asheville, Wilmington, and Fayetteville. In addition, a substantial rotational site for University of North Carolina at Chapel Hill residents was created at WakeMed/Wake AHEC. These residency programs in family medicine, general internal medicine, pediatrics, and obstetrics and gynecology have graduated nearly 2000 graduates since the late 1970s. Of these, over 1100 are now practicing in North Carolina, providing vitally needed primary care services to communities across the state. Without these physicians, a substantially higher number of North Carolina counties would currently be categorized as health professional shortage areas than is currently the case.

In addition to primary care, since 1985 the AHEC Program has partnered with the 4 departments of psychiatry at the medical schools in the state. Through AHEC, psychiatry residents from all 4 schools receive rotations in community settings across North Carolina, many of these in rural and small towns. These rotations are designed to give residents experiences in community and public psychiatry and to expose them to opportunities for practice upon graduation. Although the evidence is antidotal, it appears that these experiences have increased the number of graduates choosing careers in the public mental health field.

> *"The AHEC Program was created ... to influence all stages of the health professions education and practice pipeline."*

The Area Health Education Centers Program has also been a partner in the dramatic growth in the numbers of students and graduates in the physician assistant, nurse practitioner, and

Thomas J. Bacon, DrPH, is executive associate dean and director of the North Carolina Area Health Education Centers Program at the School of Medicine at the University of North Carolina at Chapel Hill. He can be reached at tom_bacon@med.unc.edu or 101 Medical Drive, CB 7165, Chapel Hill, NC 27599-7165.

Samuel Cykert, MD, is associate director for medical education and quality improvement for the North Carolina Area Health Education Centers Program and an internist and director of the internal medicine residency program at Moses Cone Health System.

nurse midwifery programs in the state. The Area Health Education Centers Program's support for community primary care experiences for these students has contributed to the schools' abilities to expand enrollments and further impact the availability of primary care services in the state. The number of primary care nurse practitioners (NPs) and physician assistants (PAs) has nearly doubled during the past 10 years to approximately 1300 NPs and 1100 PAs actively practicing in the state.

The mission to support North Carolina's health care workforce remains active and the North Carolina AHEC Program is addressing the state's primary care practitioner needs in several ways. First, the program continues its support for educational opportunities in the state's communities for medical, physician assistant, nurse practitioner, and nurse midwifery students at every level of training by recruiting preceptors, providing nominal preceptor payments, and arranging housing and library services for participating students from all schools in the state.

Second, AHEC-supported primary care residency programs, with a robust 65% North Carolina retention rate, continue to serve as an efficient reservoir of new primary care doctors in the state. These residencies produce approximately 50 graduates in family practice, 24 in internal medicine, 6 in pediatrics, and 12 in obstetrics and gynecology annually.

Third, AHEC has been working in close collaboration with the Office of Rural Health and Community Care, the Division of Mental Health, Developmental Disabilities, and Substance Abuse Services, the professional associations, and others to develop a series of community-based initiatives to build on the existing infrastructure of primary care with integration of psychiatric clinical care and consultation to simultaneously meet patients' physical and mental health needs. These model programs are being developed in a number of communities across the state by building on the unique characteristics and assets of each community.

Ongoing efforts have been productive, but AHEC will have to do more to address looming practitioner shortages and ongoing concerns of maldistribution and lack of diversity in our health care professions. If we are truly to create a strong and stable primary care workforce for all communities in the state, though, it must be acknowledged that more comprehensive solutions need to be forthcoming. For instance, there will never be an adequate pool of primary care physicians or psychiatrists without payment reform at the national level that narrows the income gap between specialties. Such reform should place appropriate value on primary care as well as other cognitive services. We will not draw large numbers of graduates to rural areas without selectively admitting rural students to medical school, alleviating heavy medical school debt, and providing monetary incentives and systems of care that make rural practice more attractive to future practitioners.

Similar issues and solutions apply to the recruitment of underrepresented and disadvantaged students as well. Our pipeline programs to support students must be better connected at all levels of the educational process. Additional scholarship funding is essential, and strong academic and social support services are critical if all students are to thrive and reach their full potential.

Given these caveats and limitations, what more can AHEC do? One step is to leverage the success of our primary care residencies. We can increase the number of residency slots. By simply maintaining current retention rates, we will produce more doctors in needed specialties for North Carolina. One of the recommendations of the North Carolina Institute of Medicine Primary Care and Specialty Supply Task Force is to create 100 new residency positions in North Carolina, and AHEC is prepared to play a lead role to assure that the state's investment gives us the return we need by producing doctors in specialties most needed by the state's communities.

In the same vein, we are prepared to expand training opportunities for students of all types and to create stronger incentives for moving training into rural and underserved sites. We also must track our pipeline programs better and identify strategies that most effectively direct talented young people to the health professions of our state.

In addition and most importantly, simply adding students and residents to the educational pipeline will not keep pace with the escalation of services needed for the anticipated pace of population growth and aging. Improving and organizing systems of care, especially for chronic illness, will be crucial to improving access to care and health outcomes for North Carolinians. Given AHEC's strong ties to the health profession schools, its faculties on and off campus, and practitioners in local communities, it is in a unique position to coalesce and disseminate novel approaches to care in rural and underserved regions in collaboration with the nationally recognized Community Care Networks across the state. These approaches can use new options for technology support, regional on-call systems, and multidisciplinary teams to create and monitor coordinated systems of care that achieve excellence in health care milestones. With such innovation, we will build teams that make rural health care more rewarding and relieve the imponderable stress on harried practitioners in small practices who want to but cannot muster the resources to provide such comprehensive care. It will be crucial for residents and students to venture away from large medical centers and fully participate in these new styles of care so that they can embrace careers in these communities and serve as leaders in the transition toward innovative approaches.

Increasing the number of trainees at every level will inevitably increase the cost of medical education. We will need new teachers that include AHEC-based faculty and dedicated community preceptors. Sites for comprehensive care models will need to be recruited and created. If we want quality sites and quality teachers, we will need to pay for them. We will also have to finance the informatics systems and other innovative changes required to achieve new paradigms for educational and chronic care work. Finally, residency positions, traditionally supported by the Medicare program, are frozen, so we will have to pay directly for any new AHEC residency slots until federal policy changes. The reward for this investment will be better care for all North Carolinians garnered through prevention of practitioner shortages, improved distribution of care, and use of more efficient, more organized, and more effective systems of care. **NCMJ**

The Impact of Primary Care and What States Can Do

Barbara Starfield, MD, MPH; Leiyu Shi, DrPH, MBA

Despite the availability of evidence on the benefits of primary care on population health, little has been done to incorporate this evidence into planning for and evaluation of health services in the United States. In contrast, many industrialized nations have undergone major health system reform to make primary care the essential infrastructure of their health system. Some of these reforms resulted from legislation, as was the case in Spain and Australia, and others have entailed policy decisions to strengthen the practice of good primary care, as has occurred in the United Kingdom (UK) and is now occurring in various aspects of primary care in Sweden, France, and Germany. The reasons the US has not embraced primary care are complex and get to the heart of the characteristics of the US health services system, particularly its increasing dominance by special interest groups such as the academic medical establishment and specialty orientation, medical device manufacturers, and fee-for-service reimbursements that favor specialty practice.[1]

In this paper we briefly review the evidence for the impact of primary care in improving health, increasing equity, and reducing total health system costs; discuss the rationale for benefits of a primary care orientation within health services systems; and conclude with a discussion of needed additional research and policy attention.

Benefits of Primary Care

The first systematic study of the benefits of primary care on health and costs of care consisted of an international comparison of 11 western industrialized nations using data from the mid-1980s.[2] The study was repeated a decade later with 13 countries including Japan.[3] Both studies rated countries on policy characteristics encouraging primary care and practice characteristics reflecting primary care organization: first contact care; person-focused care over time; degree of comprehensiveness within primary care; and coordination of care. The studies were consistent in showing that some countries rated very poorly on primary care whereas others rated better. Those in the former group had poorer health on many population health measures including but not limited to life expectancy at various ages, age-adjusted mortality, and infant mortality (neonatal and postneonatal separately). They also were more costly health systems. These findings were robust and persisted even after controlling for various health-related characteristics of the population (such as extent of risky behaviors in the population). Confidence in the findings was provided by a pooled time series analysis of 18 Organization for Economic Co-operation and Development (OECD) countries that controlled for additional health and health system-related characteristics (such as percent

Leiyu Shi, DrPH, MBA, is an associate professor of health policy and management and health and public policy and codirector of the Primary Care Policy Center for the Underserved at Johns Hopkins University.

elderly, gross domestic product, and total number of physicians). This analysis showed that life expectancy in countries with weak primary care was lower than that in countries with stronger primary care and that this difference had been widening over time.[4]

Although there is additional evidence of similar benefits of primary care from other studies,[5] in this paper we focus primarily on findings from studies of US states because of the particular interest of North Carolina in the physician workforce. In all studies we included family physicians and general practitioners, general internists, and general pediatricians as primary care physicians because earlier evidence showed that these "specialties" rated higher on primary care characteristics than did other specialties.[6]

Primary Care in US States

In the 1990s, a series of studies examined and found a significant and positive relationship between the supply of primary care physicians and a variety of measures of health including all-cause mortality; mortality from heart disease, cancer, and stroke; infant mortality; low birth weight; and self-reported health. This relationship existed even after controlling for personal and environmental characteristics at the state level including education, income, environmental pollution, unemployment, percentage elderly, percentage urban, minority composition, and lifestyle factors including seatbelt use, obesity, and smoking.[7,8,9]

Consequent to the appearance of new literature on the relationship between income inequality at the state level and some health outcomes,[10,11] a series of analyses was designed to examine the relationship between primary care physician supply and health measures at the state level, while also considering the influence of income inequality in the state. In 1999, Shi and colleagues[12] showed that both income inequality and primary care physician supply had strong relationships with life expectancy, all-cause mortality, stroke mortality, and postneonatal mortality. They also found that smoking rates were related to these outcomes, but the influence of primary care physician supply persisted after controlling for smoking rates.

Subsequent studies refined the analysis to take account of possible other influences on population health levels including the supply of other specialists. In both time-lagged as well as contemporaneous studies, the supply of primary care physicians was associated with lower all-cause mortality whereas a greater supply of specialists was associated with higher rates of all-cause mortality. Furthermore, the beneficial influence of primary care physicians was entirely due to the supply of family physicians (rather than general internists and pediatricians).[13] Additional confirmation of these positive impacts of primary care physicians came from studies of mortality from stroke, using 11 years of state-level data and adjusting for degree of income inequality, educational level, unemployment rates, racial/ethnic composition, and percentage of the population living in urban areas.[14] The benefit on stroke mortality of better access to primary care is consistent with hypothesized mechanisms by which better primary care is associated with earlier and better control of common risk factors for stroke (especially hypertension). Similarly, the reduction in low birth weight and infant mortality (especially postneonatal mortality), even after one-, three-, and five-year lag periods, is associated with primary care physician supply,[15] a finding that is consistent with better maternal health before pregnancy and better availability of resources to deal with infections—a common cause of death in the postneonatal period.

Analyses of the impact of access to primary care and to different levels of quality of primary care services are all consistent in showing that the greater the access to primary care and the better the quality of primary care, the better the health—regardless of the measure of health—whether at the aggregate or individual level of analysis. These benefits have also been quantified. Macinko and colleagues[16] identified 10 studies that met the criteria for adequacy of study of the relationship between primary care physician supply and all-cause mortality; cancer, heart disease, stroke, and infant mortality; low birth weight; life expectancy; and self-rated health. The relationship held regardless of the year studied (from 1980-1995) and geographic level of analysis. Pooled results for all-cause mortality indicated that an increase of one primary care physician per 10 000 population was associated with an average mortality reduction of 5.3%, or 49 deaths per 100 000 population per year.

Additional analyses within some of these studies indicate that the beneficial impact of primary care on African Americans was even greater than for the majority population—evidence of an equity-producing effect of primary care.[5]

A wide variety of other studies conducted at different levels of geographic aggregation (metropolitan, county, urban, rural areas), both in the US and in the UK, support the conclusions of the US state-level analyses, with a few exceptions. For example, Ricketts and Holmes,[17] using pooled 1996-2000 US county data, found that the association between primary care physician supply and mortality was not uniformly observed and that strong regional patterns may explain the lack of a consistent national association based on their county-level data. Primary care physician supply was associated with decreased mortality on the East Coast and in the upper Midwest, but that correlation disappeared or was reversed in the west (with the exception of Washington state) and south central states. Further study is needed to understand these regional differences and the policy alternatives to address them because it is likely that the balance between the supply of primary care and specialist physicians and the influence of major medical centers (with their strong specialty focus) have an influence on people's use of primary care rather than specialty care. Overall, these empirical analyses (particularly at the state level, where there is less of a "cross-over" effect, ie, people seeking medical care across state borders) are consistent with theoretical considerations as to why primary care should have a beneficial impact on population health. Primary care is more accessible than specialty care, and its individual features (first contact care, person-focused care over time, comprehensiveness of care, and coordination of care) have all been shown to produce better outcomes.[5,18] International comparisons of countries show that, of the 4 features just mentioned, comprehensiveness of the package of services offered in primary care practices is the practice characteristic most consistently associated with better primary care overall.[3] That is, the more aspects of health care that are covered in primary care, the better the health outcomes, at least partly due to fewer unnecessary referrals to specialists. Common problems belong in primary care; less common or rare ones belong in specialty care because the training of specialists in tertiary medical centers better suits them to care for people who have been filtered by primary care and thus have a higher likelihood of serious or more uncommon illness. When patients go directly to specialty care, much of their care is inappropriate, as they are suffering from illnesses that are common in the population and thus better dealt with by physicians with training in how illness presents in the community, ie, primary care practitioners. As a result, US studies show that higher ratios of specialists to population are often associated with worse outcomes for common causes of mortality and morbidity.[19]

Popular belief that specialist care is superior to primary care is contradicted by the results of a variety of studies in which the outcomes are generic, ie, not specific to particular diseases. In this category are life expectancy, all-cause age-adjusted mortality, self-reported health, and low birth weight. In fact, for common causes of death, such as acute myocardial infarction, the outcomes are equally good for family physicians as for cardiologists, once a variety of patients' characteristics are taken into account.[20] The fact that generalists' patients are usually sicker than the patients of specialists in studies of this type provides clues about why direct access to specialists leads to worse population outcomes. Because of where specialists are usually trained, they are unaccustomed to seeing patients other than those with problems clearly in their field of specialty; these patients are not representative of patients in the community because the general population of patients has more comorbidity and a more complex pattern of illnesses, even though any given problem seen in a specialty clinic is more likely to be serious than the same problem in the community. Specialists thus learn to do more testing than would be necessary in generalist practice, with consequently more false positive results, adverse effects from the resulting cascade of tests, and with much higher costs.

What Can States Do to Maximize Population Health Through Workforce Policy?

In the absence of federal efforts to reform health care financing and to enable either a single payer system or more uniform health insurance policies through regulation of the many insurance programs, states have a limited number of options to encourage greater and better provision of primary care. At the very least, they can initiate policies to target state funding of medical teaching programs to institutions focusing on primary care training and provide greater financial support (as through loan forgiveness) to physicians who specialize in primary care. They also can encourage or mandate lower payments to specialists for patient visits NOT made by referral from a primary care practitioner. Additionally, they can increase reimbursement rates to providers who demonstrate that they deliver primary care in ways to achieve its benefits; instruments are available to document the primary care orientation of practices.[18]

States could also encourage professional collaboration to develop guidelines for referral or at least to examine the nature of the relative contributions of primary care practitioners and specialists in the care of people with particular health problems or combinations of health problems. The important characteristics of primary care are well known; the same is not the case for specialist practice.[19] As licensing of medical practitioners is in the jurisdiction of states, new licenses could be granted to practice in the state only for areas needing physicians, thus enabling more equitable distribution of both primary care and specialist physicians. Where states have jurisdiction over reimbursement for services, they can use this power to better equalize professional earnings of primary care and specialist physicians. States could also, through their support of medical training programs, require that physicians in training evaluate their own practices with regard to the costs of care that they generate, improvement of the patients' problems (not only biomedical markers for the disease of particular interest) as a result of their interventions, and occurrence of adverse effects consequent to their interventions. And, through the National Governors Conference, states could bring pressure on the federal government to develop a workforce policy that is better informed with evidence on population health needs and maldistribution of the physician workforce.

State efforts to use existing evidence to develop their own workforce policies could be key in improving the poor position of the US, relative to other industrialized countries, with regard to the population's health. **NCMJ**

The Impact of Health Care and the Allied Health Workforce on North Carolina's Economy

Friday, June 15, 2007
9:00 am - 2:30 pm

The William and Ida Friday Center for Continuing Education, Chapel Hill, NC

Sponsored By:
Council for Allied Health in North Carolina
North Carolina Area Health Education Centers Program
Cecil G. Sheps Center for Health Services Research
North Carolina Department of Commerce

For more information:
Contact the Council for Allied Health in
North Carolina at (919) 966-8566.

Program Description

This symposium is designed to educate policy and decision makers about the relationship between economic development and allied health workforce development efforts in the state. We will discuss the challenges confronting allied health workforce educators and employers, and profile some best practice models. The conference will also create an opportunity for networking and building collaborations among the many folks from the allied health workforce and economic development groups who are working on these issues every day.

There will also be an important announcement made by the National Governors Association Allied Health Sector Strategy Initiative team regarding a future RFP for regional planning grants.

Objectives:

- Discuss the relationship between economic development and allied health workforce development efforts in the state.
- Describe the challenges confronting allied health workforce educators and employers.
- Identify best practice models used to meet these challenges.

COMMENTARY

Critical Connections Between Health Care and Economic Development in North Carolina

Aaron McKethan

This issue of the *Journal* opens with a discussion of how the supply and distribution of health professionals in North Carolina is important to access to care. As the authors point out, policy action is necessary to ensure the right mix of health care professionals in the right locations to meet the state's current and future health care needs. Moreover, current and future health workforce shortages have important implications that go beyond the specific health care needs of individuals and communities. By providing important health care services, health care professionals also play an increasingly important but often underappreciated role in creating and sustaining vibrant economies.

The Health Care Industry as a Growing Source of Jobs

By now every policymaker in North Carolina is keenly aware that the state's economic landscape is changing. This transition is from a largely goods-producing manufacturing-based economy to an economy and workforce increasingly oriented around service industries. A prime example of the latter is the expansion of the number of health service occupations and the number of jobs in those occupations in recent decades.

Job growth in health services at all skill and wage levels has taken place in both rural and metropolitan areas of the state. In 1990, there were about 261 000 health care and social assistance workers in North Carolina, representing about 9% of the state's total workforce. By 2006, that figure had nearly doubled to 509 000 workers, accounting for 13% of the state's total workforce (roughly the same size, in terms of total employment, as the manufacturing industry).[1]

Growth in health service jobs has been particularly rapid in rural parts of the state. As the state's total economy changes, the growing health care industry has helped to sustain local economies, particularly in rural areas where plant closings and business downsizing have eliminated jobs and transformed communities. This growth is likely to continue. As the issue brief points out, growing demand for health care professionals and other workers will be driven by demographic changes, population growth, and epidemiological trends as well as new advances in medicine.

> *"Ensuring an optimal supply of health care professionals to ensure a region's health care needs can also have important spillover effects on a region's attractiveness for new or existing businesses."*

The Flow of Health Care Money

To view the health services industry through the lens of economic development, it is important to understand the health care system's complex (some would say "Byzantine") third-party financing structure. Public and private health care expenditures typically flow not to patients who receive health care services, but directly to health care institutions and medical providers supporting health care jobs. Additionally, some regions are more dependent on government health care spending than others. In Avery County in rural northwest North Carolina, Cannon Memorial Hospital is the largest employer. Cannon receives about 70% of its inpatient revenue from the Medicare program and another 10% from Medicaid. Thus, the county's largest employer receives a substantial portion of its income from federal and state health care programs.[2] This suggests the importance for economic developers and policymakers to

Aaron McKethan is a PhD candidate in public policy at the University of North Carolina at Chapel Hill and a senior associate with The Lewin Group. He can be reached at Aaron.McKethan@Lewin.com and 3130 Fairview Park Drive, Suite 800, Falls Church, VA 22042.

understand the flow of health care dollars in different parts of the state and to observe how public and private health care dollars trickling through the economy are connected to growth in health care jobs.

Health Care and Business Competitiveness

Ensuring an optimal supply of health care professionals to ensure a region's health care needs can also have important spillover effects on a region's attractiveness for new or existing businesses.

First, businesses seeking new areas in which to locate facilities must ensure, among other things, that the local health care infrastructure is adequate to meet the needs of its employees. *Expansion Management*, a publication that disseminates information for businesses seeking to identify the best locations to establish new plants and other facilities, recently developed a "Health Quotient" ranking of regions. This was done partly in response to business demand for information to evaluate the availability of health care providers and other health-related issues at a regional level. Like information about tax rates, local schools, transportation infrastructure, and crime rates, business executives making site selection decisions may consider health care infrastructure and provider supply measures in their research of prospective regions.

Second, access to health care professionals can also have an important impact on the health and productivity of a region. This may play a role in businesses' site selection decisions as well. Bob Greczyn, chief executive officer of Blue Cross and Blue Shield of North Carolina, has suggested that promoting a healthy population can serve as a competitive advantage for corporations considering relocating to the state. Greczyn argued that a "a healthier work force [would] be more productive, have a significantly lower absenteeism rate and probably generate lower workers' comp costs," which could help North Carolina "stand out from the pack in the competition for new jobs."[3] Of course, regional health care status and worker productivity are also key issues affecting the bottom lines of existing firms as well. This includes some of the state's leading firms in the biotechnology, medical devices, and other health-related industries that are providing an increasing supply of high-tech jobs in the state.

To be sure, healthy regions depend on, among other things, an adequate supply of health care professionals including physicians, physician assistants, nurse practitioners, and others.

Moving Forward

In sum, the growing health care sector has created new jobs in a state undergoing a profound economic transition. Adequate access to health care professionals can increase quality of life and worker productivity through healthier individuals and communities.

Policy choices governing health care supply and provider reimbursement issues should be based on meeting the state's health care needs, not explicitly on job creation or achieving other economic benefits. However, it is important for policy makers and economic developers to understand the numerous connections between health care infrastructure, provider reimbursement, and regional economic attractiveness and productivity.

Of course, the health care community should be willing to embrace change and innovation as well. Given very high health care costs and uneven quality outcomes in the health care arena, health care professionals themselves can play a lead role in improving the economic value their profession confers on individuals and local communities.

On balance, the connections between health care and economic development are indeed critical for North Carolina. **NCMJ**

Are Your Patients Having Trouble Tolerating CPAP?

We offer alternatives to CPAP or soft palate surgery to treat snoring and obstructive sleep apnea (OSA). Jaw advancement (utilizing either oral appliances or jaw advancement surgery) may be the answer for your noncompliant patients, or simply for those who don't want or can't tolerate CPAP or soft palate surgery.

Newly published Practice Parameters produced by the American Academy of Sleep Medicine recommend oral appliances as an important first line treatment option for patients with mild to moderate Obstructive Sleep Apnea, and as a viable second-tier treatment for some patients with severe OSA.*

How do you know if your patient is a candidate for an oral appliance? All it takes is a sleep study and an upper airway evaluation. Don't allow your patients to suffer from the symptoms and sequelae of obstructive sleep apnea any longer. *Journal SLEEP, February 2006

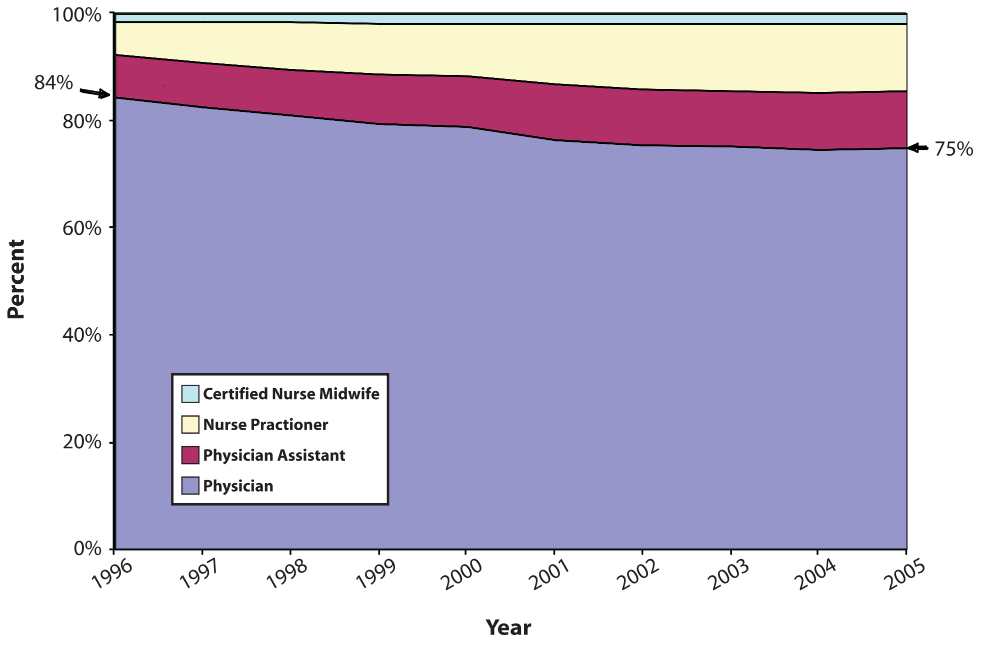
Supply of Primary Care Practitioners by Profession

As highlighted in this issue's commentary by Barbara Starfield and Leyiu Shi, primary care practitioners are important to the overall health of populations. Historically, the primary care practitioner from whom most individuals received care was their local general practice physician. However, over time factors have changed the landscape of primary care practice. Today, many individuals receive primary care from nurse practitioners, physician assistants, and certified nurse midwives as well as from physicians. This section will evaluate how the composition of primary care practitioners has changed over time and may vary in communities across North Carolina. For the purposes of this analysis, primary care practitioners are defined as those practitioners who self-designated in their license application a specialty in family and general medicine, obstetrics/gynecology, pediatrics, or internal medicine. However, specialists also may provide particular aspects of primary care such as blood pressure checks and cholesterol screenings.

Data from the North Carolina Health Professions Data System show the composition of the primary care practitioner supply from 1996 to 2005. In 1996, 84% of primary care practitioners were physicians. By 2005, physicians accounted for only 75% of all primary care practitioners. (See Figure 1.) This indicates the proportion of nonphysician primary care practitioners increased over 50% during that time period, from 16% to 25% of all primary care practitioners.

Figure 1.
Composition of North Carolina Primary Care Practitioner Workforce, by Practitioner Type



continued on page 212

continued from page 211

continued from page 212

The main factor contributing to this change in the composition of the primary care practitioner workforce is the rapid increase in the number of primary care physician assistants and nurse practitioners relative to the growth in primary care physicians. While the number of primary care physicians grew 36% from 1996 to 2005, the number of primary care physician assistants doubled and primary care nurse practitioners grew 220%.

The distribution of primary care practitioners provides valuable information for policy makers. Data indicate that primary care nurse practitioners, physician assistants, and certified nurse midwives are 50% more likely than primary care physicians to practice in rural areas. Furthermore, these practitioners are playing an increasing role in providing primary care services across the state. In 1996, physicians accounted for 75% or more of the primary care practitioner workforce in 80 of North Carolina's 100 counties. By 2005, the same was true in less than half (37) of those counties. (See Map 1 and Map 2.)

The tendency of each discipline to practice primary care changed slightly between 1996 and 2005 (all certified nurse midwives, using the HPDS definition of primary care, practice primary care). The percent of physicians practicing primary care increased slightly from 41% to 43%. Whereas the tendency of physician assistants to practice primary care increased during the late 1990s, the percent in primary care (40%) was the same in 2005 as it was in 1996. The proportion of nurse practitioners practicing primary care generally increased from 1996 to 2002 but declined in more recent years. (See Figure 2.)

Given the increased reliance of populations in rural areas on nonphysician practitioners for their primary care, trends suggesting a declining tendency of nurse practitioners and physician assistants to practice primary care portend a possible decrease in access to primary care in such communities.

Figure 2.
Proportion of North Carolina Practitioners in Primary Care, by Profession, 1996-2005

Smart Partnerships: KBR Uses Resources Wisely to Encourage Health Care System Innovations

John H. Frank, MBA; Julie E. Alexander, RN, MSN

In fulfilling its mission to improve the quality of life and health for future generations of North Carolinians, the Kate B. Reynolds Charitable Trust often partners with health care innovators at the local and state level. Last year, the Trust announced a strategy to invest resources in addressing the root causes of poverty and disease, promote innovation through best practices, and increase influence on behalf of those it serves by expanding its role as an educator, convener, and advocate.

The ICARE Partnership, a statewide initiative supported by the Trust, is one example of a collaboration that fulfills KBR's strategy. ICARE represents a broad spectrum of public and private stakeholders committed to integrated care, a collaborative approach that comprehensively addresses physical and behavioral health care needs. ICARE's vision is ambitious—a health care system that is Integrated, Collaborative, Accessible, Respectful and Evidence-Based (ICARE). As a funding partner for ICARE, the Trust is leveraging the support and energies of a broad network of health care leaders and organizations.

The Trusts' strategic plan also includes a commitment to support prevention and provide treatment in several target areas, including mental health services. Integrated care shows promise as an effective approach to care of mind and body, and the Trust has previously funded successful local integrated care projects. ICARE provides an opportunity for the Trust to extend these approaches to more people across North Carolina.

ICARE's vision is being implemented through three projects targeting practice, training, and process and policy. Like a "three-legged" stool, each project supports ICARE's central objectives, which aim to improve patient outcomes by increasing collaboration and communication between primary care and mental health, developmental disabilities, and substance abuse service providers and to increase their capacity to provide appropriate, evidence-based care. Although separate, ICARE's three projects interact to create a whole greater than the sum of its parts.

The Local Model Development Project addresses practice by developing replicable integrated care systems in four North Carolina pilot sites. Local implementation partners, representing different facets of the health care community, advise and support each site's model development. Each pilot uses a common approach to organize, but has chosen a locally-relevant focus area.

The Trust is funding two pilots in the western and eastern regions of the state. The western site (Buncombe and Henderson counties) is focusing on care for citizens with severe and persistent mental illness. The eastern site (New Hanover and Pender counties) is expanding community capacity by placing part-time psychiatrists in four primary care practices and promoting the use of patient care algorithms for anxiety and attention-deficit/hyperactivity disorder. Two additional pilots, a northcentral site (Vance, Warren, and Granville counties), and a southeastern site (Robeson County) are targeting addictive disease and crisis management, respectively.

The Statewide Education and Assistance Project addresses training by developing provider tools, education, and opportunities for relationship building across the state. Based on an initial needs assessment, a variety of training venues are offered including regional conferences, office-based training and technical assistance, and web-based resources. Among others, collaborators included the North Carolina Area Health Education Centers Program, North Carolina Academy of Family Physicians, and North Carolina Association of Psychiatry. A website (www.icarenc.org) serves as a clearinghouse of information on integrated care in North Carolina. As ICARE progresses, the training component will disseminate new information and best practices through its programs.

The Process and Policy Change Project addresses the final component of ICARE. The project aims to remove barriers and promote implementation of integrated care. Key process and policy change targets have been identified and are being tracked by two groups including public and private health care leaders. As these groups advocate for a more favorable environment, their efforts will be informed by feedback from participants in ICARE's local pilot sites and training programs.

The ICARE Partnership represents a broad collaboration between public and private stakeholders dedicated to creating a new paradigm for health care in North Carolina. The Kate B. Reynolds Charitable Trust, through its strategic investment, is a key partner in fulfilling this bold vision. **NCMJ**

John H. Frank, MBA, is director of the Health Care Division for the Kate B. Reynolds Charitable Trust.

Julie E. Alexander, RN, MSN, is a health care consultant. She coordinated the development and initial launch of the ICARE Partnership on behalf of the NC Foundation for Advanced Health Programs.

Spotlight on the Safety Net

A Community Collaboration
Kimberly M. Alexander-Bratcher, MPH

Gaston County Collaboration

Gaston Family Health Services (GFHS) was created by the Gaston County Health Department (GCHD) to help provide comprehensive medical care to indigent citizens. Today the two organizations collaborate to ensure the Gaston County safety net remains intact. Together, they provide primary care for adults, children, and special populations including HIV positive and mentally ill patients; pediatric and adult dental services; hospital care; reproductive health services; immunizations; behavioral health services and case management; and access to specialty providers.

The Gaston County collaboration, developed in 1989, brought these two safety net health care providers, under the same roof. This proximity allows them to share many of the same resources such as lab and billing staff and enables the provision of unduplicated comprehensive health care to the uninsured, low-income community. The GCHD primarily serves women and children whereas GFHS tries to fill in the gaps by providing primary care, acute care, and treatment for chronic diseases in populations who do not receive care at the health department.

Both GFHS and GCHD have physicians on staff to care for patients. In addition, GFHS has volunteer clinics staffed by specialists, such as ophthalmologists and podiatrists, as well as volunteers who work on pharmaceutical medication assistance programs for patients. Case management also is provided and is primarily targeted to chronic disease or HIV positive patients. There are no eligibility criteria for patients desiring to be seen by GFHS or GCHD; however, patients must reside within county lines for some health department programs. Both GFHS and GCHD use a sliding fee scale, although some services at the Health Department are provided free of charge. Together, the Gaston County collaboration sees about 78 000 patients annually—60 000 through the health department and 18 000 through GFHS. Approximately 55% of the patients seen at GFHS are uninsured, while the remaining 45% are covered by Medicaid (22%), Medicare (18%), or private insurance (5%).

Colleen Bridger, MPH, Gaston County Health Director, shared several valuable lessons for other communities considering this type of collaboration. Colocation is ideal because it facilitates the flow of information and communication between providers and patients. Preventing duplication of services is important because competition for insured patients can weaken care to uninsured, indigent consumers. Collaborations should utilize the strengths of each collaborating organization to best serve the patients' needs. By working together, organizations can fill in gaps in the services that are provided and the populations that are reached—frequently neither organization receives enough funding to provide all needed services to indigent patients. Collaborators should advocate for one another because doing so can build confidence in the community and in the collaboration. Finally, partners should communicate openly and honestly. Incorporating these lessons can help develop a tight knit environment for the collaboration and strengthen the work and success of both organizations.

Contributions from Colleen Bridger, MPH, Gaston County Health Director, and Morgan Jones, MSPH, North Carolina Institute of Medicine Research Assistant.

Surgery and science combine to unlock the secrets of diabetes

A partnership between Pitt County Memorial Hospital and the Brody School of Medicine at East Carolina University is at the forefront of bariatric surgery research. In more than 2,500 documented cases, our surgeons have seen patients overcome dependence on insulin and oral therapy in a matter of days. Some patients have required no further medication for as long as two decades.

The confirmation of these findings by surgeons throughout the world has led to a major grant from the Johnson & Johnson Corporation. The grant will help researchers find an explanation for this medical advance and to see if medication can achieve the same result. Dr. Walter Pories, an ECU professor of surgery and bariatric surgery pioneer, and his colleagues will lead a two-year clinical study of adults with diabetes that evaluates insulin sensitivity and glucose metabolism before and after gastric-bypass surgery. For more information on the study, call 252-744-3290.

Working together, Pitt County Memorial Hospital and Brody School of Medicine surgeons have been performing and studying gastric bypass surgery since 1978. To watch a live web cast of bariatric surgery at Pitt County Memorial Hospital or learn more about bariatric surgeons at the Brody School of Medicine and Southern Surgical Associates, visit www.bariatric.uhseast.com.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

Emergency Medical Services in North Carolina

COMMENTARIES

DEPARTMENTS

"On November 16, 1973, Congress approved the Emergency Medical Services Systems Act of 1973 ... which funded and authorized the US Department of Health, Education and Welfare to help develop EMS programs throughout the country."

Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

Stanley Wardrip

Stanley Wardrip is what many would consider a model emergency medical services (EMS) professional. Mr. Wardrip started his EMS career at the age of 15 with the Jacksonville Volunteer Rescue in Jacksonville, North Carolina. During his tenure at Jacksonville Rescue, he and his fellow rescuers received recognition for their superior service and performance delivering EMS care. Throughout high school, Mr. Wardrip worked in EMS and in 1987 he won the North Carolina Governors Award for Youth Rescuer of the Year. Mr. Wardrip went on to graduate at the top of his paramedic class and graduated with an Associate Degree in Emergency Medical Science from Catawba Valley Community College.

Mr. Wardrip has worked for New Hanover EMS for 17 years. He is a senior paramedic, public relations coordinator, and field training officer. As a member of the New Hanover County Board of Health and the New Hanover County Public Health and Safety Committee, Mr. Wadrip has worked hard to help promote the health and safety of New Hanover's citizens. He has a strong appreciation for the role EMS plays in community health which is why he also started a Boy Scout Explorer Post for New Hanover Regional Medical Center EMS to help encourage younger people to get involved in EMS. His community-based efforts have been well-received and have positively impacted eastern North Carolina.

As an advocate for EMS, Mr. Wardrip identified a gap in representation for eastern North Carolina EMS professionals at the state and national level. To address this gap, he helped start the Eastern Carolina EMS Association, a professional organization of individuals within eastern North Carolina who are engaged in EMS and who wish to make an impact upon the health and welfare of the public and also promote, represent, and provide guidance for the practice of prehospital care. This association is open and free to all emergency responders in eastern North Carolina. The association offers first aid instruction and CPR classes to the public at a low or no cost. Other safety topics promoted by the association include child bike and gun safety.

Currently, Mr. Wardrip works for Pender EMS as a paramedic and member of the North Carolina State Medical Assistance Team. Friends feel he is one of the top paramedics in the state due to his great patient care and his kind heart. He always finds time for his family and friends, something that is very difficult to do in EMS.

Besides being a tireless advocate for EMS and community health and being family man, Mr. Wardrip works with Medical Missions to help others in times of need. In 2007 he plans to work with Wrightsboro United Methodist Church Medical Mission to provide medical assessment and treatments to those who cannot afford medical care in St. Anne's Bay, Jamaica. The *North Carolina Medical Journal* would like to recognize Stanley G. Wardrip Jr. as a model EMS professional and offer appreciation to EMS professionals across the state who offer their time and talent to help improve prehospital care in North Carolina.

Contributions from Doug Strickland, NREMT-I

Readers' Forum

To the Editor:

In the March/April 2007 issue of the *North Carolina Medical Journal*, Roche et al wrote about the importance of screening for intimate partner violence (IPV) after a study of 321 adult female patients were surveyed in an urban medical center in North Carolina. Respondent characteristics of the women screened are offered in the article.

I agree wholeheartedly with the authors' assertion that IPV is a very common and serious problem that is perhaps underinvestigated by health care providers. Teaching medical students and residents how to appropriately screen their patients in the outpatient and inpatient settings as well as the emergency department is essential. However, as much as a history of IPV is frequently not obtained by health care practitioners, more often than not a sexual orientation history is not obtained either. I commend the authors of this study for using the inclusive and nonjudgmental term "partner" repeatedly in their article. However, in the authors' survey they address their patients' marital status. Because same-sex marriage is legal in very few places, they therefore do not specifically address IPV in same-sex relationships. Data shows that IPV in lesbian couples occurs at a frequency similar to that in heterosexual couples. In a 2005 study published by the Centers for Disease Control and Prevention (CDC), 11% of women aged 15 to 44 reported having been in same-sex relationships—not an insignificant number. Perhaps a number of the 43.9% of patients claiming to be "single" in this study include some of these patients.

One may ask why obtaining a sexual orientation history is important. Studies show that victims of IPV by a same-sex partner find it more difficult than their heterosexual counterparts to seek help for their problem. This seems to be largely out of fear of homophobia by the organizations offering assistance or fear of being "outed" if they seek help. Perhaps if they are asked about who their partner is in a way that is supportive and nonjudgmental (ie, not "are you married or single?"), they will feel safer in divulging the violent situation they are trapped in. Instead of asking "Are you married," simply ask "Are you in a relationship? With whom?" Those questions are simple to ask, even for the provider not completely comfortable with addressing specific questions about sexual orientation.

I urge the authors of this study and interested readers of this journal to see the CDC-sponsored National Violence Against Women Prevention Research Center website on this particular topic (http://www.vawprevention.org/lesbianrx/factsheet.shtml). Several references are offered on the website for further information. With careful screening for IPV by caring and nonjudgmental health care providers, we can hopefully better address the needs of all patients trapped in destructive relationships.

John E. Snyder, MS, MD

Editor's note: In the May/June 2007 issue of the *Journal*, the article *Issue Brief: Weathering the Practitioner Workforce Shortage* inadvertently omitted reference to the central role the Kate B. Reynolds Charitable Trust (KBR) played in the formation, funding, and deliberation of the task force. The original impetus for the task force grew out of a meeting convened by KBR that focused on trends in provider supply. In addition, KBR provided the funding for the task force, and shared its experience in this area through task force participation. The Kate B. Reynolds Charitable Trust has a long history of grant making to improve access to practitioners in rural and underserved areas. The editor and authors apologize for the oversight in failing to reference the important role that KBR played in the task force's work. This oversight is corrected in an online version of the article available at: http://www.ncmedicaljournal.com/may-jun-07/toc0607.shtml.

Awareness of the Bicycle Helmet Law in North Carolina

Kelly A. Carter, MD; Kori L. Brewer, PhD; Herbert G. Garrison, MD, MPH

Abstract

Background: *One in 3 bicyclists killed in North Carolina is under the age of 16. Since enactment of a mandatory bicycle helmet law for children in 2001, there has been no observed increase in helmet use in North Carolina. The goal of this study was to assess perceptions of helmet effectiveness and the level of awareness of the North Carolina bicycle helmet law.*

Methods: *A written survey was distributed to parents, physicians, teachers, and emergency medical services (EMS) personnel throughout Pitt County, North Carolina, to ask their knowledge of the bicycle helmet law, the frequency of their helmet use, their perceptions of the effectiveness of helmets, their opinions of who should be providing education about bicycle helmets, and their knowledge of proper bicycle helmet use.*

Results: *The survey response rate was 72% (n= 413). Seventy-five percent of teachers and EMS personnel, 69% of parents, and 58% of physicians were aware of the North Carolina helmet law. Nineteen percent of parents responded that their children wore helmets "always," 21% answered "often," and 18% answered "never." The effectiveness of helmets in preventing head injuries was underestimated by many respondents with 49% estimating 50%-75% effectiveness.*

Limitations: *This survey was distributed only in Pitt County and does not reflect helmet awareness for the state as a whole.*

Conclusions: *The majority of parents, teachers, physicians, and EMS personnel in Pitt County, North Carolina, are aware of the mandatory bicycle helmet law for children. Enforcement of and education about the bicycle helmet law should be increased.*

The North Carolina Division of Transportation reports that a bicyclist is injured or killed in the state every 6 hours, with one in 3 bicyclists killed in North Carolina being under the age of 16.[1] Among bicycle injuries, one-third of emergency department visits, two-thirds of hospital admissions, and three-fourths of deaths are due to head injuries.[2] Bicycle helmets have been shown to reduce the incidence of head injury by 85% and the risk of traumatic brain injury by 88%.[3] Because head injuries from bicycle crashes are such a significant problem, 20 states have implemented statewide mandatory helmet laws and another 16 states have counties with helmet use laws.[4] In October of 2001 North Carolina passed a law requiring all children younger than 16 years of age to wear a helmet while riding a bicycle. This law holds the parent or legal guardian responsible for the child's helmet use with a penalty of a civil fine of $10.[5]

A 2002 study[6] conducted by the University of North Carolina Highway Research Center concluded that the mandatory helmet law had little impact on the use of helmets by children under the age of 16. The study observed helmet use in the same randomly picked cities in 3 regions of the state in 1999 and 2002. They found that on-street helmet use by children under the age of 16 increased from 12% to 16% (reported Law Effect, p =0.5627), and one-fifth of helmets observed in 2002 were misused. Weighted estimates of total helmet use (including adults) found that the coastal region of North Carolina, which includes Pitt County, had the lowest observed helmet use and no observed increase in overall helmet use after the law was implemented (9.5% pre-law, 9.2% post-law, with a state average of 17.8% and 24.3% respectively). In support of these findings, a database from the North Carolina Department of Transportation[7] on bicycle-car crashes also found no reported

Kelly A. Carter, MD, is an emergency medicine resident physician at the Department of Emergency Medicine of the Brody School of Medicine at East Carolina University. She can be reached at ECU Emergency Medicine, 600 Moye Boulevard, Greenville, NC, 27834 or carterke@ecu.edu.

Kori L. Brewer, PhD, is an associate professor and associate chief of the Division of Research at the Department of Emergency Medicine of the Brody School of Medicine at East Carolina University.

Herbert G. Garrison, MD, MPH, is a professor of Emergency Medicine at the Department of Emergency Medicine of the Brody School of Medicine at East Carolina University and director of the Eastern Carolina Injury Prevention Program at the University Health Systems of Eastern Carolina.

increase in helmet use in children under the age of 16 after the law was implemented. In the 4 years prior to the law, 42 of 1303 (2.3%) children involved in bicycle-car crashes wore helmets; in the 4 years following implementation of the law only 22 of 849 (1.3%) children were documented to be wearing helmets.

The purpose of this study was to determine if the ineffectiveness of the mandatory helmet law is due to a lack of awareness of this law or a lack of knowledge of the utility of helmets in preventing head injury. We assessed these factors by surveying parents, teachers, physicians, and prehospital emergency medical services (EMS) personnel in Pitt County, North Carolina, a geographically distinct area that included communities with bicycle helmet ordinances in place before the statewide law. Ultimately, our goal was to define areas of focus that will improve bicycle helmet use among children.

Methods

All protocols were reviewed and approved by the University Medical Center Institutional Review Board. The study was conducted in Pitt County, North Carolina. Pitt County is mostly rural with a year 2000 population of 138 690. It is located in the eastern region of the state and is comprised of approximately 650 square miles.

A written survey was distributed to the following groups: a convenience sampling of Pitt County public school district parents of school-aged children (n=150); a convenience sampling of Pitt County public school district teachers from elementary to high school, both rural and urban (n=210); pediatricians, emergency physicians, and family physicians (n=88); and EMS personnel (n=124). We used the following strategies to recruit survey participants: (1) to obtain a survey of parents, Parent Teacher Associations (PTAs) in Pitt County were contacted and surveys were given to interested PTA leaders which were then distributed to parents and collected by the PTA leaders for return; (2) principals from Pitt County public elementary, middle, and high schools were contacted and those interested in the project distributed surveys to their teachers and returned them by mail; (3) all pediatricians, emergency physicians, and family physicians in the Pitt County Medical Society were mailed surveys with response envelopes; and (4) all Pitt County EMS personnel were given surveys to be mailed in when completed. These groups were chosen since they are most likely to interact with children on a daily basis or to see the results of a bicycle crash when it occurs. The survey was distributed between October and December of 2006. All surveys included in the study were returned by January 2007.

Table 1.
Survey Questions

Is there a North Carolina law requiring bicycle helmet use in children younger than 16 years old?
Yes____ No ____ Don't know____
If not, should there be a law?
Yes____ No____ Don't know____
How often does your child (age 5-15) wear a bicycle helmet? *
Always____ Often____ Sometimes____ Rarely____ Never____
How often do you wear a bicycle helmet?
Always____ Often____ Sometimes____ Rarely____ Never____
What percentage (%) of head injuries due to bicycle accidents can be prevented by wearing a helmet?
0%-25%____ 25%-50%____ 50%-75%____ 75%-100%____
Who do you think is responsible for providing education about bicycle helmets?
EMS Personnel____ Doctors____ Teacher____ Internet____
Parents____ Police Officers____ Other: ____________________
Who do you think parents expect to provide education about bicycle helmets to children? **
EMS Personnel____ Doctors ____ Teachers____ Internet____
Parents____ Police Officers____ Other: ____________________
How would you rate your understanding of proper helmet fit and helmet use?
Very good____ Good____ Okay____
I don't know anything about helmets____

* Asked only to parents
** Asked only to physicians, teachers and EMS providers

The survey included questions about: (1) the presence of a mandatory helmet law for children; (2) helmet use among respondents and use among the children of the parent group; (3) perception of helmet effectiveness in preventing head injuries; (4) perceptions of who should be providing education about proper helmet use and laws (more than one answer was allowed for this question); and (5) familiarity with the proper use and fit of helmets. (See Table 1.)

Responses were recorded in a database and response percentages were calculated. Differences in response rates between groups (eg, teachers vs. parents) were analyzed using chi-square analysis with $p<0.01$ indicating statistical significance. The use of $p<0.01$ to indicate significance is a more stringent criterion than $p<0.05$ and helps adjust for the necessary multiple testing. The relationship between helmet use and knowledge of the helmet law and perceived effectiveness of helmet use was assessed using logistic regression. Helmet use and perceived effectiveness were each used as the dependent variable and assessed using simple logistic regression (LR) to produce a coefficient of determination (r-squared calculated using STATVIEW by SAS, Inc). The adjusted r-squared was calculated based on the following equation: Adjusted $r^2 = 1-(1-r^2)\ ((n-1)/n-k-1))$ where n = # of observations and k = # of independent variables.

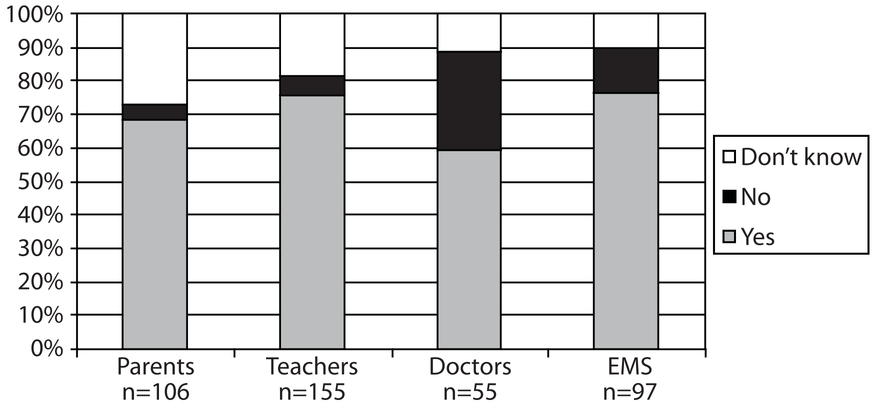
Results

The overall response rate for this survey was 72.2%. One hundred six of 150 parents (71%), 155 of 210 teachers (74%; 61/88 elementary school, 16/22 middle school, 78/100 high school), 55 of 88 physicians (63%; 14/27 emergency physicians, 16/20 family physicians, 25/41 pediatricians), and 97 of 124 (78%) EMS personnel returned surveys.

Awareness of the Helmet Law

Four years after the implementation of the bicycle helmet law, 69% of parents, 75% of teachers, 58% of physicians, and 75% of EMS personnel surveyed were aware of the law. (See Figure 1; p=0.06). Of those who answered "no" or "don't know," most (91/115 or 79%) thought there should be a law.

Figure 1.
Knowledge of Helmet Law: Is There a Law?



Among teachers, elementary teachers were most aware of the law (80%) followed by middle school teachers (75%) and high school teachers (72%). These differences were not statistically significant (p=0.049). Knowledge of the law was not associated with physician specialty (p=0.098). However, pediatricians had the highest awareness of the law (68%); only 57% of emergency physicians and 47% of family physicians were aware of the law.

Helmet Use

When asked how frequently their children wore their bicycle helmets, 18% of parents with children ages 5 to 15 responded "never" with 5% adding that their children do not ride bicycles. Nineteen percent of parents stated their children "always" wear a helmet. Among the respondents themselves, 21% reported "always" wearing their helmet when riding a bicycle. Physicians were statistically more likely to report "always" wearing a helmet (46%) compared to all other groups (12% of EMS personnel, 11% of teachers, and 8% of parents; p<0.001). Parents (65%), teachers (65%), and EMS providers (57%) most often reported "never" wearing a bicycle helmet.

There was no relationship between helmet use and knowledge of the law (adjusted $r^2 = 0.020$), perceived effectiveness of helmets (adjusted $r^2 = 0.008$), or knowledge of proper helmet fit (adjusted $r^2 = 0.050$).

Knowledge of Proper Helmet Use

The respondents' understanding of proper helmet use and fit was reported by them to be "okay" for the majority in all groups. Ten percent of parents, 20% of teachers, 7% of physicians, and 8% of EMS personnel answered that they "don't know anything about helmets." Sixty-four percent of those responding that they "don't know anything about helmets" answered "no" (17%) or "don't know" (47%) when asked about the existence of the helmet law.

Perceived Effectiveness of Helmet Use

All groups underestimated the effectiveness of helmet use in preventing injuries with the majority of teachers (53%), physicians (64%), and EMS personnel (57%) perceiving that 50%-75% of head injuries could be prevented by a helmet. Thirteen percent of all responders answered that less than 50% of head injuries could be prevented. The perceived effectiveness of the helmet was independent of their knowledge of the law (adjusted $r^2= 0.17$). Forty-nine percent of those who knew there was a law and 51% of those who stated there was not a law thought that helmets prevented 50%-75% of head injuries.

Education

A majority (80%) of respondents indicated that the burden of educating children about bicycle helmets should fall on parents, a finding that was consistent across all groups of respondents. Fewer expected that teachers (60%), physicians (46%), law enforcement officers (34%), and EMS personnel (22%) should provide education.

When asked "Who do you think parents expect to provide education about bicycle helmets to children?" only 18% of teachers, 26% of physicians, and 26% of EMS personnel responded "parents." The majority of respondents (61%) responded that parents expected teachers to provide education on bicycle helmets.

Discussion

This study demonstrates that while there is general awareness of the North Carolina bicycle helmet law, there is a lack of knowledge about helmet effectiveness and proper fit and a limited use of helmets by those with frequent contact with children. Based on the responses from parents, a substantial portion of children do not wear helmets while riding bicycles despite their family's awareness of the law.

Mandatory helmet use legislation in Canada and New York has been shown to increase helmet use among children by observing helmet use among those admitted to the hospital for bicycle crashes.[8,9] An international systematic review of published observational studies relating to mandatory helmet use legislation also showed an increase in helmet use; however, it did not control for time since law enactment, enforcement, or education about the law.[10] In contrast, the observational study performed in North Carolina 6 months after the passage of its helmet law failed to show an increase in helmet use among children younger than 16.[6] There were no educational programs associated with the North Carolina bicycle helmet law prior to this study. This provides an opportunity for improvement because research has shown that helmet use in communities where bicycle helmet legislation is combined with educational programs is greater than in communities without these programs.[11,12]

The results of our study suggest that education is necessary among parents, teachers, physicians, and EMS personnel in North Carolina in order to improve the number of children wearing helmets and decrease the number of bicycle-related head and brain injuries. The survey results suggest that most people expect parents to be the main educators of children about bicycle helmets. Reaching parents could provide the greatest impact. The survey participants are potential role models for children. Only 21% reported "always" wearing a bicycle helmet, suggesting that an educational campaign should also be extended to adult use.

This education should also include instructions on proper fit of the bicycle helmet. Of the 21% of improperly used bicycle helmets observed among children aged 5-15 in the 2002 North Carolina study,[6] the most frequent misuse (40%) was due to the helmet being tipped back, exposing the forehead. The next most frequent (31%) mistake was a helmet that was too large or a chin strap that was loose. (See Figure 2 for details of proper helmet use.)

Many methods to educate about helmets as well as increase the use of helmets among children have been studied including free helmet giveaways,[13,14] requiring the purchase of a helmet with a bike,[15] police enforcement of legislation,[16] physician involvement in behavior change counseling and education,[17] and community programs.[18] A 2005 Cochrane Review of nonlegislative interventions aimed at increasing helmet use among children found that the most effective method is a community-based education program along with free helmet distribution with some evidence supporting interventions in the school setting.[19]

Bicycle helmet use and legislation is comparable to seat belt use and legislation. North Carolina was the pilot state for enforcing seat belt use. In 1985 the North Carolina General Assembly passed a law requiring all front-seat passengers to wear seat belts. An initial rise in seat belt use followed, but by 1993 the seat belt use returned to near prelaw levels at 65%.[20] The *Click It or Ticket* campaign started in October of 1993 with a month of public education and high-visibility enforcement. Seat belt use rose to 80%, but by May 1994, just 7 months later, it had dropped to 73%. A return of enforcement and education in July of 1994 brought seat belt use back to 81%.[21,22] According to the National Highway Traffic Safety Administration (NHTSA), seat belt use in North Carolina was reported to be 86.7% in 2005.[23] This shows that coupling education and law enforcement increased seat belt use in North Carolina. A similar strategy may increase bicycle helmet use among children.

Limitations

The data from this study was collected by survey which introduces nonresponder bias. It is possible that those recipients of the survey not interested in or educated about helmet use may have been less inclined to complete and return the survey, creating a bias towards awareness of the law or helmet use.

The question about knowledge of the law may have been misinterpreted. The survey asked about the state law (enacted 2001) when there also was a citywide law in place in Greenville, North Carolina (roughly half of the population of Pitt County) since 1998 requiring bicycle helmets in children under the age of 16. This could create a bias towards knowledge of the law. Also, for the question asking how frequently helmets were worn, an option was not given stating "do not ride a bike." This response was written in on some surveys, and it is possible respondents answered "no" to this question when in reality they do not ride a bike. Furthermore, frequency of and reason for bicycle use was not addressed, and this may also impact helmet use. Respondents who frequently use their bicycle for exercise could be more likely to wear a helmet than those who infrequently ride their bicycle. Some responders did not answer all questions on the survey; however, this was limited to the follow-up item to the question asking about the need for a law. This question was "If not, should there be a law?" Results were reported only on the respondents who answered "no" to the initial question, all of whom answered the follow-up question.

Further limitations provide areas for continued research. This study did not include an observational component and therefore only shows the opinions of the respondents, not actual helmet use. The survey was distributed only in Pitt County, North Carolina, and does not reflect helmet awareness for the state as a whole. A state-wide observational study should be repeated.

Conclusion

Helmets have been shown to be effective in reducing head and brain injuries among children which is the basis for the mandatory helmet law for children in North Carolina. A majority of surveyed parents, teachers, physicians, and EMS personnel in North Carolina were aware of the helmet law, yet they underestimated the effectiveness of helmets and felt uncomfortable with their level of understanding about proper helmet use and fit. Education aimed at parents and teachers may improve the overall understanding of helmets. However, awareness is not enough. Enforcement of and education about the helmet law is necessary to improve helmet use among children. **NCMJ**

Table 2.
Proper Bicycle Helmet Fit[24]

Step 1: Size	With the helmet sitting flat on top of your head, make sure it doesn't rock side to side. Sizing pads come with new helmets; use the pads to securely fit the helmet to your head.	
Step 2: Position	The helmet should sit level on your head and low on your forehead —one or two finger-widths above your eyebrow.	
Step 3: Buckles	Center the left buckle under the chin by shortening and lengthening the straps.	
Step 4: Side strap	Adjust the slider on both straps to form a "V" shape under, and slightly in front of, your ears.	
Step 5: Chin strap	Buckle your chin strap. Tighten the strap until it is snug, so that no more than one or two fingers fit under the strap.	
Step 6: Final fitting	A. Does your helmet fit right? Open your mouth wide…big yawn! The helmet should pull down on the head. If not, refer back to step 5 and tighten the chin strap. B. Does your helmet rock back more than two fingers above the eyebrows? If so, unbuckle, shorten the front strap by moving the slider forward. Buckle, retighten the chin strap, and test again. C. Does your helmet rock forward into your eyes? If so, unbuckle, tighten the back strap by moving the slider back toward the ear. Buckle, retighten the chin strap, and test again.

Call for Papers

John W. Williams Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

POLICY FORUM

Emergency Medical Services in North Carolina

COMMENTARIES

> *"Groundbreaking ideas and advances in EMS research and education are incubated and cultivated in North Carolina ... State officials are tackling the most pressing challenges—recruitment and retention—by describing the extent of the problem and offering alternative solutions."*

INTRODUCTION

Policy Forum:
The North Carolina System of Emergency Medical Services

Running on adrenaline and altruistic motives, nearly a million first responders, emergency medical technicians (EMTs), and paramedics across the US perform life-saving procedures every day. They do this under stressful and dangerous work conditions, for very little pay, and with little recognition. Funding and support for maintaining readiness is limited. Reimbursement for services rendered is often below actual costs. Low patient volumes, limited billing capacity, high turnover, and reliance on volunteers force many rural-based emergency medical services (EMS) systems, including some in North Carolina, to close or convert to a different type of EMS model.

Current research and policy reviews indicate that we possess very little knowledge and understanding of EMS; how it works today, how it is supported, how the personnel are trained and educated, what professional issues emergency responders face, and what operational and political obstacles prevent timely and high quality EMS care.

The public's visibility of the current status of EMS was raised recently by the Institute of Medicine of the National Academies (IOM) report on the status of EMS. The report pointed to inefficiencies, workforce problems, and other systems-level challenges. The overarching recommendation from the IOM was for the establishment of a permanent federal lead agency within the US Department of Health and Human Services dedicated to EMS. This issue of the *North Carolina Medical Journal* follows the IOM's footsteps by focusing attention to the challenges and needs of North Carolina's EMS system.

Lifelong EMS professionals in North Carolina feel the state has been on the forefront of the EMS evolution. Many national and internationally recognized EMS leaders live in North Carolina and have contributed to this issue of the Journal. Groundbreaking ideas and advances in EMS research and education are incubated and cultivated in North Carolina institutions of higher learning. State officials are tackling the most pressing challenges—recruitment and retention—by describing the extent of the problem and offering alternative solutions.

All of health care delivery is under scrutiny as we seek ways to provide the best possible care at a reasonable cost. However, we often don't look at this problem in a fully systematic way—largely because we do not have a uniform system of care. A uniform health care system would link and coordinate its many parts, including the emergency services components that have immediate and important roles to play in keeping our citizens healthy and bringing them quickly to definitive care.

This issue of the Journal seeks to highlight this part of the system by describing its origins and development and outlining the future organization and operation of EMS. There are decisions to be made at the local and state levels regarding how we can keep this important part of health care delivery functioning effectively for the citizens of North Carolina and the nation.

ISSUE BRIEF

Overview of Emergency Medical Services in North Carolina

William K. Atkinson II, PhD, MPH, MPA

The emergency department is an integral part of our nation's health care safety net. Emergency medical services (EMS) are the integral thread in the safety net.[1] The position EMS care has in health care is significant and the services it provides are unique. There are more than 18 000 EMS systems in the United States[2] and approximately 800 separate service units operate in North Carolina. Coordinated at the county level, giving North Carolina 100 local "systems," North Carolina EMS systems incorporate local rescue squads and hospital, public health, and public safety personnel.[3] In many rural areas of the US, there may be a single volunteer rescue squad that serves as the only form of health care for miles.[4] Spread across almost every community in the US, there are nearly one million paramedics, emergency medical technicians (EMTs), and emergency first responders.[5] An estimated 33 000 EMTs and paramedics are currently certified in North Carolina and most are volunteers.[6]

In most communities, EMS care is available to anyone, for any reason, at any time. On average, individuals use EMS care twice in their lifetimes.[4] The likelihood of using EMS care increases as an individual ages.[7,8] In some communities, demographic and socioeconomic factors associated with EMS utilization include lower income (poverty), minority race, female gender, and Medicaid or health maintenance organization insurance coverage.[9-15]

It is unclear exactly how frequently EMS care is accessed on a national scale. A recent Institute of Medicine of the National Academies report estimated 16 million EMS transports to emergency departments (EDs) in 2002.[16] Other publications cite much higher frequencies with as many as 28 million EMS encounters.[17] Thousands of other EMS encounters involve interfacility transports or transports to clinics, physicians' offices, or other institutions. North Carolina citizens use EMS over 1 million times each year.[18]

Emergency medical service systems are well known for their ability to handle cardiac emergencies and traffic-related trauma, but much of the medical care EMS provides is nonemergent in nature.[14,19-22] Research shows that an overwhelming number of visits to the ED are nonemergent[23] and, in fact, are unnecessary,[19,24,25] and use life-saving and expensive health care services needed by others.

A Call to Action

There are things in life and in health care that move along at yesterday's pace for seemingly no good reason. Many aspects of today's system of EMS care vary little from what was seen in the 1970s. In the 1950s and 1960s in North Carolina and across the nation, ambulance services provided little more than "scoop and run" transport.[26] Untrained personnel in hearse-type vehicles sped to an emergency scene, "scooped" up the patient with no regard to injury, illness, or care and raced—sometimes with both the driver and an attendant (if present) riding in the cab—to an ill-equipped and poorly staffed emergency room. Such was the case in almost every community across this nation.

> *"Before the 1960s, ambulance transportation was often provided by volunteer rescue squads or through local funeral homes."*

Before the 1960s, ambulance transportation was often provided by volunteer rescue squads or through local funeral homes. It was the norm and something that was accepted. Funeral home ambulances were solely for convenient, horizontal transportation. As of 1959, local governments were also authorized to help finance rescue squad operations.[31] At that time, North Carolina's volunteer emergency squads were structured and

William K. Atkinson II, PhD, MPH, MPA, is president and chief executive officer of WakeMed Health & Hospitals and board chair of the North Carolina Institute of Medicine. He can be reached at batkinson@wakemed.org or 3000 New Bern Avenue, Raleigh, NC 27610.

funded in a haphazard way. These volunteer squads were mostly dependent on local donations to fund their activities. Rescue squads were sometimes formed through local fire departments, police departments, or civil defense units. Regardless of affiliation, the availability and quality of rescue and ambulance services across North Carolina was generally questionable. North Carolina wasn't alone; emergency services across the country were much the same.

Physicians and other health care providers insisted we could do better. In 1965, the National Academy of Sciences (NAS) published a report entitled *Accidental Death and Disability: the Neglected Diseases of Modern Society*.[27] The report forced public officials to take concrete steps to establish standards for ambulance design and construction, EMS equipment and supplies, and training programs and protocols for personnel. The NAS, drawing on lessons learned in the military in Korea and Vietnam, reported 52 million accidental injuries in the US, with 107 000 deaths. Of those who survived their injuries, more than 10 million were temporarily disabled and another 400 000 permanently disabled, all at a cost of $18 billion. The report described accidents as the "neglected epidemic of modern society" and "the nation's most important environmental health problem."

The report stimulated the passage of the National Highway Safety Act of 1966, which called on the US Department of Transportation (DOT) to develop minimum standards of care for accident victims. It also gave the federal DOT the right to withhold 10% of its highway design, construction, and operation funds to states that did not comply. This risk equated to millions of dollars annually for each state and, as intended, quickly drew the attention of state governments.

Between the DOT and the National Highway Traffic Safety Administration (NHTSA), model EMS systems were developed. The appropriations for each agency included more than $48 million for national training standards for emergency medical training. This structure provided for multiple levels of training to include emergency medical technician-basic (EMT-Basic), EMT-Intermediates, and EMT-Paramedics.[28]

On November 16, 1973, Congress approved the Emergency Medical Services Systems Act of 1973 (PL 93-154)[29,30] which funded and authorized the US Department of Health, Education and Welfare to help develop EMS programs throughout the country. Funding allocated $30 million for the fiscal year ending June 30, 1974, $60 million through June 30, 1975, and $70 million through June 30, 1976. The act identified 15 "key elements" of an EMS system including manpower, training, communications, transportation, facilities, critical care units, mutual aid, consumer participation, accessibility to care, transfer of patients, standard record keeping, consumer information and education, review and evaluation, disaster linkage, and use of public safety agencies. Because PL 93-154 called for the development of a comprehensive system with a minimum of 15 complex components, an EMS system built around the federal model actually became many different innovations rolled into one umbrella known as EMS.

North Carolina as a Leader in EMS Innovation

North Carolina was one of the first states in the nation to address EMS development through state government involvement and on a statewide basis. National and state-level legislation led the way in the formation of modern EMS programs across the country. But while many states approved EMS development on an element-by-element basis, North Carolina approached EMS from a comprehensive system development perspective. Considerable federal and state resources were applied to system development and talent was drawn from both in-state and out-of-state to support the overall program and its implementation.

North Carolina adopted the federal 15-element model and actively pursued implementation of EMS across the state. The central theme and intent of the EMS Systems Act was to develop systems of emergency medical care that would significantly decrease death and disability rates. However, implementation is often far more complicated than planning. In North Carolina's case, some volunteer emergency squads were just as ready to block federal intervention then as other types of North Carolina volunteers were ready to block Union troops in the American Civil War. Federal ambulance and training standards, even though they were to be administered through state government, were viewed by many local rescue volunteers as an intrusion on their rights, values, and way of life. This set the stage for another battle. This time it was state regulators, armed with federal standards and an innovative concept called emergency medical services, squaring off with community volunteers from across the state.

Due to many factors, by August 1966, 56 counties in North Carolina were threatened with the loss of ambulance service. Some municipalities stepped up to the plate to offer services that were lost, and some commercial providers began operation, but those services were normally of poor quality and limited financial means. Some commercial providers were allocated subsidies from local governments, but even with that, most still failed. By 1967, the lack of a sound approach to ambulance service was more visible than ever before. Many public and private interest groups, along with a growing list of medical professionals, began to focus on the statewide ambulance issue. Funeral directors began to withdraw from the delivery of the service, in part driven by the cost of labor due to newly introduced federal labor standards. The North Carolina General Assembly responded by passing the Ambulance Act of 1967. The act placed the legal responsibility for ambulance availability on county governments as an extension of public health.

In North Carolina, the Ambulance Act of 1967 represented the first major step for ambulance legislation in the state. More states across the country were taking advantage of federal dollars for technical assistance and funding in support of ambulance improvements and model projects. With money from the US Department of Transportation, the Jacksonville, Florida, fire department began efforts to reduce traffic related deaths by implementing a citywide EMS system.[32] Overnight, the city government became involved in ambulance service. All of the community funeral homes and commercial ambulance services quit providing the service during a strike. In 1968, a similar situation occurred in North Carolina's Guilford County. The county had to step in and assume immediate responsibility for ambulance service when the only local, private service went on strike. Incidents like these were not isolated and occurred in numerous locations across the nation and throughout North Carolina.

State government, with limited funding, began to oversee North Carolina's ambulance and rescue services. For the first time in the state's history, minimum training standards, very minimum by today's rules, were established. Ambulance "attendants" were required to complete a 24-hour course in standard first aid through the American Red Cross or other training source. The North Carolina Board of Health also established equipment standards for all ambulances, based on recommendations from the American College of Surgeons' Committee on Trauma. Even with the minimal requirements, some rescue squads still refused to participate because they were wary of government intervention and they resisted change.

The North Carolina Board of Health was designated to inspect ambulances, but again, the quality of this oversight process was poor. Staff was assigned to monitor a system that truly didn't exist. F. O'Neil Jones, a freshman senator from the 24th district (Anson County), learned of the problems from Dr. Bill McKennon, a friend and physician, who said that something needed to be done. Armed with McKennon's advice and help from David Warren at UNC-Chapel Hill's Institute of Government, Jones created a research commission to examine statewide issues in emergency care and transportation. The results of the commission were outlined in the 1972 report *Emergency Medical Services in North Carolina: Transportation, Communication and Personnel*. The report stated:

> North Carolina has approximately 400 organizations with 927 vehicles and 6,300 persons providing ambulance and/or rescue services. About one half of these providers is volunteer agencies and one-fourth is funeral home operators. Though volunteer and funeral home units represent almost 75 percent of the providers, they respond to only 43 percent of the calls. Governmental and commercial responders, who constitute less than 20 percent of the providers, respond to 52 percent of the calls. Other providers, such as hospitals, respond to the remaining calls.… It is estimated that only 202 service units meet the minimum requirements. (RTI, 1972:3)[33] … The presumption is that people are dying needlessly at the hands of ambulance attendants who are so medically under skilled that they do not know how to deal effectively with many common medical emergencies.

Jones' work and the report of the commission resulted in the North Carolina EMS Act of 1973 and the creation of the North Carolina Office of Emergency Medical Services (NC OEMS) in the North Carolina Department of Human Resources. Subsequently, North Carolina was one of the first states in the country to begin a statewide effort to establish an EMS system in every community.

This lead agency, under the secretary of the North Carolina Department of Human Resources, established broad powers and responsibilities to create, maintain, and oversee prehospital EMS operations and hospital-based trauma and helicopter ambulance services in the state. David Warren was appointed as acting chief of NC OEMS with instructions to get the office organized and do a national search for the best person to become permanent chief. That led to the hiring of a man who many emergency service professionals across the globe now describe as an emergency medical services pioneer—James (Jim) O. Page.

Jim Page, an attorney and a Los Angeles County fire battalion chief, was a leader of one of the first agencies in the nation to train paramedics and provide advanced prehospital care. Page, at the time, was also technical advisor to the NBC hit show "Emergency!" This program and Page's leadership brought him to North Carolina to lead the new agency after he came to the state for a speaking engagement and was enticed to apply for the newly created chief's position. He assumed the role as chief of North Carolina OEMS on December 19, 1973.

Page and the talented OEMS team he developed found it straightforward to upgrade vehicles and equipment through federal funding and new national standards in ambulance design and construction. Funds were also available to assist with the initial development of local and statewide EMS communications systems and air ambulance services. Likewise, the designation of hospital trauma centers was also a duty assigned to NC OEMS.

Implementing training standards and working with the hundreds of emergency service providers across the state proved to be another challenge—one that would eventually cost Page his job. The task of training and certifying basic EMTs was monumental. Urban areas rapidly accepted and adopted the new training standards while eastern and western parts of the state resisted implementation. Specifically, major pockets of opposition quickly built within the volunteer squads in and around Wayne County in the east and Gaston County in the west. The resistance was "organized, highly vocal, media intensive and politically active."[34]

Rescue squads and funeral homes saw the training as an extra burden that was too much to ask of their members or employees. Page's support for training and education set him up as a political lightning rod. A number of state senators were complaining to the secretary of the Department of Human Resources that their local rescue squads were angry and putting significant political pressure on them about Page and NC OEMS.

Another looming problem and one that hints at reasons why some squads resisted initial training was illiteracy. For the first time, ambulance personnel would be required to attend formal training, read an EMT textbook, and pass written and practical exams. At the time, illiteracy was a problem plaguing squads from the mountains to the coast. Political pressure mounted to extend the basic EMT certification deadline, which Page was willing to do, and allow for oral examination for EMT candidates, which he was not. Giving in to "voter pressure," Page was asked to resign by the secretary, but he refused to do so. Page was then terminated. He was at the helm less than two years.

Page was replaced with Colonel Charles A. Speed, former commander of the North Carolina Highway Patrol. Speed was a highly principled man who also refused to compromise on the training standards. Although the road remained rocky for some time, the statewide training program moved forward; by 1977 all 100 counties had adopted basic EMT training, and by 1984 the number of certified EMTs had climbed to more than 50 000.

Following Colonel Speed's retirement, strong leadership continued to be a characteristic of NC OEMS. Under each chief, including the current chief, Drexdal Pratt, the implementation of all 15 key elements and many more add-on components and policy advances of the state's EMS system have continued to take place.

EMS Today

Today no one debates the merits of a 9-1-1 system, skills certification for paramedics, or the need for understood "levels" of care whether those be in the hospital-based trauma program or the neonatal intensive care unit. As September 11, 2001 taught us, the ability to communicate is essential in order to protect lives. When terrible things happen, people turn to their hospitals for help. As the recent tragic events at Virginia Tech also showed us, a level III trauma center handled more than 20 wounded students, many of them in critical condition, with skills and processes that make us all proud.

Are all of our hospitals in North Carolina and all of our first responders ready to handle such a terrible event? What should be the level of care we expect of any hospital in our state that has an emergency department? Many of our state's original emergency services physicians, nurses, physician assistants, and paramedics have or are approaching retirement. How will we replace their skills and expertise?

These are important questions the state's hospitals, physicians, policy makers, and their partners in emergency medical services are considering and debating. Once again, it will be surprising if North Carolina does not lead the way in finding solutions.

Essential Components of EMS: A Status Report

Over time, EMS systems in North Carolina and in the nation have evolved into sophisticated and mobile medical care units with highly trained medical professionals. In this special issue, local, state, and national experts and leaders in EMS provide detailed discussions and commentaries on the essential components of EMS.

Recruitment and retention of EMS personnel at all levels is perhaps the most visible challenge for EMS systems in North Carolina and nationally.[35] The EMS industry is in a struggle at the moment with advancing the profession while sustaining the existing workforce to meet rising public need and demand. Dr. Daniel Patterson comments on the nature of the manpower challenge for our state and the nation. Although research is limited, many states, local leaders, and colleagues in foreign nations are experimenting with a variety of approaches to ensure every citizen has access to the emergency care they need. We in North Carolina should monitor these trends and adopt emerging and innovative approaches to sustaining the EMS workforce.

In most locales, EMS professionals are first trained at the basic level of certification to deliver essential life saving care. With additional training, professionals are certified as intermediate technicians, paramedics, or critical care professionals. The bulk of the nation's and North Carolina's EMS professionals are trained in the community college system. Studies of EMS professionals show that many would prefer a degree over certification only.[36] In several commentaries, national and state leaders in EMS education and training discuss the role of community colleges, universities, and national registration organizations in the training of EMS professionals.

EMS communications include the transmission of information between EMS professionals, members of public safety (ie, police), and others. Cell phones and text messaging are increasingly being used to facilitate EMS communications. Much consideration has been given to gaps in communications due mostly to the communications challenges experienced during September 11, 2001 and during recent natural disasters. Communications experts Carl Van Cott of North Carolina and Kevin McGinnis of the National Association of State EMS Officials outline EMS communications in North Carolina, the challenges we face, and what is on the horizon in terms of new communications technologies and how they can help prevent miscommunication.

Data are the foundation for research that advances knowledge and even a profession. While we know that our nation's emergency departments receive over 100 million visits annually, we have no true sense of how many EMS responses and transports are made in America. Nor do we know very much about the details of EMS utilization or how best to go about reducing unnecessary use and improving the quality and safety of care for those who need EMS assistance. Sporadic record keeping in EMS is partly to blame. A lack of data has in many respects stalled the advancement of EMS as a service to our citizens. Work performed right here in North Carolina with support from a variety of federal agencies has helped to construct a national EMS information system, NEMSIS. Dr. Greg Mears of the University of North Carolina at Chapel Hill describes NEMSIS and what it can do for the state of North Carolina and EMS nationally.

EMS has evolved such that it works in concert with public safety and health care while standing on the outside looking in. EMS is a very fragmented system where it is difficult to make the vertical and horizontal connections between EMS and many of its partners in public safety or health care. Poor integration impacts patient transportation and transfer (by air or ground) to different facilities such as critical care units. It also impacts how one EMS system communicates and works with other EMS systems. Several commentaries included in this issue touch on these components from a variety of vantage points.

Emergency medical service was founded under the umbrella of traffic safety. Over time, various federal and state agencies have assumed responsibility for some or all aspects of providing EMS care. Identifying who or what agency is responsible for EMS can be difficult. Bob Bailey, a former chief of the NC OEMS, describes federal EMS legislation and what the legislation is intended to do. Drexdal Pratt, the current chief of the North Carolina Office of EMS, describes North Carolina's EMS legislation.

Financing EMS services is a very complex and often contentious issue. Many EMS systems receive some support from federal, state, and local governments. This funding usually represents a very small component of total system revenues or capital. In many instances, EMS systems must bill for services rendered which means transportation. If an EMS system responds to a scene and the patient is not transported, most systems are not reimbursed for the costs incurred. Todd Hatley, a former North Carolina local EMS training officer and EMS quality consultant, describes the EMS financing system, financial challenges, and experiences.

When one compares the amount of published research on topics specific to EMS to the amount published on non-EMS topics or in other disciplines, one word comes to mind: paucity.[37] Some our nation's most recognized leaders in EMS research are located right here in North Carolina. Two leaders, Dr. Herb Garrison of East Carolina University and Dr. Jane Brice of the University of North Carolina at Chapel Hill, discuss research and evaluation in EMS, focusing their attention on gaps in EMS research and where we need to be in terms of advancing the profession.

A survey of some Eastern North Carolina residents found that many have very little idea what their local EMS system provides in terms of medical care.[38] This lack of understanding also extends to many medical professionals. EMS professionals are designated agents of a physician.[39] In other words, EMTs and paramedics provide medical care under the license of a physician. With supervision and guidance, EMS professionals administer medications and perform many cognitively complex medical procedures outside of the hospital setting. Added to the list of 15 essential components of an EMS system after the 1973 legislation was written, medical oversight is an extremely important element of EMS care and delivery.[40] Local EMS systems, their chiefs, and their personnel must overcome many challenges in order to access and receive the medical oversight they need to perform their duties. Rural areas are known to have limited access to adequate medical oversight.[41] The National Association of EMS Physicians (NAEMSP) and others have published a list of duties all physicians engaging in medical oversight activities must provide a local EMS system.[42,43] Dr. Brent Myers, the medical director for Wake County EMS and WakeMed's Emergency Services Institute, comments on medical oversight in North Carolina and in the nation.

Providing a very in-depth look into one of the most controversial medical procedures performed in the prehospital setting is Dr. Henry Wang of the University of Pittsburgh. Endotracheal Intubation (ETI) is the insertion of a plastic tube into the mouth and throat of a patient in order to establish or maintain an open airway. For many reasons, performance of this procedure by EMTs has attracted a great deal of scrutiny from the medical community. Dr. Wang comments on the origins of ETI, outlines some of the controversies, and speculates on the future of ETI in EMS.

Threats of terrorism and natural disasters are prominent on the minds of most citizens and policymakers. Regardless of the type of event, EMS must be prepared for mass casualties. Drs. Roy Alson and Jane Brice are intimately involved in EMS preparedness activities and planning. They comment on preparedness in North Carolina.

Conclusion

At some point in time, virtually every North Carolinian and every American will require the assistance of EMS. One Congressionally supported report published in the late 1980s anticipated that every American could anticipate a minimum of two EMS encounters in his/her lifetime.[4] The importance of our state and nation's EMS system should not be understated. When EMS is needed, we expect them to get there as fast and safely as possible. It is only at that point in our own history that we can truly appreciate the significance of our local EMS system, the training EMTs and paramedics go through, and the challenges they encounter while tending to our emergency needs.

Unfortunately, while we may all voice our appreciation for EMS in our community, the state's system of prehospital care, and that of the nation, is in jeopardy. In the recently released *Rural and Frontier EMS Agenda for the Future*,[44] the authors noted that the infrastructure upon which EMS was built is crumbling. More recently, our nation's emergency care system received an overall grade of C- in the first ever National Report Card on the State of Emergency Medicine.[45] Overcrowding, poor access to emergency care, and liability issues were identified as prominent factors. The nation's leading independent health policy body, the Institute of Medicine of the National Academies, released three scathing reports on the state of emergency departments, EMS, and pediatric emergency care in 2006. The reports focused on the lack of federal leadership in the development of EMS systems as the most critical of factors in the delivery of EMS care today.[16]

Throughout its 50-year history, North Carolina's modern EMS system has played a prominent role in the evolution of EMS health care nationally. While there are many obstacles and many challenges, as the reader will learn in the pages that follow, North Carolina EMS authorities are well positioned to lead efforts in innovation and improvement. With recognition from state policymakers that EMS is a vital component of health care, public safety, and public health, our state's EMS system can continue to improve and serve as the EMS model for the nation. **NCMJ**

Emergency Medical Services Legislation in North Carolina

Drexdal Pratt

North Carolina's history of emergency medical services (EMS) legislation dates back to 1967. The study commission and subsequent legislation in the state was a result of the federal National Highway Safety Act of 1966. This federal act created the National Highway Safety Administration and directed each state to develop a regional EMS system. The North Carolina Governors Highway Safety Program was charged with assisting in the funding of such a program in our state. Soon after the enactment of this act the US Department of Transportation released national standards for the design and equipment of ambulances and training for ambulance attendants.

In 1967 the North Carolina General Assembly passed the Ambulance Services Act under Chapter 130, Article 26, Regulation of Ambulance Services. This act placed the regulatory responsibilities of EMS under the North Carolina State Board of Health and provided the board authority for adopting standards for equipment, inspection of medical equipment, and supplies required for ambulances. In addition, the law required that ambulances have permits and the board adopted regulations setting forth the qualifications required for certification of ambulance attendants.

The 1967 law also created an Advisory Committee on Ambulance Service to assist the North Carolina State Board of Health in developing standards for use in Article 26. The advisory committee consisted of 9 members and representative of the North Carolina Funeral Directors Association Inc., Funeral Directors and Morticians Association of North Carolina Inc., North Carolina Ambulance Association Inc., North Carolina Medical Society, North Carolina Hospital Association, American Red Cross, North Carolina State Association of Rescue Squads Inc., North Carolina Association of County Commissioners, and North Carolina League of Municipalities.[1] This advisory committee still exists today and has expanded in membership to represent the many EMS stakeholders. The committee's name has changed to the North Carolina EMS Advisory Council, and it continues to offer a valuable service to the state and the citizens of North Carolina.

In 1971 Senator F. O'Neil Jones sponsored Senate Resolution 827 authorizing a Legislative Research Commission "to study and investigate the problem of emergency care in North Carolina and to plan and develop an adequate system of providing comprehensive emergency medical care throughout the state with sufficient resources to save human lives and diminish the immeasurable emotional burden and vast economic losses of avoidable disability."[2] The Commission was instructed to report its findings and recommendations to the 1973 session of the General Assembly. Senator Jones chaired the commission and provided its report and recommendations to the General Assembly in January 1973.

> *"North Carolina's history of EMS legislation dates back to 1967. The study commission and subsequent legislation in the state was a result of the federal National Highway Safety Act of 1966. This federal act created the National Highway Safety Administration and directed each state to develop a regional EMS system."*

Drexdal Pratt is chief of the North Carolina Office of Emergency Medical Services. He can be reached at Drexdal.Pratt@ncmail.net or 2707 Mail Service Center, Raleigh, NC 27699.

One of the recommendations of the commission was the establishment of the Office of Emergency Medical Services within the Department of Human Resources (now Health and Human Services). In addition, the agency should be adequately funded and empowered to coordinate and control all state EMS programs and have the ability to pursue federal and private funding and make allocations to both governmental and private local EMS systems. There were several other recommendations to increase the minimum standards for EMS training and to change the name of the Advisory Committee to the EMS Advisory Council and increase its membership to better reflect all of the state's EMS stakeholders.

As a result of the study commission's work, the Office of Emergency Medical Services was established in 1973 and placed in the Division of Facility Services. Funding was appropriated to the agency to improve training, transportation, hospital emergency rooms, and communications consistent with the 15 federally recognized components of an EMS system. Chapter 224 of the law consolidated the rule-making authority over ambulances and personnel in the Medical Care Commission. In Chapter 1121 the law authorized training emergency medical technicians to perform advanced first aid and limited medical procedures under the rules and regulations of the Board of Medical Examiners.

Over the next 20 years some minor changes were made to the EMS statutes and many administrative rule changes were made. In 1976 the North Carolina Medical Care Commission published a document entitled "Rules & Regulations Governing Ambulance Services," thus creating the state's basic life support rules. Also in 1976 the North Carolina Medical Board adopted rules to allow advanced skills for EMTs under the certification of Mobile Intensive Care Technicians.

In 1993 G.S. 131E-162 was passed and required the department to develop a Statewide Trauma System and, in 1995, G.S. 131E-155.1 was enacted to require the licensing of EMS providers. This legislation served EMS in our state well for many years and established a solid foundation to build on for the future.

North Carolinas EMS Legislation Rewritten in 2001

In 1999 the NC Office of Emergency Medical Services embraced the National Highway Traffic and Safety Administration's plan entitled *Emergency Medical Services, Agenda for the Future*. The agenda listed 14 attributes of an EMS system much like the previous 15 components but revised to meet the needs of a more expanded and developed profession. Realizing that EMS continues to be a local community based system, the new vision brings clarity and places emphasis on the fact that EMS is truly a port of entry to the overall health care system. Integration of health services are needed with such partners as public health, social services, community agencies, and academic institutions as part of the new vision.[3] The new attributes address areas such as EMS research, system finance, prevention, information systems, evaluation, and others requiring additional statutory authority for implementation and funding. Those of us that have worked in the EMS system since its inception realized that North Carolina needed to rewrite its laws and rules governing EMS to fully embrace and implement the agenda.

Therefore, in 1999 we began the process to educate EMS stakeholders on the National EMS Agenda for the Future and rewrite the existing EMS laws. With help and support from the secretary of the Department of Health and Human Services, the director of the Division of Facility Services, the North Carolina EMS Advisory Council, 18 EMS stakeholder groups, and the dedicated staff of the Office of Emergency Medical Services, Representative Thomas Wright, New Hanover County, agreed to introduce House Bill 452, An Act to Revise and Update the EMS Act of 1973, and House Bill 453, Regulation of Emergency Medical Services, two of the most comprehensive EMS system bills in the country. The bills were passed in the 2001 session of the General Assembly and became law on January 1, 2002. The North Carolina Medical Care Commission adopted temporary rules to coincide with the legislation's enactment.

The new legislation required many changes to the structure of EMS in the state. Since most EMS providers in the state had progressed using the previous enabling legislation to provide advanced life support, it was apparent that EMS rule making needed to reside under the authority of one entity, either the NC Medical Care Commission or the NC Medical Board. After much discussion with the stakeholders it was decided to move all rule-making authority under the authority of the NC Medical Care Commission. The NC Medical Board retained statutory authority in G.S. 143-514 for defining the scope of practice for all levels of EMS personnel.[4]

The law now defines emergency medical services in G.S. 131E-155 (6) as: "services rendered by emergency medical personnel in responding to improve the health and wellness of the community and to address the individual's need for emergency medical care within the scope of practice defined by the North Carolina Medical Board in accordance with G.S. 143-514 in order to prevent loss of life or further aggravation of physiological illness or injury." The law also defines the Statewide Emergency Medical System in G.S. 143-507 (b).

Another major change in the law clearly places the responsibility of ensuring that every citizen has access to EMS to the Board of County Commissioners for each county. The new law establishes local EMS systems with no more than one system per county. New rules require that all counties submit a comprehensive EMS system plan to the Office of EMS and that all EMS providers licensed to operate in the county function as part of the county's EMS system. These requirements help standardize and coordinate the EMS care provided by the more than 850 EMS agencies operating in the state.[5]

New rules enacted by the NC Medical Care Commission enable counties to advance their systems to earn the designation of "Model System."[a] Model System designation far exceeds the minimum system requirements, is voluntary, and allows counties less regulatory oversight by the state. Less regulatory oversight includes self inspection of vehicles with appropriate documentation and more flexibility in all areas of their program management. In order to obtain the designation, counties must provide documentation that all system components of medical oversight, peer review, continuing education, and emergency medical dispatch are met and ensure the same high level of care is being provided to its citizens 24 hours, 365 days per year. The OEMS reviews the documentation then verifies through an on-site visit with the county before awarding the designation. The designation is awarded for a six-year period. Currently there are 12 counties in North Carolina that have obtained this designation.

Although air medical services were included in the previous rules, the new rules changed the terminology to include Specialty Care Air and Specialty Care Ground to address the interfacility patient transport. The term specialty care also assists EMS systems with reimbursement issues because this is a recognized term for Medicare and Medicaid. The law also provides liability protection for local and regional peer review meetings and requires electronic patient records to be submitted to the department on a daily basis. The data provides valuable information to assist the counties and state in assessing needs and looking at statewide patient outcomes for prehospital care.

The law also expanded membership on the EMS Advisory Council to be more representative of today's EMS system and created a 7-member EMS disciplinary committee that reviews all EMS personnel disciplinary cases and provides recommendations to the Office of EMS for possible action.

Throughout North Carolina EMS history the General Assembly, the Department of Health and Human Services, and the Division of Facility Services have supported efforts to improve the state's EMS system and have been proactive in passing legislation and rules to meet the needs of an ever expanding North Carolina EMS system. **NCMJ**

COMMENTARY

Federal Policy Leading the Way in Emergency Medical Services

Bob W. Bailey, MA

The most influential piece of federal legislation during my 30-year tenure with the North Carolina Office of Emergency Medical Services (NC OEMS), the last 15 as the state Emergency Medical Services (EMS) director, was creation of the EMS program at the National Highway Traffic Safety Administration (NHTSA). Since then, federal EMS legislation, programs, and agencies have profoundly impacted the evolution of EMS throughout our nation and my personal career in North Carolina.

Federal EMS legislation permitted NHTSA to 1) assist states and local communities with the purchase of ambulances; 2) fund for automobile extrication courses; 3) provide national-level guidance and support to evolving EMS systems; and 4) standardize emergency medical technician (EMT) training across the nation. The NHTSA also made the term EMT a household word and created a universally recognized symbol for EMS, the blue "Star of Life."

The 1973 National EMS Systems Act helped shaped state legislation including that of North Carolina. The NHTSA state EMS assessments and reassessments program, a program supporting expert team evaluations of state EMS systems, continues to help guide the development of state EMS systems. NHTSA publications, such as the *EMS Agenda for the Future* and its various spin-off documents including the *EMS Education Agenda for the Future: A Systems Approach*, the *EMS Research Agenda for the Future*, and others, encouraged the nation to adopt a collaborative, consensus-based, and forward-thinking approach to EMS issues.

The passage of the Emergency Medical Services Systems (EMSS) Act of 1973 brought positive changes to EMS. Health care provided in the hospital could now be extended into the community[1] and mechanisms were now available for funding the development of regional EMS systems.[2] The EMSS Act brought much needed recognition to emergency medicine as a field of medicine.[3] It also placed substantial obligations on hospitals which compelled them to provide new funding for emergency and trauma facilities including adding laboratory, imaging, and other services as resources for emergency departments.[4]

Under the EMSS Act of 1973, requirements for medical direction were nonnegotiable, which in turn stimulated the involvement of prominent physicians in EMS. Hospitals, specialty care centers, and rehabilitation facilities became recognized as essential components of an effective EMS system. The EMSS program and the North Carolina 1973 EMS legislation fundamentally changed the North Carolina EMS system for the better. Unfortunately, the federal program was discontinued in the early 1980s when the funding was incorporated into the Preventive Health and Health Services Block Grant program.

> *"The EMSS Act brought much needed recognition to emergency medicine as a field of medicine."*

Since 1984, the Emergency Medical Services for Children (EMS-C) program at the Health Resources and Services Administration (HRSA) within the Department of Health and Human Services (HHS) has provided national leadership in the improvement of emergency medical care for children in both prehospital and hospital environments. The program helps ensure that each state EMS office has someone dedicated to the emergency medical care needs of children, has utilized special projects or "targeted issues grants" to develop pediatric products and tools, and has promoted research in pediatric care. Although the EMS-C program is primarily intended to improve EMS care for children, HRSA recognizes that emergency medical

---

Bob W. Bailey, MA, served 30 years in state government serving his last 15 years as director of the North Carolina Office of EMS. He currently is working as a contractor to the Centers for Disease Control and Prevention National Center for Injury Prevention and Control Division of Injury Response and The Duke Endowment and runs his own EMS consulting firm, Bob Bailey, Inc. He can be reached at bbaily@nc.rr.com or 10605 Hanarry Court, Raleigh, NC 27614.

care for children cannot be built on the foundation of a crumbling EMS system. As a result, the program also plays a prominent role in promoting comprehensive EMS system development overall. Through this and other programs, HHS coordinates extensively with all federal agencies involved with EMS.

In 1990, the Trauma Care Systems Planning and Development Act, which focused on improving emergency care of the seriously injured patient, became law. The resulting federal trauma program was located at HRSA. Some of the program successes include creating a Model Trauma Systems Plan for states to use as a template to develop inclusive trauma systems, providing limited grant funding for states to develop trauma systems, and stimulating national interest in and attention to trauma systems. As a state EMS director, we used federal highway safety funds through the NC Highway Safety Office and later the federal Trauma Program grants to convene trauma system stakeholders, develop a trauma system for North Carolina, and initiate a state trauma registry. Ultimately, this resulted in comprehensive state trauma system legislation. Although program authorization and funding for the federal program has lapsed several times, this program has demonstrated strong leadership and the wise allocation of limited federal resources to further the development of trauma systems. The program has again been reauthorized, but not yet funded.

Several years ago Drew Dawson, the Montana State EMS director for 20 years became the head of NHTSA's EMS program. Under Drew's leadership I've seen an unprecedented level of federal activity in relation to EMS. With its long-standing history of providing support to EMS, the NHTSA EMS Division was elevated to the Office of Emergency Medical Services (OEMS) with a mission to "reduce death and disability by providing national leadership and coordination of comprehensive, evidence-based emergency medical services and 9-1-1 systems."

Although working with other federal agencies has long been daily business for NHTSA, the importance of federal agency collaboration on EMS was further emphasized by Congress in the creation of the Federal Interagency Committee on Emergency Medical Services (FICEMS). Created by the secretaries of the departments of Transportation, Health and Human Services, and Homeland Security, FICEMS comprises high-level representatives from a variety of federal departments and is charged with identifying the nation's EMS needs, coordinating EMS support among federal agencies, and reporting to Congress. The National Highway Traffic Safety Administration is responsible for providing staff and administrative support to FICEMS. With the advent of FICEMS comes the opportunity to further enhance and institutionalize the already excellent cooperation among those federal agencies with an EMS mission.

To provide a formal mechanism for nonfederal input to NHTSA's EMS activities, the Department of Transportation created a National EMS Advisory Council (NEMSAC). This 26-member advisory council membership reflects the national diversity of EMS including volunteers, fire-based EMS providers, trauma surgeons, emergency physicians, nurses, and private EMS services. The combination of FICEMS and NEMSAC will help to formalize and improve the long-term federal support of EMS.

Other promising developments in federal EMS support are also occurring. For example, the creation of the Office of Health Affairs at the Department of Homeland Security (DHS) provides a DHS-specific focal point for all things medical—including EMS. The Pandemic and All-Hazards Preparedness Act (2006) assigns additional responsibilities for EMS preparedness to the Assistant Secretary for Preparedness and Response at HHS. In addition, Congress recently established a National 9-1-1 Office. Jointly operated by NHTSA and the National Telecommunications and Information Administration at the Department of Commerce, the office is physically located at the NHTSA Office of Emergency Medical Services. Its mission is to provide leadership and coordination of comprehensive and technologically enhanced 9-1-1 services. Another important example of federal collaboration efforts to assist states includes the collaboration among NHTSA, EMS-C, the Department of Homeland Security, and the Division of Injury Response in the National Center for Injury Prevention and Control at the Centers for Disease Control and Prevention (CDC) to develop information related to world-wide bombings, surge capacity issues for hospitals, and revision of the American College of Surgeons Committee on Trauma Field Triage Decision Scheme.

The synergism of several federal agencies working collaboratively to enhance EMS clearly exceeds that generated by any single agency. Collaboration and cooperation, not silo building, continue to be the mantra of federal agencies involved in EMS. Federal EMS programs have had an enormous impact on the development of state EMS systems throughout the country including North Carolina. **NCMJ**

COMMENTARY

Recalling the Birth of Emergency Medical Services in North Carolina

George Johnson Jr., MD, April 6, 1926–May 15, 2007

In 1972 a legislative committee was formed to study emergency medical services in North Carolina with Senator O'Neil Jones as chairman. The committee included doctors, legislators, and everyday citizens who were concerned with emergency medical services (EMS) in the state.

At that time, most of the people needing emergency care were transported by hearse. There were many problems with this system of emergency transportation. We had a hearse arrive at an emergency room with no patient in the back—they'd either driven off without them or lost the person on the way. In another instance, a woman gave birth and the hearse attendants never took her underpants off. The baby died.

The members of the legislative committee wanted to improve emergency care across the state; we felt emergency services should be as good in Chinquapin as they were in Raleigh. Martin Hines from the Department of Public Health was very interested in emergency medical services and helped us in many ways. There was interest in a centralized system based in Raleigh, but we recognized that a one-man show would not work. We engaged a group in Tennessee, and they suggested dividing the state into several trauma center areas—regionalization of services was a big trend at the time. The Regional Medical Program was in full-swing, and we were on the verge of setting up the North Carolina Area Health Education Centers (AHEC) program. We didn't think a regionalized trauma system would work for emergency services because of the proximity of the medical centers at Duke University, the University of North Carolina at Chapel Hill, and Wake Forest University. We did think that we ought to upgrade the whole system, and we pushed for a new office to coordinate training and organization. We helped set up a trauma center classification system that worked well with the American College of Surgeons system. That led to the creation of a trauma system database that we still use to track cases through the system.

> *"We helped set up a trauma center classification system that worked well with the American College of Surgeons system. That led to the creation of a trauma system database that we still use to track cases through the system."*

Legislation was passed in the North Carolina General Assembly that created an Office of Emergency Medical Services (OEMS) within the Department of Human Resources. Jim Page from Los Angeles, who was a paramedic and wrote a television program about EMS, was the first chief of the OEMS. An advisory committee was formed to advise the OEMS. It was emphasized that this was an advisory committee and had no authority. The members were emergency department personnel, members of the North Carolina College of Surgeons

---

George Johnson Jr., MD, widely regarded as the father of modern EMS systems in North Carolina, passed away in May of 2007 shortly after contributing his recollections of the development of EMS in North Carolina. Johnson was a distinguished, nationally prominent surgeon serving on the faculty of the University of North Carolina at Chapel Hill School of Medicine and on the staff of UNC Hospitals from 1959 until shortly before his death. In recognition of his seminal contributions to emergency care in the state, the North Carolina Office of Emergency Medical Services established the George Johnson Award for Emergency Medical Services for individuals who have made significant impact on EMS in the state.

Trauma Committee, and other personnel interested in emergency medical care. These members were included to contribute based on their expertise in emergency medicine.

Although there have been several efforts to move OEMS out of the Department of Human Resources (DHR), thankfully this could not be done. We felt emergency personnel ought to be linked closely to health, and we advised that they stay in DHR. The OEMS worked with rescue squads, EMS training programs, pediatricians, hospital personnel, physicians involved in emergency medical care, and the NC Board of Medical Examiners. Standards were set up in order to deliver emergency medical care that was uniform throughout the state.

All this worked well enough, but there were bumps along the way. Several areas wanted exemptions to the statewide rules because they thought they already had superior emergency care; this was not allowed. The firemen and rescue squads were in a different department of the state and had their own training. It was difficult to get them to abide by the standards of the OEMS, but eventually they came on board. The OEMS was able to make great use of the community colleges to train personnel; this was a great success and it continues today. **NCMJ**

Research and Evaluation in Out-of-Hospital Emergency Medical Services

Herbert G. Garrison, MD, MPH; Jane H. Brice, MD, MPH

When people dial 9-1-1 to request assistance for a medical emergency, they expect the responding paramedics and emergency medical technicians (EMTs) to provide safe, competent, and effective care. Competent practice in medicine and health care should be based on evidence that is substantiated by research. Such is far from the case for out-of-hospital emergency medical services (EMS), whose practitioners commonly utilize protocols and interventions that have limited substantiation from research. Instead, much of the EMS care delivered is based on expert opinion and consensus or has been taken directly from the hospital to the street with no investigation.

The gaps in EMS knowledge and the structural barriers to filling those gaps have been well-documented.[1-3] Investigators in North Carolina have a good track record in EMS research and are working toward filling those gaps. Research in EMS in North Carolina will be even better once investigators access a new statewide population-based data system that the state Office of EMS has implemented. There are, however, many more steps to take to allow EMS research to fill the gaps in knowledge.

Gaps in Knowledge

The gaps in EMS knowledge were made clear by a recent systematic review of the medical literature. Smith et al[4] identified 400 out-of-hospital trials with steady increases in trials through the late 1990s. Nearly two-thirds (63%) of the 400 reports of trials concerned resuscitation and cardiac care. While resuscitation research has improved outcomes from cardiac arrest and demonstrated the benefit of different specialties collaborating on one disease entity, similar progress is lacking on other fronts. As the authors point out: "The principal finding of this study is the contrast between the wide scope of the out-of-hospital field (resuscitation, airway diseases, injury, out-of-hospital medical treatments, etc) and the lack of high-quality evidence on which to guide practice. Although taking nothing away from the quality of research in this area, cardiac arrest and acute resuscitative attempts account for only 2% of all ambulance responses.… Therefore, the majority of interventions used in the out-of-hospital environment are not based on strong evidence.…"[4]

There are many other EMS interventions that require study. The National EMS Research Strategic Plan[3] assembled and prioritized an exhaustive list of core topics for which there is a

> *"Competent practice in medicine and health care should be based on evidence that is substantiated by research. … Instead, much of the EMS care delivered is based on expert opinion and consensus or has been taken directly from the hospital to the street with no investigation."*

Herbert G. Garrison, MD, MPH, is a professor of Emergency Medicine at the Brody School of Medicine at East Carolina University, director of the Eastern Carolina Injury Prevention Program of the University Health Systems of Eastern Carolina, and associate director of Medical Services for the North Carolina State Highway Patrol. He can be reached at garrisonh@ecu.edu or 600 Moye Boulevard, Greenville, NC 27834.

Jane H. Brice MD, MPH, is an associate professor in the Department of Emergency Medicine at The University of North Carolina at Chapel Hill School of Medicine, medical director of Orange County EMS, and chair of the Disaster Committee for UNC Hospitals.

need for investigation. Questions in need of research answers include: What are the most effective and safe EMS airway management strategies? Which EMS treatments, including destination decisions, are effective for acute cardiac ischemia? Does out-of-hospital therapeutic hypothermia mitigate brain injury? Which patients, if any, require spinal immobilization? What are the attributes of professional competency in EMS? Is air medical transport cost-effective? What is the impact of emergency department overcrowding on the delivery of EMS care?

Some questions have significant implications for North Carolina. For example, what is the right mixture of staffing an ambulance: one paramedic and one EMT, two paramedics, or two EMTs with backup from a paramedic-staffed quick response vehicle? This question is unimportant when resources are plentiful. However, resources for EMS are shrinking, volunteers are fewer, and paramedics are in short supply.[5]

Are the gaps in knowledge important? The answer is an unequivocal yes. While a call to 9-1-1 will likely produce an ambulance and a ride to the hospital, there is no guarantee the care will be consistent from one EMS system to another. A recent study comparing systems across the nation found that out-of-hospital care for trauma patients varied substantially.[6] As Delbridge and March[7] pointed out in their commentary on this study, "Rather than indicating areas of poor quality, variation in out-of-hospital care for trauma patients may indicate a collective uncertainty about the effectiveness of some interventions."

Structural Barriers

The National EMS Research Agenda[1] highlighted 5 impediments to high quality EMS research: (1) a paucity of highly skilled researchers; (2) inadequate funding; (3) failure of EMS professionals to understand the importance of conducting EMS research and translating the findings into clinical practice; (4) a lack of integrated information systems that provide for meaningful linkage with patient outcomes; and (5) logistical problems in obtaining informed consent.

Removing these barriers takes on a special urgency when one considers the impact they may be having on EMS research productivity. Since 2000 there has been a precipitous drop in the number of published EMS research trials.[4] It is unclear why this decrease in studies has occurred. But the implication is very clear: the structural barriers to EMS research are effective.

North Carolina's Role in Filling the Gaps

The good news is that researchers in North Carolina are doing their part to bridge the gaps in EMS knowledge despite the barriers. The record of EMS contributions from North Carolina is too long to list here. As examples, investigators in our state are producing new knowledge on the effectiveness of out-of-hospital electrocardiograms,[8] the role of EMS in public access defibrillation,[9] the duty of EMS in reporting domestic violence,[10] and the out-of-hospital care of stroke patients.[11] But much work remains.

Next Steps

What should we do here in North Carolina to facilitate research and evaluation of EMS interventions and to assure that the care provided on the streets and in the homes of our state is evidence-based? First, we should and do congratulate the emergency medicine programs on the work already accomplished and encourage them to keep EMS research as a priority in their departments. The academic departments of emergency medicine in this state have an obligation to lead the efforts to evaluate the evidence, conduct high quality EMS research, and make recommendations on what paramedics and EMTs should and should not be doing in the field. To this end, they should foster collaborative partnerships with other specialties that can be leveraged for external funding. In addition, they should seek EMS fellows with passion and energy and facilitate their learning and investigations. Emergency medical services research will take off when investigators with passion have the partnerships and resources in place to advance knowledge.

Second, these departments should work closely with their respective institutional review boards (IRBs) to jointly explore the problem of obtaining consent on EMS patients who are minimally to nonresponsive and who have no relatives at hand. Mutual understanding of the issues implicit in out-of-hospital informed consent will lead to stronger research protocols. The more EMS researchers interact with the IRB on the problem, the easier it will be to gain approval of out-of-hospital clinical research on unresponsive patients.

Third, while North Carolina has a good system for approving new therapies and practices, the system could benefit from a few modifications. In the current process, proposed additions are vetted by the state EMS medical director and the Office of EMS (OEMS). The medical director then makes a recommendation to the NC EMS Advisory Council. The members of that group will approve the recommendation, which then goes to the NC Medical Board. This system works well but could be improved with two modifications: (1) the state medical director should have the discretion of commissioning outside systematic reviews of proposed interventions, especially for those therapies that are controversial or are being pushed by a special interest group; and (2) the NC OEMS should develop a system for periodic examination of current approved therapies and practices to determine what should be eliminated due to a lack of support from research.

North Carolina is very fortunate to have a progressive Office of EMS. Because of its progressiveness, North Carolina now has a statewide, state-of-the-art population-based data system to which data are submitted by all EMS agencies in North Carolina.[12] Once this data is linked to outcomes, investigators will be able to study—on a broad scale—very important questions about the effectiveness of EMS interventions. This is one of the most important developments in EMS research and evaluation for our state in a long time.

Expectations

North Carolinians expect and receive a prompt response from EMS when they call 9-1-1. They have an equal expectation that EMS care will be the best possible and will be based on evidence from credible research. North Carolina provides leadership for so many other fields and we should likewise be leaders in EMS research and help break down the barriers and advance EMS knowledge. The people of our state should expect nothing less. **NCMJ**

COMMENTARY

Emergency Medical Services Education:
Past, Present, and Future

Gregg S. Margolis, PhD, NREMT-P

As medical technology expanded and became increasingly specialized in the 1960s a need emerged for a cadre of health care workers with specific skills and knowledge. In 1966, Congress passed the Allied Health Personnel Training Act (P.L. 89-751) which paved the way for a virtual explosion in the variety and types of occupations collectively referred to as "allied health professions." Most established and newly forming allied health professions developed specialized educational program accreditation models that paralleled those of nursing and medical schools. The American Medical Association Council on Medical Education collaborated with professional associations to establish educational standards and guidelines for many health sciences education programs in this era.[1]

As a result, the educational infrastructure of most allied health programs followed a health care or medical model. Most allied health professions built educational systems by providing funding for pilot programs in established institutes of higher learning, developing faculty, and investing in national educational program accreditation and credentialing systems. Emergency medical services (EMS) education developed down a very different path which by all accounts has played a significant role in the way in which the EMS professional has been integrated into the larger health care workforce and system.

Also in 1966, the National Academies of Science National Research Council published the landmark paper *Accidental Death and Disability: The Neglected Disease of Modern Society*, which provided considerable funding for the development of EMS throughout the nation.[2] It reported that "there are no generally accepted standards for the competence or training of ambulance attendants" and recommended that "there is a need for delineation of a standard course of instruction [for ambulance personnel]." It was from this recommendation that the practice of developing nationally standardized education for EMS personnel began and continues today.

> *"An EMT in one state may not have the same (or even similar) education, training, or scope of practice as in another state. This variation causes confusion among the public and colleagues in other disciplines as well as making professional mobility and recognition challenging."*

In contrast to the model followed in most other emerging allied health professions, EMS began what would become a reliance on a centralized curriculum model. In 1969, the Highway Safety Bureau (now the National Highway Traffic Safety Administration, NHTSA) contracted with Dunlap and Associates to develop a curriculum to standardize ambulance attendant education. In 1971, the Emergency Medical Technician-Ambulance (EMT-A) National Standard Curriculum (NSC) was released and included specific learning objectives, highly detailed lesson plans, and hours of instruction.[3] This document established a precedent, and to a large extent,

an expectation from the EMS educational community for federally developed, highly detailed course support materials.

The EMT-A NSC was a highly efficient method of stimulating the creation of EMT training programs nationwide. Especially in an area where few EMTs existed and in a time when many courses were taught by nurses or physicians, the NSC proved to be a useful way of providing consistent training to a new occupational group. In part due to the success of the EMT-A NSC, NHTSA contracted with Dr. Nancy Caroline, then with the University of Pittsburgh, to develop the first EMT-Paramedic National Standard Curriculum in 1977.

Throughout the late 1970s and 1980s, the NHTSA EMS curricula became the defacto standards for EMS education and were referenced in many state laws and administrative rules. The NSC had an impact beyond education and in many states became the basis for the scope of practice for EMS personnel. All levels of the NSC were revised in 1984 by the National Council of State EMS Training Coordinators and again in the mid-1990s under contract with the Center for Emergency Medicine in Pittsburgh, PA. The 1990s revisions became particularly contentious because the NSC revision process was the only major national forum for discussing EMS education and scope of practice issues. While the EMS community began to ask the question "Is there a better way?" another major EMS initiative was beginning to take shape.

In the mid-1990s NHTSA began a bold project to set a path for the future of EMS. The *EMS Agenda for the Future* proposed a vision for EMS beyond that of an emergency response system. Specifically, it proposed that EMS assume a larger public health role.[4] To support this goal, the agenda recommended a number of changes to the EMS educational infrastructure, including an expansion of accreditation, affiliation of higher level EMS education with academic institutions, and replacing the NSC with "core content."

NHTSA convened a work group to deliberate on ways to improve EMS education. The *EMS Education Agenda for the Future; A Systems Approach* proposed an improved system intended to prepare the next generation of EMS professionals. Drawing on the strengths of the existing system that relied heavily on federally developed curricula and those of other professions, a system was proposed that provides for efficiency, consistency, and coordination. The *EMS Education Agenda for the Future* proposed the replacement of the National Standard Curricula with 3 documents (National EMS Core Content, National EMS Scope of Practice Model, and National EMS Education Standards) and the further support of National EMS Certification and Educational Program Accreditation. The authors believe this approach blended the advantages of the experiences of both EMS and allied health education.

The EMS Education Standards, under development in 2007, are intended to replace the need for highly detailed, nationally standardized curricula. The standards are being written in such a way as to encourage instructional creativity and educational innovation while clearly conveying what must be included in EMS educational programs. The creation of the *National EMS Scope of Practice Model* (released in 2006) as a separate document facilitates the decoupling of education and scope of practice issues and should facilitate educational change initiatives.

The format of education standards, modeled after accreditation standards and guidelines, is admittedly broader and subject to more interpretation than detailed curricula or lesson plans. For this reason, the success of the EMS education standards will rely on the entire EMS educational system. When supported by national accreditation and certification, there will be considerable guidance as to what must be taught in each level of EMS education, with the flexibility of how to teach it left up to individual programs and instructors, where it should be.

In 2006, the Institute of Medicine of the National Academies (IOM) released the report *Emergency Medical Services at the Crossroads* which recommended that states strengthen the EMS workforce by adopting common EMS certification levels, accepting national certification for state licensure, and requiring national accreditation of paramedic education programs.[5] For EMS to evolve, these educational initiatives should receive support.

Four Recommendations

Adopting Nationally Consistent Levels of Practice and Nomenclature

There is considerable state to state variation in the titles and scope of practice of EMS personnel; thus, the training and education of EMS personnel varies from state to state. A recent study conducted by the National Council of State EMS Training Coordinators identified at least 39 unique levels of EMS provider (many with slightly different titles) in a survey of 29 states. An EMT in one state may not have the same (or even similar) education, training, or scope of practice as in another state. This variation causes confusion among the public and colleagues in other disciplines as well as making professional mobility and recognition challenging. The lack of consistency creates inefficiencies because educational support materials and services (eg, accreditation and certification) may not be aligned with an individual state's requirements.

Require National Certification for State Licensure

The primary purpose of licensure and certification must be to protect the public against subcompetent providers.[6] Most mature health care professions have a single national standard for the measurement and verification of entry level competence. Unfortunately, no such system exists in EMS. The National Registry of EMTs is utilized by 45 states as part of the credentialing process for each level of EMS personnel. Fourteen states and the District of Columbia use a state level credential for at least one level of EMS personnel.[7] These systems vary in credibility, validity, and content. For EMS to mature as a discipline, a single national definition of competence at each provider level must exist and be adhered to by all states.

The EMS Name Game

The credentialing and titling of emergency medical personnel is currently a confusing picture for individuals not intimately familiar with emergency medical services (EMS). First, it is essential to realize that each state has the responsibility and authority to create EMS licensure/certification levels. While many other levels exist, the National Highway Traffic Safety Administration has developed curricula for 5 levels of EMS personnel: First Responder, Emergency Medical Technician (EMT)-Basic, EMT-Intermediate (1985 edition), EMT-Intermediate (1999 edition), and EMT-Paramedic. Most states have adopted some of these levels (with minor changes in scope of practice), and many states have created additional levels to address local needs.

National level	Approximate number of training hours	Number nationally certified[1]	General role	Examples of skills and knowledge
First Responder	40-60 hours	13 510	Intended to serve as the initial responder generally arriving before other EMS resources.	Cardiopulmonary resuscitation (CPR), oral airways, bleeding control, ventilation.
EMT-Basic	110-140 hours	198 200	Intended to represent the minimum training necessary to serve as an ambulance team member.	Basic airway management, bag valve mask ventilation, automated external defibrillator (AED) use, spinal immobilization, splinting, extrication.
EMT-Intermediate 85	60-120 hours[2]	12 701	An EMT-Basic with a few selected advanced skills.	Dual lumen airways, intravenous access and fluid administration.
EMT-Intermediate 99	200-400 hours[2]	2527	Intended to provide core advanced resuscitation skills, especially in rural settings.	Endotracheal intubation, basic electrocardiogram (EKG) recognition, cardiac arrest resuscitation medications.
EMT-Paramedic	800-1200 hours[2]	61 121	Represents the highest level of EMS credential and intended to provide advanced assessment and treatment of a broad range of emergency conditions.	Needle cricothyrtomy, needle thoracentesis, advanced EKG recognition, emergency medications and pain relief.

The recently released National EMS Scope of Practice Model proposes 4 levels of credentialing for EMS personnel: Emergency Medical Responder, Emergency Medical Technician (EMT), Advanced Emergency Medical Technician (AEMT), and Paramedic. It is expected that many states will be transitioning to these levels over the next few years.

---

[1] As of Jan 2007. Note, no reliable data exists on the number of state licensed/certified EMS personnel, but it may be 2 to 3 times the number of those nationally certified.

[2] In addition to EMT-Basic, which is generally a prerequisite.

Link National Certification Eligibility to Graduation from an Accredited Institution

The primary purpose of the accreditation of educational programs is to protect students and potential students from enrolling in an educational process that lacks credibility. Accreditation of educational programs plays a small role in EMS compared to most other allied health professions. The Committee on Accreditation for the EMS Professions (CoAEMSP) currently accredits 220 paramedic programs—probably representing one-half to one-third of the paramedic programs nationally. While accreditation is technically a voluntary process, most professions limit eligibility of entering the credentialing process to graduates from accredited programs. Without requiring a single national educational program accreditation process, it will be effectively impossible to implement national EMS educational change initiatives.

Increase the Role of Higher Education in EMS

One educational issue not recommended by the IOM but that deserves support is to increase the role of higher education in EMS. Formal post secondary educational institutes play a comparatively small role in EMS education. While many community college, technical schools, and universities sponsor EMS educational programs, a large percentage of EMS education remains agency or hospital based. A significant portion of EMS education still occurs in an academy setting or is sponsored by small proprietary training companies. While some of this training is excellent, it offers the student little in terms of formal recognition of EMS education toward the achievement of larger academic or degree goals.

The EMS community should recognize the associate degree as the appropriate academic preparation for paramedic level education. Emergency Medical Technician-Basic education should be sponsored by academic institutions that have the resources, student/faculty support services, and stability necessary to assure quality education. All EMS-related courses should offer college level credit.

Currently, 14 institutions offer bachelor's degrees in EMS.[8] Unfortunately, there is no consensus as to the role that these degrees play in EMS career progression and there is little consistency in the curricula. While these programs should be supported, they must be encouraged to develop a vision for the role of bachelor's (and master's) level education in EMS.

Conclusion

Occupational groups that have successfully transformed themselves have typically done so through improvement of their educational systems. Education is the catalyst for change, growth, and evolution of groups of people. The history and sociology of professions are filled with examples (many in health care) of workers who had a desire for an expanded role that offered greater service to the community. The EMS professions are at such a crossroads and will be able to realize the vision of the *EMS Agenda for the Future* only through bold leadership and support of educational change initiatives. **NCMJ**

COMMENTARY

Responding to the Educational Needs of Our Emergency Medical Services Responders

William Lineback, BS, EMT-P

Almost 30 years ago, community colleges across North Carolina began providing instruction to members of fledgling emergency medical service (EMS) agencies—known then as "rescue squads." The role that North Carolina community colleges currently play in educating future emergency medical technicians is a direct result of the federal 1973 EMS Systems Act.

Presently, 58 North Carolina community colleges serve several roles in the delivery of medical education to current and future EMS personnel. In 2005-2006 there were 32 777 individuals enrolled in one or more EMS courses at North Carolina community colleges. In addition to preparing students with no prior medical background to become EMS personnel, community colleges provide credentialed EMS personnel with ongoing continuing education. Because community colleges throughout the state are readily accessible to the majority of North Carolina's EMS and firefighting personnel, these institutions provide much of the education necessary for these first responding professionals to remain proficient and knowledgeable of medical developments. This accessibility also serves the public well by making first aid, CPR, and safety and prevention instruction readily available at a reasonable cost. By consolidating state and county resources, community colleges also can provide access to EMS educational equipment that is beyond the budgetary reach of many smaller EMS agencies or systems. Paramedics must have access to intraosseous drills, 12-lead electrocardiogram (EKG) monitors, simulation manikins, ventilators, continual positive airway pressure devices, and other expensive equipment to become proficient. North Carolina community colleges are uniquely poised to provide access to these and other necessary pieces of equipment.

> *"In addition to preparing students with no prior medical background to become EMS personnel, community colleges provide credentialed EMS personnel with ongoing continuing education."*

Our state's community colleges also are playing a role in meeting the medical care needs of our communities across the state. With the ranks of senior citizens swelling with the influx of the baby boomers, the demand for health care workers in all fields, especially EMS, will increase for the foreseeable future. This presents several challenges to our state's community colleges that must be solved. Our colleges must be able to locate qualified and knowledgeable EMS faculty. This is difficult to do when community college faculty salaries are often lower than those found at EMS agencies, which are already shorthanded and forced to compete with colleges for the limited number of experienced EMS professionals. Also, colleges must attract more students into their EMS and health care programs. This is challenging because average starting EMS salaries in the state are low. Last, but certainly not least, community colleges must be better funded. Too many colleges are forced to squeeze by with outdated equipment, facilities in need of major repair, and inadequate staffing. Funding is a critical issue to meeting these challenges.

Emergency medical service education underwent a significant change in 2004 when modifications to the North Carolina Administrative Code were enacted. Section 10A-NCAC-13P allowed community colleges and other educational institutions

---

William (Bart) Lineback, BS, EMT-P, is department head of the Emergency Medical Science Department at Wake Technical Community College. He can be reached at wblineba@waketech.edu or Wake Technical Community College, Health Sciences Campus, 2901 Holston Lane, Raleigh, NC 27610.

that were providing EMS education to assume more control of their programs. These approved institutions were charged with serving as the gatekeepers for those choosing to enter the EMS workforce.

Additional changes lie ahead for education in EMS, especially in the community college setting. The National Highway Transportation Safety Administration's *EMS Education Agenda for the Future: A Systems Approach* details 5 major national education system components to be developed and implemented in the not-too-distant future: core content, scope of practice, education standards, program accreditation, and certification. While physicians will govern core content and regulatory bodies govern scope of practice, North Carolina community college EMS faculty members will have input into developing and updating education standards and community colleges will apply for EMS program accreditation.

Community colleges will also play a part in shifting EMS workforce demographics to become more representative of the communities the EMS agencies and the colleges serve. Community colleges must work to target underrepresented populations in EMS—African American, Hispanic, female—and assist their members to enter and succeed in the completion of EMS programs.

Our community colleges must look to partnering with other agencies to develop new programs and new venues for increasing the health care workforce. Those community colleges offering 2-year Associate in Applied Science EMS degree programs will need to partner with 4-year colleges and universities to offer seamless bridging to health care-related bachelor of science degree programs in EMS, nursing, premedicine, and other health care fields. Within their own programs, community colleges will need to develop bridging programs for health care workers to move from one discipline to another: registered nurse to EMT, paramedic to respiratory therapist, and so forth.

As EMS evolves and the paramedic scope of practice increases in complexity, access to EMS associate degree programs will become a necessity for potential students so that they can master the patient care procedures to be added. Currently in North Carolina, paramedics may perform intraosseous infusions, read and interpret 12- and 18-lead EKGs, perform needle cricothyrotomies, intubate (oral and nasal intubation), perform rapid sequence induction, and perform needle thoracotomies. Five to 10 years from now, especially as community needs for health care workers drive paramedics from the ambulance into the public health arena, the number and complexity of allowed procedures will likely grow.

One challenge currently being addressed by our community colleges is the increasing need for distance education offerings. Even though EMS has a strong hands-on component, much of the cognitive and affective instruction could be conducted through various nontraditional methods including Internet web-based instruction. Several community colleges in the state have developed "hybrid" courses in which the students meet in a traditional lab setting for skill instruction and evaluation while they attend the didactic portion of the course online. For courses without a psychomotor component, some colleges are offering them entirely online.

North Carolina community colleges are also adapting to meet the scheduling needs of the medical community. They are designing and providing programs with flexible scheduling to accommodate those students with rotating shift work schedules —"flip-flop" scheduling—allowing students to attend classes on changing days of the week. Several colleges are developing or offering specialized academies to EMS agencies so that newly hired personnel with limited EMS education can rapidly be taught and immediately begin to contribute to the workforce. Our North Carolina community colleges play an important part in the maintenance and growth of our state's EMS workforce and look to provide even greater contributions in the coming years. **NCMJ**

Baccalaureate Emergency Medical Services Education in North Carolina:

History, Challenges, and Opportunities

Michael Hubble, PhD

Emergency medical services (EMS) is a critical component of the public health response system, treating and transporting 25 to 30 million patients per year.[1] The number of patients treated by EMS is expected to continue to increase, and for some of these patients, their prehospital treatment will have a dramatic impact on their clinical outcomes. Consequently, a well-educated and competent prehospital workforce is an essential component of community health.

Prior to 1976 all paramedics received nondegree "certificates" as opposed to degrees to verify their training. Today these certificate programs exist alongside associate in applied science (AAS) and bachelor of science (BS) degree programs. For some, this raises questions about the necessity of simultaneously offering both degreed and nondegreed paramedic programs. Unfortunately, there is a paucity of research about the influence of educational preparation on patient outcomes.

However, some evidence suggests that education improves the delivery of EMS health care. One study noted that paramedics who held degrees, although not EMS degrees specifically, were better able to calculate drug dosages than nondegree paramedics.[2] There is also evidence that students who attend an accredited program are more likely to pass the National Registry of EMT-Paramedic exam,[3] and by extension, are better prepared for roles as field clinicians. This same study also found pass rates to be higher for those holding an AAS degree and baccalaureate degree. A separate investigation found a link between pass rates and the instructor's educational level. The first-time pass rate was 62.7% for students taught by an instructor with an associate degree, 69.4% for bachelor's degree, 72.7% for master's degree, and 78.5% for doctoral degree, which suggests the need for baccalaureate and/or graduate-prepared educators.[4] Moreover, Brown et al found that although the EMS administrators rated both degree and nondegree paramedics equally, 46% preferred hiring AAS degree paramedics over nondegree paramedics, and 40% reported promotion preference for degree paramedics.[5]

> *"Western Carolina University supports the paramedic programs within the North Carolina Community College System and recognizes the need for seamless articulation of students from the community college programs."*

In addition to the perceived clinical advantages of EMS degrees, degree programs also prepare the future generation of EMS leaders including researchers, administrators, and educators. The *EMS Education Agenda for the Future* (EMSEAF) recommends that all EMS programs attain national accreditation. At the baccalaureate level it will be particularly important to expand opportunities for degrees for EMS educational program directors because that credential is crucial for the community colleges to be able to meet the Committee on Accreditation of Educational Programs for the Emergency Medical Services Professions (CoAEMSP) accreditation requirements.

Michael Hubble, PhD, is program director of the Emergency Medical Care Program at Western Carolina University. He can be reached at mhubble@email.wcu.edu or 122 Moore Hall, Western Carolina University, Cullowhee, NC 28723.

The Role of Western Carolina University in EMS Education

College level paramedic education in North Carolina began in 1976 when Western Carolina University (WCU) established the Emergency Medical Care (EMC) program as the nation's first baccalaureate program for EMS. Concurrently, Guilford Technical Community College established North Carolina's first paramedic program leading to an AAS degree. Since then, 13 additional community college degree programs have been established in North Carolina. Accredited in 1988, WCU's EMC program remains the only baccalaureate program in North Carolina and one of only 12 similar programs in the US.

As a baccalaureate program, the EMC program has a unique dual educational role: to educate paramedic practitioners and future EMS leaders. Broadly defined, future EMS leaders include EMS administrators, educators, advanced practice clinicians, and researchers. To achieve these goals, the curriculum requires two years of general education and preprofessional coursework followed by two years of the paramedic core curriculum and area of concentration. Unique to baccalaureate degrees, the general education component develops skills in writing, thinking, and analyzing. These, along with two semesters of chemistry and two semesters of anatomy and physiology, serve as the foundation for the paramedic curriculum. The junior and senior years constitute the professional course sequence and in addition to the core paramedic curriculum, require 17 semester hours in one of two areas of concentration: science or health services management. The science concentration is essentially premedicine and includes upper level courses in biology, chemistry, and physics. The management concentration prepares graduates to assume management roles and incorporates courses in personnel administration, marketing, accounting, finance, and health policy. Both concentrations require a course in research methods and biostatistics because of the increasing role of research in EMS.

Building upon the preprofessional courses in chemistry and biology, the paramedic curriculum promotes clinical reasoning as opposed to rote memorization of signs, symptoms, and treatment algorithms. In addition to addressing state and national paramedic learning objectives, the curriculum is heavily influenced by evidence-based medicine and Bayesian clinical decision making. Furthermore, in an effort to facilitate integration into the overall health care system, students are introduced to epidemiology, injury and illness prevention, and occupational health. The curriculum is also buttressed by an extensive clinical program that includes rotations through coronary intensive care unit (ICU), neurotrauma ICU, neonatal ICU, pediatrics and pediatric ICU, labor and delivery, operating room, cardiac catheterization lab, psychiatry, and dialysis rotations, in addition to emergency department, helicopter, and ambulance rotations. Because paramedics are increasingly choosing to practice in nontraditional venues such as urgent care clinics and emergency departments, broad-based clinical experiences are crucial for well-rounded clinicians.

Challenges and Opportunities

The National Standard Curriculum (NSC) describes the knowledge base for EMS in the United States.[6] The curriculum proved useful during the formative years of EMS, however, the NSC is being replaced by a new approach to EMS education as outlined in the *EMS Education Agenda for the Future.*[7] Once implemented, the EMSEAF recommendations will define the EMS general body of knowledge, delineate the technical skills within an EMS scope of practice, provide education standards for instructors and educational programs, and define procedures for national certification of paramedics and accreditation of educational programs. The EMSEAF is EMS education's guidebook for advancing the profession.

North Carolina has many opportunities to advance EMS education. Likewise, there are many challenges to delivering educational opportunities for current and future North Carolina paramedics. Due to changing demographics in the US, the demand for paramedics is expected to climb. The National Bureau of Labor Statistics estimates that between 2004 and 2014 an additional 21 000 paramedics will be needed to meet demand.[8] This will be a serious challenge because North Carolina and the nation as a whole are currently experiencing a paramedic shortage.

Like most community college programs, WCU responded to the paramedic shortage by expanding enrollment capacity for initial paramedic training. In addition, WCU has been supportive of increasing access to baccalaureate and master degree programs using distance learning venues. It has allocated faculty and technical support to expand online access at both levels over the past 7 years. However, a stronger collaborative approach to recruitment and education is needed. A successful network should include the public school system, local EMS systems, community colleges, and WCU to consistently recruit students and deliver efficient, effective, and coordinated educational services at the associate and baccalaureate levels.

Articulation

Western Carolina University supports the paramedic programs within the North Carolina Community College System and recognizes the need for seamless articulation of students from the community college programs. To facilitate this transition, WCU has established articulation agreements with all North Carolina associate degree EMS programs. These agreements are particularly important for the distance learning program which is offered only to practicing paramedics who hold AAS degrees. The distance learning technologies enable paramedics across the state to access the program without displacing them from the communities in which the serve.

Student Support

Many students come to a university setting unprepared for the rigor of university-level academic work. While our distance learners are older and bridging from an associate degree, they face some of the same challenges as our traditional college-aged students. Many must strengthen writing, math, and science skills. To address these needs, WCU has a writing and math tutoring center that is available to all resident students and has been extended to distance learning students through distributed learning technologies.

Increasing tuition costs, coupled with limited scholarships and shrinking financial aid for students in general, have negatively impacted both student recruitment and retention. From 2001 to 2005, the cost of attending a public university in North Carolina increased 33%, and a year in school now consumes 25% of the average North Carolinian's household income.[9] To put this increase in perspective, the urban consumer price index rose only 18% during the same period. A dedicated scholarship for students interested in EMS would help attract students into the profession and make the EMS educational programs more affordable. Furthermore, graduation rates would be improved if students were not obligated to work while in school to pay for tuition and other financial obligations.

Clinical Support

The cornerstone to any paramedic training program is its clinical rotations. Unfortunately, EMS programs at WCU and the community colleges must compete for clinical space with nursing and other allied health programs. While EMS agencies recognize the recruiting benefit of entering into clinical agreements with paramedic educational programs, most hospitals have a less clearly-defined benefit.

Clinical rotations are guided by the National Standard Curriculum which recommends a minimum number of patient contacts and skills for paramedic students, but these recommendations are not based upon empirical evidence. Furthermore, in a recent analysis of paramedic graduates across the US, only 6% completed all of the clinical experiences recommended by the current National Standard Curriculum and less than half of the graduates completed the required geriatric, trauma, psychiatric, obstetric, and pediatric patient assessments.[10] Complicating matters, more recent research indicates that the NSC recommendations may underestimate the true number of repetitions necessary to attain clinical competence. Wang et al reported that up to 25 intubations were necessary to attain competence, despite the recommendation of 5 by the NSC.[11] Many EMS education programs encounter difficulty gaining access to the operating room to perform intubations.[12] To ensure the clinical competence of paramedics, it is imperative that hospitals and the physician community recognize the importance of their participation in clinical rotations for paramedic programs.

Research Support

The *National EMS Research Agenda* (NEMSRA), published in 2002, noted the lack of scientific evidence in support of most prehospital interventions.[1] The NEMSRA specifically noted the lack of cost-effectiveness and outcome studies. This widely disseminated report recommended, among other things, that educational programs include an introduction to the research process as part of the paramedic curriculum. It also recommended that academic institutions develop programs to train EMS researchers and to establish organizational partnerships that promote collaboration between academia and EMS agencies to advance the EMS scientific body of knowledge.

Recognizing the research opportunities afforded by its unique location in a university setting, WCU's EMC program is committed to promoting research in EMS. A research methods and biostatistics course is a required component of the undergraduate curriculum. At the most basic level, this course promotes an appreciation for the scientific method and the use of scientific evidence in clinical medicine as well as EMS administration. The course also prepares students for designing and implementing their own studies.

In an effort to increase the number of EMS researchers as recommended by the NEMSRA, the EMC program is launching a graduate program in the fall of 2008. The graduate program will offer tracks in EMS administration and EMS education. In addition to courses specific to each track, the curriculum requires substantial course work in research methods, epidemiology, quantitative methods, and biostatistics. This degree program will be entirely online in an effort to make it widely available to practicing EMS professionals.

To facilitate the research process for faculty and graduate students, the EMC program developed the Consortium for the Advancement of Research in EMS (CARE). The CARE consortium is composed of 15 EMS systems and 15 EMS education programs, and its goal is to facilitate EMS research by forming a partnership between academic settings, community college EMS programs, and EMS agencies. Launched in 2007, the CARE consortium will focus on the research priorities described in the NEMSRA Implementation Plan including clinical outcomes assessment, cost-effectiveness analyses, professional competence, and EMS systems.[13]

Although these research efforts are designed to advance the body of knowledge specific to EMS, they cannot occur in a vacuum. The investment of faculty time must be valued by academic institutions, and EMS agencies must also be willing to commit staff time and resources. Furthermore, an adequate funding stream for EMS research must be identified, which will likely include public and private funding.[1]

Conclusion

Although many challenges lie ahead, Western Carolina University is committed to taking the necessary steps to address the paramedic shortage, meet EMS research needs, and offer undergraduate and graduate level education for the future leaders of the paramedic profession. However, these efforts will be successful only to the extent that effective partnerships can be established and maintained with the EMS community, the North Carolina Community College System, hospitals, and the medical community at large. **NCMJ**

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

North Carolina MEDICAL JOURNAL

COMMENTARY

Management and Financing of Emergency Medical Services

Todd Hatley, MHA, MBA, EMT-P; P. Daniel Patterson, PhD, MPH, EMT-B

Like other organizations, emergency medical services (EMS) systems have revenues and expenses. The unpredictability of calls and the oftentimes inefficient nature of EMS operations make EMS management and financing difficult. Annually, EMS costs patients, insurers, and the federal government billions of dollars.[1] In fiscal year 2002, Medicare spent $3 billion on ambulance transportation.[1] The insufficiency of reimbursement for the total cost associated with 24 hour, 7 days per week coverage is the subject of constant debate and discussion among EMS managers. Recent modifications to the reimbursement formula used by the Centers for Medicare and Medicaid Services (CMS) has both benefited and disadvantaged many of the more than 18 000 EMS systems in America;[2-4] reducing the gap between costs and revenues for some while increasing that gap for other EMS systems. The purpose of this commentary is to describe the major components of EMS financing and management and to discuss the current and ongoing challenges in EMS financing.

Revenues to an EMS system include subsidies from local governments, income from special event support, and reimbursement for transportation of patients. Fifty-five percent of revenues for an average EMS system come from Medicare, 15% from Medicaid, 5% from private payment, and 25% from the commercially insured.[5] Personnel and benefits are the largest fixed expenses for the average EMS system.[6]

Revenues and expenses are not completely uniform across systems. For volunteer-staffed EMS organizations in very rural areas, processing bills for transportation is either not possible or an unattractive practice that would take away from the volunteer nature of the organization. Thus, most revenues for such organizations come from donations and support from local governments. In addition, submitting a bill to Medicare or Medicaid does not guarantee payment. In 2000, the average collection rate for bills submitted by North Carolina EMS systems was 25%.[7]

The average cost for an ambulance transport is $415, but ranges from $99 to $1218. Average costs in very rural areas are significantly higher than costs in urban areas, $538 and $409, respectively.[8] Ten years ago, the estimated average charge for transport to the emergency department approached $400.[9] It is unclear what the true average charge for an EMS transport actually is today. In some communities, a ride to the hospital or elsewhere can be as high as $700.[10] For a trip in a helicopter, the cost can reach thousands of dollars.[11,12] A combination of factors result in high transport costs including the need to cross subsidize transport for the indigent and uninsured and the cost of 24 hours a day readiness. Extremely high rates of turnover among personnel also contribute to inefficient budgetary practices.

> *"Fifty-five percent of revenues for an average EMS system come from Medicare, 15% from Medicaid, 5% from private payment, and 25% from the commercially insured."*

The medical necessity of EMS transportation is used by CMS to determine whether or not a patient's transportation

P. Daniel Patterson, PhD, MPH, EMT-B, is a research assistant professor for the Department of Emergency Medicine in the University of Pittsburgh School of Medicine, and director of research for the Center for Emergency Medicine of Western Pennsylvania.

will be paid. For some systems, convincing the intermediaries that an ambulance transport was medically necessary is a daily and ongoing battle. Submitting multiple claims for the same ambulance transport is not uncommon. In fiscal year 2002, the Health and Human Services Office of Inspector General (OIG) determined that 25% or $402 million dollars in ambulance transports did not meet the government's criteria for medical necessity.[1] For emergency ambulance transports, CMS defines medical necessity as a medical condition that manifests itself with acute symptoms of such severity that the absence of immediate medical attention would jeopardize the patient's health.[1] For nonemergent transportation, a ride in an ambulance is medically necessary when the patient is bed-confined and/or his/her condition is such that other methods of transportation are contraindicated.[1] The OIG report identifies transports to dialysis centers as a significant source of unnecessary transports.

Financial Obstacles

Due to the rapid increase in expenditures and difficulties in administrating benefits, the federal government in the Balanced Budget Act of 1997 called for ambulance reimbursement to be placed on a fee schedule.[2] The act proposed an implementation date of January 1, 2000. Due to the quick action and concerns of numerous EMS administrator groups throughout the United States, CMS agreed to enter into a negotiated rule making process that ultimately led to a proposed fee schedule implementation date of April 1, 2002 and a final implementation date of January 1, 2006.

While EMS administrators were able to buy some time before implementation, the final rule is now in place and the financial effects are being felt by EMS providers throughout the nation. The final rule led to the establishment of a national base rate of $171 for the transport of a patient to a medical facility. This $171 rate is supplemented by adjustment factors that modify reimbursement based patient severity, region of the country, and a special adjustment for the super rural regions. However, it still falls short of covering the actual cost of transport for most EMS providers.[4]

The national base rate of $171 dollars was chosen largely on the direct cost of providing care and transporting a patient (personnel cost, equipment cost, supply cost) and failed to incorporate the significant indirect cost associated with readiness to respond to a request for service. Factoring in the total cost of providing the temporal and geographical demand coverage necessary to respond in a timely manner to medical and surgical emergencies increases per transport estimates to as much as $300 to $400. This gap between the established national rate and the total estimated cost per transport is creating a critical financial situation for many EMS providers. Some in the EMS community have even begun litigation against the government.[13]

Compensating for this fiscal gap between the Medicare and Medicaid reimbursement is critical when one considers that this reimbursement accounts for as much as 64% of most EMS providers' patient mix. Since it is mandated that EMS providers accept this reimbursement by assignment it means that increasing rates does little to increase revenue. This leaves EMS providers with the options of either increasing their local tax subsidy or decreasing operation costs. Due to widespread fiscal pressures that are being exerted on most local municipal agencies, EMS providers are meeting enormous resistance when requesting increases to local taxes to cover the cost of providing EMS. This only leaves the second option, which is to increase operational efficiency in an attempt to decrease overall operational cost.

One of the first steps many EMS providers need to take in deciding how they will compensate for decreased revenues is to spend some time developing a clear understanding of the purpose and role of their service within a given community. Many providers find themselves involved in functions other than providing emergency care. These services include things such as technical rescue, support for hazard material incidence, and other uncompensated services. In some communities, the EMS provider may be the only provider of these services, but in other communities EMS providers duplicate services more appropriately provided by other public service agencies. The decision to provide these supplemental services should be based on the needs of the community and its willingness to financially support these added services. It is important that EMS providers remember their first priority is to provide emergency medical care and transportation of patients.

The second highest leverage area of improvement that could be undertaken by many EMS providers is in the area of resource deployment. In the mid-1980s, the EMS industry was introduced to the concept of System Status Management (SSM).[14] System Status Management is a methodology used to determine the number of ambulances needed for each hour of the day, each day of the week and where these ambulances should be placed in order to respond in a timely manner to a request for emergency assistance. While the knowledge of deploying EMS resources has expanded from the use of SSM to the existence of sophisticated computer simulation models that can predict geographical grid level coverage capability, only the most sophisticated EMS systems in the nation have even adopted the use of SSM. The use of these methods could not only decrease operation costs for most EMS providers, they could also improve their ability to respond in a timely manner to the aid of sick and injured patients.

While the two issues mentioned above are important for EMS providers to address, there are many other areas in which current EMS operations could be improved and the financial viability of EMS sustained. These include things such as the implementation of more efficient and less costly education and training methods, the improved management of supply and equipment inventories, and improvements to EMS billing processes. Addressing these issues can improve EMS care of the sick and injured. However, even after implementing these ideas, the sustainability of EMS financing and management will likely continue to be a challenge for many years to come. **NCMJ**

Service Integration and Workforce Trends in Emergency Medical Services

P. Daniel Patterson, PhD, MPH, EMT-B; Michael Yonas, DrPH, MPH

To commemorate the report credited with the development of modern emergency medical services (EMS), the Institute of Medicine of the National Academies (IOM) examined the current status and future of emergency care in America. *Emergency Medical Services at the Crossroads* reports the IOM's findings and provides an informative view of our nation's EMS or prehospital emergency care system.[1] The report is part of a trend in exploring and dissecting the American system of emergency care, identifying problem areas, and making recommendations for improvement. The IOM highlights many system-wide deficiencies that inhibit EMS from accomplishing its primary mission of responding to emergencies whenever and wherever. Based on these findings, the IOM labeled the US "ill-prepared" and referred to the current EMS situation as nothing less than a "crisis."[1]

For some time, efforts have been underway to resolve many of the EMS challenges identified in the IOM's analysis. These include promoting integration of EMS with other health care services and addressing challenges associated with maintaining a skilled and experienced workforce. More recently, health care pioneers have invested time and energy into expanding the health care role and responsibilities of EMS personnel to include more preventive and primary care tasks.[2-6] As potential momentum for the formation of future policy and research in North Carolina, these trends deserve some attention.

Integration of the EMS System

The provision of basic EMS care involves overcoming many organizational obstacles on a day-to-day basis. One such obstacle is the organizational clash between police, fire, and EMS—the 3 components of the public safety triad. While these 3 are often seen working together at the scene of an accident or emergency situation, substantial differences in roles and responsibilities have created conflict and inhibited integration.[7-9] Specifically, there appears to be a lack of mutual professional respect for the vital roles filled by EMS, hospital staff, and public safety staff. Integration among these professionals and organizations is stalled or significantly hindered by institutional and/or cultural barriers.

> *"Improved integration of EMS services with those provided by public safety, public health, and all other health care services has been touted as a solution to access and EMS infrastructure problems."*

Integration refers to the formation of a seamless communications network among all parties and agencies involved in the care of an individual's emergent or chronic health needs. Improved integration of EMS services with those provided by public safety, public health, and all other health care services has been touted as a solution to access and EMS infrastructure problems.[10,11] The Medicare Rural Hospital Flexibility Program (Flex) is perhaps the most visible integration improvement effort for EMS. This program was created as part of the Balanced Budget Act of 1997 to strengthen and improve rural health care

P. Daniel Patterson, PhD, MPH, EMT-B, is a research assistant professor for the Department of Emergency Medicine at the University of Pittsburgh School of Medicine, and director of research for the Center for Emergency Medicine of Western Pennsylvania. He can be reached at pattersond@upmc.edu or 230 McKee Place, Suite 400, Pittsburgh, PA 15213.

Michael Yonas, DrPH, MPH, is an assistant professor in the Department of Family Medicine at the University of Pittsburgh School of Medicine.

infrastructure primarily by converting small rural hospitals to critical access hospitals (CAHs). A CAH is a hospital that qualifies for special reimbursement and federal funding that reduces the likelihood of the hospital closing. The Flex program endeavors to integrate EMS into Flex-related rural health care networks. Since its inception, the program has supported numerous service integration activities led by local and state authorities. Some examples include partnerships between EMS systems in different areas of a state, support for the development of state prehospital databases and information systems, and creation of EMS partnerships with many of the 1286 designated critical access hospitals.

However, the investment in integrated EMS service structures has not been universally adopted. One evaluation finds that many states have chosen to focus on bolstering education systems, addressing human resource challenges, or providing local services small grants for purchasing equipment.[12] Integration initiatives are inhibited by uncertainty among all parties over EMS's role in health care networks, EMS fears over losing autonomy, preoccupation with day-to-day challenges, and a general misunderstanding of what integration is and what it means.[13] Despite these obstacles, interest and support for the integration of EMS is high, meaning that federal and state initiatives will likely continue to promote integration as a national EMS priority.

Addressing Workforce Challenges

Improved integration may curb poor recruitment and retention of EMS professionals which are, by all accounts the most widely reported problems for EMS systems.[14-23] National EMS organizations rank recruitment and retention first in a long list of challenges for rural EMS systems.[24,25] Exploration of new EMS staffing models was recently posited by the IOM as a possible remedy to workforce problems.[1] The National Highway Traffic and Safety Administration (NHTSA) Office of EMS, the federal Office of Rural Health Policy, and the National Rural Health Association are also actively examining these issues in order to improve knowledge around the EMS workforce.

There is very little certainty over the true size of the nation's EMS workforce. Estimates range from a few hundred thousand based on documentation from the US Department of Labor[26] to as many as 1 million (including all possible first responders) which is based on a survey of states conducted by an EMS consulting firm.[27] NHTSA is leading national efforts to improve and expand what we know by funding the Longitudinal Emergency Medical Technician Attributes and Demographics Study[1] and the Emergency Medical Services Workforce for the 21st Century project.

The current body of EMS workforce research does not adequately document the critical elements associated with turnover of EMS personnel, whether paid or volunteer, leaving many questions about the nature of the workforce problem unanswered. Factors like burnout, stress, and dissatisfaction with certain aspects of the occupation have been identified in several studies as influential or potentially influential in turnover.[28-30] Few studies have explored why individuals enter the profession. Among those studies exploring entry, excitement and altruism have been identified as two important attractants.[29,31] The influence of these factors may differ across rural and urban areas. Rural community EMS systems are staffed primarily by volunteers[32] who may enter and leave the profession for reasons that differ from paid professionals. Research is needed to identify what differences may exist between volunteer and paid personnel. With funding from the federal Office of Rural Health Policy, investigators at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina are exploring some of these issues.

In North Carolina, recruitment and retention are visible challenges for EMS and they receive substantial attention from the media and state EMS officials. In Wake, Cabarrus, Duplin, and other North Carolina counties EMS officials are facing critical human resource challenges including poor recruitment and high turnover.[18,21,33] In some North Carolina communities, fewer ambulances are put on the road due to inadequate staffing.[18] Reports suggest that EMS professionals in these areas leave for better pay in other systems or in other professions like nursing. In rural areas, low pay is a major factor detracting paid personnel,[33] whereas availability of time appears to be the primary detractor for volunteers.[15] The NC Association of EMS Administrators, in partnership with the NC Office of EMS, is surveying EMS officials, credentialed professionals, and students in an effort to increase the state's understanding of workforce challenges and help in the design of materials for increasing recruitment and retention.

Expanded Role for EMS Professionals

Career advancement is potentially an important factor in recruitment and retention of EMS professionals.[29,34,35] Other than assuming greater clinical responsibility through additional EMS-specific certifications, the EMS professional career is quite limited.[36] By placing EMS professionals inside the hospital and in primary health care clinic settings, as has been accomplished in many communities,[4,37,38] officials have expanded career possibilities while at the same time improving linkages between EMS and health care, which promotes integration. Nationally and internationally there is growing support for expanding the role and scope of EMS professionals.[2,37] The International Roundtable on Community Paramedicine (IRCP), for example, promotes expanded roles for EMS professionals and defines this new health care provider and model—the community paramedicine model—as "a model of care whereby paramedics apply their training and skills in 'nontraditional' community-based environments outside the usual emergency response/transport model."[3]

For many reasons, growth of community paramedicine programs in the US is possible and is potentially beneficial to EMS and communities. Community leaders are increasingly looking to midlevel and other health care professionals to fill voids in primary, dental, and mental health care services in rural and frontier areas where access is limited.[39] Emergency medical services professionals are traditionally paid less than nurses and other professionals also serving expanded roles, and thus community paramedicine models are potentially cheaper to administer and have the potential to reach more citizens with fewer resources. Emergency medical services systems and professionals have historically been community-based, are visible and recognizable, and are respected and trusted by the public. Existing federal programs like the National Institutes of Health (NIH) Roadmap Initiative can be used to test and evaluate the clinical and cost effectiveness of community paramedicine.[4] Growth of community paramedicine lies, in large part, with the recognition from researchers, community leaders, and policy makers that EMS systems and professionals are highly skilled medical professionals with an established rapport with the community.

Next Steps for Addressing Integration and Workforce Issues

Monitoring national EMS trends is important for continued growth and improvement of EMS in North Carolina. Integration of EMS is a national priority receiving support from federal initiatives and national associations sensitive to EMS issues. Many obstacles to integration exist. Improved integration, however, can be achieved through expanding the role and responsibilities of EMS professionals, which may also have a positive impact on reducing personnel turnover. Where possible, the state and local EMS leadership in North Carolina should partner with state health care leaders and academic researchers to promote testing and evaluation of diverse models of integration. Local and state officials and industry leaders must take the initiative.

Historically, EMS in the state of North Carolina has been led by innovators and out-of-the-box thinkers. Recent efforts by state EMS leaders to explore workforce problems represent forward thinking and a step in the right direction towards improving workforce conditions. Next steps should include a planned approach involving local EMS systems, community leaders, state and federal EMS leadership, and academic researchers. The NC Center for Nursing (NCCN) is a good example for North Carolina EMS. The NCCN is a state-supported agency that provides ongoing analyses of the state's nursing workforce. A perfect storm of factors including the nursing shortage of the late 1980s led to the creation of the NCCN. While workforce challenges have plagued EMS for more than 20 years, that perfect storm has never effectively materialized for EMS. Twenty years of waiting has proven ineffective. Local and state officials must act and be proactive to address ongoing challenges before the true negative effects of inadequate staffing are revealed.

North Carolina is fortunate to have an exceptional pool of academic researchers and research institutions. Unfortunately, few researchers have been successful or have recognized the NIH Roadmap Initiative as an opportunity for improving EMS clinical procedures and service structure knowledge. Few have recognized community paramedicine as an emerging model of EMS care offering a variety of research opportunities. As a research approach, community-based participatory research offers a unique model for EMS researchers to explore integration, workforce, and other EMS systems and clinical care issues. North Carolina EMS researchers and practitioners should explore community-based participatory research as a vehicle for expanding EMS research. It is increasingly being recognized as a particularly well-suited approach to research involving partnerships with community members and community based health care organizations like EMS.[40]

It is important to have some sense of national EMS priorities and trends by which we can compare North Carolina's EMS development in relation to the rest of the country. Like many states, North Carolina is in the middle of an EMS workforce "challenge," but it is responding by first assessing the size and nature of the problem. Supporting integration and research into expanded roles for EMS professionals could help North Carolina leverage limited federal funding that could be key to improving the state's EMS system. **NCMJ**

COMMENTARY

Emergency Medical Services Information Systems

Greg Mears, MD

Emergency medical services (EMS) are often defined as the intersection between public safety, public health, and health care. From a public safety and public health perspective, EMS is the safety net for those who become suddenly ill or incapacitated. This community-level responsibility requires EMS to anticipate events, provide services, and care for patients individually or through the management and coordination of multiple patients. Due to this anticipatory role, EMS must function from a preparedness model.

A preparedness model requires that the EMS component of health care be delivered to the patient as opposed to the patient presenting on their own. Because many EMS events such as cardiac arrest and major traumatic injuries are time dependent, EMS must provide this service and care through an organized mesh of ambulances, personnel, and resources configured to assure a timely response to every event within the EMS service area. No other component of the health care industry is required to function in their day-to-day operations from this preparedness-based, "go to the patient" model. From an operational and clinical perspective, EMS is the most complex and data dependent component of the US health care system. Unfortunately, EMS is also the most underdeveloped component of the health care industry from a personnel, data, financial, educational, or resource perspective. Information systems are critical for effective EMS system implementation because each EMS event requires knowledgeable personnel, appropriate equipment, and other required resources within an optimal EMS response time to the correct location.

> *"From an operational and clinical perspective, EMS is the most complex and data dependent component of the US health care system."*

The Importance of EMS Data

In the United States, there are over 25 million EMS events each year requiring patient care or transport. North Carolina's 8.6 million people call 9-1-1 and receive EMS services over 1 million times each year. These services range from life-threatening emergencies to medical transports between hospitals and other health care facilities.

At the local EMS system level, EMS data are critical to determining where and how to allocate EMS resources to assure that the correct equipment and personnel are provided for each event in a timely fashion. Data that describe patterns of use can direct the allocation of resources, vehicles, personnel, and supplies. Information systems provide the EMS medical record, documenting the clinical care provided as well as supporting the administrative demands of the system. This documentation also gives guidance to the content of EMS personnel's initial and continuing education. Information systems provide the framework for ongoing quality management and performance improvement initiatives and data systems feed into the billing and reimbursement systems required to operationally sustain local EMS systems.

At the state level, EMS data are required to determine how to coordinate regional and statewide systems of care such as trauma, acute cardiac, and stroke. Data drive the development of operational and clinical protocols, initial education, continuing education, and medical direction needs. Technical assistance, funding, and advocacy can and should be driven by issues and needs identified and justified through a state EMS data system.

At the national level, a national EMS database is critical to define EMS needs and to support EMS as an industry and a key component of the health care system. Emergency medical service data systems can help shape national educational standards by

---

Greg Mears, MD, is an associate professor and North Carolina EMS medical director at the EMS Performance Improvement Center in the Department of Emergency Medicine at the University of North Carolina at Chapel Hill. He can be reached at gdm@med.unc.edu or 100 Market Street, Chapel Hill, NC 27516.

identifying the needs of patients. A data system can help prioritize federal EMS funding and support decisions by the Centers for Medicare & Medicaid Services (CMS) for reimbursement levels for Medicare and Medicaid patients. A comprehensive data system can also be used for basic and policy focused research.

Linkage of EMS data to other databases at the local, state, or national level is also needed. Through the linkage of data systems, insight can be obtained beyond what each individual data source can provide. EMS data systems should be linked with vehicular crash and other injury surveillance data to provide insight into improving the safety of roadways, vehicles, and trauma systems. Linkage of EMS data to hospital data can provide insight into the service delivery, personnel performance, and clinical care provided to each EMS patient. Linkage of EMS data to trauma, stroke, injury, and medical examiner data systems can provide information on how to target, design, and implement injury prevention and public education programs.

What is NEMSIS?

In 1999 the US Department of Health and Human Services (US DHHS) through the Health Resources Services Administration (HRSA) Emergency Medical Services for Children Program (EMSC) funded a feasibility study to determine if an organized EMS data initiative could be developed to support the EMS industry as the International Classification of Diseases (ICD-9) and Health Level 7 (HL7) standards have informed the rest of the health care industry. This feasibility study led to the formal funding of the National EMS Information System Project (NEMSIS) through the US Department of Transportation (US DOT) National Highway Traffic Safety Administration (NHTSA) Office of Emergency Medical Services. The NEMSIS Project has 4 primary goals and objectives:

(1) Establish a standardized national EMS dataset which would be used to document the EMS service delivery, personnel performance, and care for every EMS event in the nation.
(2) Establish an electronic EMS documentation system in every local EMS system to support service delivery and clinical care operations.
(3) Establish a state EMS database in every state where a portion of the data collected by each local EMS system could be aggregated to support state EMS regulatory and disaster management functions.
(4) Establish a national EMS database where a portion of the data maintained by each state's EMS database could be aggregated to support federal EMS program, educational, fiscal, and advocacy needs.

Currently, the NHTSA Uniform PreHospital Dataset (Version 2.2.1) is used. This national standard has been adopted by 49 of the 50 US states. At the time of this publication New York had not adopted this EMS data standard. A total of 37 states have operational state data systems in place today. Every state has a goal, pending resources and funding, to establish a state EMS data system. In 2007, 4 states (North Carolina, Minnesota, Mississippi, and New Hampshire) are providing data to the national EMS database. Current NEMSIS Project funding and deliverables provide for a staggered implementation of the national EMS database with the addition of 10 new states per year until all states are participating.

North Carolina's EMS Data System

The North Carolina PreHospital Medical Information System (PreMIS) was developed in 2002 and currently maintains data on all EMS events in North Carolina. The data collected from the one million plus EMS events per year are used as a resource to guide local EMS systems across the state in their daily operations. Data from PreMIS are protected by North Carolina statute and are only accessible by the North Carolina Office of EMS and each local EMS System. Funding for PreMIS was initially provided through the Governor's Highway Safety Initiative. Currently, PreMIS is funded through a combination of state and federal funds associated with domestic preparedness.

Data from PreMIS are used daily in North Carolina's Bioterrorism Surveillance Program as well as in local EMS quality management and performance improvement initiatives. The Duke Endowment currently supports EMS through the EMS Performance Improvement Toolkit Project. The EMS Toolkits are detailed reports that cover a specific EMS topic. Each EMS toolkit evaluates the 100 North Carolina EMS Systems and provides custom recommendations to improve EMS service delivery, personnel performance, or clinical care. The web-based EMS toolkits have been developed to assist EMS systems with optimizing EMS system response times, thus improving EMS cardiac arrest, trauma, pediatric, and stroke care. The EMS Toolkit Project is a partnership with the NC OEMS and The Duke Endowment. Future EMS Toolkit funding will be used to assist individual EMS systems in addressing the specific problems identified by each local toolkit.

Summary

The future of EMS and the US health care system is dependent on interactive, real-time data systems that can be used to design, develop, implement, evaluate, and maintain quality evidence-based systems of care. North Carolina is a national and international leader in EMS given its support of the PreMIS System, the EMS Toolkit Project, EMS Bioterrorism Surveillance, and participation in the National EMS Database. **NCMJ**

COMMENTARY

Medical Oversight for Emergency Medical Services:
Defining Success

Brent Myers, MD, MPH, FACEP

The provision of emergency medical services (EMS) is a practice of medicine. Although it has been present in various forms since the days of Napoleon, the currently utilized EMS system in the United States began in 1966 with the publication of the EMS "White Paper" from the Institute of Medicine of the National Academies (IOM) and the passage of the Highway Safety Act.[1,2] Over the past 4 decades, the public and members of the medical community have come to rely upon the prompt, professional response of the EMS system, summoning ambulances over one million times per year in North Carolina alone.[3] Indeed, the EMS practice of medicine is one of the largest in every community because all citizens are potential patients. On an annual basis, between 7% and 9% of the population become actual patients and summon EMS via 9-1-1.

Unfortunately, these have not been 4 decades of clinical progress in EMS. There are shining examples of clinical success, but we often fail to dedicate sufficient resources to the prehospital medical effort. As the recent IOM report confirms, the federal government has not provided sufficient funding in the areas of research or disaster preparedness, with EMS receiving less than 5% of the preparedness funding since the attacks of September 11, 2001.[4] The medical community remains uncertain of exactly how to incorporate EMS physicians, for while the number of EMS fellowships continues to grow, the American Board of Medical Specialties has yet to incorporate the subspecialty of EMS into the formal board structure. Finally, the IOM report calls for a new federal agency to oversee EMS, indicating that EMS neither belongs exclusively in the National Highway and Traffic and Safety Administration (the current federal oversight agency for EMS) nor exclusively in the areas of public health or homeland security.[4] From the local to the federal level, EMS is truly at the crossroads, and leadership from physicians and the broader medical community is now urgently needed to guide us through this transition.

> *"From system design to treatment protocols to hospital destination directives, modern EMS systems require active involvement of EMS physicians to ensure clinical excellence in prehospital emergency care."*

What is an EMS Physician?

The EMS physician divides clinical activities into two spheres: the traditional, direct care activities in the emergency department and the less traditional, indirect patient care that is delegated to EMS providers in the community. In the latter role, the EMS physician is responsible for all medical components of the prehospital encounter, including dispatch algorithms for the 9-1-1 center, development and revision of patient care protocols, education for all providers, and remediation of providers when necessary. Gone are the days when the EMS physician could create protocols once every few years and meet with paramedics only when they violated these protocols. The practice of EMS medicine is truly a partnership between receiving hospitals, public health, emergency medical dispatchers, basic life support first responders, and, in most communities, advanced life support providers. This partnership requires intensive and frequent interaction with the EMS physician in order for it to function in the patient's best interest. For maximum patient benefit,

Brent Myers, MD, MPH, FACEP, is EMS medical director for the Wake County EMS System in Raleigh, North Carolina and is the medical director for the Emergency Services Institute of WakeMed Health and Hospitals. He can be reached at Brent.Myers@co.wake.nc.us or 331 South McDowell St., Raleigh, NC 27601.

these interactions should occur both in the formal settings of the classroom, boardroom, and conference room as well as in the informal settings of the 9-1-1 center and the houses and highways where EMS providers operate. The appropriate balance of administrative activity and in-the-street observation directly influences patient outcomes, particularly in the area of cardiac arrest.[5]

Rather than simply performing the "sign and go" tasks related to infrequent protocol revision and remediation, the modern EMS physician will be actively involved in the initial and continuing education of all participants in the medical practice. This includes reviewing protocols for the dispatch center, ensuring first responders have access to the latest medical information, and interacting with advanced life support providers on a regular basis.

The need for physician leadership is most urgent as we begin to address this simple question: Are we providing quality clinical care for our EMS patients? The overall clinical care provided by EMS involves two components: the treatments provided by EMS providers and the decisions reached about patient disposition. In regards to the former, a surprising majority of the treatments and interventions provided by EMS are supported only by anecdotal evidence and deference to historical precedent. Medical antishock trousers (MAST) and high dose epinephrine for cardiac arrest are familiar examples of established treatments that did not survive the test of scientific scrutiny. More recently, the "established treatments" of endotracheal intubation (with or without rapid sequence induction) and ventilations during cardiopulmonary resuscitation (CPR) have been called into question. Finally, with the advent of automated external defibrillators (AEDs) and thus defibrillation by basic life support first responders, the relative importance of paramedic response time is being reexamined in a scientific manner.

Decisions regarding patient disposition also directly impact the quality of care rendered by EMS, not only in the urban environments but in the suburban and rural settings as well. In the urban setting, there is compelling evidence suggesting patients with ST-segment elevation myocardial infarction be diverted to a hospital capable of percutaneous coronary intervention (PCI).[17,18] In the rural setting, investigators with the Reperfusion of Acute Myocardial Infarction in Carolina Emergency Departments (RACE) initiative and others are working to ensure prompt treatment for this patient population either by primary lytic therapy or early activation of the air ambulance for transfer to PCI.[19]

Finally, the EMS physician has the responsibility for caring for patients who suffer cardiac arrest in the out-of-hospital setting, both from sudden cardiac death and from a variety of other medical and traumatic etiologies. Mandating hospital transport for all of these patients not only consumes limited emergency department resources for futile cases, it may also impede resuscitation for those cases which are not futile. We now know that interruptions in cardiac compressions as brief as 20 seconds may decrease the probability of successful resuscitation in a meaningful way, and the movement of a patient from the location of the arrest to the ambulance will inevitably create many such pauses. In the optimal setting, the EMS system is responsible for the resuscitation of cardiac arrest, and the emergency departments and hospitals are responsible for postresuscitation care. Obviously, the EMS physician must be actively involved in all components of the EMS system for such a system to function appropriately.

The EMS system, led by the EMS physician, has the opportunity to improve the outcomes for individual patients as well as to enhance the health of the community as a whole. From system design to treatment protocols to hospital destination directives, modern EMS systems require active involvement of EMS physicians to ensure clinical excellence in prehospital emergency care.

The Challenges Ahead

The EMS physicians of 2007 face many challenges. First, we must provide leadership in the area of workforce stability and career development for our prehospital providers. No matter how involved in our medical practice we become, it is for naught in the absence of a qualified and willing workforce. As the demand for all allied health workers exceeds supply, paramedics become attractive candidates to educational institutions training nurses and respiratory therapists as well as to hospitals and medical clinics seeking highly qualified technicians to operate in the cardiac catherization lab, emergency department, or other settings. In nearly all of these situations, scheduled work in a climate-controlled environment is offered for a higher salary than EMS currently offers. Paramedics may most accurately be viewed as members of the allied health community and, as such, reimbursement must be reexamined. EMS physicians must be allies for our prehospital providers and seek to improve reimbursement for the important work they do.

The EMS physician must actively participate in defining quality in EMS. In just one example of unintended consequences, it may appear logical to support improved response times for EMS. It will surprise some to know, however, that there is no evidence in the medical literature indicating an association between advanced life support response times and survival.[14-16] Moreover, there is a clear association between response time of a BLS defibrillator and survival from cardiac arrest, but this is often not measured or reported.[21] Finally, it appears that the annual experience of a paramedic may be at least as important as the response time. In each community, cardiac arrests occur with a predictable annual incidence of about 1 per 10 000 population. As one adds more paramedics to a system with a stable population, the individual paramedic encounters fewer patients in cardiac arrest each year. Preliminary studies indicate improved survivability from cardiac arrest in areas with fewer paramedics, raising the hypothesis that rapid response of a basic provider with an AED followed by a delayed response of a well-experienced paramedic may be superior to rapid response of a relatively less experienced paramedic.[22,23] This is not surprising, as the same has been demonstrated for invasive cardiologists and other medical specialists: there is a minimum number of high acuity encounters required on a regular basis in order to maintain clinical excellence.[24-26] This, combined with the known short supply of paramedics mentioned above, may eventually place the EMS physician in the seemingly unusual position of calling for fewer paramedics while ensuring the paramedics that are in the field receive the best training, equipment, and reimbursement possible.

This is not to say the historical duties of the EMS physician may be neglected. Protocol revision and assurance of protocol compliance remain the cornerstones of excellent EMS practice. For today's EMS physician, however, these revisions must occur frequently because evidence regarding treatment and transport decisions is emerging more rapidly than at any time in the 4-decade history of EMS. Just in the past 12 months, evidence from North Carolina researchers indicates noninvasive positive pressure ventilation (NIPPV) may become the standard of care for prehospital treatment of pulmonary edema and potentially other forms of respiratory distress.[27] National and international manuscripts have challenged our current methods of CPR and defibrillation with indications that continuous compressions can markedly increase the proportion of patients with neurologically intact survival from cardiac arrest.[9,20,28] The timely revision of EMS protocols is now required to ensure optimal patient outcomes.

Assurance of protocol compliance may be adequately performed with chart review but is only optimally performed after observation in the field. Response with EMS personnel to assess both the quality of the care provided as well as the quality of the medical protocols is necessary for excellence in medical oversight.

Finally, the EMS physician is called upon to perform duties not directly related to routine, individual patient encounters. The events of September 11, 2001 and Hurricane Katrina reminded us that disaster preparedness is not an optional activity. Fortunately, in North Carolina we have several resources including Med-1 at Carolinas Medical Center in Charlotte, the Special Operations Response Team in Winston-Salem, and the State Medical Assistance Teams to assist local resources in any such response. Issues surrounding public health response to infectious disease as well as injury prevention and public safety are also issues for the EMS physician.

Where Do We Go From Here?

Although the challenges are great, the dedication of resources to address them is perhaps the most significant it has been in our 4-decade history. The clarity of the recent IOM report, the multi-center NIH supported Resuscitation Outcomes Consortium (ROC), and the outstanding initiatives emerging from the EMS Performance Center in North Carolina are just a few examples of this dedication. Funding remains a challenge, but as our treatments become more evidence-based, a more cogent argument for dollars becomes available to us. In Hubble's paper for example, we learn that the need for an intubation in the emergency department is avoided for every 6 pulmonary edema patients treated with prehospital NIPPV. The health care dollars saved by the avoidance of a single intensive care unit admission could pay for many NIPPV units in the prehospital setting. As our evidence becomes more robust, the appropriateness of increased funding will hopefully become self-evident.

In conclusion, despite all of the challenges we face, the career of the EMS physician is satisfying and rewarding. When I began my fellowship in EMS, someone with years of experience in the field stated that the duties were 80% political and 20% clinical. They actually were wrong—they are 90% political and 10% clinical on the best days. Yet, despite all of this, the opportunity to care for those cannot otherwise care for themselves is afforded every day. We impact those who have been down on their luck for years as well as those from all walks of life who experience an unexpected illness or injury—and we can help them each in unique ways. At the end of the day, via this dedicated practice, I am able to recall why I entered the medical field in the first place: to help my fellow man. **NCMJ**

COMMENTARY

Paramedic Endotracheal Intubation

Henry E. Wang, MD, MS

Prehospital practitioners perform a range of critical life saving interventions such as delivery of cardiopulmonary resuscitation chest compressions, rescue defibrillation shocks, administration of intravenous fluids and drugs, and establishment of a patient airway. The equipment used in these interventions require special modifications to enable their portability and delivery in the field setting. For example, while inhospital cardiac arrest equipment is often stored in large mobile "crash carts," such devices would be impractical for prehospital use. Instead, paramedics use portable "jump bags" filled with medications as well as a lighter portable defibrillator/cardiac monitor.

One of the most important recent scientific findings is that medical procedures executed in the field setting may not perform equivalently to the same interventions carried out in the hospital. Thus, simply imitating inhospital practices may not necessarily improve outcomes. In some cases these prehospital interventions may lead to worsened outcomes.

Paramedic Endotracheal Intubation

An excellent example of the challenges surrounding prehospital medical interventions is endotracheal intubation (ETI). Airway management is the process of establishing an open passage between the mouth and the lungs in order to deliver life-saving oxygen. Critically ill individuals such as those suffering from cardiac arrest or major trauma are often unconscious and cannot maintain an open airway on their own. Therefore, airway management is a fundamental priority in the care of the critically ill. Without an adequate supply of oxygen, vital organs (in particular, the brain) begin to die. Airway management may encompass a spectrum of basic methods (eg, mouth-to-mouth or bag-valve-mask ventilation) or more advanced techniques (eg, endotracheal intubation).[1,2]

Endotracheal intubation (ETI) is the most prominent and invasive form of airway management. A plastic breathing tube is inserted through the mouth, between the vocal cords, and into the trachea (windpipe). Endotracheal intubation provides a direct, patent conduit to the lungs to facilitate optimal and controlled delivery of oxygen.[2] The endotracheal tube also has an inflatable cuff designed to prevent the aspiration of stomach contents into the lungs. Endotracheal intubation is the standard method for airway management in the hospital setting including the operating room, emergency department, and intensive care unit.

> *"One of the most important recent scientific findings is that medical procedures executed in the field setting may not perform equivalently to the same interventions carried out in the hospital."*

The History of Paramedic Endotracheal Intubation

Paramedics in the United States first performed field ETI over 20 years ago during an era of intense efforts to improve the out-of-hospital care of patients suffering from sudden cardiac arrest.[3] Experts viewed delivery of oxygen as a fundamental component of cardiac arrest care, and most viewed ETI as the best way to deliver oxygen to the lungs in comatose individuals. Endotracheal intubation was widely performed on cardiac arrest patients in the hospital, and thus it seemed reasonable to train paramedics to act similarly on out-of-hospital patients. Prior to this time paramedics used older methods of airway management such as bag-valve-mask ventilation and the esophageal-obturator airway, neither of which was seen as adequate in this clinical context.[4]

Henry E. Wang, MD, MS, is an assistant professor in the Department of Emergency Medicine at the University of Pittsburgh. He can be reached at wanghe@upmc.edu or 230 McKee Place, Suite 400, Pittsburgh, PA 15213.

The first scientific reports of paramedic ETI originated from San Diego, Columbus (Ohio), Boston, and Pittsburgh.[5-8] These groups of paramedics received intense preparation encompassing classroom and mannequin training as well as practice in the operating room on live patients. Anesthesiologists, viewed as the masters of ETI and airway management, played active training and mentoring roles in the pilot efforts. These studies garnered significant scientific attention and spurred efforts to generalize paramedic ETI throughout the United States.

Today, ETI is a standard of paramedic care. In Pennsylvania alone, paramedics perform ETI on over 11 000 out-of-hospital patients annually.[9] Clinicians view ETI as one of the interventions that distinguishes paramedic care.[10]

Controversies Surrounding Paramedic Endotracheal Intubation

Is Paramedic ETI Life-Saving?

The intention of a resuscitation intervention is to improve patient survival or other health outcomes. Since its inception, most have assumed that paramedic ETI is beneficial: ETI provides a direct protected conduit to the lungs—how could it possibly be harmful? However, many recent studies suggest that paramedic ETI may in fact not improve survival or other outcomes. In some cases, the intervention may even worsen outcomes.

Multiple studies have examined the connection between paramedic ETI and patient outcomes.[11-18] The recurrent finding among these studies is that paramedic ETI does not improve survival and, in some cases, may actually increase mortality. These studies also have not identified any neurological benefit from the procedure. For example, Gausche et al performed a prospective pseudo-randomized controlled trial alternating ETI with bag-valve-mask ventilation of critically ill children; the authors found no difference in survival or neurological outcome.[14] Davis et al evaluated out-of-hospital head injured patients intubated with the assistance of succinylcholine, a neuromuscular blocking agent.[12] The use of these drugs causes temporary paralysis of the patient to facilitate ETI and is normally reserved for physician use in the hospital.[2] Compared with historical matched controls that did not receive ETI, the experimental ETI group exhibited a higher adjusted odds of death.

We analyzed over 4000 head injured patients treated by paramedics in Pennsylvania over a 4-year period.[16] We found that those intubated by paramedics had a 4 times higher adjusted odds of death than those intubated in the receiving hospital emergency department.

ETI Adverse Events and Errors

Some have attributed worsened outcomes to adverse events and errors occurring during out-of-hospital ETI. Clinically, this is plausible since ETI is an inherently difficult process requiring the coordination of numerous cognitive and manual steps. In addition, paramedics face other latent challenges when performing ETI such as the uncontrolled chaotic nature of the field environment. For example, it is not unusual for a paramedic to provide airway management on a patient entrapped in the wreckage of a motor vehicle collision. Given these many factors, the occurrence of adverse events is not only possible but probable.

The most serious adverse event associated with ETI is inadvertent placement of the breathing tube in the esophagus. If not recognized and corrected, this error results in oxygen delivery to the stomach instead of the lungs. Katz and Falk presented the most prominent report of ETI adverse events, finding the endotracheal tube misplaced in 25 of 108 patients intubated by paramedics; in two-thirds of these cases, the tube was in the esophagus.[19] Other studies using similar methods found lower—but not negligible—rates of tube misplacement.[20,21]

Recent efforts have highlighted previously undefined ETI errors. Endotracheal intubation ideally should occur rapidly so that there is minimal disturbance to the patient's oxygen level or heart rate. Dunford et al examined a subset of 54 patients receiving succinylcholine-assisted paramedic ETI.[22] The authors found that patient oxygen saturation and/or heart rate decreased significantly during ETI in over half of the patients. Of greater concern, the paramedics considered 84% of these ETI cases to be "easy." Thus, even when equipped with state-of-the-art monitoring equipment, paramedics were not aware of these adverse events.

When individual events are aggregated, the resulting ETI error rates may be higher than expected. We collected data on over 1900 ETI performed by paramedics across Pennsylvania, focusing on reports of three error events: (1) ETI tube misplacement or dislodgement; (2) multiple ETI attempts; and (3) failed ETI efforts.[23] We found that one or more of these errors occurred in 1 in 4.5 patients receiving ETI efforts.

ETI Training and Practice

Given the complexity of ETI, one would expect that paramedics receive substantial training and practice in the procedure. However, current ETI training standards and practices may not afford adequate baseline or maintenance experience.

For example, whereas resident physicians in emergency medicine and anesthesiology must perform 35-50 ETI prior to graduation, paramedic students are required to perform only 5 ETI.[24,25] Examining a series of 7500 ETI performed by 800 paramedic students, we found that paramedic students perform a median of only 7 ETI (IQR: 4-12) during their training.[26] We also found that paramedics students required at least 15 to 20 ETI encounters to achieve adequate baseline proficiency. Emergency medicine residents typically spend 160 hours in the operating room learning ETI under the tutelage of anesthesiologists. However, in a survey of paramedic training program directors, we found that most paramedic students spend only 16 to 32 hours in the operating room learning ETI.[27]

Paramedic clinical ETI experience also falls below expected levels. Using Pennsylvania statewide data for 2003, we found that paramedics perform a median of only one ETI annually.[9] While the minimum annual number of procedures is not defined, the best air medical programs require that paramedics perform at least 12 ETI annually.[28]

While some agencies provide additional training and experience using mannequins or human simulators, the effectiveness of these training modalities remains unproven. Mannequins and human simulators do not accurately recreate the feel of live human flesh nor the heterogeneity in airway anatomy between different persons.[29] Studies linking mannequin and simulator training to paramedic ETI performance have significant limitations.[30,31]

Is Change Possible?

We now recognize that efficacy demonstrated in small controlled settings may not necessarily translate to widespread success when replicated on a large scale. In the case of ETI, the original demonstrations of the technique involved relatively small teams of paramedics receiving intense training and monitoring.[5,6,8,30] Few considered that many EMS agencies nationally would not have the resources necessary to ensure the same degrees of success. Today, our current systems of EMS care and education lack the resources to ensure success on a national scale.

There are, in fact, potential system level solutions. For example, one approach might involve substituting ETI with simpler alternate airway devices such as the Combitube or King LT airway.[1,32,33] These newer devices are relatively easy to insert, work well in a variety of different clinical scenarios, are easier to master than ETI, and may not depend on live human practice for adequate training. In order to adhere to the most recent Advanced Cardiac Life Support guidelines, several individual paramedic agencies nationally have switched from ETI to alternate airway devices.[34]

Facilitating change in ETI, however, comes accompanied by other challenges. One such challenge would be the workplace culture of EMS. Endotracheal intubation is a defining procedure of paramedic care.[10] Taking ETI away from paramedics would be like taking scalpels away from surgeons—this proposition would likely face significant resistance. The optimal method for facilitating change in the face of these many challenges remains unknown. **NCMJ**

Emergency Preparedness in North Carolina:
Leading the Way

Jane H. Brice, MD, MPH; Roy L. Alson, MD, PhD

North Carolina is situated in an ideal climatic location to be at risk for natural disaster. Hurricanes, ice and snow storms, and tornadoes all strike the state with fair regularity. As such, the emergency responders in North Carolina have had to develop and hone their preparedness skills and maintain a state of readiness. They do not have the luxury to let down their guard. Man-made disasters such as recently experienced in the chemical fire in Apex or the pharmaceutical plant explosion in Kinston also test the preparedness of our responders on the front lines.

Changes in the environment in which we live require constant surveillance and assessment of threats in the community. Recent experiences with SARS in Canada and the isolated case in Chapel Hill dramatically illustrate the effect of new pathogens on communities. As we watch the progression of avian flu in the world, EMS must be ever vigilant as both they and the emergency department are likely to be the first to report the spread of disease in their environments.

In addition, the practice of medicine has evolved in the last few years. Hospitals have fewer available beds due to downsizing, nursing shortages, and minimizing the financial margin. Medicine has begun to emphasis home care. Patients are discharged from the hospital sooner and sicker. There is a smaller margin of error for these patients. More patients are maintained at home on ventilators, home oxygen, and in bed-bound states. When disaster strikes, these patients are most at risk. Finally, our emergency departments are overcrowded with admitted patients awaiting an available and clean bed, making surge capacity slim.

The last 10 years have taught several major lessons to EMS, hospitals, and the medical community at large. First and foremost, we have recognized that hospitals do not provide medical care in a vacuum. Hospital disaster plans used to focus solely on the hospital and were primarily mass casualty plans. We now see hospitals, the medical community, EMS, fire departments, and law enforcement working together with public health and emergency management to develop comprehensive community-wide plans. Lines of communication and coordination are being established before events. As mandated by the Joint Commission on the Accreditation of Healthcare Organizations, hospitals have embraced this community approach to disaster preparedness and are partners with EMS in emergency preparedness.

> *"Responding to a major statewide disaster such as experienced on the Gulf Coast in 2005 is not a matter of if but when. 'Will North Carolina be ready?'"*

Responding to a major statewide disaster such as experienced on the Gulf Coast in 2005 is not a matter of if but when. "Will North Carolina be ready?" is the question many emergency planners are asking. In the past 6 years, funding for preparedness equipment and activities has increased substantially thanks to the attention of the federal government in the wake of the 9/11 events. Planners have also embraced the notion that disaster preparedness must be scalable, flexible, and sustainable. Cross-institutional planning between emergency responders, hospitals, community officials, and industry has resulted in more robust,

---

Jane H. Brice, MD, MPH, is an associate professor in the Department of Emergency Medicine at The University of North Carolina at Chapel Hill School of Medicine, medical director of Orange County EMS, and chair of the Disaster Committee for UNC Hospitals. She can be reached at brice@med.unc.edu or CB# 7594, University of North Carolina, Chapel Hill, NC 27599-7594.

Roy L. Alson, MD, PhD, is an associate professor in the Department of Emergency Medicine at Wake Forest University School of Medicine, medical director of Forsyth County Emergency Medical Services, and medical advisor for the NC State Medical Assistance Team program.

comprehensive, and integrated plans that allow a community or region to react in concert to mitigate the effects of disasters.

As required by Homeland Security Presidential Directive-5, adoption of the National Incident Management System by all emergency responders (eg, hospitals, EMS, public health) has allowed for a common language and better communication among providers. Incident command uses the concept of management by objective and is task-oriented rather than person-oriented.

Mass-casualty incidents affect particular segments of communities, but disasters have consequences that are felt across entire communities and regions. An “all-hazard” approach to emergency preparedness has demonstrated the greatest potential for success. In an “all-hazards” model a standardized framework for disaster response is developed and followed with the ability to supplement response with specific entities such as decontamination as the incident dictates. While the federal government offers substantial assistance in the event of a disaster, this help may be days to weeks away and communities have to plan to be self-supporting for 72 to 96 hours.

Where Does North Carolina Stand?

North Carolina’s emergency responders stand at the forefront of emergency preparedness compared to the rest of the nation. The North Carolina State Medical Response System (SMRS) is a joint partnership of the North Carolina Office of Emergency Management, the North Carolina Office of Emergency Medical Services, and the North Carolina Department of Public Health. Role modeling at the state level the partnerships that are most effective in emergency preparedness, the SMRS has set the standard for both regional and local level preparedness. Utilizing a comprehensive approach based around the administrative organization of the Trauma Program’s Regional Advisory Councils, the SMRS has set up several layers of emergency preparedness.

The central concept of SMRS is that it is scalable and flexible. Incorporating assets at the local, regional, and state levels, the SMRS is able to mount an integrated response with common equipment, protocols, and training. At the core of this response is the State Medical Assistance Team program (SMAT) with tiered levels of team response. The SMAT layers are based out of county (SMAT 3), regional (SMAT 2), and state (SMAT 1) bases. This concept has been proven effective in responses to tornados and the recent Apex chemical plant fire as well as responses to Hurricane Katrina.

Through Health Resources and Services Administration (HRSA) grants, North Carolina has provided funding and other resources for individual counties to develop SMAT 3 teams. While not required, counties are encouraged to develop and maintain the training for SMAT 3 teams. At present, 25 counties have taken advantage of this opportunity. Primarily prehospital in orientation, these teams have the ability to rapidly set up technical decontamination systems to deal with weapons of mass destruction (WMD) or hazmat events. SMAT 3 teams also have the ability to assist with onsite medical care and triage in a mass casualty incident and are currently undergoing training to deal with blast injuries and structural collapse events.

Each of the 8 trauma regional advisory councils (RACs) in the state serves as the sponsor for a SMAT 2 team. These teams have the ability to support hospital based decontamination as well as provide care in a portable 50-bed medical facility that can be set up in either temporary shelters or fixed structures. Each facility is contained in a 55-foot tractor trailer (See Figure 1.) and can be used as a stand-alone acute care or alternate care facility. The units can be utilized in combination forming a larger medical facility with maximum surge capacity of 400 beds for our state. To form the SMAT 2 response, each hospital within a RAC commits a few staff members to support the SMAT operation based upon the size of the member hospital. SMAT 2 operations are thus enabled without compromising the staffing of any one medical facility. Members of the SMAT 2 team train with the system on an annual basis and, in addition to disasters, the units have been deployed to support events such as the Tall Ships sail in Beaufort last summer. Current purchases to augment the SMAT 2 operations include 2 portable digital field x-ray systems for the state, 3 pharmacy trailers, and a stock of portable ventilators.

The SMAT 1 is based at the Special Operations Response Team (SORT) headquarters in Winston-Salem. Containing a

Figure 1.
NC SMAT 2 Trailer

more robust decontamination capability to deal with large-scale WMD events, the SMAT 1 inventory includes a tractor trailer-based field hospital and an 80-bed special medical needs trailer, which allow set up of a special needs shelter in a fixed facility. The Special Operations Response Team also maintains a tractor trailer with basic medical supplies for deployment during disasters as well as a rapid deployment field medical unit.

Carolinas Medical Center in Charlotte has developed and deployed under government funding a tractor trailer mounted intensive care unit and operating room facility called MED 1. Serving as the critical care area during the NC SMAT deployment to Waveland, Mississippi during the aftermath of Hurricane Katrina, the team has received extensive media coverage and accolades.

Public health has not been neglected in the process. Funding has been provided to increase training of public health agencies across the state and to upgrade laboratory facilities for the Division of Public Health to allow for timely diagnosis. Seven public health regional surveillance teams (PHRST) have been established and are operational, providing both technical support and epidemiological tracking for unusual diseases in our state. Lastly, the North Carolina Health Alert Network (NCHAN) uses a multimodel system for 24/7 distribution of health related information to health departments, medical facilities, and response agencies.

In a related function, the NC State Medical Asset Resource Tracking Tool (SMARTT) has been successfully deployed. It allows hospitals to enter bed status and availability in real time so that planners can use this information to allocate patients and assets during real events. The SMARTT system will eventually include EMS responders, special teams such as hazardous materials teams, and local clinics and physicians' offices.

Much has been done, but there is still much to do. Dealing with the special needs populations remains problematic and unsolved. Development of SMAT 4s to specifically address the special needs communities with input from home health agencies and nursing facilities is now underway along with a system to track medical records and medications for this population. Special needs equipment is being purchase and stockpiled. Dual use capability of special needs equipment is being pursued with home health agencies and community colleges across the state. Equipment can be used to train nursing and allied health professions students on a daily basis and, in an emergency, equipment would be used by the students and other health care providers to provide a special needs shelter on the campus in a coordinated manner, with all the necessary assets centrally located for the region.

North Carolina is extremely fortunate. Due to our cooperative approach, North Carolina is a leader in disaster response and states across the southeast are emulating our system of tiered response. We cannot rest on our laurels. We must continue to examine the risks and adapt our preparations. Finally, as practitioners we must realize that the victims we discuss are our patients. Therefore, we must take an active part in the preparation for and the provision of disaster medical care by volunteering to serve on a team, being certain that our practices can and do remain open in the event of a disaster or other incident in our communities, or being personally prepared with our families for disaster. Above all, we must remember that disaster response is really the ultimate team sport and that we are fortunate to be part of a top team. **NCMJ**

COMMENTARY

Emergency Medical Communication in North Carolina:

Past, Present, and Future Challenges

Carl C. Van Cott

If the best equipped ambulance arrives unannounced at the emergency room door and the hospital is unprepared for the arrival, the system has broken down and patients can be lost because of it. There must be good reliable communications between the person reporting the accident, the dispatcher of the appropriate vehicle and personnel, the police and fire departments (when called for), the hospital emergency department, the medical specialists available to the hospital, and those bigger hospitals (trauma centers) to which the patient might in some cases be sent directly.

This excerpt from the 1973 Report of the Legislative Research Commission to the General Assembly of North Carolina recognized the importance of emergency medical services (EMS) communications to the safety and quality of emergent care. Since its inception, EMS communications has made measured progress. This article explores some history, examines the current status of EMS communications, and highlights some of the future challenges faced in North Carolina.

An EMS communication system must be examined under two operational conditions: routine or day-to-day operations and disaster or larger scale emergency situations. For the local systems to be effective, wide area standards for operations and equipment, radio frequencies, and technical requirements must be provided. These standards must be sufficient to ensure compatibility and interoperability throughout all systems statewide. Communication functions must also adapt if an emergency situation escalates. Communications must be capable of extending to adjacent counties, states, and national disaster management agencies. The establishment of interoperable systems requires time to develop and needs consistent financing and direction. System creation is an evolutionary process requiring understanding and acceptance. Common goals and language must exist to facilitate this development.

> *"National long-term plans may convert all public safety communications to a common frequency band, but this will not be possible in the short term and requires interim systems to remain functional as the new systems and equipment become defined and available."*

Public Access Communication

In the 1970s public access to emergency services was uncoordinated. Numerous telephone numbers were listed on the inside cover of local telephone directories for the various sources of EMS and rescue services. Callers seeking assistance were fortunate if they could identify the telephone number necessary for their needed emergency service; they may have had to call multiple phone numbers and choose between the various services and providers, thus being delayed in obtaining assistance.

Carl C. Van Cott is communications director for the North Carolina Office of Emergency Medical Services. He can be reached at carl.vancott@ncmail.net or 2707 Mail Service Center, Raleigh, NC 27699-2707.

Currently, public access to EMS is achieved through universally available 9-1-1 emergency telephone systems. Public Safety Answering Points (PSAPs) have been established in all 100 North Carolina counties and the state has progressed to being served fully by "Enhanced 9-1-1," also known as E9-1-1. Enhanced 9-1-1 enables a PSAP to determine the caller's location from data linked to the telephone number. Considerable effort has been expended in implementing these E9-1-1 systems. The introduction of new communications technologies has, however, created new challenges. For example, an estimated 70% of calls to PSAPs in North Carolina are now made from cellular telephones, but many PSAPs cannot accurately identify the location of the cellular telephone. Similarly, Voice over Internet (VoIP) telephones, also a popular new technology, do not automatically tie to the system that provides user location information. This requires the user to register the VoIP telephone to a location. These differences may cause delays and inaccuracies in dispatching emergency help, which can result in loss of life and property.

Cellular telephones also offer new advantages for EMS communication. They have features such as geographic positioning systems (GPS), digital picture and video transmission and reception capabilities, text messaging, and mapping capabilities. These new capabilities, however, are not utilized by most 9-1-1 centers. They could have considerable usefulness in the emergency dispatching system. Methods to utilize these new system capabilities for EMS systems should be explored. For example, a cellular caller could send pictures of a crash location or other emergency situation, in essence extending the eyes of the dispatcher to the emergency scene. Consider the range of possibilities when the cell phone device in the field can also receive messages or video from the 9-1-1 dispatcher. This could provide information on how to perform cardiopulmonary resuscitation (CPR) or other emergency procedures or even direct evacuations in preparation for an impending weather event or other large scale emergency.

Dispatch and Coordination Communication

In times past, virtually no training was provided to emergency dispatchers. Dispatching services were not recognized as having a high degree of importance and were not always provided 24 hours a day. Sometimes emergency telephone numbers changed from day to night depending on which person took the ambulance home that evening. Times have changed. Telecommunicators that function in a coordinated PSAP are generally required to have a minimum level of telecommunications training. There is increasing recognition of the important role telecommunicators play as the first of the first responders and the sole point of contact for all emergency services. The dispatcher is responsible for making the decision of what services are to be dispatched and for the coordination of all of the emergency functions and field responses. If this function is poorly performed, nothing else will go well in the response. Telecommunicators are rightfully assuming recognition in a new profession.

Emergency medical dispatch (EMD) training is available throughout North Carolina. Emergency medical dispatch certification is an advanced life support service that requires a medical director. Currently, 73 communications agencies or 63% of the approximately 115 emergency dispatch centers within the state have approved EMD programs.[1] These centers are trained to recognize life-threatening conditions and provide telephonic direction in medical emergencies such as childbirth and CPR.

Emergency medical services communications understanding must extend further to the educational requirements for all users of the system. This education must include training for the public on how and when to call for assistance and what to expect when they call. The dispatcher's training must include providing prearrival medical instructions. Field responders and hospital personnel need instruction on how to use their communications equipment. Methods must be developed to accurately and quickly exchange information about a patient's condition and treatment, and a standardized radio reporting template to present a patient to the emergency department must be developed. Finally, education must extend to licensing radio systems, maintaining the equipment, and testing the operational readiness of the entire emergency communications system.

Public Safety Answering Point operations should be encouraged to recognize the importance of certification and training programs. These certifications also extend to fire and law enforcement operations. Caller algorithms (flip cards and computer programs) for directions to provide assistance to callers must continue to be reviewed and expanded to a broadened array of programs and to additional medical conditions where early intervention can be critical. All emergency communications centers should have the ability to provide CPR instructions over the telephone. All emergency answering points should be able to provide information on the location of nearby automatic electronic defibrillators in high population areas such as malls, airports, fairs, and other public gathering places and to be able to provide instruction on the use of these devices to the caller.

Devices that provide mapping, location, and direction information to emergency events must be made commonly available to PSAPs, emergency response vehicles, and field responders. Vehicle GPS systems should be widely available to report to the PSAP the location of ambulances and to provide the dispatcher with information on the location of the closest units available to respond to any given situation. Coordination of emergency communications services between geographic areas such as cities and counties must become the rule and not the exception. There should be a common statewide approach to providing public safety services.

Medical Communication

In the early 1970s physician medical direction communication to field EMS units did not exist. Notification of an impending patient arrival via ambulance at a hospital was sporadic and information concerning a patient's condition was provided only as a local service option. In most instances it did not exist. Hospital radio systems operated on various radio frequencies with different channel designations. A statewide common hospital radio frequency was not available. Ambulance personnel making patient transports to out-of-county hospitals generally were not able to communicate after leaving their local service area.

A statewide common hospital very high frequency (VHF) was implemented in the later half of the 1970s and a standardized channel name was designated. During the 1980s and 1990s every ambulance and every hospital with an emergency department had a radio that operated on 155.340 MHz, now commonly called “340.” A state publication entitled Dial Codes provided information about each hospital’s radio frequencies and telephone and radio access numbers or codes. Ultra high frequency (UHF) “MED” radio systems were widely implemented and paramedic advanced life support communications systems were installed. These radio systems had the ability to transmit a patient’s electrocardiogram to aid in patient care and treatment.

In the late 1990s wide area compatible hospital radio systems in parts of the state began to decline, both in numbers and in operational reliability. In part this was due to the lack of consistent funding to encourage hospitals and EMS agencies to install systems that met statewide standards and to the failure of hospitals to keep their radio equipment in prime operating condition. At times there was disagreement on who was responsible for providing the radio or maintaining the ambulance-hospital equipment serviced, especially when the services were under different administrative structures.

All hospitals in North Carolina with emergency departments currently have radios licensed on the state hospital 340 VHF frequency. Some of these radios have not been replaced or upgraded since the original installation 25 or more years ago. Even when functional, the single frequency hospital radio system is overloaded in metropolitan areas and during disaster situations.

Some counties and EMS agencies that previously had equipment operating on the state standard UHF MED channels have now removed these radios, electing not to repair or replace older radio equipment in favor of purchasing new 800 MHz systems. The expanded capabilities of the 800 MHz trunked systems, however, extend only to users that function within the same communications network. Compatibility between adjacent counties or to other communications systems may not exist or is difficult to achieve due to differences in the equipment when it is supplied by different manufacturers. Unless common direction and standards are consistently available, system designs may fail to maintain common statewide frequencies. This can result in situations where an ambulance transporting outside the county is not able to communicate with the receiving hospital or is unable to maintain contact en route. Cellular telephones appear to fill this communications gap, but they do not function when the telephone network becomes overloaded. This situation is common during disasters and can occur even during moderate traffic congestion situations.

The North Carolina Medical Communications Network (NCMCN) has been developed to provide common geographic wide area UHF radio coverage. The state network of radio repeater installations operates on two channels to increase connectivity between hospitals. The system functions both for routine radio communication and during disasters. The system serves as a redundant system to local EMS radio systems and as an interim system for disaster medical communication. By October 2007 NCMCN radios will be installed in all hospitals within North Carolina. Even with this advancement in statewide capabilities, channel capacity of the system is not sufficient to ensure communications during large scale emergencies or disasters. Additionally, there are currently insufficient numbers of ambulances equipped with UHF radios to ensure operational capability with the system.

Efforts are underway to create a new public safety statewide radio network in the 800 MHz spectrum. This system is the Voice Interoperability Plan for Emergency Responders or “VIPER” network. The system is intended for use by all emergency responders including law enforcement, fire, and EMS services.

A medical communications component has been added to the VIPER network to provide an additional layer of compatible medical radio operation to hospitals and EMS services. This component is designated the Viper Medical Network (VMN), and it provides another radio option for hospitals and EMS services. Funding to encourage wide participation in this system has not yet been identified. The first level of deployment of the VMN is underway through funding provided by the US Health Resources and Services Administration (HRSA). Eventually, it is envisioned that every hospital in the state will have access to its own “talk group” on the network, which will enable any hospital or ambulance to establish voice contact from anywhere within the state.

Complicating the advancement of the new VIPER system is the necessity to provide additional radios to ambulances. In the short term this could result in an ambulance being required to have up to three separate radios installed—one functioning on the hospital VHF 340 for communications on the statewide VHF hospital frequency and with its local dispatch operations, a second for the UHF NCMCN, and a third to participate in the VIPER VMN 800 MHz state trunked network. This amount of radio equipment is costly to acquire and maintain. Unfortunately, there does not appear to be any easy alternative. Some efforts are underway by the state and some counties to install gateway systems that will patch between various radio systems. For these systems to function, however, the radio coverage between the patched systems must be geographically coincidental. Until all systems statewide can be upgraded to a common band or to the VIPER system or until equipment becomes available to enable radio operation compatibility on the many systems and radio bands, multiple radios in hospitals and ambulances will continue to be required. Furthermore, alternative sources for equipment compatible with the VIPER network must be identified. Equipment is currently available from only a very limited selection of suppliers. Technical assistance and guidance regarding radio communications as well as the VIPER network must be made available to hospitals and EMS providers.

National long-term plans may convert all public safety communications to a common frequency band, but this will not be possible in the short term and requires interim systems to remain functional as the new systems and equipment become defined and available. There are already known technical situations and pending FCC actions that impact the development of these high capability systems. Developments of new capability systems and technology will keep EMS systems in a state of flux for years to come.

Implementation of an EMS communications system is an evolutionary process. Implementation requires a series of compromises and trade-offs made within the confines of time and funding. Directives, rules, laws, technology, motivation, and expectation all influence the outcome. Every aspect of the communications system must continually be revisited, evaluated, refined, refurbished, and improved to maintain North Carolina's readiness and ability to provide the services to respond and be prepared for the eventualities. **NCMJ**

The Future of Emergency Medical Services Communications Systems:

Time for a Change

Kevin K. McGinnis, MPS, EMT-P

Modern emergency medical services (EMS) are approximately 35 years old. The transformation of ambulances from "horizontal taxicabs" capable of little more than patient transportation to a system capable of sophisticated, life-saving, prehospital and hospital intervention has been dramatic. Emergency medical services communications systems have, by and large, not experienced similar transformation. Current and developing advances in communications technology could address this.

Immediate opportunities for EMS communications systems to integrate such advances exist, and more are evolving in the federal and national arenas. Incorporating broadband as a means of improving communications among EMS providers, between EMS, fire, and police, and between EMS and hospitals is one example. In affecting these advances, EMS has the potential to become the greatest user of public safety bandwidth and a very large user of federal communications funding.

There is no assurance that EMS will have access to such capabilities or funds. Additionally, EMS is not prepared to lobby for new resources and capabilities. First, we need to determine what information prehospital and hospital emergency care providers need, in what form, and at what stage in the course of an EMS patient care episode. It is the EMS community itself, including state and local government agencies responsible for EMS, that must organize to take advantage of these opportunities and capabilities.

Where We Are

The commentary by Carl Van Cott highlights the evolution of the existing EMS radio systems including the very high frequency (VHF) radio channels and ultra high frequency (UHF, in the 460MHz range; often called the "10 med channels") channels for ambulance to hospital (for reporting patient condition and seeking medical direction) and other communications. With the exception of electrocardiogram (EKG) biotelemetry sent over the UHF EMS channels, these communications were solely for voice use. Even today, the EMS communications system probably consists of 98% voice and 2% biotelemetry and other data transmissions.

Some local EMS systems have been solicited to participate in new or existing regionwide or statewide 700MHz and 800 MHz radio systems that are usually operated by law enforcement and/or government transportation agencies. These systems offer more voice channels for specializing communications but have significantly less transmission range, which makes them less practical in rural areas. Governmental owners of such systems solicit new users like EMS when the cost of maintaining an existing system becomes challenging. For rural EMS operations, this can be an expensive proposition. Erecting new antennae, for example, would be necessary. In addition, when urban EMS systems become integrated into 700/800 MHz systems, the

> *"Each segment in the EMS response presents potential delays. Each also presents opportunities to accelerate appropriate medical intervention through improved communications that enable some events, decision making, and actions to occur more simultaneously."*

Kevin K. McGinnis, MPS, EMT-P, is a program advisor for the National Association of State EMS Officials. He can be reached at mcginnis@nasemso.org or 201 Park Washington Court, Falls Church, VA 22046-4527.

specialty centers involved must often maintain VHF/UHF capabilities for communicating with ambulances coming in from outside of that area.

Broadband capacity at 2.4 MHz is a technology being provided by some municipalities for public internet access in urban environments. Municipalities are also encouraging public safety agencies to employ this technology. Broadband will become increasingly important to EMS as data communications are utilized more. Careful consideration, however, should be given when considering its use for mission-critical communications and for any communications involving confidential patient information. The unlicensed and public access characteristics of this system render its reliability and security suspect. Another broadband service at 4.9 MHz is reserved for licensing by public safety organizations. Use of this service is believed to alleviate reliability and security issues to a greater extent. Both 2.4 MHz and 4.9 MHz services are extremely short range and, thus, of use in primarily urban environments.

Where We Could Be

During an EMS emergency call today, events, decision making, and resulting actions largely occur on a sequential basis as new information is presented. In a rural car crash, for instance, the crash occurs, the crash is detected, EMS is called, EMS responds, EMS arrives and evaluates, additional resources are called (eg, extrication services, helicopter), additional resources respond, medical direction is sought and provided, treatment is administered, and the patient is transported. Each segment in the EMS response presents potential delays. Each also presents opportunities to accelerate appropriate medical intervention through improved communications that enable some events, decision making, and actions to occur more simultaneously. Delays during EMS calls can cost tens of minutes, if not hours, during the patient's "golden hour," the time from the crash event to when the patient arrives under a surgeon's scalpel.

In the future, through advanced automatic crash notification (AACN) systems in cars, standard equipment on many car models now produced, the crash event and location will be available to local EMS and other responders almost immediately. Current and future AACN features can also transmit change in velocity at crash, direction of impact, air bag deployment, seatbelt status, number of occupants, and rollover status. Future systems may include an "urgency algorithm" which notifies responders of the likelihood that an occupant was severely injured in the crash. Not only does this virtually eliminate the delay in detecting and locating crashes, but it allows prehospital and hospital providers to be immediately notified of all or severe crashes in their response/catchment areas. With appropriate protocols in place, simultaneous dispatch of ground and air ambulances and extrication services could then occur in severe crashes. Similarly, hospitals and trauma centers could notify their staffs to be ready and notify prehospital responders of their availability to take patients. One can imagine similar capabilities in "help, I've fallen and can't get up" devices for populations at risk.

When EMS responders arrive at the scene in the future, they will be able to do more simultaneously. The initial provider at a car crash will make a quick, triaging assessment of each patient, placing and leaving a small electrocardiogram (EKG) and vital signs monitor on each, inserting each patient's emergency health record "smart card" into his personal digital assistant (PDA) or communications device, describing brief findings about each into a lip microphone which is translated to a text file, and shooting brief video of each through a shoulder or head camera. Each of these data streams goes into patient-specific data bases in the responder's PDA and is transmitted to a mobile data unit in the ambulance.

Once additional responders are assigned to patients, their devices are used to enter their identifications, monitor patient vital signs, and add new voice/text and video data into the respective patient-specific data files. The EMS scene coordinator, as well as yet to arrive EMS, extrication, and helicopter crews and the local and trauma center hospital staffs can access databases for updates on any or all of the patients' conditions. Field providers utilize PDAs or mobile data units like laptop or tablet computers. Hospital staff may use the same or desktop units. All are combination voice and data communications units. Looking at a screen with a patient's real-time vital signs, video image, and provider's notes, medical direction physicians can begin to anticipate more information they may want and orders they will give crews at the scene or en route to the hospital. As patients become assigned to specific EMS crews for transport to specific hospitals, access to their databases becomes limited to their prehospital and hospital providers. Best routing to a scene and then from scene to hospital by ground ambulance can be determined through local transportation agency real-time traffic monitoring databases.

The Technology Required

This vision for where we could be comes at a price and with risks. In April 2007 the Blackberry network crashed. Technology such as mobile data units, PDAs, and computers with integrated voice communications exist today, but these can be costly. Personal digital assistant-based emergency health record entry and reliable speech-recognition technology has been developed in military systems such as the Battlefield Medical Information System Tactical,[1] which is available for commercial licensure. Video and vital signs monitoring for one or multiple patients through miniaturized devices has been demonstrated by a research and development group coordinated through Johns Hopkins.[2] A number of EMS systems have piloted video use in ambulances

If hospital and prehospital emergency care and other public safety players involved in any EMS call maintain databases detailing the status and availability of their resources, it becomes theoretically possible to network them in a system that is accessible by the field PDAs and other devices described. Then we add to the network those databases created by public safety, advanced automatic crash notification, traffic and other control/dispatch centers that describe evolving car crashes, EMS call, traffic flow, and other system events. Finally added is the ad hoc patient databases created at the scenes of EMS calls, and these 3 components become a "network of networks" in which voice and data communications can exist. To complete the system picture, the screen of any of the data/voice communications devices could present a simple, map-like picture of the provider's response or catchment area. The screen would depict icons for all the relevant events occurring in real time (eg, car crashes, ambulance calls) and resources (eg, local hospital emergency department, EMS, fire rescue). By selecting an icon, an authorized user could then drill down on an event or resource to find out more about it. At the lowest level of a car crash event icon, one might find the patient video, vital signs, and provider notes data described earlier.

Federal and National Activities and Opportunities for State and Local Action

If EMS is going to participate in the type of data communications network described above, it must acquire communications frequencies with greater bandwidth than it has now. The VHF/UHF and 700/800MHz capabilities it now utilizes have bandwidth sufficient for voice communications and simple EKG biotelemetry. Sending text data (like provider's notes), real-time vital signs data, basic streaming video, higher definition video, and medical quality video require increasingly wider frequency bands to provide the speed of data transmission needed to send these files for real-time use. Transmitting a huge video file on one of today's EMS VHF frequencies would be slower than sending it by dial-up internet access. For vital signs transmission, at least wide-band capability would be needed, and for high to medical quality video, broadband is required. With multiple EMS crews sending data to various hospitals in any one area at the same time, the bandwidth required could well outstrip that available.

Congress and the Federal Communications Commission (FCC) have ordered analog television stations off a frequency band in the 700 MHz range (channels 60-69; 746 MHz-806 MHz). They have allocated some of this for public safety use and the FCC is now considering proposals for how it will be divided up when it is released in 2009. The remainder was to be auctioned in 2009 for commercial use with a billion dollars of the proceeds to go to public safety in states and locales for improving radio interoperability. Congress is likely to approve the expenditure of that $1 billion to be spent this year. The National Public Safety Telecommunications Council, FCC, and US Department of Homeland Security (SafeCom Interoperability Program) websites can be monitored for progress.[3,4,5] Despite the early availability of these funds, there are proposals before the FCC to give the remaining analog TV channel range to public safety for a national broadband network under the supervision of a public safety controlled consortium rather than auctioning them off for commercial use.

The SafeCom Program is constantly developing tools for state and local interoperability and system development efforts. Included in these are guidelines for the development of statewide interoperability executive committees. Such committees exist in most states by one name or another and should be targeted by EMS interests to seek inclusion for public safety broadband planning efforts and access to bandwidth.

The FCC has ordered that the VHF and UHF frequencies that include the traditional EMS frequencies be made even narrower by 2013. This means that where there once existed one narrow-band channel for use, there will be as many as four. Local EMS agencies that have been attracted to the current 700/800MHz system offerings in their states because of the availability of many open channels for EMS use may find that sticking with their VHF/UHF systems provides not only greater range and less expense but more voice channels in few years. **NCMJ**

Spotlight on the Safety Net

A Community Collaboration
Kimberly M. Alexander-Bratcher, MPH

Mecklenburg Emergency Medical Services Agency

Mecklenburg Emergency Medical Services Agency, better known as Medic, provides emergency and nonemergency paramedic level medical services to the citizens of Mecklenburg County. Medic is part of a unique partnership between Mecklenburg County, Carolinas HealthCare System, and Presbyterian Health Care/Novant Health. Since fiscal year 1997, Medic has reduced ambulance response times, implemented higher clinical standards, and reduced the taxpayer subsidy per call by half. The agency will answer more than 85 000 calls for medical help this year. Medic also conducts frequent community education programs on health, safety, injury prevention, and emergency-related issues.

In 1996, the Mecklenburg Board of County Commissioners and the county management staff worked closely with emergency medical services (EMS) management and leaders in both the medical and business communities to address the needs of the county's EMS department. Together, they were committed to meeting future needs in the ever-growing Charlotte-Mecklenburg community. The goal was and continues to be enhancement of Mecklenburg's emergency medical services to create a high-performance EMS system. A joint plan was also received by the community's two major hospital systems—the Carolinas HealthCare System and the Presbyterian Health Care System. In the fall of 1996, the Mecklenburg Board of County Commissioners decided to form a partnership with the two hospital systems to provide prehospital emergency medical care and transportation.

Medic maintains its own communication center known as Central Medical Emergency Dispatch (CMED). Central Medical Emergency Dispatch's 3 primary responsibilities are to: (1) prioritize and dispatch 9-1-1 requests for service and coordinate all EMS resources within Charlotte-Mecklenburg; (2) dispatch all Mecklenburg County volunteer fire departments; and (3) serve as the central warning point for two nuclear power facilities or other disasters that may occur. All requests for emergency services are handled via an enhanced 9-1-1 system. All 9-1-1 calls for Medic and/or county fire are routed to CMED by the Charlotte-Mecklenburg Police Department, which serves as the primary public safety answering point (PSAP). Central Medical Emergency Dispatch serves the community as the backup PSAP should there ever be a problem with the primary PSAP communications center. Efficient use of emergency medical resources is achieved by a state-of-the-art Computer Aided Medical Priority Dispatch System, global positioning satellite tracking equipment, onboard mobile status terminals, System Status Management programs, and nationally-certified emergency medical dispatchers who prioritize incoming calls and provide prearrival medical instructions to all 9-1-1 callers. Medic's CMED received national accreditation from the National Academies of Emergency Dispatch as a Center of Excellence in 2002.

At present, there are approximately 170 full-time and approximately 32 part-time field employees working at the paramedic or emergency medical technician (EMT) levels. There are also education and quality improvement staff, logistics team members, fleet maintenance workers, and human resource and financial staff. Medic currently responds to greater than 90% of all requests for emergency services within 9 minutes and 59 seconds. During any given 24-hour period, 150 to 300 calls are dispatched. Mecklenburg Emergency Medical Services Agency is the busiest EMS provider in North and South Carolina. In 2002, Medic units responded to over 70 000 calls (all responses) and conducted over 48 000 transports.

A new and innovative division at Medic is the Education and Simulation Center. Under the direction of Kevin Staley, Medic's Medical Services director, a state-of-the-art medical simulation center has been

continued on page 287

continued from page 286

developed which includes multiple sound stages, high-fidelity mannequins, control rooms, digital reproduction capabilities, and review rooms. This resource affords EMTs and paramedics a unique and progressive methodology for their continuing education. Multiple scenarios have been developed and adopted that enhance the provider's ability to deliver evidence-based emergency medical care. Similar training is currently being adopted at medical universities and nursing schools across the country. A human gross anatomy lab has also been included in this center to enhance each provider's understanding of the anatomical relationships in the human body. Medic is in partnership with the Center for Prehospital Medicine at Carolinas Medical Center which provides full-time EMT-paramedic and EMT-basic courses of instruction throughout the year. These courses are open to the public as well.

The field of emergency medical service is rapidly evolving. The Mecklenburg Emergency Medical Services Agency is mirroring the larger changes being experienced throughout the medical marketplace as a whole. This model has been designed to ensure high quality clinical care, provide efficient and reliable EMS services at a reasonable cost to consumers, and provide the community with an operationally and financially stable system. Prehospital emergency medical care is in essence the provision of health care to those afflicted by unexpected illness or injury. While EMS is considered a public service, many will debate the notion of EMS being a component of public safety. Regardless, incorporating EMS into both health care systems and county oversight in the community strengthens the concept of health care delivery and ensures that citizens and visitors in the Charlotte-Mecklenburg community receive the highest level of quality patient care possible. As such, Medic is modeling a new design for the future of EMS.

North Carolina Emergency Department Visit Data Available for Public Health Surveillance

The National Center for Health Statistics estimates there were 110.2 million emergency department (ED) visits throughout the United States in 2004 and has documented a steady increase in the number of ED visits over the past decade.[1] Secondary data from ED visit records are timely, comprehensive, population-based, and electronically available through hospital information systems. These data are increasingly in demand for use in biosurveillance and other public health surveillance efforts.

In North Carolina, 111 hospital-based EDs provide unscheduled acute patient care on a 24 hours a day, 7 days a week (24/7) basis. The North Carolina Emergency Department Database (NCEDD) project began in 1999 as a voluntary pilot project to demonstrate the ability to collect and standardize ED visit data from disparate hospital electronic information systems. In 2004 the North Carolina Division of Public Health partnered with the North Carolina Hospital Association and the University of North Carolina at Chapel Hill School of Medicine to create the North Carolina Hospital Emergency Surveillance System (NCHESS) and the provision of ED data for public health surveillance became mandatory.

As of July 1, 2007 93% (103 of 111) of hospital-based, 24/7 acute care EDs in North Carolina are providing visit data electronically at least once a day through NCHESS to be used by the North Carolina Disease Event Tracking and Epidemiologic Collection Tool (NC DETECT). (See Map 1.) NC DETECT is the web-based early

event detection and timely public health surveillance system in the North Carolina Public Health Information Network (See http://www.ncdetect.org.). The ED data in NC DETECT include all visits to North Carolina EDs: patients who were admitted to the hospital, transferred to another facility, discharged home or into law enforcement custody, or who left without being seen or against medical advice. NC DETECT uses the algorithms from the Early Aberration Reporting System (EARS) of the Centers for Disease Control and Prevention (CDC) to monitor several data sources for suspicious patterns. The reporting system also provides broader public health surveillance reports for emergency department visits related to hurricanes, injuries, asthma, vaccine-preventable diseases, occupational health, chronic diseases, and other topics.

For the purposes of biosurveillance, ED visits in North Carolina are grouped into syndromes based on analyses of the chief complaint, initial ED temperature, and history of the present illness (when available). The syndromes are based on the CDC's Syndrome Definitions for Diseases Associated with Critical Bioterrorism-associated Agents.[2]

NC DETECT serves more than 200 hospital-based and public health users at the local, regional, and state levels. All users must be approved by the North Carolina Division of Public Health before access to the system is granted. Depending on the assigned user role and data source, users have access to secure, web-based county and/or hospital views of the data and can access a variety of tabular and graphical reports. On several reports, users can specify the date ranges and can display the results by ICD-9-CM final diagnosis codes. Reports with dynamic mapping capabilities as well as an ad hoc query tool are under development.

As ED participation in NC DETECT approaches 100%, these data provide population-based analysis opportunities. The NC DETECT database will add approximately 3.5 million new ED visits each year when all hospital EDs are participating. Table 1 presents the distribution of primary diagnoses for the almost 3 million North Carolina

Table 1.
Number and Percent Distribution of Emergency Department Visits, by Major Disease Category (Primary Diagnosis Only): North Carolina, 2006

Major disease category*	ICD-9-CM code range	Number of visits	Percent distribution
All visits		2 977 543	100.0
Infectious and parasitic diseases	001-139	77 549	2.6
Neoplasms	140-239	10 563	0.4
Endocrine, nutritional and metabolic diseases, and immunity disorders	240-279	78 397	2.6
Mental disorders	290-319	112 427	3.8
Diseases of the nervous system and sense organs	320-389	122 958	4.1
Diseases of the circulatory system	390-459	124 264	4.2
Diseases of the respiratory system	460-519	249 851	8.4
Diseases of the digestive system	520-579	156 799	5.3
Diseases of the genitourinary system	580-629	124 667	4.2
Diseases of the skin and subcutaneous tissue	680-709	81 685	2.7
Diseases of the musculoskeletal system and connective tissue	710-739	201 680	6.8
Symptoms, signs and ill-defined conditions	780-799	595 237	20.0
Injury and poisoning	800-999	511 647	17.2
Supplementary classification	V01-V82	80 073	2.7
All other diagnoses	280-289 630-677 740-779	62 793	2.1
Unknown/Missing**		386 953	13.0

* Based on the *International Classification of Diseases, 9th Revision, Clinical Modification* (ICD-9-CM).
** Includes invalid codes and blank diagnoses.

continued from page 290

ED visits reported for 2006. One in 5 ED visits received a primary diagnosis related to nonspecific symptoms and conditions (eg, fever, syncope, headache, chest pain) and a similar proportion have a primary diagnosis related to injury or poisoning. Many ED visits (13%) are submitted with missing or unknown primary diagnoses, including visits assigned invalid diagnosis codes.

A distinctive feature of the ED data in NC DETECT is their timeliness. Because the data are submitted and updated twice a day, they are particularly useful for surveillance and situational awareness in rapidly developing outbreaks or disasters. However, not all data elements are immediately available. Thus, early analyses of the data rely on the patient's presenting information, including demographics, chief complaint or reason for visit, history of the present illness, and initial vital signs, whereas analyses that require final diagnosis codes may need to wait 3 to 6 months to ensure acceptable levels of completeness.

NC DETECT allows public health epidemiologists and infection control specialists to significantly increase the speed of detecting, monitoring, and investigating public health events statewide. State and hospital-based epidemiologists monitor the biosurveillance syndromes daily to identify suspicious signals. Epidemiologists systematically review visit-specific information for detailed signal analysis and can also view syndromes and signals stratified by age groups. If an outbreak is suspected, additional investigation measures and appropriate notification can be quickly applied. In addition, rapid initiation of surveillance for new conditions and situations (eg, chemical explosion, peanut butter contamination) can be established by NC DETECT using keyword-based analyses of ED chief complaint and triage notes. These custom reports can be developed and disseminated in less than 2 hours.

All 111 North Carolina EDs are expected to be providing data to NC DETECT by the end of 2007. Efforts are underway to present reports of counts, percents, and population-based rates through the web-based reporting system. Additional users of the data are welcomed, based on application and authorization through the website and the North Carolina Division of Public Health. For further information, contact the authors at ncdetect@listserv.med.unc.edu or visit http://www.ncdetect.org.

Scotland Memorial Hospital Emergency Center Improvements

In 2004 when Scotland Health Care System approved a project that would renovate and expand the Emergency Center at Scotland Memorial Hospital, it was decided the hospital would not borrow money for the project, but that funding would come from hospital reserves and fundraising—including grants. The health system approached The Duke Endowment with their plans and were awarded two grants of $200 000 each to support the development of Scotland Memorial Hospital's vision for its emergency facility and the services it provides.

Scotland Memorial Hospital is a 104 acute care bed, not-for-profit, community-owned hospital in Laurinburg, North Carolina. Located in the Sandhills region of the state, the hospital serves the health care needs of citizens of Scotland, Robeson, Hoke and Richmond counties in North Carolina and Marlboro County, South Carolina. Built in 1983, Scotland Memorial Hospital's Emergency Center (EC) was a state-of-the-art facility at the time of the hospital's construction. With 6400 square feet, the EC was designed to accommodate 10 000 patients annually. With the exception of a small addition in 1986, the EC underwent no major changes or expansions in the next two decades, while the annual number of patients treated rose to approximately 23 000. This significant increase in patient visits overwhelmed available space and forced patients, equipment, and care into every corner of the EC.

Many patients presenting to the EC are sicker than in years past, requiring more time-consuming assessments and testing. In fact, nearly 20% of Scotland Memorial's EC patients require hospital admission in order to treat their illnesses. Over 60% of all inpatients are admitted through the EC. These numbers indicate that the EC has become the hospital's "front door." Compounding the problems caused by lack of EC space was that inpatient hospital beds were often full. The patients who need to be admitted from the EC had nowhere to go, thus exacerbating the Center's capacity limitations for patients requiring treatment.

To address the growing need, Scotland Health Care System approved a multifaceted project that included renovating and expanding the Emergency Center. The first grant from The Duke Endowment provided capital funding for the structural expansion of the EC. The EC increased from 6400 square feet to over 24 000 square feet along with growing from 14 curtained bays to 20 private rooms. Additionally, the new EC includes:

- A "fast track center" for nonurgent patients to receive care.
- A second triage and evaluation room to permit patients to be assessed more quickly.
- Two separate trauma rooms, offering greater privacy for patients and their families.
- An expanded waiting room.
- A separate pediatrics waiting area to protect children from the potentially traumatic experience of an EC waiting area.
- A modernized and expanded nurse's station that increases the visibility to patient rooms and houses computers and modern communication equipment.
- A quiet, private space for families coping with life-threatening illness, injury, or death of a loved one.

A second grant from The Duke Endowment helped fund the cost of hardware, software, and employee and physician training required for implementation of a new Emergency Center Patient Tracking and Information System that will go online August 14, 2007. This comprehensive system will result in increased patient safety and quality of care, improved provider efficiencies, and decreased patient waiting times. Benefits of a tracking and information system include:

- Identifying a patient's physical location and the status of his or her examination and diagnosis with the touch of a computer screen.
- Eliminating breakdowns in communication and long wait-times in the multi-step process of physician examination, order writing, and order completion.
- Reducing errors from illegible handwriting through touch screen technology.
- Diminishing misdirected lab requests and misplaced lab results.
- Monitoring and advising patients from outside of the EC through off-site access to patient records.

The expansion and renovation of the EC, along with the requisite changes, and the renovation of acute care bed space was a major project for Scotland Memorial Hospital. Through this initiative the citizens of the Scotland area receive quality, compassionate emergency care 24 hours each day, 7 days a week, in a facility that offers them privacy and security while accommodating the equipment and staff needed to serve them. The multifaceted project has had a significant impact on the health and economic well-being of Scotland Memorial Hospital and the community.

Karen Gainey, marketing coordinator, and Becca Hughes, foundation director, of Scotland Health Care System contributed to this profile.

ACIPHEX® \a-sə-ˌfeks\
(rabeprazole sodium)
Delayed-Release Tablets

BRIEF SUMMARY

Before prescribing ACIPHEX®, please see full prescribing information.

INDICATIONS AND USAGE

Healing of Erosive or Ulcerative Gastroesophageal Reflux Disease (GERD)

ACIPHEX® is indicated for short-term (4 to 8 weeks) treatment in the healing and symptomatic relief of erosive or ulcerative gastroesophageal reflux disease (GERD). For those patients who have not healed after 8 weeks of treatment, an additional 8-week course of ACIPHEX® may be considered.

Maintenance of Healing of Erosive or Ulcerative Gastroesophageal Reflux Disease (GERD)

ACIPHEX® is indicated for maintaining healing and reduction in relapse rates of heartburn symptoms in patients with erosive or ulcerative gastroesophageal reflux disease (GERD Maintenance). Controlled studies do not extend beyond 12 months.

Treatment of Symptomatic Gastroesophageal Reflux Disease (GERD)

ACIPHEX® is indicated for the treatment of daytime and nighttime heartburn and other symptoms associated with GERD.

Healing of Duodenal Ulcers

ACIPHEX® is indicated for short-term (up to four weeks) treatment in the healing and symptomatic relief of duodenal ulcers. Most patients heal within four weeks.

Helicobacter pylori Eradication to Reduce the Risk of Duodenal Ulcer Recurrence

ACIPHEX® in combination with amoxicillin and clarithromycin as a three drug regimen, is indicated for the treatment of patients with *H. pylori* infection and duodenal ulcer disease (active or history within the past 5 years) to eradicate *H. pylori*. Eradication of *H. pylori* has been shown to reduce the risk of duodenal ulcer recurrence. (See **CLINICAL STUDIES** and **DOSAGE AND ADMINISTRATION** in full prescribing information.)

In patients who fail therapy, susceptibility testing should be done. If resistance to clarithromycin is demonstrated or susceptibility testing is not possible, alternative antimicrobial therapy should be instituted. (See **CLINICAL PHARMACOLOGY, Microbiology** in full prescribing information and the clarithromycin package insert, **CLINICAL PHARMACOLOGY, Microbiology**.)

Treatment of Pathological Hypersecretory Conditions, Including Zollinger-Ellison Syndrome

ACIPHEX® is indicated for the long-term treatment of pathological hypersecretory conditions, including Zollinger-Ellison syndrome.

CONTRAINDICATIONS

Rabeprazole is contraindicated in patients with known hypersensitivity to rabeprazole, substituted benzimidazoles or to any component of the formulation.

Clarithromycin is contraindicated in patients with known hypersensitivity to any macrolide antibiotic.

Concomitant administration of clarithromycin with pimozide and cisapride is contraindicated. There have been post-marketing reports of drug interactions when clarithromycin and/or erythromycin are co-administered with pimozide resulting in cardiac arrhythmias (QT prolongation, ventricular tachycardia, ventricular fibrillation, and torsade de pointes) most likely due to inhibition of hepatic metabolism of pimozide by erythromycin and clarithromycin. Fatalities have been reported. (Please refer to full prescribing information for clarithromycin.)

Amoxicillin is contraindicated in patients with a known hypersensitivity to any penicillin. (Please refer to full prescribing information for amoxicillin.)

WARNINGS

CLARITHROMYCIN SHOULD NOT BE USED IN PREGNANT WOMEN EXCEPT IN CLINICAL CIRCUMSTANCES WHERE NO ALTERNATIVE THERAPY IS APPROPRIATE. If pregnancy occurs while taking clarithromycin, the patient should be apprised of the potential hazard to the fetus. (See **WARNINGS** in prescribing information for clarithromycin.)

Amoxicillin: Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported in patients on penicillin therapy. These reactions are more likely to occur in individuals with a history of penicillin hypersensitivity and/or a history of sensitivity to multiple allergens.

There have been well-documented reports of individuals with a history of penicillin hypersensitivity reactions who have experienced severe hypersensitivity reactions when treated with a cephalosporin. Before initiating therapy with any penicillin, careful inquiry should be made concerning previous hypersensitivity reactions to penicillin, cephalosporin, and other allergens. If an allergic reaction occurs, amoxicillin should be discontinued and the appropriate therapy instituted. (See **WARNINGS** in prescribing information for amoxicillin.)

SERIOUS ANAPHYLACTIC REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH EPINEPHRINE. OXYGEN, INTRAVENOUS STEROIDS, AND AIRWAY MANAGEMENT, INCLUDING INTUBATION, SHOULD ALSO BE ADMINISTERED AS INDICATED.

Pseudomembranous colitis has been reported with nearly all antibacterial agents, including clarithromycin and amoxicillin, and may range in severity from mild to life threatening. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of "antibiotic-associated colitis".

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to discontinuation of the drug alone. In moderate to severe cases, consideration should be given to management with fluid and electrolytes, protein supplementation, and treatment with an antibacterial drug clinically effective against *Clostridium difficile colitis.*

PRECAUTIONS

General

Symptomatic response to therapy with rabeprazole does not preclude the presence of gastric malignancy.

Patients with healed GERD were treated for up to 40 months with rabeprazole and monitored with serial gastric biopsies. Patients without *H. pylori* infection (221 of 326 patients) had no clinically important pathologic changes in the gastric mucosa. Patients with *H. pylori* infection at baseline (105 of 326 patients) had mild or moderate inflammation in the gastric body or mild inflammation in the gastric antrum. Patients with mild grades of infection or inflammation in the gastric body tended to change to moderate, whereas those graded moderate at baseline tended to remain stable. Patients with mild grades of infection or inflammation in the gastric antrum tended to remain stable. At baseline 8% of patients had atrophy of glands in the gastric body and 15% had atrophy in the gastric antrum. At endpoint, 15% of patients had atrophy of glands in the gastric body and 11% had atrophy in the gastric antrum. Approximately 4% of patients had intestinal metaplasia at some point during follow-up, but no consistent changes were seen.

Steady state interactions of rabeprazole and warfarin have not been adequately evaluated in patients. There have been reports of increased INR and prothrombin time in patients receiving a proton pump inhibitor and warfarin concomitantly. Increases in INR and prothrombin time may lead to abnormal bleeding and even death. Patients treated with a proton pump inhibitor and warfarin concomitantly may need to be monitored for increases in INR and prothrombin time.

Information for Patients

Patients should be cautioned that ACIPHEX® delayed-release tablets should be swallowed whole. The tablets should not be chewed, crushed, or split. ACIPHEX® can be taken with or without food.

Drug Interactions

Rabeprazole is metabolized by the cytochrome P450 (CYP450) drug metabolizing enzyme system. Studies in healthy subjects have shown that rabeprazole does not have clinically significant interactions with other drugs metabolized by the CYP450 system, such as warfarin and theophylline given as single oral doses, diazepam as a single intravenous dose, and phenytoin given as a single intravenous dose (with supplemental oral dosing). Steady state interactions of rabeprazole and other drugs metabolized by this enzyme system have not been studied in patients. There have been reports of increased INR and prothrombin time in patients receiving proton pump inhibitors, including rabeprazole, and warfarin concomitantly. Increases in INR and prothrombin time may lead to abnormal bleeding and even death.

In vitro incubations employing human liver microsomes indicated that rabeprazole inhibited cyclosporine metabolism with an IC_{50} of 62 micromolar, a concentration that is over 50 times higher than the C_{max} in healthy volunteers following 14 days of dosing with 20 mg of rabeprazole. This degree of inhibition is similar to that by omeprazole at equivalent concentrations.

Rabeprazole produces sustained inhibition of gastric acid secretion. An interaction with compounds which are dependent on gastric pH for absorption may occur due to the magnitude of acid suppression observed with rabeprazole. For example, in normal subjects, co-administration of rabeprazole 20 mg QD resulted in an approximately 30% decrease in the bioavailability of ketoconazole and increases in the AUC and C_{max} for digoxin of 19% and 29%, respectively. Therefore, patients may need to be monitored when such drugs are taken concomitantly with rabeprazole. Co-administration of rabeprazole and antacids produced no clinically relevant changes in plasma rabeprazole concentrations.

In a clinical study in Japan evaluating rabeprazole in patients categorized by CYP2C19 genotype (n=6 per genotype category), gastric acid suppression was higher in poor metabolizers as compared to extensive metabolizers. This could be due to higher rabeprazole plasma levels in poor metabolizers. Whether or not interactions of rabeprazole sodium with other drugs metabolized by CYP2C19 would be different between extensive metabolizers and poor metabolizers has not been studied.

Combined Administration with Clarithromycin

Combined administration consisting of rabeprazole, amoxicillin, and clarithromycin resulted in increases in plasma concentrations of rabeprazole and 14-hydroxyclarithromycin. (See **CLINICAL PHARMACOLOGY, Combination Therapy with Antimicrobials** in full prescribing information.)

Concomitant administration of clarithromycin with pimozide and cisapride is contraindicated. (See **PRECAUTIONS** in prescribing information for clarithromycin.) (See **PRECAUTIONS** in prescribing information for amoxicillin.)

Carcinogenesis, Mutagenesis, Impairment of Fertility

In a 88/104-week carcinogenicity study in CD-1 mice, rabeprazole at oral doses up to 100 mg/kg/day did not produce any increased tumor occurrence. The highest tested dose produced a systemic exposure to rabeprazole (AUC) of 1.40 µg•hr/mL which is 1.6 times the human exposure (plasma $AUC_{0\text{-}\infty}$ = 0.88 µg•hr/mL) at the recommended dose for GERD (20 mg/day). In a 104-week carcinogenicity study in Sprague-Dawley rats, males were treated with oral doses of 5, 15, 30 and 60 mg/kg/day and females with 5, 15, 30, 60 and 120 mg/kg/day. Rabeprazole produced gastric enterochromaffin-like (ECL) cell hyperplasia in male and female rats and ECL cell carcinoid tumors in female rats at all doses including the lowest tested dose. The lowest dose (5 mg/kg/day) produced a systemic exposure to rabeprazole (AUC) of about 0.1 µg•hr/mL which is about 0.1 times the human exposure at the recommended dose for GERD. In male rats, no treatment related tumors were observed at doses up to 60 mg/kg/day producing a rabeprazole plasma exposure (AUC) of about 0.2 µg•hr/mL (0.2 times the human exposure at the recommended dose for GERD).

Rabeprazole was positive in the Ames test, the Chinese hamster ovary cell (CHO/HGPRT) forward gene mutation test and the mouse lymphoma cell (L5178Y/TK+/–) forward gene mutation test. Its demethylated-metabolite was also positive in the Ames test. Rabeprazole was negative in the *in vitro* Chinese hamster lung cell chromosome aberration test, the *in vivo* mouse micronucleus test, and the *in vivo* and *ex vivo* rat hepatocyte unscheduled DNA synthesis (UDS) tests.

Rabeprazole at intravenous doses up to 30 mg/kg/day (plasma AUC of 8.8 µg•hr/mL, about 10 times the human exposure at the recommended dose for GERD) was found to have no effect on fertility and reproductive performance of male and female rats.

Pregnancy

Teratogenic Effects. Pregnancy Category B: Teratology studies have been performed in rats at intravenous doses up to 50 mg/kg/day (plasma AUC of 11.8 µg•hr/mL, about 13 times the human exposure at the recommended dose for GERD) and rabbits at intravenous doses up to 30 mg/kg/day (plasma AUC of 7.3 µg•hr/mL, about 8 times the human exposure at the recommended dose for GERD) and have revealed no evidence of impaired fertility or harm to the fetus due to rabeprazole. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers

Following intravenous administration of ^{14}C-labeled rabeprazole to lactating rats, radioactivity in milk reached levels that were 2- to 7-fold higher than levels in the blood. It is not known if unmetabolized rabeprazole is excreted in human breast milk. Administration of rabeprazole to rats in late gestation and during lactation at doses of 400 mg/kg/day (about 195-times the human dose based on mg/m^2) resulted in decreases in body weight gain of the pups. Since many drugs are excreted in milk, and because of the potential for adverse reactions to nursing infants from rabeprazole, a decision should be made to discontinue nursing or discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use

The safety and effectiveness of rabeprazole in pediatric patients have not been established.

Use in Women

Duodenal ulcer and erosive esophagitis healing rates in women are similar to those in men. Adverse events and laboratory test abnormalities in women occurred at rates similar to those in men.

Geriatric Use

Of the total number of subjects in clinical studies of ACIPHEX®, 19% were 65 years and over, while 4% were 75 years and over. No overall differences in safety or effectiveness were observed between these subjects and younger subjects, and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

ADVERSE REACTIONS

Worldwide, over 2900 patients have been treated with rabeprazole in Phase II-III clinical trials involving various dosages and durations of treatment. In general, rabeprazole treatment has been well-tolerated in both short-term and long-term trials. The adverse events rates were generally similar between the 10 and 20 mg doses.

Incidence in Controlled North American and European Clinical Trials

In an analysis of adverse events assessed as possibly or probably related to treatment appearing in greater than 1% of ACIPHEX® patients and appearing with greater frequency than placebo in controlled North American and European trials, the incidence of headache was 2.4% (n=1552) for ACIPHEX® versus 1.6% (n=258) for placebo.

In short and long-term studies, the following adverse events, regardless of causality, were reported in ACIPHEX®-treated patients. Rare events are those reported in ≤1/1000 patients.

ONE YEAR AGO IT ONLY EXISTED IN OUR MINDS. NOW IT'S IN OUR HEARTS.

We'd like to thank the doctors, staff and everyone
who has made Southeastern Heart Center a reality.

In just one year, Southeastern Heart Center has touched the lives and hearts of thousands living in our community. In fact, we've performed over 6,800 heart-related procedures since our first open-heart surgery one year ago today. Backed by the experience and expertise of Duke University Health System, the Heart Center provides open-heart, thoracic and endovascular surgery, including diagnostic and interventional catheterizations such as angioplasty and stents—all right here at home. From all of us at Southeastern, thank you for your support. Without you, the Heart Center would still be just a dream.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

---

Paula Nobles, RN, BSN
Pediatric Case Manager, Washington Pediatrics – AccessCare

AccessCare is a network of primary care physicians committed to providing the highest quality medical care for North Carolina's Medicaid population. AccessCare is the largest of 14 local networks of primary care providers that contract with the North Carolina Department of Health and Human Services to develop disease management and case management initiatives and coordinate prevention, treatment, and other services. This system of networks, coordinated by Community Care of North Carolina, enhances the Carolina ACCESS Medicaid program by developing physician-led community partnerships to improve care and reduce costs by connecting Medicaid enrollees with a medical home.

Within AccessCare, patient educators and case managers play a special role in helping patients understand their conditions and options along with managing their often complicated diseases. Paula Nobles, RN, BSN, is definitely an invisible hero in the world of case management for the enrollees of Beaufort County. A 1997 Magna Cum Laude graduate of the East Carolina University School of Nursing, Ms Nobles formerly worked as a staff nurse in obstetrics, pediatrics, and the newborn nurseries at Beaufort County Hospital and Pitt County Memorial Hospital. She joined AccessCare in June 2004 as a pediatric case manager with Washington Pediatrics. Her supervisors say that Ms Nobles has used her solid nursing education to cohesively mesh the worlds of hospital nursing and community case management.

Ms Nobles' current areas of specialty include asthma and pediatric obesity. She coordinates the monthly asthma and weight reduction clinics and has received further training in childhood hearing, chronic obstructive pulmonary disease, and smoking cessation. She is a referral resource for the provider staff of Washington Pediatrics, Beaufort County Health Department, Beaufort County Department of Social Services, and Children's Developmental Services Agencies. In addition she assists school nurses and other community health care providers and always graciously accepts assignments to orient new staff at AccessCare as well as staff from other North Carolina Medicaid networks. Ms Nobles also has volunteered to assist staff in other counties assess high-risk patients that may be in need of case management services.

Ms Nobles, who once described herself as being quiet and meticulously organized, has quietly yet dramatically evolved into one of the best community case manager leaders in her county. A typical work week for Ms Nobles may consist of conducting patient-practitioner education, coordinating and directing the Asthma and Weight Reduction Clinics, planning and implementing patient care plans for various disease processes, electronically documenting all case management duties in the NC Medicaid Case Management Information System, attending local and statewide meetings, and effectively serving the providers and case managing the enrollees of Washington Pediatrics. Her work helps to improve quality of care while implementing cost savings. At the 2005 North Carolina Pediatric Society meeting, one eastern North Carolina pediatrician was quoted saying, "I heard about the case manager at Washington Pediatrics, and I want a case manager in our office that mirrors exactly what Dr Ainsworth's case manager does for their office. I hear she is excellent!"

In addition to serving as an advocate for the Carolina ACCESS enrollees of Beaufort County, Ms Nobles is involved in other health-related community activities. She serves as a preceptor for ECU School of Nursing bachelor of science in nursing students, provides asthma education to students at Beaufort Community College, and has written articles on pediatric obesity for the *Washington Daily News*. She serves on the Beaufort County Task Force on sudden infant death syndrome and codirects the Weight Reduction Summer Camp in Beaufort County with pediatrician Dr Debbie Ainsworth.

For her efforts and accomplishments in case management and support services for the pediatric Access patients in Beaufort County, the editors of the *North Carolina Medical Journal* are pleased to recognize Paula Nobles, RN, BSN, and all case managers and patient educators across the state for their contribution to the health and well-being of all North Carolinians.

ARTICLE

Knowledge and Practice of Foodborne Disease Clinical Specimen Testing and Reporting in North Carolina, 2004

Pia D. M. MacDonald, PhD, MPH; Michelle R. Torok, PhD, MPH; Jean-Marie Maillard, MD, MSc; Martha Salyers, MD, MPH; Leslie A. Wolf, PhD; Amy L. Nelson, PhD, MPH

Abstract

Background: *Detection of foodborne disease outbreaks relies on health care practitioners (HCPs), infection control practitioners (ICPs), and clinical laboratorians to report notifiable diseases to state or local health departments.*

Methods: *To examine knowledge and practices about notifiable foodborne disease reporting among HCPs and ICPs in western North Carolina and among clinical laboratorians statewide, participants responded to a self-administered questionnaire about foodborne pathogen testing and reporting, referencing* Campylobacter, *shiga-toxin producing* Escherichia coli, *and other organisms.*

Results: *Three hundred seventy-two of 1442 health care providers participated in this survey. Of 372 study participants, fewer than 20% knew that both the clinician and the laboratorian were legally responsible for reporting the study pathogens. Most laboratorians identified the ICP (57%) as responsible for reporting. There was a lack of understanding about which infections and test results were reportable.*

Limitations: *The response rate was very low, particularly among HCPs; participants may have been biased towards those with a particular interest in foodborne disease or surveillance. This descriptive study cannot be used to determine rates of reporting among the medical community.*

Conclusions: *Although not legally obliged to report, ICPs were found to play a significant role in disease reporting. Dissemination of surveillance information and training through the established network of North Carolina ICPs may be ideal for improving foodborne disease surveillance in this state.*

Key words: *Foodborne disease, surveillance, reporting*

Foodborne pathogens are responsible for an estimated 76 million illnesses, 325 000 hospitalizations, and 5200 deaths annually in the United States.[1] Reporting of foodborne disease by physicians and laboratories (passive surveillance) is the backbone of outbreak detection; local health departments also identify outbreaks by those affected in the community. Passive surveillance in the US has been shown to be inadequate for many foodborne diseases when compared to other sources of data.[2-8]

Additionally, the US food supply has been targeted in at least two successful deliberate releases of biological agents.[9,10] Enhancement of disease surveillance, laboratory identification, and outbreak detection and control are needed to prepare for bioterrorist acts involving the food supply.[11] Therefore, the foodborne disease reporting system in North Carolina should be described and evaluated in order to identify areas to improve foodborne disease reporting and better protect North Carolina citizens.

Pia D. M. MacDonald, PhD, MPH, is a research assistant professor in the Department of Epidemiology and director of the North Carolina Center for Public Health Preparedness at the University of North Carolina at Chapel Hill. She can be reached at pia (at) email.unc.edu or Campus Box 8165, Chapel Hill, NC 27599-8165.

Michelle R. Torok, PhD, MPH, is an epidemiologist at the North Carolina Center for Public Health Preparedness at the University of North Carolina at Chapel Hill.

Jean-Marie Maillard, MD, MSc, is head of Prevention, Investigation, and Surveillance in the Epidemiology Section of the North Carolina Division of Public Health.

Martha Salyers, MD, MPH, is leader of the Public Health Regional Surveillance Team Six at the Buncombe County Health Center.

Leslie A. Wolf, PhD, is director of the North Carolina State Laboratory of Public Health.

Amy L. Nelson, PhD, MPH, is an epidemiologist at the North Carolina Center for Public Health Preparedness at the University of North Carolina at Chapel Hill.

In North Carolina all clinical laboratory facilities and physicians are required by state law to report certain diseases/organisms to the state or the local health department. While not legally mandated to report communicable diseases, infection control practitioners (ICPs) also may play an important role in the passive surveillance system. Clinical surveillance for foodborne illness in North Carolina is conducted through clinician reports to the local health department via a mail-in card reporting system, which should be preceded by a phone report for diseases reportable within 24 hours. Most laboratory-based diagnoses are reported at the state level to the General Communicable Disease Control Branch of the Epidemiology Section via mail, phone, fax, or Internet. Foodborne diseases that are currently notifiable in North Carolina include *Campylobacter*, *Escherichia coli (E. coli)* O157:H7 (Shiga-toxin producing *E coli*, STEC), foodborne *Clostridium perfringens*, *Listeria monocytogenes*, *Staphylococcus aureus*, *Salmonella*, *Shigella*, *Vibrio vulnificus*, *Vibrio* other, and the category "foodborne other or unknown."[12]

The NC State Laboratory of Public Health accepts clinical specimens for the isolation of enteric microorganisms from public health care providers. Fecal specimens are examined for the presence of enteric pathogens including *Salmonella* serotypes, *Shigella*, *Campylobacter*, *Yersinia*, and *E. coli* 0157:H7. Reference isolates are accepted from public and private health care providers for identification and/or serotyping. The State Laboratory of Public Health also participates in the Centers for Disease Control and Prevention PulseNet System,[13] which permits detection of foodborne outbreaks within a state or widespread and diffuse outbreaks across states or countries.[14]

Although passive surveillance systems are relatively incomplete,[2] consistent disease reporting is thought to provide enough information to discern important occurrences of excess disease. However, it is important to ensure that these passive components of the notifiable disease reporting system are operating efficiently to detect outbreaks, bioterrorist incidents, and emerging infectious diseases. In this study, we describe the knowledge and practices of foodborne disease reporting and screening as well as diagnostic testing among North Carolina health care practitioners (HCPs), ICPs, and laboratorians.

METHODS

Survey of Health Care and Infection Control Practitioners in Western North Carolina

Health care practitioners and ICPs were surveyed in 2004. Contact information for HCPs in western North Carolina came from a database compiled by the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill (UNC-Chapel Hill) and maintained by the NC Medical Board. All medical and osteopathic doctors (excluding residents), physician assistants, and nurse practitioners whose professional status was "active" were included. Health care practitioners with at least 8 hours per week of direct patient care and a business address in 1 of the 19 counties in western North Carolina were included in the study. A list of ICPs in hospitals located in western North Carolina was obtained from the Statewide Program for Infection Control and Epidemiology at UNC-Chapel Hill. Surveys, an introductory letter, and an Institutional Review Board fact sheet were mailed to HCPs and ICPs in western North Carolina. Nonresponding individuals were mailed another survey package 4 weeks after the original mailing. Nonresponders to the second mailing were sent an identical mailing 8 weeks after the original, for a total of 3 mailings. Health care practitioners included in the analysis practiced in internal medicine, pediatrics, family practice, general practice, obstetrics/gynecology, and emergency department specialties.

Survey of Laboratories in North Carolina

Laboratories statewide were contacted in 2004 through NC Micronet, a database designed for rapid dissemination of emergency information to clinical microbiologists in North Carolina. Laboratories were included in the study if they had fecal specimens submitted for bacterial screening in 2003. The survey was posted on a secure server/Web site at the State Laboratory of Public Health, and the contact person on the NC Micronet list at each laboratory was e-mailed survey information, an introductory letter, and an Institutional Review Board fact sheet and was asked to participate. Contacts who did not complete the survey within 2 weeks received a reminder e-mail, and contacts who did not complete the survey within 4 weeks of the initial e-mail were contacted by telephone. Because laboratory surveys were sent electronically, the resources existed to survey laboratories statewide.

Survey Content and Data Analysis

This survey was modeled closely after the Centers for Disease Control and Prevention's FoodNet surveys.[15] All study participants were asked questions about the diagnostic testing and reporting requirements of *Campylobacter*, Shiga-toxin producing *E coli*, *Salmonella*, *Shigella*, and infection with *Vibrio* species. Some questions also included *L monocytogenes* and *Yersinia* infection.

The major domains of the survey included practice information (specialty, setting, location); foodborne disease experience (number of patients seen with acute diarrheal illness in past 30 days, clinical history of last patient seen with acute diarrheal illness, factors relating to requesting/not requesting a stool specimen, location of bacterial stool culture testing); and reporting practices (who in the facility reports positive test results to the local and state health departments). Questions about foodborne illness and prevention patient education, confidence in diagnosing, and treating foodborne illness as well as confidence in the local health department's ability to investigate disease outbreaks also were asked. The survey contained both closed and open-ended questions as well as a 5-point Likert scale.

Data from HCP and ICP surveys were manually entered into a Centers for Disease Control and Prevention EpiInfo database and reviewed for accuracy and completeness. Laboratorian surveys were downloaded into a Microsoft Access database. Data frequencies and proportions were examined.

All participants provided informed consent for the survey.

This study was approved by the University of North Carolina at Chapel Hill's Biomedical Institutional Review Board.

RESULTS

Survey of Health Care and Infection Control Practitioners in Western North Carolina

Surveys were sent to 1442 HCPs in western North Carolina. There were 319 respondents who fit the inclusion criteria; 53 respondents worked less than 8 hours per week and were excluded from the analyses (response rate: 319 of 1389, 23%). Respondents included physicians (228 of 319, 72%), nurse practitioners (55 of 319, 17%), and physician assistants (36 of 319, 11%). Among physicians, 38% were in family practice (87 of 228), 16% were in internal medicine (36 of 228) or a subspecialty (7%, 16 of 228), 13% each were in the emergency department and pediatrics (30 and 29 of 228, respectively), and the remainder were in obstetrics/gynecology (10%) or pediatric subspecialties (3%). Medical specialties for 18 participants were unknown.

Surveys were sent to ICPs at 21 facilities in western North Carolina and 11 responded. Seven of the responding ICPs worked in a hospital while the remaining 3 worked in more than one setting (eg, a hospital and long term care facility).

Diagnostic Testing Knowledge and Practice

The majority of HCPs noted that stool samples were tested at their hospital laboratory (74%, 227 of 306); 21% reported that screens were performed at independent laboratories (65 of 306); and 5% (14 of 306) did not know. Thirteen participants

† Noted as part of an "other" response, percentage not calculable

failed to respond to this question.

In general, HCP respondents identified the same pathogens as part of a routine screen. (See Table 1.) About half thought *E coli* O157:H7 was tested for routinely. Fewer thought *Vibrio* species were included in the routine screen, and many respondents were unsure about *Vibrio* and *E coli* O157:H7. Two individuals noted that *E coli* O157:H7 was screened for in cases with bloody stool. In an open-ended response, 4 individuals said *Yersinia* and 4 said *Giardia* testing were part of the screen.

Most ICPs (10 of 13) noted that stool samples were tested routinely at their hospital laboratory while several (3 of 13) indicated that the samples were tested by independent laboratories. According to most (8 of 9) of the ICPs, hospital laboratories conducted all stool screens, and 1 ICP reported 90% of cultures being conducted there. An additional ICP reported that all routine cultures were performed at a commercial laboratory.

Knowledge of Reporting Requirements

Among HCPs, 45% to 57% incorrectly thought that only clinicians were responsible for reporting, depending on the pathogen (Figure 1), while 13% incorrectly thought that only the laboratorian was responsible for reporting these diseases (range, 12% to 14%). On average, 5% to 7% of HCPs correctly noted that both clinicians and laboratorians were legally responsible for notifying the health department of these pathogens. An additional 21% to 31% did not know who should report the study pathogens. Eight percent of HCPs (24 of 296) incorrectly identified *Campylobacter* as nonreportable, 8% (22 of 289) correctly identified *Yersinia* as nonreportable, and 1% to 3% of HCPs incorrectly identified the remaining diseases as nonreportable.

Among ICPs, almost half (4 of 11) incorrectly thought that only the clinician was responsible for reporting infections with the study pathogens; a few (2 of 11) incorrectly thought that only the laboratorian was responsible for reporting these pathogens; the same proportion (2 of 11) correctly thought that both the clinician and the laboratorian were responsible for reporting; and some (4 of 11) thought some other person was responsible for reporting. *Yersinia* infection was correctly identified as nonreportable by 1 ICP. No ICP identified *Campylobacter*, STEC, *L monocytogenes*, Salmonellosis, Shigellosis, or *Vibrio* as "not reportable."

Reporting Practices

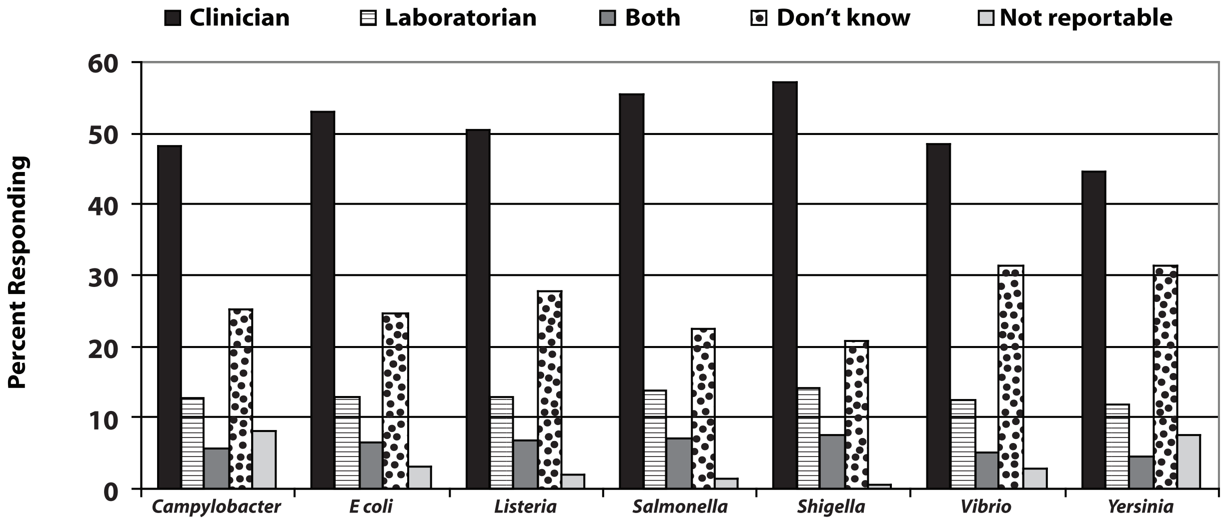
When asked who in the facility completes the state's communicable disease report card, HCPs reported that the physician (38%, 121 of 315), nurse (14%, 45 of 315), nurse practitioner (6%, 19 of 315), physician assistant (3%, 9 of 315), or another provider who saw the patient (3%, 10 of 315) completed the disease report card. However, 15% of respondents (48 of 315) did not know who completed the card in their office. Another 29 HCPs (9%) said that ICPs, the laboratory (8%, 24), or the office manager or other administrative personnel (<2%, 6) completed the card.

Infection control practitioners may report notifiable diseases to the health department, but they are not legally required to do so. Nevertheless, most of the Infection control practitioners (8 of 11) noted they completed the disease report card; 2 reported that the physician and 1 reported that the laboratorian completed the card.

Survey of Laboratories in North Carolina

E-mails giving the Web site for the survey were sent to 108 clinical diagnostic laboratories in North Carolina. Forty-eight laboratories responded and 42 fit laboratory inclusion criteria,

Figure 1.
Percent of Western North Carolina Health Care Practitioners Who Think Clinicians and/or Laboratorians Are Legally Responsible for Reporting *Campylobacter*, *E coli* O157/STEC, *L monocytogenes*, *Salmonella*, *Shigella*, and *Vibrio* Species, and *Yersinia* to the Health Department.



for a response rate of 41% (42 of 102). The participating laboratories were primarily hospital or medical-center based laboratories (39 of 42), but 2 were independent commercial laboratories, and 1 was a military base laboratory.

Diagnostic Testing Knowledge and Practice

We asked laboratorians about pathogens included in their routine enteric screen and most reported including *Salmonella*, *Shigella*, and *Campylobacter*. Fewer included *E coli* O157:H7, *Yersinia*, and *Vibrio*. Routine screening for *L monocytogenes* was rare. (See Table 1.)

When a positive result was determined for a foodborne pathogen, more than half of laboratorians (25 of 40) forwarded isolates to the State Laboratory of Public Health within 24 hours. Several (3 of 40) forwarded isolates weekly while others (4 of 40) never sent isolates, and the remaining respondents forwarded isolates monthly, yearly, within some other time frame, or whenever needed. Some sent isolates to the county health department (n=8), presumably to forward to the State Laboratory of Public Health.

Knowledge of Reporting Requirements

For *Campylobacter*, *L monocytogenes*, Shiga-toxin producing *E coli*, *Shigella*, and *Salmonella*, 36% to 41% of 39 respondents from clinical diagnostic laboratories incorrectly thought that only the laboratorian was responsible for reporting (Figure 2); 26% to 32% incorrectly thought only the clinician was responsible for reporting; and 5% incorrectly thought *L monocytogenes* was nonreportable. For *Vibrio*, 33% of laboratorians thought only laboratories were responsible for reporting, 33% thought only clinicians were responsible, and 3% thought *Vibrio* was nonreportable. For *Yersinia*, 28% said only the laboratorian was responsible for reporting, and 31% said only the clinician was responsible; 10% correctly thought *Yersinia* was nonreportable. For all study pathogens, an average of 27% (range, 23% to 28%) of respondents (n = 9-11) identified both clinician and laboratorian as responsible for reporting.

Reporting Practices

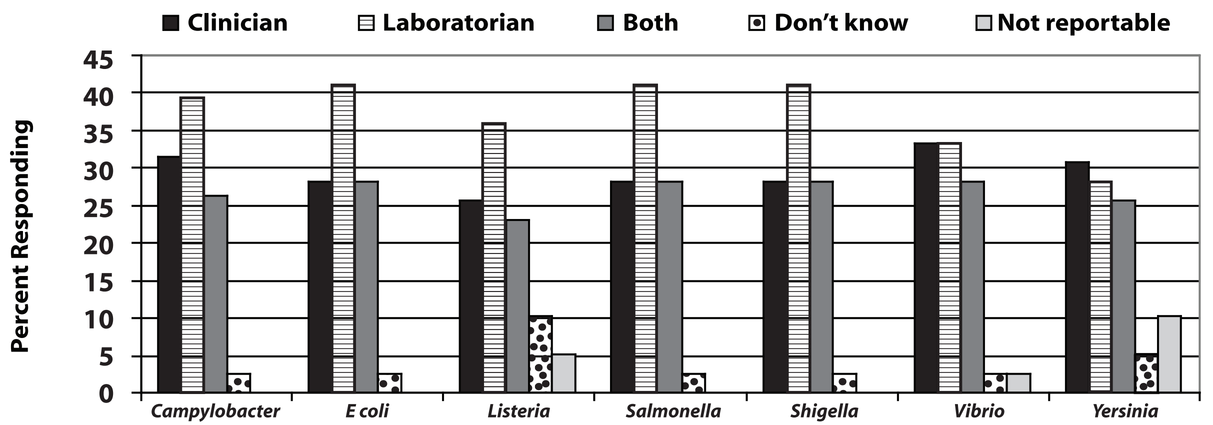
The majority of laboratorians (21 of 38) reported notifiable test results to the health department by mail. Some (10 of 38) used a fax, 1 individual each reported using the telephone and the Internet, and some (5 of 38) did not know how data was reported. When asked who in their laboratory actually reported notifiable results, most laboratorians (23 of 41) said the ICP was responsible while others (15 of 41) said the microbiologist was responsible. One each said the laboratory manager was responsible, automated computer reporting was used, or he/she notified an epidemiology clinic.

DISCUSSION

This survey of participants in the North Carolina communicable disease reporting system identified gaps in knowledge of foodborne disease testing and deficiencies in foodborne disease reporting practices. All of the pathogens included in this survey are part of the routine bacterial stool culture screen at the State Laboratory of Public Health, but hospital and independent laboratories may include different pathogens. Survey results indicate HCPs and ICPs were uncertain about the pathogens included in a routine screen at the laboratories used by their office or facility. Lack of knowledge about the routine panel at their reference laboratory could result in significant underdiagnosis and underreporting of foodborne pathogens if clinicians assume diagnostic tests will be performed on stool samples because they are considered "routine," when they are not actually part of the routine screen at their particular reference laboratory.

The routine screening practices of laboratories to identify the pathogens in the survey are comparable to those of the

Figure 2.
Percent of North Carolina Laboratorians Who Think Clinicians and/or Laboratorians Are Legally Responsible for Reporting *Campylobacter*, *E coli* O157/STEC, *L monocytogenes*, *Salmonella*, *Shigella*, and *Vibrio* Species, and *Yersinia* to the Health Department.



national foodborne surveillance sites of FoodNet, where most laboratories routinely culture for *Salmonella*, *Shigella*, and *Campylobacter* species, but fewer routinely culture for *E coli* O157:H7 (57%) and *Y. entercolitica* (50%). Fifty percent of FoodNet sites routinely test for *Vibrio* species,[16] which is more than among the North Carolina laboratories surveyed. In a study of laboratories in Gulf Coast states, only 22% of stool specimens submitted to laboratories with *Vibrio* culturing capability were screened for *Vibrio* species, and only 24% of the laboratory directors in these facilities knew that the organism was reportable in their state.[17] There may be a potential for underdiagnosis of this infection in North Carolina and other US states due to lack of testing. The costs in materials and labor of testing stool samples may continue to be one barrier to reporting.[17]

A limitation of the present study was the low response rate among HCPs (22%) and laboratorians (39%) and the small number of ICPs (n=11). Since respondents may have more interest and knowledge in foodborne illness testing and reporting compared to other clinicians and laboratorians, the data presented here may overestimate the knowledge and practices around foodborne disease testing and reporting. Data on the workplace setting of nonresponders was not available.

Participants seemed aware of the most frequently tested foodborne pathogens but they were deficient in knowledge of reporting requirements. All pathogens included in the survey are reportable in North Carolina except *Yersinia*. Eight percent of HCPs, 1 ICP, and 10% of laboratorians correctly thought *Yersinia* was not a reportable diagnosis. Three percent to 5% of laboratorians incorrectly thought *L monocytogenes* and *Vibrio* species were not reportable, and 8% of HCPs incorrectly thought *Campylobacter* was not reportable. *L monocytogenes* was added to the North Carolina notifiable disease list in 2001.

An average of 57% of HCPs knew the clinician was responsible for reporting notifiable diseases to the health department whereas an average of 64% of laboratorians knew that reporting the study pathogens was their responsibility. Health care practitioners may be expected to report confirmed cases less often than laboratories because there is a delay in obtaining diagnostic confirmation from the laboratory and patients may no longer be under the clinician's treatment. Only 6% of HCPs and 25% of laboratorians recognized that both clinicians and laboratorians were required to report notifiable diseases. Schramm,[18] who assessed the origins of confirmed case reports in Vermont in the late 1980s, found that 71% of case reports were from laboratories, 10% from nurses including ICPs, 10% from physicians' offices, and 9% from elsewhere. Thus, recognition by laboratorians of their responsibility to report may be key in the passive surveillance system. In North Carolina physicians are required to report "after the disease or condition is reasonably suspected to exist."[12] In many circumstances, reasonable suspicion of a foodborne acute diarrheal illness may be difficult to define without laboratory confirmation.

Most laboratories forward foodborne pathogen isolates to the State Laboratory of Public Health within 24 hours, but some forward them less frequently or never. As part of the Centers for Disease Control and Prevention PulseNet system, the State Laboratory of Public Health serotypes some foodborne pathogens. Thus, especially in the context of a foodborne disease outbreak, timely forwarding of isolates by laboratories should be encouraged.

Limited knowledge among laboratories about the legal responsibility for reporting notifiable results may reflect the fact that many hospital laboratories depend on ICPs to report laboratory results under surveillance. Nevertheless, since reporting is the legal responsibility of the clinical laboratory, our findings indicate a need to educate laboratorians on the communicable disease reporting process and requirements.

The study also points to a need to increase awareness and knowledge among HCPs. The vital role played by clinicians in state surveillance systems is undisputed.[19-21] The HCP's interaction with the patient is the front line of disease surveillance. Studies in the US and elsewhere have found that knowledge of the reporting system is deficient among physicians with low rates of reporting notifiable disease,[3,22] suggesting that increased communication with physicians could enhance passive reporting.[22]

This survey is the first study to examine notifiable disease testing and reporting awareness in North Carolina. To our knowledge it is also the first assessment of awareness of reporting requirements among participants in the disease reporting system through which foodborne illness due to a biological attack may be likely to first appear: ICPs, clinical diagnostic laboratorians, and primary care physicians and health care professionals.

The study results indicate that ICPs play a significant role in reporting diseases though they are not currently legally obligated to report in North Carolina. Infection control practitioners were identified by 9% of HCPs, 73% of ICPs, and 57% of laboratorians as being the persons who actually submitted reports of disease to the health department. Many ICPs actively monitor their institution's laboratory and clinical data to identify reportable cases. Dissemination of surveillance information and training opportunities through the well-established network of ICPs may offer opportunities to improve foodborne disease surveillance in North Carolina. Formally incorporating ICPs into the disease reporting structure also may enhance the passive surveillance system. Reaching HCPs who do not have contact with an ICP is an issue that needs further exploration. Efforts to facilitate disease reporting for HCPs also should be considered. For example, a printed statement on laboratory test results could serve to remind laboratorians and HCPs which pathogens are included in a routine stool culture screen and increase indirect communication between the laboratory and HCPs. Laboratory results for reportable positive pathogens also could include a reporting reminder to the HCP or, for computerized laboratory results, could provide an Internet link for web-based reporting. **NCMJ**

Urgent Medical Decision Making Regarding a Jehovah's Witness Minor:

A Case Report and Discussion

Paul R. Brezina, MD, MBA; John C. Moskop, PhD

Abstract

Background: *Physicians strive to respect the autonomy of patients. The emergent care of Jehovah's Witnesses, however, leaves health care providers struggling with ethical and legal questions. These are further compounded when the patient in question is a minor.*

Case: *A girl aged 15 years presented with anemia, a large ovarian mass, massive hemoperitoneum, and parents who were devout Jehovah's Witnesses who refused administration of blood products. Following discussion of the patient's condition and treatment options with the patient, her family, members of the treatment team, and consultants, the patient was transferred to a hospital that offered a blood conservation program for surgical patients. The patient received surgical management without the need for blood transfusion. Her surgeons, however, reserved the legal right to give blood if an emergent need arose despite the lack of parental consent.*

Conclusion: *Society grants considerable legal latitude in dealing with Jehovah's Witness minors, and physicians must be aware of the legal and ethical parameters surrounding the care of such patients.*

The right of competent adults to make decisions regarding their medical care is well established in US law and ethics and widely recognized throughout the medical community.[1] Jehovah's Witnesses' refusal of blood products is a commonly referenced example of this right.[2] Whether minors also have a right to make such decisions regarding care, however, is much less clear.[3] Legal and ethical standards regarding the autonomy and rights of minors have evolved over time. Due to this evolution, confusion exists within the medical community regarding the appropriate response to a minor whose parents refuse medically necessary treatment.

We present a patient who is a female minor with anemia, an urgent surgical need, and parents who are devout Jehovah's Witnesses who refuse administration of blood products. The following article describes this case, reviews the beliefs of Jehovah's Witnesses regarding blood products, discusses legal standards for medical treatment of minors, and offers practical guidelines for physicians in these situations.

Case Description

A girl aged 15 years presented to the emergency department of a tertiary care hospital with the chief complaint of 2 weeks of increased abdominal girth and constipation. These symptoms had previously been evaluated by primary care doctors who instructed the patient to come to the emergency department after failed outpatient treatments for constipation. On exam, the abdomen was tensely distended with no guarding or rebound, and the remainder of the physical exam was normal. There was mild tachycardia of approximately 105 beats per minute but otherwise normal vital signs. The rest of the review of systems was negative.

The patient stated she had no prior medical, obstetric, or surgical history, had never used any alcohol, tobacco, or drugs, had no significant family history, no history of sexual activity, and no known drug allergies. She noted normal monthly menses since age 11. Her last menstrual period began 1 week prior to presentation. The patient's family was present at all times in her care and stated they were devout Jehovah's Witnesses. The parents, upon meeting the medical team, expressed their intention to remain at the patient's bedside at all

---

Paul R. Brezina, MD, MBA, is a resident physician in the Department of Obstetrics/Gynecology and Internal Medicine at the Brody School of Medicine, East Carolina University. He can be reached at BREZINAP (at) ecu.edu or 600 Moye Blvd., Greenville, NC 27834.

John C. Moskop, PhD, is a professor of Medical Humanities at the Brody School of Medicine, East Carolina University, and director of the Bioethics Center of University Health Systems of Eastern Carolina.

times during her hospitalization. This was not challenged by the medical staff. The parents stated that under no circumstance would they accept a transfusion as a part of their daughter's treatment even if it meant the death of their daughter. When questioned directly, the patient also refused blood products even if this could save her life. The hospital ethics team was consulted and risk management was notified.

Laboratory results showed a negative urine pregnancy test and hematocrit of 32.5%. A computed tomography scan showed a right adnexal mass, likely ovarian in origin, with mixed solid and cystic components, measuring 10 x 10.6 cm and with massive ascites. There was no evidence of peritoneal seeding. The liver, spleen, adrenals, appendix, pancreas, and kidneys were normal. No adenopathy or osseous lesions were seen. Ultrasound-guided paracentesis was performed, removing 3 liters of fluid. Analysis showed a large amount of blood and an albumin level consistent with an exudative process.

The patient was given intravenous hydration, and a repeat complete blood count showed a drastic drop in her hematocrit to 20.9% with worsening tachycardia. Intravenous iron and *Procrit*® were begun, and interval monitoring of the patient's blood levels was changed to every 6 hours. An urgent consultation meeting with the patient and her family, the medical team, and the ethics team was conducted. Also present were several elders from her church. The parents stated their refusal to permit the use of blood products. In response to an option suggested by the ethics consultants, they requested transfer to a facility "more comfortable with bloodless surgery."

Following this meeting with the ethics consultants and family, the treatment team began aggressive efforts to accommodate the request for transfer. Hospital attorneys made preliminary contact with a local judge in case a court hearing was deemed necessary. Six hours later the hematocrit remained stable at 22%. Another tertiary care center in the state that offered a "blood conservation program" accepted the patient, and within 24 hours the patient was transferred in stable condition.

The patient was taken to surgery at that institution 2 days later with a hematocrit of 25%. The parents were told that blood would be given if needed, and the parents signed an "acknowledgement statement" detailing their understanding that emergency transfusion would not be withheld from a minor regardless of parental refusal. In surgery, a right salpingo-oophorectomy was performed as was removal of a 10 cm right ovarian mass and 5 liters of bloody ascites. Blood loss during the procedure was reported to be 25 cc. Pathology of the mass revealed a granulosa cell tumor, juvenile type. No blood was given and the patient was discharged in stable condition.

The Religious Context: Jehovah's Witnesses

Jehovah's Witnesses are members of an international religious community who adopt a literal interpretation of the Bible and assert that their faith is a restoration of early Christianity.[4] Jehovah's Witnesses comprise a small proportion of the population in both North Carolina and the nation. In 2001 approximately 0.6% of the US population and less than 0.5% of North Carolina residents identified themselves as Jehovah's Witnesses.[5] Jehovah's Witnesses cite the following biblical passages from the King James Bible to support their belief that accepting blood products is a serious sin:[6,7]

- Genesis 9:4 "Blood ye shall not eat."
- Leviticus 17:12-14 "No soul of you shall eat blood… whosoever eateth it shall be cut off."
- Acts 15:29 "That ye abstain…from blood."
- Acts 21:25 "Gentiles…[should] keep themselves from things offered to idols and from blood."

This sin is considered so grave by the faith that any direct partaking of blood results in the "loss of eternal life."[3] Therefore, it is common for Jehovah's Witnesses in critical need of blood transfusions to choose death over acceptance of blood products. The right of adults to make this decision is well accepted in the medical and bioethics literature and widely respected in medical practice.[3] The ability of minors, however, to comprehend the gravity of such a decision or to make an autonomous decision independent of the wishes of their parents is much less clear.

The Legal Context: Treatment of Minors

The legal limits of Jehovah's Witness parents to dictate the activity of their children were first addressed in the 1944 US Supreme Court case *Prince v. Commonwealth of Massachusetts*.[8] This case involved a girl aged 9 years named Sarah Prince who was instructed by her Jehovah's Witness guardian to sell religious literature on public streets in Brockton, Massachusetts. This prompted discontent in the community, and the child and her guardian were convicted of violating a child labor law that read, "No boy under twelve and no girl under eighteen shall sell, expose, or offer for sale any newspapers, magazines, periodicals or any other articles of merchandise of any description."

The case was appealed to the US Supreme Court which upheld the conviction. The Court concluded that there exists an "interest of society to protect the welfare of children" and supported the "State's assertion of authority to that end." Furthermore, the Court established that "Parents may be free to become martyrs themselves. But it does not follow they are free, in identical circumstances, to make martyrs of their children before they have reached the age of full and legal discretion when they can make that choice for themselves."[8]

This decision established the right of the state to supersede parental authority, and it has shaped current legal opinion regarding the administration of emergency blood transfusions and other medical care to minors. Indeed, legal protection of minors from abuse and neglect is now well established in both federal and state law. The federal Child Abuse Prevention and Treatment Act defines child abuse or neglect as any act or failure to act by a parent or caretaker of a child, usually under the age of 18 years, "resulting in imminent risk of serious harm, death, serious physical or emotional harm, sexual abuse, or exploitation."[9]

Although federal law provides a general framework for and funding support of child protection activities, each state establishes its own specific child abuse and neglect policies and enforcement programs. The case described above took place in North Carolina which has a clearly defined policy regarding the state's authority to supersede the wishes of parents or guardians. The North Carolina "Treatment of Minors Act" of 2005 includes the following passage:

> It shall be lawful for any physician licensed to practice medicine in North Carolina to render treatment to any minor without first obtaining the consent and approval of either the father or mother of said child . . . where the parents refuse to consent to a procedure, and the necessity for immediate treatment is so apparent that the delay required to obtain a court order would endanger the life or seriously worsen the physical condition of the child. No treatment shall be administered to a child over the parent's objection as herein authorized unless the physician shall first obtain the opinion of another physician licensed to practice medicine in the state of North Carolina that such a procedure is necessary to prevent immediate harm to a child.[10]

This statute gives physicians the authority to provide emergency medical care to minors including blood transfusions without parental consent or a court order, provided that they obtain a second physician's opinion that there is an immediate need for treatment. The statute also provides an account of when treatment constitutes an emergency, namely, "when the delay required to obtain a court order would endanger the life or seriously worsen the physical condition of the child."

Hospitals have an ethical obligation to delineate expressly to the guardians of minors the parameters of the law and how medical care will be administered. The institution operating the "blood conservation program" in the above case routinely utilizes acknowledgement statements in circumstances involving the medical care of minors whose parents seek to refuse blood transfusions.[11] These statements serve as a tool ensuring and documenting that clear and complete disclosure of the hospital's intentions are conveyed to the patient's guardians. Similar statements may be viewed at http://www.noblood.com. Failure of the parents to sign such a document would not alter the care administered to the minor under North Carolina law in the event a life saving transfusion is required. From a legal and ethical standpoint, the statement serves to document formally that a clear dialogue was conducted between the hospital and the parents regarding the emergent administration of blood products.

It is important to note that North Carolina's minor treatment statute also provides legal protection to physicians who choose not to override parental refusal of treatment for a minor child. The minor treatment statute cited above goes on to state:

> "Provided, however, that the refusal of a physician to use, perform or render treatment to a minor without the consent of the minor's parent, guardian, or person standing in the position of loco parentis, in accordance with this Article, shall not constitute grounds for a civil action or criminal proceedings against such physician."[10]

North Carolina law thus gives legal protection and discretion to physicians to make a considered decision, based on the moral arguments and the specific circumstances of the case at hand, either to honor or to override parents' refusal of treatment for their minor child. To make this decision, physicians must identify and weigh a constellation of values including family integrity, religious freedom, the wishes of the parents and of the minor patient, and the life and health of the minor patient.

It is also worth noting that North Carolina is one of a small minority of states that does not grant to parents an exemption from charges of child neglect if they withhold medical treatment from their child as a result of their religious beliefs.[12] At least 41 states provide such a religious exemption from child abuse and neglect laws, although many of these states permit courts to order necessary treatment for children even when parents are protected by religious exemption laws from conviction for criminal abuse or neglect.[13]

In addition to the emergency treatment exception noted above, North Carolina law allows treatment of minors without parental or guardian consent in several other particular circumstances. By statute, minors can consent to treatment for the following specific medical conditions: sexually transmitted and other reportable diseases; pregnancy (but not abortion); abuse of controlled substances or alcohol; and emotional disturbance.[14] Emancipated minors can consent to their own medical treatment.[15] In North Carolina, minors aged 16 and 17 years may petition the court for a judicial decree of emancipation. Minors who are married or members of the armed forces of the United States are also emancipated under North Carolina law. In nonemergency situations, the Department of Social Services may, after investigation, assume custody for a minor when it determines that the minor needs treatment that parents are unwilling to provide.[16] Finally, although some states permit older or "mature" minors to make at least some of their own medical treatment decisions, North Carolina law does not recognize this "mature minor rule."[16]

The Case Revisited: Practical Guidelines

In the United States, adult patients with decision-making capacity have wide-ranging authority to accept or refuse medical treatment recommendations. Parents also have significant responsibility and authority to choose the medical care of their children, but that authority is circumscribed by certain legal and moral limits. Conflicts between the medical treatment choices of parents for their minor children and the treatment recommendations of physicians often resist easy resolution because they pit deeply held principles of professional ethics, such as respect for the wishes of parents and minor patients and the duty to protect the life and health of patients, against one another. The case described above offers a widely recognized example of this type of conflict. When such conflicts occur, physicians should be able to recognize their causes and pursue options for conflict resolution. In the concluding section of this article, we offer several practical guidelines for addressing these situations.

When a patient or the patient's representative refuses a recommended treatment, it is important to elicit and acknowledge the reasons for that refusal. In the case we describe here, both the parents and the adolescent patient clearly expressed their refusal of blood products and cited their religious beliefs as Jehovah's Witnesses as the reason for that refusal. In open and respectful discussion with members of the treatment team, the patient and her parents demonstrated that they had an adequate understanding of the patient's medical condition, the potential need for blood products to treat that condition, and the potential consequences of forgoing this treatment. The team could thus establish that the refusal of blood products was not based on a misunderstanding about the nature or seriousness of the patient's condition or about the rationale for this treatment.

In most situations, we suggest that health care professionals discuss treatment options with adolescent patients both with and apart from their parents or others to ensure that the patient is able to express wishes or concerns that he or she is unable or unwilling to express to family members. In the case discussed, the family chose to remain with the patient, presumably to prevent administration of unwanted treatment without their knowledge or consent. The patient appeared to understand the situation and clearly expressed a refusal of blood products. There was no indication that she disagreed in any way with her parent's views or wished to speak privately with her physicians, so the treatment team decided not to insist on a private discussion with the patient.

By acknowledging a family's religious beliefs and values as the reason for their refusal of treatment, members of the health care team can demonstrate that they have listened to and understood that reason and that they respect the importance of those beliefs and values. We hold that it is important to do this as a sign of respect for the patient and parents as moral agents. For similar reasons, it is important for the health care professionals to articulate the reasons for their treatment recommendation. In this way, the health care professionals make clear the values that underlie that recommendation and commend those values to the patient and family. By offering reasons for their recommendation, the health care professionals also make clear that they too are moral agents responsible for their actions.

When professionals, patients, and parents express their opinions, beliefs, and guiding values, they can begin to seek common ground. Recognizing the value of respecting family wishes and religious freedom, for example, physicians might pledge to the patient and family that they will not pursue blood transfusions or will not do so unless the patient's life is in imminent danger. Recognizing the value of life, the patient and parents might express a willingness to accept blood products if absolutely necessary to save the patient's life, although they did not do so in this situation. This search for common ground can identify shared beliefs and values and can sometimes lead to a resolution of conflict.

Table 1.
Practical Guidelines for Addressing Refusal of Treatment for Minor Patients

(1) Elicit the reasons for the refusal.

(2) Clarify any misunderstandings about the patient's condition, prognosis, or treatment options.

(3) Seek a private discussion with adolescent patients.

(4) Acknowledge beliefs and values informing the refusal.

(5) Articulate the reasons for the treatment recommendation.

(6) Seek common ground.

(7) Enlist assistance in identifying and evaluating options.

(8) If conflict is intractable, make a considered moral judgment.

We recommend that health care professionals seek assistance from others when they encounter conflicts with patients and families regarding treatment choices. In the case we describe, the treatment team sought advice from both the hospital's ethics consultation and risk management services. Risk managers offered advice on the legal options available to the team. Ethics consultants suggested an option unavailable in the hospital, namely, a surgery program better prepared to accommodate the family's wishes. As described above, the family expressed interest in this option and a transfer to a hospital with such a program was accomplished with a successful outcome for the patient.

When conflict about treatment for a minor patient is rooted in incompatible and deeply held values, it may prove intractable. In this case, the parents and the patient might have refused transfer, but also persisted in their refusal of blood products. The patient's condition might have deteriorated, and the need for a blood transfusion might have become more urgent or emergent. As described above, North Carolina law permits 2 physicians to administer emergency medical treatment over the patient's and parent's objections, but it also protects physicians from liability if they choose to honor the parent's refusal of treatment. Thus, law does not dictate the physician's action, and the physician's decision is ultimately a moral one. Physicians should exercise this important moral responsibility with careful reflection on the relevant moral principles and values and on the particular circumstances of the case at hand. **NCMJ**

Call for Papers

John W. Williams Jr, MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

POLICY FORUM

Effective Patient-Practitioner Communication

COMMENTARIES

> *“Patient-centeredness requires a fundamental redesign of clinical communication from speaking the language and syntax of health care professionals to the plain language all people understand.”*

INTRODUCTION

Policy Forum:
Effective Patient-Practitioner Communication

The Institute of Medicine of the National Academies released its report, *Health Literacy: A Prescription to End Confusion*, in April 2004. The report made clear that low health literacy affects the educated and wealthy as well as the uneducated and poor, touching the lives of countless individuals. Miscommunication affects every facet of our lives. It occurs for many different reasons including someone not listening closely, people misinterpreting what they hear, or someone not understanding. Regardless of how miscommunication occurs, it can lead to inappropriate action, inaction, frustration, or anger. When miscommunication happens in a relationship, it can be hurtful or confusing. When miscommunication occurs within the patient-practitioner relationship in a health care setting, it can lead to illness, inappropriate procedures, slow or no recovery, and even death.

The potential for such serious consequences prompted the North Carolina Division of Public Health and North Carolina Institute of Medicine to form a task force on health literacy. The task force was supported with funding from the Heart Disease and Stroke Prevention Branch in the Chronic Disease and Injury Section of the Division of Public Health via a US Centers for Disease Control and Prevention grant and with additional support from the NC Division of Medical Assistance. The task force found that low health literacy is a major, perhaps the most important, contributor to poor patient-practitioner communication. The health care system is very complex, medical terminology takes years of training to master, and the stress of illness can make the simplest things difficult. Communication between practitioner and patient can be impaired by these and other things including differences in language and cultural perceptions of disease and health care.

This issue of the *North Carolina Medical Journal* explores many facets of the patient-provider communication process. We draw on national and state-level work on health literacy and communication to highlight problems that occur and to suggest improvements to make our health care system safer and more effective. North Carolina is fortunate to have some of the nation's foremost researchers in the area of health literacy, and we are pleased that Darren DeWalt, MD, has shared some of his research on the epidemiology of low health literacy as well as naming possible interventions. Strategies are explored for improving practitioner-patient communication in physician and dentist offices, pharmacies, long-term care facilities, and hospitals. We also focus on the role of lay health educators and advisors whose use and effectiveness in North Carolina has been demonstrated. We present the perspectives of individuals with low literacy and English as a second langue and offer ideas for implementing communications strategies for practitioners and low literacy adults through education and public marketing.

One-third of the nation's population may have difficulty understanding basic health information. It is imperative that we take a closer look at health communication, improving individuals' understanding of their health and how to appropriately manage illness when it occurs.

ISSUE BRIEF

Addressing Health Literacy Through Improved Patient-Practitioner Communication

Mark Holmes, PhD; Thomas J. Bacon, DrPH; L. Allen Dobson, MD, FAAFP; E. Kiernan McGorty, JD, PhD; Pam Silberman, JD, DrPH

Our health care system relies increasingly on the patient to exercise clinical decisions, perform self-management, and navigate the complex health care system. In 2003, the Institute of Medicine of the National Academies of Science released a report on the quality of the United States health care delivery system and included patient-centeredness among the 6 dimensions of quality.[1] Recent developments in the US health care system embrace this fundamental shift in health care delivery including increased use of self-management for chronic diseases, consumerism (eg, higher deductible health plans and cost and quality transparency initiatives), and patient activation (eg, Web sites and patient-oriented electronic medical records). All these developments help transform our system to one that holds the patient, rather than the provider, at the center of the system.

> *"If patients have difficulty compiling, processing, understanding, and acting on the information necessary to make informed decisions consistent with their desires, then the central assumptions underpinning the movement toward patient-centeredness are unfulfilled."*

However, all these policy and market developments rely on the ability of patients to act effectively as stewards of their own health. In actuality, people vary widely in their capability to understand and analyze health information and to make informed decisions. A patient's ability to make informed decisions is dependent on his ability to process and synthesize information. Patients may have difficulty understanding clinical information, treatment regimens, or how the health system works. If patients have difficulty compiling, processing, understanding, and acting on the information necessary to make informed decisions consistent with their desires, then the central assumptions underpinning the movement toward patient-centeredness are unfulfilled.

Researchers have long understood high quality patient-provider communication is a key determinant of a patient's health.[2,3] Effective communication has multiple dimensions, but attention has recently turned to the concept of health literacy. *Health literacy* can be defined as the degree to which individuals have the capacity to obtain, process, and understand the basic health information and services needed to make appropriate health decisions. Note that the concept of *health literacy* differs from that of *literacy*. Health literacy entails a broader set of skills and abilities than basic reading and writing. Health literacy requires

L. Allen Dobson, MD, FAAFP, is former assistant secretary for health policy and medical assistance of the NC Department of Health and Human Services and cochair of the NC Institute of Medicine Task Force on Health Literacy.

E. Kiernan McGorty, JD, PhD, is project director at the North Carolina Institute of Medicine.

Pam Silberman, JD, DrPH, is president and CEO of the North Carolina Institute of Medicine and publisher of the *NC Medical Journal.*

some reading skills but also the abilities to understand oral communication, use numbers and math skills, and understand the health system on a basic level. Health literacy also encompasses the ability to communicate with health care providers and their staffs.

In the summer of 2006, the Chronic Disease and Injury Section of the NC Division of Public Health (NC DPH) asked the NC Institute of Medicine (NC IOM) to convene a Task Force on Health Literacy. The task force was a collaborative effort between the NC IOM, the NC Department of Health and Human Services (NC DHHS), and the NC Area Health Education Centers (NC AHEC). The task force was funded by the Chronic Disease and Injury Section in the Heart Disease and Stroke Prevention Branch of NC DPH through a Centers for Disease Control and Prevention grant and the NC Division of Medical Assistance. Cochairs of the task force were Thomas J. Bacon, DrPH, executive associate dean of The University of North Carolina at Chapel Hill (UNC) School of Medicine and director of NC AHEC, and L. Allen Dobson, MD, FAAFP, assistant secretary for health policy and medical assistance of the NC Department of Health and Human Services. The task force consisted of 49 other members representing providers and state medical associations, patient and consumer advocates, state government, adult literacy organizations, and other interested parties. The task force met 7 times over 9 months and made 14 recommendations which are discussed below.[a]

Health literacy plays a central role in the patient-practitioner exchange and improving this type of communication can help address the adverse impacts of low health literacy. Patients with low health literacy may have difficulty reading a bus schedule or interpreting a simple bar graph. The prevalence of low health literacy is remarkably high; nearly one-half of US adults function at marginal or limited health literacy.[b] Although everyone is at risk for low health literacy, especially during times of considerable stress (eg, immediately following an unexpected diagnosis), low health literacy is more common in some populations. Older, less educated, lower income, and uninsured and publicly insured adults, along with racial and ethnic minorities, are more likely to have low health literacy. Using the known prevalence rates of low health literacy by demographic group, along with population data for each North Carolina county, prevalence estimates of low literacy can be computed for most North Carolina counties. (See Figure 1.) As with many health conditions, poverty-stricken areas tend to have higher prevalence of low health literacy.

Those who primarily speak a language other than English tend to have lower health literacy, even when literacy is assessed in their native language. Cultural issues, in addition to language issues per se, may inhibit effective patient-practitioner communication. For example, practitioners treating patients from Mexico may interpret *mal de ojo* (the evil eye) literally as conjunctivitis without appreciating the patient's cultural perspective. These cultural misunderstandings greatly inhibit effective patient-practitioner communication and hence are important to consider. In this issue, H. Nolo Martinez, MS, PhD,

---

[a] For brevity, the recommendations are simplified and shortened here. The full recommendations are contained in the report available on the NC Institute of Medicine Web site at http://www.nciom.org.

[b] Most assessments of health literacy are of literacy per se. Although some instruments specifically designed to assess health literacy have been developed, they are relatively recent and have not been used widely.

expands on communication issues particular to nonnative English speakers in his commentary "Communicating Health Information to English as a Second Language Patients."

Low health literacy affects many measures of health in a negative way. In fact, there is no one factor more important in predicting an individual's overall health status than literacy ability. Low health literacy is associated with poorer outcomes in general health status, depression, asthma, diabetes control, and HIV control. Low literacy leads to higher rates of hospitalization and late stage prostate cancer on detection and lower rates of mammography, Pap smear, pneumococcal immunization, influenza immunization, and sexually transmitted disease screening. Furthermore, low literacy patients have higher average medical costs.[4] Low health literacy affects the health of children as well. Asthmatic children of low health literacy parents are more than twice as likely to miss school and more than 3 times as likely to be hospitalized as asthmatic children of adults with higher health literacy.[5] Darren DeWalt, MD, MPH, a national expert in health literacy, discusses the epidemiology of health literacy in greater detail in his article "Low Health Literacy: Epidemiology and Interventions" later in this issue of the journal.

Although research demonstrating the negative health effects of low health literacy is well developed, few interventions designed to improve understanding, knowledge, and other key factors leading to improved health outcomes have been shown to be specifically effective for low health literacy populations. Dr DeWalt and other researchers in North Carolina are developing national expertise in this area. However, translating research into practice remains a challenge; despite efforts across the nation to speed the translation of research from "bench to bedside," there remains a considerable time gap between when research is published and the point at which that knowledge is incorporated into widespread practice. **The task force recognized this fact and recommended that state foundations should leverage the research expertise existing in the state and fund a Center for Health Literacy Excellence** charged with increasing provider awareness of low health literacy, enhancing the capacity of adult literacy professionals to address problems of low health literacy, developing a library of health information and best practices, and increasing the skills of providers in treating patients with low health literacy.

Some of the most promising research on improving patient understanding and ability to self-manage is associated with chronic disease. For example, UNC researchers have identified effective strategies to improve outcomes for diabetes patients with low health literacy, and a pilot study on heart failure patients demonstrated strong evidence of improved outcomes (eg, a 30% reduction in hospitalization and death).[6] Because chronic diseases account for such a large portion of medical spending[7] and for diminished quality of life,[8] strategies to improve outcomes for patients with low health literacy can yield tremendous results.

In addition to the evidence-based models shown to be effective, there are some models currently existing in North Carolina that appear to be promising. Two such models are outlined in "Lay Health Educators' Roles in Improving Patient Education" by Susan Auger, MSW, and Sarah Verbiest, MSW, MPH. These models appear to improve the ability of patients with low health literacy to understand and act on health information. For example, Ms. Auger helped develop *Teach with Stories*. This method uses narratives and *photonovellas*, which are illustrated brief stories popular in Spanish-speaking societies, to frame and personalize a particular health issue, allowing the patient/client to more effectively identify with and internalize the conveyed information.

Communication also can be hindered when practitioners are unaware of the low health literacy levels of their patients and, thus, use medical terminology that is too technical. Unfortunately, national studies have found practitioner awareness of limited health literacy to be low. One study presented medical residents with case studies and histories suggesting limited health literacy as a cause of an adverse outcome, yet less than 25% of the residents identified it as a cause.[9] Another study that assessed the health literacy knowledge of graduating nursing students found less than half correctly identified the age group with the highest risk of low health literacy, and only 15% correctly identified health literacy—not socioeconomic status—as the more important predictor of health status.[10] Furthermore, practitioners underestimate the prevalence of low health literacy in their patient panel.[11] One of the reasons practitioners underestimate the prevalence of low health literacy may be that many patients have learned how to mask their literacy problems. Clues are often subtle. Patients may dismiss conveyed written information by stating they left their glasses at home and will read it later, or they may seem to be unengaged in a discussion about their health or therapy. Medical histories and other forms filled out by patients may be missing key information. In short, it is incumbent on practitioners to be aware of the subtleties that suggest a patient has low health literacy. When practitioners miss these cues, the results may be dramatic. Toni Cordell powerfully outlines her experience with these problems in "Chasing the Monster."[c] Although every patient has a different experience, one of Ms Cordell's central points is that patients need to feel sufficiently empowered to let their providers know when they do not understand the plan developed for them.

Because low literacy may be difficult to perceive, some experts advocate for universal precautions and treatment of all patients as if they have low literacy. Other experts have developed screening tools that are useful in identifying patients who may have low literacy. One example is a 6-question screen that presents the patient with a nutrition label from an ice cream box and takes 3 minutes to administer.[12] Timothy W. Lane, MD, and J. Carson Rounds, MD, discuss the practitioner's view of health

---

[c] Ms Cordell, along with many others who have experienced the adverse effects of poor health communication, chronicles her experience in a video available on-line from the AMA Foundation at http://www.ama-assn.org/ama/pub/category/8115.html.

literacy in "A Failure to Communicate." Medical practitioners aren't the only health care professionals who are faced with the problem of low literacy and poor communication, M. Alec Parker, DMD, outlines the issues existing in dental settings in his commentary, "A Perspective on Doctor-Patient Communication in the Dentist's Office."

There are best practices designed to maximize communication effectiveness with patients with low health literacy. For example, the teach-back method—querying patients with phrases such as "OK, I just gave you a lot of information. Let me make sure you got it all. How often are you going to take this medicine?"—allows practitioners to assess patient understanding. This method has been shown to increase patient recall from 61% to 84%.[13] As an additional example, the Partnership for Clear Health Communication has identified the *Principles for Clear Health Communication*[14] that should be used when developing written health information:

(1) Use easy to follow layouts and simple pictures.
(2) Write information at an appropriate level.
(3) Replace complicated medical words with plain language.
(4) Use pictures and diagrams.
(5) Focus on desired behavior instead of medical facts.
(6) Make information culturally sensitive and personally relevant.

Although these principles are somewhat obvious, they may be violated in daily practice. For example, medical histories may ask patients whether they have ever had hypertension, but many patients may only know they have "high blood pressure." Patient-centeredness requires a fundamental redesign of clinical communication from speaking the language and syntax of health care professionals to the plain language all people understand.

Health professions certification and licensing boards recognize the value of effective communication and require evidence of effective communication for maintenance of certification. Nonetheless, most practitioners receive little to no training on communication techniques during their formal training. Although recent trainees may be more aware of literacy issues, other strategies will be necessary to increase awareness among current practitioners. Karen D. Stallings, RN, MEd, and Thomas J. Bacon, DrPH, outline strategies the NC Area Health Education Centers program can utilize in their commentary "Health Professions Education to Promote Health Literacy: Leverage Points and New Opportunities." The task force recognized the barrier of low awareness among practitioners and endorsed a systemwide effort to combat this knowledge gap. **The task force recommended that institutions and organizations that train health professionals incorporate health literacy training into their curricula.** Medical and health professional schools, community colleges, the NC Area Health Education Centers program, professional associations, and organizations offering practice support should ensure their curricula are designed to increase the understanding of health literacy among all practitioners. Gail S. Marion, PA-C, PhD, Sonia J. Crandall, PhD, Frank Celestino, MD, William McCann, PsyD, and Julienne K. Kirk, PharmD, describe how Wake Forest University School of Medicine is integrating effective communication pedagogy into curricula for its health professional training programs in "Cultivating Patient-Centered Communication Skills Training Across the Medical Education Continuum: A Model for Practice."

Of course, the list of changes practitioners are being asked to incorporate into their daily practice pattern is ever increasing. One study found that primary care physicians would spend, on average, 7.4 hours a day delivering evidence-based preventive care guidelines to a typical patient panel—allowing no time for the acute needs for which many patients seek care.[15] Effective communication strategies are but one of many practice changes demanded of practitioners. Changes will be more effective and permanent if the practitioner internalizes the issue and understands the importance of the improvement and the value of the change. Although health care practitioners are committed to delivering high quality health care to their patients, changes in reimbursement policy could encourage providers to practice effective communication—such as the teach-back method. The task force recommended that reimbursement policy can encourage more effective communication. Furthermore, some promising practices—such as group visits—are not reimbursed by all payers. Therefore, the task force adopted some recommendations related to reimbursement policy. For example, **NC Medicaid should pilot reimbursement models that teach patient self-management, and other payers should consider reimbursing for existing billing codes for individual and group self-management visits.**

Disease and case management, which focus on chronic conditions, are excellent candidates for achieving quality improvement in patients with low health literacy. Disease and case management often include components that attempt to increase a patient's knowledge and ability to manage her own health. **The task force recommended that the NC Department of Health and Human Services, Community Care of North Carolina, NC Division of Public Health, and payers incorporate best practices into disease and case management initiatives and explore the use of nonprint information to enhance the understanding of patients with low health literacy.**

Although there are many promising practices for enhancing the effectiveness of communication with patients with low health literacy, some of these practices may not be sustainable in the current reimbursement environment. Cost savings and improvement in quality of life for the patient (which often drive reimbursement design) might be evident only within a deliberate demonstration project aimed at developing a sustainable new model of care. Traditionally, funding other than reimbursement revenue is necessary to develop and refine such a model; providing funds for such projects has often been the domain of foundations. **Therefore, the task force recommended that foundations fund demonstration projects that use promising new models of care that increase communication to patients, and payers should modify reimbursement policy to support successful models.**

Enhancing patient-practitioner communication could not only lead to better compliance, but it may also reduce the risk of malpractice claims. Research has shown a better patient-practitioner relationship reduces the risk of malpractice claims.[16] Some malpractice carriers conduct risk management workshops for covered practitioners. **As a result, the task force recommended that malpractice carriers incorporate information on health literacy into risk management seminars.** Gerald B. Hickson, MD, and A. Dale Jenkins discuss the relationship between communication and malpractice in greater detail in their commentary "Identifying and Addressing Communication Failures as a Means of Reducing Unnecessary Malpractice Claims."

Naturally, health care is often delivered in settings other than a medical office. Promising practices exist in these settings as well. For example, the Iowa Hospital System has prioritized addressing low health literacy throughout its system of 24 hospitals and 430 clinics. Individual hospitals choose specific initiatives aimed at improving practitioner-patient communication. Mary Ann Abrams, MD, MPH, and Barbara Earles, RN, MHA, CPHRM, from the Iowa Health System explain how they redesigned the informed consent process, typically one of the more complicated forms patients are required to sign and digest, in "Developing an Informed Consent Process With Patient Understanding in Mind." The consent form signing process offers an important time for patient learning.

The task force recommended that all health care organizations and institutions develop criteria and policies to ensure best practices are followed for written information, Web sites, and other audio and visual media designed for client and family use. Additionally, philanthropic foundations should give priority to those organizations and institutions that enact these changes. The task force recognized that insurers and payers may be limited by existing laws and regulations regarding consumer insurance information, so the North Carolina Department of Insurance should seek changes in existing insurance laws that may inhibit understandability. The types of organizations charged in this recommendation include hospitals, health care systems, dental offices, and long-term care facilities.

Long-term care facilities face a multitude of challenges that might make the effects of low literacy more problematic in those settings. These include lower patient cognition, more acute health care needs, higher prevalence of chronic disease, and more reliance on medications. Yet, in these settings there is often increased reliance on patient empowerment because there are more opportunities for problems to arise due to a greater need for coordinating care among the facility staff and consulting clinicians. Dennis Streets, MPH, MAT, LNHA, outlines issues particular to long-term care facilities in "Effective Practitioner-Patient Communication in Long-Term Care."

Just as health care is delivered by practitioners from many disciplines and in settings other than the physician or dentist in an office, health is affected by entities other than health care providers. The state has many disparate forms of interactions with individuals which may affect their health directly or indirectly. The NC Department of Health and Human Services consists of many agencies providing direct services to North Carolinians such as public health, aging, and mental health services. Because many of the department's clients are at higher risk for having low health literacy and department actions affect so many people, creating a department-wide culture to adopt practices known to be effective with low health literacy patients can lead to considerable improvement in communication effectiveness. **The task force recommended that the NC Department of Health and Human Services develop criteria and policies to ensure best practices are followed for written information, Web sites, and other audio and visual media designed for client and family use.**

In addition, the task force recommended that agencies within the department, including but not limited to Community Care of North Carolina, the Division of Public Health, the Division of Mental Health, Developmental Disabilities and Substance Abuse, and the Division of Aging, have staff at the local level trained in best practices for low health literacy patients and charged with disseminating that information to staff.

Today, patients receive health information from many sources in addition to their health care practitioner. For example, the Internet is a common source of information, and friends, family, and coworkers often volunteer or are consulted for advice. **Therefore, the task force recommended that the NC Department of Health and Human Services, health care systems and providers, and payers explore and improve other ways of educating patients that may be more effective for patients with low health literacy.** Examples include trained lay health advisors and patient navigators, group education settings, and information dissemination in nontraditional forums (eg, religious institutions, community fairs, and barber shops).

The task force spent considerable time on the special challenges inherent in pharmaceuticals. Medication errors lead to high costs and adverse health effects (including preventable deaths) in our health care system. Research has found that patients with lower health literacy have poorer understanding of drug labels. Even patients who correctly explain the instructions may struggle to demonstrate how to correctly take the medication.[17,18] Studies have found that instructions such as "Take two pills twice a day" are more likely to be misinterpreted by patients with lower health literacy. Part of this confusion may be due to the design of the "average" medication bottle. A study of medication labels from across the country found that the types of elements most pronounced on the label—such as the pharmacy name and prescription number—are not pertinent to helping the patient take the medication correctly. Furthermore, warning stickers on labels are commonly misinterpreted, and patients with lower health literacy are more likely to misinterpret labels such as "Take with food" or "Swallow whole: do not crush or chew." **Therefore, the task force recommended that the NC Board of Pharmacy, in collaboration with other key stakeholders, develop requirements for consumer information and medication labels making them more readily interpretable to those with low health literacy.** Michael S. Wolf, PhD, MPH, and Stacey Copper Bailey, MPH, explore this issue in more detail in their commentary "Improving Prescription Drug Labeling."

Likewise, the role of pharmacists as medication counselors can be enhanced to improve patient understanding and compliance. The Asheville Project, a program that intensively used medication therapy management to increase patients' abilities to effectively manage asthma and diabetes, demonstrated the cost savings associated with such interventions during and beyond the intervention period.[19,20] One barrier to enhancing the role of pharmacists as medication counselors is the current reimbursement environment. Pharmacists have experienced a 56% increase in their workload filling prescriptions in the last decade.[21] In light of such increased demands, it is difficult to expect pharmacists to undertake more active medication counseling without a realignment of incentives. Although there is some evidence that these types of practice redesigns are effective, more studies are needed. Traditionally, foundations have been willing to fund pilot projects demonstrating the effectiveness of new models of care. **Therefore, the task force recommended that North Carolina foundations fund demonstration projects enhancing the role of pharmacists as medication counselors and that payers reimburse successful models.** Michael D. Murray, PharmD, MPH, discusses what North Carolina state law requires in terms of pharmacist counseling and highlights successful pharmacy initiatives in "Medication Instruction by Pharmacists: Making Good on an Offer."

Of course, the most direct approach to limiting the adverse health effects of low health literacy is to increase literacy skills for everyone. The task force believed initial efforts aimed at improving consumers' health literacy should be targeted at the most vulnerable populations. Adult education services and systems, such as literacy councils and adult basic education offered by community colleges, provide an existing mechanism through which to achieve that goal. Although adult education only reaches a small segment of the population (ie, between 2 and 3 million of the 94 million US adults with limited literacy skills), these individuals can bring the skills they learn back to their families and communities. Adult education teachers, state directors of adult education, and basic skills program leaders all see the benefits of using health issues to teach literacy. In a survey of adult basic educators, over 90% of teachers viewed adult education as an appropriate setting to teach and learn about health issues.[22] Teachers who used health to educate their students reported lessons based on health issues enhanced students' dialogue, discussion, vocabulary, reading, language development, and critical thinking. Teachers report students' interests, participation, and motivations were greater when health was the topic of the educational exercise when compared to other areas. A national survey of state directors of adult education found respondents believed health was an appropriate topic for adult education both as a content area and as a skills area.[23] **The task force recommended that adult literacy programs incorporate health literacy concepts into curricula.** Sandra J. Diehl, MPH, discusses her experience and possible approaches in adult education in "Incorporating Health Literacy Into Adult Basic Education: From Life Skills to Life Saving."

Naturally, patients have a responsibility to do their part to improve communication with their practitioner. The health care environment can be intimidating to the average consumer, and medical language can be confusing. The task force believed that patient activation can be enhanced through adoption of a social marketing campaign aimed at increasing awareness of the importance of asking questions when consumers do not understand health information. Again, there are some promising practices to guide these efforts. The Justus-Warren Task Force and the Chronic Disease and Injury Section of the NC Division of Public Health partnered on an award-winning campaign called "Lost In Translation,"[24] which targeted people with cardiovascular disease. The campaign conveyed the importance of having a dialogue with practitioners to ensure understanding of clinical information. Messages need not be disease-specific. The Partnership for Clear Health Communication developed a campaign called Ask Me 3 which directs consumers to ask 3 questions at each health care visit: (1) What is my main problem? (2) What do I need to do? (3) Why is it important for me to do this?

This population-based message can lead to more effective communication and hence better understanding and outcomes. **The task force recommended that the NC Division of Public Health adopt a social marketing campaign, including partnerships with key organizations and stakeholders, to increase awareness of the importance of effective patient-practitioner communication among all North Carolinians.** Marcus Plescia, MD, MPH, and Mike Newton-Ward, MSW, MPH, discuss this issue further in "Increasing the Public's Awareness: The Importance of Patient-Practitioner Communication."

Addressing health literacy through patient-practitioner communication is certainly not a cost-free exercise. Practitioners will have to learn new skills, develop new tools, and train staff to be aware of the issue. Although health care providers want to provide the best possible care to all patients, the American health care practitioner today is facing increasing demands on her time in and out of practice. Many of these demands ask practitioners to do more—spend more time with patients, order more tests, or educate oneself more on an issue. Among the myriad of issues the practitioner faces, health literacy may be easy to dismiss. However, in addition to negatively affecting patient health as outlined here, poor communication with patients may negatively affect practitioners' livelihoods. Although the business case for addressing health literacy is still currently unproven, many potential benefits exist. In the increasingly competitive environment, providers compete daily for patients in the health care marketplace. Because patient satisfaction tends to be higher for those practitioners utilizing best practices, a commitment to addressing low health literacy may lead to increased market share. Increased communication leads to a more satisfying work environment and can increase morale and decrease staff turnover. As discussed above and elsewhere in this issue, malpractice liability may be reduced. Perhaps most importantly, the increasing number of initiatives addressing health care quality presents additional leverage on investment in low health literacy mitigation strategies. Outcome measures—such as the percent of diabetics with most recent Hemoglobin A1c less than 7.0%—are affected by patient understanding and compliance. Practitioners who value their performance on these measures are given incentives to develop strategies addressing their low health literacy patients. However, although many of the strategies outlined here may lead to cost savings, the toll on individual patients and their families adversely affected by poor understanding is perhaps the most important reason to improve communication. **NCMJ**

COMMENTARY

Low Health Literacy:
Epidemiology and Interventions

Darren A. DeWalt, MD, MPH

Health literacy entered the mainstream medical literature in 1995 with an article published in the *Journal of the American Medical Association*.[1] Since that time, we have witnessed the emergence of a field of research and advocacy that attempts to improve health communication so that all people can understand and act on health information. In this commentary, I will review the epidemiology of low health literacy, our understanding of the relationship between literacy and health outcomes, and emerging interventions to mitigate the effects of low health literacy. As this field rapidly gains new insights, we are beginning to learn how to address the problem.

Epidemiology of Low Health Literacy

Health literacy, as defined by Healthy People 2010 and described in the issue brief in this issue of the *North Carolina Medical Journal*, is a construct which has been elusive to measure as a single variable. Most of the research to date has focused on the ability to read basic health information. However, all of us can identify a friend or colleague who has excellent reading skills, but who has low health literacy. This person has trouble understanding and acting on health information. As such, describing the epidemiology of health literacy requires an explanation of what has been traditionally measured in these studies. To date, researchers have measured reading ability as a proxy for health literacy. Measuring reading ability emphasizes the role of understanding written health information and would likely classify our colleague with excellent reading skills as having "high health literacy." So, although measuring reading ability does not give us the full picture of health literacy, understanding the problems associated with not reading well can help us identify key principles for addressing health literacy.

> *"If close to half of the population we serve is unable to accurately participate in health care, we need to fundamentally restructure how we operate."*

The most up-to-date portrait of reading ability in the United States was the 2003 National Assessment of Adult Literacy (NAAL).[2] The NAAL found that 43% of adults read at basic or below basic levels. Based on analysis by economists and educators, people who read at these levels are not adequately skilled to compete in the current economy or to effectively negotiate much of the health care system.[3] This current state of affairs is astounding and should call close attention to how we provide health care. If close to half of the population we serve is unable to accurately participate in health care, we need to fundamentally restructure how we operate. As we pursue patient-centered care, we must consider the information processing skills of those we serve and adjust our actions to match the skill level.

Health Literacy and Health Outcomes

The importance of health literacy is underscored by its relationship to health outcomes. The research to date has focused on the relationship between reading ability and health outcomes, largely because reading ability is easier to measure than the broader concept of health literacy. Regardless, if poor reading ability translates to poor health outcomes—after controlling for variables like insurance, income, race, ethnicity, and disease severity—then we are more confident that inability to understand health information is an important factor for health outcomes. In 2004, the Agency for Healthcare Research and Quality (AHRQ) released a report on the relationship between literacy and health outcomes.[4,5] This report found that, across several

Darren A. DeWalt, MD, MPH, is an assistant professor of medicine in the Division of General Internal Medicine at the University of North Carolina School of Medicine. He can be reached at dewaltd (at) med.unc.edu or Campus Box 7110, Chapel Hill, NC 27599-7110.

areas of health and health care, low literacy was associated with a worse prognosis than higher literacy even after controlling for confounding variables.

Since the publication of the systematic review, several new articles have added to the evidence by evaluating new populations and new outcomes. Two studies have documented that people with lower literacy die at a faster rate than people with higher literacy.[6,7] Patients with low literacy are more likely to misunderstand prescription medication instructions and warning labels.[8-10] Young children with asthma who have parents with low literacy have more days of school missed and more hospitalizations.[11] The body of literature associating low literacy with worse health outcomes becomes more robust each year. Some studies are beginning to explore potential mediating variables such as self-efficacy,[12,13] medication knowledge,[10,14,15] and patient-physician communication.[16] As we begin to understand the mediators between literacy and health outcomes, our intervention design will become more informed and effective.

Interventions to Mitigate the Effects of Low Health Literacy

Interventions to mitigate low health literacy usually fall into one of 4 categories:

(1) Improve health literacy skills in the population
(2) Improve written and multimedia communication
(3) Improve patient-provider communication in health care visits
(4) Alter systems of care

No doubt, such a framework is an oversimplification, but it lays out what we need to think about when addressing health literacy at the state level. I will briefly review each category and the current state of knowledge for each.

1. Improve Health Literacy Skills in the Population

Although the most attractive solution, this may be the most elusive. Improving the reading ability of an adult takes hours of personalized instruction and self-motivation. With one year of intense adult basic education, a person's reading level increases about one or two grade levels. Such improvements, if targeting germane topics, may improve function in the health care environment, but educating 90 million adults with such specificity and intensity is not feasible. No studies have been published that demonstrate improved health literacy over time. As such, we do not know if specific health-related information processing can be improved faster than general reading ability.

We have a small amount of evidence that literacy training programs can improve depression outcomes, regardless of the improvement in literacy. Two studies have enrolled people in adult literacy courses, and both showed an improvement in depression symptoms when compared to a control group.[17,18] The mechanism of the effect may be related to self-confidence and life skills improvement for people who have been struggling to get by. Regardless of the mechanism, the outcome suggests that further study in this area could be promising.

What about the children? Unfortunately, approximately one-third of our nation's children do not graduate from high school, a statistic that has not changed in 30 years.[19] As such, I anticipate that the problem of low health literacy will remain with us in the foreseeable future. Expanding curricula in health literacy for primary and secondary education may help to familiarize students with the health care environment, but improving graduation rates may be more important for the overall health of the population.

2. Improve Written and Multimedia Communication

Most of the research and advocacy related to health literacy has focused on written and multimedia communication. Numerous studies have shown that the readability of health information almost always exceeds the reading ability of its intended audience. If we (health care professionals) were a communications agency, we would be fired. Creating better written messages and using other forms of media (audio or video) have been tested in clinical research and can improve knowledge.[5] Written messages targeting specific illnesses can increase the rate of physician-patient dialogue on a topic and increase the receipt of clinical preventive services.[20,21] Creating health messages that are understandable by most of the intended audience is an imperative for any systematic approach toward addressing low health literacy. Experts have developed guides for creating health messages,[22] and more and more examples are published in the medical literature.[23-25]

Beyond improving specific patient education materials, we need to consider broad-based campaigns to activate people to ask questions and seek clarity. Such campaigns have been created including the Justus-Warren Heart Disease and Stroke Task Force message "Start with Your Heart"[26] and the AHRQ funded message "Questions Are the Answer: Get More Involved With Your Health Care."[27] Although we do not know how much effect these messages have had, they normalize the behavior of seeking clarity in the health care setting. Such social marketing approaches may lead to more efficacious health care encounters.

3. Improve Oral Communication in Health Care Visits

Health communication researchers have known for years that patients remember about 50% of what they are told in a visit with a physician.[28] Even that which is remembered is often remembered incorrectly.[29] This is especially of concern when most health communication takes place orally in the health care setting. Therefore, strategies that improve oral communication may lead to better health outcomes, particularly for those with low health literacy.

People who have strong reading and information processing skills can get by in the current environment because they can seek more information after they leave the health care setting by looking on the Internet or in books. Unfortunately, a large part of society cannot access information so easily and must rely on good information transfer in the clinic or hospital. Although an important area of research, we do not have much empirical evidence on what strategies work best.

The most promising strategy to facilitate understanding in the office setting is the teach-back method. Using this method, the clinician explains a concept or behavior to a person, then asks the person to explain it back in his or her own words. This can give the clinician the opportunity to clarify any areas the person did not adequately understand. This method is the only way a clinician can be certain that the patient or family understands the content. An added bonus to this method is that the patient recall will be better because of having to communicate it to the clinician.

One published study has evaluated the use of the teach-back method by audiotaping visits between patients with diabetes and their physicians.[30] The study found that the teach-back method was used with only 20% of the patients. However, those patients had 9 times the odds of having their blood sugar below the average (a lower blood sugar is good in this context). Although an observational study, it suggests this approach may have benefit. It was also noted that those visits which included the teach-back method were not longer. In addition to this study, the teach-back method and its variants are tried and true pedagogic methods advocated by educators as far back as Socrates.[31]

Another strategy for improving oral communication is to limit the number of topics communicated at one time. In the context of a health care encounter, the clinician often mentions several different ideas, prescribes medications, and suggests specific self-care behaviors. Frequently, there is no summation of the main points, and the clinician is not aware of the elaborate content he or she has just imparted. People have a variety of capacities for remembering things, so the clinician must tailor the amount of information to a given patient. I advocate that clinicians try to limit the number of points they expect the patient to remember to 3. Anything beyond that requires supplementary methods to help the patient remember and reinforce the information.

4. Alter Systems of Care

Lastly, we must consider the role of our care systems in making health care less effective for patients with low health literacy. Most current care systems rely on complex organizations that make lots of errors including problems in scheduling, prescriptions, administering medications, and receipt of self-management support. In these systems, patients with higher health literacy can often get by, but not easily. A patient with low health literacy is left extremely vulnerable and likely receives substandard care. At the time of the 2004 AHRQ systematic review, no studies directly demonstrated whether system changes could mitigate the effects of low health literacy.

Making health care systems responsive to the needs of people with low health literacy is not easy. In many quality improvement programs, the provision of self-management support is the hardest improvement to implement with fidelity and efficacy.[32] Fortunately, models are beginning to emerge,[33] and some practices have shown improved health outcomes for patients with low health literacy.

One system in North Carolina created a diabetes disease management program within the practice that included clinical pharmacist practitioners, diabetes educators, and care assistants to help educate and respond to the needs of the patients with diabetes.[34] This program focused mostly on the patient's desired behavior goals and used the teach-back method when communicating. However, the program also helped patients navigate the health system by teaching them how to get rides to the clinic and how to register for pharmacy benefits when the forms were too complicated. Although patients of all literacy levels benefited from the program, those with low literacy received much greater benefit from the program.[35] In essence, this program reduced disparities in outcomes for patients with low literacy.

The same practice developed a heart failure self-management training program targeted toward patients with low literacy skills.[25] This program offered training for the patient with several follow-up phone calls to reinforce the education. Although this program did not offer specialized medical care or ancillary help like the diabetes program, it did reduce hospitalizations among all patients.[36] Patients with low literacy benefited as much or more than those with higher literacy, but the study was not large enough to explore whether the disparities in fact narrowed.

A large public hospital in California tested 2 forms of diabetes support versus usual care.[37] One of the intervention arms used automated telephone disease management (ATDM) to call patients and gather information on how the patient was doing. If any concerns were elicited, the patient received a call from a nurse educator. The other intervention arm used group visits to provide self-management support. The study found that patients in the ATDM had improved functional status, self-management, and mental health compared to patients in the group visits arm and in the control arm.

System changes to provide more comprehensive care appear promising for patients with low literacy. A system that does not require advanced literacy skills will likely improve care for patients regardless of literacy level. Hence, health literacy meets quality improvement. As we proceed with redesigning our care systems, we should consider the role of the patient and how we can reduce the navigation burden, eliminate clinical inertia, and provide tailored and effective self-management support to reach optimal health outcomes.

Conclusions

Understanding and addressing low health literacy will require further basic research but also implementation science and quality improvement. Basic research in the field is expanding rapidly and we will continue to identify best practices. Implementation has lagged behind because, until recently, we did not have evidence-based methods to improve outcomes. The emergence in the past 3 years of evidence-based approaches should lead to the next phase of implementation science to help us provide health literacy sensitive care to patients in our clinics, hospitals, and public health venues. **NCMJ**

COMMENTARY

Chasing the Monster

Toni Cordell

While attempting to do the task before her, a young woman stated in frustration, “I am only as good as the information I am given.“ Communication offers an opportunity for understanding and success or misunderstanding and failure. As we all know, the lack of crystal clear health communication can put lives in danger.

Medical professionals have extensive training and education. Face to face with the doctor, health issues can be talked through if both the practitioner and the patient are on the same page while communicating. But some patients also hope that the doctor not only hears their words but also understands the feelings associated with them when they have the courage to express them. That puts a great deal of responsibility on doctors, nurses, and other medical professionals.

> *“Communication offers an opportunity for understanding and success or misunderstanding and failure.”*

About 30 years ago, I visited the gynecologist knowing there was a problem (I later learned it was a prolapsed uterus). During the exam the physician said that the problem had “an easy repair.“ I asked no questions. We just set the surgical date, and I showed up at the hospital for that “easy repair.”

I graduated from high school reading at the fifth grade reading level. When I was in school there was no help for those of us with learning problems. So, I’ve spent my life facing challenge after challenge and attempting to gain enough knowledge so I can feel normal.

Because of my poor reading skills, I simply signed every paper pushed in front of me at the admissions desk before my surgery. This was not my first surgical procedure, and I knew I was required to sign those papers in order to have the “easy repair” procedure. I didn’t read a single word. I didn’t even try because I suspected the medical jargon would make the documents too difficult to understand.

Looking back, it would have been so helpful if the documents needing my signature could have been mailed out ahead of time. Then I could have gone over them at my own pace or asked my husband, an educated man with a high IQ, to check them out. Another option may have been to call ahead of time and request the paperwork so I could familiarize myself with it.

The surgery was a successful “repair.” However, during the 6-week follow–up appointment in the doctor’s office, the nurse walked into the examining room and cheerfully asked, “Toni, how are you doing since your hysterectomy?” Shocked and humiliated, I behaved as normally on the outside as possible. However, it caused an emotional overload with my insides screaming at me for being so stupid. The word hysterectomy meant they cut something out. That is more than a “repair.” How could it happen that I did not know? I just realized part of my body was cut out, and I only thought it was a surgical repair. Although I was not hoping for more children, it was still a traumatic day for me.

Several years ago, after numerous surgeries attempting to correct the organs in my lower abdomen, I was sent to a urologist, Dr Niall Galloway, at Emory University Hospital in Atlanta. His nurse told me that he gets all the train wrecks. Thankfully, he serves as an excellent example of a very positive experience within the medical community.

Of course at the initial appointment I had to deal with the clipboard and the papers needing my signature. By this point in my life I had been to an adult literacy program and my reading level had improved but I still loathed paperwork. I was led back into the examining room. Dr Galloway came in and sat chair to chair and face to face with me. We were both fully clothed. He asked lots of questions. Then as he left the room he instructed his nurse to prepare me for the physical exam.

When I was properly set on that horrible table and fully draped, Dr Galloway returned. Before he laid a hand on me, he spoke with care letting me know what he was doing and even

Toni Cordell is a patient advocate. She can be reached at tcordell2 (at) yahoo.com.

warned me to expect the uncomfortable part. After Dr Galloway left the room, the nurse helped me take time to recover and get up right, and she asked if I needed any help to get dressed. So, when Dr Galloway returned, once again I was dressed. That tends to put physician and patient on more of a peer relationship. While in a paper or cloth drape one can feel vulnerable. Being dressed in street cloths takes some of that out of the encounter.

Dr Galloway clearly stated his evaluation and what he believed the treatment should be to correct the current problem. His Picasso-like hand drawings illustrated the places where there would be cuttings, stretching, and stitches. Although I am still not as good at asking questions as I need to be, Dr Galloway communicated so clearly that I went into that surgery very well informed of what to expect.

As a result of my interaction with the medical field and attending conferences on patient safety, I now know about the Ask Me 3 campaign.[a] Ask Me 3 gives a patient a place to start to become better informed and educated about his or her own medical needs. I never want to suggest that all of the responsibility for communication rests on the shoulders of the medical professional. It needs to be a partnership in which the patient also plays a role.

Many of us with low literacy skills or a poor education have emotional baggage from the many years of feeling stupid. After all, many of us sat in high school classrooms alongside of you. I graduated from high school reading at the fifth grade reading level. I know I am not your academic equal. I have a high regard for all who have earned a college education and beyond. But now I have learned that I no longer have to just do as I am told. I suspect one physician has written "noncompliant" on my chart because I argued with him about depression and refused antidepressant drugs. But it is my body and my life, thus it is my choice.

I have lived my life being attached to the stupid monster that is my lack of formal education. No, I am not suggesting I think there are really monsters around every corner waiting to get me. It is just that when I say or do something that reveals my lack of education I get slammed in the face with humiliation. So when a staff member in your office gets frustrated with me, I know it and I tighten up.

Most of the time, I make an effort to be very honest about my reading skill or lack thereof. After I sign the HIPAA papers, I hand the clipboard to the person at the desk and say, "I signed these, but I don't understand them." Most of the time that person just looks at me. Sometimes they will joke that they don't either. I believe at that moment I have just put the ball back in your court, and if there is a problem you could be open to a legal suit. I am not sure, just a guess. I am not personally interested in suing anyone.

Not all patients lack the education to communicate with medical professionals on a peer level. However, even those with advanced educations may not be at peak performance while visiting the doctor. What happens to those with college degrees when their temperatures soar over 100 degrees? Are they able to understand and follow every bit of instructions coming at them when a flu bug has moved in with a bit of diarrhea and vomiting? Okay go one step further. If the word cancer has just come out of the doctor's mouth, can you, at that moment, process all instructions to deal with that life-threatening illness?

Health literacy is not just a problem for those of us with a poor education. No matter how difficult the task, all medical decisions need to be made in partnership with the medical professional and the patient. That requires crystal clear communication with mutual respect. **NCMJ**

---

[a] The Ask Me 3 campaign was developed by the Partnership for Clear Health Communication to improve communication between practitioners and patients. It endeavors to teach patients to ask 3 questions of the practitioner during a health encounter: What is my main problem? What do I need to do? Why is it important for me to do this? For more information, visit http://www.askme3.org/for_patients.asp.

Lay Health Educators' Roles in Improving Patient Education

Susan Auger, MSW; Sarah Verbiest, MSW, MPH

There is an urgent need to transform our health care system to improve the quality of and access to care, more efficiently use limited resources, and be more cost effective. The convergence of trends, many studied by the North Carolina Institute of Medicine, driving this need for transformation include the alarming increase in chronic diseases across the lifespan, persistent shortages of health care professionals and interpreters, the increasing uninsured population, and limitations of our health care safety net to meet growing demands. Demographic changes, environmental health risks, and health literacy issues further compound these problems. All these factors contribute to health disparities and underscore the need for culturally relevant and linguistically appropriate health education and care. A key to health care transformation is the shift from a traditional hierarchical, clinician-centered approach to a patient or relationship-centered approach in interpersonal communication and service delivery strategies.

> *"Lay health educators are respected and trusted members of a community who know most of the residents they educate. They help translate health information into culturally meaningful, understandable messages that their neighbors can critically think about and act on."*

Given the current milieu, it is time to take a fresh look at the role lay health educators (LHEs), also known as lay health advisors, community health workers, or *promotoras*, can play in improving communication, increasing access to quality care, and reducing costs. Research in health literacy has heightened awareness that it is not enough, from a practical or ethical standpoint, to simply disseminate health information. It is problematic when the information is laden with medical jargon and technical terms and written at too high a reading level. For effective disease treatment and prevention and behavior modification, individuals must be motivated and able to access, understand, and use health information in the context of their daily lives. Lay health educators are respected and trusted members of a community who know most of the residents they educate. They help translate health information into culturally meaningful, understandable messages that their neighbors can critically think about and act on. The LHE model was first endorsed by the federal government in the 1960s as a way to expand access to care for underserved populations. These natural helpers build bridges between systems of government, educational institutions, and medical and social services that might otherwise be out of reach to individuals and their communities. Acting in a spirit of collaboration and mutuality, their work and use of "living room" language embody the principles and best practices of health literacy and relationship-centered care.

Susan Auger, MSW, is president of Auger Communications, Inc. She can be reached at auger (at) augercommunications.com or PO Box 51392, Durham, NC 27717.

Sarah Verbiest, MSW, MPH, is executive director of the Center for Maternal & Infant Health, School of Medicine, and a doctorate in public health candidate, School of Public Health, the University of North Carolina at Chapel Hill. She can be reached at sarah_verbiest (at) med.unc.edu or University of North Carolina at Chapel Hill, CB# 7181, Chapel Hill, NC 27599-7181.

Although currently an underutilized service delivery strategy, the versatility and effectiveness of LHE programs make them an attractive and vital option in today's health care environment. Lay health educator programs are typically used to accomplish 3 interrelated goals: (1) strengthen the therapeutic alliance between health care professionals and community members; (2) improve appropriate health care utilization; and (3) reduce health risks.[1] Diverse program structures and roles and responsibilities of lay health educators reflect the uniqueness of communities and their resources. Amidst this diversity, common program components exist. For example, many programs include outreach to underserved communities through activities such as networking with neighbors, providing simple health screening, and staffing mobile units. Lay health educators often help develop or select health materials for their peers based on their knowledge of language as well as local cultural beliefs and practices. Many LEH models have roots in Paolo Freire's work in adult literacy and seek to empower community members to identify their own needs and then develop and implement a plan that is right for them.[2] Health advocacy, home visits, health promotion, support for lifestyle changes, and the provision of transportation are other program components that are often part of LHE outreach efforts.

Lay health educators' primary allegiance is to their communities and social networks. This is a critical element and must be both respected and maintained by programs. The degree to which LHE programs are integrated within the health system varies. On one end, LHEs are fully integrated into the health care team as paid employees. On the other end, LHEs work autonomously in their community with no connection to the health care community and no compensation. Within these extremes lie a wide variety of partnerships and structures. The level of formal and informal linkages between LHEs and health care providers should be balanced based on the program's focus. In some cases, strong ties with health care providers assist LHEs in their work and health promotion efforts. In other cases, particularly when reaching more isolated and difficult to access communities (such as those with HIV/AIDS), strong links to providers might create a sense of distrust within communities and undermine a LHE's effectiveness. In other circumstances, activities that are integrated with a health center's clinical operations may facilitate better access to comprehensive services.[3] For example, consistent contact between physicians, case managers, and LHE home visitors can help ensure appropriate referrals and more effective follow up. Lay health educator programs must consider ways to respect the contribution of time and expertise of LHEs as well as ways to keep them engaged over time. Cash compensation is one obvious incentive. Increased access to services, training opportunities, respect from their peers, and a deep sense of knowing they have helped their community are other ways that LHEs benefit from their labors.

Programs that actively work with LHEs can build capacity at individual and system levels. Lay health educators commonly report an increased level of self-confidence, assertiveness, and ability to speak their minds as a result of their role. Their increase in knowledge and enhanced health and science literacy skills help increase the capacity of the entire community to take action on behalf of their members. Individuals and communities are empowered to get involved and stay connected with outside systems, a crucial function in times of health crises and natural disasters. Identifying motivated individuals in communities through LHE training can foster opportunities to recruit new talent from underserved communities for possible careers in health care.

With appropriate training and supervision, LHEs can benefit health care systems by providing a cost effective way to address cultural and language differences and more effectively meet the needs of an increasingly diverse patient population. One example of potential system efficiency is to use LHEs with groups of mothers to provide prenatal education as a complement to short physician visits. This can expand and heighten the cultural sensitivity of health care information received by women. The pregnant mothers would also receive greater social support, which has been shown to improve birth outcomes.[4] In addition, sharing the educational responsibilities with LHEs would allow health professionals and clinic interpreters an opportunity to use their time more effectively. In fact, nurse-supervised LHEs provided group prenatal education to high-risk Latinas in a recent study to improve quality of care and reduce health disparities among Medicaid managed care enrollees. They used *photonovellas* (or "photo-stories") and the Teach-With-Stories Method. This innovative approach, developed in North Carolina, is an internationally recognized best practice model for addressing prenatal care, empowerment, and health literacy needs of women. Latinas who received the Teach-With-Stories intervention had higher rates of optimal prenatal care (90.5% vs 64.7%) than the overall prenatal population at Neighborhood Health Plan of Rhode Island, the statewide health maintenance organization conducting the study.[5]

Lay educators have been used successfully with diverse populations to address specific health problems such as cancer, HIV/AIDs, diet and nutrition, prenatal care, environmental health issues, and health disparities within all these issues. The lack of standardization in the program structures, roles, and responsibilities described above as well as differences between community and research cultures pose evaluation challenges. While more research is needed, there are additional studies that demonstrate that LHE interventions can improve access to care, increase client knowledge, and facilitate behavior changes.[5,6,7] Research has also shown that LHEs can improve the health status of individuals with chronic diseases such as diabetes and high blood pressure.[8] The studies available that evaluate the financial impact of LHE programs provide evidence that they are economically sustainable.[9] One study, designed to assess the return on investment of LHEs working with underserved men, examined service utilization, charges, and reimbursements. Primary and specialty care visits increased while urgent care and inpatient and outpatient behavioral health care utilization decreased. Consequently, uncompensated costs decreased; the return on investment was \$2.28 for every \$1.00 in costs.[9]

Meaningful dialog and greater insight into the strengths and needs of communities are needed to improve health literacy, increase access to quality health care, and use limited resources more efficiently. This cannot be accomplished in isolation. Lay health educators offer a unique opportunity to strengthen the relationships between health professionals and patients through more culturally sensitive communication. They are able to adapt and discuss health information with their neighbors in a way that is understandable and encourages improved health promotion and risk reduction. With appropriate training and supervision, these natural helpers can also give community members practical support to navigate systems and make changes in their lives. Despite mounting evidence of their efficacy and cost-effectiveness, barriers exist to the use of LHEs and the sustainability of such programs. For example, while grant funds may be available to start community-based programs, innovative ways to fund LHEs and maintain a program's infrastructure are needed. Also, data systems must be improved to allow better tracking and assessment of LHE programs. Working together, health professionals, community members, researchers, and policy makers can make better use of lay health educators in North Carolina to the benefit of all. **NCMJ**

Incorporating Health Literacy Into Adult Basic Education:

From Life Skills to Life Saving

Sandra J. Diehl, MPH

Our health care system increasingly encourages patient involvement in care, yet patients are often not well-equipped to assume such a role. A contributing factor is having marginal health literacy skills. Health literacy does not just refer to reading and writing skills but a much broader set of communication, cognitive, social, and inquiry skills that allow individuals to meet personal health goals. Approximately half of North Carolina's population has marginal literacy skills.[1] Furthermore, almost a quarter of our state's population has severely limited skills. These individuals can perform tasks such as signing one's name or locating the expiration date on a driver's license but cannot perform more difficult tasks such as locating an intersection on a map, identifying and entering background information on a social security card application, or totaling the costs of a purchase from an order form.[2] Adequate health literacy skills play an integral role in preparing individuals to interact with our health care system. They also have important implications for health promotion, disease prevention, and disease management because they influence actions such as making informed decisions, following health advice and instructions, and seeking and using health information and services.

> *"Adult education principles suggest that learning occurs best when the material being taught is immediately relevant and useful to the student."*

The Role of Adult Education in Improving Health Literacy

Skill building is a critical component of a multidimensional approach to addressing North Carolina's health literacy concerns. Fortunately, we have a community college system that serves all 100 North Carolina counties and has enjoyed a long, stable history of building basic skills among adults. Complementing this system are the efforts of literacy councils and community-based organizations. Basic skills classes at the community college build functional skills that lead to a stronger workforce, and many of these same skills translate to building a more health-literate population. Between 136 000 and 153 000 North Carolinians took part in basic skills classes annually from 2001-2006, according to community college data.[4] Classes are offered free of charge for students attending any of 4 distinct programs under the basic skills umbrella. Two of these programs, English as a Second Language (ESL) and Adult Basic Education (ABE) are especially well-suited for teaching health literacy skills.

Adult Basic Education classes are designed for adults who lack proficiency in reading, writing, speaking, problem-solving, or computation at a level necessary to function in society, on a job, or in the family.[4] English as a Second Language classes are designed to help adults who are limited English proficient achieve competence in the English language.[4] Language and cultural barriers contribute to special health literacy needs among these students.

The adult education setting offers a compelling opportunity for building health literacy skills because of the compatibility between health literacy goals and adult education goals, the flexibility offered to ABE and ESL instructors in choosing a curriculum, teaching methods that are friendly to adult learners, and the potential to reach a high-risk population. Adult education is rooted in a long tradition of encouraging social change and empowerment[5,6] among vulnerable populations, and educators are often passionate advocates for their students. Instructors

serve as an invaluable resource to adult learners both as links to reliable health information as well as facilitators for building health-related skills.

Qualitative data from a series of recent statewide health literacy workshops offer some insight into the literacy-associated challenges that individuals face. Attendees, representing literacy, health, and human service organizations, named misunderstanding medications, tuning out because a provider uses technical terms, and trouble with paperwork as common concerns among the people they serve. A reading center manager from Fayetteville said, "I work for an adult literacy program and see many people who do not read…they talk about the stack of papers you get to fill out the minute you walk into the doctor's office." A nurse gave another perspective saying, "As a telehealth nurse, I get calls from patients who do not understand the written instructions given to them by their doctor, the emergency department, and/or discharge instructions after hospitalization. This may include how to take their medication or manage chronic diseases such as diabetes or asthma." An adult literacy instructor from Charlotte offered, "Some students read and understand well enough to take meds, the right ones at the right times with (the) correct dosage. However, there are some that do the exact opposite. It's scary." These communication concerns are best addressed through multiple channels such as practice or policy changes to address systems issues and education to strengthen individual skills. Adult education can help complement those efforts not only by enhancing general literacy skills but by also focusing on specific needs such as understanding medicine labels or modeling and practicing communication techniques that may lead to a mutually beneficial conversation among patients and providers.

Classrooms offer a safe place for individuals who share common educational needs to learn new information, practice new skills, and receive feedback. Adult educators employ a variety of teaching methods that appeal to individual learning styles. Furthermore, students usually enjoy a sustained educational relationship with their peers and instructor. This relationship serves to enhance rapport and opportunities for information sharing. Both ABE and ESL classes are guided by a set of national objectives called Comprehensive Adult Student Assessment which outline skills that individuals need to successfully function in everyday life.[7]

Strategies for Building Health Literacy Skills in the Adult Education Setting

Integrating health information into adult education is not a new practice. The adult education arena already builds health literacy skills among adult basic skills learners, albeit framed in an overlapping 'life skills' context. For example, "identify emergency numbers and place emergency calls" is a life skills learning objective; it is also a health literacy skill. The Comprehensive Adult Student Assessment system outlines many other competencies that would also fit under a health literacy rubric. Table 1 presents a small sample of these competencies. Thus, teaching health literacy in classrooms is compatible with existing basic skills standards and helps programs meet progress goals. Because there is compatibility and growing awareness among educators of the importance of health literacy, specialized curricula have been used in adult education classrooms in North Carolina, and more are being developed to help build health literacy skills. Adult Basic Education and ESL classes don't have a set curriculum, thus instructors are able to respond to the needs of their learners and have flexibility to incorporate a variety of learning experiences.

One notable statewide effort is the *Expecting the Best* project which involved curriculum development and evaluation, a project Web site, a multidisciplinary advisory board, and active dissemination efforts. The goals of this project were to introduce teaching material into community college and community-based organizations and facilitate the formation of ties between health and literacy providers. *Expecting the Best* is a 14-lesson curriculum for ESL students that teaches a variety of health-related skills including where to seek health services, how to make an appointment, how to understand medicine labels, and how to understand nutrition labels. It was developed with considerable input from ESL students and community college instructors and administrators, and reviewed by health professionals for accuracy. An evaluation of 14 community college classes randomized to *Expecting the Best*

Table 1.
Sample Comprehensive Adult Student Assessment Competencies Related to Health and Literacy

Nutrition Competencies	Health Competencies
■ Select a balanced diet ■ Interpret food packaging labels ■ Interpret nutritional and related information on food labels ■ Compute discounts ■ Use coupons to purchase goods and services ■ Make comparisons, differentiating among, sorting, and classifying items, information, or ideas	■ Locate medical and health facilities in the community ■ Complete a personal information form ■ Identify emergency numbers and place emergency calls ■ Describe symptoms of illness, including identifying parts of the body and interpreting doctor's directions ■ Use a telephone directory and related publications to locate information ■ Fill out medical health history forms

or usual curriculum showed a significant increase in health literacy skills among female students.[8] Other curricula for low-literacy audiences are available on the web.[a] One popular web resource is a series of picture stories for beginner ESL students that can be adapted for audiences of varied literacy levels to generate discussion and teaching moments (Figure 1).[9] Furthermore, a consortium of 5 literacy programs in North Carolina is currently developing a health literacy tool kit that can be used by other programs in the future.

Adult education principles[10] suggest that learning occurs best when the material being taught is immediately relevant and useful to the student. Adult educators are not limited only to specialized health skills curricula; they can also take advantage of community resources to create a range of relevant and useful learning experiences. The ideas are limitless, and a few are described here to illustrate the possibilities. For example, health educators are often available to visit the classroom and speak about a topic of interest to students.[11] In one case, after a student's child choked and they experienced a distressing trip to the emergency department, a Red Cross trainer visited the classroom and taught students First Aid basics, including rescue skills for choking. This emergency also presented an opportunity for the class to talk about medical bills and the North Carolina Children's Health Insurance Program (NC SCHIP). In another case, at the students' request, a health educator from the local health department visited a class to talk about HIV prevention.

Encouraging civic engagement is often a goal for adult learner programs; this can tie into health literacy efforts by actively involving students in educating others. One promising idea is to consider recruiting lay health advisors from adult education programs. Another idea that has been successfully implemented in an adult education classroom involves asking students to research and create health education materials for their peers. In this program, students presented health information on breast cancer and mammography screening to fellow students.[12] Adult education students might also serve as a potential field testing audience for consumer materials prior to release.

Field trips can be a fun way to teach information in a real-life setting. The Raleigh Farmer's Market has been a popular place to bring students to teach life skills such as making nutritious choices and calculating correct change from transactions. Arranging an introductory visit to a local walk-in or sliding-scale health center can promote health by creating a familiarity with the setting before a medical visit is needed. A trip to the local library can help students build confidence and skills in learning how to research health information.

A key consideration when incorporating health literacy topics into adult education classrooms is student interest. That is, it is crucial to choose curricula, guest speakers, and other activities

---

[a] For example, see the Health and Literacy Special Collection at World Education's Web site, http://healthliteracy.worlded.org.

that are of interest to students. If students do not actively participate in selecting what they learn, then it is unlikely they will be engaged. Worse, the intent can be misinterpreted. An advocate in the Latino community explained, for instance, how students felt alienated when a health educator visited their ESL classroom to talk about sexually transmitted infections. While the intention was good, it ended up as a stigmatizing experience because the students did not ask for this information nor did they have any particular interest in it. Another suggestion, based on formative data from the *Expecting the Best* program, is to include health literacy skills as part of a diverse curriculum rather than creating a class that focuses only on improving health skills.

Finally, instructors themselves must feel confident in incorporating health literacy skills into their classes. Understanding that health literacy is a part of general literacy and life skills can help, as can viewing themselves as a link rather than a primary resource of health information. Arranging meetings between health educators and literacy organizations to share resources is mutually beneficial and can also help acquaint educators with local health resources. Literacy workers can learn how to incorporate health materials into their classrooms, while health care workers can learn how to reach low-literacy groups and can refer patients to adult education classes. Making health literacy curricula widely accessible and easy to use, accompanied by teaching workshops that orient and encourage instructors to implement new materials and which include pointers on how to link with health resources, may be a useful dissemination strategy.

Adult education is a context where meaningful learning occurs among individuals at high risk for low health literacy. It is an easily accessible, positive environment to not only provide information but to practice and reinforce skills. Best of all, it is a stable system that offers a sustainable point for intervention and which serves to contribute to a diverse approach to meeting the health literacy needs of North Carolinians. **NCMJ**

COMMENTARY

Improving Prescription Drug Labeling

Michael S. Wolf, PhD, MPH; Stacy Cooper Bailey, MPH

According to a 2006 report by the Institute of Medicine of the National Academies, *Preventing Medication Error*, approximately 1.5 million preventable adverse drug events occur each year.[1] Attention to the root causes of medication errors leading to adverse events has most often been attributed to the provider's or health care system's contributing role in errors during the prescribing, ordering, dispensing or administering of a medicine.[2,3] The reason attention was focused on those causes may be that most studies investigating medication error have been conducted in inpatient hospitals or nursing homes.[4] However, more than one-third of adverse drug events take place in outpatient settings at a cost approaching $1 billion annually.[1] It has been estimated that a large proportion of outpatient medication errors occur as a result of patients themselves not administering a medicine as intended.[3] For ambulatory care, the patient, rather than the provider, is ultimately responsible for correctly administering a medicine as prescribed. Therefore, the processes of quality control and monitoring of medication error shift from provider to patient.

The current body of evidence detailing the incidence and causes of outpatient medication error is limited. Yet problems are likely to intensify as patients increasingly self-manage greater numbers of prescription and over-the-counter medications. Chronically ill patients and the elderly are at greatest risk for experiencing medication errors as they take more prescription drugs annually than younger and healthier patients, and visual/cognitive impairments by age may limit reading ease and comprehension.[5-9] The risk for miscommunication and error may be further compounded since the average older adult sees several different health care providers annually.[10]

Health Literacy as a Medication Safety Concern

Limited health literacy is another significant risk factor that could account for outpatient medication errors that are the result of improper dosing administration. Numerous studies have found low health literacy to be significantly associated with a poorer understanding of medication names, indications, and instructions.[11-14] More recently, health literacy skills have been linked to requisite knowledge for adherence to treatment regimens.[15] This current and well-publicized body of research has focused on the ability of patients to read, understand, and demonstrate instructions on drug container labels. The line of inquiry has been supported by parallel work in human factors research.[5,6] Davis and colleagues conducted a multisite study among adults receiving primary care at community health centers and found a high prevalence of patients, especially those with limited literacy, misunderstanding seemingly simple dose instructions provided on the primary label of medication containers.[11] In this study, 46% of adults misunderstood at least one prescription container label they encountered. The problem extends to the auxiliary sticker labels that provide accompanying warnings and instructions for use of the medicine. Another study demonstrated over half (53%) of patients, especially those with limited literacy, had difficulty interpreting text and icons commonly used on these auxiliary warning instructions.[12]

Beyond the container, drug labeling also includes accompanying medication information materials that provide indications for use and

> *"...the manner in which the current health care system delivers necessary medication information to patients is clearly inadequate."*

Michael S. Wolf, PhD, MPH, is assistant professor of medicine and director of the Health Literacy and Learning Program at the Institute for Healthcare Studies in the Division of General Internal Medicine, Feinberg School of Medicine, Northwestern University. He can be reached at mswolf (at) northwestern.edu or 750 N Lake Shore Drive, 10th Floor, Chicago, IL 60611.

Stacy Cooper Bailey, MPH, is program manager of the Health Literacy and Learning Program in the Institute for Healthcare Studies in the Division of General Internal Medicine, Feinberg School of Medicine, Northwestern University.

further detailed precautions that can not fit on the container due to space constraints. Studies have found that these materials, as with the container label, are not useful for a majority of patients, particularly those with limited health literacy.[16] This includes consumer Medication Guides (aka Med Guides) that are required by the Food and Drug Administration to be dispensed along with certain prescribed medicines that have been identified as having serious public health concerns. Patients with limited health literacy were significantly less likely to attend to these materials. These findings are supported by earlier research studies that suggest consumer medication materials are too difficult for most patients to read.[17] As a result, the patient information leaflets and Med Guides that accompany many prescription medications may be ignored.

A System Failure

The 2004 Institute of Medicine of the National Academies report on health literacy, *A Prescription to End Confusion*, aptly identified the problem of health literacy as encompassing more than limitations in individual abilities.[13] Rather, the complexity of demands placed upon the individual by the health care system must clearly be addressed. While patients must have adequate cognitive capacity and proficiency to read, understand, and act on medication label instructions to ensure proper and safe use, the manner in which the current health care system delivers necessary medication information to patients is clearly inadequate. Physicians, who are legally responsible for delivering important drug information directly to patients, frequently miss opportunities to adequately counsel their patients on how to self-administer their medicines.[19] Pharmacists, next in line to counsel patients, also frequently fail to verbally communicate detailed information to patients at the point of dispensing medicines.[20]

In light of these failures, patients must depend more on the print drug labeling materials (ie, the container label, consumer medication information, Med Guides, patient information leaflets) that are challenging for patients across all health literacy levels.[17,18] With the exception of Med Guides and a very limited set of similar patient package inserts that are available for only a select number of drugs, no national standards or regulations exist for the development and oversight of consumer medication information or container drug labels. Informational leaflets are industry-generated, and state laws minimally govern content and format on prescription container vials. This all leads to what can best be described as a fragmented system of patient information.

Taking Action

Improving the readability and understanding of instructions and supplementary information for prescription drugs is warranted as it may ultimately stimulate appropriate and safe medication use among patients. Evidence is available now supporting the design of better drug labeling.[21] This includes considerations for both the container label and accompanying materials. Based on recent health literacy studies and work by the American College of Physicians Foundation (ACPF) on prescription drug labeling, certain general recommendations can be issued that espouse the importance of promoting health literacy as a medication safety issue.[22]

First, seemingly simple dosage instructions printed on the container label should be written in the most clear and concise manner. Previous research has found that patients have more difficulty understanding vague medication directions as compared to more explicit ones.[23,24] The less a patient is required to make inferences, the more easily medication schedules can be comprehended (ie, "take every 6 hours" vs "take at 8am, 2pm and 8pm"). This is especially important for more complex dosing schedules, where patients may become easily confused or more prone to errors if instructions are read in haste.

Second, Shrank and colleagues examined the variability in content and format on prescription drug container labels.[25] They found that pharmacies consistently emphasized provider-directed content versus information most pertinent to the patient. The use of bolding, highlighting, and larger font should be directed solely to label content that is most salient to the patient. Information such as prescription number or the pharmacy logo should be de-emphasized and segregated from dosage instructions, warnings, or indications so as to not detract from the most important label content detailing its appropriate use. Every effort should be made to organize the container label in the most patient-friendly manner. It likely will be the most tangible source of drug information repeatedly used by patients.

Third, accompanying materials should abide by core principles upheld by adult literacy practitioners.[17,26] Consumer medication information should keep to simple language and avoid medical jargon. The scope of information should be limited and summaries more frequently used to highlight actionable messages. Shrank and colleagues further describe the type of content that is desired by patients to support appropriate use.[21] Surveys have shown that patients want to know, in addition to dosage instructions, the indications for use of a prescribed medicine, any precautions, and the duration of treatment. Information on the benefits and side effects of drugs is also sought after by patients, and providing this information has been found to improve adherence.[20]

Finally, steps should be taken to ensure that these separate elements of drug labeling, the container label and accompanying materials, are developed together as an integrated and complimentary set of information sources. Patients should be included in this process so materials are appropriately organized, and they accurately reflect the common schemas imposed by patients of all literacy levels when seeking to understand how to use prescribed medicines.

Conclusion

System change is urgently needed to promote health literacy for greater medication safety. Patients must be able to easily understand how to use prescription drugs correctly. Standardizing and integrating drug labeling must be a central goal to ensure that best practices are implemented because evidence is already available to target improvements. This should be viewed as a short-term goal for policymakers, and some states have already made progress to this end.

In the long term, additional challenges for drug labeling include efforts to seek labeling concordance in other languages because not all prescription drug information and instructions are currently available to non-English speakers. A formative response to labeling problems would also extend to addressing how health care providers communicate to patients the information that is necessary to safely administer prescribed medicines. More broadly, health technology used by an increasing number of providers at the point of writing the prescription should be integrated with the software used by dispensing pharmacies to fill it and print out the labeling components. This would provide another layer of quality assurance that could minimize variability and the risk that instructions become lost in translation. **NCMJ**

COMMENTARY

Medication Instruction by Pharmacists:
Making Good on an Offer

Michael D. Murray, PharmD, MPH

Medications are often the most effective treatment alternative for chronic diseases. Because most of the 3 billion prescription medications are self-administered by patients in their homes, appropriate use of medications requires careful instruction tailored to a patient's level of health literacy and comprehension. Unfortunately, many patients are not getting such instruction, which increases their risk of treatment failure or otherwise preventable adverse medication events. There are many reasons for this lack of instruction. However, the primary reason is that health professionals lack sufficient time to communicate needed instruction, and they are driven by the inertia of existing practice behaviors to the extent that inadequate instruction of patients is largely ignored. Patients also have time constraints, and they expect their prescriptions to be filled quickly so they can dash to the next thing on their list. While pharmacists are legally bound to *offer* medication counseling to patients, little counseling is actually *provided* in most pharmacies. However, the general void in medication counseling presents an important opportunity for pharmacists to play a greater role in patient care by reinforcing physician-to-patient medication instructions and improving the effectiveness and safety of self-administered medications. This commentary reviews salient factors and recent research involving medication instruction by pharmacists.

> *"While pharmacists are legally bound to offer medication counseling to patients, little counseling is actually provided in most pharmacies."*

Risks of Inadequate Medication Instruction

Insufficient medication information carries a risk of harm to the patient. This, in itself, must be considered as an impetus for better medication instruction. Patients who lack adequate information about their medications are more likely to experience treatment failures due to poor adherence, medication errors, and adverse events. Gandhi and colleagues[1] conducted a prospective cohort study of 661 outpatients responding to a survey to determine the rates, severity, and preventability of adverse drug events. Of the 661 participants, 25% (162) experienced adverse drug events of which 13% were serious and 39% could have been made less severe or entirely prevented. Physician-patient communication about new somatic complaints was a major factor in mitigating or preventing many of these adverse events.

The results of the study by Gandhi et al are consistent with a study of spontaneous reports of medication errors occurring in the home that were submitted to the United States Pharmacopeia's MedMarx and Medication Errors Reporting programs.[2] Of the 802 reports submitted, 11% (87) were classified as severe and resulted in permanent harm in 3 cases, a life-threatening situation in 4 cases, and death in another 4 cases. The most frequent causes of the 802 errors were performance deficit in 34% (246), poor communication in 21% (151), knowledge deficit in 19% (135), and not appropriately following a medication-related procedure or protocol in 13% (91). These results reinforce the importance of good communication involving in-home administration of medications and remind us of the potentially catastrophic results of not providing sufficient education about medications and not monitoring their use.

Michael D. Murray, PharmD, MPH, is a Mescal S. Ferguson Distinguished Professor and chair of Pharmaceutical Outcomes & Policy at the University of North Carolina at Chapel Hill. He can be reached at mick (at) unc.edu or CB #7360 Kerr Hall, Chapel Hill, NC 27599.

North Carolina State Counseling Rule

Pharmacists are required to offer, as opposed to actually provide, medication counseling.

> Patient Counseling shall mean the effective communication of information, as defined in this Rule, to the patient or representative in order to improve therapeutic outcomes by maximizing proper use of prescription medications, devices, and medical equipment. An offer to counsel shall be made on new or transfer prescriptions at the time the prescription is dispensed or delivered to the patient or representative.[3]

While the offer to counsel may be made by nonpharmacist personnel, the counseling must be conducted by a pharmacist. The reality is that the amount of time spent by pharmacists (or others) providing medication instruction or counseling is minimal.

Lack of Time

Physicians often provide to each patient a brief overview of the rationale and directions for each medication they prescribe. However, their time is limited due to the many other important matters that must be addressed during a visit including a review of the objective findings from the physical examination, a description of the rationale for laboratory tests, interpretation of the results of previous laboratory tests, an outline of the next steps in the patient's care, and consideration of new somatic complaints. Bodenheimer termed this a "tyranny of the urgent" whereby constant attention to acute needs leaves little time for matters pertinent to the patient's chronic care planning.[4] Given that the typical visit with the physician is approximately 15 minutes (with multiple interruptions), time and attention are barriers to more comprehensive medication instruction by physicians.

Pharmacists are also pressed for time. The legal requirement to offer medication counseling prompts an all too familiar near monologue from a pharmacy assistant to the patient: "Do you have any questions for the pharmacist? Please sign here. That'll be $58.25 for today's medications. Thank you." An offer to counsel made—check; legal requirements satisfied—check; business requirements satisfied—check; written information about the prescribed medications included on the bag containing the medications—check; patient appropriately instructed on medications—likely not.

Patients are also sometimes impatient when it comes to timely filling of their prescriptions and getting out the door of the pharmacy. Ironically, for many patients, their lack of adequate medication counseling is often because they are too rushed. Additionally, pharmacies are confusing places. Patients who get their prescriptions filled at busy pharmacies often do not know which person—among several wearing a white coat behind the counter—is the pharmacist. Furthermore, the lack of a private area for counseling in many pharmacies is also an important barrier to comprehensive instruction and communication.

Recent Studies

Recent studies suggest that spending more time with patients at the pharmacy translates into important improvements in their health status and in cost reductions. In North Carolina, the success of the Asheville Project has resulted in its imitation throughout the country. The project was a prospective cohort study of workers from 2 large employers in Asheville, Mission Health and Hospitals and the City of Asheville, who were serviced by 12 pharmacies. The clinical protocol promoted intense self-care education, financial incentives to participants such as free medication copayments, and frequent follow-up by pharmacists and nurses. Specially trained pharmacists scheduled free personal consultations to provide medication education, encourage adherence to the doctor's prescription, and provide treatment monitoring. For example, pharmacists trained patients on the use of home glucose monitors (for patients with diabetes) and measured peak flow (for patients with asthma). Patients were referred to physicians as needed.

Results of studies involving patients with diabetes[5] and asthma[6] indicated favorable changes. Patients with diabetes (n=85) had lower values of hemoglobin A1c over 7 to 9 months. While the costs of diabetes-specific services and medications were increased, the total costs considering all diagnoses were lower after implementation of the program. Furthermore, participants were quite satisfied with the program.[5] Recent results involving 207 Asheville Project participants with asthma (n=207) followed for up to 5 years suggested reductions in emergency department visits, hospital admissions, and total health care costs of approximately $2000 per year.[6] While these results are generally encouraging and have been embraced by the broad pharmacy community, they must be considered in light of limitations such as participant loss to follow-up and missing data.

We recently reported a randomized controlled trial involving 314 low-income participants with heart failure.[7] The intervention involved a pharmacist who had access to patient-centered materials aimed at persons with low health literacy. We were particularly interested in whether more pharmacist time spent instructing patients would lead to improved medication adherence, which in turn could result in decreases in expensive health care utilization and associated costs. To measure adherence to cardiovascular medications for heart failure, we used a special prescription lid that contained a battery and computer chip that recorded the time and date when the medication bottle was opened and closed. Compared to the 192 participants assigned to the usual care group, the 112 participants in the intervention group took more of their medications with less day-to-day variability in the timing of their medication dosing. Intervention participants had fewer emergency department visits or hospital admissions and approximately $3000 lower total direct annual health care costs. Study participants in the intervention group were satisfied with the information provided by the pharmacist and preferred the patient-centered materials compared to the densely written medication information that is provided by most pharmacies.[8] In summary, we found that addressing the heterogeneity in health literacy among patients is important: The one size fits all written medication information for patients is not appropriate for many patients, at least not without sufficient accompanying verbal instruction.

Improving Medication Instruction and Implementation

Pharmacy practice is undergoing a transformation that will favorably influence medication instruction for patients. The forces of change surrounding this transformation include the widespread recognition that patients:

- Need more information about the potent drugs they are prescribed.
- Have more prescriptions filled than ever before.
- Are serviced with faster, more sophisticated automation and information systems.
- Have access to pharmacists and pharmacy technicians who are serving broader roles.

Implementation of any successful program to improve medication instruction for patients will require more time and individualized service from pharmacists. While time-consuming, pharmacists should consider a teach-back method for making sure the patient can understand and explain instructions in the terms he or she comprehends.

In any profession or business, more time means more money. If the returns on investment of the aforementioned studies are generalizable to broader health care settings, then it would be more feasible to consider greater remuneration for cognitive services by pharmacists. Indeed, several North Carolina pharmacies have taken progressive steps to engage its pharmacists in nondispensing aspects of pharmaceutical care, have reconfigured many of their dispensing areas to include space for private counseling, and have successfully received remuneration for nondispensing services. However, increasing cognitive services by pharmacists in the setting of increased competition for the health care dollar will more likely require a transfer of some pharmacist dispensing activities to highly trained technicians. For example, shifting the role of pharmacist work functions (dispensing, checking, adjudicating insurance claims, etc) to the pharmacy technician could allow more time for pharmacist counseling and other cognitive services. Such a redistribution of pharmacy workload between pharmacists and technicians would clearly require revision of the Board of Pharmacy's pharmacy practice rules. Notwithstanding any direct action by the Board on the medication counseling rule, the near hope would be that pharmacists will take it upon themselves to make a more concerted effort to provide medication counseling to willing patients rather than simply making an offer to do so. **NCMJ**

Increasing the Public's Awareness:

The Importance of Patient-Practitioner Communication

Marcus Plescia, MD, MPH; Mike Newton-Ward, MSW, MPH

Effective communication among professionals, patients, and communities is a significant public health concern. With up to one-third of individuals in some health care settings struggling with limited understanding of health issues and instructions, health literacy has emerged as an important cause of health disparities and a significant public health issue.[1] Effective communication to bring about behavior change requires a focus on both communities and individuals. From a public health perspective, communication must capture the collective nature of community health while recognizing individual health literacy issues. Successful communication within communities requires community involvement, the use of nontraditional approaches, and a focus on social norms. In this commentary we discuss specific public health approaches to working in communities with low levels of health literacy and the use of the social marketing process to develop an array of interventions that can impact all the determinants of a health problem in a population.

The best strategy to increase effective communication and improve health knowledge and skills is to increase health literacy levels overall. This requires significant time and resources. In the interim, the emphasis must be on working within existing levels of health literacy to develop more effective prevention and self-management of acute and chronic illness. Best practices in the medical setting have been described throughout this issue of the *North Carolina Medical Journal*. In the public health setting, promising community practices include the use of lay health advisors and engagement of important community institutions.

Lay Health Advisors as Community Change Agents

Since many causes of racial disparities have strong social etiologies, the use of lay health advisors has emerged as a focus of many interventions, particularly those in racial and ethnic minority communities. Lay health advisor projects seek to identify and recruit "natural helpers" in a community and provide training and support for them to advise and assist their neighbors and peers with a variety of health issues. Lay health advisor models enhance empowerment and capacity building by promoting and supporting individuals who assume responsibility for community improvement, seek new knowledge and skills, and actively engage and recruit others. Lay health advisor programs have demonstrated changes in the attitudes of community members about their control over health issues and their willingness to consider behavioral changes.[2,3]

> *"From a public health perspective, communication must capture the collective nature of community health while recognizing individual health literacy issues."*

A number of lay health advisor and other natural helper programs have been implemented in communities across North Carolina. The NC Office of Minority Health and Health Disparities' Community Health Ambassador Program works with faith and community-based organizations across the state to train trusted leaders and community volunteers to improve communication about access to care and self-management for

---

Mike Newton-Ward, MSW, MPH, is a social marketing consultant in the Chronic Disease and Injury Section of the Division of Public Health, North Carolina Department of Health and Human Services.

diabetes and cancer prevention. Over the last 7 years, the Charlotte REACH 2010 project has maintained a cohort of 15 to 20 lay health advisors who focus on diabetes and heart disease among African Americans in the Northwest Corridor neighborhoods of Charlotte.[4] Lay health advisors serve as an effective source for health communication by acting as peer role models, increasing community capacity, and forming new social support networks.

Community Settings to Promote Health Behavior Change

The medical setting is a good venue for health-related communications. Health care professionals are credible, highly respected, and expected to provide advice and instruction on health issues. However, other community settings are equally valuable, particularly in communities with low health literacy levels. The faith community plays a central role in many cultures and is an important source of social capital and influence. In many communities, priests and ministers are highly influential and have been effective communicators about important public health issues.[5] Many interventions in the African-American community have focused on the faith setting because the church is such an important source of social support and community leadership, especially among older women.

Numerous programs in North Carolina have engaged the faith community in effective health communication. Some of these have been highly effective. For example, the Black Churches United for Better Health project showed a significant improvement in daily servings of fruits and vegetables following a multicomponent, multichurch intervention in 10 rural counties.[6] Project Direct, a multiyear diabetes demonstration project in southeast Raleigh, has collaborated with multiple faith-based projects in North Carolina to create a manual for health communication in the faith setting.[7]

A Social Marketing Approach to Health Communication

The social marketing approach was first introduced in 1971 as a way to apply commercial marketing principles to improve social issues. It has been applied to a range of health, environmental, and social issues including breastfeeding, family planning, and tobacco control. The social marketing process provides a powerful tool to improve health and well-being at the population level. It offers a logical framework to link multiple interventions such as those described above. Behavior change at the community level requires more than increased knowledge and awareness, and individuals and populations frequently encounter barriers to engaging in desired behaviors. A consensus conference of behavioral scientists, sponsored by the National Institutes of Mental Health, identified a variety of external and internal determinants of health behavior ranging from access, policy, and cultural beliefs, to knowledge, perceived consequences, and self-efficacy.[8] A social marketing approach augments communication efforts by identifying and addressing these determinants.

Social marketing is an evidence-based approach. Commercial marketing research and planning processes are used to identify all the determinants of a given behavior in a target audience and then implement interventions that lower barriers or increase facilitators for the desired behavior. Social marketing is characterized by an emphasis on voluntary behavior change and attention to the costs and benefits of engaging in a behavior. A variety of interventions are customized for specific audiences based on an understanding of the target audience. The ultimate goal is to make a behavior "fun, easy and popular."[9] Such an approach targets 3 important determinants of behavior: (1) rewards and consequences; (2) adequate skills and knowledge; and (3) impact of family, friends, and culture. Social marketing employs the same intervention strategies as commercial marketing: product, price, place, and promotion—referred to as the "marketing mix." Product strategies include any tangible services or items that make the behavior easier and emphasize benefits that are meaningful to the audience. Price interventions include activities, outreach, policy changes, or messages that decrease barriers to the targeted behavior. Place strategies include offering times and locations that are convenient or occur where and when the audience is likely to be thinking about the issue. Promotion strategies are intended to persuade or inform. These include public service announcements, news stories, media advocacy, and word of mouth.

To illustrate how the social marketing process can integrate multiple communication strategies to impact a health problem, consider how a traditional media campaign could be enhanced with other intervention activities. The Lost in Translation campaign uses television public service announcements to raise awareness among African Americans about the role hypertension plays as a risk factor for heart disease and stroke. To augment the public service announcements, the campaign developed brochures and revised its Web site to include a section with consumer information on reducing heart attack and stroke risks. The campaign addresses two barriers to action identified in research with the target audience: lack of knowledge of one's blood pressure numbers and lack of awareness of the connection between high blood pressure and stroke.

A social marketing approach would expand this campaign beyond increased knowledge and awareness—to health promotion interventions. A social marketing approach might augment the public service announcements with a product intervention such as supplying free or low cost blood pressure cuffs and training family members how to use them. Place promotions would expand interventions beyond the medical practice setting to churches; community centers, and African-American owned businesses. Price interventions would address access and cultural barriers and could include using lay health advisors, parish nurses, or formal and informal community leaders. A price intervention might also include role playing how to ask questions of a medial provider to overcome possible social norms about questioning authority figures.

Social marketing combines the knowledge of the public health practitioner with the experiences of the community to create a unique mix of services, outreach, messages, policy change, and tangible products that make the behavior easier, more rewarding, and more acceptable. In populations with low levels of health literacy, the social marketing approach includes specific interventions to increase effective communication. These include lay health advisors or other trusted agents and outreach in important community institutions such as faith-based settings. **NCMJ**

COMMENTARY

Effective Practitioner-Patient Communication in Long-Term Care

Dennis W. Streets, MPH, MAT, LNHA

"Have you ever thought just a wee little bit, of how it would seem to be a misfit; and how you would feel if you had to sit *on the other side of the desk*."[1] This is the first stanza of a poem entitled *The Other Side of the Desk*, a copy of which I secured many years ago. While I don't know the author or the origin of this poem, its message is not unlike how my dad would describe his approach to medicine. As a general practitioner in Pennsylvania, Florida, and then North Carolina for over 50 years, he spoke of 3 keys to treating patients—gathering a solid medical history, conducting a thorough physical, and putting yourself in the other person's shoes. Although he did not have as much specialized education and training as some of his colleagues; at his funeral service this past June both former patients and fellow physicians shared their high regard for his medical practice. The thing that made his practice so good was that it was based on effective communication.

> *"There is no well-kept secret to effective practitioner-patient communication in long-term care; rather, it involves the routine application of practices that are well known."*

When I became administrator of the state's second largest nursing facility in the late 1980s, I tried to heed my dad's advice. I actually taped *The Other Side of the Desk* to my desk's pull-out extension so I would have a constant reminder of how important effective communication is in any situation and especially in long-term care where there can be many barriers. Still, I sadly recall too many situations where we provided less than ideal care to patients and less than adequate support to families largely because we failed as communicators. Here is a partial list of issues that can interfere with the exchange and understanding of information in all long-term care settings:

- Functional illiteracy is a reality for many of our state's residents of all ages. It can be particularly troublesome when people become vulnerable due to compromised health and social isolation. According to the Centers for Medicare and Medicaid Services Active Resident Information Report for the first quarter of 2007, more than one-fourth of North Carolina's nursing home residents have obtained no more than an eighth grade education.[2] While we should be careful in linking schooling to functional literacy, it may still be an indicator of risk for effective communication. A recently released article in the *Archives of Internal Medicine* made national news with the finding that medically illiterate older patients were 50% more likely to die within the 6 years of the study than patients who understood basic written medical information and instructions about such conditions as asthma, diabetes, and heart disease.[3]
- Dementia itself denotes a cognitive impairment associated with a broad set of symptoms such as memory loss, confusion, compromised judgment, and, sometimes, personality changes or unusual behavior. Alzheimer's disease is the most common cause of dementia, affecting 1 in 10 people over age 65 years and nearly half of those over age 85 years.[4] More than one-half (57%) of North Carolina's nursing home residents have a dementia diagnosis, including about 20% diagnosed with Alzheimer's disease.[5] Struggling with depression or anxiety and other mental health issues can compound the effect of dementia and present significant communication challenges in their own right. Nearly one-half (46%) of nursing facility residents are diagnosed as depressed.[6]

Dennis W. Streets, MPH, MAT, LNHA, is director of the Division of Aging and Adult Services in the North Carolina Department of Health and Human Services. He can be reached at dennis.streets (at) ncmail.net or 2101 Mail Service Center, Raleigh, NC 27699-2101.

- Even patients with well-functioning cognitive skills can find themselves at high risk of exclusion from care decisions and possible mistreatment due to sensory losses, especially sight and hearing. As reported in our *2007-2011 State Aging Services Plan*, more than 1 in 4 North Carolinians age 75 years and older have severe visual and/or hearing impairment.[7] About one-quarter of North Carolina's nursing home residents are hearing impaired and nearly half are visually impaired.
- The high turnover rate among both professional and paraprofessional direct care workers creates higher risk for mistakes and an atmosphere of instability and unfamiliarity for workers and care recipients alike. In 2005 average turnover rates for direct-care staff were 116% in nursing facilities, 111% in adult care homes, and 46% among home care agencies.[7]
- The increasing presence of workers and patients for whom English is their second language can further aggravate other existing communication barriers. While a caring attitude can help overcome this barrier, a linguistic disconnect can nonetheless jeopardize quality of care. Beyond language, there are many other cultural differences associated with increasing racial and ethnic diversity. We cannot allow diversity to contribute to disparity in health care.
- With long-term care patients, physicians can find themselves especially dependent on how well other professionals convey and act upon information. Most often responding offsite to requests from multiple caregivers such as long-term care nurses, social workers, and pharmacists, the physician must trust that information is shared accurately through multiple sources and acted upon appropriately. The complexity of health care and health insurance only makes matters more risky for providers and patients in long-term care.

The importance of health literacy vis-à-vis long-term care will surely increase as North Carolina's population ages. Already 28 of our counties have more people age 60 years and older than 17 and younger—it is projected that seniors will outnumber young people in 75 counties by 2030.[7] Those working in the health and long-term care sector will be especially challenged with meeting the needs and demands of an aging population. The increasing interest in consumer-directed care is just one example of the changing landscape in the provision of services as more boomers join the ranks of those needing long-term care for themselves or their parents.

In this commentary, I focused more on residents of nursing facilities because descriptive data are generally more available on this population than those receiving services and supports in other settings. I want to emphasize, though, that the issues are certainly no less important—and in some ways more important—for those in assisted living or receiving home and community care where there is not likely to be around-the-clock professional assistance.

So the practitioner is left with many challenges—most, if not all, of which are well-known and experienced daily. The question, then, is how to respond in providing the best possible care for consumers of long-term services and supports in all settings. I propose 5 basic elements representing the fingers of a hand extended to assist the most vulnerable:

(1) *Don't assume—take time to know the person*. I recall another poem among my collections that many senior groups have appreciated. The key message is captured in the following verses: "You tell me that I'm getting old; I tell you that's not so. The 'house' I live in is worn out, and that, of course, I know…You only see the outside, which is all that most folks see. You tell me that I am getting old? You've mixed my 'house' with me."[8]

(2) *Show empathy for vulnerability and dependency*. The idea of putting yourself on the other side of the desk or bed should be a guiding principle. People with compromised health conditions and living environments should not have to also forego the patience and respect of others. Rather we should encourage and facilitate their participation in decisions whenever possible.

(3) *Recognize and appreciate the family caregiver*. The North Carolina Institute of Medicine's 2001 Task Force on Long-Term Care acknowledged that most long-term care is provided informally by family and friends.[9] In 2006, nearly one-quarter (24%) of adults in North Carolina reported providing regular care or assistance to a family member or friend.[10] Family caregivers are a vital conduit in the communications between patients and providers.

(4) *Encourage and support effective communication*. We need to practice what we know: give information in as simple and straightforward a manner as possible; give important information verbally and in writing; don't assume understanding—use the "teach back" method and ask questions to confirm it; be a good, reflective listener—"Now, Mrs. Jones, from what you have told me, you are mainly concerned about …."

(5) *Follow up*. For patients receiving long-term care in any setting, there is no substitute for following up on interactions with and for those patients to assure understanding and implementation of care plans, address patient confusion and anxiety, and identify and respond to any other issues. Effective relationships with facility staff are essential as is an understanding of the so-called aging and adult services network (eg, councils and departments on aging, senior centers, and county departments of social services) that assists the majority of those still living in the community who need long-term services and supports.

There is no well-kept secret to effective practitioner-patient communication in long-term care; rather, it involves the routine application of practices that are well known. While communication becomes more critical and yet more difficult with patients receiving long-term services and supports because of the many barriers, the practitioner's goal must remain to extend a caring hand to the most vulnerable who face chronic diseases, disabilities, losses, and end-of life decisions. **NCMJ**

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

North Carolina MEDICAL JOURNAL

COMMENTARY

Developing an Informed Consent Process With Patient Understanding in Mind

Mary Ann Abrams, MD, MPH; Barb Earles, RN, MHA, CPHRM

As part of its 2003 Clinical Performance Improvement Strategic Plan, Iowa Health System incorporated health literacy as a cross-cutting, system-wide quality initiative.[1,2] With 10 senior hospital affiliates in 7 cities, a 14 rural hospital network, and 430 primary care physicians, Iowa Health System provides health care for a third of Iowans. Health literacy teams have been established at hospital affiliates, outpatient clinics, and home health agencies using the Model for Improvement,[3] learning sessions, conference calls, training workshops, and electronic communication to test and implement a variety of health literacy interventions. Iowa Health System's overarching health literacy goals are targeted toward improving interpersonal and written communication and creating a patient-centered care environment that welcomes questions and encourages dialogue.

Teams chose to improve consent documents and processes as part of their goals to improve patient understanding through plain language, teach back, and reader-friendly print materials. This was predicated on the increasing prominence of health literacy as a health care quality and safety priority; on case law involving communication of risks wherein claims have involved a lack of informed consent; and on concern that consent forms are written in language that patients cannot understand. Below we describe our rationale, experience, and lessons learned.

Building the Case

Health Literacy as a Quality and Safety Priority

Recognizing and communicating that a diverse set of leading health care organizations identify improving patient understanding during the informed consent process as an important quality and patient safety strategy helps garner support among physicians, staff, and organizational leaders.

The National Quality Forum (NQF) published *Safe Practices for Better Healthcare*[4] *in 2003.* Updated in 2006,[5] the report presents evidence-based practices that should be used universally to reduce the risk of harm in the health care setting. Safe Practice 2 (originally Safe Practice 10) states: "Ask each patient or legal surrogate to 'teach back' in his or her own words key information about the proposed treatments or procedures for which he or she is being asked to provide informed consent." Additional guidance is provided about teach back; reading level and language for consent documents; engaging in a dialogue about the procedure for which consent is being sought; and use of qualified medical interpreters or readers to assist those with limited English proficiency or health literacy, or visual or hearing impairments. Safe Practice 2 is relevant to practitioners in multiple clinical areas and to patient-centered care, especially for those who are particularly vulnerable to medical errors associated with communication barriers, including low health literacy.

> *"Iowa Health System's overarching health literacy goals are targeted toward improving interpersonal and written communication and creating a patient-centered care environment that welcomes questions and encourages dialogue."*

Mary Ann Abrams, MD, MPH, is a health management consultant in the Clinical Performance Improvement Department at the Iowa Health System. She can be reached at abramsma (at) ihs.org or 1200 Pleasant Street, Des Moines, IA 50309.

Barb Earles, RN, MHA, CPHRM, is director of risk management in the Iowa Health System Law Department.

The Safe Practices are included in the Hospital Quality and Safety Survey of the Leap Frog Group, an organization working to mobilize employer health care purchasing power to achieve breakthrough improvement in safety, quality, and affordability.[6]

The Joint Commission and Centers for Medicare and Medicaid Services promulgate standards and regulations related to informed consent. The Joint Commission standards address informed consent as stated in Standard RI.2.40—"Informed consent is obtained," and Standard PC.6.30—"The patient receives education and training specific to the patient's abilities as appropriate to the care, treatment, and services provided by the hospital." There are Centers for Medicare and Medicaid Services requirements related to informed consent for hospitals in several Conditions of Participation (CoP) (Patients' Rights CoP at 42 CFR 482.13(b)(2); Medical Records CoP at 482.24(c)(2)(v); Surgical Services CoP at 482.5 1(b)(2)). Revisions to interpretive guidelines in 2007 demonstrate continued emphasis on the importance of informed consent and patient involvement with informed decisions:

> The right to make informed decisions means that the patient or patient's representative is given the information needed in order to make 'informed' decisions regarding his/her care…The patient or the patient's representative should receive adequate information, provided in a manner that the patient or the patient's representative can understand, to assure that the patient can effectively exercise the right to make informed decisions. (Interpretive Guidelines §482.13(b)(2))

The American Medical Association (AMA) states, "Informed consent is more than simply getting a patient to sign a written consent form. It is a process of communication between a patient and physician that results in the patient's authorization or agreement to undergo a specific medical intervention."[7] In *Health Literacy and Patient Safety: Help Patients Understand. Reducing the Risk by Designing a Safer, Shame-Free Health Care Environment*,[8] the AMA states:

> Patient understanding is the first patient right and without such understanding there are limitations on the ability to exercise all other rights customarily credited or formally contracted to patients. This right is not one that physicians confer, but one they assist patients in exercising freely. It is neither just nor fair to expect a patient to make appropriate health decisions and safely manage his or her care without first understanding the information needed to do so.

This is underscored in the 2005 White House Conference on Aging proceedings:

> "Patients have the right to understand healthcare information that is necessary for them to safely care for themselves, and to choose among available alternatives. Healthcare providers have a duty to provide information in simple, clear, and plain language and to check that patients have understood the information before ending the conversation."[9]

Case Law

National case law addresses the way risk is communicated and recognizes that claims have involved lack of informed consent. Informed consent is a process, not merely the signing of a document. Consent documents, in conjunction with provider documentation, are used as evidence that informed consent was given. Studies have shown that 18% to 45% of patients are unable to recall the major risks of their surgery; 44% do not know the exact nature of their operation; and 60% to 69% do not read or understand the information contained in a hospital consent form.[10] Legally, a signed consent form is not proof of informed consent. If the patient does not understand, the form is meaningless.

Readability

In Health Literacy: A Prescription to End Confusion, the Institute of Medicine of the National Academies found that the readability levels of informed consent documents for research and clinical practice exceed the documented reading levels of the majority of adults in the United States, and that this has important ethical and legal implications that have not been fully explored.[1] Readability analyses from representative Iowa Health System senior hospital affiliate consent forms demonstrated that many were written at or above 17th grade level.

The Iowa Health System Experience

In 2004, the trends described above led Iowa Health System to embark on its work to create a reader-friendly written consent document to prompt action on the informed consent process using teach back. Beginning with the Consent for Surgery/Procedure document, an iterative process was used to develop a plain language consent that improved readability and patients' understanding, ability to make informed choices, and satisfaction. The revised document was also intended to help providers ensure that patients understand their procedures and have the ability to ask questions as needed while not adding complexity to the perioperative care environment. The consent was developed in collaboration with Iowa Health System health literacy teams, risk managers, health care providers, the Iowa Health System Law Department, and adult learners who reviewed multiple drafts, clarifying terms, content, and design. A cardinal feature of the consent is a space for description of the procedure not only in medical terms, but also in the patient's own words—a form of teach back. Plain language characteristics of the new consent include: simple words; short sentences; short paragraphs; minimal medical terms; clear headings, bullets, and numbering; generous white space; 12-14 point serif fonts; key uses of bold text; and 1.5 line spacing. The final document has a seventh to eighth grade reading level calculated manually using the Fry formula and electronically using *Readability Calculations* software.[11]

When team members had agreed on a near-final draft, an evaluation tool was developed for pilot testing at a single hospital. Data were collected using the original consent form followed by the new consent form on patient demographics and procedure type; time to complete the document; whether the consent was actually read; who read it (eg, patient, family, and/or nurse to patient/family); ease of patients in recounting the name of the surgery in their own words (teach back); questions asked by patients or their families during the consent discussion; and patient/family and nurse satisfaction with the process and new consent form.

Results were positive for all types of patients and procedures. Patients and staff reported high satisfaction with the reader-friendly form and process. Nurses did not find that asking for teach back (description of the procedure in the patients' own words) during the consent process was awkward; all respondents moderately/highly valued this use of teach back. Nurses also reported it was much easier to clearly evaluate patients' knowledge about their surgery, and patients' comfort level in asking questions was enhanced by the "permission" wording on the form. Patients/families reported appreciation of the easier-to-read format and being asked to state in their own words the description of their surgery. Increases in time, interruptions, or extra calls to physicians for clarifications or answers to questions that arose when patients actually read and understood the consent document have not been reported.

Following communication with key departments, senior administration, physicians, and thought/opinion leaders, the first pilot hospital adopted the new consent document for all surgical procedures. Three hospitals followed, and a fifth hospital recently initiated pilot testing. Testing is repeated at each hospital, somewhat more rapidly, to build will, acquire local data, and problem solve at the local level. Each affiliate is asked to chronicle their experience so others can learn from their work. As support for the new consent increases, widespread implementation at other affiliate hospitals occasionally has to be tempered as pilot testing, communication, and staff and provider education are conducted.

Additional health literacy-related consent work continues. The new Surgery/Procedure consent has been translated into Spanish with additional pilot testing. English and Spanish versions of a Blood/Transfusion consent have been developed and are being pilot tested by the hospitals. Work has begun on a Consent for Procedure by Non-Physician Providers.

Lessons Learned and Keys to Success

Building support among physicians, staff, and senior leaders requires underscoring the increasing focus on health literacy by professional, payer, accrediting, and regulatory organizations; health literacy's relationship to risk management; and evidence demonstrating the impact of low health literacy and its integral role in the informed consent process.

Documenting the processes of testing and adopting new forms, conducting pilot tests, communicating proactively with affected leaders, departments, and committees, and continuously learning from others' experience build will, provide local data to support the effort, and help navigate potential roadblocks. It is important to involve all those with roles in the consent process, organizational change, and quality of care. It is equally and vitally important to include patients and adult learners. Patient input and feedback helped structure the ultimate content and layout of the new consent and provided an effective counterpoint to arguments against simplification.

All providers must be educated about the difference between the informed consent process and the consent form. Signing the consent form alone is not sufficient to meet legal requirements for informed consent. It is the role of the provider to discuss, through a process of shared decision making, the recommended surgery, procedure, treatment plan, anesthesia, or other service. Physicians then need to be sure patients understand what is being recommended, its risks and benefits, other options and their risks and benefits, and risks and benefits of no treatment before patients make a decision.

Providers and staff also should be educated about the need to use simpler language and teach back. Building capacity on use of teach back should be part of improving the informed consent process because asking patients to describe or repeat back in their own words what they understood they have been told is our way to make sure they really understand. If gaps or misunderstandings are heard, further teaching can be done. Ultimately and ideally, teach back will be interwoven throughout the entire informed consent discussion, even if additional assistance (eg, trained interpreters) must be provided to help patients understand.

Other health care organizations are also working to improve the consent process.[12,13,14] Their efforts include standardized education using employee orientation and ongoing educational and peer reinforcement and requiring documentation of teach back on the consent form or in the health care record prior to the procedure.

As additional Iowa Health System affiliates adopt the reader-friendly consent, continuing emphasis will center on moving beyond use of the new form toward incorporating teach back to check for and ensure understanding and documenting these discussions during everyday interactions with patients and families. In the context of patient-centered care, consent is a shared decision-making process between the patient and their provider, not an event or a signature on a form. True informed consent is a core component of quality health care.

Cultivating Patient-Centered Communication Skills Training Across the Medical Education Continuum:

A Model for Practice

Gail S. Marion, PA-C, PhD; Sonia J. Crandall, PhD; Frank Celestino, MD; William McCann, PsyD; Julienne Kirk, PharmD

Effective patient-centered communication improves trust, patient satisfaction, health literacy, and health outcomes and reduces health disparities and law suits that occur due to poor communication.[1-3] For these reasons competency guidelines outlined by the Accreditation Council for Graduate Medical Education,[4] the Liaison Committee on Medical Education, Accreditation Review Commission on Education for the Physician Assistant,[5] and the Association of American Medical Colleges[6] require that communication skills training be mandated in undergraduate and graduate medical education. The Institute of Medicine of the National Academies report "Improving Medical Education" concluded that basic and complex communication skills are a "high priority"[2] in medical education.

Despite growing evidence that patient-centered care improves health outcomes, medical students receive mixed messages.[7] In preclinical communications courses in US medical schools, educators use available evidence to teach students to be open, reflective, and patient-centered, while in clinical clerkships students often witness directive, doctor-centered communication by those who have not had the training that current students receive.[8,9] At Wake Forest University School of Medicine Department of Family and Community Medicine our goal is to cultivate culturally competent, patient-centered communication skills across the continuum of medical education to more effectively address health literacy needs, reduce health disparities, and improve health outcomes. Since 2000, 5 Title VII Health Resources and Services Administration grants have facilitated the development of a culturally competent, patient-centered communication curriculum for faculty, family medicine residents, and medical and physician assistant (PA) students. Each grant was envisioned as a step towards the long-range process necessary to create patient-centered teachers, clinicians, and students. This article presents an overview of curricular innovations, the evaluation process, early outcomes, and next steps.

> *"Despite growing evidence that patient-centered care improves health outcomes, medical students receive mixed messages."*

The curriculum across learner groups (faculty, residents, medical and PA students) was developed using Common Ground,[10] a criteria-based training model derived from the Kalamazoo Consensus Statement.[11] This model was adopted for

Gail S. Marion, PA-C, PhD, is an associate professor in the Department of Family and Community Medicine at Wake Forest University School of Medicine. She can be reached at gmarion (at) wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157-1084.

Sonia J. Crandall, PhD, MS, is a professor in the Department of Family and Community Medicine at Wake Forest University School of Medicine.

Frank Celestino, MD, is a professor in the Department of Family and Community Medicine at Wake Forest University School of Medicine.

William McCann, PsyD, is an assistant professor in the Department of Family and Community Medicine at Wake Forest University School of Medicine.

Julienne Kirk, PharmD, is an associate professor in the Department of Family and Community Medicine at Wake Forest University School of Medicine.

its ease of use in the clinical setting and for the associated Common Ground Assessment Instrument (CGAI) which has construct validity, internal consistency, test-retest reliability, and generalizability across clinical cases.[10] The model includes 6 core skills: rapport building, agenda setting, information management, active listening, addressing feelings, and reaching common ground. The curriculum was incorporated into faculty development, residency training, and medical student training in the Department of Family and Community Medicine and also into the curriculum of the Department of Physician Assistant Studies. The following sections describe the activities into which the curriculum was included.

Department of Family and Community Medicine Activities

Faculty Development

An Administrative Units award provided infrastructure support for patient-centered communications research and funded 6 faculty pilot projects. Outcomes of this grant led to several other communications research projects including 2 National Cancer Institute grants, and to numerous presentations, publications, and curricular innovations.

Residency Training

A residency training award facilitated development of a cultural competency curriculum for residents and medical Spanish and immersion training in Guatemala for faculty, staff, and residents. It also fostered ties with 2 Latino clinics. Outcomes of this grant included the addition of 20 hours of communication skills training provided during the Human Behavior Rotation for first-year residents. Evidence indicates mindfulness training may improve a physician's self-awareness and other-awareness, help decrease anxiety, and help develop a relaxed alertness that might contribute to the incorporation of communication skills in clinical practice.[12-14] The new training includes (1) relaxation/ mindfulness training and practice including an examination of their roles in development of higher order communication skills; (2) introduction to and practice with the CGAI; and (3) videotape reviews of residents' patient encounters using the CGAI. Common Ground skills are reinforced during the required geriatric outpatient rotation in the second year. During the second and third years, residents attend a Balint support group which provides an opportunity to consider how patient-centered communication can facilitate patient care.

Medical Student Curriculum

A predoctoral training grant allowed us to develop a collaborative project with the Departments of General Internal Medicine and Pediatrics to implement a communication skills curriculum in 3 third-year clerkships. This grant facilitated a continuity experience for clinical students to further develop and refine patient-centered communication skills taught in the preclinical years to better serve diverse and vulnerable patient populations.

We worked with the course and clerkship directors to revise the first-year communications course and with the family medicine clerkship patient simulation to reflect the Common Ground skills. All evaluation instruments and the interview skills template used by the students are explicitly linked to the Common Ground skills domains. Three new standardized patient assessments focusing on vulnerable and high-risk patients were designed for and implemented in the third year ambulatory care clerkships. In the last 2 years we trained nonfaculty raters to reliably assess students' communication skills using the Common Ground criteria.

Outcomes of this grant led to the training of over 90 faculty, nonfaculty, and community preceptors as raters to reliably assess communication skills throughout 4 years of the curriculum. Use of the CGAI has helped to ensure that we are evaluating communication skills objectively across multiple assessments in preclinical and clinical years. To evaluate effectiveness of the communications curriculum, the trained nonfaculty raters were randomly assigned student interviews from the standardized patient assessments to rate. To date, they have reviewed over 3000 videotaped interviews to find that skills have significantly improved across 3 classes of first-year medical students. The next step is to evaluate longitudinal data which include a total of 14 digitally recorded video encounters per student from baseline to graduation.

Department of Physician Assistant Studies Activities

A recently completed grant established a culturally competent, patient-centered curriculum. For first-year students, core communications elements were incorporated. Students are oriented to Common Ground while reviewing DVDs of clinician-patient dyads using the CGAI. In small groups, students practice using patient-centered skills with standardized patients. To further improve communication skills students participate in a required medical Spanish course and are trained and evaluated on effective use of medical interpreters. Eight standardized patient assessments over both years and site visits in the clinical year are used to evaluate these skills. Outcomes include (1) significantly improved patient-centered communication skills across the last 2 classes (nonfaculty raters have reviewed over 1000 randomly assigned recorded interviews); (2) effective student interaction with interpreters and an increased student ability to use medical Spanish in the clinical setting; and (3) completion of an international Spanish language immersion program by 17 students.

Because we know there is no one factor more predictive of poor health status than low health literacy,[3] the current grant is devoted to integrating health literacy throughout both years (preclinical and clinical) of training; this new component will be embedded in the well-established patient-centered communications curriculum within the clinical applications and professionalism courses. Skill 6 of the Common Ground model trains learners how to (1) summarize the patient's problems and concerns; (2) check for understanding; (3) check for feasibility; (4) check for agreement;

and (5) establish mutual responsibility for the plan. Using this guide, students will consider health literacy as well as cultural, financial, and other factors as they develop a plan with the patient that effectively ties the visit to what happens when the patient leaves the office. Among other teaching strategies, standardized patient instructors (portraying patients who need to stop using tobacco or alcohol, lose weight, exercise more, or manage diabetes) will provide the students with multiple opportunities to practice and receive feedback (using validated instruments) to further develop these skills to care for patients in the clinical year. All students are required to review and self-assess their video recorded encounters after they receive feedback from the standardized patient assessments to improve future performance. These skills will be assessed and reinforced during site visits and standardized patient assessments in year 2 on at least 4 occasions.

Conclusion

Common Ground is highly transportable. Currently, among others, it is used in the California medical schools. We have trained faculty at other medical schools and physician assistant programs in North Carolina and Virginia. The model and its associated criteria-based instrument make it feasible to provide basic training for faculty in about 4 hours. With schools looking for ways to provide communication skills training in undergraduate and graduate medical education, this model offers an ideal method to incorporate patient-centered communication into clinical training programs. Health Resources and Services Administration or other medical education funding to incorporate this curriculum is helpful, but not essential because the model and curriculum materials lend themselves to relatively short training.

Future goals of the Wake Forest University School of Medicine include translating these curricula and outcomes to other health disciplines, providing an advanced communication skills elective for fourth-year medical students, and developing patient-centered communication curriculums for practicing clinicians to address health literacy assessment and use. Goethe wrote, “Knowing is not enough: we must apply. Willing is not enough; we must do.” Growing evidence suggests that we are not applying what we know and are failing to provide adequate care for millions of patients in a country with the most expensive health care system in the world using doctor-centered models of care.[15] We must be willing to do what is necessary to produce effective patient-centered clinicians to improve health outcomes for our patients. **NCMJ**

COMMENTARY

Communicating Health Information to English as a Second Language Patients

H. Nolo Martinez, MS, PhD

Large numbers of immigrants have settled in North Carolina in recent years. The immigrant population grew 58.1% (373 000 to 590 000) between 2000 and 2005. Most immigrants are unfamiliar with the basics of the US health care system and lack adequate knowledge to make informed decisions about their own health. These difficulties block many immigrants from attaining self-sufficiency and becoming full participants in our society. Basic health literacy and assistance gaining access to community resources could prevent these families from becoming mired in poor health for generations.

The University of North Carolina at Greensboro Center for New North Carolinians Immigrant Health ACCESS Project recognizes language and cultural barriers as principal health care problems for over 50% of new immigrants in North Carolina, as defined by both the providers and the limited English speaking community. Most newcomers have limited English proficiency, utilize traditional health practices from their cultures, live close to the poverty level with inadequate health insurance, work in hazardous jobs, and have limited familiarity with our health systems or preventive health practices.

With more than a dozen different major ethnicities in the state and an immigrant population that represents several different demographic profiles, languages, cultures, and needs, North Carolina health providers face extraordinary challenges. How well and how rapidly we replenish the bilingual and bicultural health care practitioner workforce in our state determines our ability to eliminate language barriers, improve health behavior of new immigrants, and save on scarce financial resources in order to reach more residents, newcomers, and the uninsured.

The state of North Carolina does not yet have enough bilingual health care personnel and culturally appropriate policies in place to fully tackle disparities among immigrants in the state. Title VI of the Civil Rights Act of 1964 requires that limited English proficiency populations have access to "culturally and linguistically appropriate services" at no cost to the client. Health providers, including both public and private entities that receive federal funds, are required to take reasonable steps to ensure meaningful access to the information, programs, and services they provide. Very few North Carolina providers offer services in multiple languages through qualified interpreters. Some rely on family members, including children, or use untrained or unqualified interpreters, thus creating ethical and confidentiality issues.

> *"Health care practitioners are often unfamiliar with the traditional practices of their patients and may not ascertain what interventions the patient is already using or willing to use, thus creating an additional health hazard."*

Cultural competency gaps magnify the health communication problems. Health care practitioners are often unfamiliar with the traditional practices of their patients and may not ascertain what interventions the patient is already using or willing to use, thus creating an additional health hazard. Newcomer immigrant patients who are unfamiliar with US health practices do not know how to best access health systems, put into practice preventive

H. Nolo Martinez, MS, PhD, is interim director of the Center for New North Carolinians at the University of North Carolina at Greensboro. He can be reached at nmartinez (at) uncg.edu or 413 S Edgeworth Street, Greensboro, NC 27401.

health behavior, or use medications as directed.

A large number of new North Carolina immigrant residents do not have the English-speaking capabilities to fully access health care, and practitioners cannot communicate in the patients' languages. As a consequence, patients are not able to speak freely with their practitioners and do not receive information on how they can better take care of themselves or their families. If the practitioners cannot explain to their patients their conditions, they cannot tell the patients why or how to follow lifestyle changes or explain why medication is necessary. Limited English proficiency immigrant patients cannot ask questions or make agreed upon changes to their treatments with their practitioners.

Communication barriers are not only connected to the inability to speak English. Immigrant residents in North Carolina show some cultural behaviors that interfere with health communication:

- Some immigrants have identified the stigma of being a refugee as a detriment. It destroys their sense of being part of the general community and may create barriers of mistrust with the health care provider, which makes communication difficult.
- Immigrant patients may be troubled when health care practitioners ask many personal questions, take notes of conversations, and fill out forms
- Men may particularly feel that talking about suffering is a sign of weakness and may be reluctant to talk about psychological dimensions of pain.
- Due to misunderstanding the role of some health care professionals (eg, nurses), some patients may feel discriminated against and refuse communication.
- People who are not confident with their English proficiency may refuse to disclose information to medical professionals.
- Many find it difficult to follow the legal procedures in North Carolina but may not ask for advice.

The key to ensuring meaningful health access for limited English patients is the ability to reach effective communication between the patient and the health provider. One strategy to achieve more effective communication, in addition to complying with the terms of Title VI to provide culturally and linguistically appropriate services, includes using trained and culturally competent interpreters. Improving the quality of interpreter services can reduce health costs, increase prevention efforts, and decrease primary care use by non-English speaking residents. Another strategy is to assist case management efforts of safety net providers by using lay health advisors to support immigrant clients' better understanding and navigation of the health care system. Lay health advisors are trusted members of the communities in which they serve. Their assistance can help immigrant clients develop stronger relationships with their practitioners.

Cultural competence means the capability and will of a provider or service delivery system to respond to the unique needs of an individual considering the culture of the person. Using interpreters and lay health advisors as cultural brokers can help health providers attain knowledge regarding beliefs, cultural values, and preferences. This knowledge becomes critical when a practitioner creates interventions to meet a person's needs. Immigrant lay health advisers have the ability to use the individual's culture as a resource or tool to aid in the intervention and explain the health needs or problems. The capacity to provide equal access to individuals from different cultural and linguistic populations results from the new understanding of immigrants' distinct needs which is gained through collaboration with lay health advisors. Culture gives meaning to health communication and provides the context for understanding health information. Health literacy education programs must be developed to reflect the unique language and cultural backgrounds of North Carolina's immigrant populations.

Communicating with patients who have limited English proficiency requires more than just finding someone who speaks their language to assist with interpretation. According to the Civil Rights Act of 1964 and Executive Order 13166, patients with limited English proficiency have the right to a trained interpreter. Trained language interpreters have formal education in interpreting and abide by a professional code of ethics that includes confidentiality, impartiality, accuracy, and respect. Good medical interpreters are not only fluent; they are also familiar with medical terminology and have experience in health care. Although there are several accredited training programs for medical interpreters, there is no national certification. Only the state of Washington offers state testing and certification. The University of North Carolina at Greensboro Center for New North Carolinians has developed curricula and testing to certify that North Carolina health interpreters have received training and certification.

A great obstacle to the practitioner-patient relationship or therapeutic bond happens when a language barrier exists between the practitioner and patient. More attention needs to be given to the process of language translation during this interaction. Some have suggested increasing the number of Spanish and other language courses for practitioners as an option for reducing the language barrier. I encourage the learning of other languages, but a quick or survival language course can also lead to significant mistakes on the part of the practitioner. Unless the practitioner is fluent in the language, it is prudent to always use an interpreter, especially following the exam, to ensure and document patient understanding. The interpreter should ask the patient if he or she has any additional questions and then request that the patient repeat back any instructions from the practitioner.

Most providers use translation of messages, documents, and materials into other languages to reach nonnative speakers of English. This process is flawed because the English language, especially technical language concerning complex medical topics, does not always translate well into other languages and may result in misrepresentations and misunderstandings. Furthermore, translating documents is also complicated by the sheer number of different languages used by residents in North Carolina. It is a tremendous and expensive challenge to translate health communication materials into a range of different languages, and meaning can be lost in translation.

Nevertheless, language is important for both access to and quality of care. Using trained and qualified interpreters can and should be implemented to improve access to health information for consumers who are not native English speakers. Health literacy is a complex issue, and improvements in the health literacy of limited English proficient clients require a variety of approaches. Health literacy not only involves the communication skills and abilities of immigrants to understand spoken, written, and mass-media communication about health and health care, but it also involves the communication skills and disposition of health care providers and the support of those that understand the client's culture and language. Effective health communication with thousands of new North Carolinians must be interactive and adaptive, utilizing many different channels of communication.

North Carolinians are well aware of the increasing diversity across the state. In grocery stores in any county one can hear multiple languages and dialects spoken. Visiting reception areas of any of our health service agencies, one will encounter people from many cultural backgrounds. The public schools report that more than 90 different languages are spoken in the home of children enrolled throughout our state's educational system. Human service providers and educators are challenged to find the best way to meet the needs of an increasingly diverse population. Partnerships between lay health advisors, qualified interpreters, health care providers, and consumers who desperately need relevant health information can help overcome many problems related to health literacy. **NCMJ**

Identifying and Addressing Communication Failures as a Means of Reducing Unnecessary Malpractice Claims

Gerald B. Hickson, MD; A. Dale Jenkins

Substantial research provides clear evidence of the relationship between communication failures and malpractice claims. Communication failures among health care practitioners are associated with most avoidable adverse outcomes.[1,2,3] Poor communication skills also adversely impact patient-provider relationships, increasing the likelihood that families sue when faced with adverse outcomes whether or not errors have occurred.[4,5,6]

In spite of the research, many within medicine cling to myths concerning why they get involved in claims, asserting, "Everyone in my specialty gets sued," or "It's just a cost of doing business." Others contend they attract litigation-prone patients or attend to the most challenging cases. Unfortunately, such myths pose a stumbling block to one approach to reducing malpractice claims that everyone should support: identifying and addressing ways to promote improved patient-practitioner communication.

Our goal is to focus on just one factor promoting lawsuit generation—poor practitioner communication skills. We will review research concerning why families file suit, why some practitioners have a "dark cloud," and the role that poor provider communication skills play in observed claims' disproportionality. Finally, we will offer suggestions concerning what health care practitioners can do to identify and address risk.

Studies reviewed widely in the media by researchers at Harvard focused national attention on errors in medicine. Their studies involving chart review suggested that 1% to 2% of hospitalized patients in the US experience adverse outcomes due to medical errors.[7,8] Study results should convince us that we share a duty to make medicine safer. How to make medicine safer is beyond the scope of this commentary, but we do want to focus on an often overlooked finding that suggests another problem needing attention. In completing thousands of reviews, the Harvard team identified cases where errors caused adverse outcomes and where families filed suit. However, for every family who filed a "valid" claim, the Harvard team identified 5 families who sued with no evidence of negligence.[9] Such findings are consistent with information from state-based claims reporting. Data from the state of Tennessee reveals that in 2006 over 80% of closed malpractice claims were dropped without an award or settlement.[10]

When such data are reviewed, many practitioners fall back on their old myths or seek to blame the plaintiff bar without asking two questions: Why are so many nonvalid claims filed, and is there anything we can do? Nonvalid claims create burdens for the families filing them because many relive painful experiences, for the practitioners who are named because they may experience emotions from anger to depression, and for members of society who ultimately pay the bill.

To understand why people sue, you begin by asking families who have filed claims. Although such studies are subject to recall bias, they provide evidence of how communication failures prompt some families to sue. When asked what prompted them to seek legal advice 25% of families interviewed mention the need for money.[4] Most, however, cited noneconomic reasons

> *"...risk is predicted by the practitioner's inability to communicate effectively and establish and maintain rapport with patients, especially in the face of an adverse event."*

Gerald B. Hickson, MD, is associate dean for clinical affairs, director of the Center for Patient and Professional Advocacy, and director of Clinical Risk and Loss Prevention at Vanderbilt University Medical Center. He is also professor of pediatrics and associate professor of Family and Health Systems Nursing at Vanderbilt. He can be reached at gerald.hickson (at) vanderbilt.edu or at the Center for Patient and Professional Advocacy at Vanderbilt, 405 Oxford House, Nashville, TN 37232-4220.

A. Dale Jenkins is chief executive officer of Medical Mutual Insurance Company.

including belief in cover-ups and the need for information.[4,5] Results also highlight how often families believe that no one ever expressed concern about the family's loss or offered an apology in the face of what the family believed was an error.

Studies examining why some physicians attract more than their fair share of lawsuits offer additional insight into how poor communication skills promote claims. Sloan and colleagues reported that physicians can be sorted into 3 risk groups: those with no suits, those with an occasional claim, and a third group with high claims. Between 2% and 8% of physicians by specialty account for more than one-half of all malpractice-related costs.[11] In a follow-up study, Bovbjerg identified that claims experience is constant over time such that physicians at high malpractice risk today will be at high risk tomorrow.[12] Study results raise an obvious question: Why do certain physicians generate so many suits? Multiple hypotheses have been proposed, but studies reveal that individual claims experience is not predicted by patient characteristics, illness complexity, or even the physician's technical skills.[13,14] Instead, risk is predicted by the practitioner's inability to communicate effectively and establish and maintain rapport with patients, especially in the face of an adverse event.[4,6,13,14] In a study examining perceptions of care, patients seeing high-risk obstetricians were 3 times more likely to assert that their physicians would not answer questions or listen when compared with families seeing obstetricians with no malpractice claims.[14] Over 30% of study subjects seeing high-risk physicians voiced dissatisfactions with care even after delivering healthy newborns.

In spite of evidence linking poor communication skills with claims experience, the question remains: Is there really anything that can be done to reduce risk? In response to this question, researchers with the Vanderbilt Center for Patient and Professional Advocacy developed 2 hypotheses. First, high-risk providers are unaware of their status. Second, if made aware, many will seek to change their practices or communication behaviors in ways to reduce risk.

To help make high-risk physicians aware of their status, the team sought a proxy for malpractice claims that is linked to risk events but occurs frequently enough to be counted and fed back to the at-risk clinicians. Many groups, clinics, and hospitals have patient advocates, called ombudsmen, who listen to families who are dissatisfied with care. Advocates record the stories and attempt to address what is perceived as wrong. Analysis of thousands of stories reveals that unsolicited complaints are not randomly distributed. Just like malpractice claims, 30% to 50% of practitioners never attract a complaint. An equal number get an occasional complaint. However, when coded for complaint type (34 separate categories) by practitioner, the complaint reports can be used to reliably identify a small subset of physicians (4% to 8% of any group) who account for over 40% of claims and 50% of all malpractice-related costs.[15,16]

The Vanderbilt team then turned its attention to how complaint data could be used to promote awareness. At each study site, peer messengers are trained to deliver intervention materials to their at-risk colleagues, including (1) a report card illustrating the individual's relative ranking, (2) a table illustrating the complaint type distribution, and (3) the actual complaint text so physicians can review and gain insight.[17,18] Visits average just over 30 minutes and are mostly received professionally. Currently, the identification and intervention model is operational in 25 geographically-distributed sites (from free-standing group practices to major medical centers) with over 16 000 medical practitioners assessed yearly.

Intervention results are encouraging and reveal that many high-risk practitioners, when made aware, address recurring sources of patient dissatisfaction within their practices.[18] Just under 60% of those receiving awareness interventions respond. Unfortunately, approximately 20% depart their practices, some seeking what is referred to as a "geographic solution," while an equal number require an authority-based intervention that mandates anything from a practice review to a comprehensive mental health evaluation.

The intervention study affirms that practitioners can act to reduce sources of patient dissatisfaction that promote risk within their practices. The study also provides important insight into common communication failures that promote risk. Review of over 200 000 unsolicited patient complaint reports leads us to a few suggestions that should benefit any provider who wants to improve patient-practitioner communication even if only for the purpose of reducing personal malpractice risk. These include making patients feel respected, using the informed consent process to build practitioner-patient relationships, and letting patients know the practitioner cares about feedback.

The first important strategy is for practitioners to send clear messages to their patients that they are respected as fellow humans. For a host of reasons, including anxiety, illness complexity, and the pressures of modern medical practice, patients sometimes can perceive a loss of connectedness with their health care providers. Such a loss impacts quality of medical history-taking, adherence with medical care plans, and risk of litigation. Practical means of sending a message of respect were identified in a study by Levinson.[19] They include attention to body language (Do you look rushed?), efforts to solicit patients' opinions ("Which option seems most workable for you?"), and encouraging patients to talk ("What can we talk about today?" followed by a mandatory pause). Such strategies take time. However, in the Levinson study, providers modeling respect-generating strategies averaged just over 3 minutes more per encounter than their colleagues who did not but who were subjects to suits.

Another strategy for improving communication suggests the practitioner view the informed consent process as an opportunity for relationship building. Review of unsolicited complaint reports reveal that families often express uncertainty about the intended procedures including what they should expect, risks versus benefits, and specifically, when they will get follow-up information. One predictor of malpractice risk is a patient's assertion that the practitioner involved failed to show up after the procedure. We commend national efforts to promote teach back in association with informed consent.[20] Patients should have an opportunity to describe back to the practitioner the proposed procedure, the most common complications, and when they should expect a follow-up discussion.

The final recommended step for improving communication is for practitioners to send the message that they want to hear from their patients, especially if the patients are dissatisfied. Both marketing and medical studies reveal that most families who experience significant dissatisfaction with care are hesitant to speak up to the provider involved or a representative of the group.[21,22] Consequently, hospitals and medical groups may fail to recognize recurrent sources of dissatisfaction that put them at risk. Most of us tend to be defensive in the face of a complaint, but complaints, if seen as an opportunity to learn, offer an important key to identifying and addressing unnecessary malpractice risk as well as a way of allowing patients to have a role in improving care for everyone. **NCMJ**

COMMENTARY

A Perspective on Doctor-Patient Communication in the Dental Office

M. Alec Parker, DMD

> *"Think like a wise man, but communicate in the language of the people."*
> W. B. Yeats

The awareness of the importance of health literacy has synergistically combined with concerns regarding disparities in access to care, questions relative to patients rights, and the growth of consumerism to initiate a reevaluation of how the various health professions communicate with their patients on a daily basis. Practitioners are beginning to examine not only how they communicate but how well the information is being received, understood, and applied to create a more positive outcome for those they counsel and serve. These types of questions have been debated for several years within the dental community, and due to that ongoing discussion I believe the dental profession may be more advanced in this arena than other health professions.

Dentistry has been exploring this issue for quite some time since most people view dental treatment decisions as being more elective than those made in medical offices. Up until recently, this has seemed to be a reasonable assumption given that most dental problems were not perceived as being directly related to systemic disease or as potentially life-threatening. However, new research strongly suggests that there are indeed associations between chronic oral infections and heart and lung diseases, diabetes, stroke, and preterm low birth weight. Therefore, the ability to clearly communicate with patients has taken on a new level of importance from the perspective of the practitioner as well as the patient and other health professionals.

Communication Styles

Currently, dentists use a variety of approaches to help patients understand their oral health status and ways to help make it better. Since most dental school curriculums do not include courses to improve communication skills, most practitioners graduate without any guidance as to how to effectively deliver the information they have acquired. Many dentists don't go any further than merely telling the patient the results of the exam and the recommended treatment. There is no attempt to involve the patient in the discovery or decision-making process. While the paternalistic style of doctor-patient communication may have produced the desired outcome for patients of previous generations, members of the current generations want to be more involved in their health care. The rise of consumerism coupled with a more informed public has sown the seeds for a more interactive communication dynamic. In fact, many dentists have begun to define the people they serve as "clients" rather than "patients." This change in perspective serves to remind dental teams that the people they serve want to be more involved in decisions regarding the care they receive. Many

"Since most dental school curriculums do not include courses to improve communication skills, most practitioners graduate without any guidance as to how to effectively deliver the information they have acquired."

patients arrive in the practitioner's office having already done research on the Internet. They are better prepared to ask questions and no longer want to abdicate treatment decisions to the dentist or other members of the dental team. Today, clients seeking dental care expect to have proposed treatment plans presented in an understandable format and to have the opportunity to discuss the merits of possible alternative procedures. They want to be informed consumers and expect practitioners to provide the facts they need to make a decision that best fits their personal goals and values.

In order to assist patients in the decision-making process, some dentists have realized that they need to make a more concerted effort to deliver their findings in a comprehensible form. In fact, one of the more frequently cited barriers to oral health literacy identified by consumers is the practitioners' use of technical dental terminology during their conversations with patients. Although the use of dental jargon seeks to provide clarity when used among dental professionals, its use with consumers tends to widen the communication gap. Unfortunately, most dental teams have not been trained to convey technical thoughts using less intimidating terminology. In many instances, while the dental team may have spent an adequate amount of time informing a patient about their oral conditions and making sound treatment recommendations, the overusage of technical jargon results in patients leaving the office more bewildered than when they arrived.

To further complicate the issue, most patients are reluctant to admit they do not fully understand the explanation delivered by the practitioner. Exacerbating this is the fact that many dentists tend to be introverts and are not comfortable with confrontation. This lack of confrontational tolerance may imply to some patients that their questions are not welcome, thus setting up additional barriers to further understanding by both parties. To counterbalance this situation, many dentists who possess an introverted personality elect to utilize dental auxiliary personnel with more open communication styles to help patients feel more comfortable asking for additional information.

Dental Technology

The ever-expanding use of dental technology has greatly contributed to the ability of the dental team to bridge some of the communication gaps that previously existed in dentistry. Most of these new technologies seek to provide patients with the ability to better comprehend their oral health status. Others provide an opportunity for patients to view possible treatment options that may provide solutions. The first technological breakthrough in this arena was the intraoral camera. This device consists of a small camera lens and a light source positioned in a wand-like device that enables the operator to capture magnified, high resolution intraoral images that are instantly visible to both the patient and the practitioner on a video monitor. Using a close focusing lens, the camera captures views of the oral cavity that have previously gone unnoticed by the average patient. From a patient education and communication perspective, one of the more useful features is the use of split screen views to illustrate and compare normal, healthy oral structures with those that may exhibit pathology. These images seem to stimulate both curiosity and concern from most observers. It provides the practitioner the opportunity to answer questions that, perhaps for the first time, are truly meaningful to patients since they can relate the images uniquely to their own personal situations or symptoms. When patients are presented with personalized health information and given the opportunity to ask more questions, an environment is created that is much more conducive to learning than situations where patients are presented with a generic brochure that may be poorly written and difficult to understand.

Another technological innovation is the use of digital radiography. In addition to allowing dental personnel to take radiographs at a much lower exposure level than that of traditional radiographs, the instantaneous viewing of captured radiographic images is a major step in assisting clinicians in their diagnostic procedures. These images are magnified and projected on a computer monitor providing greater detail and legibility than the small intraoral films used in the past. Dental team members utilize computer monitors located in the treatment rooms to assist patients in learning what structures are visible on the image and why they are relevant. Like the images taken by the intraoral camera, digital radiographic images may be used as a baseline measurement as well as an adjunct to dentists when helping patients to understand their current dental conditions. Conditions such as decay, abscessed teeth, impacted teeth, and periodontal disease are readily visible on digital radiographs.

Specially configured digital cameras have also become available and are a wonderful communication tool. Using a macro lens and specialized flash designs, these cameras can capture oral conditions in great detail. Those images are useful in many ways to the practitioner for the benefit of the patient. A growing number of dentists use the digital camera as frequently as radiographs to render a diagnostic opinion, especially when the area of concern includes a soft tissue component. Examples of soft tissue parameters that are better illustrated using a photograph include gingival inflammation, swelling, recession, or the presence of exudate. Prior to rendering a diagnostic opinion, those images may be sent to other practitioners, including dental specialists, to provide the most comprehensive information to the patient.

The field of dentistry that has experienced the most growth in recent years is cosmetic dentistry. Practitioners who provide cosmetic services have become highly dependent upon digital photography to communicate with patients. Sophisticated software programs utilize imported digital photographs that permit dental personnel to provide clinically accurate renderings of various cosmetic procedures for patient consideration. Dentists also use these images to illustrate desired cosmetic changes to laboratory personnel who may not have the benefit of direct communication with the patient.

Any discussion of technology relating to patient communication would be incomplete without mentioning the growing use of software programs that allow patients to better understand treatment options. These programs usually provide visual presentations of treatment choices delivered in easily understandable terms by a professional vocalist. Some vendors even offer interactive software that allows the viewer to control not only the subject of the information but also how the message is delivered. Although these new technological advances can come with a steep price tag, most dentists feel that the expense is justified since it invariably helps patients make better choices. It also provides the patient with a consistent message, thereby eliminating the possibility that important points might be inadvertently omitted from the discussion by the dentist or auxiliary personnel.

While technology has definitely had a positive impact on dentistry's ability to communicate with patients, there is no substitute for the personal touch. In fact, any attempt on the part of the practitioner to humanize the health care experience will be appreciated. Most people prefer health care professionals who are truly interested in them as persons rather than just being remembered as a number or a name on a chart. The challenge for the practitioner is to develop a delivery model that allows this interaction to take place without sacrificing timeliness and efficiency. Many practitioners have come to appreciate the value of incorporating a brief interview into their new patient experience. The dentist or a trained auxiliary can spend this time reviewing the patient's health history, clarifying prescription drug information, and asking open-ended questions that will help discern the patient's expectations for the day's visit as well as their oral health literacy level. A highly trained and intuitive person can gather a great deal of information in this short time frame that will support the rest of the dental team in their efforts to personally connect with this particular patient. Following the interview, some patients will appreciate a brief office tour. This affords an opportunity for the staff to familiarize the new patient with the physical layout of the office while also providing the chance to meet other team members. It is also a great time to introduce some of the technology that is available. The astute auxiliary will not only explain what the technology does but also how it helps patients better understand and participate in their treatment.

Some Ideas Enhancing Communication

There are several ways dentists can help patients make better decisions relating to their oral health. First, we need to realize that most patients are not well-informed about their oral health. Since the oral cavity is not readily visible, and many dental disease processes remain asymptomatic for long periods of time, dentists and auxiliary personnel need to make sure that they schedule enough time to allow patients to ask questions and learn more about their conditions. Second, dentists should consider purchasing various technologies that enable the patient to learn via the modality that is most effective for their individual learning style. Third, dentists and their teams need to evaluate their own ability to communicate with their patients. How well are they able to assess a patient's literacy level? Do they have a "one size fits all" approach or are they able to adjust their communication style to one that best serves the patient's level of understanding? During my years in private practice, the ability to individualize and tailor my communication was clearly the most challenging for me. Remember that dentists usually have contact with every patient who walks in the door, even those who are there for their routine continuing care visit. This means that the dentist must be able to change his or her style of personal interaction several times within a relatively brief time frame. With experience, practitioners will be able to identify those patients who want to "get in and get out" as well as those who look at their dental appointment as a social occasion.

Conclusion

The May 2000 document, *Oral Health in America: A Report of the Surgeon General*, drew national attention to the importance of oral health and provided scientific evidence of the integral relationship between oral health and general health. It alerted the entire medical and dental community that the gap between the oral cavity and the rest of the body needed to be addressed in a way that informed patients and changed behavior in an effort to improve the quality of life for all Americans. Seven years later, oral health literacy remains a challenge. America continues to become a more diverse country. Each ethnic background exhibits its own unique culture, customs, and communication preferences. Recognizing those challenges, dental education has begun to incorporate communication training into its curriculum. Dental technology continues to be developed that will help enhance the ability of patients to understand more about their oral health. It is incumbent on those who did not receive formal communication skills training to assess their own abilities. Then, they can take the appropriate steps to ensure they have done everything possible to provide their patients with the information they need to become partners in both their dental treatment and the prevention of future oral health problems. **NCMJ**

Health Professions Education to Promote Health Literacy:

Leverage Points and New Opportunities

Karen D. Stallings, RN, MEd; Thomas J. Bacon, DrPH

The issue brief makes a case for the increasingly important role the patient plays as part of the health care team in managing chronic illness, improving health outcomes, and navigating the complex health system. This commentary discusses the history of patient engagement in care decisions to show that empowering the patient to play a stronger role cannot be done in isolation. Health care practitioners must be taught new ways of relating to patients and incorporate those practices into their day-to-day routines.

One of the challenges and opportunities the North Carolina Area Health Education Centers Program (AHEC) has is to work with health professions schools and other educators to incorporate these new approaches to care into the curricula for undergraduate and graduate students, residents, and practicing health professionals. This is no simple task since students and practitioners are already stretched to the limit. They are asked to assimilate new material about medications and treatments, understand the changing economic realities of health care, and develop new ways to deliver services. As a result, AHEC looks for practical ways that we can introduce evidence-based practices for patient education and practitioner-patient communication throughout the spectrum of health professions education and practice.

Several key regulatory and policy changes over the past 35 years have had a major influence in advancing evidence-based practices in patient education and improved practitioner-patient communication. These include the American Hospital Association's Patient's Bill of Rights (1972), Medicare's prospective payment with Diagnosis Related Groups (1983), and the Joint Commission on the Accreditation of Health Care Organizations making patient and family education a focus area (1993). Each has raised awareness of the professional responsibility for teaching and the skills needed to communicate effectively with patients and families. Throughout these developments in accreditation and federal regulation, health care providers and institutions have called on the AHEC Program for continuing education and clinical training to prepare health professionals and students with the knowledge and skills they need to meet agency and public expectations for patient and family education. Many of the first patient education programs were hospital-based. The health care delivery system has changed dramatically, and clinicians practice in many different roles and settings. Patient education is integrated into care delivery in each of these.

> *"Many health professionals continue to struggle with what to teach, how to identify survival skills, and how to pare down instruction to make teaching practical."*

Professional Responsibility for Patient and Family Education

In 1972, in response to the American Hospital Association's Patient's Bill of Rights, hospitals emphasized informed consent as the way to ensure the patient's "right to know." Specifically, the patient had the right to know about his illness, the diagnostic

---

Karen D. Stallings, RN, MEd, is associate director of the North Carolina Area Health Education Centers Program at the University of North Carolina at Chapel Hill. She can be reached at karen_stallings (at) med.unc.edu or University of North Carolina at Chapel Hill, Campus Box 7165, Chapel Hill, NC 27599-7165.

Thomas J. Bacon, DrPH, is executive associate dean and director of the North Carolina Area Health Education Centers Program at the University of North Carolina at Chapel Hill.

and therapeutic processes to be used, and the prognosis for physical recovery. The patient had a right to refuse treatment and to be informed about the consequences of those actions. This led to formal statements by professional groups including physicians, nurses, and pharmacists that addressed patient teaching responsibilities in their practice standards. The Area Health Education Centers Program responded by offering continuing education programs to teach health care practitioners the legal and ethical responsibilities for patient education.

The curricula for students in the health disciplines, whether medicine, nursing, allied health, pharmacy, dentistry, social work, or others, underscore the professional, legal, and ethical responsibilities they will have to share their medical knowledge in a way that is understandable and usable in the daily management of health. Student and resident learning about patient-practitioner communication begins in the classroom. The Area Health Education Centers Program facilitates community-based clinical experiences in a variety of settings including home care, free clinics, health departments, schools, senior centers, and long-term care facilities where students are able to learn that health care encounters extend beyond basic evaluation and diagnosis; they also require communicating health care information to patients and teaching them the skills and knowledge for self-management. This process involves a relationship between patient and practitioner that is long-term and takes advantage of every encounter with the health care system to promote healthy behaviors.

Developing Patient Education Materials

In developing consent forms and patient education brochures, patient reading ability, understanding, language, and culture must be addressed by replacing medical terminology with plain language, basic concepts, and illustrations. AHEC has advised and continues to advise students and practitioners to develop materials that are at the fifth grade reading level, in the patient's native language, and sensitive to cultural and religious beliefs. While great strides have been made, researchers continue to find that patient education materials are written far above the reading levels of most patients and contribute to problematic low health literacy. Patients cannot understand directions, lack self-care skills, misuse medications, and are unable to access needed services. Health care professionals are frequently not aware of the gap in reading level and patient understanding and of how to rectify it. In light of the report of the North Carolina Institute of Medicine task force on low health literacy, the AHEC Program understands that we must continue to raise awareness among health care practitioners about the prevalence and impact of low health literacy in North Carolina. The new Center for Health Literacy Excellence proposed by the task force offers North Carolina an excellent opportunity to create a central source for the best evidence-based tools and curricula for practitioners so that these resources don't have to be developed locally.

Discharge Planning and Patient Safety

In 1983, Medicare's prospective payment with Diagnosis Related Groups tied financial incentives to shorter hospital stays. Patient education efforts focused on discharging patients safely with the ability to manage some aspects of care at home, especially medications, modified diets, and use of medical equipment. The pressure to teach more in less time and impart skills (such as insulin injection) needed for self-care initially meant that more staff were teaching patients, and teaching was started earlier, often when patients were too ill to absorb the information. The Area Health Education Centers Program continuing education workshops teach practical strategies to coordinate teaching provided by various health disciplines, document patient learning, and provide consistent information to patients and families. Practitioners are urged to reduce the number of handouts and facts to be taught and actively engage patients in learning using teach back, role play scenarios, and return demonstration of skills. Many health professionals continue to struggle with what to teach, how to identify survival skills, and how to pare down instruction to make teaching practical.

In 1993, the Joint Commission on the Accreditation of Health Care Organizations (JCAHO) made patient and family education a focus area, insisting that all patients and families receive the education necessary to acquire survival skills, utilize community resources, and understand the role patients must play in their treatment plans. The Joint Commission's patient safety initiatives place patients and families at the center of the health care team and open lines of communication among patients and practitioners which are viewed as essential. Many hospitals have called on AHEC to assist with staff development efforts for managers and front-line staff related to JCAHO mandates for accreditation.

Chronic Illness and Disease Management

Today there is a growing awareness of the improvements in health outcomes that can be realized by incorporating evidence-based prevention and disease management strategies into the patient care practices of physicians and other primary care practitioners. Patient involvement and empowerment are essential for the success of these approaches, however, and patients with chronic diseases who also have low health literacy have less knowledge about their disease, more complications, and worse health outcomes. Patients and families may seek health information from other sources including the Internet, relatives and neighbors, and cultural or religious communities. The ability to exchange ideas, identify inaccurate information, and acknowledge patient choice requires openness and flexibility. The Area Health Education Centers Program continuing education efforts bring health librarians to teach practitioners about information patients find in lay literature and on the Internet and how to help patients access reliable sources.

The cornerstones of chronic illness management include smoking cessation, weight loss, regular exercise, stress reduction, and adherence to medication regimens. Patient education efforts drive home in a forceful way the changes that patients need to make.

Health professionals tend to view cooperation or compliance as a single choice. Following a therapeutic diet, however, involves multiple choices throughout every day. Being compliant with a treatment plan for chronic illness may be costly, painful, or socially isolating. It is important to acknowledge the frustration that many practitioners feel when patients are unable or unwilling to comply with all the behavioral changes that are prescribed and to stress that patient teaching for effective management of chronic illness should have broader goals than compliance. As we prepare present and future health care practitioners to teach patients, AHEC student and continuing education programs should stress that helping patients understand their disease is a good beginning, but self-efficacy also relies on very specific action plans and daily strategies that patients choose to engage in which will ultimately lead to achieving long-term goals. Practitioners can incorporate practical strategies such as limiting the number of changes, making easier changes first, and working with families to anticipate barriers such as the cost of medications. Patient education is a partnership in which professionals must also strive to be role models and coaches for these health practices.

Future Opportunities

New initiatives currently underway in North Carolina to improve quality and patient safety in physician offices, hospitals, health departments, and other settings offer exciting opportunities to incorporate better patient-practitioner communication techniques, improve patient education materials, and create a better system of care that includes the patient as a critical part of the health care team. Incentives to improve outcomes will include moves by Medicare, Medicaid, and private insurers to begin rewarding physicians and other practitioners through pay for performance programs. The new climate will enhance motivation for health professionals to utilize the most advanced techniques in educating patients, simplifying processes of care, and incorporating the patient into the process.

North Carolina is on the cutting edge in developing programs to enhance quality and patient safety. The national program Improving Performance in Practice, funded by the Robert Wood Johnson Foundation and others, selected North Carolina as one of 2 pilot states. The project, a collaborative effort of the Community Care Networks, AHEC, the medical professional societies, and state health agencies has been successfully implemented in 2 regions this year and will be developed in 3 more regions this fall. The program seeks to support physician practices in collecting data on how chronic illness is managed in the practice and then offer assistance through a regional quality improvement coach to make improvements that lead to better health outcomes for patients.

The North Carolina Center on Hospital Quality and Patient Safety of the North Carolina Hospital Association engaged more hospitals than any other state in the national 100 000 Lives Campaign and now leads North Carolina hospitals in participating in the 5 Million Lives Campaign. Both initiatives seek to improve outcomes in hospital quality through quality collaboratives, educational programs, and greater transparency of data on quality measures of care.

Particularly in the outpatient setting, these quality initiatives require new approaches to managing chronic illness and fostering prevention at both the individual patient level and the practice level. Practitioners will be required to learn new skill sets, but patients will also have to be more engaged in the process if successful outcomes are to be achieved.

AHEC Statewide Initiatives to Promote Patient-Practitioner Communication

The Area Health Education Centers Program is committed to playing its traditional role of incorporating educational materials and curricula into all phases of the educational process in collaboration with the educational institutions of the state. The following recommendations address new efforts to meet the needs and challenges mentioned in the preceding paragraphs:

(1) AHEC can assist the health science schools in identifying and utilizing community-based clinical experiences that advance students' skills in patient education. Our mutual goal is to help students take concepts introduced in the classroom and apply them with the guidance of skilled community preceptors. The Area Health Education Centers Program can offer grant funding to support the development or expansion of new clinical experiences for health science students and would place priority for funding decisions on projects that include interdisciplinary collaboration, use of effective written patient instructions, patient and family teaching, and assessment of learning outcomes. Patients and their family members can be incorporated into training programs by sharing their stories about living with and managing chronic illness. This will add another dimension to what is taught in the classroom.

(2) AHEC will continue to offer continuing education programs that address how to evaluate and rewrite materials and that identify practical ways to screen patients for low health literacy. Interdisciplinary AHEC continuing education workshops with case studies and role play can help practitioners become more skillful using the teach-back method. It is important for each discipline to consider the unique contributions it can make to teaching. For example, when practitioners confirm the diagnosis and the daily management needs with patients, this sets the stage for ongoing teaching by other disciplines. Sharing experiences among different disciplines illustrates the gap between what patients need and what is provided. For example, when nurses make home visits, they become aware that a written action plan is critical to activating patients for self-care.

(3) AHEC librarians can provide health care practitioners with information about resources available on the Internet, how to evaluate Web sites for reading level and illustrations, and how to steer patients to reliable and accurate sources. At the same time, we must look for new ways to make this information available when practitioners and patients need it. Online resources, materials developed through the proposed Center for Health Literacy Excellence, and other nationally developed tools need to be available in real time, and practitioners need to be educated to use them most effectively. The Area Health Education Centers Program can highlight these resources in continuing education programs and include links to them via the AHEC Digital Library. The North Carolina Institute of Medicine Task Force on Health Literacy has identified many experts and agencies with valuable resources that can assist us in transforming patient education practices to address low health literacy, and AHEC can raise awareness among health care professionals.

(4) AHEC can develop learning collaboratives and invite practitioners to participate in the sharing of best practices and practical strategies for patient-practitioner communication in the management of chronic illnesses. In caring for children with asthma, the consistent use of daily management plans, family teaching, and consistent follow-up with asthma registries are effective. These effective techniques can be shared to improve care for other chronic illnesses.

For over 3 decades, the AHEC Program has been actively engaged in efforts to promote patient partnership and patient education. Incorporating communication and patient education techniques in continuing education and patient training has gained momentum as the result of new regulatory measures. The current climate places a much greater emphasis on better patient outcomes, including establishing uniform standards of care for managing chronic illnesses and assisting practitioners in measuring and improving the outcomes of their practices. This serves as a catalyst for greater strides in patient education. If we are to realize fully the kinds of improved health outcomes that everyone wants, it will be essential for patients to be fully engaged in the process of managing chronic illness and to play a greater role in making better decisions about lifestyle issues. **NCMJ**

How to Reach Us

LETTERS TO THE EDITOR

- Our e-mail address is NCMedJ (at) nciom.org
- Our fax number is 919-401-6899
- Or you can send your letter to: *North Carolina Medical Journal*, Letters, 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713
- Please include the writer's full name, address, and daytime phone number. Letters may be edited for clarity or space.

SUBSCRIPTIONS AND GIFTS

- Customer services for subscriptions or gifts can be accessed via e-mail NCMedJ (at) nciom.org or by calling the North Carolina Medical Journal's business and advertising manager, Adrienne R. Parker, at 919-401-6599 ext. 28.

SUBMITTING PEER-REVIEWED ARTICLES

North Carolina MEDICAL JOURNAL

COMMENTARY

A Failure to Communicate

Timothy W. Lane, MD; J. Carson Rounds, MD

Most people who have seen the classic movie *Cool Hand Luke* will never forget the famous admonition by the chain gang's boss, played by Strother Martin, to Paul Newman, just after he submits him to a vicious beating for insubordination. The boss justifies his psychopathic actions by informing Newman and his fellow inmates, "What we have here is a failure to communicate." Our profession has heard from multiple quarters over the past decade that we have failed to communicate in many ways with our patients and with one another. When we hear such accusations, we recall this iconic scene and the dreaded punishment for so failing. We certainly do not want be beaten up nor do we advocate beating up on ourselves. In the best spirit of professionalism, we need to examine communication problems and actively seek and apply solutions.

Some observations are obvious. We glibly use the vocabulary of medicine that took several years of intense study and repetition to master to communicate with our colleagues and, too frequently we admit, with our patients. We have all been guilty of using seemingly simple words or phrases such as "lesion," "bronchoscopy," or "intravascular catheter" and then winced at our insensitivity when our patients' eyes glazed over or faces grimaced in confusion. Sensitivity on our part would go a long way in helping our message in such circumstances. Many of our medical schools are now addressing sensitive and patient-centered methods of doctor-patient communication.

Research in the growing field of health literacy demonstrates better patient understanding when words are carefully chosen in speech or written communication and are targeted at 4th to 6th grade reading levels even when formal education may be at a much higher level.[1] Current estimates indicate that nearly one-third of our population, or over 90 million Americans, read at this basic level. Another 15 million have extremely limited to no ability to read.[1] This is not a small or isolated problem.

"We have all been guilty of using seemingly simple words or phrases such as 'lesion,' 'bronchoscopy,' or 'intravascular catheter' and then winced at our insensitivity when our patients' eyes glazed over or faces grimaced in confusion."

One immediately visible area where reading literacy affects health literacy is in administration of prescription medicines. Recent investigations show significant patient confusion over medication use and prescription directions, and this work has led to recommendations and policy actions to improve written materials for patients and parents or guardians of children.[2] Confounding this are the confusing ways pharmacies label medicine containers; there is no systematic pattern to the labels and the print is not large enough for much of our elderly population to read without magnification. Since most pharmacy laws are specific to each state, we need to advocate for change that will improve patient understanding and readability of medication labeling and of all things that we share in writing with our patients.

We also have to increase our current glacial slouching toward the broad adoption of electronic medical records. With electronic medical records, we will see a comprehensive assessment of the

Timothy W. Lane, MD, FACP, is a professor of medicine at The University of North Carolina at Chapel Hill and Moses Cone Hospital and governor of the North Carolina Chapter of the American College of Physicians. He can be reached at tim.lane (at) mosescone.com or 1200 N Elm Street, Greensboro, NC 27401-1020.

J. Carson Rounds, MD, is president of the North Carolina Academy of Family Physicians, Inc.

quality of care we provide in terms of process and outcomes. The hope is that electronic medical records will promote legibility, monitoring of chronic disease management programs, sharing of important information with other practitioners, and, not least, delivery to our patients of literacy-sensitive documents summarizing and educating them about their health.

As professionals we have always philosophically held to the principles of accountability, quality, and fairness and now, as never before, our work is cut out for us. However, despite the burdens and tasks of practicing medicine in the 21st century, we must never lose sight of our common goal and most important outcome: the well-being of our patients. As Harvard physician Francis Weld Peabody so succinctly said in 1912, "...the secret of the care of the patient is in caring for the patient."[3] New approaches to health literacy, evidence-based application of our skills, and our own sensitivity are just some of the tools of caring that we must have in our metaphorical black bags. **NCMJ**

The University of North Carolina Hospitals (UNC-H) is calling for applications to a:

Residency in General Preventive Medicine/Public Health at UNC Chapel Hill

(Commencing July, 2008)

The resident will:
1. In the academic year, undertake a Master's Degree in Public Health at UNC, and
2. In the practicum year, pursue research and practicum rotations in a variety of clinical and public health settings.

Graduates will be board eligible in Preventive Medicine.

Applications will be made to both the Preventive Medicine Residency (deadline November 1) and to the UNC School of Public Health (deadlines vary by department, but begin around January 1).

Applicants must have completed an internship year in a primary care specialty in an ACGME-accredited program; be a U.S. citizen or permanent resident; have completed medical training in an LCME-accredited medical school; possess a current certificate from the Education Commission for Foreign Medical Graduates (if applicable); and have a valid medical license in the United States.

For information on the preventive medicine residency and how to apply, please see: http://www.med.unc.edu/wrkunits/2depts/soclmed/PREVENTIVEMED/PrevMedHomePage.htm

For further information, please contact

Deborah Porterfield, MD, MPH, Residency Director at porterfi (at) email.unc.edu or (919) 843-6596.

Dedicated Neurologist Needed

Nationally recognized integrated healthcare system in Virginia Beach has immediate openings for full time Board Certified or Board Eligible Neurologist in: **General Neurology, Neurovascular, Neuro-Oncology, Neurodegenerative and Epilepsy**. Inpatient and outpatient practice with above average base salary plus production incentives, relocation, and outstanding benefits!

Spotlight on the Safety Net

A Community Collaboration
Mike Darrow, CFRE

Practitioner Volunteerism at Free Clinics: A Critical Need

According to recent estimates 1.4 million people in North Carolina, or over 17% of the adult population, have no health insurance. North Carolina's uninsured population is growing at a rate faster than the national average. Free clinics act as a safety net by attempting to bridge the gap in health care access for the state's uninsured. Because free clinics are local, volunteer-based organizations, the supply of practitioner volunteers is critical to their survival and success in serving the needs of the uninsured. Free clinics struggle with obtaining sufficient practitioner volunteers to meet the demands for services.

What Is a Free Clinic?

A free clinic is a private, nonprofit, community-based organization that provides medical care at little or no charge to low-income, uninsured, and underinsured persons through the use of volunteer health care professionals and partnerships with other health care providers. The North Carolina Association of Free Clinics (NCAFC) has 69 member clinics—more free medical clinics than any state in the country. The first free clinic in North Carolina was the Open Door Clinic in Raleigh, which was established in 1985.

No 2 free clinics are alike. They are custom designed by communities to meet identified health care needs using the community's unique health care assets and resources. Free clinics are governed by volunteer boards of directors that represent a broad cross section of the community. They may provide acute and/or chronic health care, laboratory, dental, pharmacy, substance abuse, and/or mental health services. Licensed professional practitioners render all services to the clinics' uninsured patients.

Because they are private, nonprofit organizations supported primarily by cash and in-kind contributions from the private sector, volunteerism is a central feature of free clinics. Clinic services are provided primarily or exclusively by volunteer health care professionals serving in the clinic's own facility or in their own private practice settings. Lay volunteers also perform a variety of administrative and clerical tasks, which keeps overhead costs low.

In North Carolina, low-income, uninsured, and underinsured adults have the greatest difficulty accessing affordable health care services. While eligibility criteria vary from one clinic to the next, free clinics conduct rigorous eligibility screenings to ensure that the patients they serve are truly in need. Free clinics believe that inability to pay should not prevent people from receiving quality health care. To this end, the clinics provide services at little or no charge. Free clinics place a strong emphasis on providing nonjudgmental, compassionate care that respects the dignity and self-worth of every patient.

Volunteer Practitioner Trends

In 2005 free clinics in North Carolina reported utilizing 6443 volunteers, of which 1167 were physicians.[a] The total number of physician volunteers in free clinics actually declined from 2004 to 2005 by 10.3% while the total number of hours volunteered increased by 3.8%. It appears that clinics are losing volunteer physicians, but the ones who continue to support the work of free clinics are volunteering more hours. The decrease in North Carolina's practitioner volunteers reflects a nationwide trend.[1]

---

[a] It is important to note that these numbers are most likely underreported. They do not include 12 new clinics added to NCAFC since 2005, and 7 clinics reported no data. The latter reflects the difficulty clinics have in tracking volunteer hours.

continued on page 375

continued from page 374

There are a number of reasons why fewer practitioners may choose to volunteer in free clinics. First, the number of the uninsured and the proportion needing chronic care is increasing. Managing the growing demand for the complex services needed to treat those with chronic diseases adds additional strain and stress on volunteer physicians. There is also increasing economic pressure on active physicians who are facing reduced third-party payments and increased operating costs in their private practices. This requires physicians to spend more time seeing patients in their practice, thus reducing the amount of time available to volunteer.

There are also a number of actual and perceived barriers to volunteering. Physicians often cite malpractice or insurance issues as compelling factors in deciding not to volunteer. Additionally, retired physicians cite maintaining continuing medical education hours as another barrier. Physicians also mention confusion about maintaining their licenses, unaware of the volunteer license specifically designed for volunteering at a free clinic.

Strategies to Increase Volunteerism by Practitioners

There are several strategies that NCAFC is undertaking to increase the number of physician volunteers in free clinics. The first is to increase recruitment of retired physicians. The NC Association of Free Clinics is working with the American Health Initiative on a project entitled TAP-IN, which is a Web-based project focusing on increased awareness of volunteer opportunities for retired medical providers in free clinics. This program was piloted in 3 clinics and resulted in additional volunteer practitioners in those clinics. The program went statewide as of April 2007.

The NC Association of Free Clinics is also focusing on marketing free clinics to raise awareness of their work and the people they serve. On April 24, 2007 NCAFC sponsored a Statewide Open House in which all 69 NCAFC member clinics were open to the public on the same day. The Open House received statewide media attention as well as local exposure. Raising overall awareness of free clinics and publicizing the need for volunteers should have a positive effect on practitioner recruiting.

The NC Association of Free Clinics views its partnerships with the North Carolina Medical Board and the North Carolina Medical Society as critical to the success of free clinics. Both organizations are very supportive of the work of free clinics and have been instrumental in streamlining the volunteer licensing application, informing retiring physicians about changing their licenses from active to volunteer, and working with clinics and retired physicians from out of state to obtain volunteer licenses. The NC Association of Free Clinics also works in partnership with these organizations to enhance the volunteer experience for the practitioner.

Finally, NCAFC is collaborating with insurance providers to offer special professional liability policies for volunteer practitioners at very affordable rates. This is a very important factor in recruiting more practitioner volunteers.

Conclusion

With 1.4 million uninsured in North Carolina, free clinics cannot be the solution to providing health care to our friends and neighbors. However, with the assistance of practitioner volunteers, our clinics can continue to help bridge the gap for the uninsured in our state while long-term solutions are developed. Rather than wait for those solutions, the North Carolina Association of Free Clinics is acting now to engage North Carolina's communities and enlist thousands of volunteer practitioners.

Health Promotion and African-American Baptist Churches in North Carolina

M. Anita P. Holmes, JD, MPH; John Hatch, DrPH, MSW

The General Baptist State Convention of North Carolina (GBSC) has actively sponsored disease prevention and health promotion services since 1978. The Faith and Health Initiative, sponsored by Kate B. Reynolds Charitable Trust, is the most recent of several area-based health promotion efforts. While the focus of GBSC health initiatives vary, including maternal and child health, smoking cessation, nutrition education, enhancement of parenting skills, and reduction in incidence and control of diabetes, faith-driven values and strategies motivate and direct the development, implementation, and ongoing work of each project.

Project efforts utilize the historic role of the African-American church as initiator, enabler, and sponsor of activities to improve life at the community level. Programs are initiated by discussing specific health concerns with pastors and selected lay leaders and asking them if programs focused on these concerns seem right for their congregations. Potential benefits to participants are considered as well as the role the church will be asked to play in implementation. A long tradition of lay leader participation in setting congregation priorities benefits program implementation. Each church has a structural authority to select priorities independently of central governance structures. A key component of these programs is the selection and training of volunteers who will be responsible for recruiting participants, coordinating church and community resources, facilitating participation, and providing specialized training when appropriate.

The Faith and Health Initiative, a primary and secondary prevention program, was designed to significantly change risk behaviors through encouraging nutritionally sound dietary practices, increasing physical activity and exercise, and utilizing the intersection between faith and health to strengthen and increase project viability and sustainability. Four GBSC Associations (regional subunits of the statewide Convention) serving rural underserved counties in the northeastern part of the state served as the targeted intervention points. Although the geographic area may be characterized as socioeconomically challenged, it is rich in human, cultural, and spiritual resources.

To build on this strong infrastructure, center leadership first enhanced the relationship between the Associations' pastoral faith leaders (called moderators) while seeking a shared vision as the springboard for the project. These leaders were instrumental in assisting the project in identifying 4 project facilitators (1 for each association) to coordinate the project at the regional level. Facilitators were diverse in demographic background (eg, education, age, sex, and occupation). However, the common denominator was their active involvement with their associations and the way in which they were respected by other parishioners and the community in general.

From the beginning of the project, the faith leaders of the participating associations were engaged. Recognizing the critical role pastors play in supporting project efforts and in translating health teachings in relation to theological understandings, the project continued to actively include pastors in project planning and updates through quarterly meetings of participating churches' pastors. These meetings provided an opportunity to expose pastors to the project curriculum and selected activities, allowing them to better assist in the diffusion of information to parishioners. Also key to parishioner involvement and support, were the lay volunteers and natural helpers recruited for the respect they receive, the guidance they are sought for, and the helping role they play in the lives of fellow parishioners and others in their network.

An essential component of the Faith and Health Initiative and other GBSC projects is the development of partnerships with local human service agencies. These partnerships are critical in the continued support and sustainability of these locally owned projects. The Faith and Health Initiative enjoyed partnerships with both public and private entities. These working relationships not only maximized the resources available to the project and community, but also resulted in some of the relationships between resource staff and project leaders surviving past the formal project funding period.

Positive project outcomes were evident at both the individual and organizational level. Individuals experienced increased knowledge and behavioral modification (eg, increased fruit and vegetable consumption and increased physical activity) and became advocates within their social networks for health promotion policy and environmental changes. At an organizational level, churches and associations made system-level policy and environmental changes including establishment of health committees as ongoing organizational components, changing to healthier menu selections at congregational meal functions, and establishing walking trails on church grounds. The groundwork laid by the Faith and Health Initiative continues to provide fertile soil for addressing health disparities in these communities.

M. Anita P. Holmes, JD, MPH, is the past executive director of the Center for Health and Healing, a nonprofit affiliate of the General Baptist State Convention of North Carolina. She currently services as branch head in the Heart Disease and Stroke Prevention Branch, NC Division of Public Health, and as executive director of the Justus-Warren Heart Disease and Stroke Prevention Task Force.

John Hatch, DrPH, MSW, is a senior program development officer for the Center for Health and Healing.

Selected Data Related to Health Literacy in North Carolina

Health literacy is the ability of people to understand basic health information, communicate with health practitioners, and properly use health services. Low health literacy might be associated with, for example, the inability to read and comprehend basic health-related materials such as prescription bottles and appointment slips. Studies suggest that people with low health literacy are less likely to take their medications as prescribed or follow treatment protocols, less able to manage their chronic conditions, and more frequently hospitalized.[1] There is new evidence that people with low health literacy have higher death rates.[2] Health literacy problems are more common among racial and ethnic minorities, the elderly, and people with lower education achievement or lower income, but people from all walks of life struggle with health information.

Some of the surveys fielded by the State Center for Health Statistics in North Carolina provide information about the level of health knowledge on certain topics. Health knowledge deficits may reflect underlying health literacy problems. Low rates of health knowledge could reflect that the population had difficulty understanding the message, but it could also reflect a failure of message dissemination.

The data summarized in this article are drawn from 2 surveys. The Behavioral Risk Factor Surveillance System (BRFSS) is a random telephone survey of persons ages 18 years and older in the state. The Pregnancy Risk Assessment Monitoring System (PRAMS) is a random mail and telephone survey of new mothers in North Carolina. Below are selected data from these surveys that give insight into health knowledge in our state.

Table 1.
North Carolina Health Knowledge

Measure	Source	Year	Percentage
Percentage of new mothers who have ever heard or read that taking the vitamin folic acid can prevent some birth defects	PRAMS	2004	83.1
Percentage of diabetics who check their blood for glucose or sugar every day	BRFSS	2005	62.2
Percentage of diabetics who check their feet for sores or irritations every day	BRFSS	2005	71.9
Percentage of diabetics who have ever taken a course or class in how to manage your diabetes yourself	BRFSS	2005	54.7
Percentage of adults who identified all 5 heart attack symptoms correctly	BRFSS	2005	10.0
Percentage of adults who identified all 5 stroke symptoms correctly	BRFSS	2005	16.6
Percentage of adults age 50+ years who think that people their age or older who do not have symptoms should be tested for colon or rectal cancer	BRFSS	2005	94.9
Percentage of men age 40+ years who rated their understanding of the advantages and disadvantages of PSA tests as excellent or very good	BRFSS	2005	49.0

continued on page 378

continued from page 377

The low percentages shown in the table for individuals who practice proper diabetes management, correctly identify heart attack and stroke symptoms, and report they understand PSA tests suggests substantial problems with health knowledge in the overall population of adults in North Carolina. More detailed data (for example, broken out by demographic categories) can be found at www.schs.state.nc.us/SCHS (click on BRFSS or PRAMS on the left side of the page under Health Data). For example, the 2005 percentage of adults who identified all 5 stroke symptoms correctly was 6% for those with less than a high school education compared to 26% for those with a college degree.

A study on a North Carolina heart failure self-management program showed that an intervention designed for patients with low literacy reduced the rate of hospitalization and death in the intervention group as compared to a control group.[3] In another study, patients with diabetes and low literacy benefited more from a disease management intervention compared to those with diabetes and higher literacy skills.[4] These studies suggest that well-designed programs to engage and educate patients about their own chronic illness and disease self-management will help reduce morbidity and other problems associated with low health literacy.

Health literacy depends not only on individual capacity to communicate and understand health information but also on the demands posed by society and the health care system.[5] For example, health care professionals have a responsibility to reduce the complexity of their speech and written materials and simplify access to health care services. Finally, improving the levels of literacy, education, and income in the general population will have the effect of increasing health literacy in North Carolina.

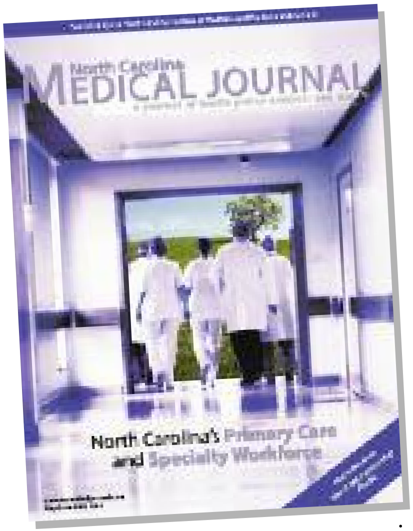
Readers' Forum



North Carolina MEDICAL JOURNAL

North Carolina's Primary Care and Specialty Workforce

To the Editor:

The North Carolina Institute of Medicine should be commended for its timely recognition of the issues relating to medical manpower as addressed in the May/June 2007 issue of the *North Carolina Medical Journal*. The North Carolina Academy of Family Physicians published similar concerns over a decade ago in its publications *Who Will Take Care of Our People?* and *Who Will Care for Our Communities?* These were red flags to the NC General Assembly and the academic community from family physicians in this state who realized that the population was increasing while growing more aged and sickly, and that fewer medical students were choosing primary care and family medicine as a career. Sadly, there was no response, but this was the age of managed care, and we did see a small increase in family medicine match rates. Since that time the state's population has more than doubled and become on average older, and we find significant maldistributions of health care. Many of our state's citizens are underserved and face health care disparities. Unfortunately, both of our calls went unheeded. Perhaps your efforts will meet with more success in arousing public awareness of this urgent issue.

It is not surprising the NC Institute of Medicine found that even if we begin training more primary care and family physicians today, there will still be a deficit in the providers of first line care in the foreseeable future. Our answer: THERE ALREADY ARE too few primary care physicians to provide a medical home for all of the citizens of our state. Unless there is a change in the number of students choosing careers in primary care, the crisis threatens to be catastrophic.

There has been significant discussion about increasing class size at each of the four academic institutions as well as proposals for a fifth training site in Charlotte. None of the suggestions include an increase in the number of primary care providers in North Carolina. For many years the legislature has required that our universities report the specialty selection of the senior class of each school. However, this is an accounting of merely the intern year and does not consider matches in general internal medicine/pediatrics for a preliminary year where many go on to subspecialize. Strong consideration should be given to a change in legislation that requires accountability upon completion of residency. The American Association of Medical Colleges and the American Medical Association have recommended a graduation rate of 50% primary care and 50% specialty care physicians. This is not happening in our state and has contributed to the current shortage of primary care providers.

If past history is a predictor of the future, the plight of health care in this state will only worsen, and North Carolina citizens will have to pay more for a system in which they receive care that is fragmented and reactive rather than preventative or comprehensive.

Why do countries such as Cuba and Great Britain rank higher in quality of care despite spending significantly less on health care than the United States? The answer is quite simple. It is the uncomplicated access to well-trained primary care physicians. The data in Barbara Starfield's research supports this premise. We have in this state demonstrated—through the work of Community Care of North Carolina—a system which achieves better access and improved quality of care while also achieving a cost savings. The basis of this system is that each patient is assigned a primary care medical home. The model utilizes care managers, pharmacists, nutritionists, and project specialists to assist in education of patients and improve standards of care. This is the model that has the potential to achieve the desired improvements in health outcomes sought by the NC Institute of Medicine. We do not need academic centers to create another model of inefficient, costly care.

I challenge our academic leaders to study the Community Care of North Carolina model, embrace the concepts of quality-based and accessible care, and provide physicians who can serve those needs in this state.

The North Carolina Academy of Family Physicians stands ready to aid in achieving this lofty goal.

Respectfully,
Michelle F. Jones, MD, FAAFP
President
North Carolina Academy of Family Physicians

To the Editor:

I would like to comment on some issues that were touched upon in the article by Dr Harvey Estes in the May/June issue of the *North Carolina Medical Journal*. I feel compelled to say that it was through Dr Estes' diligent efforts and pioneering work at Duke that the Physician Assistant Program came into being in North Carolina and subsequently became a vital link in health care delivery in our state and a model to the nation—with the Nurse Practitioner Program to follow.

I think the real core of dissatisfaction in the general public about the health care delivery system centers around concerns of expense, the limited availability (not the quality) of health care, and the general perception of diminished interest in the individual patient by physicians. It is my perception that the public would readily accept the expense and logic for the creation of another state-owned medical school. I have always felt that there has been an abundance of qualified North Carolinians for medical training.

Since the advent of the Brody School of Medicine at East Carolina University, North Carolina has grown 2 million in population. It is interesting to recall that this school was violently opposed during its inception by the state's then 3 medical schools.

I also feel that economic and social changes are apparent in the culture of the medical profession. There is a willingness to accept more professional regimentation in order to escape the added hours and business aspects of practice and a seeming desire to escape close personal relationships with clientele.

This capitalistic approach is, to me, the excessive zeal for the accumulation of wealth which leads to unfettered capitalism, control through ownership, and favoritism to hospital employed or affiliated physicians. This situation serves as a deterrent to physicians with the same credentials and staff memberships to enter private or small group practices; ergo, establishing a private or small group practice starts out more risky, and its growth and survival is problematic.

Here in my hometown there is a strong feeling or recognition in private practices that if the hospital's ownership doesn't extend to your practice, you probably won't get equal opportunity to share in the patient pool. New physicians do not come to a community expecting to be discriminated against by the management of local hospitals. Equal opportunity should be applied to physicians regardless of affiliation.

Respectfully,
John R. Gamble Jr, MD
Lincolnton, NC

To the Editor:

The May/June 2007 issue of the *NC Medical Journal* defined the challenges faced by North Carolina in providing primary care, obstetric care, and psychiatric services to individuals across the state. As a clinical specialist in child and adolescent psychiatric and mental health nursing since 1990, and a recently licensed family psychiatric and mental health nurse practitioner (PMH-NP), I would like to respond from an individual practitioner perspective.

In my work with children and families, I became acutely aware of the impact of limitations in the availability of psychiatric practitioners. Primary care practitioners (PCPs) have been instrumental in filling the gap when medication was part of the treatment plan. However, with publicized warnings about possible side effects of some psychiatric medications and a growing demand for PCP services, some PCPs became less willing to manage psychiatric medications. In my experience, it was not unusual to see a child wait months to see a child psychiatrist, which often resulted in major implications for the child's academic and social functioning. These experiences motivated me to obtain post-masters education as a family PMH-NP at the University of North Carolina at Chapel Hill School of Nursing.

I am fortunate to work for an organization that supported my ability to pursue the education and clinical placements necessary for training. FirstHealth of the Carolinas has also facilitated my ability to arrange collaborative practice agreements and supervision time with three highly skilled and experienced psychiatrists. This has been vital in my transition to this expanded role.

As resources for psychiatric and mental health services continue to be stressed, it is important that psychiatrists and community organizations be willing to provide the kind of facilitation that I have experienced. I also support Erin Fraher's recommendation to develop innovative models of interdisciplinary care that incorporate advanced practice psychiatric nurses into the psychiatric team. It is my hope that educational institutions, psychiatrists, and nursing leaders will continue to work toward developing models that serve to expand clinical resources to our citizens.

Sincerely,
Elizabeth Watson, MSN, PMH-NP
FirstHealth of the Carolinas
Outpatient Behavioral Services
Pinehurst, NC

To the Editor:

Your recent issue on physician supply indicated that there may be an emerging shortage of general surgeons. I have decided to pursue general surgery in my residency next year, and it may be useful for others to know why.

There are many reasons that I have decided to apply to general surgery residency programs this fall. During medical school, I discovered that I like the intensity of the interaction between patient and surgeon, the variety of health care issues faced while working in a clinic and an operating room, and the opportunity to master technical skills in addition to the diagnostic skills required of all physicians. Becoming any kind of surgeon could satisfy these interests, but I have chosen to practice general surgery. Although the old paradigm of general surgeons being similar to family doctors on the front lines of primary care is probably no longer true, except for in the most rural settings, the concept still appeals to me. I respect the communication and shared decision making skills that many primary care physicians possess, and I hope to emulate them in my own practice. I value practicing in a field of medicine that is accessible and comprehensible to patients. And, it is fulfilling to know that my career as a general surgeon might help fill an unmet need in the country's health care system.

ACIPHEX® \a-sa-ˌfeks\
(rabeprazole sodium)
Delayed-Release Tablets

BRIEF SUMMARY
Before prescribing ACIPHEX®, please see full prescribing information.

INDICATIONS AND USAGE
Healing of Erosive or Ulcerative Gastroesophageal Reflux Disease (GERD)
ACIPHEX® is indicated for short-term (4 to 8 weeks) treatment in the healing and symptomatic relief of erosive or ulcerative gastroesophageal reflux disease (GERD). For those patients who have not healed after 8 weeks of treatment, an additional 8-week course of ACIPHEX® may be considered.

Maintenance of Healing of Erosive or Ulcerative Gastroesophageal Reflux Disease (GERD)
ACIPHEX® is indicated for maintaining healing and reduction in relapse rates of heartburn symptoms in patients with erosive or ulcerative gastroesophageal reflux disease (GERD Maintenance). Controlled studies do not extend beyond 12 months.

Treatment of Symptomatic Gastroesophageal Reflux Disease (GERD)
ACIPHEX® is indicated for the treatment of daytime and nighttime heartburn and other symptoms associated with GERD.

Healing of Duodenal Ulcers
ACIPHEX® is indicated for short-term (up to four weeks) treatment in the healing and symptomatic relief of duodenal ulcers. Most patients heal within four weeks.

Helicobacter pylori Eradication to Reduce the Risk of Duodenal Ulcer Recurrence
ACIPHEX® in combination with amoxicillin and clarithromycin as a three drug regimen, is indicated for the treatment of patients with *H. pylori* infection and duodenal ulcer disease (active or history within the past 5 years) to eradicate *H. pylori*. Eradication of *H. pylori* has been shown to reduce the risk of duodenal ulcer recurrence. (See **CLINICAL STUDIES** and **DOSAGE AND ADMINISTRATION** in full prescribing information.)

In patients who fail therapy, susceptibility testing should be done. If resistance to clarithromycin is demonstrated or susceptibility testing is not possible, alternative antimicrobial therapy should be instituted. (See **CLINICAL PHARMACOLOGY, Microbiology** in full prescribing information and the clarithromycin package insert, **CLINICAL PHARMACOLOGY, Microbiology**.)

Treatment of Pathological Hypersecretory Conditions, Including Zollinger-Ellison Syndrome
ACIPHEX® is indicated for the long-term treatment of pathological hypersecretory conditions, including Zollinger-Ellison syndrome.

CONTRAINDICATIONS
Rabeprazole is contraindicated in patients with known hypersensitivity to rabeprazole, substituted benzimidazoles or to any component of the formulation.

Clarithromycin is contraindicated in patients with known hypersensitivity to any macrolide antibiotic.

Concomitant administration of clarithromycin with pimozide and cisapride is contraindicated. There have been post-marketing reports of drug interactions when clarithromycin and/or erythromycin are co-administered with pimozide resulting in cardiac arrhythmias (QT prolongation, ventricular tachycardia, ventricular fibrillation, and torsade de pointes) most likely due to inhibition of hepatic metabolism of pimozide by erythromycin and clarithromycin. Fatalities have been reported. (Please refer to full prescribing information for clarithromycin.)

Amoxicillin is contraindicated in patients with a known hypersensitivity to any penicillin. (Please refer to full prescribing information for amoxicillin.)

WARNINGS
CLARITHROMYCIN SHOULD NOT BE USED IN PREGNANT WOMEN EXCEPT IN CLINICAL CIRCUMSTANCES WHERE NO ALTERNATIVE THERAPY IS APPROPRIATE. If pregnancy occurs while taking clarithromycin, the patient should be apprised of the potential hazard to the fetus. (See **WARNINGS** in prescribing information for clarithromycin.)

Amoxicillin: Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported in patients on penicillin therapy. These reactions are more likely to occur in individuals with a history of penicillin hypersensitivity and/or a history of sensitivity to multiple allergens.

There have been well-documented reports of individuals with a history of penicillin hypersensitivity reactions who have experienced severe hypersensitivity reactions when treated with a cephalosporin. Before initiating therapy with any penicillin, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, and other allergens. If an allergic reaction occurs, amoxicillin should be discontinued and the appropriate therapy instituted. (See **WARNINGS** in prescribing information for amoxicillin.)

SERIOUS ANAPHYLACTIC REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH EPINEPHRINE. OXYGEN, INTRAVENOUS STEROIDS, AND AIRWAY MANAGEMENT, INCLUDING INTUBATION, SHOULD ALSO BE ADMINISTERED AS INDICATED.

Pseudomembranous colitis has been reported with nearly all antibacterial agents, including clarithromycin and amoxicillin, and may range in severity from mild to life threatening. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of "antibiotic-associated colitis".

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to discontinuation of the drug alone. In moderate to severe cases, consideration should be given to management with fluid and electrolytes, protein supplementation, and treatment with an antibacterial drug clinically effective against *Clostridium difficile* colitis.

PRECAUTIONS
General
Symptomatic response to therapy with rabeprazole does not preclude the presence of gastric malignancy.

Patients with healed GERD were treated for up to 40 months with rabeprazole and monitored with serial gastric biopsies. Patients without *H. pylori* infection (221 of 326 patients) had no clinically important pathologic changes in the gastric mucosa. Patients with *H. pylori* infection at baseline (105 of 326 patients) had mild or moderate inflammation in the gastric body or mild inflammation in the gastric antrum. Patients with mild grades of infection or inflammation in the gastric body tended to change to moderate, whereas those graded moderate at baseline tended to remain stable. Patients with mild grades of infection or inflammation in the gastric antrum tended to remain stable. At baseline 8% of patients had atrophy of glands in the gastric body and 15% had atrophy in the gastric antrum. At endpoint, 15% of patients had atrophy of glands in the gastric body and 11% had atrophy in the gastric antrum. Approximately 4% of patients had intestinal metaplasia at some point during follow-up, but no consistent changes were seen.

Steady state interactions of rabeprazole and warfarin have not been adequately evaluated in patients. There have been reports of increased INR and prothrombin time in patients receiving a proton pump inhibitor and warfarin concomitantly. Increases in INR and prothrombin time may lead to abnormal bleeding and even death. Patients treated with a proton pump inhibitor and warfarin concomitantly may need to be monitored for increases in INR and prothrombin time.

Information for Patients
Patients should be cautioned that ACIPHEX® delayed-release tablets should be swallowed whole. The tablets should not be chewed, crushed, or split. ACIPHEX® can be taken with or without food.

Drug Interactions
Rabeprazole is metabolized by the cytochrome P450 (CYP450) drug metabolizing enzyme system. Studies in healthy subjects have shown that rabeprazole does not have clinically significant interactions with other drugs metabolized by the CYP450 system, such as warfarin and theophylline given as single oral doses, diazepam as a single intravenous dose, and phenytoin given as a single intravenous dose (with supplemental oral dosing). Steady state interactions of rabeprazole and other drugs metabolized by this enzyme system have not been studied in patients. There have been reports of increased INR and prothrombin time in patients receiving proton pump inhibitors, including rabeprazole, and warfarin concomitantly. Increases in INR and prothrombin time may lead to abnormal bleeding and even death.

In vitro incubations employing human liver microsomes indicated that rabeprazole inhibited cyclosporine metabolism with an IC_{50} of 62 micromolar, a concentration that is over 50 times higher than the C_{max} in healthy volunteers following 14 days of dosing with 20 mg of rabeprazole. This degree of inhibition is similar to that by omeprazole at equivalent concentrations.

Rabeprazole produces sustained inhibition of gastric acid secretion. An interaction with compounds which are dependent on gastric pH for absorption may occur due to the magnitude of acid suppression observed with rabeprazole. For example, in normal subjects, co-administration of rabeprazole 20 mg QD resulted in an approximately 30% decrease in the bioavailability of ketoconazole and increases in the AUC and C_{max} for digoxin of 19% and 29%, respectively. Therefore, patients may need to be monitored when such drugs are taken concomitantly with rabeprazole. Co-administration of rabeprazole and antacids produced no clinically relevant changes in plasma rabeprazole concentrations.

In a clinical study in Japan evaluating rabeprazole in patients categorized by CYP2C19 genotype (n=6 per genotype category), gastric acid suppression was higher in poor metabolizers as compared to extensive metabolizers. This could be due to higher rabeprazole plasma levels in poor metabolizers. Whether or not interactions of rabeprazole sodium with other drugs metabolized by CYP2C19 would be different between extensive metabolizers and poor metabolizers has not been studied.

Combined Administration with Clarithromycin
Combined administration consisting of rabeprazole, amoxicillin, and clarithromycin resulted in increases in plasma concentrations of rabeprazole and 14-hydroxyclarithromycin. (See **CLINICAL PHARMACOLOGY, Combination Therapy with Antimicrobials** in full prescribing information.)

Concomitant administration of clarithromycin with pimozide and cisapride is contraindicated. (See **PRECAUTIONS** in prescribing information for clarithromycin.) (See **PRECAUTIONS** in prescribing information for amoxicillin.)

Carcinogenesis, Mutagenesis, Impairment of Fertility
In a 88/104-week carcinogenicity study in CD-1 mice, rabeprazole at oral doses up to 100 mg/kg/day did not produce any increased tumor occurrence. The highest tested dose produced a systemic exposure to rabeprazole (AUC) of 1.40 μg•hr/mL which is 1.6 times the human exposure (plasma $AUC_{0-\infty}$ = 0.88 μg•hr/mL) at the recommended dose for GERD (20 mg/day). In a 104-week carcinogenicity study in Sprague-Dawley rats, males were treated with oral doses of 5, 15, 30 and 60 mg/kg/day and females with 5, 15, 30, 60 and 120 mg/kg/day. Rabeprazole produced gastric enterochromaffin-like (ECL) cell hyperplasia in male and female rats and ECL cell carcinoid tumors in female rats at all doses including the lowest tested dose. The lowest dose (5 mg/kg/day) produced a systemic exposure to rabeprazole (AUC) of about 0.1 μg•hr/mL which is about 0.1 times the human exposure at the recommended dose for GERD. In male rats, no treatment related tumors were observed at doses up to 60 mg/kg/day producing a rabeprazole plasma exposure (AUC) of about 0.2 μg•hr/mL (0.2 times the human exposure at the recommended dose for GERD).

Rabeprazole was positive in the Ames test, the Chinese hamster ovary cell (CHO/HGPRT) forward gene mutation test and the mouse lymphoma cell (L5178Y/TK+/-) forward gene mutation test. Its demethylated-metabolite was also positive in the Ames test. Rabeprazole was negative in the *in vitro* Chinese hamster lung cell chromosome aberration test, the *in vivo* mouse micronucleus test, and the *in vivo* and *ex vivo* rat hepatocyte unscheduled DNA synthesis (UDS) tests.

Rabeprazole at intravenous doses up to 30 mg/kg/day (plasma AUC of 8.8 μg•hr/mL, about 10 times the human exposure at the recommended dose for GERD) was found to have no effect on fertility and reproductive performance of male and female rats.

Pregnancy
Teratogenic Effects. Pregnancy Category B: Teratology studies have been performed in rats at intravenous doses up to 50 mg/kg/day (plasma AUC of 11.8 μg•hr/mL, about 13 times the human exposure at the recommended dose for GERD) and rabbits at intravenous doses up to 30 mg/kg/day (plasma AUC of 7.3 μg•hr/mL, about 8 times the human exposure at the recommended dose for GERD) and have revealed no evidence of impaired fertility or harm to the fetus due to rabeprazole. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers
Following intravenous administration of ^{14}C-labeled rabeprazole to lactating rats, radioactivity in milk reached levels that were 2- to 7-fold higher than levels in the blood. It is not known if unmetabolized rabeprazole is excreted in human breast milk. Administration of rabeprazole to rats in late gestation and during lactation at doses of 400 mg/kg/day (about 195-times the human dose based on mg/m^2) resulted in decreases in body weight gain of the pups. Since many drugs are excreted in milk, and because of the potential for adverse reactions to nursing infants from rabeprazole, a decision should be made to discontinue nursing or discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use
The safety and effectiveness of rabeprazole in pediatric patients have not been established.

Use in Women
Duodenal ulcer and erosive esophagitis healing rates in women are similar to those in men. Adverse events and laboratory test abnormalities in women occurred at rates similar to those in men.

Geriatric Use
Of the total number of subjects in clinical studies of ACIPHEX®, 19% were 65 years and over, while 4% were 75 years and over. No overall differences in safety or effectiveness were observed between these subjects and younger subjects, and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

ADVERSE REACTIONS
Worldwide, over 2900 patients have been treated with rabeprazole in Phase II-III clinical trials involving various dosages and durations of treatment. In general, rabeprazole treatment has been well-tolerated in both short-term and long-term trials. The adverse events rates were generally similar between the 10 and 20 mg doses.

Incidence in Controlled North American and European Clinical Trials
In an analysis of adverse events assessed as possibly or probably related to treatment appearing in greater than 1% of ACIPHEX® patients and appearing with greater frequency than placebo in controlled North American and European trials, the incidence of headache was 2.4% (n=1552) for ACIPHEX® versus 1.6% (n=299) for placebo.

In short and long-term studies, the following adverse events, regardless of causality, were reported in ACIPHEX®-treated patients. Rare events are those reported in ≤1/1000 patients.

Compassion transformed into art.

Compassion and caring come in many forms, but perhaps none as expressive as The Southeastern Hospice Festival of Trees. Each year, the visions of local artists are displayed through dozens of trees themed in unique combinations of satin bows, glistening tinsel, and one-of-a-kind ornaments.

Even more enchanting is knowing behind each tree is a sponsor whose contribution helps fund the efforts of Southeastern Hospice and our new center for end-of-life care, Southeastern Hospice House.

'Tis the season for giving, and few expressions of kindness mean more than helping someone be at ease during life's most difficult time.

Sandra Inman
Brain Surgery Patient

For 23 years, Sandra has been leading church choirs.

Now she's singing our praises.

Sandra Inman has a gift for music, and it's a gift she's happy to share. Just about every week, you can find her at nursing homes in her hometown of Reidsville, leading the residents in songs of faith. Then on Sundays, there are the two church services, plus the Wednesday meeting . . . it goes on and on, and she loves every minute of it.

In the spring of 2006, however, Sandra feared her days of sharing music might soon be over. She began having difficulty concentrating and remembering things. At first, she tried to hide her problems; she just thought it was the inevitable effect of getting older. But an MRI scan revealed a large tumor spreading over nearly half her brain.

Fortunately, she was under the care of a world-class team at Moses Cone Neuroscience Center. She went into her operation buoyed by their confidence. Her doctors removed the tumor safely and told her she'd be okay. Now Sandra is back at the nursing homes every week, once again bringing music to the people she loves.

Quality Of Life Scale

A Measure Of Function
For People With Pain

0 Non-functioning	Stay in bed all day Feel hopeless and helpless about life
1	Stay in bed at least half the day Have no contact with outside world
2	Get out of bed but don't get dressed Stay at home all day
3	Get dressed in the morning Minimal activities at home Contact with friends via phone, email
4	Do simple chores around the house Minimal activities outside of home two days a week
5	Struggle but fulfill daily home responsibilities No outside activity Not able to work/volunteer
6	Work/volunteer limited hours Take part in limited social activities on weekends
7	Work/volunteer for a few hours daily. Can be active at least five hours a day. Can make plans to do simple activities on weekends
8	Work/volunteer for at least six hours daily Have energy to make plans for one evening social activity during the week Active on weekends
9	Work/volunteer/be active eight hours daily Take part in family life Outside social activities limited
10 Normal Quality of Life	Go to work/volunteer each day Normal daily activities each day Have a social life outside of work Take an active part in family life

Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

Recognizing Jean Zoda, BSN, RN

The quote from writer and humorist Leo Rosten, "I cannot believe that the purpose of life is to be happy. I think the purpose of life is to be useful…," could have been attributed to Jean Zoda, registered nurse and arthritis program instructor and advocate. But to those who know her work with the Arthritis Foundation and her advocacy on behalf of people with arthritis, Jean would probably modify the quote to say, "I believe that the purpose of life is to be happy AND to be useful." Jean has found a unique way to blend being useful to others while harvesting joy and good health for herself.

A few years ago Jean found herself 100 pounds overweight, in poor health, and unable to do more than the activities of daily living. Exercise discouraged her because it made her joints sore. Enter the Arthritis Foundation Aquatic Program. Jean decided to give water exercise a try. The water exercise classes helped Jean lose weight, recover her health, and renew her spirit. The instructor was supportive and encouraging and even suggested that Jean train to become a water fitness instructor herself. This ended up giving Jean a new life journey and a new career path.

Because of her own personal journey, her newfound commitment to exercise, and as a testament to the benefits of water exercise, Jean forged ahead with becoming an Arthritis Foundation Aquatic Program instructor. Jean's philosophy from her days of nursing, "seeing the whole person," flows into the classes she teaches. She believes it's important to support the whole person by not only providing the benefits of being in the water and exercising, but by connecting people to support groups, providing resources, and, most of all, having fun. According to Jean, "Water fitness…has to be all about FUN to keep people motivated and coming back."

Jean continues her life journey as she works to become the best instructor she can be. Jean is now a Master Trainer for the Arthritis Foundation Aquatic Program and conducts instructor courses around the state. She has become an instructor for the Arthritis Foundation Exercise Program and is always looking for opportunities to be useful to others. Jean has become an advocate for evidence-based programs for people with arthritis. She wants people to have access to exercise and self-help programs proven to be beneficial for arthritis sufferers so they do not get discouraged by ineffective programs.

Jean continues her usefulness by serving on the NC Arthritis Program Advisory Board and helping to craft the State Arthritis Plan which directs arthritis resources and services for North Carolinians through 2010. Jean also contributed as an aquatic exercise expert and advocate for the UNC TV program HealthWise: Arthritis in July 2006, and her community outreach includes promoting the Triangle Arthritis Walk for 2007. As an Arthritis Foundation volunteer, Jean promotes arthritis programs with a local continuing care retirement community and is a frequent guest speaker at Triangle-area arthritis support groups, school programs, and health fairs. Jean is particularly proud of a tremendously successful Disability Day at an area elementary school where she taught elementary-age children about arthritis and the importance of taking care of their bodies. Jean has also committed to continuing her professional growth as an arthritis advocate by attending arthritis-related conferences and seminars.

Word is getting out about Jean's advocacy and aquatic classes. Many community agencies have contacted her to come and speak. Her expertise in aquatic fitness has now broadened to include being a multiple sclerosis aquatic instructor and American Red Cross lifeguard, lifeguard instructor, and water safety instructor. She is also a member of the Aquatic Exercise Association and is a certified Aquatic Fitness Professional. In addition, she teaches weekly Arthritis Foundation Aquatic exercise classes and works part-time for the NC Arthritis Program providing technical and data support and follow-up with newly trained instructors.

Not everyone has the privilege of combining their passion and their work. Jean is one of the lucky ones. Jean will tell you, "The greatest blessing and reaffirmation of my work comes when a new participant joins my class. For example, one student recently started my arthritis aquatics class saying she couldn't do much. She had tried unsuccessfully with other types of physical activity, suffered with arthritis and fibromyalgia, and had extra weight and other health factors that barely allowed her accomplish the activities of daily living. She heard about the arthritis class at the pool and knew she needed to do something and wondered if this class would help. I just smiled at her, knowing first-hand about her journey and told her that she had come to the right place. And I began my work."

The *North Carolina Medical Journal* is proud to recognize volunteer, advocate, and professional Jean Zoda for her passion, caring, and commitment to citizens in North Carolina living and being physically active with arthritis.

Racial/Ethnic Variation in Perceptions of Medical Information Sources in Durham County, North Carolina

Jason E. Williams, MD, MPH; Kevin J. Anstrom, PhD; Joëlle Y. Friedman, MPA; Kevin A. Schulman, MD

Abstract

Background: *Concerns about health and health care disparities have led some groups to promote better communication of medical information as a potential means of empowering patients to overcome barriers to health care and to practice healthy behaviors. We examined the independent effect of race/ethnicity on perceptions of the usefulness of different sources of health information.*

Methods: *We analyzed data from a cross-sectional telephone survey of black, Latino, and white adults (n = 515) in Durham County, North Carolina, in 2002. Respondents rated the usefulness of medical information sources, nonmedical information sources, and media. We used logistic regression to determine the effect of race/ethnicity on ratings of information sources, adjusting for demographic, socioeconomic, and health status factors.*

Results: *Compared to white respondents, Latinos and black respondents were more likely to perceive as useful the local health department, ministers/churches, community centers, television, and radio. Latinos were less likely than white and black respondents to report the pharmacy as a useful source of medical information.*

Limitations: *Some findings may be particular to Durham County, especially those based on the Latino subgroup. Also, the response rate (43%) suggests that nonresponse bias may have affected our results. Finally, perceived usefulness may affect one's intent to act on information but may not correlate with the benefit gained from a particular source.*

Conclusions: *There are substantial racial/ethnic differences in perceptions of certain medical information sources. Medical information designed for minority populations may be more effective if disseminated through particular sources.*

Key Words: *Attitude to health; ethnic groups; health services accessibility; mass media; North Carolina; public opinion; social perception; social support*

Racial/ethnic minorities experience a greater burden of preventable morbidity and mortality and poorer quality of care than white patients in the United States even after controlling for access-related factors.[1-4] Concerns about health and health care disparities have led some groups to promote better communication of medical information as a potential means of empowering patients to overcome barriers to health care and to practice healthy behaviors.[1,3,5] Improved dissemination of medical information may lead to greater demand for and receipt of preventive care and other services; greater awareness and understanding of risk factors, screening tools, and treatments; greater patient and provider satisfaction; and better health outcomes.[3,5-9] Several studies have focused on patient-provider communication, but less is known about patients' attitudes and beliefs about other sources of medical information.[10-13] Because the amount of information, the number of channels employed to disseminate information, and the skills necessary to access information are increasing, enhanced understanding of

Jason E. Williams, MD, MPH, is a former medical student and research intern at the Center for Clinical and Genetic Economics, Duke Clinical Research Institute, Duke University, Durham, NC, and currently an internal medicine resident at Stanford University.

Kevin J. Anstrom, PhD, is an assistant professor of biostatistics and bioinformatics and a faculty affiliate of the Center for Clinical and Genetic Economics, Duke Clinical Research Institute, Duke University, Durham, NC.

Joëlle Y. Friedman, MPA, is a project leader at the Center for Clinical and Genetic Economics, Duke Clinical Research Institute, Duke University, Durham, NC.

Kevin A. Schulman, MD, is a professor of medicine, the director of the Center for Clinical and Genetic Economics, and an associate director of the Duke Clinical Research Institute, Duke University, Durham, NC. He can be reached at kevin.schulman@duke.edu or PO Box 17969, Durham, NC 27715.

patients' perceptions of information sources is critical.[14-16]

The source of a message and the medium used to deliver the message are key elements of effective communication.[17-19] Furthermore, previous work has suggested there may be race/ethnicity-specific preferences for sources of medical information.[20-26] These studies have suggested that higher proportions of racial/ethnic minorities use medical personnel and electronic media (ie, television and radio) as information sources whereas higher proportions of white persons use print media (ie, newspapers, magazines, and books). Previous studies, however, have some limitations. First, previous studies have investigated the frequency of use of medical information sources but not the usefulness of those sources. Although frequency of use may reflect usefulness, frequency may also be influenced heavily by exposure to information sources. Second, previous studies have evaluated a narrow set of traditional sources of medical information. Given the rapidly increasing use of the Internet as a source of medical information as well as the variety of other information sources such as churches, family, and friends, it is important to analyze responses to these sources. Third, previous studies typically focused on persons with specific medical conditions (usually acquired immunodeficiency syndrome or cancer) and compared only 2 racial/ethnic groups.

If efforts to educate and empower patients are to succeed in helping to eliminate disparities, providers and public health practitioners must consider patients' use and perceptions of various sources of medical information. Minorities' perceptions of information sources are important because they are related to trust. Previous studies have shown connections between race/ethnicity, trust, and interactions in medicine and medical research.[22,27-28] Given new sources of information and recent demographic and health care trends in North Carolina, health practitioners would benefit from studies of medical and nonmedical information sources in a wider spectrum of racial/ethnic groups and asymptomatic individuals. The objective of this study was to investigate independent associations between race/ethnicity and perceptions of the usefulness of various sources of medical information.

Methods

Data for this study are from a cross-sectional, community-based survey designed to assess attitudes, perceptions, and beliefs about access to and quality of health care among black, Latino, and white persons residing in Durham County, North Carolina. The survey contained 40 items addressing a range of issues including personal health, perceptions of various sources of medical information, personal experiences in the health care system, knowledge of racial/ethnic differences in health and health care, and demographic characteristics. Many of the items were adapted from a national survey by the Kaiser Family Foundation.[29] Additional survey items were drawn from the California Health Interview Survey, El Centro Hispano Survey–Proyecto Life, and a literature review.[30-31] We made further modifications after conducting a provider survey (administered through a local independent practice association) and interviewing community leaders. Finally, we conducted interviews with Latino and black community members to assess content validity and to ensure that an exhaustive list of precoded responses was included in the survey. The survey was translated into Spanish and back-translated into English to ensure that the English and Spanish versions were consistent. Due to the survey's length, we split the survey into 3 components (a core survey, a set of questions for split-half sample 1, and a set of questions for split-half sample 2) and asked all participants to complete the core survey and 1 of the split-half set of questions.

Sample

Eligible participants were adults aged 18 years and older residing in Durham County, North Carolina, in households with telephones. The sample was designed to generalize to the Durham County adult population and to allow for analyses stratified by race/ethnicity. Two separate samples were used for all interviews. The first sample was obtained using a standard, list-assisted, random-digit dialing procedure. Active blocks of telephone numbers (area code + exchange + 2-digit block number) that contained 3 or more residential directory listings were selected with probabilities in proportion to the number of listed phone numbers. After selection, 2 more digits were added randomly to complete the number. The resulting numbers were compared with business directories, and matching numbers were removed. Telephone exchanges with greater than average density of black households were oversampled to increase the overall sample of black respondents. For the second sample, to achieve an oversampling of Latino respondents, participants were recruited by random-digit dialing from a list of households with Latino surnames. We selected this approach because Durham has few Latino households.

We used survey weights to adjust for the sample design (ie, oversampling of black and Latino populations) and for any nonresponse bias. Specifically, the survey weights helped to ensure that the study sample resembled the population of Durham County with respect to age, sex, and education level. Additional details of the survey weighting process are available from the authors upon request.

Survey Administration

The telephone interviews were conducted between October 14 and December 16, 2002, in either English or Spanish based on participant preference. A minimum of 15 attempts were made to contact a potential respondent at each sampled telephone number. The interviewers used a standard screening technique used by major policy research organizations and designed to obtain the best distribution of male and female respondents. Interviewers asked to speak to the youngest male at home. If a male was not available, interviewers asked to speak with the oldest female at home. Interviewers contacted 2615 people by phone, and 1415 (54%) agreed to participate. Of the 1415 consenting households, 1175 (83%) met eligibility criteria. Ninety-six percent (1131/1175) of consenting and eligible households completed the survey, either split-half sample 1 or split-half sample 2. The analysis presented here focuses on the

515 participants who responded to split-half sample 1 and identified themselves as black, Latino, or white. The institutional review board of the Duke University Health System approved the study.

Dependent and Independent Measures

The primary outcome of interest was the perception of the usefulness of 12 sources of medical information. Participants were asked, "How useful do you think the following sources are for medical information for yourself?" Possible responses were "very useful," "somewhat useful," "not too useful," "not useful at all." If participants did not use a particular source, they could also choose the responses "don't know" or "refuse to respond." The sources of medical information were medical personnel sources (ie, doctors, nurses, pharmacists, health department personnel), nonmedical sources (ie, ministers and churches, community centers, friends and relatives, libraries), and media (ie, Internet, newspapers and magazines, radio, television).

Self-reported race/ethnicity was the primary independent variable. Participants were asked if they were of Latino descent and then asked to indicate their race (Asian, black, white, or other). Because of small cell sizes, we excluded participants who indicated that their race was Asian or other. In the remaining sample, we coded participants of Latino descent as Latino, and we coded all others as black or white. In addition to race/ethnicity, we collected data on demographic characteristics, socioeconomic characteristics, health status, and health care experience.

Demographic and socioeconomic variables included sex, age, education level, marital status, employment status, financial status, facility with English, and country of origin. Financial status was assessed by asking about participants' current financial situation. Possible responses included "having difficulty paying the bills, no matter what," "enough money to pay the bills, but have to cut back," "enough money to pay bills, but little to spare for extras," "bills are paid and still have enough for extras," and "don't know" or "refused to answer." All participants who were interviewed in Spanish were asked, "If you have to speak in English on the telephone, would you say you can speak in English very well, somewhat well, or not too well?" Country of origin was coded as United States or other.

Health status and health care experiences were assessed by self-reported health (excellent, very good, good, fair, poor), diagnosis of 5 chronic diseases (diabetes mellitus, hypertension, lung disease, heart disease, cancer), type of health insurance, possession of a usual source of care, and time since last physician visit (within the past year, more than 1 year and up to 2 years, more than 2 years and up to 5 years, and more than 5 years).

Statistical Analysis

Weighting was used to adjust for features of the sample design (oversampling of black and Latino populations) and for bias that may have resulted from nonresponse. To determine whether an information source was perceived as useful, the outcome variable was dichotomized. Responses of "very useful" and "somewhat useful" were collapsed into "useful," and responses of "not too useful" and "not useful at all" were collapsed into "not useful." Responses of "don't know" and "refused" were excluded from further analysis due to small cell sizes. We dichotomized age (less than 40 years, 40 years or older), education level (less than high school degree, high school degree or more), marital status (married, other), and employment status (employed, unemployed). We dichotomized financial status as less wealthy (participants reporting difficulty paying bills or those able to pay the bills with cutbacks) and more wealthy (those with "enough for extras" or "little to spare for extras"). We dichotomized health status as more healthy (excellent or very good) and less healthy (good, fair, poor), insurance status as insured (private and Medicare/Medicaid) and uninsured, and time since last physician visit as more recent (within 1 year) and less recent (all responses greater than 1 year).

We then performed univariate analyses to assess differences by race/ethnicity in perceptions of medical information sources. Chi-square tests were used to compare the groups. Next, we performed bivariate analyses to test associations between respondents' race/ethnicity and the perceived usefulness of information sources, calculating unadjusted odds ratios. We also tested for associations between covariates and perceptions of medical information sources.

We then developed multiple logistic regression models to assess the independent association between race/ethnicity and the perceived usefulness of medical information sources. Before conducting multivariate analyses, we assessed collinearity of variables and developed groups of meaningful predictors. We used a sequential modeling approach and arrived at 2 models. The first model included the variables for age, sex, education, marital status, employment status, and financial situation. The second model included the factors above along with perceived health status, insurance status, possession of a usual source of care, and time since last physician visit. Data analysis was performed in STATA (StataCorp, College Station, TX).

Results

Table 1 gives the demographic, socioeconomic, and health characteristics of the survey respondents by race/ethnicity. The sample included roughly equal proportions of black, Latino, and white respondents. The Latino subgroup was younger, had a higher proportion of men, and had less formal education than the black and white subgroups. Most respondents were employed at the time of the interview. The proportion of respondents who reported excellent or very good health was highest for white respondents. The prevalence of chronic conditions was similar among the subgroups. Black and white respondents were more likely than Latinos to have health insurance and a usual source of care.

As shown in Table 2, all subgroups perceived doctors and nurses as useful sources of information. Perceptions of other sources of information varied. For example, black and Latino respondents more often perceived ministers and churches, community centers, and television as useful sources of medical

* Values are expressed as weighted percentage unless otherwise indicated.

information, compared to white respondents. Perceptions of print media and the Internet did not vary substantially.

Unadjusted associations between respondent characteristics and perceived usefulness of information sources were also examined. The pharmacy was perceived as useful by respondents who had more education, and the health department was cited as useful by respondents who were younger, less educated, less healthy, and uninsured. The odds of perceiving a minister, church, or community center as a useful source of information were higher for respondents without a high school diploma and those who were less wealthy, less healthy, and uninsured. Radio and television were seen as more useful by respondents who had less education and poorer health and those who were uninsured. Interestingly, respondents with less education and wealth, poorer health, and without insurance found most of these sources (excluding the pharmacy) to be useful as compared to their better educated, wealthier, healthier, and insured counterparts.

As shown in Table 3, controlling for demographic and socioeconomic characteristics and health status, significant differences persisted in the ways Latinos and black respondents perceived the health department, the pharmacy (for Latinos only), ministers and churches, community centers, television, and radio, as compared to white respondents. In most cases, the model controlling for demographic and socioeconomic variables accounted for part of the racial/ethnic difference (data not shown). The model controlling for both demographic and socioeconomic characteristics and health status also did not fully explain the racial/ethnic differences observed in univariate analyses.

Discussion

Although there have been suggestions that we can reduce health disparities by educating and empowering persons from racial/ethnic minority groups, there is little information on the effect of perceptions of the tools used to educate and empower. This study found persistent racial/ethnic variation in perceptions of several sources of medical information. Compared to white respondents, Latinos and black respondents were more likely to rate health departments, ministers, churches, community centers, television, and radio as useful sources. In addition, Latinos were less likely to report pharmacies as useful sources. These differences remained after controlling for demographic, socioeconomic, and health-related factors.

In the literature on race/ethnicity and sources of medical information, most studies have surveyed respondents with specific health conditions and have examined the actual use of information sources rather than perceptions of those sources. Still, these reports have been somewhat consistent with our findings in that they also detected racial/ethnic variations for certain sources of information. Cunningham et al[24] found that black respondents were more likely than white respondents to

report using religious organizations, public health agencies, government sources, family, and friends for information about acquired immunodeficiency syndrome. Surveying black and Hispanic respondents, O'Malley et al[21] found variation in the use of health providers and radio as sources of information. Nicholson et al[25] found differences between white and black women in the use of print news media, computer-based resources, and health policy organizations. Other studies dealing with individuals' perceptions of sources of medication information for human immunodeficiency virus, cigarette smoking messages, and cancer treatment have also found racial/ethnic differences.[20,22,26]

Although some of our findings are similar to those of previous studies, the present study offers a number of contributions in this area. First, instead of using frequency of use as a measure of usefulness, we asked about the usefulness of the information sources directly. This allowed us to measure individuals' attitudes toward the sources. Second, we were able to measure an independent effect of race/ethnicity by controlling for demographic, socioeconomic, and health-related factors. Third, our study examined a broader spectrum of individuals and types of information than have other studies. We compared individuals from 3 racial/ethnic groups with different health status and asked about medical information in general rather than about information on one particular disease or health issue. Fourth, we included a wide range of information sources including some newer sources of medical information.

This study has some limitations that may affect the generalizability of the results. First, the study design sought to create a sample that was representative of one county's population rather than of the United States. Thus, some response patterns may be particular to Durham County. Conclusions based on the Latino subgroup are particularly vulnerable to this limitation. The arrival of large numbers of Latinos to Durham County is a relatively recent trend.[32] Ninety-five percent of Latinos in this study were born outside of the United States, compared to 49% in the national study by the Kaiser Family Foundation.[29] Due to recent "hypergrowth" in the Latino population in Durham County, there may not be an adequate supply of culturally and linguistically appropriate resources. In addition, Durham's

Latinos may be less acculturated than Latinos in other areas. Second, we tried to reduce confounding by controlling for demographic, socioeconomic, and health-related factors, but these factors are complex and some residual confounding certainly remained. For example, previous research has suggested that the correlation between self-reported health status and health indicators is less valid in Latino populations.[33] Third, although the response rate in this study was within the range of similar surveys of this type, the response rate increases the likelihood of some degree of bias in the results.[34] We attempted to correct for nonresponse bias by assigning weights to key demographic variables to arrive at a sample that more closely resembled Durham County's population. Finally, perceived usefulness may affect one's intention to act on information but may not always be correlated with the actual benefit gained from a particular source.

Using cross-sectional survey data, we found racial/ethnic differences in perceptions of the usefulness of various sources of medical information. Health professionals have struggled to construct high-quality informational messages that reach minorities, augment their health knowledge base, and alter their behaviors. When constructing messages designed for minorities, health professionals have begun to realize they should consider race/ethnicity when creating the format and content of the message. The present study suggests that race/ethnicity should also be considered when selecting the source that will be used to disseminate the message. Sources deemed useful by minorities should be used to spread messages that are particularly relevant to these groups. As an example, health practitioners seeking to reach minorities might consider forming new or stronger partnerships with churches and ministers because both black and Latino respondents seem receptive to health messages from these nontraditional sources of medical information. Health practitioners might also consider increasing the use of media to deliver health messages because these also seem to be trusted sources in some minority communities.

The subject of race/ethnicity and the transmission of medical information is a fertile area for further investigation that has received little previous attention. In our study we found racial/ethnic differences in perceptions of sources of medical information. Future studies should investigate the types of messages received and how these messages are integrated into health behaviors and beliefs about health care services. **NCMJ**

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

ARTICLE

Emergency Contraception for Sexual Assault Victims in North Carolina Emergency Departments

Amy Tucker Woodell, MPH; James Michael Bowling, PhD, MA; Kathryn E. Moracco, PhD, MPH; Melissa L. Reed, MA

Abstract

Introduction: *One in 5 women is a victim of sexual assault. This study examines the administration of emergency contraception to victims of sexual assault in North Carolina hospital emergency departments.*

Methods: *One hundred seventeen surveys were mailed to hospital emergency departments across the state to determine their emergency contraception practices for victims of sexual assault. The survey contained 11 questions about emergency contraception practices for victims.*

Results: *Of the 117 surveys, 103 were returned revealing that just over 50% of the hospitals in North Carolina treated victims with emergency contraception without exception. Both dispensing emergency contraception and providing information about emergency contraception were significantly associated with having a sexual assault nurse examiner program.*

Conclusion: *Results from this study demonstrate inconsistent provision of emergency contraception to victims of sexual assault; however, there is greater consistency of emergency contraception use by emergency departments using sexual assault nurse examiners.*

Grants: *None*

Keywords: *Contraception, postcoital; emergency nursing; rape*

Pregnancy resulting from sexual assault is a traumatic experience, but it is preventable with emergency contraception, a high dose oral contraceptive that prevents pregnancy if taken within 120 hours after intercourse, often referred to as the "morning-after pill." Emergency contraception cannot harm or terminate an established pregnancy.

Previous research has shown that hospitals do not consistently provide emergency contraception to victims of sexual assault.[1-5] One study of emergency physicians found 8.4% would not prescribe emergency contraception to sexual assault victims.[1] A 2002 national study of Catholic and non-Catholic hospitals by Harrison found that emergency contraception was not available at 55% of Catholic hospitals and 42% of non-Catholic hospitals.[6] A report by Patel et al[7] found that 55% of Pennsylvania hospitals had emergency contraception available onsite, and 37% offered both counseling for and provision of emergency contraception. Eighty-five percent of the 201 responding hospitals in a NY survey said it is their standard policy to dispense emergency contraception immediately, onsite, to all rape victims who choose it after having been counseled.[8]

Nationally, 1 in 5 women reports being sexually assaulted at some point in her life.[9] Timely provision of emergency contraception prevents the additional psychological and physical trauma an unwanted pregnancy may cause a victim of sexual assault. Five percent of rapes result in pregnancy.[10] This translates to 25 000 rape-related pregnancies each year in the United States, 22 000 of which could be prevented with emergency contraception.[11]

Accordingly, several medical professional organizations, including the American College of Obstetricians and

Gynecologists,[12] the American College of Emergency Physicians,[13] and the American Medical Association,[14] have recommended that pregnancy prophylaxis, such as emergency contraception, be provided to victims of sexual assault.

Across the state, there are hospitals with sexual assault nurse examiners who are specially trained to provide care to patients who have been sexually assaulted including offering emergency contraception and collecting forensic evidence. Fifty-one percent of North Carolina hospitals have a sexual assault nurse examiner program.

In 2004, the North Carolina Coalition Against Sexual Assault, Planned Parenthood of Central North Carolina, and NARAL Pro-Choice North Carolina, under the umbrella organization of North Carolina Women United, investigated whether emergency contraception was available to sexual assault victims in emergency departments. The purpose of this exploratory study was to present point estimates of emergency contraception use across North Carolina hospitals and then to examine variation in use of emergency contraception by hospital characteristics.

METHODS

Study Design

Self-administered questionnaires were mailed to North Carolina hospitals with emergency departments. The 11-question self-administered questionnaire addressed emergency department policies for dispensing emergency contraception to sexual assault victims and giving referrals to sexual assault victims. Further, hospital representatives were asked, "Is it standard policy for the hospital to dispense emergency contraception onsite to sexual assault survivors?" Participants who responded affirmatively were classified as having an emergency contraception policy.

We also assessed the presence or absence of a refusal clause, or "conscience clause," in the questionnaire. Responders that dispensed emergency contraception were asked, "Are there any exceptions to your policy based on the refusal of the provider on duty to dispense medication?" If hospitals did not provide emergency contraception or there were exceptions to their policy, they were asked if they provide prescriptions for emergency contraception or referrals to other providers.

Hospitals were also asked if they had a sexual assault nurse examiner program. Sexual Assault Nurse Examiners are defined by the North Carolina Coalition Against Sexual Assault as "specially trained Registered Nurses who perform a comprehensive evaluation and assessment, collect high quality evidence, and provide expert testimony in cases of sexual assault." Developing a sexual assault nurse examiner program was not considered as having a program because there is not automatic intervention. In addition, emergency departments were asked if these nurses are available 24 hours a day, seven days a week.

Other data collected included the title of the staff person who completed the questionnaire, hospital name, number of sexual assault victims treated per year in the emergency department, and other questions regarding emergency department practices for the treatment of sexual assault victims.

Hospital size was dichotomized according to bed number based on the median of 143 beds. Hospitals were classified as being located in a metropolitan area, micropolitan area, or neither according to the US Office of Management and Budget definitions of 2003. A metropolitan area has at least one urbanized area of at least 50 000 people, a micropolitan has an urban center of 10 000-49 999 people, and unclassified counties have towns with fewer than 10 000 people.[15] Metropolitan area is referred to as a large population and the micropolitan and "neither" areas were collapsed into one category for statistical analysis and referred to as a small population. Open-ended answers, such as title of hospital responder, were grouped and coded. Answers for "check all that apply" questions were each coded individually as checked or not checked.

Setting and Selection of Participants

Sample and setting were drawn from The North Carolina Hospital Association membership directory excluding hospitals without an emergency department, specialty hospitals, or psychiatric hospitals. Military hospitals (n=4), which are not NC Hospital Association members, were also included in the survey due to a particular interest in the policies of North Carolina military facilities by the survey sponsors. Hospitals were also excluded from the sample if they reported that they routinely transferred sexual assault victims to another emergency department (n=2).

Fifteen nonmember hospitals were not surveyed due to a lack of identifying information for these hospitals. Five of these nonsurveyed hospitals were specialty hospitals, and two others did not have emergency departments, leaving a possible 8 missed hospitals (2 with emergency departments, 6 unknown). Two questionnaires received from emergency departments belonging to hospital systems with one shared policy for the treatment of sexual assault victims were duplicated as representative responses for each of those emergency departments within those hospital systems. In all, we collected data from 117 eligible North Carolina hospital emergency departments. The NC Hospital Association directory data contained the names of hospital administrators, bed numbers, hospital ownership, and county location.

Methods of Measurement

We used data from the Emergency Care for Sexual Assault Survivors Survey collected in late 2004 and early 2005 by North Carolina Women United and the North Carolina Coalition Against Sexual Assault as well as supplemental information retrieved from the 2004 North Carolina Hospital Association Membership Directory.[16] The University of North Carolina at Chapel Hill's Office of Human Research Ethics Public Health Institutional Review Board (IRB) reviewed the application to complete a secondary analysis and determined that it was exempt from IRB governance.

The above mentioned questionnaire, Emergency Care for Sexual Assault Survivors Survey, was developed by the survey sponsors in consultation with Family Planning Advocates of New York state and pretested with 2 hospital individuals

Table 1.

*** Sample size of 50 for this question due to 2 missing responses

familiar with emergency department policies for sexual assault victims and 2 researchers with survey expertise. A questionnaire with a cover letter from the survey sponsors was mailed to each hospital's chief executive officer, director of nursing, hospital attorney, and medical director of the emergency department. These 4 positions were sent questionnaires to replicate the protocol from the New York survey of emergency departments.[7] Up to 3 calls were made to nonresponders and questionnaires were faxed to nonresponding hospital emergency departments. At the end of the questionnaire, participants could request that a listing of local rape crisis centers and sexual assault nurse examiners, a sexual assault and health care fact sheet, and a fact sheet about emergency contraception in the emergency department be sent to them.

After the data were collected and compiled, data entry was crosschecked with the original questionnaires for accuracy. When more than one questionnaire was received from a hospital (n=12), the questionnaire completed by the higher-ranking staff member (n=6) or the questionnaire filled out more completely was included in the sample (n=6). Comments written in the margins of each questionnaire were used for clarification of responses. Follow-up phone calls were made to allow hospitals to confirm their answers when inconsistencies were found for specific questions of interest. When these attempts to contact hospitals were successful, this resulted in modifications to original questionnaire responses to reflect the most accurate information.

Data Analysis

Data were analyzed using SAS System for Windows Version 8 (SAS Institute Inc, Cary, NC), and frequencies and chi-square analyses were performed.

RESULTS

One hundred three hospitals responded to the survey for a response rate of 88%. More than half of these hospitals are privately owned. The number of beds in each hospital ranged from 6 to 989 with a median of 143 beds. Various staff from hospital emergency departments completed the questionnaires including directors of emergency departments, nurse managers and directors of nursing, registered nurses, sexual assault nurse examiner coordinators, sexual assault nurse examiners, clinical directors, medical directors of the emergency department, and emergency department managers.

The majority of hospitals reported treating 50 or fewer sexual assault patients each year; one hospital reported treating more than 200. Eighty-three percent of hospitals report that it is standard policy to provide information about emergency contraception to sexual assault victims. Seventy-four percent of hospitals dispense emergency contraception onsite to sexual assault victims as standard policy, but 9 of these allow exceptions based on the refusal of the physician on duty and 12 did not answer the exception question. This leaves 53% of hospitals dispensing emergency contraception onsite without exception. (See Table 1.) Seventy percent of hospitals report that emergency contraception is available 24 hours a day. Of the 27 hospitals for which it is not standard policy to dispense emergency contraception, 63% provide prescriptions and 60% refer to another provider. Eighty-nine percent of hospitals refer all sexual assault victims for follow-up counseling, and 88% reported referring specifically to a rape crisis center. Sexual assault nurse examiner programs are established at half of the hospitals, and more than half of these are available 24 hours a day, seven days a week. (See Table 1.) Hospitals with a sexual assault nurse examiner program are significantly more likely to provide information about emergency contraception (92% vs 72%; $p<0.05$) and to dispense emergency contraception (77% vs 46%; $p<0.05$) (see Table 2).

A significant association was also found between a hospital dispensing emergency contraception and its location in an area with a small population versus a large population. Hospitals in areas with small populations are less likely to have a standard policy to dispense emergency contraception compared with hospitals located in large population areas (45% small vs 74% large population hospitals; $p<0.05$). (See Table 2.) Hospitals located in small population areas were less likely than those in large population areas to have a standard policy to provide information about emergency contraception (78.6% vs 86.3%). This association, however, was not significant ($p>0.05$).

Hospitals in large population areas were more likely to have sexual assault nurse examiner programs. In areas with large

populations, 60.8% of hospitals have sexual assault nurse examiners, and in areas with small populations, 41% have sexual assault nurse examiners (p=0.05).

Limitations

There were several limitations to this study. One potential limitation is that not all hospitals with emergency departments were included; 19 hospitals were not NC Hospital Association members at the time of this survey. However, at most, only 8 of these could have been eligible for this study, which would have resulted in a response rate of 82%. Of the hospitals that did respond, there were several cases in which data were missing due to incomplete data. Item nonresponse occurred on questions regarding how many sexual assault survivors were served (n=1), whether or not the hospital allows exception to their policy to provide emergency contraception based upon the provider on duty (n=12), the availability of emergency contraception 24 hours a day (n=11), the presence/absence of a sexual assault nurse examiner program (n=1), and availability of a sexual assault nurse examiner program 24 hours a day (n=2). However, the strength of the survey was the overall high response rate.

Questionnaires were not anonymous; therefore, responders may have been influenced to answer questions in ways they deemed to be more socially acceptable to the survey sponsors, particularly the North Carolina Coalition Against Sexual Assault. However, survey questions focused on hospital policies and services, not on personal attitudes or behaviors; therefore, the level of social acceptability bias influencing survey responses should be minimal. Personal bias or interpretation poses another question about reliability and validity of the instrument as well as the study.

Different hospital staff members responded to the survey, which may affect the comparability of responses. However, because the information requested was on hospital policy, respondents' differing positions should not have greatly influenced variability in responses. The method of follow-up phone calls introduces the possibility of a mixed-mode effect to responses, as the original survey was a written questionnaire.[17]

CONCLUSION

In North Carolina, a little more than half of hospitals dispense emergency contraception without exception. Both dispensing emergency contraception and providing information about emergency contraception were significantly associated with having a sexual assault nurse examiner. Almost all hospitals that operate emergency rooms offer information on emergency contraception to victims of sexual assault, and most refer victims to some form of counseling. In addition, hospitals in metropolitan areas were also more likely to dispense emergency contraception.

Our findings indicate that timely access to emergency contraception may be limited by hospital policy and practices. For example, it is of concern that in the one-quarter of hospitals that did not dispense emergency contraception onsite, one-half provided either a referral to another provider or a prescription, measures that are not considered adequate alternatives to dispensing onsite, particularly for a time-sensitive treatment such as emergency contraception. Previous research by Harrison[6] found most referrals provided by hospitals that did not provide emergency contraception were ineffective. Furthermore, in this study, 14% of the hospitals that dispense emergency contraception had exceptions based on the preference of the physician on duty, which could also limit timely access to emergency contraception.

This study's results indicate that emergency departments should (a) change hospital policies to meet the needs of the victim rather than the preference of the provider by creating standing orders so that emergency contraception can be provided regardless of the physician on duty and (b) institute sexual assault nurse examiner program affiliation or training to ensure that treatment for sexual assault includes pregnancy prevention prophylaxis. Hospitals, particularly those in rural areas, would benefit from having sexual assault nurse examiners, preferably available 24 hours a day, to ensure that sexual assault victims receive the optimal complement of services.

Several states have taken legislative action to ensure the provision of emergency contraception for sexual assault victims. As of October 2006 11 states[a] required emergency departments to provide emergency contraception-related services or information to sexual assault survivors. Two bills introduced during the 2007-2008 NC General Assembly session (House Bill 961 and NC Senate Bill 968) would require North Carolina hospitals to provide emergency contraception onsite to sexual assault victims in emergency departments. However, measures must be taken to guarantee that any policies and legislation put into place are adhered to and fully implemented. **NCMJ**

Perceived Barriers to Physical Activity Among North Carolinians With Arthritis:

Findings From a Mixed-Methodology Approach

Kathryn Remmes Martin, MPH; Britta Schoster, MPH; Jack H. Shreffler, PhD; Andrea Meier, PhD; Leigh F. Callahan, PhD

Abstract

Background: *A goal of the North Carolina Arthritis Plan is to reduce arthritis burden through regular physical activity. We identified community and personal factors that influence physical activity in individuals with arthritis.*

Methods: *In 2004 and 2005, 2479 individuals (53% self-reported arthritis) from 22 North Carolina communities completed a telephone survey (59.5% response rate) assessing health status, neighborhood characteristics, health attitudes, and demographic variables. Qualitative discussions (N=32) were conducted to further examine understanding of community and health and were enhanced with photographs.*

Analysis: *Descriptive analyses were conducted. A 2-sided binomial test (for each reason given for not being physically active) was used to test for significance between individuals with arthritis and the general population, using a Bonferroni test for multiple comparisons. Interviews and photographs were analyzed using qualitative software ATLAS.ti Version 5.0.*

Results: *Quantitative results show similar community-level reasons for physical inactivity (rural environment, heavy traffic, and lack of sidewalks) despite arthritis status. Yet personal reasons differed as individuals with arthritis more often cited physical inability and illness. In qualitative discussions, walking surfaces emerged as a primary barrier for those with arthritis.*

Limitations: *Findings from this exploratory study may have limited generalization and warrant further study.*

Conclusions: *The built environment and personal barriers should be considered when examining physical activity in individuals with arthritis.*

Key words: *Physical activity, community, neighborhood, perceived barriers, mixed-methodology, focus groups.*

Currently 27% or 1.75 million North Carolinians report some form of arthritis.[1,2] Estimates suggest that over 46.4 million adults in the United States (21.6%) report doctor-diagnosed arthritis,[3] with an estimated financial burden of $128 billon in 2003.[4] Additionally, about 19 million Americans (8.8%) have activity limitations caused by their arthritis,[3] and in 2005 activity limitations due to arthritis affected approximately 11% of adults in North Carolina.[2] Arthritis is the most frequently cited chronic condition for limiting activity among working-age and older adults.[5]

Both Healthy People 2010 and the North Carolina Arthritis Plan 2007-2010 set goals of increasing the amount of physical activity for the general population and for individuals with arthritis so as to decrease risk of chronic disease and increase both mental and physical benefits.[2,6] People with arthritis are encouraged to engage in regular physical activity to gain benefits of prolonged and increased function, increased mobility, flexibility, and decreased pain.[7-10] Yet recent studies have found that physical inactivity levels range from 24% to 39% in adults with arthritis.[11-15] These high rates of physical inactivity may

demonstrate the complexity of a behavior that is influenced not only by individual beliefs and perceptions of personal barriers but also by the built and social environments.

Public health researchers linked the environment to health and health outcomes long ago.[16-21] Recent research has focused on identifying and measuring characteristics of the built environment that influence physical activity levels using both subjective[22-26] and objective[27-29] methods. One review focused on the built environment found that access to facilities, availability of physical activity options, crime and safety, weather, and aesthetics were most often associated with physical activity in adults.[30] Few studies have examined the role of the built environment on physical activity in individuals with arthritis. However, known barriers to physical activity in individuals with arthritis are financial cost and lack of access to exercise facilities,[15] no transportation, lack of programs, and poor environmental conditions (eg, weather, congested parking, concrete surfaces, presence of dogs, lack of sidewalks).[31]

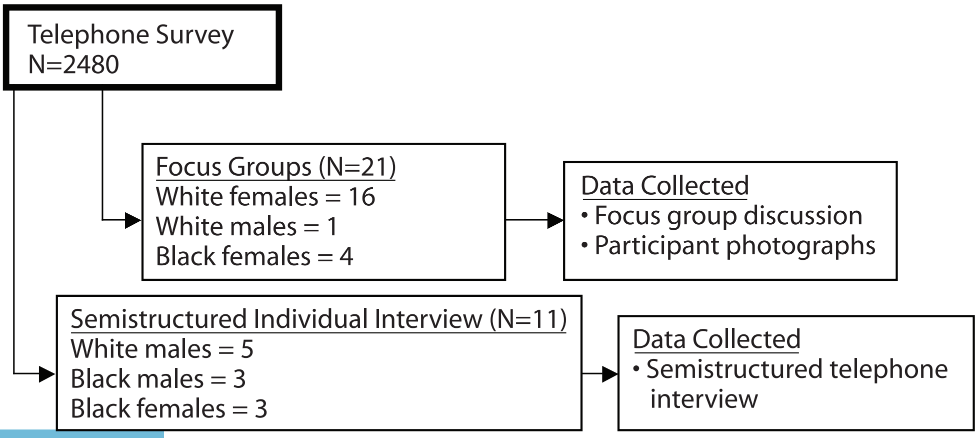
The aims of this study are twofold: (1) to understand the difference between people with and without arthritis when examining the perception of community built environment's influence upon physical activity; and (2) to identify the issues related to the built environment that are influential to the physical activity levels of individuals with arthritis. This study uses mixed methodology to evaluate both quantitative and qualitative data related to physical activity. Data were obtained through telephone surveys about general health and well-being and qualitative discussions.

METHODS

Participants and Data Collection

A cohort of 6700 participants were recruited from the NC Family Medicine Research Network.[32] The NC Family Medicine Research Network is a practice-based patient cohort for primary care research that was established in 2001 and enriched in 2004 and 2005. It currently consists of 25 practice sites. All consecutive patients (for 20 working days) seeking care at a North Carolina Family Medicine Research Network site were informed of the North Carolina Health Project. Eligible participants were those aged 18 years and older who spoke English or Spanish fluently. All study components were approved by the Medical Institutional Review Board of the University of North Carolina at Chapel Hill and all participants gave oral consent. Data sources are depicted in Figure 1.

Figure 1.
Data Collection Framework, North Carolina, 2004-2005.



Telephone Survey

Recruitment. Of the 6700 NC Family Medicine Research Network participants enrolled in 2001 and 2004, 4442 gave consent for follow-up. Participants meeting eligibility criteria (current address, telephone number, and the ability to speak English fluently) were initially mailed an introductory letter and later telephoned. A total of 277 individuals were ineligible because they lived outside the US, had no telephone, had a language barrier, were medically unable, were active military, were incarcerated, or had died. The telephone survey was completed by 2479 individuals, 59.5% of eligible participants. The 30-minute survey contained open- and close-ended questions assessing health status, chronic health conditions, community and neighborhood characteristics, health attitudes and beliefs, and demographics.

Measures. For this study, demographic measures, comorbid conditions, body mass index (BMI), community characteristics, and reasons for physical inactivity were analyzed. We calculated age using date of birth and date of the telephone interview. Education was recorded as highest grade of school completed and converted to 5 categories: less than high school, high school degree, some college, college degree, and postgraduate. Race and ethnicity data were categorized as non-Hispanic white, non-Hispanic black, and other. Participants were asked if they had ever seen a health professional for 18 different chronic conditions. The number of comorbid conditions is a sum of all self-reported comorbid conditions including arthritis. Arthritis status was determined according to the Behavioral Risk Factor Surveillance System definition of self-reported doctor diagnosis of arthritis.[33,34] For the purpose of this study, anyone self-reporting any type of doctor-diagnosed arthritis (eg, osteoarthritis, gout, rheumatoid arthritis, fibromyalgia) was included as having arthritis. Body mass index (BMI) was calculated from self-reported height and weight using the US Customary System to Metric (BMI=kg/m^2).

Questions regarding community and personal reasons for physical inactivity came from the 2000 Behavioral Risk Factor Surveillance System Questionnaire. Participants were asked in an open-ended question to list up to 3 things in their community or neighborhood that kept them from being more physically active. Participants were then asked, "Do you have access to places to be physically active?" with 4 response options.[35] Several questions assessed their perception of safety from crime and the presence of neighborhood characteristics such as sidewalks, walking/jogging/biking trails, heavy traffic, street lights, and unattended dogs.[36]

Focus Groups

Focus groups were conducted to enrich the quantitative telephone survey data by further examining community influences on health.

Recruitment. We recruited participants who had completed a telephone survey from 6 of the 25 sites specifically chosen for geographic and demographic diversity. They were contacted first by letter and then followed up with telephone invitations.

Photograph Component. To prepare for the focus groups, we asked participants to take pictures of objects and scenes in their communities that—on a typical day—either helped or hindered their health. The pictures were used to stimulate discussions of different aspects of community and health. We mailed participants a package containing a disposable camera and camera use instructions. Taking photographs was encouraged but not required for participation.

Conducting the Focus Group. Seven focus groups were held in the southeast, central, and western parts of North Carolina in urban and rural communities with 21 total participants (Range: 2-5 participants per group; average 3). Focus groups lasting 1.5 hours met at well-known community buildings (eg, senior centers, libraries) and were cofacilitated by 2 trained leaders with digital audio-recordings and hand transcription conducted at each session.

Participants were asked to describe their community and neighborhood and then discuss those community factors that they believed influenced their health. They were specifically probed on 7 topics: community connectedness, crime/safety, eating habits, environment, occupation, physical activity, and services/resources available in their community.

Focus group leaders invited participants to share their photographs if the participants believed the picture represented the topic being discussed. Participants received $20 for their participation.

Semistructured Individual Interviews

Recruitment. Because our focus groups were small and composed mostly of white women, we purposefully recruited an additional 11 individuals who were demographically underrepresented (3 black men, 3 black women, and 5 white men) in order to incorporate their perceptions into our qualitative findings. Semistructured interview participants were recruited from the same contact list we used for recruiting focus group members. Prospective interviewees were contacted consecutively by telephone and invited to participate in a semistructured individual (telephone) interview. Study staff described the interview process, discussion topic, and the $20 incentive. Interviews lasted an average of 30 minutes. As with the focus groups, participants were queried on 7 community factors and their relation to health.

Data Analyses

Telephone Survey. Demographic variables for participants with and without arthritis were examined for differences using Pearson chi-square and t-statistics for dichotomous and continuous variables, respectively. (See Table 1.) Descriptive analyses were conducted on community resource variables and key community and personal reasons for not being more physically active. Frequencies were used to numerically rank the community and personal reasons listed by respondents for not being physically active and Bonferroni tests for multiple comparisons were conducted. For a particular reason for not being physically active, a binomial test was used to see if a significant difference existed between the proportions reporting the reason in the general population and those reporting the reason in the arthritis subgroup.

Qualitative Interviews. The focus groups and semistructured individual interviews were transcribed verbatim, and transcripts were uploaded into ATLAS.ti Version 5.0. The questions asked at both the focus groups and semistructured individual interviews served as a basis for the development and definition of codes representative of converging themes. Calibration coding was conducted by independently coding 2 transcripts and comparing results to ensure interrater reliability. Any discrepancies were discussed by 2 coders with a third party brought in for resolution when needed. Transcripts from the focus groups and the semistructured individual interviews were first read independent of each other, and it was determined that there were no major thematic differences in content. Therefore, focus group and semistructured individual interviews were analyzed together and were examined for common themes within and across interviews. The constant comparison method[37] was used to identify other emerging themes, with all transcripts being reread to ensure consistent coding of the emerging themes. In addition, subanalyses were conducted by theme to examine whether differences existed by arthritis status.

RESULTS

The characteristics of the telephone survey sample and the qualitative participants are presented in Table 1 by arthritis status. Telephone survey participants with arthritis significantly differed from participants without arthritis in that they were generally older, had more chronic comorbid diseases, and had a higher body mass index. (See Table 1.) Those with arthritis also had significantly less education and lower income levels. Among the qualitative participants, only the number of chronic comorbid conditions significantly differed by arthritis status.

Telephone Survey. The response frequencies of both community and personal reasons for not being more physically active are ranked for the total group as well as for those with and without arthritis. (See Table 2.) Many participants (n=1749) responded that there was no community reason that

* N varies due to missing data

kept them from being more physically active. These participants more often cited personal reasons such as being ill, not having enough time, being too tired or being lazy as reasons for not being more physically active. The top 4 most frequently listed community reasons for participants with and without arthritis were not enough sidewalks, a rural environment, not enough recreational facilities, and unattended dogs. Two community reasons for inactivity reached statistical significance for those reporting versus those not reporting arthritis: heavy traffic ($p=0.004$) and high crime ($p=0.008$).

In contrast, ranking of personal reasons greatly differed by arthritis status. Those with arthritis reported that they were ill or otherwise physically unable to be physically active as the most common reason for not being more physically active ($p<0.001$) far more often than those without arthritis. Not enough time ($p<0.001$), already getting enough physical activity ($p<0.001$), and being a caretaker ($p=0.018$) were more often reported by those without arthritis as primary reasons for not being more physically active.

Although many of the pairwise comparisons were significant at the $\alpha=0.05$ level, we adjusted for multiple comparisons. For the 20 community reasons, Bonferroni adjustment would indicate no significant differences for the arthritis group. Similar adjustment for the 13 personal reasons shows "caretaker" losing significance while the other 3 reasons retain significance. Therefore, while the findings for community reasons may be of general interest, the findings for personal reasons are far more compelling.

Focus Group and Semistructured Individual Interview Results. Main themes that emerged from the qualitative interviews were related to accessibility of community resources, community and personal barriers to physical activity, and quality of walking surfaces. Subanalyses by arthritis status revealed that quality of walking surfaces was the only theme unique to individuals with arthritis. Embedded throughout the 7 themes was a discussion of walking for physical activity. Quotations from qualitative discussions that illustrate the primary barriers to physical activity are presented in Table 3.

Availability of Community Resources. There was consensus among members in all focus groups that there were a variety of physical activity options available in their communities. Participants listed community resources such as gyms, pools, exercise classes, and malls, and offered photographs of these resources. In each focus group, members discussed the wide range of outdoor options that were available to them (eg, walking tracks and community areas). The opinions expressed in the focus groups are reinforced by the telephone survey findings. The majority of participants, 67.6% (1647 of 2436), reported having places to be physically active both indoors and out. Few stated that they had access to indoor places only (6.2%), access to outdoors only (14.0%), or did not have access to any places to be physically active (12.2%).

Accessibility. While participants were in general agreement over the availability of community places to be physically active (especially those at little or no cost), opinions were mixed

Table 2.
Community and Personal Reasons Given in Telephone Survey Interviews for Not Being More Physically Active, North Carolina, 2004-2005

* Proportion of those with arthritis that are statistically different from the total population at $\alpha=0.05$

** Telephone survey participants were able to give up to 3 answers for this question, therefore sum of N>2479. Total group N=2479, arthritis group N=1307, and nonarthritis group N=1154.

regarding the accessibility of places for physical activity. Several participants mentioned that while there were private gyms in their community, they were expensive and memberships were prohibitive. In addition, these exercise gyms did not provide childcare for parents who used these facilities. Several participants discussed other places for physical activity (eg, YMCA) that were difficult to access due to their physical disabilities.

Quality of Walking Surfaces. We did not specifically probe participants for differences in community reasons for physical inactivity by arthritis status. However, content analyses revealed that among participants with arthritis, a theme related to quality of walking surfaces emerged as a barrier to physical activity. Many described problems they had walking for long periods on cement, uneven sidewalks (eg, cracks), and gravel and pebbles.

Community Barriers to Physical Activity. Lack of sidewalks, heavy traffic, and living in a rural area were found to be the 3 main community characteristics that acted as barriers to physical activity. While participants discussed walking as a major source

Table 3.
Barriers to Physical Activity Identified by Focus Group and Semistructured Interviewees, North Carolina, 2004-2005

	Age	Arthritis Status	Sex	Quote
Accessiblity				
High Cost	55	Yes	F	There's one gym in town but I checked out those prices and they are out of my price range any way.
	35	No	F	But if you're not employed, if you're a stay at home mom or if you're retired or whatever, you don't get the benefit of an employer subsidy. I don't know how much Curves® is, but it tends to be expensive.
Lack of access for those with disabilities	58	Yes	F	My problem with the Y was they didn't want me to take my chair in there because they said they couldn't protect it. So they wanted me to walk from the parking lot through the lobby, down the hallway, into the dressing room, through the dressing room and out to the pool. Before I got to the front door I'd have to stop and take a sit down break. Five breaks to get to the pool. By the time I got there I was so tired I didn't care about working out in the pool.
Lack of childcare	35	No	F	There are two places in town to exercise as far as gym type things. We have a Curves® and it does not have child care, which is a problem. I like it because it's all female and I like the concept, but whenever you have kids, which is another issue with physical activity, you have to either have somebody to watch them or be able to take them with you.
Community Barriers to Physical Activity				
Rural area, lack of sidewalks and heavy traffic	50	No	F	Actually, to tell you the truth I don't walk in my neighborhood, because the area where I live is not a safe place to walk. It's rural, we don't have sidewalks or it's not wide enough streetwise to be able to do that because most of the time it's two lanes cars are coming up and down, so it's just really not safe to walk.
	48	Yes	F	Well actually there are no local parks nearby, and there's constant traffic, you don't get out on the roads. Actually this road could use some speed knots, it's near an old school, but they don't pay any attention.
Personal Barriers to Physical Activity				
Personal health and comorbid conditions	58	Yes	F	...And it's a very quiet little community. It goes in a circle and it will go for almost completely a mile around if you take the circle around and come back out on the street. Up until a few years ago, my husband and I used to walk that mile every day, but then it got to where it was difficult for both of us.
	56	Yes	F	I used to walk quite a bit and since my knees and my hips are really deteriorating, it's harder to walk long distances. But I still make myself walk as much as possible. I park farther from the building at the office and things like that. And make myself get more steps in, try to get as many steps in in a day as I possibly can. But I can't go out and walk a mile any more.
	63	Yes	F	Well, I can't do too much walking on account of my knees. I had a knee replacement and all, but I get out there and clean out my flowers, I work in my flower yard. I used to have a garden, but I don't have that any more because I can't bend over and pick my stuff.
Family obligations/ care-giving	56	Yes	F	And I need to be home to cook dinner. My husband has severe diabetes and I have to have dinner on time, his insulin and things like that. So, it was a barrier getting to the Y at 7:00 in the evening, and I can't do the morning class.
Walking Surfaces				
Quality of cement surfaces	58	Yes	F	I do my walking at home because concrete and asphalt are really hard on me. I cannot go very far, I can't get from the first handicapped spot to the door at Walmart. That's too much distance. At home, on the sand and soft grass, I can probably walk that far, especially with my canes...So, when I can I walk at home.
	58	Yes	F	I have but not lately because see it's better walking outside than down yonder at the mall because it's cement. But it's cement out there too. It makes a difference whether you're on ground or on cement.
Uneven surfaces	86	Yes	M	Yeah we have sidewalks on one side. So it depends on which side you want to walk on. The sidewalk really is not all that level, so sometimes you get out on the street. And it's a wide street. It's not bad to walk on.
	64	Yes	F	I have a rough uneven, rocky walkway to my doorway. It makes walking hard.

of physical activity, a lack of sidewalks in the neighborhood emerged in all qualitative discussions as a major barrier for getting outside and feeling safe while walking for exercise. When asked in the telephone survey, 76% (1854 of 2452) stated they did not have sidewalks in their neighborhood and 65% (1580 of 2442) did not have walking/jogging/or biking trails in their neighborhood. Further, 36% (874 of 2448) of those surveyed reported heavy traffic in their neighborhood.

Personal Barriers to Physical Activity. While qualitative participants were specifically probed on the environmental factors in the community that made it hard to be physically active, many participants offered unsolicited examples of personal barriers to being physically active. They told us that poor personal health and chronic illnesses such as arthritis, diabetes, obesity, and mental illness kept them from being physically active. Nearly all participants discussed their current physical activity level in relation to their current physical health. Most mentioned that they had been more active in the past, but their health problems now limited what they could do. Participants also mentioned that family obligations often prevented them from being physically active.

Lifestyle Physical Activity. Participants told us that they were often physically active as part of daily activities and interactions with people. Several participants gave examples of gardening and mowing the yard as well as completing household chores and walking their dogs. Several other participants mentioned they considered physically demanding activities on the job as part of their daily physical activity. Some mentioned that children or grandchildren kept them active and showed pictures to illustrate this point.

Strategies to Overcome Barriers. Qualitative participants often discussed what they did to overcome barriers so they could be more physically active. They described how they worked within their physical limitations to maintain and/or increase their physical activity level by keeping active with various lifestyle activities. Some participants mentioned parking further away at shopping centers to increase their daily number of steps and also mentioned driving to places where they could walk safely.

DISCUSSION

Using quantitative and qualitative methodology, this study set out to examine community factors that North Carolinians perceive to influence their physical activity. Overall, participants reported that they had affordable and accessible community places available to them for physical activity. Participants also described community barriers to activity including no easy access for those with disabilities, lack of childcare, and cost of membership to recreational facilities. In fact, cost has been previously found to be a common reason given among adults with arthritis reporting lack of access to a fitness facility.[15] Qualitative discussions confirmed telephone survey results that a lack of sidewalks, rural environment, heavy traffic, and accessibility were community barriers to physical activity. Quality of walking surfaces emerged as a major built environment barrier for those with arthritis. Overall, a major theme that emerged was the importance of illness and physical limitations as a reason for physical inactivity, specifically in participants with arthritis. This supports previous research finding that functional and social limitations, anxiety/depression, and pain act as barriers to physical activity in people with arthritis.[15]

While this exploratory study is unique in using multiple methodologies, a few limitations should be noted. Attendance at focus groups was lower than expected despite our best recruitment efforts. Recruitment of men and minorities was particularly difficult. Adding semistructured individual telephone interviews to our methodologies allowed us to incorporate the perspectives of these underrepresented groups into our study and reach a total qualitative sample size of 32. Researchers have indicated that with adequate representation, regardless of qualitative methodologies used, a sample of 30 individuals is enough to uncover the perceptions of the majority of individuals in a population.[38,39]

Because this study lacked a measure of physical activity level for all participants we could not examine how community resources and characteristics influence physical activity level by arthritis status. Arthritis status was not validated by health care professionals but determined by self-reported doctor diagnosis. This has previously been shown to be a reliable method.[33,34] And, while we recognize that reasons for inactivity might vary due to arthritis type or location of affected joint, subanalyses were not conducted by arthritis type because the majority of participants self-reporting arthritis (60%) had osteoarthritis/degenerative arthritis and arthritis site was not collected.

CONCLUSION

In conclusion, our study suggests that while individuals living with arthritis encounter similar community and personal challenges to being physically active as those without arthritis, they navigate their environment with additional physical limitations. Goals of Healthy People 2010 and the North Carolina Arthritis Plan 2007-2010 are to prevent and reduce the burden of arthritis so as to improve quality of life.[2,6] It is imperative that the complex interactions between personal and community barriers, social networks, and built environments be better understood and discussed as part of health maintenance for individuals with arthritis. **NCMJ**

Call for Papers

John W. Williams Jr, MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

POLICY FORUM

Arthritis in North Carolina

> *"North Carolina has a higher rate of arthritis than the US national average and is one of the states with the highest projected increase in arthritis prevalence by the year 2030."*

INTRODUCTION

Policy Forum:
Arthritis in North Carolina

The aches and pains we feel when we are younger are just a hint of the kind of serious pain and disability that can accompany arthritis at a later age. Arthritis is a term that describes more than 100 different specific diseases, the most common of which are osteoarthritis, fibromyalgia, and rheumatoid arthritis. In North Carolina alone there will soon be more than 2 million adults with doctor-diagnosed arthritis. The Centers for Disease Control and Prevention predicts our state will experience a 40% increase in the number of adults with arthritis by 2030. Nationally, arthritis is now the leading cause of disability in the United States.

The impacts of pain and activity limitations on the lives of people with arthritis can extend well beyond the direct effects to include psychological distress, pressure on family and work life, and diminished ability to cope with adverse events. Fortunately, there are many new interventions and treatments for arthritis patients. Several articles in this issue of the *North Carolina Medical Journal* highlight therapeutic approaches to arthritis including physical activity, surgery, and pharmaceutical options. For some types of arthritis, effective treatments are limited, but there is promising research underway identifying new mechanisms to treat and prevent the disease. With this new information, North Carolina must address its rheumatology workforce shortages, and as the need for care grows, so must the capacity to use new interventions and treatment methods.

Population-based prevention programs have the potential to help alleviate future problems with arthritis. Obesity and arthritis are closely linked, thus obesity interventions and prevention programs could play a critical role in reducing the risk of arthritic diseases while concurrently addressing other serious chronic diseases aggravated by excess weight. North Carolina also has an invaluable source of research and information in the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill. This issue of the *Journal* is an avenue for disseminating some of the good work being done there.

The National Arthritis Action Plan provides overall guidance for public policy on arthritis prevention and control. The United States Bone and Joint Decade is part of a global plan to set guidelines and measurable objectives in the treatment and prevention of musculoskeletal conditions. These two initiatives outline strategies to reduce the burden of arthritis and to improve future outcomes. We know the direction in which to go, and this issue of the *Journal* is part of an overall effort to spread the word about what we have to do to conquer arthritis and how we need to do it.

ISSUE BRIEF

Arthritis and Its Impact:
Challenges and Opportunities for Treatment, Public Health, and Public Policy

Leigh F. Callahan, PhD; Joanne M. Jordan, MD, MPH

Although literally meaning "inflammation in a joint," the term arthritis is commonly used to describe more than 100 rheumatic diseases and conditions that affect joints, the tissues surrounding joints, and other connective tissue.[1] Conditions such as osteoarthritis, rheumatoid arthritis, fibromyalgia, systemic lupus erythematosus, gout, and bursitis are characterized by musculoskeletal pain and, in some cases, progressive physical impairment of joints and soft tissues.[2] Arthritis is one of the most prevalent chronic conditions in the United States, and the economic, social, and psychological impact associated with it is enormous.[3-6] It has been cited as one of the most pressing public health problems in the US.[3] Some of the effects of arthritis are easily translated into economic terms (eg, lost wages, medical care costs), but many other effects are not easily quantified (eg, pain, reductions in housekeeping activities, inability to enjoy leisure activities).

Although its impact is primarily on quality of life rather than mortality, arthritis significantly affects not only the individuals who have the disease but their families and society as well. Fortunately, over the past several decades there have been dramatic advances in the understanding of risk factors for arthritis and in its treatment. It is important for clinicians and other health care providers, public health officials, and policymakers to understand the burden of arthritis and recent advances in the field so that they can respond to the challenges of arthritis in terms of services and interventions to minimize its impact. In this issue brief, we will review the prevalence and impact of arthritis in terms of pain, activity and role limitations, work disability, and economic, social, and psychological consequences. We will discuss public health strategies and examine what can be done to target arthritis in terms of primary, secondary, and tertiary prevention. Finally, we conclude with some policy implications for North Carolina.

> *"It will take dedicated financial investment from the public, nonprofit, and private sectors to minimize and prevent arthritis-related disabilities from affecting the state's workforce as well as keeping people living with arthritis active and living independently."*

Prevalence

Arthritis affects an estimated 46 million Americans,[4] approximately 1 in 5 US adults. This number is expected to increase to an estimated 67 million individuals by the year 2030.[7] Approximately 21 million people have osteoarthritis,

Leigh F. Callahan, PhD, is associate professor of medicine, orthopaedics, and social medicine at the Thurston Arthritis Research Center, the University of North Carolina at Chapel Hill. She can be reached at leigh_callahan@med.unc.edu or 3300 Thurston Building, CB 7280, Chapel Hill, NC 27599.

Joanne M. Jordan, MD, MPH, is associate professor of medicine and orthopaedics, chief of the Division of Rheumatology, Allergy, and Immunology, and director of the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill.

3.7 million have fibromyalgia, and another 2.1 million have rheumatoid arthritis.[2] North Carolina has a higher rate of arthritis than the US national average and is one of the states with the highest projected increase in arthritis prevalence by the year 2030.[8] (See Figure 1.) For this issue of the *North Carolina Medical Journal*, the North Carolina State Center for Health Statistics has provided recent data on the prevalence of self-reported doctor-diagnosed arthritis in North Carolina along with a breakdown by selected demographics and risk factors. (See Running the Numbers.) More than 1.7 million North Carolinians reported having arthritis in 2005, and this number is projected to increase to more than 2.7 million by 2030. Individuals who report arthritis also are more likely to report their health as fair or poor than are individuals without arthritis.

Estimates of the prevalence of knee symptoms and radiographic knee osteoarthritis in African American and Caucasian adults aged 45 years or older were recently reported by our research group at the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill. Data were collected from the Johnston County Osteoarthritis Project, a population-based study of osteoarthritis in North Carolina.[9] Knee symptoms were present in 43% of participants. Twenty-eight percent had radiographic knee osteoarthritis, and 16% had symptomatic knee osteoarthritis. African Americans had slightly higher prevalence of knee symptoms and both radiographic knee and symptomatic knee osteoarthritis, but significantly higher prevalence of severe radiographic knee osteoarthritis compared to Caucasians. The Johnston County Osteoarthritis Project has been a unique resource for the nation as a population-based laboratory for the study of risk factors for, and racial and gender disparities in, osteoarthritis. This long-standing community-based project is discussed in the commentary by Edwin Hartman and colleagues.

Although some risk factors associated with various forms of arthritis are nonmodifiable (eg, female sex, older age, genetic predisposition), identification of modifiable risk factors is critical to improve the lives of individuals with arthritis or to prevent its occurrence or progression.[10-13] (See Table 1.) Modifiable risk factors include obesity, joint injuries, infections, and certain occupations (eg, shipyard work, farming, heavy industry, any occupation with repetitive knee bending). Several commentaries in this issue discuss arthritis risk factors. Stephen Marshall and Yvonne Golightly discuss the link between sports injuries and osteoarthritis and note the biological basis for such a relationship. Stephen Messier and colleagues describe dietary and physical activity interventions. Individuals with lower levels of formal education and lower income have long been known to be at higher risk for arthritis and poor outcomes. Our commentary on the relationship between arthritis and the environment discusses sociodemographic issues and introduces a novel approach to evaluating potential factors behind these observations.

Risk Factors for Arthritis

Nonmodifiable	Female sex Older age Genetic predisposition
Modifiable	Obesity Joint injuries Infections Certain occupations Lower levels of formal education Lower income

Impact of Arthritis

Activity and Role Limitations

In addition to its high prevalence, arthritis is the nation's leading cause of disability. Activity limitations due to arthritis were reported by nearly 19 million US adults each year during the period 2003 to 2005.[7] Individuals who are disabled from arthritis have problems in more areas of daily life than do individuals with disability from other conditions.[14,15] Arthritis has negative effects on family role functioning as well.[16] Role limitations associated with rheumatic disease include significant reductions in the amount of time individuals spend engaging in activities such as shopping, visiting the bank and supermarket, homemaking, interacting with friends and family, or participating in hobbies.[6,16,17]

Economic Impact and Work Disability

In comprehensive studies of the economic cost of musculoskeletal disease, Rice and colleagues estimated that the total cost of these conditions is equivalent to 2.5% of the Gross National Product.[6] Total costs for arthritis rose from $65 billion in 1992 dollars to $82.5 billion in 1995 dollars.[6,18] In 1995, the estimated economic impact of musculoskeletal conditions on the US economy was $214.9 billion. (See Table 2.) Of this amount, direct costs accounted for 41% and indirect costs accounted for 59%. For all types of arthritis, the total cost was $82.5 billion or 38% of the cost of all musculoskeletal conditions.[18] (See Table 2.)

Table 2.
Total, Direct, and Indirect Costs of All Musculoskeletal Conditions and All Forms of Arthritis in Billions of 1995 Dollars.*

Condition	Direct Costs	Indirect Costs	Total Costs
All musculoskeletal conditions	88.7 (41%)	126.3 (59%)	215
All forms of arthritis	21.7 (26%)	60.8 (74%)	82.5

* Adapted from Praemer, Furner and Rice, Musculoskeletal Conditions in the United States, American Academy of Orthopaedic Surgeons, 1999.

The estimated direct costs of medical care for all forms of arthritis totaled $21.7 billion. (See Table 2.) Expenditures for nursing home care were $12.7 billion and accounted for 59% of direct costs. Hospital inpatient care totaled $3.1 billion or 14% of direct costs. According to the National Hospital Discharge Survey, patients hospitalized for arthritis account for approximately 2.6 million days of care. Administration and physician outpatient costs were $1.2 billion and $1.1 billion, respectively, with each approximately 5% of direct costs.[18]

The magnitude of the estimated indirect costs due to arthritis in 1995 dollars was $60 billion[8] or 74% of total cost.[18] (See Table 2.) As noted in previous arthritis cost studies, indirect costs are almost 3 times greater than direct costs.[6] This estimate would be even larger if the costs attributed to loss of homemaking functions could be more easily determined. Also, older women have lower labor force participation rates, resulting in lower estimates of economic impact for the current cohort of women.

As reflected in the indirect costs, the capacity of individuals with arthritis to work is significantly affected.[19-24] In fact, arthritis is a leading cause of work loss and work disability payments.[22,25] In two of the most prevalent rheumatic conditions, osteoarthritis and rheumatoid arthritis, many studies have documented significant work disability.[26] Determinants of work disability in individuals with rheumatic disease exist at both the societal and individual levels. Societal level risk factors include economic conditions, attitudinal and architectural barriers, types of jobs available, employer practices, and the characteristics of disability pension plans.[25] Individual level determinants include work autonomy, social factors, and disease factors.[21,25]

The costs of arthritis extend far beyond the direct medical care costs and the indirect costs associated with work loss. The intangible costs include pain, psychological distress, changes in family structure, limitations in instrumental and nurturing activities, and changes in appearance resulting from deformity.[6,26]

Pain and Psychological Consequences

As noted in the commentary by John Winfield, pain is a major determinant of physician visits for patients with arthritis. It is a significant predictor of patient and physician assessment of general health status as well as an indicator of future level of disability. Pain also has been found to be more important than physical or psychological disability in explaining medication use among patients with rheumatoid arthritis.[27,28] Pain presents challenges to health care providers, and some important suggestions for addressing this problem in arthritis are noted in Winfield's commentary on pain and arthritis.

In addition to the significant economic costs, activity and role limitations, and pain and disability associated with arthritis, the psychological impact of arthritis has been documented in a number of clinical studies.[6] The impact of arthritis on psychological status has been measured in terms of depression, anxiety, learned helplessness, coping strategies, cognitive changes, and self-efficacy. Higher levels of psychological distress have been noted in individuals with arthritis than in members of the general population in most studies. The levels of distress reported in arthritis patients were comparable to levels noted in clinical samples of individuals with other chronic conditions.[29] Higher levels of psychological distress in individuals with arthritis have also been associated with poorer status on clinical outcome variables as well as with increased health services utilization.[30]

Research efforts in depressive symptoms and disorders have focused on osteoarthritis, rheumatoid arthritis, fibromyalgia, and systemic lupus erythematosus.[29] Although depressive symptoms and disorders are more common among clinical samples of individuals with arthritis than in samples of the general population, the majority of individuals with arthritis do not report increased depression. Among persons with rheumatoid arthritis, the loss of valued activities and the self-perception of the ability to do activities are strongly correlated with psychological status.[17] Robert DeVellis and Brenda DeVellis discuss the links between depression and arthritis in their commentary.

Public Health Strategies

Although there is presently no cure for arthritis, there are interventions targeting primary, secondary, and tertiary prevention. (See Table 3.) The aim of primary prevention is to reduce the incidence of symptomatic disease (impairment). In order for primary prevention to be successful or even feasible, the risk factors for the disease must be known. While the risk factors for some types of arthritis and many rheumatic conditions are not known, data from cross-sectional and longitudinal studies reveal that obesity and occupational and sports-related injuries are risk factors for osteoarthritis.[13,31,32] The Framingham Osteoarthritis Study demonstrated that weight change significantly affected the risk for development of osteoarthritis of the knee in women; a weight reduction of 5.1 kilograms (11.2 lb) over a 10-year period reduced the risk of symptomatic knee osteoarthritis by over 50%.[32] Greg Griggs and Marie Shelton highlight the role North Carolina's *Eat Smart, Move More...NC* program can have in reducing obesity in our state and possibly attenuating some of the arthritis epidemic.

The physical demands of an occupation as a risk factor for osteoarthritis of the knee has been observed in several studies.[13,31,33] Data from Framingham and the first National Health and Nutrition Examination Survey indicate that jobs that require knee bending and which have at least medium physical demands are associated with increased rates of radiographic and clinical osteoarthritis of the knee.[13,33] Risk factor modification such as weight reduction and avoidance of occupational and other injuries may prevent the development of osteoarthritis of the knee. Another known target for primary prevention is exposure to ticks that carry the spirochete *Borrelia burgdorferi*, a known risk factor for Lyme disease. Lyme disease is an infectious arthritis which may have chronic manifestations. Avoiding tick-infested areas, checking oneself and one's pets for ticks, and using antitick pesticides are primary preventive measures for Lyme disease.

Secondary prevention is aimed toward early detection and treatment of a disease so that its course may be controlled or favorably altered. (See Table 3.) Secondary prevention is targeted toward reducing disability and generally involves screening for disease. Currently the most appropriate screening test for arthritis is a complete history and physical examination.[34] Arthritis may have a wide variety of clinical presentations which may or may not involve the musculoskeletal system. A complete history and physical examination allow the clinician to develop a differential diagnosis, order the appropriate laboratory studies, and formulate a diagnosis and treatment plan. Since early, aggressive therapy may be associated with improved outcomes in arthritis, it is imperative that the clinician consider these diagnoses when evaluating individuals with musculoskeletal or ill-defined systemic complaints. In order for secondary prevention to be successful in improving the outcomes of persons with arthritis, it will be necessary to increase efforts to educate health

Table 3.
Examples of Prevention Strategies for Persons With Arthritis

	Primary Prevention	Secondary Prevention	Tertiary Prevention
Goal	Reduce incidence of disease	Detect disease at early, treatable stage	Reduce disease complications
Target Population	Susceptible	Asymptomatic	Symptomatic
Examples	■ Weight reduction ■ Avoiding sports & occupational associated injuries ■ Avoiding tick exposure ■ Checking self and pets for ticks (Lyme)	■ History and physical ■ Improved education of health professionals ■ Public education to encourage early diagnosis and treatment ■ HLA/genetic testing (potential)	■ Improved education of health professionals ■ Medication ■ Physical therapy ■ Exercise ■ Occupational therapy ■ Assistive devices ■ Education ■ Use of effective coping strategies ■ Joint replacement surgery

professionals about arthritis. It is also imperative to increase public awareness about the value of early treatment and diagnosis of arthritis, and it is imperative to have sufficient health care professionals to treat people with arthritis. The manpower shortage in rheumatology is reviewed by Gregory Schimizzi, and Kate Queen gives her perspective on the role of nurse practitioners and physician extenders in meeting the manpower shortage challenge.

Tertiary prevention is aimed at reducing the complications and handicaps resulting from the impairment or disease in symptomatic persons. (See Table 3.) Most research efforts in arthritis have focused on tertiary prevention. Treatment of individuals with arthritis is often a multidisciplinary effort that includes medications to reduce pain and inflammation; complementary and alternative medicines; physical exercise and occupational therapy to maintain functional status and prevent disability; and education to develop coping and health management skills. Recent therapeutic advances in the treatment of rheumatoid arthritis, including the biologic therapies, are discussed by Beth Jonas. Esi Morgan DeWitt examines medication safety in children with arthritis, Jayalakshmi Rao reviews the use of complementary and alternative medicine in arthritis treatment, and Victor Goldberg discusses joint replacement therapy later in this issue of the *Journal*.

Despite its importance in reducing disability, exercise is a frequently neglected part of the treatment plan. Arthritis is now being incorporated into public health messages regarding the benefits of exercise. In contrast to the traditional belief that those with arthritis should avoid vigorous physical activity, recent studies have demonstrated that people with arthritis can benefit from appropriate aerobic exercise without exacerbating their disease.[35,36] Compared to their peers without arthritis, people with arthritis are often deconditioned and this may worsen their disability. Prolonged inactivity can produce muscle weakness, decreased flexibility, poor endurance, osteoporosis, cardiovascular deficit, fatigue, depression, low pain threshold, and other problems which historically have been accepted as either the natural progression of arthritis or the consequences of therapy.[37]

In a trial of supervised fitness walking, people with osteoarthritis of the knee who were randomized to the walking group had significant improvement in walking distance and functional status and a decrease in pain and medication usage compared to the control group.[36] Similarly, in a trial of people with rheumatoid arthritis and osteoarthritis of weight-bearing joints, those randomized to aerobic exercises had a significant improvement over controls in aerobic capacity, 50-foot walking time, depression, anxiety, and physical activity.[37] In a 5-year follow-up study of a conditioning program for people with rheumatoid arthritis, study participants who reported more than 5 hours of exercise per week showed less radiographic progression of joint damage, less hospitalization, and less work disability than those who exercised less than that amount.[38] The Arthritis, Diet, and Activity Promotion Trial found that the combination of modest weight loss plus moderate exercise provides better overall improvements in self-reported measures of function and pain and in performance of mobility in older overweight and obese adults with knee osteoarthritis compared with either intervention alone.[39]

Studies of community-based exercise programs sponsored by the Arthritis Foundation (eg, Aquatics Program) have shown significant positive changes in participants' pain levels and their ability to perform activities of daily living. This indicates the benefits of regular aerobic exercise in persons with arthritis may extend beyond improved physical functioning. These benefits are discussed in-depth in the commentary by Stephen Messier.

Patient education programs such as the Arthritis Self-Help Course are another adjunct in the treatment of people with arthritis. A meta-analysis of 15 controlled evaluations of psychoeducational interventions for people with rheumatoid arthritis or osteoarthritis showed beneficial improvements in pain, depression, and disability.[40] There is an emphasis on educational processes which increase self-efficacy and empower the participants to make appropriate health decisions. In a 4-year follow-up study, participants in the Arthritis Self Management Course retained improvements in pain level and self-efficacy and had a 43% decrease in physician visits compared to nonparticipants.[41] Based on a reach of just 1% of the population with rheumatoid arthritis and osteoarthritis, the projected cost savings to society that would result from a broader implementation of the program would be $33 000 000. Effective self-management programs with similar content and self-efficacy enhancing processes are also available for people with systemic lupus erythematosus and fibromyalgia.

Conclusions and Policy Implications

In 1998 a consortium of national organizations produced "The National Arthritis Action Plan: A Public Health Strategy," which is a comprehensive and ambitious plan for addressing the looming epidemic of arthritis.[42] This inspiring plan was developed under the leadership of the Centers for Disease Control and Prevention, the Arthritis Foundation, and the Association of State and Territorial Health Officials. These 3 organizations were joined by nearly 90 other organizations including academic institutions, professional societies, governmental agencies, voluntary health agencies, and others with an interest in arthritis prevention.

The National Arthritis Action Plan is based on the principles that the disability and chronic pain associated with arthritis reduce quality of life and that arthritis can be prevented. The plan is based on a growing recognition that public health must shift its emphasis to include diseases that destroy quality of life and not just those that kill.

The National Arthritis Action Plan outlines a public health strategy with emphasis in 3 areas: (1) surveillance, epidemiology, and prevention research; (2) communication and education; and (3) programs, policies, and systems. Activities in the surveillance and epidemiology area address the need to establish a solid scientific base of knowledge about the prevention of arthritis. The communication and education activities are designed to raise awareness of arthritis as a public health problem and to stimulate creative responses to this problem. The emphasis in the area of program, policies, and systems is on developing approaches for systematic change based on recognition that arthritis affects individuals in a social context and that this context can be changed in ways that promote health and prevent disease.

The National Arthritis Action Plan followed 2 historic national efforts to address arthritis. The first was the National Arthritis Act of 1975 which led to the development of Multipurpose Arthritis and Musculoskeletal Disease Centers. The second was the establishment of a separate arthritis institute at the National Institutes of Health in 1986, the National Institute of Arthritis, Musculoskeletal, and Skin Diseases. The National Arthritis Action Plan, a third milestone, provided a framework for new partnerships and collaborations to address the important issues and challenges of arthritis. These partnerships helped ensure that Healthy People 2010, the nation's blueprint for improving population health, contained a chapter on Arthritis, Osteoporosis, and Chronic Back Conditions.[43] This chapter has specific objectives related to pain reduction, activity limitations, and racial disparities in the rate of knee replacements. The North Carolina Arthritis Program, discussed in the commentary by Denise Brewster and Mary Altpeter, uses these Healthy People 2010 objectives to guide much of its work.

In addition to the incorporation of arthritis-specific objectives in Healthy People 2010, the launch of the Decade of Bone and Joint Disease in the year 2000 has further enhanced society's understanding of the burden of arthritis.[44] The Bone and Joint Decade is a global, multidisciplinary initiative targeting the care of people with musculoskeletal conditions and bone and joint disorders. Its focus is on improving quality of life as well as advancing the understanding and treatment of those conditions through research, prevention, and education. Worldwide more than 750 organizations have endorsed the Bone and Joint Decade initiative. More than 50 countries, including the US, have established multidisciplinary National Action Networks to plan activities in their respective countries. All 50 states have endorsed the Bone and Joint Decade, and over 85 health care organizations have pledged their support to the US Bone and Joint Decade Network. This network supports the current efforts of the Arthritis Foundation to pass the Arthritis Prevention, Control, and Cure Act of 2007 (S.626, H.R. 1283).[45] This Act proposes to strengthen arthritis public health initiatives, which would ensure that more people are diagnosed early and avoid pain and permanent disability. It also proposes to ensure that limited federal funding for arthritis research is used in the most strategic manner possible through the formation of a federal interagency coordinating committee. Additionally, it authorizes a remedy to help address the shortage of pediatric rheumatologists as well as a prevalence study of arthritis in children and a patient registry. Neither North Carolina senator was a cosponsor of the Senate bill in the fall of 2007, but Representatives Butterfield, Etheridge, Price, and Hughes are all cosponsors of HR 1283.

Given its high prevalence and significant economic, functional, social, and psychological consequences, arthritis should receive considerable attention from a societal perspective. The burdens of arthritis will increase dramatically in the near future due to the aging of the population, and this underscores the need for a public health approach. As highlighted in this issue of the *North Carolina Medical Journal*, what we know about the prevention and treatment of arthritis has advanced considerably over the past few decades. There is much that can be done on an individual and societal level to reduce the burden of arthritis, and our challenge is to deliver that message broadly. **NCMJ**

COMMENTARY

Arthritis:
The Public Health Partnerships for Improving Health

Denise G. Brewster, MEd, CHES; Mary Altpeter, PhD, MPA, MSW

For many North Carolinians, dealing with the aches and pains and limited mobility of arthritis and joint conditions often takes a back seat to health issues such as diabetes and heart disease which may be seen as more life threatening. Many people with arthritis believe they cannot or should not be physically active with their aching joints, making management of other chronic diseases even harder. North Carolina public health professionals, the Centers for Disease Control and Prevention, and the National Arthritis Foundation recommend that people with arthritis can and should be physically active—the correct and safe way. There are proven methods for how they can successfully manage their condition, decrease pain, stay productive, improve quality of life, and reduce health care costs. To that end a collaborative public health approach to preventing and treating arthritis has been developed in the state, the North Carolina Arthritis Program.

The North Carolina Arthritis Program was revitalized in 1999 with a vision and a shoestring budget of only $70 000 from the Centers for Disease Control and Prevention to build state infrastructure and capacity to reduce the burden of arthritis across the state. Given this daunting challenge, it was clear that the Arthritis Program needed to reach out to build interdisciplinary and interorganizational community partnerships to strategically pool resources, build infrastructure capacity, and help carry out programs and advocacy efforts. An Arthritis Program Advisory Board was created with membership of key stakeholders in aging services, public health, medical care, community-based services, advocacy groups, and academia. Aging services representatives include key staff and leaders from Senior Games, AARP, Area Agencies on Aging, NC Division of Aging and Adult Services, and the Cary Senior Center. Medical community members include representatives from Vocational Rehabilitation, Sprain Strain Treatment Center, Rex Senior Health Center, WakeMed, Wilson Medical, Blue Cross Blue Shield of NC, and NC Division of Medical Assistance. Community-based organizations include the Arthritis Foundation, Pitt County Community Schools and Recreation, NC Citizens for Public Health, City of Raleigh Parks and Recreation, Mid-Carolina Council of Government, and local health departments. Academic partners include the University of North Carolina (UNC) at Chapel Hill (Schools of Public Health and Nursing, Institute on Aging, Department of Health Policy and Administration, and Thurston Arthritis Research Center), NC Office on Disability and Health, East Carolina University Brody School of Medicine, Duke University Divisions of Community Health and Rheumatology, UNC Charlotte School of Nursing, and Wake Forest University School of Medicine.

> *"Many people with arthritis believe they cannot or should not be physically active with their aching joints, making management of other chronic diseases even harder."*

This broad-based advisory board serves as the driving force of the Arthritis Program. The board has reviewed the statistics and services available in our state (documented in the North Carolina Arthritis Report 2002) and crafted the North

---

Denise G. Brewster, MEd, CHES, is acting NC Arthritis Program coordinator in the Physical Activity and Nutrition Branch, Chronic Disease Section, NC Division of Public Health. She can be reached at denise.brewster@ncmail.net or 1915 Mail Service Center, Raleigh, NC 27699-1915.

Mary Altpeter, PhD, MPA, MSW, is associate director for program development at the Institute on Aging, the University of North Carolina at Chapel Hill, and NC Arthritis Advisory Board member.

Carolina Arthritis Plan,[1] a 3-goal, 3-year road map for decreasing the burden of arthritis. The NC Arthritis Plan is consistent with NC General Statute 130A-222 which mandates a state arthritis program and the Healthy Aging People 2010 national health objectives.

The first goal is to increase the number and accessibility of evidence-based arthritis programs and to increase the number of people participating in them. There are 5 programs nationally recognized as effective in helping manage arthritis. Three programs are oriented to physical activity: the Arthritis Foundation Exercise Program, the Arthritis Foundation Aquatics Program, and the EnhanceFitness exercise program. Two programs focus on self-management skills and patient-physician communication strategies: the Arthritis Foundation Self-Help Program and the Stanford University Chronic Disease Self-Management Program. These evidence-based programs have proven to provide benefits in symptom management, improved mobility, and reduction in depression among participants in study groups.[2,3]

To achieve the goal of reducing the arthritis burden, the North Carolina Arthritis Program and its lead partner agency, the Arthritis Foundation Carolinas Chapter, work together to identify organizational networks in areas where evidence-based programs are currently unavailable or underutilized. Most of the evidence-based programs in the state are clustered around the largest metropolitan areas and about half of the counties have no evidence-based arthritis programs at all. Community members and participants of the regional senior centers in rural communities can, however, be trained to lead Arthritis Foundation exercise, aquatics, and self-help programs.

Leading a key partnership effort, the NC Division of Aging and Adult Services has embarked on a 3-year project to train volunteers in Stanford University's Chronic Disease Self-Management Program and deliver the program in 46 counties. The program has been shown to provide the same benefits (managing their disease, continuing activities of daily living, and coping with emotions) to people with arthritis as arthritis only self-help programs.[4] The Division of Aging and Adult Services project will reach over 3000 North Carolinians living with chronic diseases such as arthritis. This effort is crucial—nationally, less than 1% of people with doctor-diagnosed arthritis participate in self-help programs.[5]

The second goal in the Arthritis Plan is to conduct community campaigns to raise public awareness that physical activity is an effective way to manage arthritis symptoms. To begin to address this statewide goal, the Arthritis Program has conducted 3 regional communication campaigns in North Carolina saturating 15 counties with media messages. The key message of the campaigns has been "Physical Activity. The Arthritis Pain Reliever." The communication campaigns have been pivotal opportunities for identifying community interest and commitment to establishing local exercise, aquatics, and self-help programs. For example, during the 6-week communication campaign in Pitt County, a special one day "Move More with Arthritis" event was held along with Arthritis Foundation aquatic program leader training. The two components, educating community members about the benefits of physical activity and building community capacity to meet the demands of an informed citizenry, depend upon community-based partnerships like Pitt County Community Schools and Recreation who hosted the event and the aquatic leader training.

Since arthritis affects people of all ages and is also a leading cause of disability and work-related disability,[6] senior communities are not the only focus of the Arthritis Program's efforts. Key arthritis messages are shared with participants of all wellness programs to encourage them to see their doctor, stay active, watch their weight, and protect their joints. Information about the evidence-based Arthritis Foundation Exercise Program will be included in the web-based menu of activities available in the "Worksites Eating Smart and Moving More" materials available to every workplace with a wellness program. The Arthritis Program is also working to make evidence-based program information available to all NC State Health Plan enrollees through the more than 150 state wellness committees currently established. The exercise program is an ideal fit for employees who have permanent disabilities that prevent participation in more vigorous physical activities or who have been sedentary and need a graduated approach to becoming more physically active. Families also benefit from learning to protect the joints of their children to reduce the possibility of future arthritis.

The third goal of the Arthritis Plan is directed toward creating policies and environments supportive of arthritis management in North Carolina by working with state legislators and local elected officials and organizations. Although some health savings accounts recognize the value for enrollees participating in evidence-based programs to maintain health and reduce medical costs, not all employers and insurance policies recognize this. Other types of plans and actions for supportive policies and environments are multi-faceted and long term in scope. For example the Arthritis Program hopes to increase the use of prescriptive physical activity recommendations from health care providers, but such prescriptions demand the availability of community resources for safe and effective physical activity opportunities.

What does the future hold for citizens living with arthritis in North Carolina? There are 3 major challenges. First, with the continuing momentum toward a dedicated plan to reduce the burden of arthritis, more evidence-based programs need to be available throughout communities. Citizens should have the opportunity to engage in physical activity that is safe, effective, and close to home. Persons living with arthritis will gain greater control over their lives and condition from participating in chronic disease self-management programs. Our challenges are to increase the number of master trainers, identify organizational sites for programs, and train program leaders. Currently there are only 8 Arthritis Foundation master trainers in North Carolina. The number of Arthritis Foundation exercise, aquatic, and self-help program leaders varies from year to year (currently around 100) due to attrition. There are only 8 Chronic Disease Self-Management Program trainers in the state who have completed Stanford University's intensive training preparation.

Second, employers need to recognize that supporting physical activity for employees with arthritis keeps them on the job and performing better. A major challenge will be to create and implement strategies to address people with arthritis who may experience periodic or increasing functional impairment. We need to work with employers to examine how the work environment, employee tasks, and schedules may be adapted to offer flexibility for workers with arthritis while at the same time maintaining expected performance levels and overall productivity.

Third, these challenges cannot be met without cooperative efforts and dedicated funding. Strong collaborative partnerships are the biggest asset in accomplishing the goals of the Arthritis Plan. The biggest challenge is the cost of building infrastructure with severely limited dollars. Currently the Arthritis Program budget for fiscal year 2007-2008 is supported by a grant of $135 000 from Centers for Disease Control and Prevention, an increase of only $65 000 from its initial funding 9 years ago. With a 2005 estimate of 1 754 000 North Carolina citizens diagnosed with arthritis,[7] that means less than 8¢ per person is available for evidence-based programming, raising community awareness, and creating supportive policies and environments. It will take dedicated financial investment from the public, nonprofit, and private sectors to minimize and prevent arthritis-related disabilities from affecting the state's workforce as well as keeping people living with arthritis active and living independently. Basic funding and partner agencies working together through the comprehensive, multi-faceted public health response to arthritis can build a state in which all citizens enjoy the high level of wellness and quality of life that all tarheel citizens deserve. **NCMJ**

COMMENTARY

Recent Therapeutic Advances in the Treatment of Rheumatoid Arthritis

Beth L. Jonas, MD

Rheumatoid arthritis is a systemic disease which targets the joints as well as other organ systems. It is the most prevalent of the inflammatory arthropathies and is estimated to affect about 1% of the world's population. The clinical presentation is varied, but most patients have a progressive disease that leads to joint destruction and the associated disability if left untreated. There is significant morbidity associated with some of the extra-articular manifestations of the disease including pulmonary disease, osteoporosis, inflammatory eye disease, and in rare cases a systemic vasculitis. Recent studies have highlighted the role of chronic inflammation in the development of cardiovascular disease which leads to excess mortality in patients with rheumatoid arthritis.

Rheumatoid arthritis is thought to occur in a genetically susceptible host in response to some antigenic trigger. While the factors that initiate this process are poorly understood, the pathogenesis of the disease is beginning to be understood. Pathologic changes in the joint begin in the synovial lining of the diarthroidal joints. Early pathologic changes include neovascularization and thickening of the normally thin and delicate synovial membrane. There is infiltration of the tissues with leukocytes, increased expression of adhesion molecules, proteolytic enzymes, and cytokines and other inflammatory mediators. Together, these factors lead to the development of a pannus, a localized tissue that invades articular cartilage, bone, and the supporting structures of the joint.

It has been known for some time that joint damage can occur early in the course of the disease, and a majority of rheumatoid arthritis patients have erosion of bone within the first 2 years of disease onset.[1] It has also been established that treatment with disease modifying antirheumatic drugs during this early phase of rheumatoid arthritis can result in improved outcomes.[2] An appreciation of the importance of early intervention prior to the development of erosive disease has led to an algorithm of early detection and aggressive intervention. However, until recently the therapeutic options were limited to single or combination therapies with only modest benefits in most patients. Medications such as intramuscular gold, cyclosporine, azathioprine, sulfasalazine, hydroxychloroquine, and methotrexate comprise the majority of oral agents used to treat rheumatoid arthritis, yet only hydroxychloroquine, sulfasalazine, and methotrexate are currently in wide use. Combinations of oral therapies may be beneficial in some patients, and the addition of a newer oral agent, leflunomide, has added to the armamentarium of therapeutic options. Despite this, oral therapies are clearly inadequate for the majority of patients with rheumatoid arthritis.

> *"Although the precise etiology of rheumatoid arthritis is not known for certain, significant advances in understanding the pathogenesis of the disease have led to new and more effective therapies."*

Although the precise etiology of rheumatoid arthritis is not known for certain, significant advances in understanding the pathogenesis of the disease have led to new and more effective therapies. The most significant breakthrough over the last 10 to 15 years has been the development of the tumor necrosis factors (TNF) - inhibitors Etanercept, Infliximab, and Adalimumab. Each drug has a unique mechanism of action, but they all inhibit the biologic action of TNF, a cytokine known to play a role in the pathogenesis of joint inflammation in rheumatoid arthritis. Tumor necrosis factors has myriad effects that may

Beth L. Jonas, MD, is an assistant professor of medicine in the Departments of Medicine and Orthopedics at the University of North Carolina at Chapel Hill. She can be reached at bjonas@med.unc.edu or 3300 Thurston Building, CB #7280, Chapel Hill, NC 27599-7280.

initiate or perpetuate inflammation in rheumatoid arthritis including regulation of other proinflammatory cytokines, growth of new blood vessels, activation of endothelial cells and osteoclasts, and induction of metalloproteinases. Etanercept is a fusion protein of a TNF receptor linked to the Fc portion of IgG1. Its action prevents TNF from interacting with cell surface receptors. Infliximab is a chimeric mouse/human monoclonal antibody which binds TNF, thus inhibiting its biologic activity. Adalimumab is a fully humanized monoclonal antibody which has a similar mechanism of action to Infliximab. These drugs have had a profound impact on the ability to treat patients who had previously shown little or no response to traditional disease modifying antirheumatic drugs. Numerous studies of these agents have confirmed their ability to control signs and symptoms of disease, improve quality of life, and retard, or in some cases halt, the progression of erosive disease. Clinical studies also indicate that the combination of TNF inhibitors with Methotrexate yields better outcomes than either drug alone.[3]

Despite the therapeutic advances demonstrated by the TNF inhibitors, there remains a subset of patients who have an inadequate response to available therapies. These patients may continue to have evidence of disease activity with tender and swollen joints or may have progressive radiographic changes despite a good clinical response. Two newer agents approved by the FDA, Abatacept and Rituximab, may be effective with these patients. Abatacept is a T cell inhibitor which acts by blocking the second signal necessary for effective T cell stimulation. Rituximab is an anti-CD20 chimeric monoclonal antibody which selectively depletes pre-B, naïve, mature, and memory B cells, leaving stem cells and mature plasma cells unaffected. Both drugs, given by intravenous infusion, have been shown in well-controlled clinical trials to decrease signs and symptoms of rheumatoid arthritis as well as retard the structural progression of the disease.[4]

Research and investigation of the next generation of biologic therapy continues with agents aimed at new targets. Anticytokine therapies targeting IL-1, Il-6, Il-15, and IL-17 are currently under development. Tocilizumab, an anti-IL-6 monoclonal antibody, is currently in phase III clinical trials for rheumatoid arthritis, and preliminary results suggest that it has good efficacy. In addition, second generation drugs targeting TNF and B cells are also in clinical trials. Some investigators believe that gene therapy may someday play a role in the treatment of the most aggressive disease, but there are many hurdles to overcome.

Primary care physicians are often the first point of care for patients with early rheumatoid arthritis. With the recent advances in understanding the importance of early diagnosis and aggressive management of the disease, primary care physicians are in a position to take that knowledge and apply it to clinical practice. It is critical to consider the diagnosis and pursue the workup since intervening early can make a significant impact on the long-term outcome. Working closely with their rheumatology colleagues and remaining vigilant for signs of early inflammatory joint disease, the primary care provider plays a most important role for patients with rheumatoid arthritis. **NCMJ**

COMMENTARY

Medication Safety in Children with Arthritis

Esi Morgan DeWitt, MD, MSCE

Chronic arthritis affects approximately 1 out of 1000 children, many of whom will be affected into their adulthood.[1] Over the past decade the advent of potent biological therapies such as tumor necrosis factor-alpha (TNF-alpha) antagonists has altered our expectations for the outcomes of polyarticular arthritis for the better. It is now rare to see arthritis leave a child wheelchair-bound, and measures such as serial casting and bracing to treat fixed joint flexion contractures are now infrequently needed. These advances are due in part to maturation of the field of pediatric rheumatology but also due in large part to available therapeutic options that are more effective than were the agents used in the past. However, by virtue of their novelty, these biologic medications lack much data on long-term safety. The safety data are limited in adults, and they are even sparser in children given smaller numbers of patients, less data collection, and fewer studies performed. When we consider that individuals affected with chronic arthritis from childhood will be exposed to various immunomodulatory and other medications (eg, nonsteroidal anti-inflammatory drugs, nonbiologic disease-modifying antirheumatic drugs) over the course of many years, it is important to be systematic in our study of the possible long-term side effects in children. Extrapolating from adult studies is inadequate because there are unique safety considerations in children.

> *"Treating children with arthritis on the basis of studies in adults is not sufficient and arguably not ethical."*

Lack of safety data for medications in children is not confined to novel biologic therapeutics. In the past the lack of systematic drug testing in pediatric therapeutics has resulted in widespread off-label use—across primary and specialty care—of an estimated 75% of medications and well-publicized examples of resultant harm done to children.[2] Despite the knowledge that children are not little adults in terms of therapeutic regimens, it has long been practice to treat children with medications studied only in adults by adjusting dosage for weight. Due to differences in pharmacokinetics and the added complexity of metabolism changes with age, growth, and development, treatment of children based on studies in adults could result in harm from underdosing and exposing patients to potential side effects without therapeutic benefit, from potentially overdosing, or from unknown pediatric-specific adverse effects.[3]

Recent legislation has stimulated and mandated more widespread testing in children. The Best Pharmaceuticals for Children Act of 2002 and the Pediatric Research Equity Act of 2003 were recently reauthorized for another 5 years as Public Law 110-85.[4] The first act creates an incentive for pharmaceutical companies to study existing medications in children by granting an additional 6 months of marketing exclusivity (ie, pediatric exclusivity).[5] The Pediatric Research and Equity Act requires drug manufacturers applying for a new product or new product indication to submit data on testing the product in children. These acts served to expand the knowledge of appropriate medication use in children with subsequent pediatric label changes for over 130 medications resulting from the Best Pharmaceuticals for Children Act[6] and more than 60 new listings resulting from the Pediatric Research and Equity Act.[7] The Best Pharmaceuticals for Children Act also has resulted in mandatory study of adverse events specific to children for 12 months postexclusivity which has provided some new information on pediatric-specific adverse events.[8]

The resultant increase in clinical trials for pediatric patients spurred by these legislative acts has implications for the practice of rheumatology. They have expanded the evidence base with which to prescribe and set expectations of therapeutic effectiveness. The successful pursuit of clinical trials in pediatric patients also has practical implications from the standpoint of being able to seek

insurance coverage for therapeutics that have a pediatric indication. Even so, the challenge to conduct pediatric rheumatology clinical trials remains daunting. The relative rarity of these conditions in children generally requires a multisite, multinational effort over a lengthy enrollment period to reach sample sizes necessary to adequately power a study. Despite the best of planning, this may still result in a negative study. For example, a recent clinical trial of the TNF-alpha antagonist infliximab in juvenile rheumatoid arthritis failed to reach the primary endpoint despite the apparent benefit observed in the clinical practice setting.[9] Such a frustration does not mean that similar studies should not be performed, but rather that the pediatric rheumatology research community needs to redouble its efforts in the conduct of randomized clinical trials of novel therapeutics with improved study design and identification of more effective trial endpoints.

Treating children with arthritis on the basis of studies in adults is not sufficient and arguably not ethical. Just as children are not small adults, rheumatoid arthritis is a distinct entity from the various forms of childhood arthritis.[10] In addition to studying results of drug manufacturers' 12-month safety extension of clinical trials under pediatric exclusivity, it behooves pediatric rheumatologists to pursue independent means of better assessing medication safety through the development of safety registries to capture larger numbers of treated patients, to promote more systematic adverse event reporting through the Food and Drug Administration Med Watch system (www.fda.gov/medwatch), and to conduct studies of administrative claims data for evidence of adverse events as has been done in several studies of TNF-alpha antagonists safety in treatment of adult rheumatoid arthritis.[11-13]

When information was released on the adverse cardiovascular risk profile of the selective Cox-2 inhibitor VIOXX in adults and it was withdrawn from the market (ironically just 6 weeks after its approval for treatment of juvenile rheumatoid arthritis), there were few data to provide parents about long-term cardiovascular risk in children. The reply in response to questions about possible ill effects of these medications with long term use, "There have been no such reports in children," while true to the best of our knowledge is not a rigorously studied answer. For this reason, once childhood arthritis is under control, it is often a goal of the pediatric rheumatologist to try and taper off systemic medications in order to limit cumulative exposure.

From the standpoints of the individual primary care provider, parent, and pediatric rheumatologist, there are practical steps to advance safe medication use in children with arthritis. One of the key steps to promoting patient safety in children with arthritis is a strong partnership between the prescribing rheumatologist and the child's primary care provider. There are 3 primary threads to this relationship. First, collaboration to ensure patient compliance with routine laboratory testing (often performed locally every 4-8 weeks) to monitor for medication toxicity[14] and communicating these results to the rheumatologists for review; second, maintenance of up-to-date immunization status including yearly influenza vaccination with inactivated virus vaccine (live vaccines are currently contraindicated in children on immunosuppressive medications);[15] and third, prompt evaluation and treatment of patients on immunosuppressant medications who present with suspected bacterial infection due to the decreased ability to contain the infection.

The partnership between primary care providers and rheumatologists extends in other ways. For example, in some cases the primary care provider's office administers subcutaneous injection arthritis medications for the patients where the parent or guardian is unable. This partnership in care is particularly important in our state because many patients travel long distances across North Carolina to see a pediatric rheumatology specialist located at an academic medical center. The local medical provider will be the first responder to these children in case of infection or disease flare. Good communication between the local treating physician and the pediatric rheumatologist in the care of children with arthritis is invaluable.

The partnership extends to patient education, acceptance of the diagnosis, and comfort with the treatment plan. Pediatric rheumatologists face hurdles with new patients. They begin with overturning the misconception that the child will simply outgrow the arthritis. When parents arrive with this notion, it takes some convincing to explain that medication is indicated and that the known benefits of averting disability and pain from untreated arthritis outweigh the potential risks, some of

Information on Arthritis in Children:

Readers interested in more information on arthritis in children or specific therapeutics are encouraged to consult the Web resources listed below. The Pediatric Education Drug Safety (PEDS) project underway at the University of North Carolina at Chapel Hill (UNC) is developing online continuing medical education for primary care providers along with downloadable provider resources. One of 3 PEDS modules is devoted to medication use and safety in childhood arthritis. The resource will be free to all and available in 2008 (http://harryguess.unc.edu/index.htm).

which are unknown. The primary care provider may use the trust resultant from a long-term relationship with the family to help cope with the diagnosis and facilitate care.

The family may be preoccupied by the child's pain, worried by his or her present functional limitations, and concerned that the child is standing on the sidelines instead of participating with peers. Although they may be eager for their child to get better, many parents are anxious about giving their child any medications because they fear side effects, although not infrequently these same individuals may administer a host of natural supplements that are not regulated or scientifically tested. Time and care are necessary for patient education. It is important to review the medications, indications, the administration process, known and potential side effects, and toxicity monitoring. This helps make the family more comfortable with the treatment plan and enhances compliance. In rare instances parents have reported that the pediatrician told them the medications prescribed by the rheumatologist for arthritis are too strong for a child and advised against taking them. On occasion even some pharmacists have told parents their child should not have been prescribed a medication recommended by the rheumatologist. As a pediatric rheumatologist, I would rather discuss the rationale for prescribing a medication with the pharmacist or local care provider than have a child return to the office for his or her follow-up appointment with untreated ongoing inflammation, risking permanent joint damage. Partnership along the chain of medical care will result in more effective treatment.

The future is bright in arthritis care. Increasing numbers of new therapeutics will be available, particularly new biologic therapeutics currently under development. Indeed, a number of emerging biologic treatments studied in arthritic adults remain to be studied in children. It is imperative that clinical trials proceed in children to ultimately allow for evidence-based rather than experimental medication use in children. Until we routinely and systematically collect safety data on children using medications for arthritis, we will be left with anecdotal reports, the lowest level of scientific evidence. **NCMJ**

COMMENTARY

Sports Injury and Arthritis

Stephen W. Marshall, PhD; Yvonne M. Golightly, MS, PT

> *"…Then come home my children, the sun is gone down*
> *And the dews of the night arise…"*
> William Blake, 1757–1827

A major theme in William Blake's poetry is the transformation of youth's innocence and simplicity into disfigurement, pain, and bitterness in old age. The "dews of the night" that arise in today's society are largely chronic diseases such as arthritis. In this commentary, we explore the connection between acute sports injury, which occurs during the playful period of early life, and arthritis, a widely prevalent later-life chronic condition with high impact on quality of life.

Relationship Between Sports Injury and Arthritis

It is helpful to begin by comparing the basic descriptive epidemiology of these two apparently divergent conditions. Nationally, the incidence of sports injury rises dramatically through the middle and high school years and then subsides throughout adult life.[1] (See Figure 1.) This is largely a reflection of the fact that children and youth play a greater amount of high-intensity sports than adults. Likewise, the incidence is higher in males than females in large part because boys have greater participation in full-contact sports (eg, football, wrestling, and some martial arts) and these sports have a higher risk of injury.

Trauma from sports injury is most closely linked with osteoarthritis. Reliable national data for osteoarthritis is not readily available, but national prevalence data for overall arthritis is available. Osteoarthritis comprises over 50% of the more than 100 types of arthritis in the United States, and thus arthritis prevalence is a reasonable proxy for osteoarthritis prevalence. The prevalence of arthritis is essentially zero for adolescents and young adults (when sports injury incidence is at its peak), but steadily rises with increasing age. (See Figure 2.) Arthritis is more prevalent in women than in men.

How are the curves in Figures 1 and 2 related? It is widely believed that if we could drive down the spike in sports injury incidence during adolescence (eg, through prevention programs), the arthritis curve would be shifted further to the right—that is, pushed further into later life—because there would be less early-onset osteoarthritis.

Is this belief correct? A strong association between injury and osteoarthritis is widely acknowledged in the biomedical community, but the epidemiologic evidence for this relationship is surprisingly sparse. For the knee, several epidemiologic studies have suggested that a history of injury is positively associated with an increased occurrence of knee osteoarthritis.[2-4] However, the few studies published on injury and osteoarthritis of the

"… based on the available evidence, it appears that programs addressing the prevention and care of sports injury will pay dividends in terms of preventing early onset of osteoarthritis."

Stephen W. Marshall, PhD, is an associate professor in the Department of Epidemiology, associate professor in the Department of Orthopedics, adjunct associate professor in the Department of Exercise and Sport Science, and senior biostatistician in the Injury Prevention Research Center, the University of North Carolina at Chapel Hill. He can be reached at smarshall@unc.edu or the University of North Carolina at Chapel Hill, Campus Box 7435, Chapel Hill, NC 27599-7435.

Yvonne M. Golightly, MS, PT, is a doctoral student in the Department of Epidemiology and a graduate research assistant in the Thurston Arthritis Research Center, the University of North Carolina at Chapel Hill.

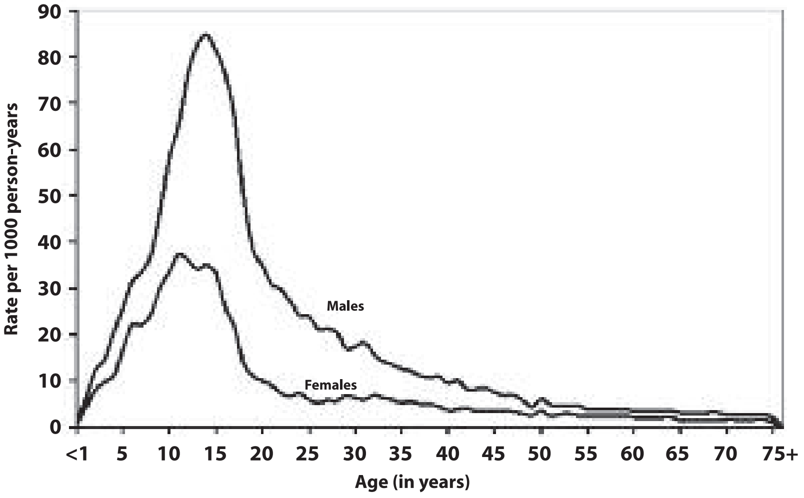
hip[5,6] and the hand[2,7] present conflicting results. There is no research on the association between injury and osteoarthritis at body sites other than the knee, hand, and hip.

Despite the limited epidemiologic data, there is a strong biological basis for linking injury to early onset of osteoarthritis, at least at load-bearing joints. Trauma to the soft tissues (eg, tendons, ligaments, cartilage, and muscles) that surround and support a load-bearing joint such as the knee erodes their ability to absorb and dissipate impact forces. Thus, the cumulative force transmitted to the joint surfaces from simple everyday activities such as walking, running, and jumping is increased. Breakdown of cartilage could result in narrowing of the joint space or fragments of cartilage or other tissues in the joint, common radiographic features of osteoarthritis. Further loss of cartilage may lead to greater contact between the joint surfaces, and bone may respond to this stress by developing osteophytes, another radiographic feature of osteoarthritis. Animal models of meniscus damage[8] and human studies of surgical removal of the meniscus after knee injury[9] support the biological rationale of load-bearing tissue defects contributing to knee osteoarthritis.

Youth Sports Injury in North Carolina

Despite the fact that the epidemiologic data is underdeveloped, it is reasonable to assume a causal relationship between sports injury and osteoarthritis based on the available biological information. Thus, from a public health standpoint, we need to ask, *What do we know about sports injury in North Carolina?* There is no surveillance system that adequately captures the extent of the youth sports injury problem in our state. However, by combining data from various sources some portions of the picture come into focus. Some key statistics are presented in the accompanying sidebar.

Figure 1.
Incidence of Injury from Sports and Recreational Physical Activity, by Age and Sex



Source: Emergency Department Records (National Electronic Injury Surveillance System All Injury Program), United States, July 2000-June 2001 (reproduced from *MMWR* 2002;51:736-740).

The problem of sports injury is concentrated in youth and in males. Important facts to note are:

- For boys ages 10 to 14 years, sports injuries account for over 50% of all emergency department visits for treatment of an unintentional injury.[1]
- For girls ages 10 to 14 years, sports injuries account for nearly 40% of all emergency department visits for treatment of an unintentional injury.[1]
- Boys account for 60% of high school athletes in North Carolina but sustain nearly 75% of high school athletic injuries.
- Football accounts for 16% of high school athletes in North Carolina but over 40% of high school athletic injuries.

Statistics such as these have stark implications for the burden of osteoarthritis in later life and underscore the need for prevention programs aimed at youth sport injury. Recommendations for preventing youth sports injury include correct preparation and care of playing surfaces, improved physical fitness and conditioning of athletes, care and maintenance of playing equipment, and a requirement for the provision of qualified health care professionals (preferably certified athletic trainers) in all schools. The American Academy of Pediatrics' Committee on Sports Medicine has an extensive set of recommendations on preventing injury in specific youth sports including soccer, hockey, baseball/softball, and horseback riding.[10] The National Athletic Trainer's Association also has an extensive set of online resources addressing youth sports injury prevention.[11]

Sports medicine professionals are very concerned about the increasingly competitive nature of youth sports. Over the past few decades, youth sport has evolved from informal neighborhood pick-up games into highly-structured and financially-lucrative competitive leagues that, in the case of at least one sport, are nationally televised. Parents are progressively more focused on collegiate scholarships and the high salaries earned in some professional sports, although only a tiny fraction of youth athletes ever compete at the collegiate or professional level.[12]

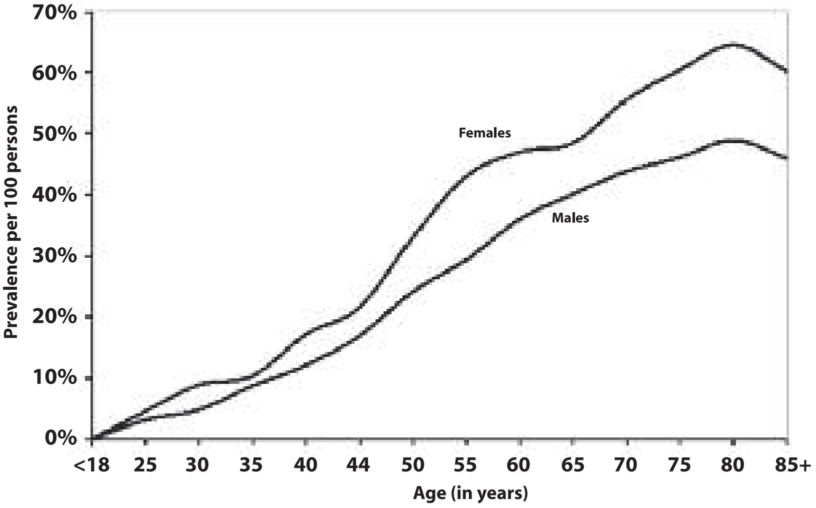
As an example of this trend, it is worrisome that weight gain is now being emphasized at the junior levels of football. The combination of more weight being placed on weight-bearing joints (such as the knee) and a higher risk of joint trauma (due to increased competitiveness) is likely to be a "double whammy" for developing osteoarthritis in later life.

Parents and coaches need to remember that winning and excelling should be secondary goals in youth sport. Personal development, increased physical fitness, skills development, and simply having fun are the primary goals.

Obesity Prevention Through Youth Sports

Aside from trauma due to sports injury, another major factor that increases joint loading is body weight. North Carolina, like the rest of United States, has experienced an alarming increase in prevalence of obesity and overweight over the past few decades.[13,14] The rapid increase in sedentary recreational activities, such as home computers and electronic games, has fueled an equally spectacular growth in our children's body mass index.[14,15] Increasing academic pressures from schools further limit leisure time for children and youth. Obese/overweight children grow into obese/overweight adults who are more likely than the rest of the population to develop osteoarthritis of the hip and knee in addition to diabetes, cardiovascular disease, and other chronic conditions.[16,17]

Figure 2.
Prevalence of Self-Reported Arthritis, by Age and Sex



Source: National Health Interview Survey, United States, 2001.

One obvious solution to the obesity epidemic is to encourage kids to participate in youth sports. In addition to obesity prevention, youth sports are widely surmised to have beneficial effects in terms of personal development and team skills. But not all youth sports are created equal; some carry a high risk of injury. The expected reductions in arthritis from increased promotion of youth physical activity could be negated if we do not also devote resources to preventing and caring for youth sports injuries. Even when sports injuries cannot be prevented completely, proper treatment and rehabilitation of these injuries is important to restore optimal movement patterns, likely reducing the risk of both reinjury and developing osteoarthritis. Thus, the public health equation is not:

More sports in early life = Fewer adults with
lower extremity osteoarthritis

but rather:

More sports in early life + fewer sports injuries
+ maintenance of healthy body weight
+ good rehabilitation after sports injuries
= Fewer adults with lower extremity osteoarthritis

Additionally, injury often forces participants into reducing their level of activity. Uninjured participants, on the other hand, are more likely to maintain their activity program.[18,19] Thus, programs addressing the prevention of sports injury will increase the public health benefit of physical activity promotion campaigns. Sports injury prevention advice should always be incorporated into physical activity health promotion campaigns.[20]

Future Directions for Research and Policy

Epidemiologically, the relationship between injury and osteoarthritis needs to be further clarified through additional research. However, based on the available evidence, it appears that programs addressing the prevention and care of sports injury will pay dividends in terms of preventing early onset of osteoarthritis. Reductions in osteoarthritis prevalence can also accrue from obesity prevention through increased sports participation. However, increasing participation in youth sports without addressing the potential for a resultant increase in injury incidence may fail to attain the overall goal of arthritis prevention. One sport of particular concern in this regard is football, not only for its high incidence of injury, but because the sport is increasingly associated with weight gain during the high school years. **NCMJ**

Sports Injury in North Carolina Youth—Key Statistics

- Total number of North Carolina high school athletes … 175 582
  - Girls: 67 774 (39%)
  - Boys: 107 807 (61%)
  - Football: 28 074 (16% of total)

- Annual number of North Carolina high school sports injuries …10 531
  - Girls: 2864 (27%)
  - Boys: 7667 (73%)
  - Football: 4381 (42% of total)

- Annual number of emergency department visits for sports injury in North Carolina…123 000

- Proportion of all emergency department visits for treatment of unintentional injury that is due to sport:*
  - Across all age groups: 16%
  - Girls ages 10 to 14 years: 38%
  - Boys ages 10 to 14 years: 52%

Depression and Arthritis

Brenda M. DeVellis, PhD; Robert F. DeVellis, PhD

The onset of symptoms and eventual diagnosis of chronic disease typically cause emotional distress. In most cases this distress subsides over time as psychological adaptation to the condition occurs.[1] A significant minority of people, however, develop less transient, more severe psychological distress that can result in significant additional disability and suffering. The comorbidity of depression and arthritis is a major problem compromising the health of a significant number of Americans. This type of comorbidity is far more prevalent than previously thought and can have a negative impact greater than the sum of the 2 illnesses separately.[2] Thus, failure to appreciate the presence of depression in patients with arthritis can significantly compromise not only diagnosis and treatment of the affected patient but the impact of both illnesses and the health of the public overall.

Depression: Prevalence and Impact

In a lead editorial in the *American Journal of Public Health* in 1999, Neugebauer called for increased attention by the medical and public health communities to the devastating personal and economic impact of mental illness.[3] He cited findings from the 1994 National Comorbidity Survey showing that 17% of a national probability sample of US noninstitutionalized adults aged 15 years to 54 years had experienced one or more episodes of major depressive disorder in their lifetime.[4] Of equal concern were the 12-month prevalence findings; in the previous year, 10% of adults had experienced one or more depressive disorders. In a replication study of the 1994 survey, Kessler found that the prevalence numbers from 2001-2002 for a new population sample of 9282 were similar for lifetime prevalence (16.6% of people with one or more episodes of major depression in their lifetime) and somewhat lower (6.6%) for those experiencing an episode in the past year.[5,6] These findings are important because of the intense suffering and the significant morbidity and mortality associated with depression. One of the most tragic consequences of depression is suicide. In 2004, 32 439 people died by suicide in the US making it the 11th most frequent cause of death. In contrast, the number of homicides in 2004 was almost half this number at 17 357.[7] Further, more than 90% of people who commit suicide have a diagnosable mental disorder, most commonly a depressive disorder or a substance abuse disorder.

When Schulz et al examined mortality in adults over 65 years of age, they found that depressive symptoms at baseline were an independent risk factor for all cause mortality 6 years later even after controlling for multiple sociodemographic, disease, and health risk factors.[8] Pennix et al also studied the relationship of earlier self-reported depressive symptoms to later morbidity in older adults (age greater than 64 years) who were initially free of disability. Of these 6247 disability free people, 496 had scores greater than 20 out of 60 on the Center for Epidemiologic Symptoms Depression Scale, scores suggestive of depression.[9] At follow-up, instances of new heart attacks and new hip fractures occurred more frequently among those with more initial depressive symptoms but no initial disability. In addition, incident activities of daily living and mobility disability were higher in the initially-depressed group which, by 6 years of follow-up, had an activities of living disability rate of 36% and a mobility disability rate of 67% compared to those with fewer or no initial depressive symptoms (24% and 48% for activities of daily living and mobility disability, respectively). This significant difference in activities of daily living scores between those with more versus fewer depressive symptoms emerged after the first year of the study and steadily increased over the following 5 years. Almost half of this increased disability risk was explained by sociodemographic (gender, education, and income) factors, and a smaller part of the increase was explained by physical activity and having close contacts with relatives. However, after controlling for all of these factors, arthritis and angina were the 2 health conditions that contributed the most to the increased risk for disability in depression.

Depression and Arthritis

Increasing recognition of the importance of studying psychiatric and medical comorbidity has emerged over the past 15 years due to several large scale and pivotal studies in the areas of health services research and psychiatric epidemiology.

Brenda M. DeVellis, PhD, is a professor in the Department of Health Behavior and Health Education and a member of the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill.

Robert F. DeVellis, PhD, is a professor in the Department of Health Behavior and Health Education and a member of the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill.

The Medical Outcomes Study involved over 22 000 patients who visited 523 different medical providers during a specified period of time in 1986.[2] The major focus of this 4-year prospective study was on the consequences (outcomes) of chronic illness; it was the first large scale study "to include a psychiatric condition (depression) on equal footing with chronic medical conditions." Of the many important findings that have emerged from the Medical Outcomes Study, 4 are particularly relevant. First, Wells et al found that depression was associated with the same level or more of disability than 6 of the major medical chronic conditions studied and that only myocardial infarction in the previous year or current congestive heart failure and arthritis were associated with greater morbidity in any domain of functioning when compared with the functioning of people with depression.[2] Moreover, this finding was maintained over time in the longitudinal analyses. Second, Wells et al concluded that when arthritis was comorbid with depression, the resulting disability exceeded the disability level one would expect from simply combining disability due to depression with disability due to arthritis. That is, the negative effects of depression and arthritis are multiplicative rather than additive. Third, the negative consequences of subthreshold depression (ie, having some depressive symptoms without reaching the threshold for a depressive disorder diagnosis) were similar to consequences for people whose symptoms did reach diagnostic criteria. And, fourth, people's subthreshold depressive symptoms "remained unchanged in functioning and well-being over two years," which suggests that subthreshold depressive symptoms are not transient.

Other studies underscore the negative impact of comorbid depression and arthritis. Ang et al followed 1290 consecutive outpatients with rheumatoid arthritis over an 18-year period and found that depressive symptoms at baseline increased the risk of mortality many years later.[10] Stang et al used National Comorbidity Survey Replication data to examine the relationship between major depressive disorder and self-reported arthritis.[11] When controlling for age and other sociodemographic factors, they found that arthritis and major depressive disorder were significantly associated. Finally, Lin et al did the first, and to our knowledge only, major intervention study aimed at decreasing depression in patients with arthritis.[12] Their randomized controlled trial included 1801 depressed older adults (aged 60 years or older) from 18 primary care clinics in 5 states. The intervention consisted of antidepressant medications and/or 6 to 8 sessions of psychotherapy (Problem Solving Treatment in Primary Care). At 12 months they found a significant decrease of depressive symptoms in the intervention group compared to the usual care treatment control group as well as lower mean pain scores. In addition, they found improved activities of daily living and improved quality of life.

Overall, the pattern of findings from research indicates a substantial impact of depression on the trajectory of comorbid arthritis. In addition, the pain and loss of function associated with arthritis can contribute to depression. Both arthritis and depression have substantial prevalence rates. Thus, patients presenting with comorbid arthritis and depression are fairly common. It is important that health care providers recognize the presence and effects of depression as they treat patients with arthritis. Better control of depressive symptoms should be an integral component of treating people with arthritis who also experience depression. Helping arthritis patients obtain relief from their depression promises both to mitigate the added risk associated with depression and to enable the patient and physician to manage the arthritis itself more effectively. A first step to optimal treatment may simply be an awareness of the role that depression can play in the course of arthritis and its treatment. A second achievable step is screening for depression using one of several brief instruments developed for use in primary medical care settings. Finally, physicians should assist patients who have depression in finding appropriate care. Doing so will not only reduce unnecessary suffering arising from the depression itself but will also improve arthritis outcomes. **NCMJ**

Physical Activity and Weight Loss Interventions in Older Adults With Knee Osteoarthritis

Stephen P. Messier, PhD

Osteoarthritis is a degenerative disease that affects articular cartilage and the underlying subchondral bone. The cartilaginous surfaces become pitted resulting in hypertrophic changes along the joint margins and reactive changes in the subchondral bone. Severe osteoarthritis is characterized by joint space narrowing, absence of articular cartilage, increased density and stiffness of the subchondral bone, and osteophyte formation along the joint margins.[1,2]

The knee is the most commonly affected weight-bearing joint. The major symptoms of knee osteoarthritis are pain and stiffness. Decreased mobility leading to muscle atrophy, an accelerated decline in physical function, and the inability to engage in activities of daily living such as walking and climbing stairs are clinical consequences that often lead to a loss of independence and a poor quality of life.[2-6]

The etiology of primary (idiopathic) osteoarthritis is unknown, although biomechanical and inflammatory mechanisms have been proposed as causative factors. Biomechanically, either structural abnormalities such as obesity or neuromuscular dysfunction may cause increased joint loads during walking. Failure to absorb these loads properly may cause microcracks in the subchondral tissue leading to increased stresses and cartilage degradation.[7]

Recent studies demonstrate that low-grade inflammation plays a pathophysiological role in osteoarthritis. The inflammatory cytokine interleukin-1 beta (IL-1ß) is present in the joint fluids of osteoarthritis patients.[8] Interleukin-1 beta is believed to play a role in mediating joint inflammation and cartilage degradation in osteoarthritis.[9] Likewise, an inflammatory component associated with osteoarthritis can be detected in the circulation since serum concentrations of inflammatory markers such as cytokines (interleukin-6, IL-6; tumor necrosis factor alpha, TNFα) and the acute-phase reactant C-reactive protein are higher in persons with knee or hip osteoarthritis compared to those without osteoarthritis.[10-13] Longitudinal studies demonstrate that high serum levels of C-reactive protein and TNFα predict increased radiographic progression of knee osteoarthritis as much as 5 years later.[11,14,15] Moreover, a few studies associate osteoarthritis severity and physical function with higher inflammatory markers in the blood.[10,16,17] Thus, severity, mobility, pain, stiffness, and radiographic progression are at least partly mediated by the level of chronic inflammation in osteoarthritis patients. Diffusion of cytokines from the synovial fluid into the cartilage could contribute to the cartilage matrix loss observed in osteoarthritis by stimulating chondrocyte catabolic activity and inhibiting anabolic activity.

Obesity is a major risk factor for knee osteoarthritis.[18] Weight change and the risk of developing knee osteoarthritis are significantly associated. Felson et al showed that a 5.1 kg loss in body mass over a 10-year period reduced the odds of developing osteoarthritis by more than 50%.[19] Obese individuals have higher concentrations of inflammatory markers than lean people, and a large percentage of people with knee osteoarthritis are overweight or obese. Hence, obese individuals with knee osteoarthritis may have an even greater contribution of inflammation to functional limitation and disease progression.[20] Besides direct effects on the joint, inflammatory mediators can also affect muscle function and lower the pain threshold.

> *"Several studies have shown that pain and disability improve with short-term (3 to 6 months) exercise."*

Unfortunately, treatments that affect the underlying biomechanical and inflammatory disease pathways are limited. The primary aim of therapies currently available is pain relief.

Stephen P. Messier, PhD, is a professor and director of the J.B. Snow Biomechanics Laboratory in the Department of Health and Exercise Science, Wake Forest University. He can be reached at messier@wfu.edu or Department of Health & Exercise Science, Wake Forest University, Winston-Salem, NC 27109.

Antiinflammatory medications and orthopaedic procedures are primary methods of treatment. More recently, exercise and weight loss have been used as therapeutic modalities for knee osteoarthritis patients.

The difficulty patients with knee osteoarthritis have with activities of daily living often result in activity avoidance.[21] Physical exercise, however, is an effective nonpharmacologic treatment. Several studies have shown that pain and disability improve with short-term (3 to 6 months) exercise. Short-term walking programs improve aerobic capacity, walking time, and self-reported function.[22,23] Similarly, lower extremity resistance training increases strength, decreases pain, and improves function in patients with osteoarthritis.[24,25] More recently, long-term walking and resistance training programs have been effective in slowing the decline in physical function commonly seen in this disabled population. A randomized clinical trial of 18-month walking and resistance training programs in 439 community-dwelling older adults with knee osteoarthritis reduced disability and pain and improved balance and mobility relative to a health education control group.[26] In a similar population, greater adherence to a physical activity program was associated with better physical performance and self-reported physical function.[27] Exercise also has been shown to improve late-life minor depression.[28]

Short- and long-term aerobic and resistance training programs are safe and effective treatments for knee osteoarthritis.[21] Traditional 3 days per week, 1 hour per day programs have been the most common regimens studied. Unfortunately, little is known regarding the dose response to exercise in the older, mostly female, sedentary, and predominately overweight population. Continuous weight-bearing aerobic exercise such as walking can initially be difficult for patients with knee osteoarthritis who experience significant pain. Starting with short bouts of exercise and inserting several rest periods when the patient has progressed to 30 or 40 minutes of walking improves adherence. Adding several resistance training exercises between periods of walking has proven effective and popular with patients.[8,29] The intensity of the exercise intervention may differ depending on the desired outcomes. If the goal is making exercise a part of a healthy lifestyle, then continued participation is more important than intensity. The exercise prescription should be flexible enough to accommodate periods of greater pain.

An important component of treatment for knee osteoarthritis is the reduction of body weight in patients who are overweight or obese. Results of a randomized, controlled clinical trial have shown that a program of diet and exercise results in greater improvements in self-reported function, mobility, and pain than exercise only, diet only, or healthy lifestyle interventions.[29] A dose response to weight loss indicated that participants who lost between 7.5% and 11.0% of their body weight exhibited significantly better self-reported function than participants who exhibited more modest weight loss (2.5% to 7.5%) or no weight loss (gained to 2.5%).[2] Christensen et al[30] recently found that an 11% weight loss in an intensive diet group over an 8-week period produced a 3-fold improvement in function in older, obese adults with knee osteoarthritis relative to a control diet group that lost 4% of their body weight.

Studies have shown that weight loss decreases inflammation, reducing the cytokine activity that may be related to cartilage degradation. Nicklas et al[20] showed that a 5% weight loss over 18 months significantly reduced C-reactive protein, IL-6, and TNFα receptor 1 concentrations compared with a weight stable group. However, it is not yet known whether a specific amount of weight loss maximally reduces inflammation or whether improvements in physical function, pain, and osteoarthritis progression are related to a decline in chronic inflammation with weight loss.

Weight loss also has a beneficial effect on knee joint loads. Messier et al[31] found that every 1 lb in weight loss was related to a 4 lb decrease in knee compressive forces per step. These results imply that if an average weight knee osteoarthritis patient (about 200 lb) lost 10 lb, each knee would be subjected to 48 000 lb less in knee compressive forces per mile walked. Accumulated over thousands of steps per day, a reduction of this magnitude would appear to be clinically meaningful.

Both exercise and weight loss interventions improve pain and self-reported function, reduce inflammation, and enhance balance and mobility in older, obese adults with knee osteoarthritis. While effective, neither exercise nor weight loss interventions have attenuated disease progression. We suggest that a weight loss of 10% to 15% of baseline body weight, or 2 to 3 times greater weight loss than achieved in recent long-term studies, may provide the necessary stimulus to reduce inflammation and knee joint loads to levels that result in less cartilage degradation and a slowing of disease progression. **NCMJ**

COMMENTARY

Community and Environmental Factors and Arthritis Outcomes

Joanne M. Jordan, MD, MPH; Leigh F. Callahan, PhD

Great strides have been made in the past century in preventing disease and reducing early mortality, but disparities in health between and within countries are still pervasive.[1-3] The National Institutes of Health defines disparities broadly as "differences in the incidence, prevalence, mortality, and burden of diseases and other adverse health conditions that exist among specific population groups in the United States."[4]

The national health care research agenda places high priority on reducing disparities in health outcomes among persons of different socioeconomic and racial/ethnic groups through examining the mechanisms for disparities and proposing prevention strategies.[5] There is now an increasing interest in more explicit investigations of the complex issues regarding disparities and health outcomes. The urgency of understanding the effects of external forces at multiple levels including individuals and their behaviors, communities and environments, and social policies was made vividly apparent in the wake of Hurricane Katrina. The same could be illustrated in how we reacted to the fall 2007 California wildfires. We cannot deny that place can have a significant impact on outcomes regardless of an individual's resources. We also cannot deny that there are racial and ethnic differences in communities in the US.

The association between lower levels of individual socioeconomic status and poorer health outcomes has been documented for centuries in various parts of the developed world.[6-9] Associations between lower socioeconomic status and increased prevalence of disease, morbidity, and mortality in persons with arthritis and rheumatic conditions have been demonstrated in a number of population-based and clinical studies.[10-13] The role of individual socioeconomic status has been studied examining variables such as formal education level, income, occupation, and home ownership. Health outcomes have been shown to be associated with the socioeconomic environment of an individual's neighborhood,[14-16] independent of the individual's socioeconomic status.[15-17] Although there is a long tradition of public health research relating community factors to patterns of health and disease,[18,19] this has traditionally been in the context of hygiene, clean water, and the presence/eradication of infectious disease-bearing vectors. Increasingly, research findings are beginning to focus on the upstream determinants related to the community in the context of chronic diseases. These include place of residence, work environment, or wider social and economic policies. These community variables often are described as "social context," a catch-all phrase referring to the spectrum of societal factors that may not be directly measured at the individual level. The socioeconomic context of communities may affect characteristics of the social, service, and physical environments to which all residents are exposed regardless of their own socioeconomic position[20,21] and may have a greater negative impact on those with fewer individual resources.[22,23]

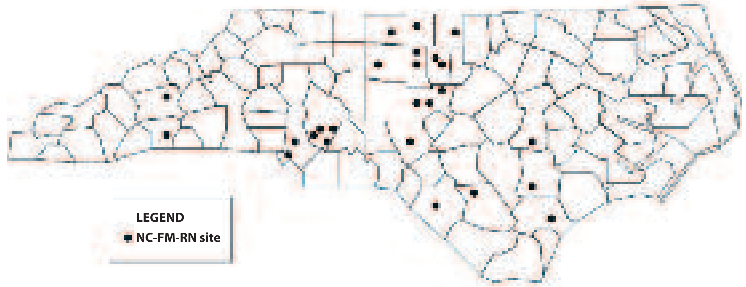
Joanne M. Jordan, MD, MPH, is an associate professor of medicine and orthopaedics, chief of the Division of Rheumatology, Allergy, and Immunology, and director of the Thurston Arthritis Research Center at The University of North Carolina at Chapel Hill. She can be reached at Joanne_Jordan@med.unc.edu or 3300 Doc J. Thurston, Jr Building, CB#7280, Chapel Hill, NC 27599.

Leigh F. Callahan, PhD, is an associate professor of medicine, orthopaedics, and social medicine at the Thurston Arthritis Research Center, the University of North Carolina at Chapel Hill.

Figure 1.
Map of the 25 North Carolina Family Medicine Research Network (NC-FM-RN) Sites



We at the Thurston Arthritis Research Center at the University of North Carolina also have been very interested in the role of individuals' community and socioeconomic environments on health outcomes in people with arthritis throughout the state of North Carolina. We have examined the associations of community poverty level with arthritis prevalence and health status.[24,25] (L. F. Callahan, T. Mielenz, B. Schoster, et al, unpublished data, 2007; L. F. Callahan, J. Schreffler, T. Mielenz, et al, unpublished data, 2007) We have also embarked on a novel research agenda that examines one particular aspect of the environment—chronic environmental metal exposures—in relationship to osteoarthritis in Johnston County, the site of a longitudinal community-based research study of racial/ethnic disparities in osteoarthritis and disability outcomes between African Americans and whites.[26]

Community Poverty Level and Health Outcomes in North Carolina

In one study using patients from the North Carolina Family Medicine Research Network, a research consortium of 25 family medicine sites in rural, urban, and suburban practices across the state[27] (see Figure 1), we observed that white patients with low educational attainment (defined as less than a high school degree) and who lived in high poverty areas (defined for the block group using the 2000 Census as the percentage of the population in households with income below the poverty level) had 1.56 times the odds of reporting arthritis compared to white patients with higher educational attainment who lived in low poverty areas. African-American patients with low education living in an area with high poverty levels were more than twice as likely to report arthritis compared to African-American patients with high education levels living in low poverty areas. (L. F. Callahan, T. Mielenz, B. Schoster, et al, unpublished data, 2007)

We have also examined associations between education and census-based community-level measures of socioeconomic status in 4565 whites and African Americans in the Research Network. We used health-related quality of life assessed by the SF-12v2 Physical Component Summary and Mental Component Summary and 3 Centers for Disease Control and Prevention health-related quality of life measures to summarize the impacts of the environments.[28,29] Analyses also were conducted on subgroups of arthritis and cardiovascular disease patients. In whites, all 5 health-related quality of life outcomes had significant and meaningful associations for those with the lowest education and poorer outcomes; and 4 outcomes associated high community poverty level with poorer status. Four outcomes had associations with poorer status for the lowest education and high community poverty levels in the African-American group. Arthritis and cardiovascular disease subgroup analyses showed parallel findings. (L. F. Callahan, J. Schreffler, T. Mielenz, et al, unpublished data, 2007) These findings indicate that even using crude environmental measures, community level variables are important.

Environmental Exposures as Potential Explanations of Community and Social Determinants of Outcome

What could explain geographic, socioeconomic, and community variation in arthritis outcomes? One potential explanation is environmental exposures to harmful substances in areas that are economically depressed. Many of the rheumatic illnesses such as systemic sclerosis, systemic lupus erythematosus, and rheumatoid arthritis are autoimmune in nature with both genetic and environmental components. Environmental exposures in relationship to autoimmune conditions have usually been examined in response to report of a cluster of affected persons surrounding an environmental pollution source or a common occupational exposure.[30-34] Such exposures have included organic solvents, petroleum products, mercury, and silica dust,[35-37] all of which can affect the immune system. However, interest in the role of *routine* environmental exposures, including those from childhood or throughout the lifecourse, is gaining traction. There is concern that routine environmental exposures could act as "triggers" to induce or maintain an autoimmune response or poor health outcome in individuals not exposed to overt environmental disasters. These include risk factors such as prior infections and tobacco and hormone use.[38,39] Since some of these hypotheses are preliminary, their penetration into clinical practice has not yet widely occurred; nonetheless, the impact of treating these exposures as potentially modifiable targets for primary and secondary prevention could be significant.

Examination of environmental causes of nonautoimmune musculoskeletal conditions such as osteoarthritis has been limited. Some occupations, particularly those requiring heavy physical labor or repetitive knee bending, are more likely to be associated with osteoarthritis presumably through their physical demands and the biomechanical loads they entail.[40] Dietary intake and use of hormones and tobacco have also been examined in relationship to osteoarthritis[41-45] but few other environmental exposures have been examined.

We have recently begun examination of metal exposures, many of which occurred throughout the lifetime, and osteoarthritis using data from the Johnston County Osteoarthritis Project, a longitudinal community-based research study of racial/ethnic disparities in osteoarthritis and disability outcomes between African Americans and whites.[26]

Environmental Metal Exposures as Potential Risk Factors for Osteoarthritis

Heavy metals are ubiquitous, and exposure through drinking water, contaminated food, pesticides, and other means is widespread in our society[46-51] and remains a significant public health problem particularly in high-risk sociodemographic groups and certain geographic locations.[46,51] The varied and sometimes subtle health effects of low-level, chronic exposures to multiple elements such as lead, mercury, arsenic, and cadmium have only recently been recognized.[52-61] Many metals are divalent or trivalent cations with a tropism for bone and the potential to bind to negatively charged components of proteoglycans in cartilage.[55,62-65] Yet little attention has been directed at the possible roles of these metals in relationship to osteoarthritis, a condition accompanied by profound disruption in both bone and cartilage.[66-69]

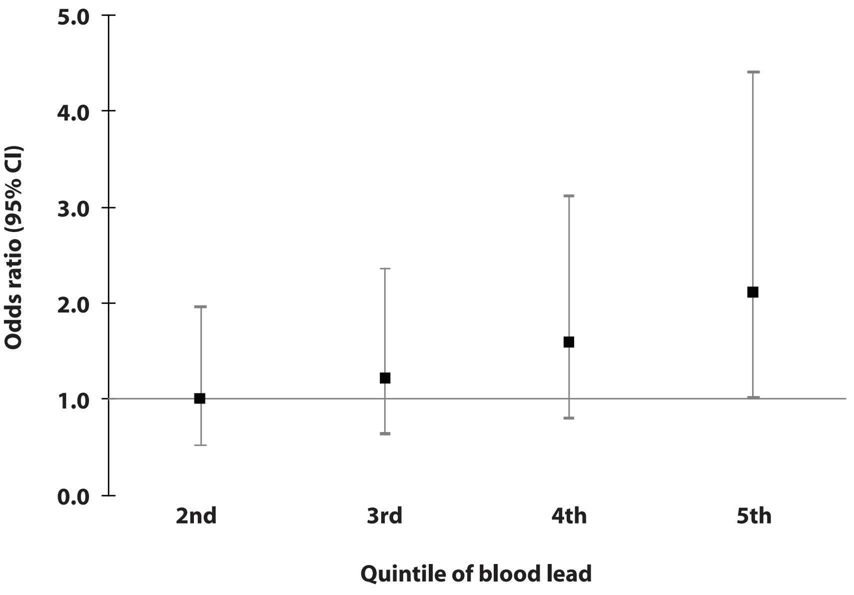
Lead and Osteoarthritis

Approximately 95% of total body lead burden in adults is stored in bone with accumulation occurring into the 7th decade. Bone lead is released into blood chronically, making bone a target tissue for lead toxicity and an endogenous source of persistent lead toxicity particularly after menopause.[70-73] Lead affects bone formation and resorption, and recent data suggest that lead affects cartilage as well.[74] In preliminary data from the Johnston County Osteoarthritis Project, we observed higher blood lead levels were associated with knee osteoarthritis severity in men and women (see Figure 2) and with serum and urine osteoarthritis biomarkers in women with possible racial differences in effect.[75,76]

Selenium and Osteoarthritis

One potentially protective environmental exposure is selenium. Selenium is an essential trace element and a required cofactor for glutathione peroxidase and antioxidant defense against free radicals and peroxide.[77,79] It has been evaluated for its protective role in cardiovascular disease, cancer, and other conditions of aging.[77,79] Animals with selenium deficiency have irregular bone formation, decreased bone strength, and abnormalities in types I and II collagen in cartilage.[80-82] In areas of China and eastern Asia where selenium levels in the soil are among the lowest in the world, low selenium, among other risk factors, has been associated with Kashin-Beck Disease, an endemic, early onset osteoarthropathy. Early intervention regarding deficiency in this environmental factor has decreased the incidence of this disease.[83,84] Selenium levels may be low in the southeastern United States as well,[85] leading us to investigate the role of selenium in osteoarthritis. Interestingly, preliminary data showed that those with low selenium levels, measured in toenails, were more likely to have knee osteoarthritis and more severe knee osteoarthritis,[86] and women with low selenium were more likely to have hip osteoarthritis. (J. M. Jordan, F. Fang, J. B. Renner, et al, unpublished data, 2007).

Figure 2.
Blood Lead Levels and Severity of Radiographic Knee Osteoarthritis



These results are compelling in that they suggest there may be modifiable environmental factors that could influence the onset and progression of osteoarthritis with the potential for intervention. We suspect these factors interact with genetic and other risk factor susceptibility, and future studies of these issues are planned.

Examination of the role of both individual and community social determinants of health outcomes in arthritis and rheumatic conditions is overdue. Future studies will be needed to verify cross-sectional associations longitudinally and to tease out explanatory factors behind observations. Arthritis and autoimmune conditions are areas in need of further research in the role of environmental exposures in etiology and maintenance of disease. The possibility that environmental exposures could contribute to these conditions and to ethnic disparities in these conditions would likely lead to changes in clinical practice and public policy. **NCMJ**

Pain and Arthritis

John B. Winfield, MD

Arthritis is virtually synonymous with pain. Arthritis-associated pain is the number one reason patients visit a doctor. For the past 8 years, I have been practicing rheumatology in western North Carolina. Before that, my entire career had been in academic or medical research institutions, most notably at the University of North Carolina at Chapel Hill. The current foray into the "real world" of medicine has been enlightening, to say the least, and has allowed some insight into how arthritis pain is approached in North Carolina that could come only from being part of a local medical community. In this commentary, I will make some suggestions as to how we could do a better job. In addition to medical practice issues such as diagnosis, classification, and management, I will touch upon several less conventional topics such as physician attitude and behavior in the approach to pain.

Chronic pain is an extremely important aspect of illness, yet it is woefully neglected at all levels of training and practice starting with medical school curricula. The public health burden of chronic pain falls mostly on the primary care physician. It has been my experience in "the real world" that there is enormous variability in the willingness and effectiveness of the primary care physician to manage chronic pain in his or her patients. All too often there is a direct "punt" of the entire problem to the local anesthesia pain clinic where after a series of epidural blocks—which don't help—the patient is "punted" back to the primary care physician and then to me.

Suggestion 1

Address pain as a disease entity, not as a sensory entity.[1] Not infrequently in office-based practice, treatment of pain is secondary to diagnosis and treatment of the disease state. This is unfortunate because pain, especially chronic pain, is among the most disabling and costly medical problems in Western countries.[2] Patients suffering with chronic diffuse pain who lack objective clinical and laboratory findings (ie, fibromyalgia) are especially likely to be dismissed as not having "real" pain, which only perpetuates their illness. Presence of pain should be specifically sought and evaluated in all patients and, if present, relief of pain should be a primary focus of the physician's efforts.

"Presence of pain should be specifically sought and evaluated in all patients and, if present, relief of pain should be a primary focus of the physician's efforts."

Suggestion 2

Classify pain immediately after recognition. Pain classification is not difficult. Nociceptive pain is due to stimulation of peripheral pain receptors on thinly myelinated Ad and/or unmyelinated C afferents during inflammation or injury of tissues. The pain experienced generally matches the noxious stimulus. Both peripheral and central nervous system processes play a role in neuropathic pain, which may occur with direct nerve injury. There are 3 common types: (1) peripheral neuropathic pain (eg, postherpetic neuralgia, painful diabetic neuropathy, radiculopathic pain due to injury to spinal nerve roots); (2) central neuropathic pain (eg, central poststroke pain, spinal cord injury pain); and (3) cancer-associated neuropathic pain. Complex regional pain syndrome (reflex sympathetic dystrophy), while very rare, is another neuropathic pain syndrome. Neuropathic pain may be paroxysmal, with unusual characteristics such as electric shock-like shooting or burning, and may be

John B. Winfield, MD, is the Herman and Louise Smith Distinguished Professor of Medicine in Arthritis Emeritus at the University of North Carolina at Chapel Hill School of Medicine and currently is a practicing rheumatologist with Appalachian Regional Rheumatology. He can be reached at john_winfield@med.unc.edu or 400 Shadowline Drive, Suite 100, Boone, NC 28607.

associated with hyperpathia (persistence after the stimulus has ended, spreading or worsening in crescendo-fashion with repeated touching). Chronic pain of complex etiology occurs in fibromyalgia and a large number of substantially overlapping regional pain syndromes such as migraine headache, temporomandibular disorders, irritable bowel syndrome, and atypical chest pain, to name a few. Previously termed "functional pain syndromes" on the basis of absent structural pathology, these illnesses share very close relationships etiologically and pathophysiologically. Recent advances in the understanding of the psychophysiologic/neurophysiologic dysregulation in such illnesses is impelling a unifying reclassification as central sensitivity syndromes.[3] More purely psychogenic pain is seen in somatoform and somatization disorders and hysteria and is quite rare.

Suggestion 3

Invest some time catching up on recent developments in fibromyalgia. Forget the disparaging and dismissive comments of your professors and senior residents. These patients are not crocks or neurotic whiners. Rather, they have a complex neurosensory disorder manifest by multiple abnormalities in how the central nervous system processes and interprets sensory input. At least 5% of adult females have fibromyalgia. Approximately 25% of patients with rheumatoid arthritis and perhaps 50% of patients with lupus also have fibromyalgia, and both illnesses must be treated for optimum therapeutic response. In fibromyalgia, altered central nociceptive processing results in a decrease in the pain perception threshold and in the threshold for pain tolerance. Except for pain with palpation of tender points, the physical examination and all routine laboratory tests are normal yet the pain is very real, as can be demonstrated by sophisticated quantitative sensory testing methods and functional MRI studies. Multiple genes[4,5] that increase vulnerability to this and related disorders have been identified. These genes encode molecules involved in nociceptive processing, and their identification is proving to be invaluable in new drug discovery. Very effective management strategies have evolved,[6,7] and for the first time a drug, pregabalin (Lyrica), has been specifically approved by the Food and Drug Administration for treatment of pain in fibromyalgia. Several more (eg, duloxetine/Cymbalta and sodium oxybate/Xyrem) should receive Food and Drug Administration approval shortly.

Suggestion 4

Apply some simple approaches for measuring pain, fatigue, sleep, psychological well-being, and daily functioning in your patients. This sounds complicated and time-consuming, but it is not. Pain intensity can be measured with either a verbal or numerical rating scale or a visual analog scale. Observation of pain behaviors such as guarding, rubbing, grimacing, and sighing provides insight into self-efficacy for control of chronic pain—more prominent pain behavior equates to low self-efficacy—which in turn greatly compromises a patient's capacity to cope with chronic pain conditions. A number of measurement tools can be applied in just a few minutes while the patient is in the waiting room through use of a multidimensional health assessment questionnaire. This instrument combines simple self-report forms that incorporate validated scales for physical and psychological health status (modified health assessment questionnaire); visual analog scales for pain, fatigue, and patient global self-assessment; a checklist of current symptoms; and scales for helplessness and cognitive performance.[8] Easily adaptable to a busy practice, such information is invaluable for the psychosocial assessment of pain both diagnostically and in monitoring response to therapy.

Suggestion 5

Do not be afraid of opioids. It is my experience that certain primary care physicians or even entire practice groups have a policy of not prescribing narcotics, period! This is ridiculous, bad medicine, and perhaps even malpractice. Some chronic noncancer pain can be managed only with opioids including pain in occasional patients with fibromyalgia. Not every patient who requests hydrocodone is a drug-seeker. Low-dose opioids taken concurrently with nonsteroidal anti-inflammatory drugs or Cox-2 inhibitors for patients with osteoarthritis who fail acetaminophen are not only effective when used as part of a multimodal approach to pain control, but may have fewer potentially life-threatening complications.[9] Reasonable guidelines for use of opioids in more severe musculoskeletal pain include exclusion of substance abusers, concomitant attention to psychological and social perpetuators of pain, use of an opioid treatment contract, a one physician-one dispensing pharmacy policy, and close monitoring. It should be remembered that drug-seeking behavior (pseudoaddiction) may indicate that pain is not being controlled adequately.

Summary

Address arthritis-associated pain as a disease entity, not as a sensory entity. Attempt to classify chronic pain as nociceptive pain, neuropathic pain, fibromyalgia-type pain, or psychogenic pain (very uncommon); specific treatment approaches are required for these different types of pain. Overcome your negative bias against fibromyalgia and review recent discoveries that have led to classification of fibromyalgia as a biologically-based neurosensory disorder. Use the simple and convenient ways that are available to measure pain and its concomitants (fatigue, poor sleep, depression, anxiety, and impaired physical functioning) both at initial evaluation and in follow-up visits as a guide to therapy. Do not fear use of opioids; just be careful with this class of drug. **NCMJ**

COMMENTARY

Contemporary Total Joint Arthroplasty

Victor M. Goldberg, MD

Total joint arthroplasty has become a successful and reproducible surgical treatment for significant arthritis. Both pain relief and functional outcomes have been excellent. In 2004 over 475 000 total knee replacements and more than 230 000 total hip replacements were performed in the United States, and this number is increasing at a rate of 11% for knee replacement and 2.5% for hip replacements each year. Although joint replacements have an excellent outcome, there still has been a small although disturbing incidence of mechanical and biological failures. The causes of these failures include implant surface wear, loosening, and instability. Infection remains a long-term concern.[1,2]

Early in the history of joint arthroplasty, younger, more active patients and very elderly patients were discouraged from having replacements because of the increased incidence of failures in these populations. Recent advances in implant design, materials, and surgical techniques have widened the indication for total joint arthroplasty in all patients with end stage arthritis. For example, alternative bearing surfaces such as metal-on-metal articulations have significantly reduced wear and its associated bone loss and implant loosening.[3-6] Minimally invasive surgical procedures have accelerated patient rehabilitation, and enhanced instrumentation has provided excellent restoration of joint anatomy.[7-9] An understanding of the present state of the art of joint arthroplasty is critical in order to provide physicians and patients with the basis of contemporary indications and expected realistic outcomes of the procedure.

Total Knee Arthroplasty

Enhanced designs and techniques have improved the long-term survival rates of total knee replacements so that 90% to 95% of active patients can expect a satisfactory result for 15 to 20 years. Implant fixation can be accomplished by either cementless or cemented methods. The success of cementless fixation depends upon a stable implant with a porous surface composed of either titanium or cobalt chromium alloys configured to support bone regrowth. Stability of the components can be achieved by using screw fixation and press-fit stems and/or pegs.[10-12] Precise surgical instruments provide close implant-bone interface. Studies indicate that component movement of less than 75 to 100 micrometers will support bone ingrowth, whereas motion of greater than 150 micrometers encourages fibrous tissue ingrowth.[4]

> *“Recent advances in implant design, materials, and surgical techniques have widened the indication for total joint arthroplasty in all patients with end stage arthritis.”*

Contemporary knee component designs have closely reproduced knee anatomy. Recently gender-specific implants have been introduced to better match the size and geometric dimensions of the female distal femur. (See Figure 1.) This should improve patellar tracking and ligament balancing. Knee flexion is important for functional activities. Newer designs are now available that allow as much as 140° to 150° of knee flexion.[12] This is especially important in patient populations that require kneeling activities.

Wear of contact surfaces is a significant cause of failure of total knee replacement. Improvement in the manufacturing technique of polyethylene has reduced wear debris from the articulating surface. These advances include processes to reduce oxygenation of polyethylene to improve fatigue wear of the material.[4] The use of thicker polyethylene tibial inserts and optimization of component designs has also reduced wear failures in total knee arthroplasty.[12] Another approach to reducing stress on polyethylene has been to increase conformity between

surfaces. Mobile bearing prostheses have been developed that provide conformity without sacrificing rotational movements of the knee.[13] Although the results are satisfactory with a follow-up of 9 to 12 years, there is still an incidence of periprosthetic bone loss as a result of wear-induced osteolysis.

Traditional total knee arthroplasty has been highly successful in pain relief and functional long-term survivorship. Patients, however, have expressed dissatisfaction with the postoperative pain and prolonged rehabilitation. These issues have encouraged surgeons to adopt minimally invasive surgical techniques which use smaller skin incisions and muscle-sparing approaches.[8] The early results of minimally invasive surgical techniques are encouraging, but usually by 6 months to 1 year after surgery there is no difference in results when compared to traditional approaches. Longer term data will be necessary to substantiate the early results of minimally invasive techniques which are inherently more difficult and have the potential for increased complications.

Optimizing surgical techniques in total knee arthroplasty has been reported to improve long-term survivorship of the procedure.[7] Adapting computer assisted navigation to the total knee arthroplasty surgical technique may improve knee alignment and component position. The early results indicate that these outcomes can be accomplished using this technique, but extensive exposure is necessary and the instrumentation is complex and difficult to master.[7] Ultimately this approach combined with a minimally invasive technique will assure anatomically aligned knees with the least intrusion on bone and soft tissues.

Total Hip Arthroplasty

Since total hip arthroplasty was introduced into the United States in 1969, there have been extensive changes in implant designs, materials, and surgical techniques. Using contemporary designs, hip implant survival rates have approached 90% to 95% at 15 to 20 years after surgery.[14] Early concerns focusing on perioperative infection have largely disappeared due to the use of perioperative antibiotics, ultraclean operating rooms using laminar flow methods, and exhaust exclusion hoods that isolate the surgeon from the patient. Implant breakage has virtually been eliminated by the use of high strength materials such as titanium and forged cobalt chromium stems. Newer hip stem designs use more flexible materials that match the stem's material characteristics with the surrounding bone to enhance implant integration with the patient's femur and also preserve native bone.[15] (See Figure 2.) Fixation methods have evolved so that either cemented or cementless modes of fixing the component to bone have been highly successful.[14,16,17] Major advances in this area have included methods of assuring excellent cementing techniques to provide optimum fixation of the implant to the host bone.[18] Porous surfaces have been redesigned to closely mimic the structure of the surrounding bone.[15] These newer surfaces provide the best geometric configuration to enhance bony ingrowth and long-term component fixation.

The major focus of research and development over the past decade has been directed towards reduction of bearing surface wear and the biologic reaction to this periprosthetic debris.[3]

Figure 2.
Arthroplasty Radiographs of a Hip Six Years After Replacement With a Component Stem Made of Flexible Materials Demonstrating Excellent Bone Preservation

The resulting bone loss or osteolysis may compromise implant fixation and ultimately result in component loosening. Alternative bearing surfaces have been developed which may reduce wear of the articulating surfaces and prolong the longevity of the total hip replacement.[4-6] Hard surfaces include metal-on-metal or ceramic-on-ceramic. Although wear is reduced significantly with these surfaces, there still are potential problems that could compromise the replacement. For example, metal-on-metal surface wear results in the release of metal ions which circulate systemically and could have long-term consequences.[5] Ceramic surfaces have the potential to fracture if any impingement results because of even minor implant malposition.[6] The recent introduction of highly cross-linked polyethylene as a counter surface to the femoral head also has significantly reduced the generation of wear particles.[4] However, the ultimate role of each of these bearing surfaces requires longer term follow-up, so that the choice of the best articulating surface can be adapted cost-effectively to the appropriate patient.

Computer assisted navigation and minimally invasive surgical techniques have also been used at selected centers to improve implant positioning and early rehabilitation. Initial experience with both of these approaches has been encouraging, but long-term follow-up is necessary to assess the real value of these approaches compared to established methods.[9]

The use of total hip replacement in young, active patients has always been controversial considering the reported increased failure rate in these patients.[16] Revision total hip replacement is significantly more complicated than the primary procedure because of the bone and soft tissue loss seen with the failed total hip replacement. Recently metal-on-metal surface replacement arthroplasty has been introduced to replace the hips of this younger, active patient population.[19] (See Figure 3.) This replacement preserves bone and resurfaces the acetabulum and femoral head. The larger ball size may enhance range of motion and hip function without the risks of hip dislocation. The early results have been good, however, an additional complication not seen in classical total hip replacement has been observed.[20] Femoral neck fractures have been reported which require an early revision, perhaps because the surgical procedure itself compromises the blood supply to the femoral head. The reported incidence of this complication varies from 1.5% to 3%. Prevention of this early failure requires surgeon education and improved sophisticated instrumentation. Longer follow-up is necessary to define the role of this replacement compared to a standard total hip replacement with large heads, now available with the new alternative bearing surfaces.

Total Ankle Arthroplasty

The reported results of the first generation total ankle arthroplasty were significantly poorer than total hip and total knee replacement. Loosening and mechanical failure were the primary reasons for failure of the total ankle replacement.[21,22] As a result, ankle arthrodesis, inducing ossification between bones, was the preferred treatment for end-stage ankle arthritis. Recently contemporary implants have been introduced with improved designs, surgical techniques, and materials, and early results have been encouraging.[21] Both mobile bearing designs and fixed bearing implants have reported satisfactory intermediate clinical results. One recent systematic review of the literature comparing ankle arthrodesis with total ankle replacement indicated that each procedure had about 25% poor results, and the revision rate was 9% for arthrodesis compared to 7% for total ankle replacement.[22] However, these results are predominantly retrospective and uncontrolled without direct comparison between the 2 procedures. The major difficulties in designing implants for total ankle replacement are a lack of complete understanding of the complex kinematics of this joint, material properties of the tibia compared to talus, and the very thin and poorly vascularized soft tissues. By contrast to total knee arthroplasty, the surgical techniques required to obtain anatomical alignment of the ankle and soft tissue balance are not well established. Indications for this procedure are still being refined. It appears that with the second generation total ankle replacement the optimal patient is older with lower demands. Patients who exhibit significant arthritis in the subtalar or midtarsal joints may be better functionally after an ankle replacement compared to arthrodesis. Absolute contraindications for the procedure include active infection and inadequate soft tissues or vascularity. Marked ankle instability, poor bone, or osteonecrosis of the talus are relative contraindications. Presently there are a number of ongoing clinical trials in the United States evaluating the different design philosophies.[21] Each of the 4 new total ankle replacements being studied do have some clinical concerns such as subsidence and/or dislocation of the components. Wear of the surfaces still remains a long-term worry. Current recommendations are for the procedure to be performed for low-demand patients by surgeons who have completed special training for the technique.

Figure 3.
Arthroplasty and Lateral Radiographs Demonstrating Surface Replacement

Summary

Total joint arthroplasty is a highly successful procedure for end-stage lower extremity arthritis. Excellent pain relief and significantly improved function is usual after surgery when used for appropriate indications by highly skilled surgeons using contemporary designed components. Future improvement in design and materials to reduce wear will further enhance clinical outcomes and long-term implant survival. **NCMJ**

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the *Journal*.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

COMMENTARY

Eat Smart and Move More to Combat Arthritis

Greg Griggs, MPA, CAE; Marie Shelton, MPH, RD

The statistics are alarming. In the recent publication *F as in Fat: How Obesity Policies are Failing in America, 2007*, North Carolina was ranked 17th in the nation in adult obesity.[1] In fact, nearly 2 out of 3 older North Carolinians (aged 65 years and above) are either overweight or obese. This excess weight has enormous health implications for diabetes, cardiovascular disease, and, yes, arthritis.

Arthritis is often overshadowed by other conditions related to obesity, but the fact remains that 70.4% of obese North Carolinians over the age of 65 years have been diagnosed with arthritis. In comparison, only 49.8% of our state's older citizens who are considered normal weight or underweight have been diagnosed with this disease.[2] These numbers make it clear: we cannot address arthritis without addressing the issue of weight.

> *"Persons who are overweight or obese are also more likely to incur activity limitations due to arthritis."*

Obesity is considered a risk factor for arthritis and can exacerbate already existing conditions. According to the Centers for Disease Control and Prevention, the prevalence of arthritis increases as weight does. Maintaining a healthy weight can help prevent onset and help slow the progression of this condition. Persons who are overweight or obese are also more likely to incur activity limitations due to arthritis. In North Carolina, of those 65 years and older who have been diagnosed with arthritis and are also obese, 46.5% report that their activity is limited by joint pain. On the other hand, only 32.6% of normal and underweight persons report such limitations.[2] However, even a small weight loss can have a significant positive impact. Research has shown that losing only 11 pounds can reduce the incidence of knee arthritis.[3]

Ironically, one of the key behaviors to weight management also has positive outcomes for arthritis. Physical activity not only helps with weight loss and maintenance, but regular activity also has been shown to improve the health of muscles and bones, reduce pain, and increase flexibility of joints and ease of movement. Despite these health benefits, in North Carolina only 1 in 3 adults over the age of 65 years who have been diagnosed with arthritis achieve the recommended amounts of physical activity.[2]

Eat Smart, Move More…NC is a statewide movement to reduce the rising tide of obesity and related chronic disease among North Carolinians by helping them to eat smart, move more, and achieve a healthy weight. The *Eat Smart, Move More…NC* Leadership Team representing over 40 academic, government, nonprofit, health care, and private organizations helps to guide the movement and ensure that healthy eating and physical activity choices become easier to make in North Carolina.

The *Eat Smart, Move More…NC* Leadership Team executive committee provides guidance to the leadership team and includes chairs of the various committees. Greg Griggs, MPA, CAE, from the North Carolina Academy of Family Physicians, serves as chair of the leadership team. Carolyn Dunn, PhD, of North Carolina State University and the North Carolina Cooperative Extension Service, assists as vice chair. Dave Gardner, DA, of WakeMed Health and Hospitals, leads the advocacy committee in its efforts to recommend legislation, regulations, policies, and funding to enhance physical activity and healthy eating in North Carolina. The communications committee is headed by Patrick Gibbons of RTI International. This committee is responsible for communicating the need for physical activity and healthy eating opportunities particularly as they relate to policy and environmental change.

Greg Griggs, MPA, CAE, is executive vice president of the North Carolina Academy of Family Physicians and chair of the *Eat Smart, Move More...NC* Leadership Team. He can be reached at ggriggs@ncafp.com or PO Box 10278, Raleigh, NC 27605.

Marie Shelton, MPH, RD, is a healthy weight communication specialist in the Physical Activity and Nutrition Branch of the Chronic Disease and Injury Section, NC Division of Public Health.

Eat Smart Move More
NORTH CAROLINA™

Maggie Sauer, MS, MHA, is chair of the implementation committee which supports and promotes programs and efforts that enhance physical activity and healthy eating opportunities.

Through *Eat Smart, Move More…NC* citizens gain knowledge, resources, and support needed to achieve and maintain a healthy weight. A consumer Web site at *www.MyEatSmartMoveMore.com* provides tools and tips for incorporating good nutrition and physical activity into daily life. Advertisements on billboards, in print media, and on the radio and television encourage North Carolinians of all ages to spend less time in front of the television and computer, be active every day, drink fewer sugar-sweetened beverages, prepare more meals at home, decrease portion sizes, and eat more fruits and vegetables. These messages serve as a reminder of how simple changes in daily lifestyle can have a large impact on weight management.

Eat Smart, Move More…NC increases healthy eating and physical activity opportunities wherever North Carolinians live, learn, earn, play, and pray. In order to make healthy behaviors the norm, rather than the exception, appropriate policies and environmental changes must be put into place at both the state and local level to encourage eating smart and moving more. Examples of these polices and environmental changes include creating healthy worksites or faith communities that encourage and facilitate these behaviors as well as building walking trails and greenways that provide opportunity for moving more.

Helping our citizens reach a healthy weight and maintain healthy eating and physical activity behaviors will have a profound impact on the health of our state. Eating smart and moving more also may be key to addressing the incidence and severity of arthritis in North Carolina. **NCMJ**

COMMENTARY

Complementary and Alternative Medicine for Arthritis

Jaya K. Rao, MD, MHS

Since the mid-1990s, the prevalence and costs associated with the use of complementary and alternative medicine have attracted the interest of health care organizations, policy makers, providers, and consumers. Complementary and alternative medicine is usually defined as medical interventions that are neither taught widely in US medical schools nor generally available in US hospitals[1] and includes modalities such as herbal medicine, spiritual healing, and aromatherapy. It is important to remember, however, that with data from efficacy studies complementary and alternative medicine treatments have the potential to become part of mainstream medicine. For example, digitalis and colchicine were once considered "alternative" but are now prescribed by mainstream practitioners. In this commentary, I will briefly review the epidemiology of complementary and alternative medicine use by patients with rheumatologic conditions and highlight recent data on selected complementary and alternative medicine treatments for arthritis.

"While most individuals use complementary and alternative medicine to supplement conventionally-prescribed treatment, many do so without informing their doctor, raising concerns about the potential for adverse interactions with prescribed treatments."

Epidemiology

It is well documented that people with chronic conditions use complementary and alternative medicine to treat their symptoms. Depending on the study population and how it is defined, the estimated prevalence of complementary and alternative medicine use by Americans ranges from 33% to 90%.[1-5] In a landmark study, Eisenberg and colleagues reported that 33% of Americans used an alternative therapy in 1990.[1] By 1997 the percentage of Americans reporting complementary and alternative medicine use increased to 42%, and 46% reported visiting a complementary and alternative medicine practitioner.[2] While most individuals use complementary and alternative medicine to supplement conventionally-prescribed treatment, many do so without informing their doctor,[1,2,6] raising concerns about the potential for adverse interactions with prescribed treatments.

Complementary and alternative medicine use is particularly common among people with musculoskeletal disorders.[1,3] Population- and clinic-based data indicate that 28% to 90% of people with arthritis and other rheumatologic conditions use complementary and alternative medicine.[4-8] Studies of patients with specific rheumatologic conditions (eg, fibromyalgia, osteoarthritis, systemic lupus erythematosus) demonstrate a similar degree of use. In general, people with a higher educational level, a longer duration of disease, poorer functional status, and higher levels of pain are more likely to use complementary and alternative medicine.[4,7] Data also indicate that use (and the specific types used) varies by race and ethnicity.[9,10]

Data From North Carolina

Population-based data document a geographic variation in complementary and alternative medicine use with higher rates

---

Jaya K. Rao, MD, MHS, is an adjunct clinical associate professor of medicine in the Division of Rheumatology at Emory University School of Medicine. She can be reached at jkrao@mindspring.com or Emory University School of Medicine, Division of Rheumatology, 49 Jesse Hill Jr Drive SE, Atlanta, GA 30303.

reported by residents of the western United States.[1,3] While the variation in rates may relate to the definition of complementary and alternative medicine used in the survey, it is also important to note, however, that complementary and alternative medicine use is not uncommon in the South.[3]

Data from studies of North Carolina residents underscore this point. In a study of 1059 adult residents of western North Carolina, nearly one-half (45.8%) reported using complementary and alternative medicine to treat their chronic conditions.[11] Although its use was not associated with the number of chronic conditions or health care utilization, people with less education were more likely to use honey-lemon-vinegar-whiskey combinations while people with greater education were more likely to have visited a complementary and alternative medicine practitioner. In a study of 211 rural community-dwelling adults with arthritis, Arcury and colleagues reported that complementary and alternative medicine use was common and they found differences in the types used based on race and ethnicity. African Americans were more likely to rely on prayer and topical treatments (eg, liniments, turpentine) than European Americans.[9] Finally, in a study of 752 arthritis patients who were seen in 16 primary practices in rural and urban North Carolina, 89% reported using at least one complementary and alternative medicine.[5] Interestingly, 71% of those who used at least one treatment discussed this behavior with the physician.[5]

Given the widespread interest in complementary and alternative medicine, it is not surprising that medical universities have developed integrative medicine programs. Three medical universities in North Carolina (Duke University, the University of North Carolina at Chapel Hill, and Wake Forest University) have established such programs to provide selected forms of complementary and alternative medicine treatment to patients and to conduct research.

Recent Data on Selected Complementary and Alternative Medicine Treatments for Arthritis

Complementary and alternative medicine is big business in the United States. Since the passage of the Dietary Supplemental Health and Education Act of 1994, dietary supplements and herbal products have become widely available. In 1997 an estimated 165 million adults (18.4% of all prescription users) used herbal medicines along with conventionally prescribed medications, and they spent $5.1 billion dollars out-of-pocket on these remedies.[2] Furthermore, they made 629 million visits to alternative practitioners, far exceeding the total number of visits made to primary care providers in 1997.[2] An extensive review of complementary and alternative medicine therapies is beyond the scope of this commentary. Instead, I will highlight data on 2 treatments used for arthritis symptoms that have been the focus of recent investigation: glucosamine/chondroitin sulfate and acupuncture.

Since the 1980s glucosamine and chondroitin have been used to treat osteoarthritis, primarily in European countries.[12] Notably, in Europe and other countries, glucosamine sulfate is approved as a prescription treatment for osteoarthritis.[13] Glucosamine is a precursor to the glycosaminoglycan molecule, and chondroitin is the most abundant glycosaminoglycan found in cartilage.[13] Short-term (4 to 6 week) controlled trials indicate that patients treated with glucosamine experience modest improvements in pain and function compared to those receiving placebo[14] and experience treatment effects comparable to nonsteroidal anti-inflammatory drugs.[15]

Two recent meta-analyses that examined randomized trials of glucosamine and chondroitin report mixed conclusions regarding efficacy which may relate to the specific formulations of glucosamine used in the trials, methodologic concerns, and industry bias.[12,16] A large multicenter trial was designed to address some of these concerns: patients with symptomatic knee osteoarthritis were randomized to glucosamine, chondroitin, glucosamine plus chondroitin, celecoxib, or placebo treatment for 24 weeks.[17] Patients who were treated with glucosamine and chondroitin sulfate alone or in combination did not experience a significant improvement in pain compared to controls.[17] Unfortunately, this trial involved treatment with glucosamine hydrochloride, a formulation that other investigators have concluded is not effective compared to the glucosamine sulfate formulation.[16,18] At this time, patients who are considering using glucosamine for their osteoarthritis symptoms should be advised to take glucosamine sulfate rather than glucosamine hydrochloride, and those with severe pain might consider adding chondroitin sulfate to this regimen.[18]

Acupuncture is an important modality in traditional Chinese medicine that involves the transcutaneous placement of needles, sometimes with ancillary electrical current, heat, or moxibustion (ie, incense burning), to specific sites in order to restore the person's balance of vital energy (also known as qi or chi).[19] Acupuncture, which is often used for pain relief, has been the focus of several recent trials. These trials have highlighted the methodological dilemma of finding an appropriate comparison to acupuncture. Sham acupuncture may stimulate pain inhibitory fibers or endorphin release while positive comparisons to a wait list control may be due to treatment expectations or placebo effects.[20]

Witt and colleagues reported significant improvements in outcome among those who received acupuncture compared to a wait-list control group.[21] These investigators also performed a 3-arm randomized trial in which one group received sham acupuncture.[22] Compared to the sham acupuncture or wait-list control groups, the group who received acupuncture experienced significant improvements in pain and function immediately after receiving the entire intervention (12 acupuncture sessions over 8 weeks), but these improvements declined over time.[22] Another study reported significant improvements in outcome when the acupuncture and sham acupuncture groups were compared to a wait list control group, but no differences when the acupuncture group was compared to the sham acupuncture group.[23] Given the heterogeneity of study findings and clinically minimal effects when acupuncture is compared to sham therapy, a recent meta-analysis concluded that it is premature to recommend this treatment as part of routine care for knee osteoarthritis and suggested that clinicians and patients might consider acupuncture as one option in a multidisciplinary treatment approach.[20]

Managing Patients Who Also Use Complementary and Alternative Medicine

Regardless of their particular beliefs about complementary and alternative medicine, physicians have an ethical obligation to discuss treatment alternatives with their patients. Although physicians should acknowledge their level of knowledge regarding complementary and alternative medicine during these discussions, they should also make sure that the patient has received information about the safety (eg, potency, drug interactions) and efficacy of these treatments.[24] Because patients' complementary and alternative medicine usage may change over time,[25] physicians should periodically review their patients' current regimens.

Since most alternative therapies are unproven, physicians may have legal concerns when they are asked to recommend specific complementary and alternative medicine treatments, provide referrals to practitioners, or tolerate continued use of these therapies. As a general rule, the mere referral to a complementary and alternative medicine practitioner does not expose the referring physician to liability unless the referral itself deprives the patient of receiving appropriate care (ie, referral delays or eliminates an opportunity to receive important care).[26] On the other hand, the physician could be held liable if he or she recommends a complementary and alternative medicine that is associated with serious risks or is known to be ineffective.[27] Thus, when recommending specific complementary and alternative medicine, physicians should review the literature to determine the level of risk for the treatment, discuss the potential risks and benefits with the patient, document this discussion, and continue to monitor the patient conventionally.[27] When referring patients to complementary and alternative medicine practitioners, physicians should also inquire about the practitioner's credentials, competence, and practices.[27]

Final Thoughts

People with rheumatologic conditions often use complementary and alternative medicine to treat their symptoms. To date, epidemiologic studies have focused on describing patients' use of complementary and alternative medicine and identifying predictors of this behavior. Given that many patients do not discuss their use of complementary and alternative medicine with their physicians, future investigations might focus on developing methods such as office-based tools to facilitate patient-provider communication regarding complementary and alternative medicine. Furthermore, complementary and alternative medicine is an evolving field as results emerge from efficacy studies of specific treatments. Clinicians should keep abreast of the findings of these trials because these data will be helpful in managing and advising patients who use such therapies. **NCMJ**

Use of Nurse Practitioners and Physician Extenders in Rheumatology:

A Western North Carolina Perspective

Kate T. Queen, MD, FACR, CCD

Western North Carolina enjoys tremendous popularity. For years it has been a vacation and recreation destination, but today young and old alike are attracted to the mountains and find our communities an ideal place to consider calling home. Residents of western North Carolina have benefited from a long tradition of excellence, depth, and diversity in the medical community historically centered in Asheville. However, over the past 25 years the demand for quality specialty care closer to home has escalated in smaller, surrounding communities. A growing need for clinicians skilled in the evaluation and treatment of patients with rheumatic diseases and musculoskeletal complaints reflects this demand.

My experience is that of a solo rheumatologist practicing within a multispecialty internal medicine group in a rural mountain community. I struggled unsuccessfully to recruit a second rheumatologist for years and discovered that an alternative strategy for success in meeting the needs of my region was the integration of a midlevel practitioner. The development of collaborative practices with nurse practitioners or physician assistants has been an effective way for others to respond to this sometimes overwhelming demand for care. As we face the challenge statewide of meeting the needs of a "graying" North Carolina and embrace the opportunity to address issues related to health and aging, this model deserves serious consideration.

Who Benefits?

Patients are the most important beneficiaries of this collaborative approach to care. Improved access is a high priority to anyone with pain or impairment in independent function. Collaborative practices have the flexibility to develop strategies to not only expedite the evaluation of new patients but also deal with the needs of established patients promptly when new problems or concerns arise.

Patient satisfaction also improves. Nurse practitioners and physician assistants attracted to outpatient care typically have a special interest in patient education and teaching. This skill and focus is invaluable to patients with rheumatologic conditions who need to learn what to expect from their illness as well as how to avoid, recognize promptly, and respond to complications of their treatments.

> *"… as the demand for care increases and the financial pressures for efficient and effective service intensify, rheumatologists working collaboratively with nurse practitioners and physician assistants have real opportunities to build rewarding relationships."*

Kate T. Queen, MD, FACR, CCD, is a consulting rheumatologist at Mountain Medical Associates. She can be reached at katequeen@charter.net or 600 Hospital Drive, Suite 9, Clyde, NC 28721.

Rheumatologists who adopt this style of practice have much to gain. For a solo rheumatologist like me, the addition of a midlevel practitioner facilitated a healthier balance between the desire to provide quality patient care and follow-up and my own need for personal time and a balanced lifestyle.

It has been demonstrated in a wide variety of clinical settings that the utilization of a midlevel practitioner to maximize productivity has enhanced financial rewards as well. According to the Medical Group Management Association's *Physician Compensation and Production Survey: 2006 Report Based on 2005 Data*, physician assistants and nurse practitioners are able to generate practice income well above their costs.

In a practice setting of mutual respect and collaboration, midlevel practitioners can find great rewards. They have the opportunity to practice within the scope of their training and experience with the back-up and support of their physician. The expansion of new knowledge and therapeutic options makes this a particularly exciting time to be part of a rheumatology team. In addition, the freedom to focus on patient care and supervision without the burden of managing the financial and accounting aspects of practice contributes to the professional satisfaction inherent in their role.

Is There a Significant Difference Between Nurse Practitioners and Physician Assistants?

The background and training of nurse practitioners and physician assistants are not identical. Nurse practitioners are registered nurses who have attended accredited programs to pursue both advanced academic and clinical training. Physician assistants may come from a variety of prior experiences including work in other allied health roles and the military. Physician assistants typically have a baccalaureate degree as well as a degree from an accredited physician assistant training program.

In North Carolina, physician assistants are licensed by the North Carolina Medical Board (www.ncmedboard.org). Nurse practitioners receive their authorization to practice from both the North Carolina Medical Board and the North Carolina Board of Nursing (www.ncbon.com). State laws, including the Medical Practice Act of the North Carolina General Statutes, and the rules of the North Carolina Medical Board clearly delineate many facets of the primary supervising physician's responsibilities.

Individual physicians have substantial autonomy to decide how best to use an extender in their practice. It is important to the successful integration of a midlevel practitioner that his or her scope of practice be identified and that the delegation of medical tasks is appropriate to the skills of the supervising physician as well as the competence level of the physician assistant or nurse practitioner. It is not surprising that this role often expands and evolves over time as the midlevel practitioner matures and demonstrates his or her competency.

Enhancing Success

In the field of rheumatology there are no training programs designed to help a nurse practitioner or physician assistant specifically prepare to join a rheumatology practice. Such training has traditionally been left to the individual physician who seeks to integrate a midlevel practitioner. The Allied Rheumatology Health Professionals, a sister organization to the American College of Rheumatology, has had a strong interest in recent years in providing continuing education opportunities for advanced practice nurses and other midlevel practitioners. However, at the present time, standardized preceptorships to develop the skills and knowledge base unique to rheumatology have not been developed.

Preparing your patients as well as your medical community for the addition of a nurse practitioner or physician assistant is critical to their acceptance, particularly if you are in a region where these practitioners are not found in specialty practices. Your confidence in their knowledge and skills is key to building a foundation for years of successful collaboration.

In addition, this model requires not only an initial commitment to training and integration but an ongoing willingness to review the care they provide and serve as a mentor. I have found this to be one of the most rewarding aspects of collaborative practice but cannot deny that to do this well requires an input of real time and energy. A commitment to provide ongoing supervision of care, to enhance opportunities for learning and professional growth, and to consistently be available to address questions or concerns is, I believe, fundamental to a long-term successful relationship

While a collaborative approach to practice will not appeal to all, as the demand for care increases and the financial pressures for efficient and effective service intensify, rheumatologists working collaboratively with nurse practitioners and physician assistants have real opportunities to build rewarding relationships. It has been my experience that practicing rheumatology with a midlevel practitioner can improve access to care, enhance patient satisfaction and clinical outcomes, and at the same time expand productivity and secure financial success. **NCMJ**

COMMENTARY

The Johnston County Osteoarthritis Project:

An Illustration of a Community-University Partnership for Population-Based Research

Edwin L. Hartman, MD; Janice Woodard, BS; Carol Patterson, MA; Joanne M. Jordan, MD, MPH

Community-based participatory research has been defined as "an approach to health and environmental research meant to increase the values of studies for both researchers and the community being studied."[1] This cooperative approach to research continues to gain recognition and popularity and has particular potential for the future of epidemiological studies.[2] Investigators from the University of North Carolina at Chapel Hill (UNC) and residents in Johnston County, North Carolina have worked together in and benefited from community-focused research for over 23 years. This partnership was an early adopter of the community-based approach to research through formation of the Rural Health Research collaboration, just the beginning of many "firsts" for this partnership.

> *"In order to foster and maintain long-standing grassroots support for the work of Rural Health Research, it is critical for residents to feel that Rural Health Research is serving the interests and needs of the county. In keeping with this, it has been our long-standing philosophy and policy to give back to the community."*

History of Rural Health Research

Rural Health Research is a community-based, university-affiliated research center in Johnston County, a mostly rural county in eastern North Carolina. Preliminary work in the community by UNC investigators began in the late 1970s. A multidisciplinary group of researchers came together with Johnston County residents to develop an ongoing research presence in the county. The participants included the directors of the Thurston Arthritis Research Center, the Center for Health Promotion and Disease Prevention, the Injury Prevention Research Center, and the Cecil G. Sheps Center for Health Services Research. The office of the Vice Chancellor for Health Affairs also provided vitally important input and support. Local

Janice Woodard, BS, Janice Woodard, BS, is project director at Rural Health Research, Smithfield, North Carolina, and research associate at Thurston Arthritis Research Center, the University of North Carolina at Chapel Hill.

Carol Patterson, MA, Carol Patterson, MA, is research associate at Thurston Arthritis Research Center, the University of North Carolina at Chapel Hill.

Joanne M. Jordan, MD, is associate professor of medicine and orthopaedics, chief of the Division of Rheumatology, Allergy, and Immunology, and director of the Thurston Arthritis Research Center at The University of North Carolina at Chapel Hill. She can be reached at Joanne_Jordan@med.unc.edu or 3300 Doc J. Thurston, Jr Building, CB#7280, Chapel Hill, NC 27599.

advisers and participants have included lay and professional community leaders, state and national government officials, county managers, education superintendents, hospital and county health department personnel, and nonprofessional constituents with an interest in health issues.

A critical next step toward the establishment of this endeavor as a local entity came with an award from the Centers for Disease Control and Prevention to the UNC Health Promotion and Disease Prevention Center in 1987. This enabled Rural Health Research to incorporate and open a local research field office in Johnston County, directed and staffed by Johnston County residents. In order to determine the interests of the people in the county, 65 focus groups were held throughout the county with broad representation by race, gender, and age (ranging from 45 to 54 years, 55 to 64 years, and 65 years and older). The medical community was involved and kept informed through a local medical liaison, and awareness of Rural Health Research and its goals was increased through presentations given by the researchers to the county medical society in a meeting held at Johnston Memorial Hospital.

Over the years community-based research has flourished in Johnston County. Rural Health Research benefits from dedicated local volunteers who bring vitality and support to the studies. Local participants are involved in helping to map and enumerate streets for statistical sampling, assisting with project management duties both in and out of the Johnston County office, and serving as key study ambassadors to the county and other local organizations. In 2002 an adjoining research clinic was opened, including a fully-functional radiology suite, a bone density/body composition suite, facilities for phlebotomy and frozen storage of specimens, and multiple examination rooms.

Currently, the local staff includes 9 full-time employees, all Johnston County residents, including the director, administrative assistant, interviewers, data collectors, radiology technologist, and phlebotomist, and a cadre of fully-trained part-time and intermittent employees available for substudies and other tasks as necessary.

Over the years, Rural Health Research has been the site of studies in injury prevention, health care access and utilization, cardiovascular disease, nutrition, and dizziness and physical activity in frail elders. Arthritis and disability have been the primary focus of Rural Health Research since 1990, with over 25 studies conducted. (See Figure 1.) The first of these began in 1985 with an award from the National Institute of Arthritis and Musculoskeletal and Skin Diseases to the Thurston Arthritis Research Center to evaluate the reliability and validity of selected arthritis psychosocial measures used to assess arthritis beliefs, self-care practices, use of health services, and psychosocial health status of lower-income African American and white residents. This study provided the foundation for all subsequent research carried out in Johnston County.

A prospective cohort of osteoarthritis of the knee and hip in Johnston County, known as the Johnston County Osteoarthritis Project, has received continuous funding by the Centers for Disease Control and Prevention since 1990 (recently renewed through 2010) and by the National Institutes of Health since 1993. This study has facilitated the development of additional projects funded by multiple federal agencies, foundations, private philanthropic sources, and industry groups. (See Figure1.) The scope of these studies ranges from the biomedical (eg, development and validation of serum and urine biomarkers of joint metabolism, proteomics, metabolomics, and, most recently, genome-wide association studies) to the psychosocial (eg, the role of psychiatric comorbidity in the pain and disability of arthritis, individual and community social determinants of arthritis outcome, and spirituality). The Johnston County Osteoarthritis Project has been a part of research studies with investigators throughout the nation and the world. Collaboration has served not only to advance science but also to support the continued work of Rural Health Research which would be impossible without the financial backing of numerous investigations.

The Johnston County Osteoarthritis Project has contributed other notable "firsts." It was the first longitudinal study of osteoarthritis to include African Americans and it remains the only such study in a rural setting. The study revealed early on that osteoarthritis and its resultant disability were more common than expected.[3-6] Pursuing an explanation for this observation led to the examination of data on overweight and obesity in the study group.[7,8] The Johnston County Osteoarthritis Project also revealed that African Americans were not spared from hip osteoarthritis as had generally been thought.[9,10]

With this history of pioneering into new areas, this study is the largest biracial population-based study to describe associations between radiographic osteoarthritis and osteoarthritis biomarkers and blood and urine markers of the osteoarthritis disease process. It also is the first to recognize that values of these markers, and factors associated with them, varied by gender and racial groups.[11-14] Recognizing that the experience of osteoarthritis has significant psychosocial consequences, the Johnston County Osteoarthritis Project partnered with the Arthritis, Coping and Emotions study to generate one of the largest psychosocial databases for an osteoarthritis cohort of African Americans and Caucasians in the world.[15,16]

Research into the role common environmental exposures play in osteoarthritis over a lifetime produced preliminary results showing that higher blood lead levels are associated with more severe osteoarthritis,[17] and low selenium levels are also associated with osteoarthritis presence and severity.[18,19] The examination of selenium and osteoarthritis was suggested by studies of Kashin-Beck Disease, an endemic osteoarthropathy in China associated with low selenium levels in the soil among other things.[20] The Johnston County analysis was the first large epidemiologic investigation into this relationship in a Western population. These observations have given birth to a new interdisciplinary field of "environmental rheumatology" currently being developed at the Thurston Arthritis Research Center at UNC.

Today, the community connection for the Johnston County Osteoarthritis Project and Rural Health Research remains alive and strong. As one county staff person said, "What impressed me the most about this study was that it came to the community. It

was more accessible to people who would not have had such an opportunity if they were required to travel. As an interviewer I see how participants begin to think about their arthritis perhaps in new ways as they have the chance to talk about their experiences with us. I think it has to make a positive difference for these people in our community." As the concept of community-based research has evolved to embrace more of the social impact of disease and public health, the Johnston County Osteoarthritis Project has collaborated with other researchers interested in the individual and community social determinants of health and disease.

Giving Back to the Community

In order to foster and maintain long-standing grassroots support for the work of Rural Health Research, it is critical for residents to feel that Rural Health Research is serving the interests and needs of the county. In keeping with this, it has been our long-standing philosophy and policy to give back to the community. This takes many forms. For example, all local employees receive considerable and continuing education in methods of field research, and full-time employees become permanent employees of UNC with its attendant benefits. As much as is possible, we utilize and support local businesses for the work of the center. In addition, the Thurston Arthritis Research Center publishes an annual newsletter in Johnston County (*Johnston County Osteoarthritis Project Update*), and UNC and local colleagues give talks to local groups (eg, Smithfield Veterans of Foreign Wars, Kiwanis, Rotary, Lions Club, Civitan, Johnston Memorial Hospital) to keep the 2-way flow of information active. Project participants receive regular study updates and are invited to open houses in which they have an opportunity to meet with research staff and UNC faculty to learn about arthritis and the progress of the many studies ongoing in the center.

Rural Health Research is a member of the Chamber of Commerce, the Human Services Council, and other local groups. Each year for the past 20 years, the Rural Health Research director has attended the Chamber of Commerce Washington Issues Seminar in Washington, DC. This meeting is sponsored by North Carolina's US senators and representatives and is attended by state representatives, mayors, town managers, other Chambers of Commerce members throughout the state, national representatives and senators, and other national government officials. It is a highly effective forum for bringing local issues to the attention of elected officials in Congress. We have been able to increase awareness of arthritis and disability issues, inform officials about research studies underway in the county, and advance the mission of Rural Health Research as well as the community-based research role of UNC among these representatives and other government officials. **NCMJ**

Manpower Shortage in Rheumatology

Gregory F. Schimizzi, MD

Several articles have appeared in the literature regarding the looming shortage of various specialties.[1-5] It is surprising that some of the projected shortages in professional manpower include highly visible specialties such as neurosurgery, cardiology, and pediatrics. While shortages in these specialties are a newly recognized problem, a decline in rheumatology manpower has been expected for many years despite an increase in demand for services. The number of fellows in rheumatology has been steadily declining since 1995. In a survey and analysis of manpower in rheumatology done in 2000, the American College of Rheumatology projected a steady decline in the number of clinical rheumatologists until the year 2030.[6] For the year 2010, the needs estimate for rheumatologists is 7500 physicians. The current number of practicing rheumatologists is 2200, and the projected number of practicing rheumatologists for the year 2010 based on new fellows entering practice and those rheumatologists leaving the field is estimated to be 2500.[6]

As the population of the United States ages, there has been an expected increase in the number of people afflicted with arthritis. The Centers for Disease Control and Prevention recently announced that according to their most recent data over 46 million Americans are afflicted with arthritic diseases which are the most frequently occurring chronic illnesses. Arthritic diseases of all types are the leading cause of disability in our country. Rheumatoid arthritis alone affects 1 in 200 Americans and costs the United States approximately $80 to $85 billion dollars per year. It has been projected that by the year 2030 an estimated 67 million Americans will be affected by chronic arthritic diseases.[7]

Ask any rheumatologist or medical group about the difficulty of recruiting a new physician in rheumatology, and you will likely get the same answer from coast to coast. In an era of new and promising therapies and with an increasing number of patients in need of rheumatology care, it seems counterintuitive that a decline in manpower is upon us in this field. But the reasons for our predicament are not as simple or straightforward as one might think. A detailed study commissioned by the American College of Rheumatology and published earlier this year enumerated and analyzed causes for the manpower crisis in rheumatology. According to this report, factors affecting the manpower crisis in rheumatology include technological advances, limited advances in practice design and organization, minimal increases in training positions, changes in population characteristics, low reimbursement rates, and workload capacity changes.[6]

> *"In an era of new and promising therapies and with an increasing number of patients in need of rheumatology care, it seems counterintuitive that a decline in manpower is upon us in this field."*

Technological Advances

An increase in technological sophistication has occurred in the practice of rheumatology just as in other fields of medicine. This technology is very costly and has added to other cost centers (eg, malpractice rates, insurance costs, labor costs, increased costs due to workload) which are contributing to a rapid rise in overhead expenses. The American Medical Association has estimated that in the same years that the Medicare Modernization Act 2003 mandates drastic reductions in physician reimbursements there will be a 25% increase in overhead expenses for physicians.

Gregory F. Schimizzi, MD, is a board certified rheumatologist at Carolina Arthritis Associates, assistant clinical professor of medicine at New Hanover Regional Medical Center, and president of the Coalition of State Rheumatology Organizations. He can be reached at gfschimizzi@carolinaarthritis.com or 1710 S 17th Street, Wilmington, NC 28401.

Practice Design and Organization

There has been little change in practice organization and efficiency in delivering rheumatologic care. Utilization of family nurse practioners and physician assistants has not increased dramatically over the last decade. This may in part be due to the nature of the specialty. Adoption of electronic medical records systems has been very slow in rheumatology possibly due to the complicated nature of the subspecialty as well as the associated expenses. Furthermore, a high energy of initial activation is associated with electronic medical records, and rheumatologists may not be interested in investing their time or financial resources to install an expensive system when retirement may be only a few years away.

Training Positions

The number of new fellowship-trained rheumatology positions has not kept pace with the demand for rheumatologists over the last 1 to 2 decades relative to the number of older physicians leaving the field and the demand for services. Physicians leave rheumatology primarily due to retirement or death. A few rheumatologists leave active rheumatology practices to accept industry positions. The average age of rheumatologists is approximately 57 years of age. The median age for rheumatologists is 53 years for male physicians in adult rheumatology and 46 years for the female physicians. For pediatric rheumatology the median ages are 51 years and 47 years respectively. There are 378 adult rheumatology fellowship training positions in 105 programs in this country and the fill rate for these positions was about 88% in 2004-2005.

One of the reasons for the reduced supply of new rheumatologists as well as other specialties can be traced back to several previously published reports such as the Graduate Medical Education National Advisory Committee's 1981 recommendation to reduce the number of medical schools and medical school positions based upon forecasts for a 23% surplus of physicians (approximately 145 000) by the year 2000. In response to this and other similar reports, Congress reduced support for medical school education.

Changes in Population Characteristics

Demand for rheumatology services is increasing due to the aging of our population, the increased sophistication of the populace, and the rise in per capita gross domestic product. Richard Cooper and his colleagues observed a strong correlation between the size of the economy measured in gross national product per capita and the demand for specialty physician services. Cooper argued this correlation was indicative of a pending increase in the demand for health care services to the extent that a physician shortage of 50 000 physicians would occur by 2010.

Reimbursement Rates

Reimbursements for rheumatology services have historically been the lowest of all subspecialties. This began to change in 1998 with the introduction of more sophisticated and complex services provided by rheumatologists in their offices. Despite the fact that reimbursements for rheumatology services increased 28% between 1998 and 2002, reimbursements are on the decline again after passage of the Medicare Modernization Act in 2003 and recent changes in reimbursement for ancillary services. These latest changes make rheumatology a less attractive field to prospective fellows. This is especially true for those who have accumulated large loans during their education and training.

Maximal Workload Capacity Changes Among Rheumatologists

Workload capacities for rheumatologists vary with age and sex of the practitioner. Female rheumatologists (whose numbers have been increasing) tend to see fewer patients than male rheumatologists at all ages. Females have peak workload capacities when they are between 40 and 49 years of age. Male rheumatologists have a peak workload capacity between the ages of 50 and 59 years. To some extent, the increase in the number of female fellows entering practices in rheumatology will accentuate the shortage of rheumatology supply.

Solutions

The remedies for the shortage of rheumatologists will not be easily implemented and likely will not be rapidly achieved. Four possible solutions are outlined here.

(1) It will be necessary to increase the number of fellowship positions or add new rheumatology programs. Finding funding for expanding programs will be difficult in times of overall health care cutbacks and without a will on the part of government to not only recognize the problems facing rheumatology and other specialties but to act upon the problems in a meaningful way.
(2) Adoption of newer technologies and/or increased use of physician extenders in the practice of rheumatology will help improve efficiency and increase practice visit capacities.
(3) Inherent in adopting more widespread use of physician extenders there will need to be a commensurate increase in the number of training programs for these professionals.
(4) There must be a concerted effort to advocate for medical liability reform, fair reimbursements, and removal of clerical workloads in an attempt to improve patient access to care while reducing overhead costs that accompany excessive interferences from multiple sources. Reduction of costs and fair reimbursements for services will create an incentive for younger physicians and trainees to consider rheumatology.

The goal of any resolution to a potential shortfall in physicians in any subspecialty should include, above all else, a desire to deliver the highest quality care possible to our patients as efficiently as possible with the best choice of therapies available based on medical evidence. No solution should occur at the expense of continued efforts to find cures for these diseases that disfigure and deform. Treatment must be continued since inadequate or delayed treatment of arthritic diseases not only decrease the quality of life for millions of our patients but also creates hardship for families and late complications that will increase disease management costs. We must never forget that mortality is also increased in many of these patients, and this may be even more significant in those patients who are inadequately treated. **NCMJ**

North Carolina
MEDICAL JOURNAL

Spotlight on the Safety Net

A Community Collaboration

Kimberly M. Alexander-Bratcher, MPH

Community Health Centers

> *Across North Carolina, communities have come together to form nonprofit health centers governed by the people that use them. For over 30 years these community health centers have ensured that no one is left without a place to turn to when they are in need of medical care, regardless of their ability to pay. The focus of community health centers is quality and comprehensive primary care with a strong emphasis on disease prevention and health maintenance.*[1]

What Is a Community Health Center?

Federally qualified health centers, also known as community health centers, are public or private nonprofit, charitable, tax-exempt organizations. They receive funding from the Public Health Service Act or are deemed by the US Department of Health and Human Services to meet requirements to receive funding without actually receiving a grant. They serve medically underserved areas and are governed by a board whose majority must be users of the center's services and representative of the service area's demographics. They provide, either directly or by contract, a comprehensive scope of preventative and primary health services including translation, transportation, and other support services regardless of the ability to pay. Community health centers have a schedule of charges designed to cover the reasonable costs of operation and consistent with locally prevailing rates that are adjusted based on a patient's income and family size.

Community health centers facilitate access to comprehensive health and social services including outreach, transportation, interpretive, and case management services; services to assist the health center's patients gain financial support for health and social services; referrals to other providers of medical and health-related services; and substance abuse and mental health services.

Community health centers assess the full health care needs of their target populations, form a comprehensive system of care incorporating appropriate health and social services, manage the care of their patients throughout the system, and maintain ongoing referral arrangements with one or more hospitals. Clinicians have admitting privileges and hospital staff membership at their referral hospital(s).

They assure quality special medical, diagnostic, and therapeutic services are available to patients through a system of organized referral arrangements. Community health centers form or join integrated delivery systems and provide comprehensive and continuous care including hours in which the health center is closed. They also educate patients and the community regarding the availability and appropriate use of health services.

Current Statistics

North Carolina's community health centers are comprised of 26 health center grantees, 1 migrant voucher program, 104 clinical services sites, 20 migrant voucher program sites, 7 migrant health center grantees, 3 healthy schools/healthy community grantees, 4 homeless health care grantees, and 2 federally qualified health center look-alike organizations with 6 clinical service sites. In 2006 there were 139 physicians, 80 nurse practitioners and physician assistants, 311 nurses and other medical personnel, and 42 dentists working at community health centers statewide. Those providers saw 333 283 patients for 1 109 600 patient visits. Of those patients, 52% were uninsured, 22% receive Medicaid, 71% live below the 200% of the federal poverty guidelines, and 54% live below 100% of the federal poverty guidelines. There were also 56 585 migrant and seasonal agricultural workers who received services.[2]

Within the past 5 year, community health center patients increased by 36%, patient visits increased by 36%, and uninsured patients increased by 53%. These programs prove to be extremely cost effective by serving these patients for just over $1 per day per patient. North Carolina's community health centers also create jobs and an economic base. They employ more than 1692 full-time employees.[2]

North Carolina Community Health Center Association

Alone, community health centers would struggle for resources, training, and a medium to express their concerns. Collectively, health centers have banded together to secure their common mission through the North Carolina Community Health Center Association (formerly known as the North Carolina Primary Health Care Association).

The NC Community Health Center Association was created in 1978 so that health centers across the state would have a collective voice and representation at the federal, state, and local levels. The NC Community Health Center Association also seeks support from foundations, corporations, and other private entities to increase the access of primary health care to all North Carolinians. Its staff serves on state and national coalitions and task forces to foster collaboration, leverage resources, and avoid duplication of services.

The NC Community Health Center Association is a valuable resource to health centers, providing training and technical assistance in areas such as clinical service delivery, governance, workforce development, and administration. It regularly presents workshops, trainings, and conferences to keep health center staff on the cutting edge of effective and cost-efficient service delivery. The NC Community Health Center Association consistently analyzes key issues facing health centers and provides members with critical information in a timely fashion and helps communities to create new health centers or expand existing ones.

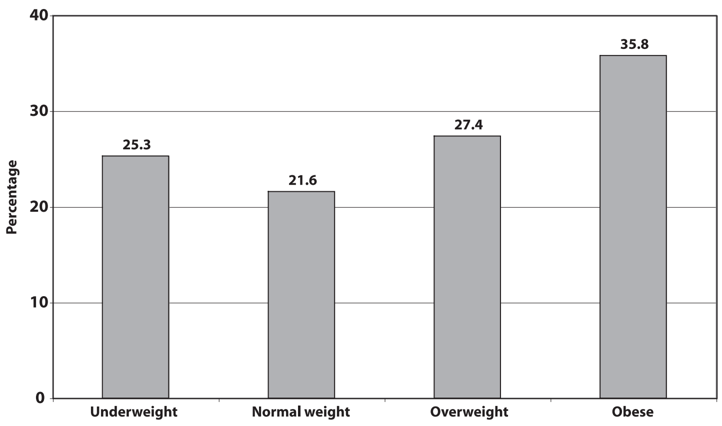
Arthritis Prevalence and Risk Factors in North Carolina

Arthritis is one of the most common chronic diseases and is the leading cause of disability in the United States.[1] Arthritis refers to more than 100 different conditions affecting the joints, surrounding tissues, and other connective tissues. Several common forms of arthritis are gout, osteoarthritis, rheumatoid arthritis, and juvenile arthritis. People with these diseases experience pain, stiffness, and/or limitation of motion. The cause of most types of arthritis is unknown.

The number of adults in North Carolina in 2005 with doctor-diagnosed arthritis (diagnosed by a physician or other health professional) is estimated at 1 754 000; this number is projected to increase to 2 761 000 in 2030.[2] In 2005, there were an estimated 681 000 adults in North Carolina with arthritis-attributable activity limitation.[2] While arthritis is not a leading cause of death in North Carolina, it is an important cause of hospitalization. In 2005 in North Carolina, there were 23 921 hospital discharges with a principal diagnosis of arthropathies (joint diseases) and related disorders (ICD-9-CM codes 710-719). The average length of stay for these hospitalizations was 4.1 days and the associated hospital charges were $675 748 000. Approximately 90% of these charges resulted from hospitalizations with a principal diagnosis of osteoarthritis (degenerative joint disease).

The Behavioral Risk Factor Surveillance System (BRFSS) is a random telephone survey of adults (aged 18 years and older) that collects information on health conditions, health risk factors, and use of health services. It is conducted in all US states and the data are self-reported. In the 2005 North Carolina BRFSS, a number of questions related to arthritis were asked of more than 17 000 adult respondents. According to the 2005 BRFSS, 38.4% of adults in North Carolina had symptoms of pain, aching, or stiffness in or around a joint in the past 30 days. Of these adults whose joint symptoms began more than 3 months earlier, 74.4% had ever seen a doctor or other health professional for their joint symptoms. And 33.0% were limited in any of their usual activities because of their joint symptoms.

Figure 1.
Percentage of Adults With Doctor-Diagnosed Arthritis by Weight Categories, 2005 North Carolina BRFSS



In 2005, 27.3% of adults in North Carolina had doctor-diagnosed arthritis, an increase from 24.8% in 2000. North Carolina's rate was slightly above the 2005 US average of 26.9%. Table 1 shows the 2005 prevalence of self-reported doctor-diagnosed arthritis in North Carolina by selected respondent characteristics. Prevalence is higher among females, American Indians, non-Hispanics, older adults, adults with lower education and income, adults who report a disability, veterans, and adults who report having diabetes or asthma. Figures 1 and 2 show the association of doctor-diagnosed arthritis prevalence with body mass

continued on page 469

index and level of physical activity. Obese adults have a higher rate of arthritis as do adults with lower levels of physical activity.

Figure 3 indicates that adults with doctor-diagnosed arthritis are much more likely than adults without arthritis to report their health as fair or poor and much less likely to report their health as very good or excellent. This association may be partly because adults with arthritis are older and thus have a higher rate of other health problems, too.

The associations shown here do not indicate cause and effect. For example, veterans may have a higher rate of arthritis in part because they are much older on average than other North Carolina adults. Hispanics in North Carolina who speak primarily Spanish are much younger than average and also much less likely than other population groups to have health insurance or a personal doctor, which reduces the chance for a diagnosis. Though physical activity can maintain joint health and reduce the risk of arthritis, the presence of arthritis may lead to lower levels of physical activity. The data shown in this report do indicate population subgroups that can be targeted by arthritis prevention and management programs.

Hospital Quality and Patient Safety

Notable News from The North Carolina Center for Hospital Quality and Patient Safety

North Carolina Center for Hospital Quality and Patient Safety

The North Carolina Surgical Care Improvement Project

Substantial variations in the rates of surgery and outcomes of surgical care are well demonstrated.[1] Failure to apply standards of care known to prevent adverse events results in harm to the patient. Research shows that a significant percentage of the 30 million operations performed in the United States each year result in preventable, often life-threatening, complications.

The 1999 Institute of Medicine of the National Academies report *To Err is Human* highlighted a study from a large medical center which found that 5.4% of 44 000 patients who underwent surgery suffered complications; nearly one-half of those complications were attributed to error.[2] Therefore, with 30 million surgical procedures performed each year in the United States, an estimated 1.6 million patients suffer complications as a result of surgical care. In North Carolina alone, 221 326 nonobstretical operations at nonfederal acute care hospitals were performed in fiscal year 2005[3] and if the proportions from the national study hold, approximately 12 000 patients may have suffered surgical complications.

Surgical site infections and cardiovascular, respiratory, and thrombolic complications represent some of the most common postoperative problems. Despite an abundance of scientific knowledge in the medical literature providing evidence-based guidance for prevention of many of these complications, there is substantial evidence that these standards aren't applied reliably in health care today.[4]

As stated in the 2001 Institute of Medicine Report *Crossing the Quality Chasm*, "Between the healthcare we have and the care we could have lies not just a gap, but a chasm."[5] For example, evidence that properly timed antimicrobial prophylaxis is effective has existed for more than 30 years. However, only 56% of Medicare patients received prophylaxis within the appropriate time frame.[6]

Patients who experience postoperative complications have increased lengths of hospital stay, increased readmission rates, and increased mortality.[7,8,9] Recently a number of successful projects have shown that implementation of evidence-based practices can have a significant impact on surgical complications.[10] As a result, over 30 national organizations, including the Centers for Medicare and Medicaid, Centers for Disease Control and Prevention, Department of Veterans Affairs, American College of Surgeons, American Hospital Association, Institute for Healthcare Improvement, and the Joint Commission have aligned efforts aimed at reducing surgical complications and mortality. This collaboration is called the Surgical Care Improvement Project (SCIP).[11]

The Surgical Care Improvement Project is a national quality partnership committed to improving the safety of surgical care through the reduction of postoperative complications. Launched in 2005, the goal of SCIP is to reduce the incidence of surgical complications 25% by the year 2010. The Surgical Care Improvement Project identifies evidence-based processes of care related to prevention of cardiovascular events, surgical site infections, postoperative pneumonia, and venous thromboembolism.[12] (See Table 1.)

In North Carolina, 48 hospitals are working together to improve surgical care processes by participating in the NC SCIP collaborative. These hospitals are committed to reducing complications associated with surgical care; through collaborative participation, they will design systems to reliably implement the care processes of SCIP. In August the 160 hospital representatives came together in Chapel Hill to learn about the SCIP network, share best practices, and begin the work of designing reliable processes of care related to SCIP.

Hospital—continued on page 472

continued from page 469

Table 1.
NC SCIP Process of Care Measures

Prevention of infection	Prophylactic antimicrobial initiated 1 hour before surgical incision (2 hours for vancomycin or fluoroquinolone)
	Prophylactic antimicrobial consistent with published guidelines
	Prophylactic antimicrobial discontinued within 24 hours of surgery end time (48 hours for cardiac patients)
	Blood glucose control in patients undergoing cardiac surgery
	Proper hair removal
	Maintenance of normothermia in colorectal surgery patients
Prevention of venous thromboembolism (VTE)	VTE prophylaxis ordered consistent with current guidelines
	Appropriate VTE prophylaxis administered within 24 hours before and after
Prevention of cardiac events	Administration of peri-operative β-blockers to patients on β-blockers prior to admission

The North Carolina Surgical Care Improvement Project collaborative is led in partnership by the North Carolina Center for Hospital Quality and Patient Safety, the Carolinas Center for Medical Excellence, and the North Carolina Chapter of the American College of Surgeons. Participating hospitals receive consultative support and secure online data collection tools and reports from the partners in addition to networking meetings, teleconferences, and other resources. The North Carolina Area Health Education Centers Program and the Southern Atlantic Healthcare Alliance provide additional support by coaching collaborative hospitals.

Thanks from the *North Carolina Medical Journal*

Without the voluntary assistance and carefully executed reviews of a number of anonymous reviewers, no journal can offer the kind of peer-review for submitted manuscripts that can assure its readers the highest quality of published articles. We are fortunate for the service of a number of individuals who have given generously of their time and expertise in service to the *North Carolina Medical Journal* this past year, and we are pleased to have this annual opportunity to acknowledge their efforts.

Marking A Milestone

Highlighting a long-term commitment to improving health care services for North Carolina communities and citizens

A Milestone in Arthritis Care
Alvin Daughtridge

Alvin Daughtridge always held the philosophy that businesses and communities flourish if relationships are built on integrity, cooperation, and trust. According to Daughtridge, "When people park their ego at the door and engage in face-to-face dialogue, problems frequently become opportunities and win-win solutions emerge." In 1999, while serving on the boards of both the Thurston Arthritis Research Center at the University of North Carolina at Chapel Hill (UNC) and Caldwell Memorial Hospital in Lenoir, North Carolina, the vice president of Fairfield Chair Company and life-long community advocate saw an opportunity to put his philosophy into action.

Recognizing the need for Caldwell Memorial to add more specialists at the same time the Arthritis Center was looking for opportunities to expand its outreach efforts across the state, Daughtridge immediately began work to build just such a win-win partnership between the two entities. He knew, however, that opportunity does not always result in success. The newly formed partnership would need to show a strong return on investment in order to succeed and thrive in the long term. To help accomplish that, Daughtridge worked closely with Thurston and Caldwell Memorial to ensure arthritis care would be provided in the area and that the area primary care physicians would offer referrals.

His efforts paid off. In 2001, a new clinic opened its doors and was named the Alvin W. Daughtridge Arthritis Clinic in honor of his vision. Dr John Winfield, retired founding director of Thurston Arthritis Research Center and rheumatologist at the clinic, says, "Alvin was instrumental to bringing arthritis care to Caldwell County and has continued to be a staunch supporter of arthritis research. Alvin has been active in arthritis care and research for many years and the dedication of the arthritis clinic in his name was a much deserved tribute to his efforts." The clinic quickly grew from a 1 to 2 day a month operation to 3 days a week. It also expanded from clinical care to a site location for drug studies and grand rounds.

"I can personally attest that Alvin's efforts have resulted in greater access to improved arthritis care for Caldwell County residents," says Dr Winfield. Daughtridge, a man well-known for his gentle and humble nature, is quick to deflect the credit and offers his own praise of Dr Winfield. "John's effectiveness with his patients is outstanding," he says. "He has made a marvelous difference in the lives of arthritis patients here in Caldwell County."

Throughout his life, Daughtridge has been a tireless community volunteer and advocate in multiple areas including health, business, and education. He has served on the boards of Caldwell County's Cancer Society, Red Cross, and Board of Health and as chairman of the Caldwell County Blood Mobile. He is a former president of the Lenoir/Caldwell Chamber of Commerce and a member of the Lenoir Jaycees, the American Furniture Manufacturer's Association, and the Furniture Shippers Association. A former Caldwell Community College and Technical Institute board member, he has served on the Caldwell Schools Career Center Advisory Council and the Planning Team. Founding chair of Communities in Schools of Caldwell County, other educational endeavors include work with the King Creek Parent Teacher Association, Communities in Smart Start Program, Children's Advocacy Council, and Preschool Interagency Council. Additional civic activities include Caldwell County's United Way, Planning Board, and City/County Services Committee, and the Lenoir Recreation Commission. A member of the Caldwell Baptist Association, Daughtridge is a deacon and Sunday school teacher at Lenoir First Baptist Church.

Daughtridge has described the clinic as a "godsend" to the people of Caldwell County. He was perhaps most pleased, however, to see his philosophy of win-win relationships between business and community come to fruition. "Because of the clinic, more people in North Carolina became aware of the University of North Carolina at Chapel Hill and its arthritis expertise through the Thurston Arthritis Research Center," he said. Dr Joanne Jordan, director of Thurston and chief of the Division of Rheumatology, Allergy, and Immunology at the UNC School of Medicine, says, "Every member of the Thurston staff works to ensure better arthritis care and improved outcomes for the people of North Carolina. We thank community advocates like Alvin Daughtridge who make such efforts possible."

Contributions from Randall Mounce, Thurston Arthritis Research Center, the University of North Carolina at Chapel Hill.

FAMILY PRACTITIONER or INTERNIST OPPORTUNITY in Wilmington NC. Established Internist & Medical Nutritionist (19 years) seeks motivated BC/BE FP/INTERNIST for immediate opportunity to practice outpatient Primary Care. Welcome inquiries from candidates interested in office expense-sharing arrangement with current physician who is committed to promoting your practice along with assisting with start-up costs. Beautiful office within close proximity (1/4 mile) to New Hanover Regional Medical Center. Coastal growth area with possibility for lucrative income, partnership in practice, & real estate ownership. CALL 910-762-8077 OR FAX RESUME WITH COVER LETTER TO 910-762-2760.

DIRECTOR OF CLINICAL SERVICES Campus Health Services at the University of North Carolina at Chapel Hill is seeking a Medical Director. Campus Health Services operates under the auspices of the Division of Student Affairs and serves a diverse community of over 27,000 undergraduate, graduate, post-doctoral, and professional students including health professional students. The Medical Director is responsible for ensuring the overall quality of medical care for the entire Campus Health Program and for all medical staff activities including quality management initiatives, supervision and evaluation of medical staff personnel, and compliance with JCAHO accreditation standards. In addition, the Medical Director provides direct patient care, provides consultation to clinical colleagues and advocates, and teaches preventative and public health measures. Requirements: MD or DO degree with appropriate board certification, license to practice in North Carolina, and a minimum of two years of relevant administrative experience as well as 3-5 years of clinical experience. Review of applications will begin immediately and continue until the position is filled. Send curriculum vitae and letter of interest to: Medical Director Position, Attn: Janet Winters, Campus Health Services, CB#7470, UNC-Chapel Hill, NC 27599-7470. The University of North Carolina at Chapel Hill is an Equal Opportunity Employer.

Exceptional Opportunities for NC Physicians. Both Locum and Permanent jobs. We have immediate positions available in Family Practice, Urgent Care, Occupational Medicine, Pediatrics, State and County Agencies as well as Corporate accounts. Flexible schedules, exceptional wages, and great benefits. Contact Physician Solutions by Phone: 919-845-0054 Email: physiciansolutions@gmail.com Web: www.physiciansolutions.net.

Physician Solutions has an excellent long-term opportunity for a BC/BE Pulmonary Physician in a well-established multi-specialty group practice in the Triad area of NC This flexible opportunity offers great income guarantee with exceptional benefits package which includes housing, travel mileage, and professional liability insurance. Send CV for immediate consideration to Email: physiciansolutions@gmail.com Fax: 919-8451947.

General Surgeon Needed Immediately for a small upscale hospital in the Triad area of NC. Excellent pay with great benefits which include housing, mileage, and professional liability insurance. This is an outstanding long-term locum tenens assignment. Contact Physician Solutions by Phone: 919-845-0054 Email: physiciansolutions@gmail.com Web: www.physiciansolutions.net.

FACULTY POSITION OPEN RANK/CHIEF OF INTERNAL MEDICINE RESIDENCY TEACHING PROGRAM Seeking qualified candidates for Chief of the Internal Medicine Residency Teaching Program, Moses Cone Health System/Greensboro Area Health Education Center, Greensboro, NC. We are an affiliate of the University of North Carolina at Chapel Hill Department of Medicine and an integral teaching site for UNC medical students. ABIM Board certification, NC Medical license, current DEA certification, and demonstrated experience in IM practice, administration, and education required. Creativity, consensus building, and comfortable communication skills reflect the leadership tradition in this innovative program. Financial management and budgetary experience preferred. Must have ability to promote/facilitate excellent teaching and research within a scholarly environment. Academic rank is open and can be either tenure or fixed-term track. Rank, track, and salary will be commensurate with qualifications and experience. Submit cover letter, CV, and at least two letters of recommendation to Rebecca Knight, Executive Director, Moses Cone Health System, 1200 N Elm Street, Greensboro, NC 27401. rebecca.knight@mosescone.com. UNC-CHAPEL HILL AND GREENSBORO AHEC ARE EQUAL OPPORTUNITY EMPLOYERS.

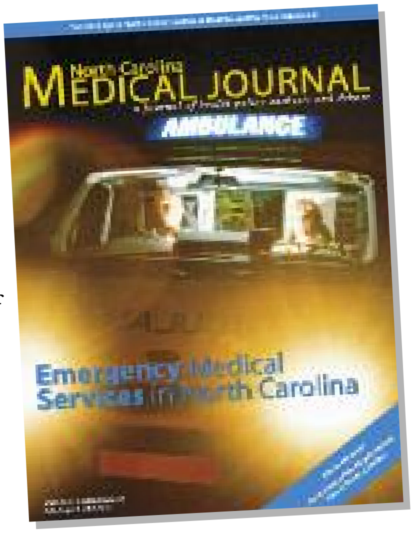
ORGANIZED BILLING SOLUTIONS, INC. Credentialing, Electronic Billing Services rated on a sliding scale based on what we collect. We work for the MD service on a friendly personal level. 888-944-2455 or obsinc@bellsouth.net

DOES YOUR MEDICAL PRACTICE HAVE A WEB PAGE? We can design a professional and informative 3-page web site for your practice that contains a Home Page, Information Page and Patient Appointment Page. We have hundreds of professional medical pictures to choose from and suggest putting a picture of the physician, your staff, or your medical practice on the site. Our price of $1,695 includes your .com or .net name, hosting for one year, and quarterly changes to your site. Patients have turned from the phone book to the computer to find health care services. Can patients find you online? We specialize in medical practice web sites for half the price of most web masters. Find us at: HalfPriceWebPage.com or phone our web master at 919-810-7437.

Primary Care Physicians Needed For Locum And Permanent Jobs in NC. We have several locum and permanent opportunities in NC. Send us your CV and get informed on the outstanding jobs available. Email us at physiciansolutions@gmail.com or phone us at 919-845-0054. Find dozens of opportunities on our web site: www.physiciansolutions.net.

Readers' Forum

To the Editor:



I was delighted to see the research article in your July/August issue on "Awareness of the Bicycle Helmet Law in North Carolina." Hopefully, it will serve as a reminder to the primary care providers in your readership that a little guidance to children and parents alike on the efficacy of helmets can save lives and reduce serious injuries.

Interestingly, the authors seem more pessimistic about compliance with the law than those of us on the NC Child Fatality Task Force who pushed for passage of the law in 2000-2001. The authors seem disappointed that regular helmet use in Pitt County increased in the 5 years after passage from less than 10% just before passage to 40%. Though much more improvement is needed, those of us involved with children's safety issues are encouraged by this significant increase in helmet use, especially since the law does not require those age 16 and older to wear helmets. Thus, parents often are not the role models they need to be.

While acknowledging the limitations of a one-county study, the authors neglect to present statewide data on the measure of greatest importance to the Task Force: bicycle-related deaths in children. In the 6 years prior to consideration and passage of the law (1994-1999) there were 71 bicycle-related deaths among children in North Carolina. In the 6 years since then (2000-2005), there were 43. That's a remarkable 40% reduction in such deaths. Given that the number of children has been increasing each year, it is likely that the death rate has dropped by almost half!

While these data are particularly encouraging, the research article makes it clear that we have a long way to go. Raising awareness is critical. Let's hope the article does just that.

To the Editor:

Concern has been raised recently by both consumers and physicians about the safety of drugs and implants after release to the market and the widespread television advertising of these new medications and devices. These two issues are important and closely interrelated. Last year, the Institute of Medicine of the National Academies issued a report calling for the Food and Drug Administration (FDA) to increase vigilance for possible drug complications after release. This report also recommended that direct marketing of a new medication to consumers should be restricted for two years after release of the new drug.

There has been an explosion of new and expensive technology in total hip and knee replacement devices. With the increasing prevalence of arthritis in the maturing baby-boomer generation, the orthopaedic device companies have also increased direct marketing of joint replacement products to consumers. Some examples include ceramic hip bearings, metal on metal hip resurfacing, rotating plastic knee replacements, knee devices designed for women only, and computer assisted surgery. Obviously, the orthopaedic device companies must be getting a good return for their advertising budgets. However, do consumer-patients truly benefit from this new expensive technology?

At a recent national meeting of orthopaedic surgeons in San Diego, data were presented on all these new devices. There is yet no proven benefit from these new, more expensive devices compared to standard hip and knee implants. Computer-assisted orthopaedic surgery has yet to improve patients' outcomes. The American Academy of Orthopaedic Surgeons, the Hip Society, and the Knee Society have again called on the Centers for Medicare and Medicaid Services to establish a national registry for hip and knee replacements. Such a registry would identify, at an earlier time, problematic or less effective devices. The United States has a much higher rate of revision (redo) hip and knee replacement surgery than other countries such as Canada, Sweden, and Norway, which have such national registries. With patients changing insurance plans and physicians frequently, only a national registry will detect the problematic devices early. At present, patients and

ACIPHEX® \a-sə-ˌfeks
(rabeprazole sodium)
Delayed-Release Tablets

BRIEF SUMMARY
Before prescribing ACIPHEX®, please see full prescribing information.

INDICATIONS AND USAGE
Healing of Erosive or Ulcerative Gastroesophageal Reflux Disease (GERD)
ACIPHEX® is indicated for short-term (4 to 8 weeks) treatment in the healing and symptomatic relief of erosive or ulcerative gastroesophageal reflux disease (GERD). For those patients who have not healed after 8 weeks of treatment, an additional 8-week course of ACIPHEX® may be considered.

Maintenance of Healing of Erosive or Ulcerative Gastroesophageal Reflux Disease (GERD)
ACIPHEX® is indicated for maintaining healing and reduction in relapse rates of heartburn symptoms in patients with erosive or ulcerative gastroesophageal reflux disease (GERD Maintenance). Controlled studies do not extend beyond 12 months.

Treatment of Symptomatic Gastroesophageal Reflux Disease (GERD)
ACIPHEX® is indicated for the treatment of daytime and nighttime heartburn and other symptoms associated with GERD.

Healing of Duodenal Ulcers
ACIPHEX® is indicated for short-term (up to four weeks) treatment in the healing and symptomatic relief of duodenal ulcers. Most patients heal within four weeks.

***Helicobacter pylori* Eradication to Reduce the Risk of Duodenal Ulcer Recurrence**
ACIPHEX® in combination with amoxicillin and clarithromycin as a three drug regimen, is indicated for the treatment of patients with *H. pylori* infection and duodenal ulcer disease (active or history within the past 5 years) to eradicate *H. pylori*. Eradication of *H. pylori* has been shown to reduce the risk of duodenal ulcer recurrence. (See **CLINICAL STUDIES** and **DOSAGE AND ADMINISTRATION** in full prescribing information.)

In patients who fail therapy, susceptibility testing should be done. If resistance to clarithromycin is demonstrated or susceptibility testing is not possible, alternative antimicrobial therapy should be instituted. (See **CLINICAL PHARMACOLOGY, Microbiology** in full prescribing information and the clarithromycin package insert, **CLINICAL PHARMACOLOGY, Microbiology**.)

Treatment of Pathological Hypersecretory Conditions, Including Zollinger-Ellison Syndrome
ACIPHEX® is indicated for the long-term treatment of pathological hypersecretory conditions, including Zollinger-Ellison syndrome.

CONTRAINDICATIONS
Rabeprazole is contraindicated in patients with known hypersensitivity to rabeprazole, substituted benzimidazoles or to any component of the formulation.

Clarithromycin is contraindicated in patients with known hypersensitivity to any macrolide antibiotic.

Concomitant administration of clarithromycin with pimozide and cisapride is contraindicated. There have been post-marketing reports of drug interactions when clarithromycin and/or erythromycin are co-administered with pimozide resulting in cardiac arrhythmias (QT prolongation, ventricular tachycardia, ventricular fibrillation, and torsade de pointes) most likely due to inhibition of hepatic metabolism of pimozide by erythromycin and clarithromycin. Fatalities have been reported. (Please refer to full prescribing information for clarithromycin.)

Amoxicillin is contraindicated in patients with a known hypersensitivity to any penicillin. (Please refer to full prescribing information for amoxicillin.)

WARNINGS
CLARITHROMYCIN SHOULD NOT BE USED IN PREGNANT WOMEN EXCEPT IN CLINICAL CIRCUMSTANCES WHERE NO ALTERNATIVE THERAPY IS APPROPRIATE. If pregnancy occurs while taking clarithromycin, the patient should be apprised of the potential hazard to the fetus. (See **WARNINGS** in prescribing information for clarithromycin.)

Amoxicillin: Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported in patients on penicillin therapy. These reactions are more likely to occur in individuals with a history of penicillin hypersensitivity and/or a history of sensitivity to multiple allergens.

There have been well-documented reports of individuals with a history of penicillin hypersensitivity reactions who have experienced severe hypersensitivity reactions when treated with a cephalosporin. Before initiating therapy with any penicillin, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, and other allergens. If an allergic reaction occurs, amoxicillin should be discontinued and the appropriate therapy instituted. (See **WARNINGS** in prescribing information for amoxicillin.)

SERIOUS ANAPHYLACTIC REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH EPINEPHRINE. OXYGEN, INTRAVENOUS STEROIDS, AND AIRWAY MANAGEMENT, INCLUDING INTUBATION, SHOULD ALSO BE ADMINISTERED AS INDICATED.

Pseudomembranous colitis has been reported with nearly all antibacterial agents, including clarithromycin and amoxicillin, and may range in severity from mild to life threatening. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of "antibiotic-associated colitis".

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to discontinuation of the drug alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an antibacterial drug clinically effective against *Clostridium difficile colitis*.

PRECAUTIONS
General
Symptomatic response to therapy with rabeprazole does not preclude the presence of gastric malignancy.

Patients with healed GERD were treated for up to 40 months with rabeprazole and monitored with serial gastric biopsies. Patients without *H. pylori* infection (221 of 326 patients) had no clinically important pathologic changes in the gastric mucosa. Patients with *H. pylori* infection at baseline (105 of 326 patients) had mild or moderate inflammation in the gastric body or mild inflammation in the gastric antrum. Patients with mild grades of infection or inflammation in the gastric body tended to change to moderate, whereas those graded moderate at baseline tended to remain stable. Patients with mild grades of infection or inflammation in the gastric antrum tended to remain stable. At baseline 8% of patients had atrophy of glands in the gastric body and 15% had atrophy in the gastric antrum. At endpoint, 15% of patients had atrophy of glands in the gastric body and 11% had atrophy in the gastric antrum. Approximately 4% of patients had intestinal metaplasia at some point during follow-up, but no consistent changes were seen.

Steady state interactions of rabeprazole and warfarin have not been adequately evaluated in patients. There have been reports of increased INR and prothrombin time in patients receiving a proton pump inhibitor and warfarin concomitantly. Increases in INR and prothrombin time may lead to abnormal bleeding and even death. Patients treated with a proton pump inhibitor and warfarin concomitantly may need to be monitored for increases in INR and prothrombin time.

Information for Patients
Patients should be cautioned that ACIPHEX® delayed-release tablets should be swallowed whole. The tablets should not be chewed, crushed, or split. ACIPHEX® can be taken with or without food.

Drug Interactions
Rabeprazole is metabolized by the cytochrome P450 (CYP450) drug metabolizing enzyme system. Studies in healthy subjects have shown that rabeprazole does not have clinically significant interactions with other drugs metabolized by the CYP450 system, such as warfarin and theophylline given as single oral doses, diazepam as a single intravenous dose, and phenytoin given as a single intravenous dose (with supplemental oral dosing). Steady state interactions of rabeprazole and other drugs metabolized by this enzyme system have not been studied in patients. There have been reports of increased INR and prothrombin time in patients receiving proton pump inhibitors, including rabeprazole, and warfarin concomitantly. Increases in INR and prothrombin time may lead to abnormal bleeding and even death.

In vitro incubations employing human liver microsomes indicated that rabeprazole inhibited cyclosporine metabolism with an IC_{50} of 62 micromolar, a concentration that is over 50 times higher than the C_{max} in healthy volunteers following 14 days of dosing with 20 mg of rabeprazole. This degree of inhibition is similar to that by omeprazole at equivalent concentrations.

Rabeprazole produces sustained inhibition of gastric acid secretion. An interaction with compounds which are dependent on gastric pH for absorption may occur due to the magnitude of acid suppression observed with rabeprazole. For example, in normal subjects, co-administration of rabeprazole 20 mg QD resulted in an approximately 30% decrease in the bioavailability of ketoconazole and increases in the AUC and C_{max} for digoxin of 19% and 29%, respectively. Therefore, patients may need to be monitored when such drugs are taken concomitantly with rabeprazole. Co-administration of rabeprazole and antacids produced no clinically relevant changes in plasma rabeprazole concentrations.

In a clinical study in Japan evaluating rabeprazole in patients categorized by CYP2C19 genotype (n=6 per genotype category), gastric acid suppression was higher in poor metabolizers as compared to extensive metabolizers. This could be due to higher rabeprazole plasma levels in poor metabolizers. Whether or not interactions of rabeprazole sodium with other drugs metabolized by CYP2C19 would be different between extensive metabolizers and poor metabolizers has not been studied.

Combined Administration with Clarithromycin
Combined administration consisting of rabeprazole, amoxicillin, and clarithromycin resulted in increases in plasma concentrations of rabeprazole and 14-hydroxyclarithromycin. (See **CLINICAL PHARMACOLOGY, Combination Therapy with Antimicrobials** in full prescribing information.)

Concomitant administration of clarithromycin with pimozide and cisapride is contraindicated. (See **PRECAUTIONS** in prescribing information for clarithromycin.) (See **PRECAUTIONS** in prescribing information for amoxicillin.)

Carcinogenesis, Mutagenesis, Impairment of Fertility
In a 88/104-week carcinogenicity study in CD-1 mice, rabeprazole at oral doses up to 100 mg/kg/day did not produce any increased tumor occurrence. The highest tested dose produced a systemic exposure to rabeprazole (AUC) of 1.40 μg•hr/mL which is 1.6 times the human exposure (plasma $AUC_{0-\infty}$ = 0.88 μg•hr/mL) at the recommended dose for GERD (20 mg/day). In a 104-week carcinogenicity study in Sprague-Dawley rats, males were treated with oral doses of 5, 15, 30 and 60 mg/kg/day and females with 5, 15, 30, 60 and 120 mg/kg/day. Rabeprazole produced gastric enterochromaffin-like (ECL) cell hyperplasia in male and female rats and ECL cell carcinoid tumors in female rats at all doses including the lowest tested dose. The lowest dose (5 mg/kg/day) produced a systemic exposure to rabeprazole (AUC) of about 0.1 μg•hr/mL which is about 0.1 times the human exposure at the recommended dose for GERD. In male rats, no treatment related tumors were observed at doses up to 60 mg/kg/day producing a rabeprazole plasma exposure (AUC) of about 0.2 μg•hr/mL (0.2 times the human exposure at the recommended dose for GERD).

Rabeprazole was positive in the Ames test, the Chinese hamster ovary cell (CHO/HGPRT) forward gene mutation test and the mouse lymphoma cell (L5178Y/TK+/-) forward gene mutation test. Its demethylated-metabolite was also positive in the Ames test. Rabeprazole was negative in the *in vitro* Chinese hamster lung cell chromosome aberration test, the *in vivo* mouse micronucleus test, and the *in vivo* and *ex vivo* rat hepatocyte unscheduled DNA synthesis (UDS) tests.

Rabeprazole at intravenous doses up to 30 mg/kg/day (plasma AUC of 8.8 μg•hr/mL, about 10 times the human exposure at the recommended dose for GERD) was found to have no effect on fertility and reproductive performance of male and female rats.

Pregnancy
Teratogenic Effects. Pregnancy Category B: Teratology studies have been performed in rats at intravenous doses up to 50 mg/kg/day (plasma AUC of 11.8 μg•hr/mL, about 13 times the human exposure at the recommended dose for GERD) and rabbits at intravenous doses up to 30 mg/kg/day (plasma AUC of 7.3 μg•hr/mL, about 8 times the human exposure at the recommended dose for GERD) and have revealed no evidence of impaired fertility or harm to the fetus due to rabeprazole. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers
Following intravenous administration of ^{14}C-labeled rabeprazole to lactating rats, radioactivity in milk reached levels that were 2- to 7-fold higher than levels in the blood. It is not known if unmetabolized rabeprazole is excreted in human breast milk. Administration of rabeprazole to rats in late gestation and during lactation at doses of 400 mg/kg/day (about 195-times the human dose based on mg/m²) resulted in decreases in body weight gain of the pups. Since many drugs are excreted in milk, and because of the potential for adverse reactions to nursing infants from rabeprazole, a decision should be made to discontinue nursing or discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use
The safety and effectiveness of rabeprazole in pediatric patients have not been established.

Use in Women
Duodenal ulcer and erosive esophagitis healing rates in women are similar to those in men. Adverse events and laboratory test abnormalities in women occurred at rates similar to those in men.

Geriatric Use
Of the total number of subjects in clinical studies of ACIPHEX®, 19% were 65 years and over, while 4% were 75 years and over. No overall differences in safety or effectiveness were observed between these subjects and younger subjects, and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

ADVERSE REACTIONS
Worldwide, over 2900 patients have been treated with rabeprazole in Phase II-III clinical trials involving various dosages and durations of treatment. In general, rabeprazole treatment has been well-tolerated in both short-term and long-term trials. The adverse events rates were generally similar between the 10 and 20 mg doses.

Incidence in Controlled North American and European Clinical Trials
In an analysis of adverse events assessed as possibly or probably related to treatment appearing in greater than 1% of ACIPHEX® patients and appearing with greater frequency than placebo in controlled North American and European trials, the incidence of headache was 2.4% (n=1552) for ACIPHEX® versus 1.6% (n=258) for placebo.

In short and long-term studies, the following adverse events, regardless of causality, were reported in ACIPHEX®-treated patients. Rare events are those reported in ≤1/1000 patients.

Readers' Forum continued

physicians can rely only on institutional (Mayo Clinic) or personal surgeon (UNC) databases for this information. Individual problems with devices such as squeaking ceramic hip replacements are likely underreported to the FDA at present. Patients should also realize that the experience and skill of the surgeon is more important for the long-term success of a hip or knee replacement than the use of the newest or most advertised product.

Patients should write their national legislators this year to encourage the FDA and the Centers for Medicare and Medicaid Services to enact a national registry for hip and knee replacements. Television and print advertising of these devices to patients should be discouraged. Until this system is functional, patients with hip and knee replacements should have regular checkups of their artificial joints by their surgeon.

The Arthritis Foundation, Carolinas Chapter

Forty-six million Americans have doctor-diagnosed arthritis. Arthritis is one of the most common diseases in the United States and the leading cause of disability among people 15 years of age and over. By the year 2020, an estimated 60 million people in the US will be affected. North Carolina ranks ninth among the 50 states in estimated prevalence, and arthritis is the most common cause of chronic disease in the state.

The Arthritis Foundation is the only nationwide, not-for-profit health organization providing people with arthritis the resources to control and manage their disease. Through evidence-based exercise programs and educational resources, the Arthritis Foundation is providing help to those who are in need. The Arthritis Foundation Carolinas Chapter serves more than 1.8 million people in North Carolina who have arthritis. The Carolinas Chapter works in collaboration with the North Carolina Arthritis Program to increase awareness of arthritis in the state. The Chapter's main office is located in Charlotte with staff also located in the Triangle and Triad to serve those areas of the state. In addition to offering the Arthritis Foundation's aquatic, exercise, tai chi, and self-help programs, the Carolinas Chapter funds arthritis research.

Over the past 2 years the Arthritis Foundation Carolinas Chapter has funded over $2 million dollars of research at institutions in the Carolinas. At Duke University, Arthritis Foundation-funded researcher Kelly K. Anthony, PhD, and her colleagues are investigating the social and emotional impact of having juvenile arthritis. Juvenile arthritis affects over 300 000 children in the United States and is one of the most common chronic diseases of childhood, occurring nearly as often as insulin-dependent juvenile diabetes. The results of this study at Duke will assist in the development of an early intervention program for the families of children living with juvenile arthritis. It will also provide physicians a better understanding of how to care for children with the disease.

The Arthritis Foundation Carolinas Chapter raises funds for such research with the support of thousands of committed volunteers and sponsors who participate in chapter events such as the signature Arthritis Walks and the Jingle Bell Run. These events are held in cities across the Carolinas including Wilmington, Asheville, Winston-Salem, Greensboro, Raleigh, Durham, Lenoir, and Charlotte. The money raised by these events supports research as well as public policy and public health initiatives, and the events focus on the importance of exercise in the management and treatment of arthritis. People with arthritis need to know they do not face this disease alone. For information or to get involved, call the Arthritis Foundation at 1-800-883-8806.

Gail Norman is president and CEO of the Arthritis Foundation Carolinas Chapter. She can be reached at gnorman@arthritis.org or 4530 Park Road, Suite 230, Charlotte, NC 28209.

Compassion transformed into art.

Compassion and caring come in many forms, but perhaps none as expressive as The Southeastern Hospice Festival of Trees. Each year, the visions of local artists are displayed through dozens of trees themed in unique combinations of satin bows, glistening tinsel, and one-of-a-kind ornaments.

Even more enchanting is knowing behind each tree is a sponsor whose contribution helps fund the efforts of Southeastern Hospice and our new center for end-of-life care, Southeastern Hospice House.

'Tis the season for giving, and few expressions of kindness mean more than helping someone be at ease during life's most difficult time.

2007 Costs and Coverage of Antiretrovirals Under Medicare Part D for People With HIV/AIDS Living in North Carolina

Sohini Sengupta, PhD, MPH

Abstract

Background: *Effective January 1, 2006 Medicare Part D became a new source of prescription drug coverage for people with HIV/AIDS in the United States. The implementation of Part D has affected access to antiretrovirals for people with HIV/AIDS. In North Carolina, access can be difficult because of the state's struggling safety net programs and the growing HIV-infected populations among Blacks and in poor rural counties. This analysis examines Medicare Part D antiretroviral coverage in 2007 for beneficiaries with HIV/AIDS in North Carolina, particularly those who did not qualify as dual eligibles or for a full low-income subsidy.*

Methods: *Data describing program coverage were obtained from the Web site www.medicare.gov and descriptive analyses were performed to assess changes in antiretroviral coverage in Part D prescription drug plans in North Carolina.*

Results: *Most of the 26 antiretrovirals are covered in some way by 76 North Carolina prescription drug plans. There may be variability in coverage however associated with (a) antiretroviral classification within formularies; (b) drug premiums; (c) whether premiums can be waived; (d) annual deductibles; and (e) whether coverage is provided in the "doughnut hole."*

Limitations: *The data may not reflect actual patterns of drug use and realized access to the drugs. The findings are limited to antiretroviral coverage in North Carolina's Part D offerings but could be generalized to other states with similar prescription drug plan costs and coverage.*

Conclusion: *These concerns continue to pose significant challenges to accessing antiretrovirals for Part D beneficiaries with HIV/AIDS in North Carolina. Variability demonstrated within prescription drug plans will continue, and beneficiaries with HIV/AIDS who do not qualify as dual eligibles or for low-income subsidies will need to evaluate these issues when selecting a prescription drug plan in future enrollment periods.*

Key Words: *HIV, AIDS, Medicare, antiretrovirals, health services accessibility*

In many states, the implementation of Medicare Part D in 2006—a new source of prescription drug coverage for eligible beneficiaries—had the potential to improve access to care for people with human immunodeficiency virus (HIV) or acquired immune deficiency syndrome (AIDS) given the critical role of antiretroviral treatment in their care. Along with state-sponsored AIDS Drug Assistance Programs (ADAPs), Medicaid, and industry-sponsored Patient Assistance Programs, Part D could strengthen the tenuous health care safety net[1] by providing drug coverage for people with HIV/AIDS who are under the age of 65 years and who qualify for Social Security Disability Insurance payments (and thus Medicare) as a consequence of HIV-related disabilities.[2] Concerns persist, however, that Medicare Part D jeopardizes access to AIDS care for some patients because Medicaid, as of 2006, no longer provided drug coverage for dual eligibles (persons on both Medicare and Medicaid);[3] some states require all of their ADAP clients to enroll in Part D;[4] and a new kickback statute may make companies sponsoring Patient Assistance Programs criminally liable if they compete with the Part D program.[5]

North Carolina is an example of a state where Medicare Part D could have important consequences for the safety net as Part D becomes a source to cover AIDS-related treatment for the poor with HIV/AIDS. In North Carolina access to antiretrovirals is an ever-increasing problem because of increases in the number of people infected by HIV and the state's struggling ADAP and

Patient Assistance Programs. HIV-infection growth rates are growing rapidly among Blacks and those living in poor rural counties. As of December 31, 2006 North Carolina reported 15 746 AIDS cases with 67% of those cases among Blacks (well above the national average of 40%) at an annual rate of 36.6 per 100 000.[6] In the same surveillance report, two rural counties in North Carolina—Wilson and Edgecombe counties—had 3-year average incidence rates from 2004-2006 of greater than 30 per 100 000.[6] As the number of AIDS cases continues to increase, the role of Part D will grow over time. Indeed, the proportion of those required to use Part D in North Carolina will expand for 3 major reasons: (a) ADAP clients may have no other choice but to enroll in a prescription drug plan (PDP) under Part D;[4] (b) the roughly 18% who are dual eligibles[7] are automatically enrolled into prescription drug plans; and (c) the future of company-sponsored Patient Assistance Programs remains uncertain.[5] This article will describe the 2007 landscape of prescription drug plans covering antiretrovirals in North Carolina with a focus on the coverage and cost implications for HIV-positive beneficiaries, particularly for those who do not qualify as dual eligibles or those who may not qualify for a full low-income subsidy to help with paying the out-of-pocket costs for their antiretrovirals.

Medicare Part D Vernacular

Medicare Part D has its own nomenclature. Table 1 presents terms and definitions that will be used throughout this article.[8]

Methods

Data were obtained from the Web site www.medicare.gov in the period May 16-18, 2007. The number of PDPs offered in North Carolina and their general out-of-pocket costs were identified under "Learn More About Health Plans In Your Area" for North Carolina.[9] The result was a list of the number of stand-alone PDPs and Medicare Advantage-Prescription Drug (MA-PD) plans, their monthly premiums, annual deductibles, and whether or not they cover any classifications of medication in the "doughnut hole." The doughnut hole refers to the gap in coverage when no prescription drug benefit is available; an enrollee must pay a designated amount of out-of-pocket drug expenses before coverage continues.[8] Stratifying these PDPs by type, descriptive statistics were calculated that included median and ranges for monthly premiums and frequencies for annual deductible categories, number of PDPs covering generics in the doughnut hole, and number of PDPs offering $0 monthly premiums to beneficiaries who qualify for a full low-income subsidy.

Next, 26 antiretrovirals approved by the US Federal Drug Administration were selected under "Formulary Finder" for North Carolina within www.medicare.gov.[10] The result is a list of the PDPs that cover all or a majority of the 26 antiretrovirals. In accessing each PDP, additional information is provided about each antiretroviral's formulary status classification and whether or not there are any restrictions set by the PDP for each antiretroviral. Two analyses were conducted describing

Table 1.
Medicare Part D Glossary

Coverage gap (or "doughnut hole")	The coverage gap is the period when beneficiaries pay 100% of their Part D medication expenditures. In 2007, the coverage gap begins when the total spending for drugs reaches $2400, exclusive of the beneficiary's monthly premium, and ends when the beneficiary has reached $3850 in true out-of-pocket costs (TrOOP). Afterwards, beneficiaries pay 5% of their costs as coinsurance or copayments.
Dual eligible	An individual who is eligible for both Medicare and Medicaid coverage. In the past, Medicaid paid for drugs for this population. Dual eligibles will now receive most of their prescriptions from a Part D plan. Their premiums and deductibles will be fully subsidized and their copayments will be zero or nominal (approximately $3 for brand/$1 for generics).
Formulary	A list of specific drugs covered by a Part D prescription drug plan (PDP).
Stand-alone prescription drug plan	The most common PDP that Medicare beneficiaries could enroll in if they wish to stay in traditional Medicare and receive drug coverage.
Low-income subsidy (or extra help)	Financial assistance that lowers the premiums and copayments for beneficiaries with income limits defined as a percentage of the federal poverty guidelines (FPG). To qualify for a full low-income subsidy, beneficiaries need to be below 135% FPG, or $13 784 for an individual and $17 820 for a couple in 2007. Full subsidy pays for the entire premium and deductible for recipients and nearly all of the cost-sharing below the out-of-pocket threshold.
Medicare Advantage Prescription Drug Plan (MA-PD)	A private managed care plan established under Medicare Part C (formerly known as Medicare + Choice) that also provides standard Part D drug coverage.
Prescription drug plan (PDP)	Also known as "Part D plans," can be either stand-alone or MA-PD.
True out-of-pocket spending (TrOOP)	The amount a beneficiary must pay on covered drugs to reach catastrophic coverage. An individual's payment of the deductible, coinsurance, and/or copayments and drug costs in the doughnut hole count towards TrOOP. For 2007 the TrOOP limit is $3850. Currently, the Part D premium and ADAP subsidies do not count towards TrOOP.

Source: A Medicare drug benefit glossary. MedicareRxMatters Web site. http://www.medicarerxmatters.org/People/Glossary/index.asp#partial_subsidy. Accessed May 27, 2007.

antiretroviral coverage and cost-sharing responsibility within North Carolina PDPs. The first analysis focused on the number of PDPs classified by formulary status and restrictions (prior authorization and quantity limits) set by PDPs for each of the 26 antiretrovirals. Analysis involved producing a summary table that was a total count of the number of PDPs (a) in each tier of the formulary status and (b) that had quantity limits or prior authorization for each of the 26 antiretrovirals. The second analysis looked at antiretroviral coverage classified by formulary status for each North Carolina PDP. The first step of this analysis involved calculating a total count of the number of antiretrovirals covered in each tier for each PDP. The second step involved stratifying the PDPs by type (stand-alone or MA-PD) and by the number of antiretrovirals they covered within each tier. These data were presented in bar graphs to demonstrate clustering patterns of the number of antiretrovirals covered by the PDPs.

Results

Overview of North Carolina Prescription Drug Plans

A total of 51 stand-alone prescription drug plans and 41 MA-PD plans are offered in North Carolina. Fifty of the stand-alone PDPs cover all or a majority of the antiretrovirals; only 26 of the MA-PD plans offer this extent of coverage. (See Table 2.)

Table 2.
Summary of North Carolina's Prescription Drug Plans Covering All or the Majority of Antiretrovirals

					Annual Deductible		
PDP Type	**N**	**Monthly Premium** Median (Range)	**Doughnut Hole Coverage Generics**	**$0 Premium For Low Income Subsidy**	**$0**	**$1 to $264**	**$265**
Stand Alone	50	$36.05 ($17.80 - $85.90)	30%	42%	62%	6%	32%
Medicare Advantage (MA-PD)	26	$21.80 ($0.00 - $44.90)	19%	0%	81%	8%	12%

Source: Medicare Prescription Drug Plan Finder: Plans in Your Area. http://www.medicare.gov/MPDPF/Public/Include/DataSection/Results/ListPlanByState.asp. Accessed May 16, 2007.

Monthly drug premiums for the 50 stand-alone PDPs range from $17.80 (Humana PDP Standard) to $85.90 (Humana PDP Complete). For the MA-PD plans, monthly drug premiums could be $0, but the drug benefit premium is usually incorporated into the overall health care premium.[9] Medicare Advantage Prescription Drug plans with monthly drug premiums range from $5.70 (Security Horizons Medicare Complete Choice) to $44.90 (Partners Medicare Options Enhanced).[9] Annual deductibles range from $0 to $265. Forty-two percent of the stand-alone plans and none of the MA-PD plans allow for beneficiaries to pay a $0 monthly drug premium if the participant qualifies for a full low-income subsidy. Thirty percent of the stand-alone and 19% of the MA-PD plans offer coverage of generics in the doughnut hole which means that beneficiaries with these plans only would need to pay copays for Tier 1 drugs.

Out-of-pocket costs have changed since Part D's inception. In 2006, only one of the stand-alone PDPs—Humana PDP Complete—offered coverage of brand-name drugs for participants caught in the doughnut hole. The plan, however, converted to only covering generics and increased the monthly premium from $50 to $85 in 2007 as a way to reduce costs.[11] Variability also is demonstrated both within and across insurance companies (data not shown). For example, Humana offers Humana PDP Complete and Humana PDP Standard. Humana PDP Complete has a no annual deductible and generics are covered in the doughnut hole, but it does not offer $0 monthly drug premiums for beneficiaries who qualify for a full-low-income subsidy. In contrast, Humana PDP Standard has a $265 annual deductible and does not cover generics in the doughnut hole, but it offers $0 monthly drug premiums for beneficiaries who qualify for a full-low-income subsidy. Variability is quite significant across insurance companies. For example, Partners Medicare Options Enhanced has a $0 annual deductible and generics are covered in the doughnut hole, whereas Security Horizons Medicare Complete Choice also has a $0 annual deductible but does not cover generics in the doughnut hole.

Analysis 1 evaluates the number of PDPs classified by formulary status, prior authorization, and quantity limits for each antiretroviral. A total of 26 antiretrovirals were selected that are considered standard of care to treat HIV-infected patients; 24 are brand-name drugs and 2 are approved generics. (See Table 3.)

As mentioned, 50 stand-alone PDPs and 26 MA-PD plans cover all or the majority of the 26 antiretrovirals; 6 PDPs (3 stand-alone and 3 MA-PDs) do not cover Videx (Didanosine) and 2 MA-PD plans do not cover Reyataz (atazanavir sulfate). Both of these antiretrovirals are used to treat naïve patients, and Reyataz (atazanavir sulfate) is one of the preferred protease inhibitors.[12]

Within each PDP, the antiretroviral formulary's cost-sharing is classified into tiers. Tier 1 represents the lowest cost-sharing responsibility, and Tier 4 represents the highest cost-sharing responsibility. Tier 1 drugs are usually generics with copays anywhere from $0 to $10, or 25% of the drug's cost. Tier 2 drugs are delineated as "Preferred Brand" or "Formulary Brand" with copays ranging from $17 to $66, or 25% of the

Fusion inhibitors

Fuzeon (enfuvirtide, T-20)

Single tablet regimen

Atripla (efavirenz, emtricitabine and tenovir disoproxil fumarate)

Source: United States Department of Health and Human Services Panel on Antiretroviral Guidelines for Adults and Adolescents. Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents. Washington, DC: Department of Health and Human Services; 2006.

Note: Brand name of antiretrovirals followed by their generic names in ( ).

* Indicates antiretrovirals that have generic versions approved by the Federal Drug Administration.

drug's cost. Tier 3 drugs are delineated as "Non-Preferred Brand" or "Brand" with copays anywhere from $40 to $60, or as high as 75% of the drug's cost. Tier 4 drugs also are called "Specialty" with copays anywhere from 25% to 33% of the drug's cost.[13] Each PDP also indicated whether or not any restrictions were imposed on the antiretrovirals in the form of quantity limits or prior authorization, factors that may further affect access to specific drugs.

In Table 4 the data are organized to demonstrate the variability in which antiretrovirals are classified into the formulary status of the 76 North Carolina PDPs, beginning with the 2 generic antiretrovirals—Retrovir (zidovudine) and Videx (didanosine)—that have been classified into Tier 1 by the highest number of PDPs.

Retrovir (zidovudine) is classified in Tier 1 for all 76 PDPs, but Videx (didanosine) is not covered by 6 PDPs; it is classified as Tier 3 for 5 of the PDPs. The majority of the PDPs cover the Brand antiretrovirals at Tier 2. The cost-sharing for Atripla, Aptivus, Retrovir IV, and Fuzeon will be the highest since they are classified more often in Tier 3 and Specialty; Fuzeon is classified as Specialty in 64 of the PDPs. Only 4 of the antiretrovirals—Aptivus, Emtriva, Reyataz, and Fuzeon—are subject to quantity limits. Some PDPs use quantity limits to restrict how much of a drug they will dispense at one time. Plans commonly limit dispensing to a one month supply or 90 to 100 days for so-called "maintenance drugs" for persons with chronic conditions such as HIV/AIDS.[14] Only Fuzeon is subject to prior authorization which is a process whereby plans require clinical justification before dispensing a drug.[14]

Analysis 2 evaluated antiretroviral coverage classified by formulary status for North Carolina PDPs. Figure 1 illustrates antiretroviral coverage within the 76 PDPs' formulary status by presenting a summary of PDPs (stratified by type) by the number of antiretrovirals they cover in Tier 1 through Tier 4.

What is evident when looking at the 4 graphs is that all 50 stand-alone PDPs and 26 MA-PD plans cover one or more antiretrovirals in Tier 1 or Tier 2. For the Tier 1 graph, most of the PDPs cover 1-2 drugs (generics); only one MA-PD plan covers 24 of the antiretrovirals at Tier 1. In the Tier 2 graph, most of the PDPs cover between 19 and 23 of the antiretrovirals; one MA-PD plan covers 24 antiretrovirals at Tier 2. The Tier 3 and Tier 4 graphs show that very few of the antiretrovirals covered are categorized in these Tiers by the PDPs. Twenty stand-alone PDPs and 9 MA-PD plans cover no antiretrovirals in Tier 3 and the same is true for Tier 4 antiretroviral coverage among 9 stand-alone PDPs and 4 MA-PD plans. Although 2 of the stand-alone PDPs cover 17 antiretrovirals in Tier 3, and 5 stand-alone PDP and 5 MA-PD plans cover 15 of the antiretrovirals at Tier 4, the largest clustering of PDPs illustrated have only between 1 and 3 antiretrovirals in both Tier 3 and Tier 4.

Discussion

Similar to another study of prescription drug plans conducted in 2006,[13] the 2007 landscape of Medicare Part D PDPs covering antiretrovirals in North Carolina continues to demonstrate several barriers for beneficiaries with HIV/AIDS living in the state and particularly for those who are not dual eligibles or who may not qualify for a full low-income subsidy. The barriers relate to changes and variability within and across Part D prescription drug plans that affect affordability, access, and

Table 4.
Number of Prescription Drug Plans Classified by Formulary Status, Prior Authorization, and Quantity Limits for Each Antiretroviral

	Formulary Status					
Name of Antiretroviral	**Tier 1**	**Tier 2**	**Tier 3**	**Specialty**	**Quantity Limits**	**Prior Authorization**
Retrovir (Zidovudine)	76	0	0	0	0	0
Videx (Didanosine)[a]	65	0	5	0	0	0

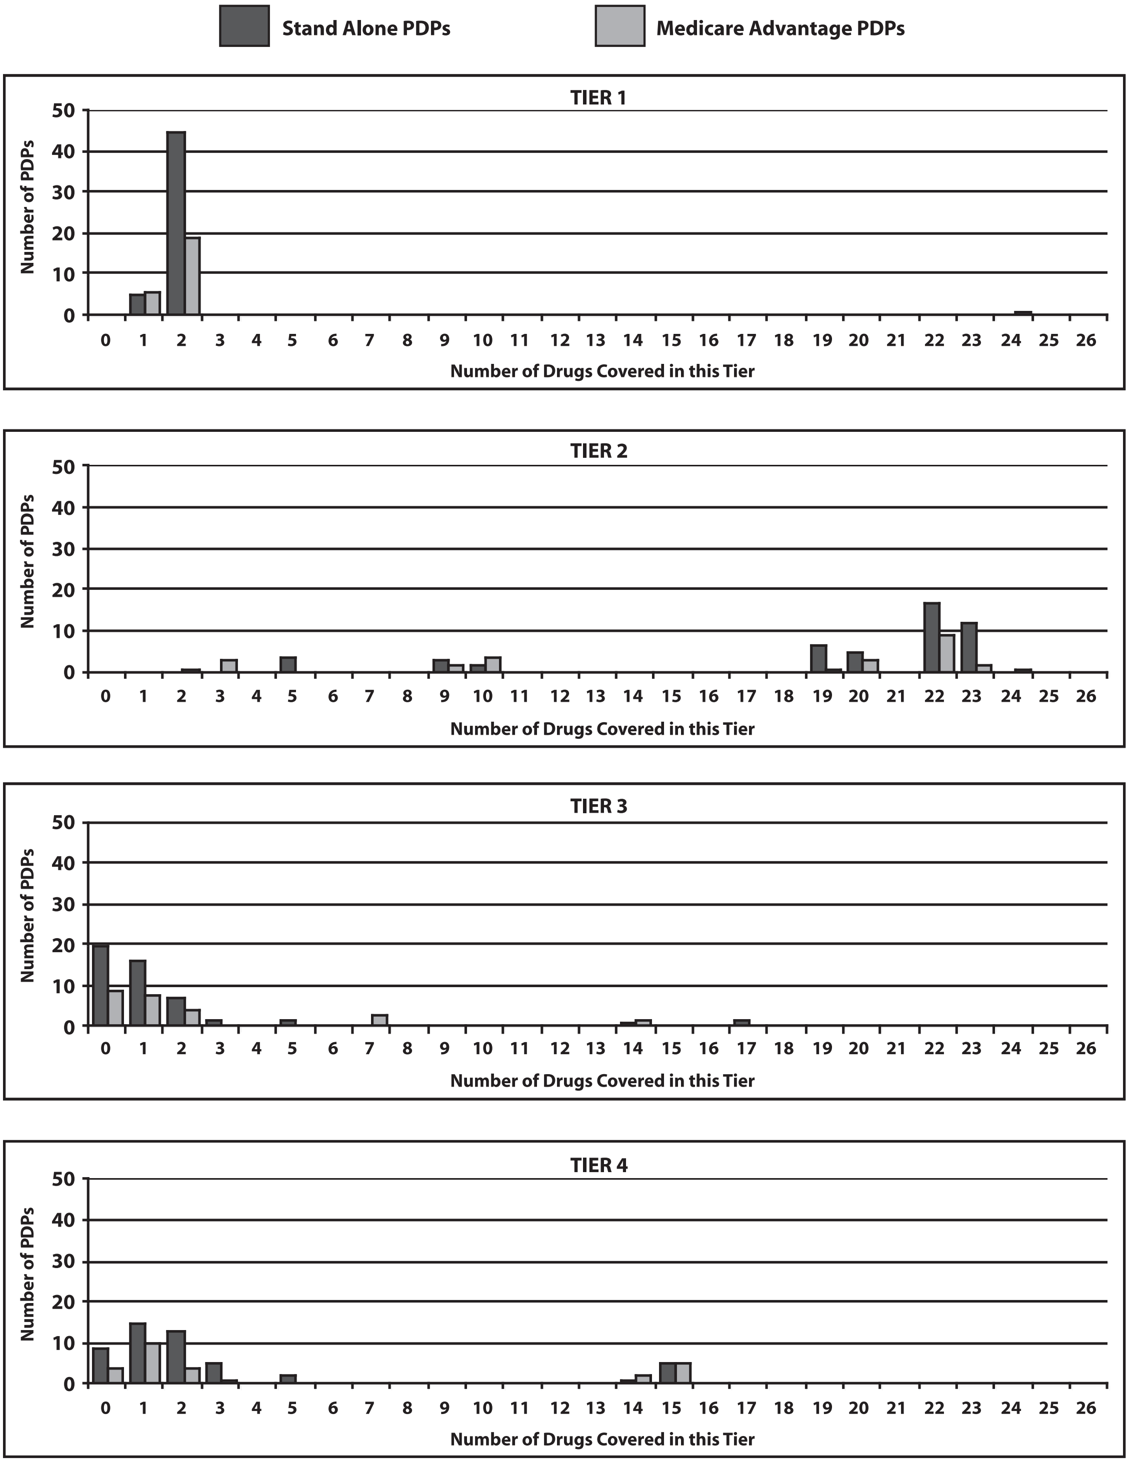
Note: Most antiretrovirals are covered by 76 PDPs; n = 76 when totaling number in each column under "formulary status."

[a] Videx (didanosine) is not covered by 6 PDPs (n = 70), and Reyataz is not covered by 2 PDPs (n = 74).

utilization. Because of these barriers, state-sponsored ADAPs and industry-sponsored Patient Assistance Programs must continue to assist HIV-positive individuals for whom Part D is unaffordable. According to James Coburn, JD, a senior policy analyst with Health & Disability Advocates, the good news is that ADAP in North Carolina has recognized this problem and is allowing enrollees who were required to sign up for Part D to obtain their HIV-related medications from ADAP while in the doughnut hole.[15] These costs covered by ADAP, however, do not count toward true out-of-pocket expenses—the amount a beneficiary must pay on covered drugs to reach catastrophic coverage—although recent Congressional hearings have been held that may change this current rule.[16] Another disadvantage with using North Carolina ADAP is that the program requires prior authorization of Fuzeon,[17] which in comparison is required by only 10 of the 76 PDPs covering antiretrovirals. Moreover, we do not know for how long ADAPs and Patient Assistance Programs will be able to bridge the safety net gap at the state and national levels.

The descriptive analyses presented in this paper focus on antiretroviral coverage and costs in Medicare Part D after 2007 enrollment. On a positive note, the majority of the 26 FDA-approved antiretrovirals are covered by 76 North Carolina PDPs in Tiers 1 and 2, and most of these PDPs do not require quantity limits and prior authorization for these antiretrovirals. Challenges remain, however, relating to the

Figure 1.
Number of Prescription Drug Plans (PDPs) by Number of Antiretrovirals Covered in Each Tier[9,10]



persistent and changing variability within these PDPs. The analysis demonstrated significant variability in antiretroviral classification in the formulary; only one MA-PD plan covered 24 antiretrovirals in Tier 1 whereas the majority of PDPs covered most antiretrovirals at Tier 2, and nearly 25% of the PDPs covered most antiretrovirals in Tiers 3 and 4. Furthermore, the one MA-PD plan covering 24 antiretrovirals in Tier 1—AETNA Medicare Open Plan—was not available to the 3 urban and rural counties in North Carolina with the highest cumulative AIDS cases (urban Mecklenburg and Wake counties and rural Pitt County) (data not shown). It is unclear how insurance companies make decisions about antiretroviral placement within the formulary status of PDPs since there is no correlation between antiretroviral placement and drug manufacturer (data not shown). Indeed, classifying most of the antiretrovirals at Tier 2 or greater makes the cost-sharing responsibility unaffordable for people with HIV/AIDS with incomes more than 150% of federal poverty guidelines. A second concern relates to the variability of other out-of-pocket costs when comparing PDPs. The analysis demonstrated that even within an insurance company there is variability pertaining to monthly drug premiums, annual deductibles, generic coverage in the doughnut hole, and availability of $0 monthly premiums for beneficiaries qualifying for a low-income subsidy.

The implications of these out-of-pocket costs can be demonstrated in a case example of a North Carolina beneficiary with HIV/AIDS whose income is $1700/month (200% federal poverty guideline) and who is enrolled in AARP MedicareRX (one of the top PDPs nationally in 2006[18]). This person would not be eligible for Extra Help, the low-income subsidy. The out-of-pocket costs would include a $30 monthly premium that cannot be waived, no annual deductible, no coverage within the doughnut hole, and a cost-sharing responsibility per drug of roughly 25% to 33% (based on Tier 4 estimates). Without knowing this PDP's specific summary plan description, the beneficiary's annual cost-sharing responsibility, assuming the simplest antiretroviral regimen, Atripla ($1150.88 for a 30-day supply[19]), would be $360 in total monthly PDP premiums which cannot go towards true out-of-pocket expenses, and $4258.03 in coinsurance. Table 5 roughly estimates this beneficiary's monthly out-of-pocket costs for Atripla in 2007.

Thus, this person would be spending 23% of his or her income to pay for out-of-pocket Part D drug costs (including premiums). Seventy percent of those out-of-pocket costs would be spent during the doughnut hole. In reality, the annual costs would be much higher if this person was taking a combination of antiretrovirals and other medications to manage his or her disease, given that the 5% copays after the doughnut hole could be significantly higher.

Table 5.
Estimated Beneficiary Out-of Pocket Costs for Atripla, by Month, 2007

Month	25% Coinsurance (until $2400)	100% Pay (doughnut hole until $3850 TrOOP* limit)	5% Coinsurance (catastrophic limit)	Monthly Payment (excluding premium)
January	$287.72	$0.00	$0.00	$287.72
February	$287.72	$0.00	$0.00	$287.72
March	$24.56	$1052.64	$0.00	$1077.20
April	$0.00	$1150.88	$0.00	$1150.88
May	$0.00	$1046.48	$5.22	$1051.70
June-December	$0.00	$0.00	$57.54	$57.54
Total annual coinsurance				$4258.03
Total (coinsurance + $360 premiums)				**$4618.03**

* TrOOP - true out-of-pocket expenses

The case example indirectly addresses the relationship between affordability, access, and utilization. As mentioned, people with HIV/AIDS may take a number of HIV and non-HIV-related medications to manage their HIV and comorbid conditions. It is not unusual for people with HIV/AIDS to change their medication regimens one or more times even within a year. A person with HIV/AIDS, however, cannot change to another PDP mid-year. Thus, he or she may discover the new medication is either not offered, offered at a higher tier, or offered with restrictions in his or her current PDP. This situation not only could make a change in regimen financially unaffordable, but also the patient could decide to stop taking an antiretroviral or stretch out the prescription of an antiretroviral to save money, leading to serious consequences of medication noncompliance and HIV resistance.

With so many issues to consider, how does a North Carolina beneficiary with HIV/AIDS choose a PDP from among the 76 with antiretroviral coverage? This paper may be useful in helping consumers and their advocates recognize the numerous factors —plan availability, antiretroviral tier classification, monthly premium costs, annual deductibles, and generic coverage (for HIV or non-HIV medications) offered in the doughnut hole—that need to be taken into consideration before selecting a PDP. The process of selecting a PDP could be very daunting for beneficiaries with HIV/AIDS who, compared to the majority of elderly Medicare beneficiaries, are more likely to be poorer and less well-educated. Indeed, HIV clinicians must continue to assist patients in understanding these issues and facilitate better access to affordable antiretrovirals within the struggling safety net for years to come. **NCMJ**

Acknowledgement

I would like to thank my colleagues from the University of North Carolina at Chapel Hill Department of Social Medicine for their helpful comments on an initial presentation of these data. A special thanks to Jonathan Oberlander, PhD, who provided feedback on drafts of the manuscript. Lastly, I would like to thank John Coburn, a senior policy analyst with Health & Disability Advocates, who reviewed a draft of the manuscript and provided essential clarification of the overlapping policies between ADAP and Part D.

Disclosure of Conflicts of Interests: None reported.

ARTICLE

Tuberculosis Knowledge, Attitudes, and Beliefs Among North Carolinians at Increased Risk of Infection

Elizabeth L. West, PA-C; Lara Beth Gadkowski, MD, MS; Truls Østbye, MD, MPH, PhD; Carla Piedrahita; Jason E. Stout, MD, MHS

Abstract

Objective: *The purpose of this study was to capture and describe knowledge, attitudes, and beliefs about tuberculosis (TB) among persons at high risk for TB infection.*

Methods: *We conducted 11 focus groups in 3 different populations at high risk for TB infection: Spanish-speaking immigrants, homeless shelter residents, and persons attending a drug/alcohol rehabilitation center. A standardized list of open-ended questions was used to guide discussion. Using grounded theory, transcripts of the focus group sessions were reviewed by 4 independent reviewers to identify emergent themes.*

Findings: *Participants (N=52) generally understood that TB is an infectious disease that frequently affects the lungs and can be fatal if untreated. They also knew that a skin test can be used to diagnose TB. However, participants frequently had incorrect beliefs regarding the cause, transmission, and treatment of TB. Many participants thought that TB is transmitted in the same fashion as other infectious diseases such as human immunodeficiency virus or aquired immune deficiency syndrome (HIV/AIDS). A general sentiment of fear and aversion toward persons ill with TB was expressed.*

Limitations: *Focus groups were a convenience sample and subjects were not necessarily representative of the underlying populations.*

Conclusions: *Tuberculosis knowledge among high-risk populations is suboptimal, and false beliefs regarding transmission and treatment were common in this study. Knowledge regarding transmission of other infectious diseases such as HIV/AIDS was frequently translated into incorrect knowledge regarding TB. Stigma continues to be a barrier to TB diagnosis and treatment.*

Key words: *Health knowledge, attitudes, practice; focus groups; tuberculosis; homeless persons; emigration and immigration; alcoholism; substance-related disorders*

Tuberculosis (TB) is a significant cause of morbidity and mortality worldwide. Eight million persons become ill with TB and 2 million die of TB worldwide each year.[1] However, in the United States, TB has become relatively uncommon; 13 779 tuberculosis cases were reported in 2006, representing an incidence rate of 4.6 cases per 100 000 population. However, TB is still a significant problem in certain high-risk groups including the foreign born, persons who abuse alcohol or illicit drugs, and the homeless. In 2006, of persons with active TB in the US, 57% were foreign born, 14.2% reported abusing alcohol within the previous 12 months, and 6.2% were homeless.[2]

Tuberculosis remains a problem because infected, asymptomatic persons serve as a reservoir for future disease. When an individual with pulmonary TB coughs, sneezes, or speaks, respiratory droplets containing viable *Mycobacterium tuberculosis* bacteria are aerosolized. A susceptible host can inhale these droplets and become infected. In most cases, the immune response controls this primary infection. As a result of this imperfect immune

Truls Østbye, MD, MPH, PhD, is a professor in the Department of Community and Family Medcine, Duke University Medical Center.

Carla Piedrahita, BA, is a health educator in the Communicable Disease Program, Wake County Human Services.

Jason E. Stout, MD, MHS, is an assistant professor in the Department of Medicine, Duke University Medical Center. Dr Stout can be reached at stout002 (at) mc.duke.edu or Box 3306, Duke University Medical Center, Durham, NC 27710.

response, the infected individual remains asymptomatic but frequently harbors viable TB bacteria. This individual is then said to have latent tuberculosis infection (LTBI). Persons with LTBI may remain well (and not contagious), but approximately 10% become ill with active TB during their lifetime and may then infect others.[3] The detection and treatment of LTBI is thus essential to TB eradication efforts. Latent TB infection is currently diagnosed by tuberculin (purified protein derivative) skin testing, although blood tests to diagnose LTBI are becoming available.[4] Persons with LTBI, defined as having a positive tuberculin skin test without clinical or radiographic signs of disease, can be treated with isoniazid to reduce the risk of progression to active TB. Treatment of LTBI with 6 to 9 months of daily isoniazid reduces the likelihood of progression to active disease by up to 90%.[5] Unfortunately, a relatively low proportion of persons with LTBI complete a full course of therapy. In a general public health clinic population, only about 60% of patients prescribed isoniazid completed a full course, and in homeless populations completion rates have been as low as 15-20%.[6,7]

Understanding TB knowledge and beliefs among high-risk groups may significantly enhance efforts to diagnose and treat both active TB and LTBI in those groups. Several studies have examined TB knowledge and beliefs in selected populations,[8-15] but data are lacking for some high risk groups in the United States. We conducted 11 focus groups comprised of persons from groups at high risk for TB as part of a larger effort to understand and improve adherence to LTBI therapy.

Methods

Study Design

Eleven focus groups were assembled in order to gather data about TB knowledge, attitudes, and beliefs. Focus groups have been used extensively in primary care settings to explore patients' and practitioners' perceptions and opinions of illness, services, and programs.[16] Participation in the focus groups was voluntary and anonymous. Food was offered at some of the sessions, but participants did not receive any monetary compensation for participation. Both the Duke University Medical Center Institutional Review Board and Wake County Human Services approved the study protocol.

Table 1.
Emergent Themes and Illustrative Focus Group Quotations

Tuberculosis is communicable and serious	"…it is communicable and can be deadly" "It will kill eventually." "It's life-threatening if not treated." "highly infectious" "easily spread"
Tuberculosis can affect anyone	"I think society in general can get it [TB]." "I would say that if you are exposed to anyone in the general public you are at risk, it doesn't discriminate."
Tuberculosis is more likely to affect people who are not like me	"People from other countries [are more likely to get TB]" "Street people [are more likely to get TB]"
Tuberculosis stigma	"People would feel ashamed about TB at a hairdresser, or store."
Health care costs are significant barriers to receiving good health care including tuberculosis care	"I'm supposed to be on all kinds of medications but I can't afford the prescriptions 'cause I don't have insurance." "I feel like the more money or more insurance you have the better doctor care you get."
Perception of responsibility for health affects the likelihood of taking treatment for tuberculosis	"Of course you are going to have people who aren't going to take it [treatment for LTBI] no matter how bad it is, 'cause they are just that way. But people who care about themselves and their health and their family are going to do it. You can't make people care, but they either care or they don't but the ones who do I think if they have the right information, if they were educated, they would."
Incentives (financial or emotional) will increase adherence to latent tuberculosis infection treatment	"Society loves money, pay them [persons who need TB/LTBI treatment.]" "Give them encouragement for taking the pills." "Spend time with the person so they don't feel so alone."
Persons who do not have regular, healthy practices will not take tuberculosis / latent tuberculosis infection treatment	"I think the biggest problem is, is that right now a lot of people who would have to take it [the TB treatment], their lifestyle doesn't really coincide with doing things at a normal time, like taking the medicine every day is like taking a bath every day, well a lot of people on the street don't take a bath every day it would be hard to get them to do something on a regular basis all the time."

Focus Group Participants, Data Collection, and Analysis

Focus groups were conducted at various sites in Chapel Hill, Durham, and Raleigh, North Carolina. (See Table 1.) The participants in the focus groups were selected from 3 populations with relatively high rates of latent TB infection and active disease: foreign-born Hispanics, homeless persons, and persons with a history of illicit drug or alcohol abuse. Participants represented a convenience sample of persons at the site who were willing to participate at the time the facilitator was present.

Three focus group sessions targeting Hispanic immigrants were conducted at a local church, an elementary school, and a community center. Six sessions targeting homeless persons were conducted at 4 homeless shelters. Two sessions targeting persons with drug/alcohol abuse problems were held at a drug/alcohol rehabilitation facility. Focus groups included a median of 5 participants (range 2-6) with a total of 52 participants in the study. The racial/ethnic composition of participants included

21 Caucasians, 15 African-Americans, and 16 Hispanics. Five sessions included only males, 2 included only females, and 4 included both males and females (30 male and 22 female participants total). Participants at the homeless shelters and the rehabilitation facility did not provide demographic information. Among the Hispanic participants, 5 persons were under 30 years of age (range 25-52 years), and 6 had been in the United States under 5 years (range 6 months-16 years). Ten were from Mexico, 2 from Colombia, and 1 each from the Dominican Republic, Peru, and Honduras, while the country of origin for 1 subject was unknown. A standardized list of questions was used to guide the discussions. (See Box 1.) All sessions were audio-recorded and transcribed. The Spanish transcripts were translated by one bilingual person, and a second bilingual person reviewed the original transcripts and the translation for accuracy.

Box 1.
Focus Group Questions

1 What have you heard about TB?
2 Have you heard any other names for TB?
3 In your opinion, how serious is TB?
4 What is the cause of TB?
5 How do you get TB?
6 What kinds of people get TB?
7 What would you think about a person with TB?
8 How can a person find out if they have TB?
9 Where would you go to get a TB test?
10 Would you like a nurse to knock on the door and offer it to you?
11 What are the chances that a person with TB infects others?
12 Have you ever known anyone with TB?
13 Do you think you are at risk of getting TB?
14 If you thought you were at risk for getting TB, would you do what you could to get tested?
15 What is the best treatment for TB?
16 Can TB be cured?
17 Where would you go for treatment if you (or someone you knew) thought they had TB?
18 Do you have any concerns about receiving medical treatment in the US?
19 Would you take a pill every day for 9 months to prevent a disease (even if you didn't feel sick)?

TB = Tuberculosis

Using grounded theory,[17] the 4 reviewers (LM, LG, JS, and TO) read the English versions of the transcripts independently, initially looking for key words and emerging themes. After half the focus groups had been completed and transcribed, the researchers compared and combined their independent analyses. This procedure permitted exploration, expansion, and testing of themes in subsequent focus groups. An extensive list of key words and themes was maintained and revised throughout the process resulting in a final analysis template which allowed the researchers to organize and code the data. All the transcripts were coded using the analysis template, making it easier to organize and manage the qualitative data. At this stage of the analysis, all the researchers met several times to examine similarities and differences across and within the identified themes. Several iterations of the findings were circulated among the research team for clarification and consensus before they were considered final.

Results

What Did the Participants Know About Tuberculosis?

Signs, symptoms, and contagiousness. Participants understood that tuberculosis is a disease associated with significant morbidity and mortality. There was also generalized knowledge among the participants in each group about the signs and symptoms of active TB: persistent cough, coughing or spitting up blood, fever, and night sweats were all mentioned. Although most participants did not report having known anyone with TB, they thought a person with TB would look very ill: "I picture them being lethargic, pale, bad cough, dark circles under their eyes" and "Coughing, shortness of breath, run down easy, someone who could only do like four hours of work instead of eight a day, drained and tired." Those who had observed someone with active TB depicted similar images: "She looked like a walking cadaver." Most group participants knew that TB was infectious. Participants most commonly responded that TB was spread by the cough of an infected person: "It's mostly airborne. I mean people cough. Like you could be in a cab with somebody and they cough and you can get it that way."

Skin Testing. Participants knew there was a skin test that could be used to diagnose TB. Participants also knew the test was available at a physician's office, clinic, hospital, or health department. Many of the participants had previously undergone tuberculin skin testing. All participants indicated they would be willing to be tested for TB if they thought they were at risk of having TB.

What Did The Participants *Not* Know About Tuberculosis?

Cause and Transmission. The most obvious knowledge deficits were in the areas of causation and transmission of TB. At least one person in each group responded that TB was caused by either a bacteria or, even more commonly and erroneously, by a virus. Other suggested causes of TB were smoking, "malnutrition," "sleeping in cold breezy places and wet floors," and "uncleanliness." At least one person in each group knew TB could be transmitted when an infected person coughs. Several participants indicated TB could be transmitted by using the same glass or utensils as the infected person, by holding hands with an infected person, from dirty needles, by blood, and even "like AIDS."

BCG vaccine. The Spanish-speaking groups were asked if they knew about a vaccine for TB. Few participants were aware of the existence of such a vaccine. Confusion between the vaccine and the TB skin test was common.

Treatment. Participants did not have a good understanding of TB treatment. Many were unsure whether there was a treatment for TB; in all groups there was mixed knowledge about whether there was treatment. Of those participants who thought there was a treatment, most simply said it was a medication of some type. A couple of participants mentioned that it required taking antibiotics for 9 months, which is the standard length of therapy for LTBI. One Spanish-speaking participant answered that vitamins were the treatment. Several participants thought treatment was only available if the disease was diagnosed relatively early in its course.

Attitudes and Beliefs About the Diagnosis and Treatment of Tuberculosis

Participants did not verbalize any overt prejudice or negative attitudes about people with TB: "It's not their fault." In addition, the majority of those who responded to the question "Who gets TB?" answered that anyone can get it: "I think society in general can get it," and "I would say that if you are exposed to anyone in the general public you are at risk, it doesn't discriminate." While few participants expressed any negative attitudes towards someone with TB, some participants stated that certain groups of people were more likely to have TB than others. For example, the men in the alcoholic recovery group said that "street people" and the "homeless" are more likely to be infected. Many participants commented that persons with AIDS and depressed immune systems are at increased risk of acquiring TB. Several Spanish-speaking participants said that "people from other countries," and people of other races tend to have it. Other groups more likely to have TB mentioned by the participants were older people, asthmatics, those who smoked or drank alcohol, those who lived in big cities, those with a low income, those who did not receive the vaccine, those who lived in "harsher environments," and those who were malnourished.

Many participants voiced that their first inclination was to "stay away" from someone diagnosed with TB. Few participants acknowledged having known anyone with TB. A few participants had childhood memories of persons with TB:

> *I remember my momma saying to me not to let certain people cough on me or spit on me 'cause he got TB stuff so we used to stay away from him because he was a cougher and a spitter 'cause he was contagious, so she told us to stay away from him 'cause he was contagious.*

Trust of the Health Care System and Health Care Professionals

Participants in all groups stated that in general they trusted medical professionals to provide appropriate care. Furthermore, participants indicated they had greatest trust in physicians who were specialists in treating their specific illness. A few participants expressed negative feelings and distrust toward specific medical institutions but not toward physicians or other medical providers in general. Despite this trust, participants were not enthusiastic about having a nurse come to their home for TB testing. Several participants were afraid of an unknown person coming to their door, and some participants also voiced fears of being stigmatized by neighbors because a nurse was visiting the house.

Participants in the Spanish-speaking focus groups were asked whether they would seek out a traditional healer ("curandero") for medical care. Participants were skeptical of the ability of *curanderos* to treat medical illness and did not express a great deal of trust for traditional healers. However, several Spanish-speaking participants stated they would go to a "naturalist" to supplement traditional medical care.

The cost of health care was an important issue for participants and was mentioned in all 11 focus groups. In all focus groups, health care costs were felt to be too high and represented a significant barrier to seeking care. However, Spanish-speaking participants also stated they knew they would receive health care in the United States regardless of their ability to pay for it, which was not true in some of their countries of origin.

Prejudice and Stigma

While most participants explicitly stated that TB could affect anyone and did not discriminate on the basis of race or socioeconomic factors, TB was usually described as a disease that affected persons belonging to a social group different from that occupied by the speaker. For example, members of the men's alcoholic recovery group stated they were at risk of being infected with TB because they were regularly in contact with "street people" and unknown people in Alcoholics Anonymous meetings. The homeless women said that people of "low income" and "low social status" were more susceptible to being infected with TB. One nonimmigrant participant said the incidence of TB has increased because immigration has increased. A Hispanic immigrant described a Chinese acquaintance being ill with TB. This projection of disease onto other social groups, particularly groups perceived as less desirable in the eyes of the participant, is evidence for the persistent stigma associated with TB:

> *There was a drunk in my town that died and he was lying on the corner coughing. That is, but he wasn't anyone I knew… we just knew he had TB, but…Oh, he was so skinny, you could see his skeleton. He didn't… he just had his skin hanging off, but I don't remember… I was little. I remember that we weren't to go near him. He was always on the corner.*

Participants also expressed a strong aversion to persons with TB. Many participants responded "Stay away" to the question "What would be your reaction to someone who you found out has TB?"

Willingness to Take Medication

Most participants responded when asked that they would be willing to take 9 months of oral medication to prevent TB (LTBI treatment). However, when the question was rephrased, emphasizing that LTBI treatment would consist of taking medication when one did not feel sick, the responses changed. For example, when subjects at one of the homeless shelters were asked "Would you be willing to take a drug every day for 9 months to prevent TB?" they answered unanimously in the affirmative. However, when asked, "Would you be willing to take a drug every day for 9 months if a doctor told you that you had TB even though you felt well and not sick?" they answered "it depends" or "not without a lot of tests."

Participants had various suggestions to improve patient adherence to LTBI therapy. Suggestions ranged from showing graphic pictures of people dying with TB to offering education about TB. One participant suggested that bringing LTBI therapy to the patient, rather than making the patient pick it up at the health department, would improve adherence. Many participants stated that incentives, including food and money, would be effective for increasing rates of LTBI treatment adherence. Emotional support by health care providers also was mentioned: "Give them encouragement for taking the pills" and "Spend time with the person so they don't feel so alone."

Several participants felt that persons who were in the habit of taking medications or vitamins every day would be more able to remember to take LTBI therapy. Conversely, participants were skeptical that persons who do not have regular, healthy practices could be expected to take medication every day:

> *I think the biggest problem is, is that right now a lot of people who would have to take it [the TB treatment], their lifestyle doesn't really coincide with doing things at a normal time, like taking the medicine every day is like taking a bath every day, well a lot of people on the street don't take a bath every day it would be hard to get them to do something on a regular basis all the time.*

Locus of Responsibility for Health

Participants' perceptions of who is primarily responsible for their health had important effects on attitudes toward TB prevention and treatment. Many participants felt responsibility for health care rests primarily with the individual:

> *Of course you are going to have people who aren't going to take it [treatment for LTBI] no matter how bad it is, 'cause they are just that way. But people who care about themselves and their health and their family are going to do it. You can't make people care, but they either care or they don't but the ones who do I think if they have the right information, if they were educated, they would.*

However, other participants placed the responsibility for TB prevention with health care providers and the health care system. For example, one participant said that she distrusted a local hospital, and when she was asked if this could ever affect her seeking out treatment there if necessary for TB, she responded "No, I would still go, but it would be up to them to do it all." Several participants believed that it is the health care professional's job to convince, coax, and bribe persons with LTBI or active TB into making healthful choices: "Society loves money, pay them." A summary of emergent themes with illustrative quotations is provided in Table 1.

Discussion

Misconceptions About Tuberculosis

As in reported studies,[8,11,15,18,18] we found participants had many inaccurate perceptions of TB cause and transmission. They frequently believed TB was transmitted by fomites, direct contact with another person's skin, and sharing eating utensils. These beliefs have been reported in a number of different populations including migrant farm workers[14] and Vietnamese refugees.[9] Participants inappropriately applied what they knew about other common diseases to TB. In particular, participants often applied what they knew about the spread of HIV to TB, and several participants said TB was transmitted "like AIDS." Like the present study, homeless persons surveyed in San Francisco similarly applied HIV concepts to TB transmission.[13] Participants appeared to apply knowledge of other diseases to TB; for example, "TB is only curable if caught early" may reflect knowledge about cancer. Although these statements attest to the efficacy of public health education efforts for other diseases, the resultant misinformation may have unintended deleterious consequences for TB control efforts. If TB is perceived (as it was by at least one participant) as an incurable disease (like HIV at present), patients will be discouraged from seeking care, thus delaying diagnosis with resultant increased transmission and morbidity.[12] Furthermore, perceptions that hand washing or other general hygienic measures prevent TB infection may give persons a false sense of security that they are protected from TB disease.[9] Tuberculosis education should stress the distinctions between TB and other diseases and must include information about cause, transmission, and treatment of LTBI and active TB.

Stigma

Stigma may have a significant impact on a person's willingness to be tested and treated for TB.[14,19] In a Chicago survey of African Americans with TB, study participants overwhelming reported feelings of embarrassment and isolation among their community, family, friends, and coworkers.[20] In another survey of Latinos receiving LTBI treatment, 17% of participants reported having TB was an embarrassment in their country of origin.[8] Stigma may result in severe social consequences; in one study in Mexico City 50% of hospitalized TB patients were not received back into their homes after hospital discharge.[21] Fear of being stigmatized by family, friends, coworkers, and community may be an important potential predictor for whether the patient initiates and completes therapy for LTBI.

Participants' Ideas on Adherence to Latent Tuberculosis Infection Therapy

Participants' ideas of what would affect an individual's likelihood to complete LTBI therapy can be divided into 3 groups: habits, social factors, and motivation. Health care-related habits may play a significant role in LTBI treatment adherence. A recent study of adherence to LTBI noted a positive univariate association between having a primary care physician and completion of LTBI treatment, and the belief that seeing a health care worker regularly keeps one healthy was also associated with treatment completion.[22] Social factors, including availability of stable housing, have been associated with likelihood to complete LTBI treatment.[23] Motivation is also clearly important when considering likelihood to complete LTBI treatment. Patients who feel they are at risk to develop active TB are more likely to complete LTBI treatment whereas those who expressed aversion to venipuncture (used in some patients for liver function monitoring) were less likely to complete treatment.[22] Understanding where different patient groups place responsibility for their health may be a key factor in designing strategies to improve adherence to LTBI treatment in these groups. The emotional dynamics between a particular health care provider and patient play an important role in patients' perceptions of responsibility for their health and resultant motivation to adhere to a treatment plan.[24] A study of Haitian immigrants demonstrated the importance of emotional needs related to the treatment of LTBI, and the authors concluded that a "personal approach" was an important aspect of treatment.[10] Some studies suggest that directly observed therapy, which provides for frequent one-on-one encounters between patients and health care workers, increases completion rates for LTBI treatment.[25] At least one study demonstrated that monetary incentives improve adherence to LTBI therapy among homeless persons.[23] The current study suggests the hypothesis that patients' attitudes toward emotional or financial incentives could predict initiation and completion of LTBI treatment.

Strengths and Limitations

The findings of this study are strengthened by the fact that our focus groups were assembled from 3 different high-risk populations and conducted in diverse settings. The demographic mix was also diverse with a balance of gender and ethnic groups. A standardized set of questions was used to guide the groups. In addition, the focus group transcripts were reviewed independently by 4 persons to identify recurring themes.

There were several limitations of this study. The subjects represented a convenience sample and may not be representative of their respective populations. The number of participants in each focus group was relatively small, with a small number of total participants from the drug/alcohol treatment centers, which may result in suboptimal theme saturation and reduced generalizability of the results. Furthermore, persons participating at the homeless shelters and drug rehabilitation facilities refused to provide demographic data. The 8 English-speaking focus groups were conducted by a white female, which may have affected the group dynamics. A focus group facilitator of a different sex, race, or age might possibly have provided a more conducive environment to talking about such a sensitive subject. Obviously, there are many high-risk populations that were not represented in this study (eg, non-Hispanic foreign-born persons, prisoners), but the 3 populations chosen are frequently targeted by TB control programs in the United States.

Implications

The information presented here regarding TB knowledge, attitudes, and behaviors in 3 key high-risk populations is a first step in understanding how to reduce the burden of TB in these populations. This study of 3 populations at relatively high risk for LTBI has identified several possible predictors of initiation and completion of LTBI therapy: (1) knowledge of cause, transmission, and treatment of LTBI; (2) stigma associated with TB; (3) health maintenance practices; and (4) financial and emotional needs. We intend to use these potential predictors to develop a survey that will be administered to persons with LTBI prior to initiation of LTBI treatment. Survey responses can then be correlated with adherence to LTBI treatment, and specific interventions can be developed to improve LTBI adherence when specific knowledge deficits, attitudes, or beliefs are expressed. **NCMJ**

Call for Papers

John W. Williams Jr, MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

POLICY FORUM

Taking Care of Those Who Serve

> *"Through carefully crafted polices, education of our clinical workforce, and intelligent research investments, North Carolina can excel in meeting its obligation to support the health needs of its citizen soldiers."*

COMMENTARIES

INTRODUCTION

Policy Forum:
Taking Care of Those Who Serve

There has been a steady flow of information from the War on Terrorism since Operation Enduring Freedom began in October of 2003. As the war expanded into Iraq and continues today, more American families and communities are feeling its impact. Children, spouses, parents, friends, and neighbors are regularly leaving for war and returning from combat. Safety and health in the war zone are the greatest concerns of those seeing loved ones leave. They hope their soldiers will never need medical care during their service but are comforted to know that, if needed, the military will provide them with immediate and necessary care.

Once our soldiers return home, those with serious physical injuries will need ongoing care. In addition, those who served without obvious physical harm may also need assessment and attention. As noted in this issue of the *Journal*, as many as 20% of active and 40% of reserve soldiers returning from a combat theater may have a mental illness and should have mental health services available to them. Fortunately, the Veterans Health Administration (VHA) is prepared to address both the physical injuries and mental illnesses of our soldiers.

This issue of the *Journal* describes how VHA has identified the mental health and physical needs of our returning soldiers and is responding to these needs by modifying both its assessments of soldiers and services for soldiers. The Veterans Health Administration also has developed new mental health screenings, instituted a second mental health screening, and is strongly encouraging military personnel to seek care for more than just bodily injuries. It is doing more to reach out to families of deployed service members to be sure they have access to community supports while their loved ones are abroad.

Despite the presence of multiple VHA facilities in North Carolina, many servicemen and women are accessing care outside of VHA. For example, National Guard and Reserve personnel frequently live in communities away from a base or a VHA facility and are more likely to access care in a private practitioner's office. This pattern of care seeking is particularly relevant for our readers practicing medicine across North Carolina. Included in the commentaries in this issue of the *Journal* are resources and recommendations for providers serving returned soldiers: Recognize your patients' connections to the military. If possible, identify returning soldiers and ask questions of them and their families to assess how reintegration or reunification may be affecting their health and well-being. When concerned about a patient, access resources such as those outlined in these commentaries that may help in determining the need for referrals or additional care.

Our military forces and their families have made and continue to make great sacrifices for our state and nation. We hope this issue of the *Journal* offers examples and information that can help providers across the state offer the best care to these brave and much valued members of our communities.

Serving the Health Needs of Our Military and Veterans

John W. Williams Jr, MD, MHS

"...to care for him who shall have borne the battle, and for his widow and his orphan."
— Abraham Lincoln, Second Inaugural Address

War has a profound adverse affect on public health.[1] In times of war rates of infectious diseases, malnutrition, mental illness, and mortality increase for both combatants and civilian noncombatants. Weapons of war are associated with increased malignancies (eg, Agent Orange, atomic weapons), chronic illnesses such as Diabetes mellitus (eg, Agent Orange), sensory impairment (eg, decreased hearing in artillery gunners), and of course, traumatic injuries. In the past 100 years, the US has been directly involved in 6 major wars (World War I, World War II, Korea, Vietnam, the Persian Gulf, Iraq) and fielded active combatants in other conflicts (Grenada, Panama, Somalia, Bosnia and Herzegovina, Afghanistan). We have been at war in Iraq since March 19, 2003 where over 1 500 000 Americans have been deployed.[2] Thankfully, most of these troops will return home unscathed, but for those who are injured the nature of the injuries are presenting new challenges for the health care system.

North Carolinians play an important role in supporting our military forces, hosting major military bases at Fort Bragg, Pope Air Force Base, Seymour Johnson Air Force Base, and Camp Lejune. Many of our citizen soldiers from the ranks of the active reserve and the National Guard have been called up. In the health care sector, North Carolina clinicians care for our troops, their families, and our veterans. Given the major presence of the military in North Carolina, we are devoting this issue of the *North Carolina Medical Journal* to the health and health care of our active duty and retired military forces. We hope that by shining a spotlight on the health effects of war we will help North Carolinians better serve our military personnel and veterans, encourage the private sector and military medicine to share best practices, and stimulate policy makers to proactively plan for the effects of war on our communities and health care system.

Who Are Our Military Personnel and Veterans?

America's fighting forces number 1.4 million men and women from all across the nation with the largest proportion, over 40%, coming from the southern United States. Of these,

John W. Williams Jr, MD, MHS, is professor of medicine and psychiatry at the Duke University Medical Center and Durham VA Medical Center and scientific editor of the North Carolina Medical Journal. Dr Williams can be reached at 2424 Erwin Road, Suite 1105, Hock Plaza, Durham, NC 27705.

106 838 are based in North Carolina, the fourth largest concentration of active duty members in the continental US (Department of Defense Public Affairs Office, oral communication, November 2007). During the Vietnam War, the average soldier in a combat unit was 19 or 20 years old, male, and unmarried. Less than 0.5% of the 2 594 000 who served in Vietnam were women; most of these were nurses.[3] Since the advent of the all-volunteer military in 1973, its composition has changed substantially. Today, our active duty military are older (median age 39.5 years), more educated, more female (14.6%), more likely to be married (50%), and more ethnically diverse (35% minorities). Both the wealthy and the most socioeconomically disadvantaged members of society are underrepresented.[4]

When active duty military exit the service they become veterans. For some, the word veteran evokes unfortunate images of "down and out" individuals, images that are reinforced by movies such as *Born on the Fourth of July*. Data from the US Census Bureau paint a sharply different picture.[5] Just over 10% (23 425 051) of American adults and 11.4% of North Carolina adult civilians are veterans of the armed services. Approximately one-third are Vietnam veterans; the next largest group (18.7%) are veterans of the Gulf War. Veterans are disproportionately male (93%) and younger than the civilian population. Compared to the entire American adult population, veterans are more likely to be White (84.7% vs 75.0%), have some college education (58.3% vs 53.8%), and live above the poverty level (94.1% vs 88.3%) despite having higher rates of disability (26.8% vs 17.3%). Among individuals age 18 to 64 years, employment rates are almost identical to the civilian population. Given the changing demographics of our active duty forces, we can expect the future composition of our veteran population to be more ethnically diverse and more female.

These changing demographics have important implications for our communities. In past wars, we agonized as our sons marched off to war. Now it is increasingly likely that our spouses and daughters will be marching beside them. Consequently, the disruptive effects of war may be magnified for families and communities. From a public health perspective, we need to consider how best to meet the needs of families who keep the home fires burning and be prepared to care for wounded warriors and facilitate reintegration into civilian life. In this issue of the *Journal*, Denisse Ambler describes the effect of war on military families, and Steven Moore describes the Citizen Soldier Project, a federally-funded program to build bridges between community resources and families in North Carolina.

The Price of War: Effects on Health

As of late 2007, over 28 000 service members had been wounded in Iraq.[6] Most were treated and returned to duty within 72 hours, but over 3000 had serious injuries requiring intensive, long-term care including severe traumatic brain injuries, amputations, burns, blindness, or polytrauma. Traumatic brain injury (TBI), a signature injury because of its higher incidence in this war is estimated to affect about 50% of soldiers injured in combat; most TBI is classified as mild. Traumatic brain injury may cause headaches, sleep disturbances, and sensitivity to light and noise. Adverse effects on cognition include disturbances in attention, memory, or language as well as delayed reaction time during problem solving. Depressed mood, anxiety, impulsiveness, and emotional outbursts are particularly troubling symptoms and may overlap with the symptoms of posttraumatic stress disorder (PTSD).[7] The long-term consequences of mild to moderate TBI are not fully known but current estimates are that one-third of TBI affected individuals will develop chronic symptoms. Compared to other major medical problems, we know relatively little about effective care for these individuals. George Jackson, Natia Hamilton, and Larry Tupler describe TBI in greater detail in this issue of the *Journal* and give recommendations for a brief screen and regional treatment resources. Kenneth Goldberg describes the epidemiology of health problems in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) veterans seeking care at the Veterans Health Administration (VHA).

Mental illnesses, the so-called "hidden injuries," are much more prevalent than major physical injuries, but like physical injuries, they are associated with combat exposure.[8,9] In a study of 88 235 Army soldiers and Marines returning from Iraq, clinicians identified 20.3% of active and 42.4% of reserve component solders as requiring mental health treatment.[10] Our citizen soldiers are reporting extraordinarily high rates of psychic trauma. Importantly, longitudinal studies are showing high rates of emergent PTSD symptoms that are manifest 3 or more months after return and perhaps after returning to civilian life.[10,11] In addition, the proportion of soldiers reporting interpersonal conflict (14% active and 21% reserve components) increased from time of return to follow-up assessment. Despite the high levels of morbidity, relatively few soldiers seek mental health treatment, and there is a substantial time gap between when a returning solider perceives the need for mental health services and the time the soldier receives them. In particular, soldiers report an unmet need for greater therapy/counseling, skills training, and information about mental health problems.[8,12] In this issue, Captain Michael Latzka describes an innovative Army program to bolster mental health services at 15 bases for active duty military seen in primary care settings.

The high rates of psychiatric symptoms in active duty military are supported by early data on OEF/OIF veterans who seek care in the VHA health care system. Through September 2005, 25% of the 103 788 OEF/OIF veterans seen at VHA received a mental health diagnosis.[13] Most initial diagnoses (60%) were made in nonmental health settings. Posttraumatic stress disorder was the single most common mental health diagnosis, but over one-half of patients had more than one mental health diagnosis. Neither the military nor VHA were fully prepared to cope with these extraordinary rates of mental illness. In response to the epidemiological data, VHA is attempting to expand its capacity and resources in mental health services. In this issue, Harold Kudler and Kristy Straits-Tröster present a practical clinical summary on the recognition and management of PTSD.

Edward Post and William Van Stone describe a VHA program to expand and better integrate mental health and primary care services. Both VHA and Army efforts to bolster mental health services are based on over a decade of rigorous research showing that care management models improve outcomes for patients with depression, an approach that is also showing promise for other mental health conditions.[14] These data have important implications for the state of North Carolina. Since the minority of veterans access the VHA health system, most veterans will be cared for in the private medical system. Few practices routinely screen for depression, PTSD, or TBI, and current reimbursement policies do not support evidence-based care management programs. Our public mental health services are already stretched thin and are unlikely to readily absorb the influx of new patients. Unmet mental health needs would likely have important negative impacts on our citizen soldiers, their families, and their employers.[15,16] North Carolina needs to carefully plan for increased mental health needs and monitor the accessibility and quality of services delivered.

Where Do Active Duty Military, Their Dependents, and Veterans Get Health Care?

"It is almost cliché now to find examples of a wounded Marine having initially been treated by a Navy Corpsman find himself medevac'ed by an Army helicopter to undergo emergency surgery at an Air Force Theater Hospital."[2] In the Vietnam era, 5 out of every 8 seriously injured service members survived; today, 7 out of 8 survive, many with injuries that in previous wars would have been fatal. In addition to better protective equipment, important operational and medical advances are saving lives and may have applications to civilian medicine. Past wartime medical advances included the rapid expansion in the use of penicillin in World War II and using emergency evacuation by helicopter in Korea and Vietnam. This latter advance was adopted by civilian trauma care with great success. In the current war, Forward Surgical Teams establish a functional hospital and operating team within 60 minutes of the combat zone.[17] For penetrating injuries, these teams have adopted a new approach of "damage control"—just enough surgery to stabilize the patient and then transfer to a higher level of care. In Vietnam, the average time from battlefield to arrival in the United States was 45 days; it is now less than 4 days. This change in management has improved survival rates, and some of the specific surgical approaches are being adopted in US trauma units. The crucible of war often stimulates medical advances that are applicable to civilian medical care.

As with much US medical care, health services for active duty, retired military, and veterans are provided by a complex web of services. The major health care options for nondeployed military and their dependents are the 68 military treatment facilities, the 154 military outpatient clinics, and TRICARE. TRICARE is the civilian care component of the Military Health System. TRICARE is a regionally managed health care program for active duty, activated Guard and Reserves, and retired members of the uniformed services, families, and survivors. In North Carolina, Womack Army Medical Center and its affiliated primary care clinics serve the greatest numbers of military service members.

The Veterans Administration (VA) was established in 1930 to consolidate and coordinate government activities affecting war veterans. In 1988 President Reagan signed legislation creating a new federal Cabinet-level Department of Veterans Affairs to replace the Veterans Administration. The Veterans Health Administration (VHA) is the component that implements medical programs and draws its mission from Abraham Lincoln's eloquent Second Inaugural Address. It is a single-payer, government-run health care system operating 153 medical centers, over 200 Vet Centers, and 875 outpatient clinics.[2] Over 4 million veterans are enrolled in VHA and compared to age-matched Americans, these veterans are more medically complex and poorer. North Carolina has 4 VHA Medical Centers, 2 large outpatient clinics, 6 community-based outpatient clinics, and 5 Vet Centers. Sara Haigh describes the VHA system and resources more fully in her commentary.

For multiple years running, veterans have been more satisfied with their VHA health care than patients in the private sector. Despite caring for medically complex patients, VHA has won accolades for quality of care that meets or exceeds that seen in the private sector.[18] In a Rand Corporation study, VHA matched or exceeded private sector quality scores in virtually every category studied, despite spending substantially less per patient than the national average.[19] For example, the VHA's prescription accuracy rate is greater than 99.997% compared to 92% to 97% in the private sector. Prescription accuracy has been improved by the intelligent use of technology—barcoding every medication dispensed. Among chronic care patients, VHA patients received about 70% of recommended care compared with about 60% in the private sector. Preventive care is even better with VHA patients receiving about 65% of recommended care compared to 20% in the private sector. The greatest difference between VHA and the national sample were in areas where VHA actively measured performance. While other reasons for the outperformance are not completely known, a sophisticated electronic medical record system, strong leadership with decentralized decision making, and investments in systematic quality improvement and applied research are clearly a large part of the quality gains. As America enters an election year with health care near the top of the voters agenda, VHA successes deserve closer examination for possible applications to the private sector. Eugene Oddone and Seth Eisen describe the national VHA medical research effort and examples of local impact.

Conclusion

The nature of war and the composition of our fighting forces have changed in important ways over the past 100 years. Soldiers are surviving more severe injuries that require longer term rehabilitation. Many of these soldiers will want to complete rehabilitation close to home, and there may be an opportunity for North Carolina treatment facilities to support this need.

Greater capacity for rehabilitation services is consistent with the general need to expand longitudinal care services in the US medical system. The rates of mental illness are higher than reported in previous wars—possibly due to the nature of combat but also likely related to better detection in military and VHA health facilities. Fledgling efforts to improve detection of mental illness and integration of mental health and primary care services in North Carolina need to be supported.[20] This is likely to require changes in reimbursement policies to support care management activities. Finally, it's clear that the military and VHA investment in applied research is yielding actionable data that allows for improved health services. North Carolina has made large private and public investments in medical research. We should ensure that a significant proportion has a high return on investment through better planning of workforce, services, and quality improvement. Through carefully crafted polices, education of our clinical workforce, and intelligent research investments, North Carolina can excel in meeting its obligation to support the health needs of its citizen soldiers. **NCMJ**

The Veterans Affairs Health Care System in North Carolina

Sara Haigh

The mission of the Veterans Health Administration, one of 3 divisions of the United States Department of Veterans Affairs, is to "honor America's veterans by delivering exceptional health care that improves their health and well-being." In North Carolina, that mission is carried out through an integrated network of hospitals and community-based clinics that are designed to maximize coordination and communication between sites of care. This article presents an overview of the Department of Veterans Affairs, followed by a description of services available at VA facilities in North Carolina; a brief explanation of eligibility, enrollment, and benefits; and a description of VA's integrated health care system. Special emphasis is placed on services available to veterans now returning to North Carolina from participation in Operations Enduring Freedom and Iraqi Freedom.

Department of Veterans Affairs

The Department of Veterans Affairs benefits system traces its roots back to 1636 when the Pilgrims of Plymouth Colony were at war with the Pequot Indians. The Pilgrims passed a law which stated that disabled soldiers would be supported by the colony. Since that time the system has evolved to include disability compensation, insurance, vocational rehabilitation, and education benefits. The establishment of the Veterans Administration came in 1930 when Congress authorized the President to "consolidate and coordinate Government activities affecting war veterans." World War II resulted in not only a vast increase in the veteran population but also in a large number of new benefits enacted by the Congress for veterans of the war. The World War II GI Bill, signed into law on June 22, 1944, is said to have had more impact on the American way of life than any law since the Homestead Act more than a century ago. Further educational assistance acts were passed for the benefit of veterans of the Korean Conflict, the Vietnam Era, Persian Gulf War, and the All-Volunteer Force. The Department of Veterans Affairs (VA) was established as a Cabinet-level position on March 15, 1989.[1]

> *"In North Carolina, VA has launched special efforts to provide a 'seamless transition' for those returning from service in Operations Enduring Freedom and Iraqi Freedom (OEF/OIF). Each VA medical facility has a point of contact to coordinate activities locally to help meet the needs of these returning combat service members and veterans."*

The Department of Veterans Affairs is the second largest of 15 Cabinet departments and operates nationwide programs for

health care, financial assistance, and burial benefits. The Veterans Health Administration, Veterans Benefits Administration, and National Cemetery Administration are the 3 main branches of the department, with the Veterans Health Administration (VHA) handling health care services.

Veterans Health Administration Services

In North Carolina, a system of hospitals, community-based outpatient clinics, and Vet Centers deliver the majority of health services to veterans.

Veterans Affairs Medical Centers

The Charles George VA Medical Center (VAMC)[3] in Asheville consists of a 116-bed acute care hospital and a separate 120-bed extended care and rehabilitation center serving western North Carolina as well as portions of South Carolina, Georgia, and Tennessee. The Charles George VAMC is a tertiary care facility providing primary, tertiary, and long-term care in the areas of medicine, surgery, psychiatry, physical medicine and rehabilitation, neurology, oncology, dentistry, geriatrics, and extended care. The Asheville facility also operates a home-based primary care program and a substance abuse rehabilitation treatment program.[4]

The Durham VA Medical Center is a 154-bed tertiary referral hospital with a separate 120-bed extended care and rehabilitation center. The facility serves as a major referral center for North Carolina, southern Virginia, northern South Carolina, and eastern Tennessee for subspecialty treatment, radiation therapy, neurological disorders, therapeutic endoscopy, high-risk open-heart surgery, and other special procedures. Special programs at Durham include the comprehensive Women's Health Center, a home-based primary care program, the Geriatric Research, Education, and Clinical Center (GRECC), the VISN 6 Mental Illness, Research, Education, and Clinical Center (MIRECC), the Center for Health Services Research in Primary Care, and the Epidemiology Research and Information Center (ERIC).[5]

The Fayetteville VA Medical Center is a general medicine and surgery and mental health facility with 90 beds. It also maintains a 69-bed long-term care unit. The medical center serves veterans in 19 counties in southeastern North Carolina and 2 counties in northeastern South Carolina. Comprehensive health care is provided through primary and long-term care in areas of medicine, surgery, psychiatry, posttraumatic stress disorder, ophthalmology, podiatry, physical medicine and rehabilitation, neurology, dentistry, geriatrics, and extended care. Tertiary care is referred to Durham VA Medical Center.[6]

The W G (Bill) Hefner VA Medical Center in Salisbury provides primary and secondary inpatient health care to more than 287 000 veterans living in a 23-county area of the central Piedmont region of North Carolina. This includes the Charlotte area with over 100 000 veterans and the Winston-Salem area with 65 000 veterans. Inpatient services include acute medicine, cardiology, surgery, psychiatry, and physical medicine and rehabilitation, as well as subacute and extended care.[7]

Veterans Affairs Community-Based Outpatient Clinics

Community-based outpatient clinics are located in Charlotte, Winston-Salem, Jacksonville, Wilmington, Raleigh, Greenville, and Morehead City. Additional community-based outpatient clinics are scheduled to open in Hamlet, Hickory, and Franklin by late 2008. Community-based outpatient clinics provide primary care, mental health, and selected specialty services and were established to improve geographic access for veterans. Patients receive prescriptions via a mailout pharmacy. If they need specialty care or testing, such as a CT scan or cardiology consultation, they are referred to a main VA hospital. In some cases, patients are referred to private providers on a fee-for-service basis when VA services are not available or the patient is not able to travel to a facility that provides the needed service.

Veterans Affairs Vet Centers

Vet Centers in Charlotte, Greensboro, Raleigh, Fayetteville, and Greenville are part of VA's Readjustment Counseling Service. Vet Centers provide psychological counseling for war-related trauma, community outreach, case management, and referral activities plus supportive social services to veterans and family members. Vet Centers are open to any veteran who served in the military in a combat theater during wartime or anywhere during a period of armed hostilities. Vet Centers also provide trauma counseling to veterans who were sexually assaulted or harassed while on active duty and bereavement counseling to the families of service members who die on active duty.[2]

The 4 North Carolina VA Medical Centers and 7 community-based outpatient clinics are components of the VA Mid-Atlantic Health Care Network (VISN 6), headquartered in Durham. VISN 6 includes an additional 3 VA Medical Centers in Virginia and 1 in West Virginia and 5 outpatient clinics. In fiscal year 2007, some 307 959 veterans received care throughout the network service area.

Eligibility, Enrollment, and Benefits

Eligibility for most veterans' health care benefits is based solely on active military service in the Army, Navy, Air Force, Marines, or Coast Guard (or Merchant Marines during WW II), with a discharge under other than dishonorable conditions. Reservists and National Guard members who were called to active duty by a Federal Executive Order may qualify for VA health care benefits as well. Returning service members (including Reservists and National Guard members) who served on active duty in a theater of combat operations have special eligibility for hospital care, medical services, and nursing home care for 2 years following discharge from active duty.

The Department of Veterans Affairs maintains an annual enrollment system to manage the provision of quality hospital and outpatient medical care and treatment to all enrolled veterans. A priority system ensures that veterans with service-connected disabilities and those below the low-income threshold are able to be enrolled in VA's health care system. Some veterans are exempted from having to enroll. This includes veterans with a service-connected disability of 50% or more, veterans discharged from the military within one year but not yet rated for a VA disability benefit, and veterans seeking care for only a service-connected disability. Veterans with service-connected disabilities receive priority access to care for hospitalization and outpatient care.

The Department of Veteran Affairs' enrollment allows health care benefits to become portable throughout the entire VA system. Enrolled veterans who are traveling or who spend time away from their primary treatment facility may obtain care at any VA health care facility across the country without the worry of having to reapply.

The Department of Veterans Affairs provides a medical benefits package to enrolled veterans which includes the following types of services:

- Hospital, outpatient medical, dental, pharmacy, and prosthetic services
- Domiciliary, nursing home, and community-based residential care
- Sexual trauma counseling
- Specialized health care for women veterans
- Health and rehabilitation programs for homeless veterans
- Readjustment counseling
- Alcohol and drug dependency treatment
- Medical evaluation for disorders associated with military service in the Gulf War or for exposure to Agent Orange, radiation, and other environmental hazards[2]

Integrated Health Care System

A great strength of the VA health care system is the integrated nature of the clinical care network. All sites use a computerized patient record system to document all aspects of care including office visits, provider orders, diagnostic tests, specialty consultations, prescriptions, procedures, and hospitalizations. Paper documents from non-VA providers are scanned into the electronic record as needed. The system allows a physician in Durham to look up past treatment, medication, and testing information on a patient from Fayetteville with a few clicks of the computer mouse. Since all information is typed, legibility is not an issue. The prescription ordering interface includes a variety of patient safety features such as checks for drug allergies, drug-drug interactions, or inappropriate dosing. For inpatient care, a bar code medication administration system is used to match the computerized drug order, the medication, and the patient to ensure the patient receives the right drug at the right dose at the right time. A special system of clinical reminders is used to facilitate compliance with clinical practice guidelines. For example, the computer will flag a patient who is due for an annual mammogram or depression screening. It alerts providers to patients with out-of-range lab values or abnormal radiology results by sending an electronic notification.

Another way that VA ensures health care delivery is consistent across all sites of care is through an extensive performance management system. Clinical performance measures are used to assess key aspects of the care process such as diabetes control, management of hypertension or hyperlipidemia, screening for posttraumatic stress disorder or depression, and cancer prevention. Other measures assess the process of care delivery by looking at waiting times for appointments, patient satisfaction, and utilization of hospital beds. Data is collected at all VA sites of care and compared to VA and private sector benchmarks. The performance measure system is woven into performance plans and appraisal systems for VA managers and care providers with physician pay being linked to performance.

Post Conflict Care: The Department of Veterans Affairs Newest Wounded Warriors

In North Carolina, VA has launched special efforts to provide a "seamless transition" for those returning from service in Operations Enduring Freedom and Iraqi Freedom (OEF/OIF). Each VA medical facility has a point of contact to coordinate activities locally to help meet the needs of these returning combat service members and veterans. Special interdisciplinary care teams work with National Guard Units to provide onsite information about VA health care benefits to troops returning from deployment. They also perform health care screenings and enrollment to those wishing to access VA health care. In addition, VA has increased the staffing of benefits counselors at key military hospitals where severely wounded service members from Iraq and Afghanistan are frequently sent. Once home, recent Iraq and Afghan veterans have ready access to VA health care which is free of charge for 2 years following separation for any health problem possibly related to wartime service. According to the VA Mid-Atlantic Health Care Network Data Warehouse, over 14 300 active duty service members and veterans of the Global War on Terror have sought VA health care in North Carolina since September 11, 2001. Special polytrauma care units have been established at VA medical centers, and screenings for the possible presence of traumatic brain injury is provided to every OEF/OIF enrollee. President Bush's Commission on Wounded Warriors and the President's Task Force on Returning War on Terror Heroes have recently generated additional recommendations on how VA can provide speedier, fairer, and more efficient care to returning veterans of the Global War on Terror.[8]

Focus on the Future

This is a time of challenge for VA health care. It must meet the needs of its newest veterans by providing individualized case management services while also maintaining the historic commitment to providing the highest quality care to veterans of all eras. The ability to respond quickly to new needs is sometimes affected by the Congressional budget and capital project approval and funding processes which may create a lag between when new demands for care arise and when the facilities and resources are in place to meet those needs. The Department of Veterans Affairs has successfully responded to past challenges through the dedication of its staff and an ongoing commitment to its special mission. As the other articles in this issue show, the full attention of VA's clinical and research community is focused on meeting the health care needs of veterans by fulfilling the charge made by President Abraham Lincoln in his 1862 inaugural address: "To care for him who shall have borne the battle, and for his widow, and his orphan." **NCMJ**

COMMENTARY

The Epidemiology of Health Problems in Returning Operation Iraqi Freedom and Operation Enduring Freedom Veterans

A National and North Carolina-Based Summary

Kenneth C. Goldberg, MD

As large numbers of veterans return from military service in Operation Iraqi Freedom and Operation Enduring Freedom (OIF/OEF), policy leaders will need to anticipate their health concerns and align resources to serve those needs. This population of recent veterans is younger, much more likely to be female, and has a unique set of medical and mental health needs that vary significantly from those of the majority of the veterans who obtain health care from the Veterans Health Administration (VHA). Although the care provided to these newest veterans is a small portion of the total care provided to veterans enrolled in VHA facilities, these veterans represent a rapidly growing proportion of the veterans being served.

As this is a diverse and mobile population, it is difficult to obtain definitive information about its health care needs. The following information is synthesized from multiple national, regional, and local data sources. Most data are provided by sources within VHA. This is the single most reliable and available source of information, and returning veterans are actively encouraged to seek assistance for health care needs at VHA facilities.

> *"the 3 most common health problems reported [by veterans of the wars in Afghanistan and Iraq] are musculoskeletal ailments (principally joint and back disorders), mental health disorders, and 'symptoms, signs, and ill-defined conditions.'"*

National Data

As a working definition, we consider service members discharged from the Armed Forces beginning in fiscal year 2002 as returning OIF/OEF veterans. This does not include veterans who served in the first Gulf War, but it may include veterans who served recently and did not see combat. As with any group this large, it is problematic to make generalizations about their experience or health care needs.

With those caveats, there are approximately 4.4 million veterans of the OIF/OEF conflicts, of whom 720 000 have become eligible to receive health care within VHA since the beginning of fiscal year 2002 after completing their military service.[1] Of these, 47% are former active duty troops, and the remainder served in the Reserve forces and with National Guard units. To date, approximately 252 000 (35%) eligible OIF/OEF veterans have sought care through the VHA system. This is a significantly higher percentage than the estimated 20% of the entire veteran population that receives health care through VHA. To place this number in perspective, however, the VHA system currently provides care to a total of approximately 5.5 million veterans. Therefore, although 35% of eligible OIF/OEF veterans have sought care, these newest veterans represent only 5% of the total number of veterans served by VHA.[2]

Of the care the OIF/OEF veterans have received through

Kenneth C. Goldberg, MD, is deputy chief of staff at the Durham Veterans Affairs Medical Center and assistant professor of medicine at Duke University Medical Center. He can be reached at kenneth.goldberg (at) duke.edu or 508 Fulton Street, Durham, NC 27705.

the VA Medical Centers (VAMC), 94% of the visits have been to outpatient clinics, and 4% of the encounters have occurred in an inpatient setting. When analyzed and grouped by diagnosis codes, the 3 most common health problems reported are musculoskeletal ailments (principally joint and back disorders), mental health disorders, and "symptoms, signs, and ill-defined conditions."[2]

Approximately 350 000 (48%) OIF/OEF veterans have been seen at least once at a Vet Center. These centers, of which there are currently 207 throughout the country, focus on issues specific to combat veterans and their families. They are based outside of major medical facilities and deliver counseling and outreach services.[1]

Almost 95 000 (38%) OIF/OEF veterans have received care for mental health-related problems through the VHA system. Table 1 lists the coded diagnoses assigned to those visits by category of mental health problem. Posttraumatic stress, substance abuse (which includes tobacco abuse), and depression are the most frequently coded diagnoses.[2]

Table 1.
Coded Mental-Health Diagnoses Attributed to 94 921 OIF/OEF Veterans Who Have Received Health Care Services at Veterans Affairs Medical Centers Nationwide.[2]

Psychiatric Diagnosis (ICD-9CM code)	Percent (%) of Total
PTSD (309.81)	26
Nondependent abuse of drugs (305)	21

Neurotic disorders (300)	14
Affective psychoses (296)	9
Alcohol dependence syndrome (303)	4
Sexual deviations and disorders (302)	2
Special symptoms, not elsewhere classified (307)	2
Drug dependence (304)	2
Acute reaction to stress (308)	2

North Carolina Data

There are 4 Veterans Affairs Medical Centers in North Carolina. They are arranged into a larger organizational unit, The VA Mid-Atlantic Health Care Network, which also operates medical centers in Virginia and West Virginia. Together they provide comprehensive, integrated primary, specialty, and inpatient care. The location of these facilities in North Carolina is shown in Figure 1.

Of the 147 000 enrolled North Carolina veterans, approximately 12 000 (8%) are considered OIF/OEF veterans. This is a slightly higher percentage than that seen in the national veteran population, reflecting the large number of military bases in North Carolina. Table 2 describes the demographic characteristics of this group. Compared to the overall population of veterans served by the VA system, this group is younger and contains more women. Considering this is a group of recently discharged veterans, there is a surprising percentage of older veterans. More than one-third of this group deployed to a combat theater more than once. (M. Gentry, oral communication, November 2007.)

Table 2 also lists the service-connected ratings of current OIF/OEF veterans. A service-connected rating is essentially a disability score awarded by the Veterans Benefits Administration (which is separate from the Veterans Health Administration) for injuries or conditions either caused by or diagnosed during military service. Higher

	>=50%	3

Source: M. Gentry, oral communication, November 2007.

ratings reflect greater disability, and ratings greater than 50% are designed to reflect severely disabling conditions. Compared to the general population of veterans followed by VHA, the OIF/OEF veterans are significantly less likely to have been assigned a service-connected disability. Veterans need to apply specifically to receive this rating, and many do not initially apply upon leaving the service. Once a veteran applies, the application process itself can take months or sometimes years to complete, and the percentage of veterans with a service-connected injury is expected to rise over time. The proportionally smaller number of OIF/OEF veterans with service-connected disabilities may also reflect the change from a prior policy of not allowing some veterans without service connection to enroll in the VA system and thereby selecting for veterans with service-connected disabilities. This service connection restriction does not apply to OIF/OEF veterans.

One particular disability that is associated with OIF/OEF service is traumatic brain injury. Limitations primarily in medical knowledge about the spectrum of this condition make the collection of data difficult. However, the VA has an aggressive system that attempts to identify veterans who may have suffered traumatic brain injuries. At the Durham VAMC, between April and September 2007, almost 3000 veterans were screened for traumatic brain injury (80% of them OIF/OEF veterans). (B. Capehart, oral communication, October 2007.)

Another high-profile injury from the recent conflict is "polytrauma," or severely injured veterans. These veterans have suffered significant injury that has affected multiple organ systems, often resulting in amputation and cognitive deficits. At this time the North Carolina VAMCs are currently managing fewer than 100 of these veterans (M. Gentry, oral communication, November 2007).

Table 3 summarizes care that OIF/OEF veterans have received through the North Carolina VAMCs in fiscal year 2007. The care provided to these veterans during that year is almost equal to the cumulative number of visits provided in fiscal years 2002 through 2006, showing that as more and more veterans of the recent conflict become eligible for VHA care, their use of the system is growing exponentially. Table 4 lists the most common types of outpatient visits from fiscal year 2007. Compared to veterans from other periods, OIF/OEF veterans are far more likely to be seen in a mental health clinic. Table 5 lists the primary treating specialties of the inpatient care received during the same period. Inpatient stays for

recent veterans are far more likely to occur on a psychiatric ward, and somewhat more likely to occur on a surgical ward, than they are for veterans from other periods whose hospitalizations are more likely to occur on a medicine service.

Limitations

The preceding data are the best available to provide a synthesis of the objective health needs of North Carolina OIF/OEF veterans. Unfortunately, the majority (65%) of OIF/OEF veterans have not sought care through the VHA system. It is very possible that veterans who seek VHA care differ from those veterans who do not. At this time there is no systematic and accessible system that tracks the health needs of veterans not served by VHA, so analysis of VHA data remains the best and currently only method to estimate the health needs of the entire group.

It is also likely that the needs of OIF/OEF veterans will change over time. It has already been documented that screening tools used to identify posttraumatic stress among recently returning veterans likely underestimate the prevalence of this disease, and identified cases will increase over time.[4]

Furthermore, much of the data presented here derive from specialized queries performed explicitly for this manuscript and may not be completely reproducible. **NCMJ**

Acknowledgement

Many people assisted in compiling the information presented in this manuscript. I particularly wish to thank Marsha Gentry and Becky Fox from the VA Mid-Atlantic Health Care Network offices, and also Harold Kudler MD, Bruce Caphehart, MD, and Susan Watkins, MSW at the Durham VA Medical Center for their assistance. Most importantly, I thank the men and women who have served their country so well in these, and in all, conflicts.

COMMENTARY

Veterans Affairs Research and Development:
Using Science to Improve Health Care for Veterans

Eugene Z. Oddone, MD, MHSc; Seth Eisen, MD, MSc

The Veterans Affairs Office of Research & Development (ORD) is a congressionally mandated research program established in 1947 whose mission is to study all aspects of health and disease relevant to our nations' veterans. The Office of Research & Development consists of 4 research services including the Biomedical Laboratory, Clinical Science, Rehabilitation, and Health Services. The Biomedical Laboratory Research & Development Service conducts research that explores basic biological or physiological principles in humans or animals. The Clinical Science Research & Development Service (Clinical Science) conducts research that focuses on human subjects including interventional, clinical, epidemiological, and technological studies. Clinical Science houses the VA Cooperative Studies Program which has conducted landmark studies over the last 50 years that have established the effectiveness of new treatments for tuberculosis, hypertension, and coronary artery disease to name only a few. The Rehabilitation Research & Development Service conducts research exploring areas where technology can enhance or sustain veterans' independence. Lastly, the Health Services Research & Development Service pursues research at the interface of health care systems, patients, and health care outcomes. Its researchers examine all aspects of VA health care including access to care, adherence to quality of care standards, methods of improving quality of care and patient outcomes, the impact of health system organization on care, and cost of care. The Veterans Affairs Office of Research & Development is the only national research entity that is tied directly to a fully integrated health care system—the Veterans Health Administration. In fiscal year 2007 Congress appropriated $480 million in direct funding for ORD. VA Research is an intramural program that funds only eligible VA employees through a rigorous merit review process. The majority of funded VA researchers are also VA clinicians, and their research is conducted within VA. Veterans Affairs researchers are also very successful in obtaining non-VA, other federal, and foundation funds through competitive extramural grant programs. Veterans Affairs researchers also are faculty members at affiliated academic institutions.

> *"The Veterans Affairs Office of Research & Development is the only national research entity that is tied directly to a fully integrated health care system—the Veterans Health Administration."*

VA's primary research mission is to investigate health issues that are of primary relevance to veterans. However, because the diseases and conditions studied in VA are also prevalent in the general population, VA research is widely relevant to civilian health. As such, Congress requires a continuing review of relevance and applicability. The VA research mission has gained importance given the burden of disease and injury in veterans. Research on chronic medical illnesses has dominated the research program for the last two decades reflecting the prevalence and burden of cardiovascular, neurological, and pulmonary diseases as well as cancer in the aging veteran population. With the more recent conflicts in Afghanistan and Iraq, VA has seen an

Eugene Z. Oddone, MD, MHSc, is the principal investigator for the Center for Health Services Research in Primary Care, Durham Veteran Affairs Medical Center, and vice dean for Research, School of Medicine, Duke University Medical Center. Seth Eisen, MD, MSc, is national director for the Health Services Research & Development Service, Office of Research and Development, US Department of Veteran Affairs.

influx of younger patients with both physical and mental trauma as well as other complex and chronic conditions. There has been a surge of interest in research designed to diagnose and treat these conditions. Congressional 2007 appropriations included $32.5 million for research in areas of importance to these veterans including traumatic brain injury, sensory loss, spinal cord injury, and posttraumatic stress disorder.

Quality Enhancement Research Initiative

One unique feature of VA research is its close association with the health system. While most academic research programs are conducted by university-based independent investigators, VA researchers are tied more directly to the health care system and the patients they serve. As an example, in 1998 the VA Health Sciences R&D program launched the VA Quality Enhancement Research Initiative (QUERI).[1,2] The QUERI mission is to enhance the quality and outcomes of VA health care by systematically implementing clinical research findings and evidence-based recommendations into routine clinical practice. In evaluating quality of care, the QUERI process focuses on 3 elements: structure (provider and organizational characteristics), process (practitioners' clinical actions toward patients), and outcome (health status, economic impact, satisfaction). The Quality Enhancement Research Initiative is founded on the principle that practice needs determine the research agenda, and research results determine interventions that improve the quality of patient care. It is a comprehensive, data-driven, outcomes-based quality improvement program that utilizes a 6-step process to facilitate the implementation of research findings and evidence-based clinical practices to achieve better health care outcomes for veterans. Steps in the QUERI process are:

1. Identify high-risk/high-volume diseases or problems.
2. Identify best practices.
3. Define existing practice patterns and outcomes across VA and current variation from best practices.
4. Identify and implement interventions to promote best practices.
5. Document that best practices improve outcomes.
6. Document that outcomes are associated with improved health-related quality of life.

The Quality Enhancement Research Initiative focuses on 9 diseases and conditions that are prevalent among veterans. These include chronic heart failure, diabetes, HIV/hepatitis, ischemic heart disease, mental health problems, polytrauma and blast related injuries, spinal cord injury, stroke, and substance abuse. Functionally, there is a research coordinator and a clinical coordinator as well as a cadre of experts for each of the 9 QUERI areas. These 9 focused groups of experts develop strategic plans and form collaborations with VA central, regional, and health center-based facilities across the country to develop and conduct projects to improve quality of care to veterans.

Operation Iraqi Freedom/Operation Enduring Freedom

VA Research & Development has made working to address the health care needs of our military returning from conflicts in Iraq and Afghanistan a top research priority. VA investigators are working on developing new knowledge, effective tools, and innovative ways to evaluate and treat polytrauma, mental health issues such as depression and post traumatic stress disorder, spinal cord injury, traumatic brain injury, amputations and prosthetics, and burns.

Veterans Affairs Research in North Carolina

In North Carolina, the Durham VA Medical Center has one of the oldest and largest research programs in all of VA. From its founding date in 1953, all clinical faculty have been recruited to VA with dual academic appointments at Duke University, and key leadership positions in VA have been staffed by clinician scientists. Thus the clinical expertise of VA was tied closely to the research mission. Throughout its history Durham VA has provided significant basic, clinical, and health services research training opportunities for both PhD trained and clinician scientists in the form of fellowships and postdoctoral programs as well as career development and enhancement programs. The VA medical centers in Asheville and Salisbury, North Carolina maintain smaller research programs.

In 1981 the Health Services Research Program at Durham VA was funded as one of the initial national Field Programs in Health Services. It has grown into one of the largest Centers of Excellence in Health Services Research now focusing on issues relevant to access, quality, and outcomes of primary care for veterans. The Durham Epidemiology Research and Information Center was established in 1990 as 1 of 3 national epidemiology centers in VA. Its areas of expertise are in neuroepidemiology and genomics. There are several examples of clinically relevant research in North Carolina including amyotrophic lateral sclerosis, managing hypertension outside a clinic, and posttraumatic stress disorder.

Amyotrophic Lateral Sclerosis

Amyotrophic lateral sclerosis (ALS) is an adult-onset, fatal neuromuscular disease involving progressive degeneration of upper and lower motor neurons with clinical manifestations including muscular weakness, atrophy, and spasticity with exaggeration of tendon reflexes. Concern about potential environmental exposures in the context of military service in the 1990-1991 Gulf War was an important factor in the formulation of the ALS Gulf War study run by investigators at the Durham Veterans Affairs Medical Center (VAMC).[3,4] In an effort to stimulate both etiologic and therapeutic research on ALS in veterans, the VA Cooperative Studies Program developed a National Registry of Veterans with ALS.[5] The objectives of the registry are to identify living US military veterans with ALS, track their health status and disease progression over time, collect data (including DNA) that will be available for multiple epidemiologic studies of ALS, and provide a mechanism for informing veterans with ALS about clinical trials for which they may be eligible. This VA registry is the largest fully specified cohort of patients with ALS worldwide with over 2400 patients now enrolled, 1200 of whom have provided DNA samples for future research. Because ALS is a relatively rare disease, it is often difficult to identify sufficient numbers of patients for important epidemiologic and genetic studies. It is VA's hope that the resource created in the registry will lead to important discoveries for patients with this lethal disease. To date, over 20 different investigators (both VA and non-VA) have received access to this important resource.

Managing Hypertension Outside the Clinic

Hypertension is the most common reason for primary care clinic visits both at VA and nationally. Because a significant proportion of civilian and veteran patients remain above evidence-based targets for blood pressure control, researchers at Durham VA have designed and tested a multicomponent intervention that promotes patient self-management by establishing practices around adherence to best behaviors and medication management.[6-8] This multicomponent intervention uses a combination of telehealth blood pressure monitoring devices, scripted text delivered by nurses, and medication changes initiated and monitored centrally by physicians. The main goal of this research was to move the management of hypertension outside the context of a clinic visit and into the patient's home. A series of studies have established the safety of this method of care, and ongoing research is addressing its effectiveness. Elements of this system are being tested in a pilot project in North Carolina's Medicaid population.

Posttraumatic Stress Disorder

Posttraumatic stress disorder (PTSD) is a serious and prevalent problem in veterans. While PTSD has clearly been present in all wars and conflicts, our understanding of the long-term consequences of this illness did not emerge until after the Vietnam War. VA investigators have led the nation by conducting research designed to better understand the etiology, diagnosis, and treatment of PTSD. A recent study established that as many as one-third of veterans returning from conflicts in Iraq and Afghanistan experience some psychological problems, half of whom are diagnosed with PTSD.[9] While much of current treatment is focused on patients reexperiencing the traumatic event that precipitated the disorder, researchers at Durham VA are examining the potential benefits of a treatment called "guided imagery." In a novel study that compares the effectiveness of soothing music alone to the effectiveness of tailored audio instructions and soothing music treatment delivered in the veteran's home using a dedicated personal digital assistant (PDA), researchers will discover if guided imagery will allow veterans with this debilitating disorder to achieve symptom resolution and enhanced quality of life. If the intervention proves to be successful, it is likely to be a very cost-effective treatment modality for the growing number of veterans with PTSD.

Summary

VA has a rich tradition in supporting research in areas that span basic science to health system implementation. Its unique success is tied to the fact that researchers are focused on issues that arise from a unique population—our nation's veterans. Moreover, because VA is the largest integrated health system in the country and because the health system must manage an annual budget, there is a keen interest among VA health administrators to apply research that enhances quality and efficiency of care. Furthermore, because these findings overlap with the general population, VA Research & Development programs can be applicable on a much broader scale. **NCMJ**

COMMENTARY

Identifying and Treating Post Deployment Mental Health Problems Among New Combat Veterans

Harold Kudler, MD; Kristy Straits-Tröster, PhD

North Carolina is one of the nation's most military friendly states because it is home to more than 101 000 active-duty military personnel at Fort Bragg, Pope Air Force Base, Camp Lejeune Marine Corps Base, Seymour Johnson Air Force Base, the US Coast Guard Air Station at Elizabeth City, and Marine Corps Air Stations at New River and Cherry Point. In addition, North Carolina has 164 Army and Air National Guard units comprised of nearly 12 000 members as well as another 10 234 Army, Navy, Air Force, Marine, and Coast Guard reservists.[1] North Carolina-based military units have played an important role in the Global War on Terror including multiple deployments to Operation Enduring Freedom (OEF) in Afghanistan and Operation Iraqi Freedom (OIF). Many servicemen and women have families in the state and many choose to make North Carolina their home when they become veterans. The effects of war reverberate across our state and within each of our local communities.

> *"The stigma associated with seeing a mental health provider will often drive combat veterans and their family members to seek help in primary care settings, but primary care practices are not always well prepared to identify or treat such problems."*

Treating Post Deployment Mental Health Problems in Community Settings

While it might be natural to expect that any post deployment mental health problems of service members and veterans would be identified, assessed, and treated within the Department of Defense (DoD)/Department of Veterans Affairs (VA) medical care continuum, the available data suggest otherwise. Hoge and colleagues from the Walter Reed Army Institute of Research[2] found significant reticence to discuss post deployment mental health problems in military settings among service members who had served in OEF/OIF. The National Vietnam Veterans Readjustment Study[3] showed that only 20% of Vietnam veterans with a diagnosis of posttraumatic stress disorder sought VA care. Thus far, only about 1 out of every 3 OEF/OIF veterans eligible for VA care has applied for that care. Taken together, these findings indicate that many OEF/OIF veterans may seek care outside of DoD and VA. Their family members are also subject to significant deployment-related stress, and they too will be seeking help in the greater community. The stigma associated with seeing a mental health provider will often drive combat veterans and their family members to seek help in primary care settings, but primary care practices are not always well prepared to identify or treat such problems.[4] This

Harold Kudler, MD, is interim director of the Department of Veterans Affairs Mid-Atlantic Mental Illness Research, Education and Clinical Center, and associate clinical professor in the Department of Psychiatry and Behavioral Sciences, Duke University. Kristy Straits-Tröster, PhD, is interim associate clinical director in the Department of Veterans Affairs Mid-Atlantic Mental Illness Research, Education and Clinical Center, and adjunct assistant professor in the Department of Psychiatry and Behavioral Sciences, Duke University.

article provides essential information on screening for, assessing, treating, and, when necessary, triaging disorders associated with military deployment.

Screening

Posttraumatic stress disorder (PTSD) is characterized by a constellation of symptoms that follow exposure to an extreme traumatic event which involves actual or threatened death or serious injury.[5] The response to the event must include intense fear, helplessness, or horror and symptoms that persist more than one month including (1) reexperiencing the traumatic event through intrusive recollections, dreams, or nightmares; (2) avoidance of trauma-associated stimuli such as people, situations, or noises; and (3) persistent symptoms of increased arousal which may include sleep disturbance, hypervigilance, irritability, or an exaggerated startle response. A PTSD diagnosis must also be accompanied by clinically significant distress and a decline or impairment in social, occupational, or other important areas of functioning.

A structured clinical interview such as the Clinician Administered PTSD Scale[6] (CAPS) is an optimal assessment for PTSD and has long been the gold standard for making that diagnosis in clinical studies. However, detecting possible PTSD at the population level or within a large cohort of returning combat veterans is best approached with a brief, optimally sensitive measure which minimizes false negatives while efficiently identifying those in need of further assessment.

Table 1.
The Primary Care Posttraumatic Stress Disorder Screen (PC-PTSD)

In your life, have you ever had any experience that was so frightening, horrible, or upsetting that, in the past month, you:

1. Have had nightmares about it or thought about it when you did not want to?
   YES / NO
2. Tried hard not to think about it or went out of your way to avoid situations that reminded you of it?
   YES / NO
3. Were constantly on guard, watchful, or easily startled?
   YES / NO
4. Felt numb or detached from others, activities, or your surroundings?
   YES / NO

Current research suggests that the results of the PC-PTSD should be considered “positive” if a patient answers “yes” to any 3 items.

The 4-item Primary Care PTSD screening tool (PC-PTSD)[7] has been adopted by both DoD and VA due to its brevity and sensitivity. It was developed specifically for application in primary care settings and has been incorporated into both DoD’s Post Deployment Health Assessment (PDHA), performed at the time of return from a combat area, and its Post Deployment Reassessment (PDHRA), performed 3 to 6 months after return. The Primary Care PTSD screening tool has also been incorporated into VA’s computerized medical record system as a pop-up reminder on all OEF/OIF veterans registered for VA health care. This valuable screening tool is in the public domain and can be a useful aid in medical practices outside of DoD and VA.

While a score of 3 positive answers or more is required to trigger further action in VA settings, we advise that any positive response to a Primary Care PTSD question should spur further follow up from health care providers even if only to ask basic questions about personal and family readjustment following deployment. Most service members and veterans will not meet diagnostic criteria for any mental disorder and yet all of them are dealing with significant readjustment stress (as are their families). The object of screening is not simply to rule in or rule out a diagnosis of PTSD: it is to learn more about other common post deployment medical problems (eg, substance abuse, major depression) and to identify significant functional problems including job stress, unemployment, family stress, and homelessness. Combat veterans may report anxiety, sadness, loss of interest in work or recreation, or inordinate fear for the safety of family members and friends. Psychological trauma may surface indirectly as an exacerbation of chronic physical ailments such as shortness of breath in an asthmatic or increased pain in a person with arthritis. It may be expressed in new somatic symptoms (eg, headaches, abdominal pain) or as new or exacerbated substance abuse. It may lie veiled behind vague complaints of poor energy or poor sleep. Problems with memory, concentration, emotional lability, or irritability may also suggest traumatic brain injury which might then trigger further screening such as the 3-Question Screening Tool developed by the Defense and Veterans Brain Injury Center.[8]

Perhaps the most basic and most important screening step is simply to ask patients, “Are you a veteran or are you the family member of a veteran?” This question may be key to understanding why this particular patient is coming to see you and why now.

If a patient scores a 3 or higher on the Primary Care PTSD screening tool, a good follow-up instrument for further assessment would be the PTSD Checklist, Civilian Version (PCL-C).[9] This 17-item self-report measure covers each of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) symptoms of PTSD. Patients are asked whether they were “bothered by that problem in the past month” and responses are scored on a 5-point scale ranging from 1 (“not at all”) to 5 (“extremely”). Available in several forms, the PTSD Checklist, Civilian Version is recommended for post deployment screening because, unlike the military version, it is not focused on any one specific traumatic event. This allows the respondent to make connections to a broad range of deployment experiences, any one of which might be the key stressor for that individual. The PTSD Checklist can be scored in different ways; a total score (range 17-85) can be obtained by summing the scores from each item or the responses can be reviewed to establish that DSM-IV criteria for PTSD have been met. Hoge et al[2] employed a cut-off score of 50 as a conservative indicator for a positive diagnosis of PTSD.

Treatment

A recent review of the evidence base for psychotherapies and psychopharmacological strategies in the treatment of PTSD among combat veterans by the Institute of Medicine of the National Academies[10] suggested that more research is needed before all but one of these can be recommended at the highest level of confidence (exposure therapy being that single exception). Having acknowledged that finding, a number of clinical practice guidelines exist to assist clinicians in learning about available treatments, reviewing their evidence base, and making practical, patient-specific choices among them.

Most relevant among these is the VA/DoD Clinical Practice Guideline for the Management of Posttraumatic Stress.[11] Created by a joint working group of VA and DoD clinicians and researchers, this comprehensive guideline provides clinical algorithms that walk clinicians through the necessary steps from screening and initial assessment through treatment and reassessment. Separate algorithms are defined for primary care providers and mental health professionals. Evidence tables are provided for each recommendation and a substantial literature review is included. This guideline is available on the Internet (http://www.oqp.med.va.gov/cpg/PTSD/PTSD_Base.htm.) and is in the public domain.

The American Psychiatric Association has published the Practice Guideline for the Treatment of Patients with Acute Stress Disorder and Posttraumatic Stress Disorder.[12] The International Society for Traumatic Stress Studies, the world's largest international multidisciplinary professional organization working in the field of psychological trauma, provided a comprehensive set of treatment guidelines in 2000[13] with a new edition expected in 2008. Both guidelines provide a thoughtful introduction to available therapies, significant background information, and evidence-based treatment recommendations.

A thorough review of these treatments is beyond the scope of this paper, but a brief summary statement of the most highly recommended modalities (based on the VA/DoD guidelines) may prove helpful. Among the psychotherapies, prolonged exposure therapies (based on behavioral principles including habituation and extinction), cognitive behavior therapies (focusing on correcting misattributions and maladaptive responses), and Eye Movement Desensitization and Reprocessing (believed to facilitate psychological and neurological processing of traumatic events) have the strongest evidence base. The use of psychodynamic psychotherapy (derived from psychoanalytic principles) is supported by at least one randomized control study but does not have as strong a research base. Little evidence exists to support the use of Critical Incident Debriefing in the prevention of PTSD, and there is some evidence suggesting that debriefing activities can actually increase the risk of PTSD by retraumatizing survivors who are not prepared to be reexposed to horrific memories.

Among the medications available for the treatment of PTSD, specific serotonin reuptake inhibitors and venlafaxine have the strongest evidence base. While many drugs from a wide range of classes have been studied in PTSD, there is little evidence to support their use except as adjunctive treatment. Available research suggests that prazosin reduces the frequency and intensity of posttraumatic nightmares and may be effective in managing other symptoms of PTSD, but it cannot yet be recommended as a stand-alone treatment. There is evidence that benzodiazepines are not effective as first line agents in the treatment of PTSD. Because of their potential for dependence and abuse, their use as single agents is strongly discouraged in the VA/DoD guidelines.

Accessing Additional Support

Clinical practice guidelines are of significant value in the management of PTSD. Similar guidelines for disorders that are frequently comorbid with PTSD are also available through their respective DoD/VA work groups and the American Psychiatric Association among other authoritative sources. As noted earlier, many of the problems faced by returning combat veterans and their families are not specifically clinical: they may best be conceptualized in functional terms (eg, work stress, unemployment, educational/training needs, housing needs, financial and/or legal problems), and family terms (eg, lack of social support, estrangement, family breakup). Veterans, their family members, and their practitioners may find it helpful to consult a unique service available in North Carolina: NCcareLINK.[14] NCcareLINK (http://www.nccarelink.gov) is a comprehensive health and human services Web site offering information services and bilingual support that connects patients and their care givers with over 10 000 agencies and services across our state. Administered by the North Carolina Department of Health and Human Services, NCcareLINK was developed in partnership with DoD, VA, and state and community entities following recommendations made by the North Carolina Governor's Focus on Returning Veterans and their Families.[15] People who are unable to access the Web-based service may call the toll-free telephone counterpart NC CARE-LINE (1-800-662-7030). Established in 2006, NC CARE-LINE will soon begin operating 24 hours per day 7 days per week.

North Carolina has a great stake in the post deployment health of military personnel, veterans, and their families. An impressive network of programs, services, and information systems stands ready to support these citizens and their health care providers in retaining and/or regaining their highest potential for health and function. Optimal health and function cannot, however, be attained unless key questions are asked throughout our entire health system. The first and most basic of these is "Are you a veteran or the family member of a veteran?" With this information in hand, effective work can begin. **NCMJ**

Detecting Traumatic Brain Injury Among Veterans of Operations Enduring and Iraqi Freedom

George L. Jackson, PhD, MHA; Natia S. Hamilton; Larry A. Tupler, PhD

Advances in battlefield medicine and protective devices used in Operation Enduring Freedom-Afghanistan (OEF), beginning in October 2001, and Operation Iraqi Freedom (OIF), beginning in March 2003, are saving the lives of many service members who would have died in other wars. While the mortality rate for injures was 30% in World War II and 24% in Vietnam, the rate in these recent wars has been constantly close to 10%.[1-3] The result is that many veterans who previously would have died are living with very serious injuries, and those who formerly would have had serious and apparent injuries now have conditions that significantly impact their lives but are not always obvious.

One of these conditions, traumatic brain injury (TBI), is considered the signature wound of the current conflicts.[4,5] It is estimated that almost 50% of soldiers injured in combat return with some form of TBI (mild, moderate, or severe).[6] This compares with 14% to 18% of combat casualties having a brain injury during the Vietnam War.[4]

What is Traumatic Brain Injury?

Traumatic brain injury is a form of brain damage resulting from a sudden jolt, blow, or penetrating head injury.[7,8] It most commonly occurs when the head is accelerated and then decelerated abruptly. The effect is that strain forces are applied to the axons (nerve fibers) in the brain. This type of closed TBI is broadly referred to as a diffuse axonal injury.[9,10] These injures may result from the head hitting an immovable object, being struck in the head, or waves of energy from an explosion. Penetrating objects such as bullets may also damage the brain. Traumatic brain injury can result in temporary to permanent cognitive, physical, or emotional dysfunction. The severity of the TBI depends on the symptoms that result from the injury, and outcomes can range from a complete recovery to permanent disability or death.[11-13] Table 1 lists common symptoms of TBI.[14-17]

> *"… traumatic brain injury (TBI) is considered the signature wound of the current conflicts. It is estimated that almost 50% of soldiers injured in combat return with some form of TBI (mild, moderate, or severe)."*

Traumatic Brain Injury Severity

In more serious cases, when blasts and other mechanisms of injury result in loss of consciousness producing a TBI, the injury may be defined as mild (≤ 30 minutes) [American

---

George L. Jackson, PhD, MHA, is research health scientist and epidemiologist at the Center for Health Services Research in Primary Care, Durham Veteran Affairs Medical Center, and assistant professor in the Division of General Internal Medicine, Duke University Medical Center. Dr Jackson can be reached at george.l.jackson (at) duke.edu or HSR&D Service (152), 508 Fulton Street, Durham, NC 27705.

Natia S. Hamilton, BA, is research assistant at the Center for Health Services Research in Primary Care, Durham Veteran Affairs Medical Center and graduate student in the Department of Psychology, North Carolina Central University.

Larry A. Tupler, PhD, is director of the Neurocognitive Research Core at the Mid-Atlantic Mental Illness Research, Education and Clinical Center, Durham Veterans Affairs Medical Center, and assistant professor in the Department of Psychiatry and Behavioral

Table 1.
Common Symptoms of Traumatic Brain Injury

General Symptoms of TBI	Symptoms of Moderate to Severe TBI
Headaches	Loss of consciousness (30 minutes or more)
Difficulty organizing daily tasks	Personality change
Mental confusion (easily confused, easily feeling overwhelmed)	Loss of coordination
Lightheadness or feeling dizzy	Weakness or numbness in the extremities
More sensitive to auditory stimuli, lights, or other distractions	Slurred speech
Behavior or mood changes (feeling sad, anxious, or listless)	Dilation of one or both pupils
Double vision, blurred vision, or tired eyes	Inability to awaken
Ringing in the ears	Seizures
Bad taste in the mouth	Repeated vomiting or nausea
Fatigue or lethargy (feeling tired all of the time)	A severe, persistent, or worsening headache
A change in sleep patterns	
Trouble with memory, concentration, or calculations	
Easily irritated or angered	
Impulsivity (lack of inhibition)	
Slowed movement, talking, reading, or thinking	
Sexual dysfunction	

TBI – traumatic brain injury

Congress of Rehabilitation Medicine definition], moderate (≤ 6 hours), or severe (> 6 hours).[18] Also accompanying TBI may be anterograde memory loss or posttraumatic amnesia, difficulty encoding new information following the injury. Posttraumatic amnesia may be mild (< 1 day), moderate (1 to 7 days), or severe (> 7 days).[16,19] Retrograde amnesia tends to follow the same or somewhat less of a time gradient as posttraumatic amnesia. Not all TBI victims suffer from loss of consciousness or amnesia, but those with more mild exposure to trauma may become dazed and confused, characterized by difficulties with orientation, perception, concentration, memory encoding and retrieval, and judgment.[14-16]

Table 2.
Common Criteria for Determining the Severity of Traumatic Brain Injury

	Loss of Consciousness	Brain Functioning	Posttraumatic Amnesia	Glasgow Coma Scale Score
Mild TBI	≤ 30 minutes	Normal MRI and CT	< 24 hours	13-15
Moderate TBI	≤ 6 hours	Abnormal MRI and CT	≤ 7 days	9-12
Severe TBI	> 6 hours	Abnormal MRI and CT	> 7 days	3-8

TBI – traumatic brain injury; MRI – magnetic resonance imaging; CT – computerized axial tomography scan

Sources: Coetzer et al (2002);[18] Kahn et al (2003);[16] Sternbach (2000)[19]

Because an estimated 80% of individuals sustaining TBI are classified as mild (mTBI), it is often a condition that is not readily apparent.[12] Most mTBI patients make a rapid recovery, suffer few postinjury complications, and, for these reasons, often bypass acute medical attention or hospitalization. Nevertheless, up to one-third of mTBI patients develop chronic symptoms, and delayed symptom onset is not uncommon.[11]

Postconcussive syndrome refers to an array of cognitive, physical, and emotional symptoms that can occur following mTBI.[20-22] Patients with postconcussive syndrome may complain of headaches, postural imbalance, insomnia, memory problems, fatigue, irritable or depressed mood, or interpersonal conflict.[17,23] Postconcussive syndrome is challenging to diagnose using a detailed physical exam or neuroimaging alone. It is often the case, unfortunately, that misattributions of underlying psychopathology prevent postconcussive syndrome patients from receiving appropriate care. The constellation of cognitive, behavioral, and social deficits common to TBI may impinge on interpersonal relationships and family support, thus complicating recovery.[24] Table 2 lists characteristics of mild, moderate, and severe TBI.[16,19]

Causes of Traumatic Brain Injury

Common causes of TBI, both civilian and military, include falls, motor-vehicle accidents, striking or being thrown against an object, or assault.[7] In the OEF and OIF war zones, however, the most common sources of TBI are explosives and blasts.[5,15,25,26] Traumatic brain injury accounts for approximately 60% of war injuries caused by blasts.[5]

Explosives can take the form of conventional bombs or enhanced-blast explosive devices.[15] Conventional bombs cause a blast wave that spreads out around its point of origin. It is initially a wave of high pressure which is followed by strong and forceful wind. Damage tends to increase as distance from the explosion decreases. Warfare in Iraq often uses explosive devices loaded with metal pieces which cause greater penetrating force, potentially causing penetrating injuries on top of closed injuries caused by blast waves. Enhanced blast-explosive devices can present greater damage than conventional bombs because the initial explosion triggers a secondary explosion, spreading out force that lasts longer.[15]

Four basic types of injuries are caused by blasts: (1) primary—over-pressurization of "blast wave"; (2) secondary—projectiles based on proximity of primary blast; (3) tertiary—effects due to wind, which may propel the victim into walls, the ground, or other objects; and (4) quaternary—burns, asphyxia, and exposure to toxic inhalants. (See Table 3.)[14,15,25,27]

Table 3.
Types of Blast Related Injuries

Category of Injury	Source of Injury	Implications of Injury
Primary blast injury	Overpressurization of blast wave	Tympanic membrane damage; lung damage; occipital rupture; concussion
Secondary blast injury	Projectiles based on proximity of primary blast	Penetration of extremities (including the head)
Tertiary blast injury	Blast related wind impacting the speed and force with which the body hits or is hit by objects	Fracture; amputation; closed or open brain injury
Quaternary blast injury	Random circumstances such as burns, asphyxia, and exposure to toxic inhalants	Burns; closed and open brain injury; breathing problems (eg, asthma; COPD); exacerbation of cardiovascular risk factors (eg, hypertension)

COPD – chronic obstructive pulmonary disease
Sources: Centers for Disease Control and Prevention (May 2003)[14] and (December 2006)[27]; DePalma (2005)[15]; Finkel (2006)[25]

Screening at the Time of Potential Traumatic Brain Injury

The most common initial screening tool is the Glasgow Coma Scale. It includes questions on motor responses (6 grades), verbal responses (5 grades), and eye-opening responses (4 grades). Lower scale scores indicate greater likelihood of more severe TBI.[28] Table 2 includes the scale cutoff scores for levels of TBI severity.[16,19] A copy of the Glasgow Coma Scale can be found on the Internet at http://www.strokecenter.org/trials/scales/glasgow_coma.pdf.[29]

The Defense and Veterans Brain Injury Center (DVBIC) at Walter Read Army Medical Center has developed a Military Acute Concussion Evaluation assessment procedure for use in warzones. The Military Acute Concussion Evaluation is based on the Standardized Assessment of Concussion[30] and includes more detailed assessments of the incident leading to potential TBI and current clinical status than occurs with administration of the Glasgow Coma Scale. While not yet validated, a description of this procedure is available on the DVBIC Web site at http://www.dvbic.org/.[31]

Course and Recovery of Traumatic Brain Injury

Recovery from brain injury varies significantly by severity group. Victims of moderate to severe TBI may suffer from residual neurocognitive deficits for the remainder of their lives. They can manifest amnesia, hyperdistractibility, and other attentional deficits, language impairment, motor slowing and incoordination, and changes in personality.[11]

Although most victims of mTBI suffering from PCS recover over a 3-month to 1-year time frame, many do not.[23] It has been argued that those who do not recover their function typically manifest psychiatric presentations predating the TBI or in response to the trauma.[22,32] However, more research is required to determine what post-TBI symptoms are due to mechanisms of brain injury versus functional psychiatric involvement either preceding or following the trauma

While extensive literature exists describing recovery from blunt-force trauma due to motor-vehicle accidents or falls,[7] data and studies describing blast injury are limited.[9] Whereas blunt force trauma may be somewhat more focal due to coup and contrecoup forces, blast injury may be more diffuse due to primary overpressurized waves pervasively affecting the entire brain; secondary and tertiary effects might furthermore create more multifocal effects.[15] There may also be an accumulation of effects secondary to repeated blasts. Veterans may have been exposed to multiple explosions, and while receiving only mild postconcussive effects from one blast, a second or third blast of equal force could result in more severe injury.[9]

Traumatic Brain Injury and Posttraumatic Stress Disorder Comorbidity

Posttraumatic stress disorder (PTSD) frequently follows exposure to blast and other TBI etiologies, and symptoms frequently overlap with those observed following TBI. Diagnostic discrimination between the two conditions may therefore be challenging and complicate treatment formulations. Furthermore, many brain areas typically affected in TBI such as frontal, temporal, and subcortical regions are the same as those putatively involved in PTSD symptom expression.[33]

Some authors have noted that the overlap between symptoms of PTSD and TBI calls into question current diagnostic tools for discriminating PTSD among TBI patients and thus requires the development of new measures that can differentiate the two. At a minimum, it is likely that symptoms from TBI compromise the ability to cope with the stress of PTSD (eg, through disinhibition of executive-control processes), and PTSD likewise compromises the ability to navigate the cognitive and other manifestations of TBI.[34] Those with TBI may also have more severe PTSD.[35]

Screening for Traumatic Brain Injury – Department of Defense

Because mTBI may not have obvious outward symptoms, and symptoms may overlap with other conditions,[36] extensive screening efforts are required. Starting in April 2003, all active duty, reserve, and National Guard service members and Department of Defense civilians deployed to a war zone have been required to complete an in-person post-deployment health assessment (PDHA) between 30 days before and 30 days after redeployment away from the war zone. This process includes a screening form (DD2796) that has 4 questions about potential TBI.[37] These address (1) experiences that could lead to TBI (eg, explosion); (2) condition following the event (eg, dazed, confused); (3) symptoms that began or got worse after the event (eg, memory problems); and (4) symptoms experienced in the last week. Patients indicating they were exposed to an event and have had symptoms are then referred for further evaluation.[38,39] The screening forms and specific questions mentioned in this section are available on the Department of Defense Deployment Health Clinical Center-PDHealth Web site at http://www.pdhealth.mil/.

Since March 2005, it is required that returning service members be offered a postdeployment health reassessment (PDHRA) 90-180 days (preferably 120-150 days) following redeployment. Individuals who were hospitalized must have a PDHRA 90-180 days after discharge. This includes form DD2900, which has the same 4 TBI questions described above.[40] Information from the PDHA and PDHRA, along with the predeployment health assessment form DD2795[41] (completed within 60 days prior to deployment), is maintained in the permanent medical record and Defense Medical Surveillance System.[38,42] A recent report summarizing results of the PDHRA indicated a higher rate of self-reported mental health concerns and referrals than that observed with the PDHA, suggesting increased morbidity over time following deployment.[42]

Screening for Traumatic Brain Injury – Veterans Health Administration

On April 2, 2007, a system-wide TBI Screening Clinical Reminder was introduced into the Veterans Health Administration (VHA). On April 13, VHA directive 2007-013, *Screening and Evaluation of Possible Traumatic Brain Injury in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) Veterans*, was released based on the deliberations of a dedicated task force.[43] In this directive, it was noted that "currently there are no validated [TBI] screening instruments accepted for use in clinical practice." The directive furthermore cautioned that screening can lead to positive results due to other postdeployment conditions (eg, PTSD).

The TBI Screening Clinical Reminder is part of the VA Computerized Patient Record System (CPRS) and is designed to be administered to all veteran VHA patients who separated from active duty after September 11, 2001. It embodies a branching pattern of inquiry that first determines whether a previous diagnosis of TBI has been established, and, if not, whether (1) a plausible etiology for a TBI exists (eg, being near an explosion); (2) posttraumatic neurological alterations followed the etiological event; (3) postconcussive symptoms followed the posttraumatic neurological alterations; and (4) postconcussive symptoms persisted into the week preceding the evaluation. Each of these branches (sections) of the clinical reminder is evaluated only if the branch preceding it is true. Positive findings for all 4 branches result in a positive screening result. If the outcome is positive, then follow-up ensues.

A TBI Second Level Evaluation format was recently implemented by VHA. Second-level screening probes in greater detail (a) etiological variables such as number of, types of, and parameters (eg, distance from blast) relating to events predicting TBI severity; (b) neurological sequelae such as number of loss of consciousness episodes, duration of longest loss of consciousness episode, and number of episodes; (c) nondeployment TBI; (d) pain documented as to location and degree of interference with life; and (e) physical exam and medication review. The practitioner signing the related progress note must be a physiatrist, physical medicine and rehabilitation physician, or neurologist who arrives at a final TBI diagnosis.

Traumatic Brain Injury Incidence Among Veterans of Afghanistan and Iraq

Precise numbers describing the burden of TBI among OEF and OIF veterans are not available. Estimates come from a variety of sources. As of September 30, 2007 the Pentagon listed 4471 TBI diagnoses from OEF and OIF.[44] However, this number excludes cases of TBI not initially considered battle injuries. According to the founder of the Congressional Brain Injury Task force, more than 150 000 TBI instances have occurred among approximately 1.5 million OEF/OIF participants.[44]

The rate of those who screened positive on the initial VA TBI Screening Clinical Reminder is 20%.[44] That does not mean all of these patients actually had a TBI. This figure represents those who screened positive for possible TBI, requiring further diagnostic workup which may or may not indicate a TBI. This rate is similar to that seen in at least one VA hospital in North Carolina.

Many TBI sufferers, especially if untreated, may endure medical, behavioral, and social consequences for many years—perhaps even a lifetime.[4,17,24,45,46] It is essential that health care providers in the Department of Defense, VA, and private sectors do their best to identify and appropriately treat TBI among OEF and OIF veterans. **NCMJ**

Dr Jackson is supported by a Merit Review Entry Program (MREP) award from the Department of Veterans Affairs Health Services Research & Development Service (VA grant MRP 05-312). The views expressed in this article are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs.

YOU'VE FLOWN THE FLAG. NOW WHAT?

Since September 11th, 2001, we have all witnessed a powerful resurgence of the American spirit. But patriotism alone is not enough. We must protect ourselves and our families by learning how to be safe and calm in the event of a terrorist attack.

First, make an emergency supply kit. Set aside the supplies you'll need to survive three days at home. You'll need clothes, sleeping bags, nonperishable food and a gallon of water per person, per day. Other items will be helpful too – a flashlight, a battery-powered radio, extra batteries, a first-aid kit and toilet articles.

Second, make a family communications plan. Make sure family members know how to contact each other in an emergency. It may be smart to have everyone call an out-of-state friend or relative. Keep a list of emergency numbers near the phone. Plan how you will evacuate if you are asked to do so.

Third, be informed. In emergencies, planning pays off. If your family knows what to expect, all of you will be calmer in the aftermath of a terrorist event. For details on emergency preparedness, visit our website at www.ready.gov. Or get a free brochure by calling **1-800-BE-READY (1-800-237-3239).**

COMMENTARY

Veterans Health Administration Primary Care-Mental Health Integration Initiative

Edward P. Post, MD, PhD; William W. Van Stone, MD

The Veterans Health Administration has undertaken a large national initiative to integrate primary care and mental health services. A request for proposals was disseminated throughout the Veterans Affairs (VA) system inviting proposals for new programs to promote the effective treatment of common mental health and substance use disorders in the primary care environment. Both individual facilities and Veterans Integrated Service Networks (VISNs) were eligible to apply, and proposals could encompass activities at one or multiple VA facilities. Similarly, facilities within VISNs were free to use different evidence-based models for delivering integrated care. Program funding commenced during fiscal year 2007 (FY07).

The overarching rationale for the initiative is to integrate care for veterans' physical and mental health conditions, improve access and quality of care across the spectrum of illness severity, and allow treatment in mental health specialty settings to focus on persons with more severe mental illnesses.

The report of the President's New Freedom Commission on Mental Health emphasizes that mental health and physical health problems are interrelated components of overall health and are best treated in a coordinated care system.[1] That recognition also is embedded in the VA's Mental Health Strategic Plan and its goal to "[d]evelop a collaborative care model for mental health disorders that elevates mental health care to the same level of urgency/intervention as medical health care."[2]

The important context of integrated care recognizes several facts: primary care provides opportunities to screen for unrecognized disease; mental health and substance abuse conditions are common and are often treated by primary care practitioners; patients may prefer treatment in primary care settings; an established relationship with a primary care practitioner fosters engagement in and adherence to treatment; and health conditions do not always fall neatly into "physical" and "mental health" categories. As former Surgeon General David Satcher said, "Primary care practitioners are a critical link in identifying and addressing mental disorders… Opportunities are missed to improve mental health and general medical outcomes when a mental illness is under-recognized and under-treated in primary care settings."[3]

> *"The report of the President's New Freedom Commission on Mental Health emphasizes that mental health and physical health problems are interrelated components of overall health and are best treated in a coordinated care system."*

Approximately 20% of the 5 million veterans who received VA care in FY05 received mental health services. However, the number of veterans diagnosed with mental health disorders is even greater. While some have complex or severe conditions

Edward P. Post, MD, PhD, is primary care director for primary care-mental health integration at the Veterans Affairs Central Office and staff physician at Ann Arbor Veterans Affairs Healthcare System. Dr Post can be reached at Edward.Post (at) va.gov or 2215 Fuller Road, HSR&D – 11H, Ann Arbor, MI 48105.

William W. Van Stone, MD, is mental health director for primary care-mental health integration at the Veterans Affairs Central Office and associate chief for psychiatry, Office of Mental Health Services. Dr Van Stone can be reached at Bill.VanStone (at) va.gov or 810 Vermont Avenue NW, (116A), Washington, DC 20420.

that require specialty services, others may benefit from receiving mental health treatment in the primary care setting, administered either by primary care practitioners who are given appropriate support or by mental health practitioners based in the primary care environment. Colocated collaborative treatment and care management are two evidence-based models for services that can promote patient engagement in and adherence to treatment and can avoid stigmatization and fragmentation of care. Furthermore, using these models allows providers to facilitate the coordination of care for mental health problems and other medical conditions which can translate into important patient outcomes. For example, one recent trial of an effective 2-year integrated care program for depression among older primary care patients demonstrated reduced all-cause mortality over a 5-year period.[4]

An example of the evidence base for integrated care models within VA is the Primary Care Research in Substance Abuse and Mental Health for Elderly (PRISM-E) study which VA and the Substance Abuse and Mental Health Services Administration (SAMHSA) of the US Department of Health and Human Services undertook to better understand what care delivery systems are effective for managing depression, anxiety disorders, and problem drinking in older primary care patients.[5-7] The PRISM-E randomized controlled trial demonstrated that patients were significantly more likely to engage in mental health services that were integrated with primary care than to follow through on referrals to specialty services. For example, depressed patients in integrated care were 2.86 times more likely to have at least one contact with a mental health specialist than those in referral care.[7] Findings like these led the President's New Freedom Commission to recommend important elements of integrated care such as expanded screening and collaborative care in primary care settings.

While much of the research evidence in this area has focused on depression, there also have been studies demonstrating the efficacy of an integrated approach for anxiety disorders[8-11] and problem drinking.[12-16] Although there is no current evidence demonstrating the effectiveness of this approach for managing patients with posttraumatic stress disorder (PTSD), research is in progress.

Three major categories of integrated care models are being implemented in the Primary Care-Mental Health Integration Initiative: (1) colocated collaborative care; (2) care management; and (3) blended models that incorporate features of the other two.

Colocated collaborative care entails both mental health and primary care practitioners being physically present in the primary care setting with shared responsibility for evaluation, treatment planning, and monitoring outcomes. Episodes of care in this model can vary depending on the needs of the patient, ranging from a referral with a "warm hand-off" to informal consultation with primary care practitioners. A particular example of colocated collaborative care in VA is the White River Model of open access mental health treatment in primary care. This model has demonstrated significant increases in both the proportion of depression screen-positive patients receiving any treatment as well as the proportion of patients receiving guideline-concordant treatment for depression.[17]

Care management models need not be physically located in the primary care setting, but care managers are actively involved in the process of delivering mental health treatment to primary care patients. Nurses constitute a core profession in care management, although social workers and psychologists perform the role of mental health care manager, too. Care managers interact directly with patients, facilitate ongoing evaluation, and maintain active communication that enables responsibility for mental health treatment to remain in the primary care setting. Two examples of care management models in VA are Translating Initiatives for Depression into Effective Solutions (TIDES) and the Behavioral Health Laboratory. The TIDES care management model uses registered nurses to provide guideline-based treatment support and has demonstrated high levels of treatment engagement among depressed primary care patients.[18] The Behavioral Health Laboratory uses a software-based structured assessment for initial evaluation as well as on demand follow-up in support of primary care-based mental health and substance abuse treatment. Its implementation in a primary care setting led to a significant increase in the proportion of patients screening positive for depression as well as identification of substantial numbers of cooccurring mental health disorders and substance misuse.[19]

Finally, blended models combine elements of both care management and colocated, collaborative care. In a blended model, the mental health practitioner evaluates patients and offers psychosocial treatment when preferred or needed while the care manager provides complementary services including education, ongoing assessment, monitoring of adherence, algorithm-based use of medication, and referral management when necessary.

Irrespective of the structural form of the integrated care model, there are standard minimum requirements for the scope and process of services provided under the initiative. Foremost among these is a focus on prevalent conditions in primary care, namely depression, alcohol misuse and abuse, and PTSD. This is in keeping with the overarching rationale of integrated care being a complement rather than a substitute for mental health specialty services. Integrated care programs have an existing foundation upon which to build in that VA already screens primary care patients for depression, alcohol misuse, and PTSD on an ongoing basis. Important required components of evaluation, treatment, and follow-up include the following: risk assessment and appropriate action for suicidality among patients that screen positive for depression and PTSD; watchful waiting for subsyndromal conditions; availability of evidence-based treatments in primary care including brief treatment for problem drinking and pharmacological treatment for major depression; access to evidence-based psychotherapies; and ongoing monitoring for treatment adherence, medication side effects, and clinical outcomes. The fundamental aim of these processes is to support the primary care practitioner in addressing prevalent mental health concerns in a manner that is flexible and convenient for patients as well as centered on a patient's need for disease education and preferences for treatment.

As mentioned previously, the VA Primary Care-Mental Health Integration Initiative is a large national implementation effort presently composed of 92 integrated care programs. The sites for these programs include VA Medical Centers (VAMCs), Community Based Outpatient Clinics (CBOCs), and VISN-level groups of facilities. These sites are implementing diverse models of care including 24 colocated collaborative programs, 19 Behavioral Health Lab programs, 25 care management programs including sites using the TIDES model, and 24 sites with blended models of care. Annualized funding in FY07 was $32 million representing 409 full-time equivalent positions. The program is continuing at a similar level of funding in FY08 and expansion of sites is anticipated in FY09.

In North Carolina there are 3 integrated care programs being funded through this initiative. A blended model consisting of colocated collaborative care and care management is being implemented at the Durham VAMC, the satellite Durham Clinic, and the Raleigh CBOC, which collectively represent a target population of 16 933 unique primary care patients. A similar blended model is also being implemented at primary care clinics in the Fayetteville VAMC serving a target population of 9600 veterans. Finally, the Salisbury VAMC is implementing a colocated collaborative model of integrated care in clinics serving 11 589 unique primary care patients.

The national program office for Primary Care-Mental Health Integration is undertaking a variety of activities in support of field implementation as well as evaluation of this important initiative. Program activities include national conferences attended by both primary care and mental health practitioners; monthly national educational teleconferences; policy development including procedures and tools for workload tracking, clinical utilization tracking, and performance measurement; collaboration on development and dissemination of automated decision supports; and training and technical assistance to field sites. An important example of these activities in FY07 was the development of new performance measures, processes, and tools surrounding evaluation and follow-up of positive screens for depression, PTSD, and alcohol misuse. In particular, performance measures are in place for FY08 to track whether practitioners are following up on PHQ-2 screening for depression with a PHQ-9, risk assessment for suicidality, and pertinent clinical evaluation and follow-up of these assessments; pertinent clinical evaluation and follow-up of PC-PTSD screening for posttraumatic stress disorder including risk assessment for suicidality; and follow-up of AUDIT-C screening for alcohol misuse and abuse with appropriate patient-specific counseling and follow-up.

Finally, the national program office is actively collaborating with the Serious Mental Illness Treatment Research and Evaluation Center at the Ann Arbor VAMC to develop ongoing program evaluation of primary care-mental health integration. The major goals of this evaluation are (1) to assess the extent to which integrated care programs have been implemented across the VA system; (2) to assess patient-level access to care, receipt of services, and disease-specific outcomes; and (3) to determine what factors contribute to differences in mental health-related access and quality of care including variation related to specific integrated care models, model fidelity, and other site-specific program characteristics. This evaluation effort includes so-called formative evaluation components that will enable targeting of specific areas for attention. Ongoing availability of information from the evaluation team will greatly assist the program office in its overall goal of continuous quality improvement for veterans with mental health conditions by maximizing the successful implementation of integrated care programs throughout the VA system. **NCMJ**

COMMENTARY

Integrating Primary Care and Mental Health in the Army

Michael T. Latzka, MD, LTC, MC

Fifteen months ago, a family from the 82nd Airborne Division said their goodbyes from their North Carolina home at Fort Bragg. They weren't moving to another state, and they weren't moving together. Their goodbyes were to each other as one member of that family was going to war nearly halfway around the world. This was not just an isolated incident but a scene repeated thousands of times on military parade fields and in home front yards across the state of North Carolina. It has become a familiar scene in the years since September 11, 2001. Life has changed for everybody since that eventful day, but it has especially changed for the soldiers and families stationed at Fort Bragg, North Carolina.

Fort Bragg is one of the largest and busiest posts in the United States Army. Its lead position on the Global War on Terrorism has produced great sacrifice from the soldiers on the front lines and from the families at the home front. These sacrifices can be measured in dollar costs, time away, and in lives lost, but they can not be so easily measured by the numerous stressors on the families or the soldiers who have deployed to combat. Soldiers and families must cope with a wide variety of stressors which may manifest themselves in problematic behaviors. One study that did identify a response by soldiers to the stressors of combat showed a need for greater access to mental health resources within the military.[1] In response to this need, the Fort Bragg medical system has taken the lead to battle against these stressors by becoming a center of excellence for the recognition and treatment of depression and posttraumatic stress disorder (PTSD) in the military.

> *"Fort Bragg is one of the largest and busiest posts in the United States Army. Its lead position on the Global War on Terrorism has produced great sacrifice from the soldiers on the front lines and from the families at the home front."*

RESPECT-MIL (Re-engineering Systems of the Primary Care Treatment of Depression and PTSD in the Military) is a carefully-designed system that helps identify and treat soldiers who may have depression or PTSD. It was first developed for civilian practices with a primary care emphasis to better identify and treat depression.[2] The system uses a 3-component model (see Figure 1) and works when a well-prepared primary care practice teams up with a nurse care facilitator and a behavioral health professional. The nurse care facilitator and behavioral health professional facilitate the care of patients who have been identified with depression and are being treated by a primary care practitioner. Implementation begins when primary care and behavioral health champions lead a 3-hour training session for clinicians and administrative staff. Nurse care facilitators complete 2 days of training and then continue ongoing training as they interact with their initial patients. Champions use academic detailing and case-based "lunch and learns" to reinforce concepts. The core elements of the 3-component model are (1) routine screening for depression and PTSD; (2) diagnostic assessment with structured questionnaires for all those screening positive; (3) patient engagement, education, and eliciting treatment preferences; (4) proactive follow-up by the primary care clinician and RESPECT care facilitator; and (5) enhanced support by a mental health specialist through supervision of the

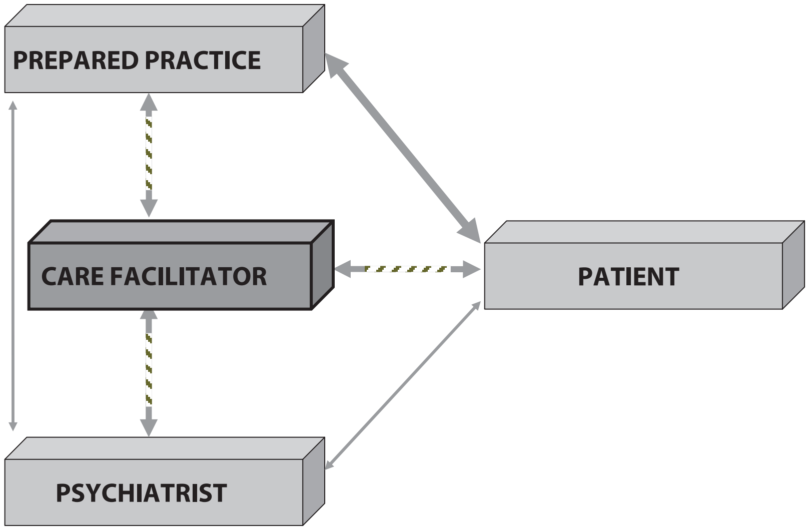
Michael T. Latzka, MD, LTC, MC, is program family medicine proponent for the Center for Excellence Group at Fort Bragg. Dr Latzka can be reached at michael.t.latzka (at) us.army.mil or Building C-1722, Fort Bragg, NC 28310.

Figure 1.
Components of the RESPECT-Mil Model



care facilitator and availability for curbside consultation. (See Box 1.) Patients with complicated illnesses (eg, significant suicide risk) or who prefer specialty care are referred to mental health providers. For patients treated in primary care, the care facilitator reinforces the primary care clinician's treatment plan through telephone follow-up that addresses treatment adherence, self-management goals, and symptom response using structured questionnaires. The care manager is supervised by a psychiatrist and communicates any recommendations for management changes to the primary care clinician. This proactive treatment model increases the intensity of follow-up (see Figure 2) and has been demonstrated to increase guideline concordant care for depression and improve patient outcomes.[3] Because of its success in the civilian community, key leaders in the Army medical department put together a study at Fort Bragg to assess the model's feasibility within the military health care system.[4]

Box 1.
RESPECT-Mil Care Processes

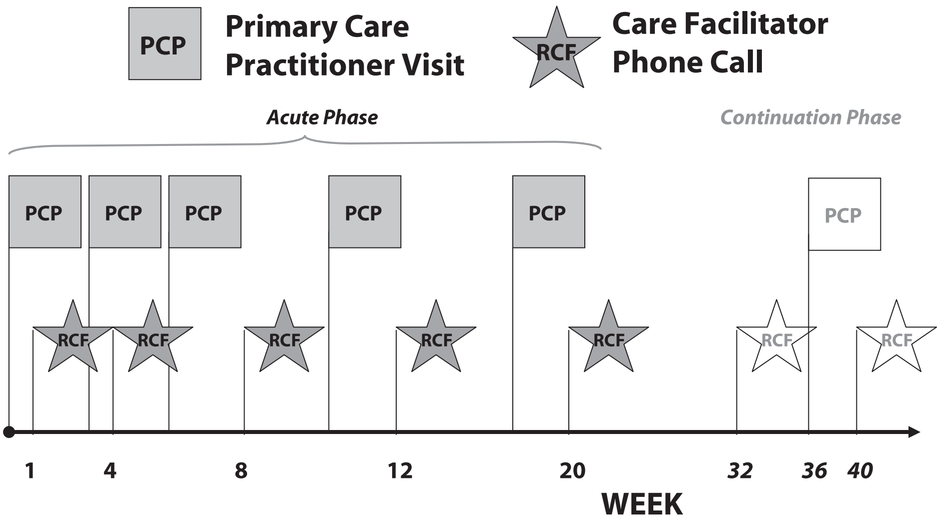
- Routine Screening
    - On arrival at sick call medic/nurse screens patient for depression and posttraumatic stress disorder as part of measuring vital signs
- Assessing Screen Positives
    - Screen positives complete PHQ-9 depression questionnaire and posttraumatic stress disorder checklist to guide diagnosis
    - Primary care providers score and complete diagnosis
- Treat Those With a Potential Diagnoses
    - Assess suicide risk
    - Elicit relevant history
    - Share diagnosis with patient, offer treatment and referral to care facilitator
- Systematic Follow-Up
    - Primary care continues to manage
    - Care facilitator provides additional telephone follow-up
    - Communication and treatment advice by team psychiatrist

The adaptation of the civilian model to one in the military included the addition of a screen for PTSD in response to the needs apparent in this important population. Another important modification was to mandate evaluation by a mental health specialist for any solider in treatment who had an upcoming deployment. This evaluation is an extra measure of safety for deploying soldiers.

In February of 2007, the first clinic at Fort Bragg began full implementation of RESPECT-MIL to include complete screening of all soldiers enrolled in General Roscoe Robinson Health Clinic, which serves soldiers and families of the 82nd Airborne Division. The soldier population for this one clinic alone is approximately 17 000. Since the beginning of February 2007, nearly three-quarters of all soldiers visiting the Robinson Health Clinic have been screened for depression and PTSD. Of the entire population of soldiers screened, just under 20% screened positive for either depression or PTSD. Of those soldiers who screened positive, roughly one-third were false positives and another one-third were already being treated for their depression or PTSD within the military behavioral health care system. The final one-third of those positive screens were newly identified depressive disorder or PTSD. About half of the soldiers chose to participate in RESPECT-MIL while the other half went to behavioral health. Only a small percentage chose no referral at all.

The RESPECT-MIL care model involves a paradigm shift from one clinician-one patient interactions to a team care model that features telephone follow-up and evaluation. It also requires a change in cultures from one where medical and mental health services are delivered relatively independently to one involving greater collaboration. Because these represent important changes in medical care delivery, we typically begin implementation with small-scale pilots (eg, the most highly motivated clinicians in a care site) and then gradually expand to involve more clinicians and more clinical sites at the base. These implementation challenges are quite similar to those seen in the private sector. Challenges that may be unique to the military include a highly mobile patient population, highly mobile clinical staff, and primary care services designed more for acute rather than longitudinal care. We have dealt with these later challenges

Figure 2.
Typical Frequency of Patient Contacts



in part by developing a greater capacity for ongoing training of new staff.

This initial experience to date has been very valuable. It has allowed for a process improvement within a military primary care clinic where a systematic approach to behavioral health needs is being addressed and is also becoming a part of the routine health care approach and culture of care at Robinson Health Clinic. It has also spread to 3 other clinics at Fort Bragg and beyond the state of North Carolina to other sites within the Army medical department as they begin to implement RESPECT-MIL. As part of this initial roll-out we plan to implement the program at 15 Army posts, including 3 in Europe. We have seen the valuable contribution of a nurse care facilitator expand the ability for primary care practitioners to treat depression and PTSD in such a way that more nurse care facilitators are being hired to meet the demand. Primary care practitioners initially concerned about the increased workload are now providing positive anecdotes about their improved ability to identify and care for depression and PTSD in soldiers. The result is that after 15 months of being in combat soldiers are returning home to their families in North Carolina, and they are also returning to a medical community that is improving its ability to help them deal with some of their health needs. In this way we can begin to address their needs and build a better military family right here at home. **NCMJ**

COMMENTARY

The Citizen Soldier Support Program:
Building Bridges Between Communities and Military Families

Steven R. Moore, RPh, MPH, FRSH, FASHP, CPHP

Citizen soldiers live across the nation, and they can be found in most local communities. In North Carolina, they are members of the North Carolina National Guard and the Military Reserves. The National Guard Armory has long been a local institution known to most citizens and readily recognized as a critical part of community structure. The needs of deployed Guard members and reservists and their families are unique and differ from those of active duty military forces. Active duty forces are primarily clustered around established military installations that usually house a wide variety of services and support networks for both the soldier and the affected family. Guard members or reservists often live far away from a military installation. Traditionally they train on selected weekends and on short tours of duty for extended training during the summer. As the concept and needs of the total military force have changed, these citizen soldiers are now being deployed for extended tours of duty, and the impact of their service upon themselves, their families, and their communities has dramatically changed.

Guard members and reservists are located in every North Carolina county, and families are routinely familiar with the short tours of duty required of Guard members or reservists in the past. When the citizen soldier is deployed, however, for an extended period of time, his or her family becomes an active military family. When faced with the active long-term deployment of a significant family member, the remaining family members must cope with a wide variety of new and unique circumstances that many had not planned for and which many may find quite daunting. Among these changes are issues affecting their health. Military families may have greater and very different health care needs compared to the general population. Nonetheless the families of Guard members and reservists still must largely acquire care in the local community. This may be challenging for both families and community providers who may not be ready to serve this population. Nonetheless the overall impact of having a deployed family member can dramatically impact the family's health.

Introduction to the Citizen-Soldier Support Program

The Citizen-Soldier Support Program is a federally-funded, national demonstration program whose mission is to mobilize and engage communities to support service members of the National Guard and Military Reserves and their families before, during, and after mobilization and deployment. The Citizen-Soldier Support Program is in its third year of operation and is rapidly moving toward implementing a variety of best practices and lessons learned in its first 2 years of operation.

As a demonstration project, the Citizen-Soldier Support Program and its products need to be readily reproducible across

> *"Community capacity is needed to adequately support citizen soldiers and their families in an effort to (1) strengthen them; (2) provide them with economic security; and (3) develop family-community connections."*

Steven R. Moore, RPh, MPH, FRSH, FASHP, CPHP, Citizen Soldier Support Program, Odum Institute for Research in Social Science, and adjunct assistant professor, School of Pharmacy, the University of North Carolina at Chapel Hill. He can be reached at mooresr (at) email.unc.edu.

North Carolina as well as in other states. Although the Citizen-Soldier Support Program in its early stages sought to develop direct community resources and show the impact there, it quickly became evident that these local models simply were economically unfeasible for real world duplication. In its current activities, the Citizen-Soldier Support Program is seeking to target its resources into larger models that impact systems and thus have a far greater potential benefit for communities and individual families.

With critical and targeted input from its National Advisory Committee, a strategic planning effort was undertaken, and the Citizen-Soldier Support Program is working to move forward on a number of targeted programs. Although these programs may impact a wide variety of family and community support activities, a number directly impact the health care status of citizen soldiers, their families, and their communities.

One area of health most dramatically impacted by deployment is mental health. Health concerns may be as subtle as the depression or anxiety of family members or as dramatic as the posttraumatic stress disorder (PTSD) or traumatic brain injury (TBI) of the returning soldier. The Governor's Focus on Returning Combat Veterans and Their Families is a statewide effort focusing on the mental health of returning soldiers. Building upon and cooperating with this effort, the Citizen-Soldier Support Program has brought together a number of varied specialists to form a steering committee to focus the joint efforts of all concerned stakeholders. The group includes representatives of the North Carolina National Guard and Military Reserves, Veterans Administration, state government, private medical practitioners, and a variety of other social support parties. Stakeholders hope to coordinate their efforts to address the mental health needs of returning combat veterans and their families. The group is intensely seeking to identify the geographic distribution of the state's mental health practitioners and then segment this population according to those who are in the TRICARE system (the Department of Defense managed health care program) and those who are not. Mental health problems may not be strictly managed through military health care, thus the continuum of mental health services including the Veterans Administration and the civilian sector are integral to serving the needs of returning soldiers and their families. A final comprehensive report on addressing this problem is forthcoming in early 2008.

Citizen Soldier Support Program Health Initiatives

The Citizen-Soldier Support Program has planned multiple initiatives. First, a training effort piloted through the Area Health Education Centers (AHEC) program seeks to provide targeted exposure to community-based medical practitioners on how to assess and treat specific problems experienced by citizen soldiers and where to refer them for additional care. Following the initial training and evaluation of this pilot project in the Coastal AHEC in January, similar efforts will be designed for other regions in the state. The goal is to export this model to similar practitioner training programs in other states as well. The Coastal AHEC training efforts target 2 groups of practitioners. An evening session targets primary care practitioners, especially family physicians, and focuses on the unique nature of the military experience and the impact of these experiences on mental health, especially PTSD. A full-day session targets the whole range of mental health professionals and presents the military perspective and its impact on mental health but also highlights aspects of assessment, clinical practice guidelines, and treatment interventions. Both programs provide attendees with a better understanding of TRICARE and how it can be used by practitioners to assist military health care coverage.

Second, a community-based health delivery model using mental health personnel in a largely rural area is being developed through the Mountain AHEC. The effort seeks to establish a real-world model that can be sustainable and effective where mental health practitioners are in short or limited supply. During the first year Haywood County will be provided psychiatric physician extenders to support community-based physicians in addressing mental health issues for the full range of military personnel, veterans, and their families. In addition to the services of psychiatric nurse practitioners and social workers, comprehensive medication management services also are being provided. The program will be expanded to Clay and Jackson counties over the next 2 years. It is hoped that the community-based effort will be effective in addressing the variety of military/veteran family community needs and can be made sustainable when properly implemented. When developed and evaluated, the exportable components of this effort will be publicly available.

Furthermore, expanded access to online AHEC resources will seek to increase the readily available information for both practitioners and concerned beneficiaries. Specific material related to military and mental health issues will be available through the AHEC Digital Library. The AHEC Digital Library provides access to military mental health information for practitioners[1] right in their own home communities. This freely available collection includes links to information on mental health aspects of amputation, deployment, depression, posttraumatic stress disorder, substance abuse, trauma, and traumatic brain injury as well as preformulated searches of the medical literature on pertinent topics, patient education materials, and information for practitioners who treat children.

Additionally, NC HealthInfo, a collection of links for health providers, services, and programs across the state, offers access to expanded information on health topics, military health care, veteran health care, and other related topics.[2] Individuals can access a series of medical and health topics and even locate local resources that provide these services. A special section devoted to military and family health concerns and issues was developed in collaboration with the Citizen-Soldier Support Program.[3] Soldiers and family members will find reliable information on amputation, deployment, traumatic brain disorder, and substance abuse. As a component of this effort, additional resources will help beneficiaries and practitioners understand TRICARE and increase their capability to enroll or utilize its services as well as navigate through the military health care system. The Citizen-Soldier Support Program Web site will also be expanding content to provide greater information on TRICARE for practitioners and streamlining practitioner enrollment in TRICARE.

Other Citizen-Soldier Support Program Initiatives

The Citizen-Soldier Support Program has undertaken several other community initiatives. It developed an Adopt-a-Soldier/Family model connecting reservists to a local faith/civic community organization. Working with the 108th Army Reserve Division in Charlotte as it expands its command responsibility from a regional to a national platform, our efforts will help to integrate adopt-a-soldier/family efforts into a comprehensive national Family Readiness Program for all Reserve members and their families.

In an effort to integrate its family support services across all active, Guard, and Reserve components and to ensure consistent delivery of quality services to all personnel regardless of component, the Citizen-Soldier Support Program was invited to develop a curriculum to train Army family service personnel in community engagement and capacity building. This will hopefully be utilized in a Chapel Hill-based national training institute which will provide this resource on an ongoing basis.

The Citizen-Soldier Support Program developed a statewide partnership to promote and deliver lower cost or pro bono legal services for Guard and Reserve families. Individuals from the North Carolina State Bar, military legal personnel, state law schools, and legal aid are working to develop mechanisms to provide needed support to citizen soldier families where deficiencies and needs exist.

Lastly, the Citizen-Soldier Support Program created community scorecards to assist communities in understanding how best to interact with citizen soldiers and to recognize those communities which are exceptional in this effort. Community capacity is needed to adequately support citizen soldiers and their families in an effort to (1) strengthen them; (2) provide them with economic security; and (3) develop family-community connections. The process will include developing critical community services (eg, child care, respite care, housing, economic stability services) and evaluating their effectiveness in the community. This effort will help communities understand both what works and what needs improvement. The ability to recognize communities who have done an outstanding effort in citizen soldier support also will be developed.

Conclusion

The Citizen-Soldier Support Program is a demonstration program and, as such, through a trial and evaluation process, we have established several efforts that can both be effective for those initially impacted as well as suitable for replication in other geographic locations. Within whatever continuum that impacts citizen soldiers, their families, and their communities, health care and its unique attributes are certainly critical. Local practitioners may experience problems adapting to this new community need, but understanding military health care is essential. Participating in the TRICARE delivery network may be new and daunting but also may be necessary. The geographical realities of widely dispersed individuals who often lack local peers experiencing the same situations, the challenges of blending existing health care and insurance within the TRICARE parameters, the lack of specialized medical practitioners in this widely dispersed geographical distribution, and the challenge of a new and changing social system that has direct impact upon the health of all involved—these are the challenges facing our citizen soldiers, their families, and our communities including our health care practitioners. The Citizen-Soldier Support Program stands ready to support this challenge and provide the coordination required to ensure that the difficult aspects of these challenges are minimized. **NCMJ**

COMMENTARY

Military Families:
Opportunities and Challenges

Denisse Marion-Landais Ambler, MD

North Carolina is home to the fourth largest concentration of active duty military personnel (101 563) in the continental United States[1] as well as substantial numbers of National Guard and Reserve members. Of the active-duty component, 37% are married with children, and 6% are single parents. Of the reserve component, 34% are married with children, and 8% are single parents. There are an estimated 96 000 military children in North Carolina.[2] More than 12 000 of North Carolina's military personnel have been mobilized and over 3000 are actively deployed.[3] The mobilization and movement of so many spouses, fathers, and mothers has an enormous impact on the families they leave behind.

> *"Understanding the experiences of the injured veteran and his or her family is a critical component of healing."*

Military families have always faced unique challenges and opportunities. Answering the call to serve the greater interests of country require members of the military to sacrifice the personal duties to family. Military family members also make great sacrifices. For the active-duty family, frequent changes in duty station are a way of life that requires concomitant changes in schools, friends, and support systems. The Military Child Education Coalition™ reports that a military child moves an average of every 2.9 years which may be 3 times more than his or her civilian peers.[4] Parent-child separations are common as one or both active duty parents leave on tours of duty. For those in the reserve component, the traditional commitment of a monthly weekend with short-term annual training no longer prevails. The wars in Iraq and Afghanistan have brought new obligations for all service members. Prolonged separations have become the norm, and repeated tours of duty to combat zones have created unpredictability for the military family. Some families have seen a loved one leave for a third or fourth tour.

For as long as there has been war, there have been loved ones waiting for the warriors to return home. Military families, like all families, come in various shapes and sizes. Given that approximately 15% of service members are female,[5] it is not always the mother who is left to handle the homefront. Single parents and dual military couples must have Family Care Plans in place that indicate how dependents will be cared for in the case of deployment. Grandparents, extended family, and sometimes even nonbiological relatives become a part of the family as they assume care of children during parental deployments. Most military support systems for families on the home front are oriented toward "military dependents" and particularly female spouses and children; those not fitting this demographic can face additional isolation. Military dependents are defined as the spouse or servicemember's children who are unmarried and under 21 years or who are incapable of self-support due to physical or mental limitations, dependent parents, and similarly dependent brothers or sisters. Family members such as grandparents or aunts and uncles who are not captured under the definition of military dependent are less likely to be familiar with the resources available to them and thus less likely to use them.

Additionally, during deployment some families choose to move closer to other support systems such as extended family, which may entail a move to another city or even state. Such a move may mean a change in school, employment, and established health care resources. It may also separate the family further from the service member's home unit and his or her Family Readiness Group. A Family Readiness Group is the family's official communication network with other military families

Denisse Marion-Landais Ambler, MD, is a subject matter specialist for Mental Health for the Citizen-Soldier Support Program, adjunct assistant professor in the Department of Psychiatry, the University of North Carolina at Chapel Hill School of Medicine, and in private practice at North Carolina Neuropsychiatry, PA in Chapel Hill. Dr Ambler can be reached at dambler (at) ncneuropsych.com or 400 Franklin Square, 1829 East Franklin Street, Chapel Hill, NC 27514.

which offers them mutual support. Family Readiness Groups also provide opportunities to share lessons learned in regards to available community resources that may or may not be present in other areas.

Being part of a military family does have advantages. By definition, one family member is employed and has access to health care resources. If the service member is part of the active duty component, there may be additional advantages such as housing assistance through government housing or a basic allowance for housing. Schools and day care are often available on base as well as access to a health care system. However, for those in the reserve component, families often do not have such military services readily available to them. Reserve component families are more likely to use their local community services and supports, particularly if they live far from a base. Given that there are service members in all 100 North Carolina counties, most civilian health care practitioners are likely to have at least one military family in their practice. Spouses who move closer to extended family (and away from military installations) during a family member's deployment may face changes in their health care services. Changing between civilian health coverage and the TRICARE system can mean a change in providers and a disruption of continuity of care at an already stressful time.

Of the many challenges faced by military families, the most daunting and obvious is that a loved one is deployed to a war zone. Rentz et al[6] examined changes in the occurrence of child maltreatment in military families and the impact of deployment increases in the period 2000-2003. The rate of maltreatment in military families after the September 11, 2001 attacks was twice as high as in the period preceding that date. This article pointed to the stress of deployment and reintegration (and the risk thereof) as the likely culprit. Gibbs et al[7] also found greater rates of substantiated child maltreatment among families of enlisted (noncommissioned) soldiers in the US Army when the soldiers were on combat-related deployments. Junior enlisted families are often among the youngest families and those who commensurately receive the least compensation, factors that are known to place civilian families at risk for domestic violence. It is important to note that entry into the military maltreatment referral process tends to be more sensitive than entry into civilian child protective services. This is because families live on base among those with whom the service member works and this allows for multiple points of observation and identification of a domestic violence situation. These articles, however, did not explore the effects of deployment on the reserve population or nonspouse caretaker referrals, populations which may in fact have fewer formal supports during a deployment.

There is no denying that war itself is a stressor. The service member undergoes physical and mental changes that allow him or her to survive living in a war zone. These adaptations are vital to mission readiness. The service member's family goes through changes during deployment as well. The wars in Iraq and Afghanistan have brought both reminders of lessons learned in past conflicts as well as new understandings of these challenges. The knowledge gained from the Mental Health Advisory Team reports, real-time assessments of behavioral health benchmarks, and treatment in-theater is allowing real-time adjustments in combat stress treatment protocols. Advances in battlefield medicine are saving many from previously lethal injuries. However, some veterans will return with mental and physical injuries. Some will not return at all. All will have experienced some change. Their families have changed and grown in their absence as well.

Children as a whole are thought to be quite resilient when facing the deployment of a parent, but data from the present conflicts must be collected to evaluate their health and needs. Deployments cause stress on the entire family unit. Pediatricians and other primary care practitioners have the opportunity to explore the effects of deployment on the individual and family. The well-being of the parent who remains at home often directly impacts the response of the children. This observation appears to be particularly meaningful for the youngest children. Children of latency age have an increased verbal ability that allows for greater understanding and discussion of a parent's absence due to trainings and deployment. A wide range of reactionary behaviors may be seen from regressions in development (eg, bedwetting, resumption of thumb sucking) to attempts at mastery (eg, initiating a school project for veterans). Teenagers may display various responses as well, ranging from the young person who takes on many of the deployed parent's responsibilities to the adolescent who develops acting out behaviors. Maintaining routines helps to provide stability for children. Remaining connected to the deployed loved one is important also. The use of the Internet and text messaging has made this interaction more possible than ever before. The availability of these technologies also has added a new dimension because service members may feel more compelled to parent from the warzone in real time.[8] At the same time as technology allows for connections, it should be closely monitored as media exposure of war can add to families' anxieties.

Families also adapt as the deployed service member reintegrates into the family. Reestablishment of routines and parental and spousal roles can take time. Patience is always required. When a family member returns with injuries the reintegration into family life may be complicated. When a parent returns with psychiatric trauma the family, spouse and children, can also be profoundly affected. The loss of a parent is undoubtedly life-alerting. There is little research to date on these aspects of the wars in Iraq and Afghanistan, but the long-term effects on families and children of service members will perhaps be one of these conflicts' greatest legacies.

In recent years there has been an explosion of information and services, both nationally and in North Carolina, directed toward support of our military families. National efforts such as the SOFAR project and Zero to Five target children of deployed parents. The American Academy of Pediatrics has compiled a list of resources to help military families with special needs children find medical homes. Various other national and state by state programs are evolving to meet the needs of military families.

In North Carolina, the Citizen-Solider Support Program is an effort established by Congress and spearheaded by the

Odum Institute at the University of North Carolina at Chapel Hill (UNC-Chapel Hill). Created to build bridges between local community resources and military families, the program focuses especially on the needs of National Guard and other Reserve component members and their families. The Governor's Focus on Returning Combat Veterans and their Families is a partnership between the state and the federal government, community practitioners, and community programs that addresses the mental health and substance abuse needs of North Carolina's veterans and their families. This year, North Carolina also became host to the nation's first statewide "Living in the New Normal: Supporting Children Through Trauma and Loss" initiative, which brought together more than 100 representatives of government, business, education, health agencies, and faith-based organizations at a Public Engagement Workshop held in Raleigh as a part of the new statewide initiative created by the Military Child Education Coalition.™[2]

At this point, the abundance of information but lack of clear direction in locating available resources stymies many families. One effort designed to guide families through the system is NC Health Info (www.nchealthinfo.org), a special Internet portal based at the Health Sciences Library at UNC-Chapel Hill. NC Health Info contains a collection of consumer health information with an easy-to-use mental health information area for military members and their families. It also has a specific portal for professional primary care and mental health providers containing comprehensive coverage of military-related mental health topics and best practice information. NC Health Info was the first "Go Local" Web site which was created and developed by librarians at the UNC-Chapel Hill Health Sciences Library to provide access to information about local health services combined with reliable health information provided by MedlinePlus, the National Library of Medicine's consumer health site. It serves as a model for more than 25 other state and regional health-information sites.[9]

As our veterans return there will be numerous opportunities to assist them as they traverse the divide between civilian and military life. The biggest barrier to meeting the needs of military families is the shortage of civilian practitioners who have an understanding of the challenges facing military families. Knowing how deployment and reintegration affects families allows practitioners to identify when additional help is warranted. Understanding the experiences of the injured veteran and his or her family is a critical component of healing. The North Carolina AHEC Digital Library is a welcome resource for the practicing clinician interested in becoming more knowledgeable about the specific needs of military members and their loved ones. All North Carolina health professionals are eligible for membership in the AHEC Digital Library, a unique digital system that supports health professionals by providing a single, customized, web-based interface into health information resources and services. The AHEC Digital Library supports the delivery of quality, evidence-based health care across North Carolina and ensures that even in rural underserved areas of the state providers have access to the current information and resources necessary to provide quality care.[10]

Most military families wish only for an acknowledgement of their sacrifices. The call to duty has come for many of our neighbors here in North Carolina. Those of you who live near one of our military bases may be familiar with the sacrifices made by our country's service members and their families. Others may not realize that a neighbor gives service as part of the Reserve component. Sensitivity to the new stressors soldiers and families face during mobilization and deployment is important. Practical assistance is required for spouses adjusting to the functional roles as a single parent. Social and emotional needs of the children of deployed parents must be addressed. Military families often rely on civilian supports, particularly if the family is not located near a base and/or service members are on their initial deployments. North Carolina medical professionals have the opportunity to provide care for military family members right now. The challenge is to take the opportunity. **NCMJ**

Pitt County Health Sciences Academy

Diane Poole; Randy Collier; Nettie Evans, RN, MSN; Janice Faulkner; Michael Priddy, PhD; and Janet Knox

In 2001 the University Health Systems of Eastern Carolina and its flagship 745-bed tertiary care center, Pitt County Memorial Hospital, were experiencing workforce shortages resulting in closed beds and subsequent service delays. Projections of a forthcoming health care workforce crisis propelled the health system to develop new strategies to address this issue. Workforce development became an organizational priority to assure that the 1.2 million citizens in its catchment area could have timely access to its tertiary care services.

A partnership was established that included University Health Systems of Eastern Carolina, East Carolina University and Brody School of Medicine, Pitt Community College, Eastern Area Health Education Center, Greenville-Pitt Chamber of Commerce, and Pitt County Schools. The partners shared a common belief that low student academic achievement was one of the largest barriers to resolving the health workforce shortage in eastern North Carolina. They agreed that investing in local students who desired to live and make a difference in the region could serve to promote economic development through increased opportunities for stable, good paying jobs while concurrently addressing the University Health Systems' workforce demands.

To respond to the needs and to take advantage of the resources available to the system, the Pitt County Health Sciences Academy was developed. With financial support from The Duke Endowment and the creative and committed leadership of this unique partnership, the Academy opened its virtual door to high school freshmen in the fall of 2003 and evolved as a broad-based, far-reaching strategy to create systemic change by improving students' academic strengths in math, science, and reading comprehension. The Academy is a high school enhanced curriculum, a school-within-a-school model, that provides 4-year health career pathways (academic and health sciences elective courses) for students pursuing health care-related careers after graduation. The Academy partners with Pitt Community College and East Carolina University's Brody School of Medicine to provide academic opportunities beyond the standard high school curriculum. Its goal was to produce students with increased academic knowledge and skills combined with an awareness of health career options. Emphasis was placed on the math, science, technology, reading, and critical thinking skills required for successful admission and completion of rigorous college or university health sciences coursework.

The first 4-year class of 51 students graduated in May 2007, and a total of 110 students have graduated since 2005. Thirty former high school participants have already entered the part-time workforce of Pitt County Memorial Hospital while pursuing health careers in colleges and universities. The program conducted 1- and 2-year follow-up studies of the graduates and found that 93% are pursuing health-related occupations.

The program has learned along the way that it can be more intensive and key modifications made to Pitt County Health Sciences Academy since its inception include opening its enhanced curriculum to all students, realigning its cohort to meet accountability standards, implementing an early college track, and enhancing early employment options such as internships and pharmacy technician certifications. In the future it plans to expand the early college option, consolidate the academy into a single facility, and explore aligning it with a regional math and science high school.

The partnership recognizes that the success of this endeavor can be expanded and continued. The program looks forward to continuing its task of expanding the academic achievement and interest in health careers of regional students.

Diane Poole is executive vice president, Pitt County Memorial Hospital.

Randy Collier is retired Pitt County Health Sciences Academy director.

Nettie Evans, RN, MSN, is vice president, Patient Care Services, Roanoke Chowan Hospital, University Health Systems and former director, Health Careers, Pitt County Memorial Hospital.

Janice Faulkner is a community volunteer, former North Carolina Secretary of State.

Michael Priddy, EdD, is former superintendent, Pitt County Schools.

Janet Knox is current administrator, Pitt County Health Sciences Academy. Ms Knox can be reached at jknox (at) pitt.k12.nc.us or 1717 West Fifth Street, Greenville, NC 27834.

Spotlight on the Safety Net

A Community Collaboration

Kimberly M. Alexander-Bratcher, MPH

Durham Veterans Affairs Medical Center

The Veterans Health Administration (VHA) provides health care to servicemen and women honorably discharged from the military. Health care is provided on a priority system. Veterans with injuries related to the current conflicts receive first priority. Priority is next given to veterans based on the magnitude of their disabilities. The Veterans Health Administration also provides health care services for nonservice-related health issues based on availability and it offers a safety net program for low-income veterans. The safety net services are provided based on the available capacity of needed health services and on the patient's income. The VHA offers 5 specific safety net programs for low-income veterans: Home Based Primary Care, Care Coordination Home Telehealth, Contract Nursing Home, Compensated Work Therapy, and Health Care for Homeless Veterans. These programs are provided through the 4 Veterans Affairs Medical Centers (VAMCs) in North Carolina located in Asheville, Durham, Fayetteville, and Salisbury.

The Home Based Primary Care program provides a safety net for veterans between hospital discharge and Medicare coverage. A multidisciplinary team including the primary care physician, psychologist, social worker, nutritionist, dietician, and pharmacist provides care in the patient's home. The average patient is 77 years old and has some cognitive deficit. Many of the program's patients would be in nursing homes without the availability of the program. The length of stay in the program may be a few months, many years, or the remainder of a veteran's life. The program simply requires that the veteran be in need of home care and have a referral from a primary care provider in the VA system. The Durham VAMC provides this program to veterans within a 35-mile radius of the center. Other programs operate in Asheville and Salisbury with plans to expand to Fayetteville, Greenville, Morehead City, and Raleigh.

The Care Coordination Home Telehealth program provides distance care management for veterans with chronic progressive health problems including diabetes, hypertension, heart failure, and chronic obstructive pulmonary diseases (COPD). The program connects patients with a care coordinator to help them avoid emergency rooms visits and serves as the eyes and ears of the patient's physician. Monitors are placed in patients' homes that allow them to measure and input health data including heart rate, blood pressure, blood sugar, and oxygen saturation. The patients and their caregivers receive training on the monitors which ask a series of customized symptom questions. Patients may be connected directly to the measuring devices or patients or caregivers can input the data. The data are transmitted through telephone lines to the care coordinator and are then stratified by patient risk so that those with abnormal values are helped first.

Patients in the program are referred by their providers and must have a targeted condition, take 10 or more medications, have been hospitalized or visited an emergency room in the past 2 years, and be able to operate the monitor or have a caregiver who can operate the monitor. Patients range in age from 20 to 90 years in age. Since the program's inception in the Durham VAMC in August 2005, 550 veterans have been served. There are currently 356 active program participants. On a sample of program participants during a 7-month period, the program achieved a 65% reduction in days in a hospital bed, a 59% reduction in patient admissions, and a 54% reduction in patient visits. Future plans include expanding the program to include posttraumatic stress and substance abuse disorders.

The Contract Nursing Home program provides long-term care for veterans on the basis of need without regard to their priority status. Those with 70% to 100% disability receive paid nursing home care, long-term care, or home care programs. These home care programs include home health aids, adult day health care,

continued on page 66

continued from page 65

and noninstitutional respite care. The Veterans Health Administration pays North Carolina's veterans' homes, located in Salisbury and Fayetteville, a stipend for each enrolled veteran. Veterans themselves may also receive payment in the form of compensation for military service-related conditions, pensions for conditions not related to military service, or Aid in Attendance funds for homebound veterans to receive care for daily living activities. Most of these veterans can receive care for free in a VAMC or satellite clinic. The program provides access to primary care, allied health, and other health care practitioners. The program has served more than 450 veterans since fiscal year 2006.

The Compensated Work Therapy program attempts to successfully reintegrate disabled veterans into the community through access to meaningful vocational opportunities aligned with the veteran's highest functional level. The program supports the idea that all veterans have potential for rehabilitation and focuses on recovery of a quality of life with which each veteran is comfortable. The program works with clinics and organizations across the Triangle including Duke University, the Employment Security Commission, the University of North Carolina (UNC) at Chapel Hill, North Carolina Vocational Rehabilitation, state agencies, and various private sector companies. It offers supported employment which specializes in working with veterans with severe mental illnesses, transitional work experience open to all veterans with any level of disability, and incentive therapy which caters to lower functioning veterans. A recently implemented program, Compensated Work Therapy served 45 veterans between August and November of 2007.

Health Care for Homeless Veterans provides health care (medical, mental, and dental), transitional housing, and special events for homeless veterans. The program helps homeless veterans establish a primary care home in a VAMC or satellite clinic. The program has a grant-in-per-diem program for transitional housing that will pay the community for transitional housing for up to 2 years. Currently, there is a partnership with Volunteers of America to build 24 housing units in Durham. Other facilities include Healing with Care, a 9-bed facility in Durham that will accept HIV-positive veterans: Servant Center in Greensboro for medically disabled and terminally ill homeless veterans; and Hospice. The UNC School of Dentistry is contracted to provide dental services for the program. In 1994 the Durham VAMC began community wide one-day events to connect homeless veterans with many services including employment, food, clothing, haircuts, financial counseling, and legal assistance in addition to mental health, posttraumatic stress disorder, and substance abuse services.

These 5 safety net programs administered by VHA provide significant services and opportunities that help bridge the gaps in care for low-income veterans across North Carolina.

Contributions from Bob Williamson, MSW, program coordinator, Health Care for Homeless Veterans; Tridell Morgan, MBA, program coordinator, Compensated Work Therapy; Ivey Chavis, MSW, coordinator, Contract Nursing Home; Peggy Becker, LCSW, program director, Home Based Primary Care; and Sue Kistler, lead care coordinator, Care Coordination Home Telehealth Program.

Readers' Forum

To the Editor:

There is no shortage of statistics about the obesity epidemic our nation faces. North Carolina is no stranger to this issue—just look around us as we shop at grocery stores or sit in doctors' offices to be treated for chronic conditions. Last year the Trust for America's Health ranked North Carolina as having the 17th highest rate of adult obesity and the 5th highest rate of overweight youths (ages 10-17) in the nation. We are taking personal risks by gaining excess weight, eating unhealthy foods, and not getting enough exercise. The costs to a person's life span are staggering, and that includes the high cost of health care needed to offset these lifestyle choices.

In response to this trend, Blue Cross and Blue Shield of North Carolina (BCBSNC) launched the Healthy Lifestyle Choices program [see also *North Carolina Medical Journal*, July/August 2006, pages 313-315]. This preventive health program began as a pilot program to help engage participants in regular exercise and nutritious eating. As part of our effort, participants received a personalized report on opportunities for lifestyle improvement, a diary to record food intake and physical activity, a step counter, a tape measure (to track waist circumference), a newsletter, and other educational materials. BCBSNC also provided physician toolkits for the treatment of obesity to 200 high-volume primary care practices. We acknowledged the critical role of the patient's physician by providing reimbursement for up to 4 office visits for the evaluation of obesity as a sole diagnosis.

Recently released results of a 2-year follow up study (2005-2006) compared the impact our Healthy Lifestyle Choices program had on the medical costs and behaviors of almost 1200 participants. Simple lifestyle changes added up to big savings—almost $200 annually per participating member in the Healthy Lifestyle Choices program. Savings over the 2-year period totaled close to $450 000. That translated into medical expenses that were one-third less than the average medical trend. The implication is that living a healthier lifestyle can save money.

Our findings are even more startling when you consider the significant impact our choices and habits have on the cost of health care. In fact, in 2004 BCBSNC found that members who are overweight cost the company 18% more than normal weight members in medical claims and expenses, and obese members cost 32% more. Preventive health programs offered by BCBSNC aim to curb that trend.

Results of the Healthy Lifestyle Choices program hit not only the bottom line, but also waistlines. Of those participants with a weight loss goal, 49% lost an average of 11.6 pounds. In addition, waist circumference decreased one-half inch for participants on average. Participating members also had real success in increasing the number of days exercised per week and in increasing consumption of fruits and vegetables to two or more times per day.

The success of the program led BCBSNC to expand its healthy living offerings into our comprehensive Member Health Partnerships program, which gives members access to a wide variety of health and disease management resources. Recently added benefits include one-on-one health coaching, where members can talk to a registered nurse about losing weight, chronic conditions, or other health issues. Most members who enroll also have access to 6 free nutritional visits. We believe these approaches are, along with physician advocacy, helping to drive changes in behavior.

The results have exceeded our expectations with the emphasis on long-term lifestyle changes to help people improve their health and manage their costs. It is encouraging to see that participants are making healthier lifestyle changes in both diet and exercise. Nutrition visits are growing quickly. We are on the right track, working with a full range of health care team members to help patients/members manage their weight and weight-related health issues.

While these results are encouraging, we have only scratched the surface of the problem. In order to inculcate true lifestyle changes we need to engage members/patients not only at home but at work and school. This is a family project in the broadest sense. In the meantime, BCBSNC will continue to offer members tools and resources to help them, working with their doctors, make the best choices for their own health. It's a marathon, not a sprint.

Don Bradley, MD
Chief Medical Officer and Senior Vice President
Blue Cross and Blue Shield of North Carolina

To the Editor:

In your Readers' Forum section of the September/October 2007 *Journal* one of your readers commented on the shortage of family physicians in the United States. He was quite correct in this evaluation and suggested solutions. One very important point he did not mention is the role that physician assistants and nurse practitioners will play in the care of sick Americans. I strongly believe these professionals will play an extraordinary role in the new health reform in this country. It is very well-known that many minor illnesses can be taken care of by these practitioners; they listen to the patient, perform a physical examination, and diagnose and treat the illness. The successful results of the retail or minute clinics is the best proof of what the aforementioned practitioners can do to cut the cost of the increasing expenses of our health care. Of course this is only one factor in our broken system; the whole problem is more complex.

C. A. Ruiz, MD

Publishers of the *North Carolina Medical Journal*

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

health policy
North Carolina Institute of Medicine

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

Mental Health Professionals in North Carolina

Nearly one-third of nonelderly adults and one-sixth of children experience a mental health disorder in their lifetimes. Thirteen percent of Americans receive some form of mental health treatment each year including inpatient treatment (0.9%), outpatient treatment (7.9%), and behavioral medication (10%).

There are 3 broad classifications of mental health patients: (1) persons with developmentally disabilities, (2) persons with substance abuse disorders, and (3) persons with mental illnesses. Within this third group, there are numerous illnesses of varying severity. A severely mentally ill person who suffers from schizophrenia or bipolar disorder may have trouble functioning independently in society. People with moderate depression or posttraumatic stress disorder may be appropriately treated with medication. Within mental health there exists a wide range of health issues that may not require intense medical treatment but which may affect a patient's well-being.

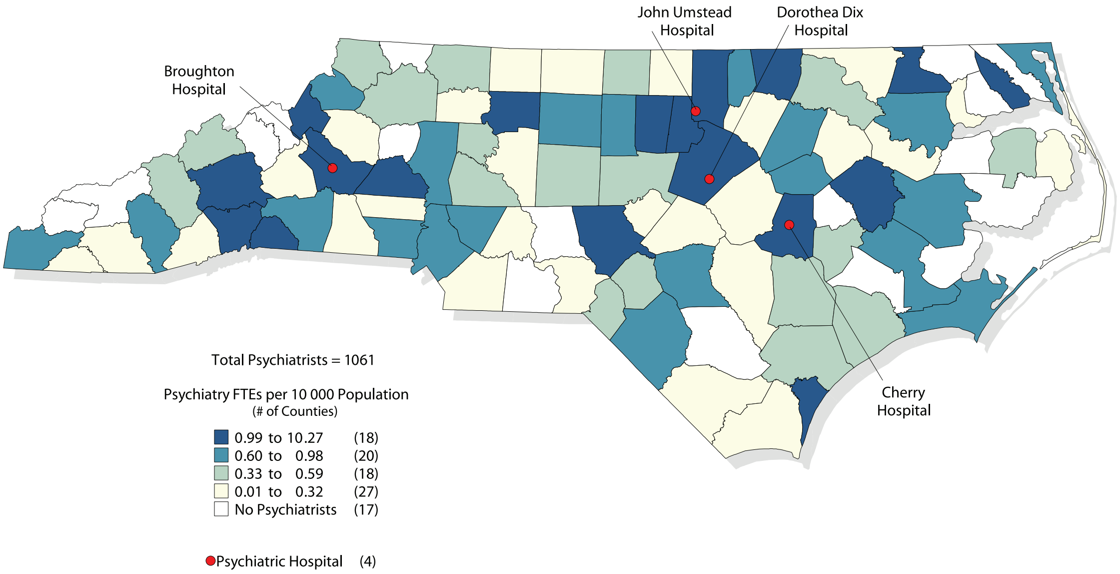
Psychiatrist Full-Time Equivalents per 10 000 Population North Carolina, 2004



Source: LINC, 2005; North Carolina Health Professions Data System, with data derived from the North Carolina Medical Board, 2004; NC DHHS, MHDDSAS, 2005.

Produced by: North Carolina Health Professions Data System, Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill.

*Psychiatrists include active (or unknown activity status), instate, nonfederal, nonresident-in-training physicians who indicate a primary specialty of psychiatry, child psychiatry, psychoanalysis, psychosomatic medicine, addiction/chemical dependency, forensic psychiatry, or geriatric psychiatry, and secondary specialties in child psychiatry and forensic psychiatry.

continued from page 69

Research estimates suggest there are 64 000 children and 49 000 adults with developmental disabilities in North Carolina. All together, research suggests 400 000 North Carolinians suffer from substance abuse disorders. Research also estimates there are 66 000 children and adolescents and 356 000 adults with serious mental illnesses within the state.

Among people with more moderate mental illnesses, depression is one of the most common ailments. According to the National Center on Drug Use and Health, 9% of North Carolina residents ages 12 to 17 years old suffered from at least one depressive episode in 2005. Among adults in the state, nearly 8% suffered at least one episode.

According to the Health Professions Data System at the University of North Carolina at Chapel Hill, 44 North Carolina counties qualified as Mental Health Professional Shortage Areas in 2004 because they had fewer than one-third of a psychiatrist for every 10 000 people. Between 1999 and 2004, 48 counties experienced a decline in psychiatrists relative to the change in population, 5 counties lost the psychiatrists they had, and 12 counties had none and gained none. In other words, during that 5-year period, nearly two-thirds of North Carolina counties either had no psychiatrists or experienced a decline in supply. The map in Figure 1 shows the uneven distribution of psychiatrists across counties and their density in relation to the state's major mental health facilities.

Compared to the rest of the nation, North Carolina ranks 20th in the density of psychiatrists. In 2005 North Carolina had 1091 psychiatrists in practice, or 1.2 per 10 000 population. Regardless of rank, North Carolina is well below the overall national average. In 2005 the United States had 41 958 psychiatrists in practice, or 1.42 per 10 000 population. For psychologists, North Carolina fell below the national average with 2.58 psychologists per 10 000 population compared to 3.35 for the nation. It is only in the social work profession where the state exceeds the national average with 17.9 per 10 000 compared to 15.8 per 10 000 population.

Primary Care Physicians Needed For Locum And Permanent Jobs in NC. We have several locum and permanent opportunities in NC. Send us your CV and get informed on the outstanding jobs available. Email us at physiciansolutions (at) gmail.com or phone us at 919-845-0054. Find dozens of opportunities on our web site: www.physiciansolutions.net.

Join an outstanding ED program at Onslow Memorial Hospital. Our community offers a solid referral base, support staff, and excellent technology to enhance your clinical skills. Quality schools, community spirit, coastal Carolina estuaries, and beaches are but a few of the many benefits of joining our team. The hospital is committed to providing superior medical care and an equally superior way of life. As the only nonprofit community hospital in the area, Onslow Memorial has 162 beds and is committed to enhancing the health of the communities it serves. The administrative team maintains a clear focus on the goal of providing exceptional healthcare to the citizens of Onslow County at an affordable cost. New 40+ bed ED and surgery center scheduled to open in May 2008. Candidates must be BC/BE in Emergency Medicine. For more information, please contact Karen-Marie Johnson at 800.848.3721 x4348 or email johkar (at) teamhealth.com.

DukeMedicine

Medical Director

The Duke Primary Care Medical Director of Wake County is a senior medical administration position within the Duke Primary Care medical group practice. The Duke Primary Care Medical Director of Wake County's time is devoted to both administrative duties and clinical practice. This position has oversight for all the activities related to the delivery of medical care and clinical services for Duke Medicine's primary care practices in Wake County, including human resources management, financial management, and clinical and operational performance improvement. This position also coordinates provider recruitment for the practice and represents Duke Primary Care's Wake County practices to Duke Primary Care Administration and Duke University Health System. If interested, contact:

John Anderson MD, MPH
Duke Primary Care
615 Douglas Street, Suite 601
Durham, NC 27705
Email: donna.ecclestone@duke.edu

Duke University is an Equal Opportunity, Affirmative Action Employer.

NDI
NATIONAL DIAGNOSTICS INC.

Physician/Medical Review Officer Needed

(Part or Full time Physicians - Work remotely)

Charlotte, NC: National Diagnostics, Inc., a comprehensive provider of employee screening management services seeks physicians/MROs for part or full time work.

Duties include administrative medical responsibilities related to the management of substance abuse testing and medical surveillance programs.

Physicians may work remotely via NDI technologies, full or part time, with flexible work schedules.

Medical Directorship position is open for full time physician committed to leadership, program and staff development, and exceptional client service. Ideal candidates will be BC/BE in OM/IM or FP and Medical Review Officer certified. Competitive salary and benefits. Submit resume: pgreene (at) natldiag.com or fax to 980-235-1100.

Private Diagnostic Clinic, PLLC

Medical Director

The Private Diagnostic Clinic, PLLC, Duke's faculty practice plan, seeks a Medical Director to align and lead our specialty and primary care physician network in Wake County. The **PDC Medical Director** of Wake County will maintain a clinical practice and will be responsible for the oversight of both primary and specialty care in Wake County. The selected candidate will work collaboratively with the Surgical Medical Director in Wake County, the Medical Director of Duke Primary Care, Duke Raleigh Hospital administration, and the Private Diagnostic Clinic to support Duke Medicine growth in the local area.

Interested candidates should contact:
Theodore Pappas, M.D.,
PDC Executive Medical Director,
3100 Tower Blvd, Suite 600, Box 80,
Durham, NC 27707
Email: donna.ecclestone@duke.edu

LOSING WEIGHT NEVER FELT SO GOOD

Now you can start living a happier, healthier life!

LAP-BAND patient Lisa lost 140 pounds and found a happy, healthy life.

For millions of people, losing weight—and keeping it off—seems impossible. Thanks to the LAP-BAND® System, you can finally take control of your hunger and transform your life.

We now offer the LAP-BAND procedure, the least invasive weight-loss surgery available in the United States. The LAP-BAND System is a tool that helps control your hunger and support your unique weight-loss needs.

THE LAP-BAND SYSTEM ADVANTAGES

- Least invasive, safest surgical option
- No stomach stapling or intestinal re-routing
- Only adjustable surgical option for customized weight loss
- Completely reversible
- More than 150,000 procedures performed worldwide

If you are 100 pounds overweight and are ready to win back your life and regain your health, contact us for more information on the LAP-BAND System solution.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

Paul A. Buescher, PhD
Director, State Center for Health Statistics

North Carolina has a deserved reputation for excellence in collecting and reporting vital and health statistics. This is due in large part to the early development of a State Center for Health Statistics (SCHS) and the quality of individuals who have led that Center. The current director, Paul Buescher, is keeping alive the tradition of objectivity, responsiveness, and accuracy that has marked the SCHS since its beginning. Paul, in a sense, is one of our own at the *North Carolina Medical Journal* since he has edited a regular feature, *Running the Numbers*, for the past 7 years. We wish to recognize him, however, for his work at the Center. Paul has steadily and constructively made the State Center for Health Statistics a trusted and relevant participant in the health policy making process in North Carolina, and his willingness to bring the data of the Center into public forums sets him apart.

Paul became director of the State Center for Health Statistics in 2005 after serving in progressively responsible roles. He began work at the SCHS in 1980 as a statistician and gained a reputation as a productive contributor to its work. In 1993 he became head of the Statistical Services Unit. Having spent most of his career at the SCHS, Paul is intimately familiar with its programs and is highly committed to its ongoing success and improvement. Leah Devlin, state health director, notes that Paul "...is a master of turning data into meaningful information that is routinely used across North Carolina to identify health problems, define effective strategies, and evaluate outcomes. He is incredibly knowledgeable and dedicated —we all stand on his recommendations with absolute confidence."

Paul's role as a communicator is an important asset for both state and community leaders. Paul has been tasked to publicly explain positions that are often hard to grasp by a layperson, such as how an unusual number of cancer cases occurring in a community is unlikely to be due to a specific environmental cause but has a much greater probability of happening due to chance. These kinds of public discussions can become stressful and contentious, but Paul is able, through his calm demeanor and clear language, to make convincing arguments that rely on statistical facts and understanding—a skill that he has mastered.

An Eagle Scout who received his undergraduate degree in Sociology from Louisiana State University, Paul went on to receive a MA in Sociology and a PhD in Sociology/Demography from the University of North Carolina (UNC) at Chapel Hill. He has been an adjunct professor in the Department of Maternal and Child Health in the UNC Chapel Hill School of Public Health since 1991 and is a ready and willing mentor to students and faculty at the university.

Paul is an accomplished scholar and has published extensively in the medical and public health literature. He was the recipient of the national 2004 Maternal and Child Health (MCH) Epidemiology Effective Practice at the State Level Award from the Coalition for Excellence in MCH Epidemiology. The Effective Practice Award recognizes individuals who make significant contributions to MCH public health practice through the effective use of data and epidemiology. North Carolina is fortunate that Paul Buescher brings his knowledge and skills to the work of the State Center for Health Statistics.

The Economic Impacts of Medicaid in North Carolina

Christopher Dumas, PhD; William Hall, PhD; Patricia Garrett, PhD

Abstract

Objective: *The purpose of this study is to provide estimates of the economic impacts of Medicaid program expenditures in North Carolina in state fiscal year (SFY) 2003.*

Study Design: *The study uses input-output analysis to estimate the economic impacts of Medicaid expenditures.*

Data Sources /Study Setting: *The study uses North Carolina Medicaid program expenditure data for SFY 2003 as submitted by the North Carolina Division of Medical Assistance to the federal Centers for Medicare and Medicaid Services (CMS). Industry structure data from 2002 that are part of the IMPLAN input-output modeling software database are also used in the analysis.*

Principal Findings: *In SFY 2003 $6.307 billion in Medicaid program expenditures occurred within the state of North Carolina—$3.941 billion federal dollars, $2.014 billion state dollars, and $351 million in local government funds. Each dollar of state and local government expenditures brought $1.67 in federal Medicaid cost-share to the state. The economic impacts within North Carolina of the 2003 Medicaid expenditures included the following: 182 000 jobs supported (including both full-time and some part-time jobs); $6.1 billion in labor income (wages, salaries, sole proprietorship/partnership profits); and $1.9 billion in capital income (rents, interest payments, corporate dividend payments). If the Medicaid program were shut down and the funds returned to taxpayers who saved/spent the funds according to typical consumer expenditure patterns, employment in North Carolina would fall by an estimated 67 400 jobs, and labor income would fall by $2.83 billion, due to the labor-intensive nature of Medicaid expenditures.*

Limitations: *Medicaid expenditure and economic impact results do not capture the economic value of the improved health and well-being of Medicaid recipients. Furthermore, the results do not capture the savings to society from increased preventive care and reduced uncompensated care resulting from Medicaid.*

Conclusions: *State and local government expenditures do not fully capture the economic consequences of Medicaid in North Carolina. This study finds that Medicaid makes a large contribution to state and local economic activity by creating jobs, income, and profit in North Carolina. Any changes to the Medicaid program should be made with caution.*

Relevance: *The rising costs of health care and the appropriate role of government health insurance programs are the object of current policy debates. Informed discussion of these issues requires good information on the economic and health consequences of alternative policy choices. This is the first systematic study of the broader economic impacts of Medicaid expenditures in North Carolina.*

Medicaid is a health insurance program for certain low-income individuals and families. The program covers children in low-income households; the aged, blind, and/or disabled; and people who are eligible to receive federally-assisted income maintenance payments.[a] In North Carolina, Medicaid is jointly funded by federal, state, and county governments. (In October 2007 the state began a 3-year phaseout of county funding with this share being assumed by the state.) The North Carolina Division of Medical Assistance manages the Medicaid program.[1] Approximately 1 out of 6 North

Christopher Dumas, PhD, is an associate professor in the Department of Economics and Finance at the University of North Carolina Wilmington. He can be reached at 910-962-4026, dumasc (at) uncw.edu, or 601 South College Road, Wilmington, NC 28403.

William Hall, PhD, is a professor in the Department of Economics and Finance and director of the Center for Business and Economic Services at the University of North Carolina Wilmington.

Patricia Garrett, PhD, is a former project director at NC Covering Kids & Families for the North Carolina Pediatric Society Foundation in Raleigh, North Carolina.

Carolinians (1.4 million people) was eligible for Medicaid coverage at some time during state fiscal year (SFY) 2003. Although considerable information is available on Medicaid program services, recipients, and costs, relatively little information is available on the economic impacts of Medicaid expenditures, especially at the state or regional level. The purpose of this study is to estimate the economic impacts of Medicaid program expenditures in North Carolina in SFY 2003.

It is well-known that Medicaid program costs are large and growing.[2] In 2001 Medicaid financed $5.32 billion of the $31.6 billion spent on health care in North Carolina, or 17% of total health care spending in the state.[3] From 1978 to 2003, Medicaid expenditures in North Carolina increased from $307 million to $6.3 billion.[4,5] By 2003, average nationwide Medicaid costs (22.3% of state government expenditure) had displaced elementary and secondary education (21.4% of state government expenditure) as the largest state expenditure.[6] In North Carolina Medicaid is a large and growing proportion of the state budget—currently about 16%.[7] Moreover, because Medicaid is an entitlement program, state expenditures cannot be capped. This introduces unpredictability into the budgetary process, which is one factor that makes Medicaid a challenging program for states to administer.[6,8]

The individual and public health benefits of Medicaid are also well-known. Figure 1 provides a schematic summary of the health and economic benefits of Medicaid for individuals and communities. Health care professionals appropriately emphasize both the clinical benefits (see Figure 1.A) and public health benefits (see Figure 1.B) of the Medicaid program. By promoting access to timely and appropriate medical care, and with an emphasis on preventive care and best practice protocols, Medicaid improves health status and mitigates the possibility that chronic conditions will become disabilities. For example, a recent study finds that enrolling children in Medicaid before they get sick promotes the use of preventive care, reduces the need for hospitalization, and improves health.[9] In a recent review study of health insurance and access to prescription medicines, insurance coverage was found to be essential for access to prescription drugs with increased access consistently observed for insured compared to uninsured children.[10] In another recent study of automobile accident victims receiving hospital care, victims without health insurance were found to receive less care and suffer a substantially higher mortality rate compared to victims with health insurance.[11] In terms of public health effects, Medicaid expenditures support health care infrastructure used by the general public (eg, community hospitals), contain communicable diseases, and promote general public health through health awareness and wellness campaigns.

In addition to health benefits, Medicaid indirectly confers economic benefits to recipients (see Figure 1.C.1-2) and to other patients in the health care system (see Figure 1.C.2-3). By improving health, Medicaid improves labor participation—an individual's capacity to stay employed and work productively. By facilitating timely and preventive care, Medicaid reduces costly emergency care,[9] thus reducing the overall cost of health care to the individual and to the economy. Additionally, by reducing unpaid medical costs, Medicaid reduces cost-shifting. Cost-shifting occurs when unpaid medical costs are absorbed by hospitals, county health departments, or other safety net providers and/or passed on in the form of higher premiums to consumers with private health insurance. For example, a recent study by Families USA[12] finds that the uninsured cannot pay two-thirds of their health costs, and of this amount, two-thirds is passed on to those with private health insurance in the form of higher premiums. The Families USA study found that in 2005 the annual premium cost for a family health insurance policy provided by private employers was an average $922 higher due to the cost of care for the uninsured.

Figure 1.
Major Health and Economic Benefits of Medicaid Expenditures for Individuals and Communities

Benefits	**Beneficiaries**	
	Individual	***Community***
Health	**A.** *Clinical effects.* By promoting access to timely and appropriate medical care, and with an emphasis on preventive care and best practice protocols, Medicaid improves health status and mitigates the possibility that chronic conditions will become disabilities.	**B.** *Public health effects.* Medicaid expenditures support health care infrastructure used by the general public (eg, community hospitals), contain communicable diseases, and promote general public health through health awareness and wellness campaigns.
Economic	**C.** *1. Improved labor participation.* . By improving health Medicaid improves an individual's capacity to stay employed and work productively. *2. Reduced cost of care.* By facilitating timely and preventive care Medicaid reduces costly emergency care, reducing the overall cost of health care to the individual and the economy. *3. Reduced cost shifting.* By reducing unpaid medical costs Medicaid reduces health care provider write-offs that are passed on to the insured in the form of higher insurance premiums.	**D.** *Direct and multiplier effects.* Medicaid expenditures stimulate the local economy through supporting jobs, labor income (wages, salaries, and sole proprietorship/partnership income), capital income (rents, interest payments, and corporate dividend payments), and taxes.

What is less well-known is that Medicaid has substantial, positive impacts on state business activity (see Figure 1.D). Medicaid expenditures stimulate the local economy, supporting jobs, labor income, business income, and taxes. Recent studies nationwide have begun to assess these impacts at the state level.[13-31] For example, studies conducted in both Alaska[14] and Texas[15] found that Medicaid has substantial economic impacts in those states. The Alaska study found that Medicaid program expenditures supported over 9 000 jobs in the state and generated more than $346 million in personal income (wages, salaries, and business income). Each dollar of Alaska state funds invested in Medicaid resulted in $2.31 dollars of personal income to state residents due to the infusion of Medicaid cost share dollars from the federal government (ie, Alaska made money on Medicaid). As would be expected, the Medicaid program has larger impacts in states with larger economies and populations such as Texas. In Texas Medicaid supported 474 420 jobs and $20 billion in personal income. Unlike Alaska, Texas didn't make money on Medicaid—each dollar of Texas state funds invested in Medicaid returned 91 cents of personal income to Texans due to the vagaries of the federal cost sharing formula. However, it is critical to remember that these figures do not include the economic value of the improved health and well-being of Medicaid recipients or the medical cost savings resulting from preventive care funded by Medicaid.

This study provides estimates of the economic impacts of Medicaid program expenditures in North Carolina in SFY 2003 including estimates of economic impacts on employment; labor income (wages and salaries); capital income (rents, interest payments, and corporate dividends); and government tax revenues at the federal, state, and local levels. These estimates do not include the economic value of the improved health and well-being of Medicaid recipients or the medical cost savings resulting from preventive care funded by Medicaid. Hence, the goal of this study is to provide results for the direct and multiplier effects in the community (see Figure 1.D). In addition, our data set allows us to investigate Medicaid expenditures at the county level and to determine whether urban or more affluent counties receive disproportionately larger expenditures relative to rural or less affluent counties. We also report the results of a policy simulation experiment in which we determine the economic impacts of shutting down the Medicaid program, returning the money (federal, state, and local) to taxpayers, and allowing the taxpayers to spend the funds according to typical consumer expenditure patterns.

Data

The study relies on North Carolina Medicaid program expenditure data for SFY 2003 as submitted by the North Carolina Division of Medical Assistance to the federal Centers for Medicare and Medicaid Services (CMS). The data included all SFY 2003 North Carolina Medicaid program expenditures including the following associated programs: Baby Love; Community Alternatives; Dental Program; Health Check; Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) Services; Managed Care; Piedmont Behavioral Healthcare and Piedmont Innovations; and Transportation Program administration.[b] The analysis does not include NC Health Choice for Children (SCHIP) program expenditures.[c] The data used in this study are unique in that they provide Medicaid expenditures by county of health care provider location rather than by county of patient residency.

Methodology

This study uses input-output analysis to estimate the economic impacts of Medicaid.[32] Input-output analysis is commonly used by economists to estimate the full economic impacts of an initial change in spending in a regional economy. Input-output models are not perfect; they are approximations of spending patterns in regional economies. Nonetheless, they are widely used as good, first-order approximations of regional economies, and their use by economists to estimate economic impacts is standard operating procedure. IMPLAN Professional® Input-Output Analysis computer software was used in this study to conduct input-output analysis.[33] IMPLAN is a leading input-output modeling software package used by university researchers, government agencies, and consultants nationwide. In a review of the literature, we identified 19 studies[13-31] of the economic impacts of Medicaid at the state level, all of which used some form of input-output analysis to estimate economic impacts. Ten of the 19 studies used IMPLAN input-output modeling software. (Five studies used the RIMS II input-output model, which is fundamentally similar to IMPLAN, and the remaining studies used custom-built input-output models or did not report the type of input-output model used.) Carbaugh et al[34] reviewed 17 studies of the role of Medicaid in state economies. Of these, 11 used IMPLAN; 3 studies, including those of Families USA,[35,36] used RIMS II. IMPLAN has also been used to estimate the economic impacts of hospital closures.[37,38] Rickman and Schwer[39] compared benchmarked versions of IMPLAN, RIMS II, and a third leading input-output software package called REMI, and found that

---

[b] For additional information on the distribution of Medicaid expenditures across program areas in North Carolina, see: http://www.dhhs.state.nc.us/dma/prog.htm.

[c] Unfortunately, this study is limited to the economic impacts of Medicaid because comparable information was not available for SCHIP dollars. Substantively, this has limited consequences because the Medicaid budget is much larger than the SCHIP budget. Nevertheless, because SCHIP dollars are targeted exclusively at children, their absence limits a nuanced appreciation of how public spending on children's health impacts the economy.

the economic impact multipliers of the benchmarked models do not differ significantly. Duncombe and Wong[40] provide a good introduction to the differences between input-output models and other methods of regional economic analysis.

Input-output models are interconnected systems of linear equations that track the flow of dollars between and among households, businesses, and government in a specified geographic region as small as a county or as large as the United States. The IMPLAN input-output modeling system consists of 2 parts: a mathematical computer model and a database. The IMPLAN modeling system contains equations for over 500 industry categories plus additional equations that model household and government spending. In essence, there is one equation for each *industry* in a regional economy. (The equation for a given industry can be different in different geographic areas.) Each industry equation specifies the dollar amounts of *input* goods and services required to produce the dollar amount of industry *output* in the region. The equations are linked together such that the output dollar amount produced by one industry is the total of all the input dollar amounts required by all of the other industries in the system. For example, the dollar value of electricity output produced by the electricity industry feeds into all of the other industry equations as the (dollar-valued) electricity inputs to those industries. (The electricity industry also uses some of its own electricity, which feeds back into its own equation.) In addition, some of the outputs leave the system as *exports* from the region, and some inputs enter the system as *imports* into the region. Furthermore, households (workers) and taxes are treated as inputs in the industry equations in the sense that industries pay for (send money to) workers and taxes. Households are treated as separate industries that receive their own inputs (eg, wages, salaries, rental income, dividend payments, government program payments) and produce their own outputs (eg, household expenditures for food, clothing, electricity, rent, mortgage payments, taxes). (In fact, there are multiple household industries, each corresponding to a different household income level, because households of different income levels have different patterns of inputs and outputs.) Each level of government (federal, state, and local) is treated as a separate industry in that it receives input tax receipts from households, businesses, and other levels of government, and it produces outputs (eg, expenditures on the military, highway construction, public schools, health care programs, payments to other levels of government).

The IMPLAN database is derived from federal and state employment and income data and government survey data of businesses and households.[33] The data are cleaned, organized, and transformed into consistent units. The industry equations, household receipts and expenditures, and government receipts and expenditures are all based on the employment, income, and survey data. The IMPLAN database is updated every few years as the government surveys are updated. The equations, receipts, and expenditures can be calculated at the national, state, or county level (or a collection of counties smaller than a state). When data are scarce for a particular industry in a particular geographic area, average results for that industry at the next level of aggregation are used (for example, if data are scarce for the widget production industry in a particular state, the average results for the nationwide widget industry might be used for that state). In addition, the database contains information on imports and exports for each geographic region.

When conducting economic impact analysis, IMPLAN is used to calculate changes in the economy relative to the baseline condition of the economy when local and system wide data were collected. The present study of Medicaid expenditures in 2003 relied on the 2002 IMPLAN database (ie, the 2002 IMPLAN structural matrix was used in the analysis). The initial change to the economy must be specified by the user. This initial change is called the direct impact. For example, if the state of North Carolina is the region of analysis then Medicaid dollars initially spent in the state constitute the *direct impact*. These initial expenditures purchase output from various health care industries. For example, in this study Medicaid dollars purchase output from the following list of IMPLAN health care industry sectors in North Carolina in 2003:

- Pharmaceutical and medicine manufacturing
- Surgical and medical instrument manufacturing
- Surgical appliance and supplies manufacturing
- Ophthalmic goods manufacturing (eg, eyeglasses)
- Home health care services
- Doctors, dentists, and other health care professionals
- Other ambulatory health care services
- Hospitals
- Nursing and residential care facilities
- Office administrative services (eg, program administration, tracking patient records)

In order to produce the purchased health care products and services, health care industries must, in turn, pay workers and purchase various goods and services from other industries. Next, the industries producing these goods and services must, in turn, purchase other goods and services, and so on. However, the process does not go on forever. At each round of purchasing, the dollar amount of purchases becomes smaller, eventually becoming negligible. The second and subsequent rounds of purchases constitute the *indirect impacts* of the initial Medicaid expenditures. At each round of purchasing, some of the dollars received by the producing industries go toward paying workers and owners of the firms. The workers and owners pay taxes on this income, save some of the income, and spend the rest. This spending by workers and owners initiates additional, attenuating rounds of purchasing called the *induced impacts* of the initial Medicaid expenditures. The indirect and induced impacts are collectively known as *multiplier effects*. The sum of the direct, indirect, and induced impacts is called the *total impact*.

The direct, indirect, and induced impacts of the Medicaid expenditures lead to changes in business sales (also known as business activity or business output), employment, labor income (eg, wages and salaries), capital income (eg, rents, interest and dividend income), and taxes paid to various levels of government. IMPLAN tracks the changes in business sales, employment, and other areas separately for the direct, indirect, and induced impacts and also cumulates them into total impacts.

Results

The Economic Impacts of Medicaid

In SFY 2003 $6.307 billion in initial Medicaid program expenditures occurred within the state of North Carolina—$3.941 billion federal dollars, $2.014 billion state dollars, and $351 million in local government funds. Each dollar of state and local government expenditures brought $1.67 federal cost-share Medicaid dollars to the state. Of the $6.307 billion in Medicaid expenditures, $1.63 billion or 25.8% was spent on children ages 0-18. The economic impacts of these Medicaid expenditures are both deep and broad. The estimated statewide total economic impacts (including economic multiplier effects) of the $6.307 billion in Medicaid expenditures within North Carolina in SFY 2003 are summarized in Table 1.

Table 1 provides impact estimates for 3 economic indicators of interest: employment (including full- and part-time jobs), labor income (including wages and salaries plus income from sole proprietorships or partnerships including many physicians' practices), and capital income (including rental income, interest income, and corporate dividend income). The economic impacts within North Carolina of the 2003 Medicaid expenditures in the state included 182 000 jobs supported (including both full-time and some part-time jobs), $6.1 billion in labor income (wages, salaries, and sole proprietorship/partnership profits), and $1.9 billion in capital income (rents, interest payments, and corporate dividend payments).

We find that Medicaid expenditures directly support 92 489 jobs (including both full- and part-time jobs) in North Carolina. An additional 89 634 jobs are supported by the indirect and induced multiplier effects of Medicaid spending for a total of 182 124 jobs statewide supported by Medicaid. Of these jobs, Medicaid directly supports the equivalent of approximately 85 000 health care industry jobs with multiplier effects supporting an additional 6 000 health care jobs for a

NOTES:

1. Employment includes all jobs both full- and part-time.
2. Labor Income includes wages, salaries, sole proprietorship income, and partnership income. Values are 2003-year dollars.
3. Capital Income includes rental income, interest income, and corporate dividend income. Values are 2003-year dollars.

total of about 91 000 health care jobs supported. Estes[3] estimated that 395 000 individuals were employed in the North Carolina health care sector in 2001. Allowing for moderate growth (8% per year) in the total number of health care jobs in North Carolina between 2001 and 2003, Medicare conservatively supports at least 20% of all health care jobs in the state.

The direct impact of Medicaid spending on capital income is $497 million. The indirect and induced impacts of Medicaid spending on capital income are nearly 3 times larger than the direct effects. This means that the multiplier effects of Medicaid expenditures on capital income are very strong. It is not just the corporations in the health care industry that benefit from Medicaid; business quite broadly benefits as well.

The aggregate impact of Medicaid expenditures on labor income ($6.1 billion) is much larger than the impact on capital income ($1.9 billion). This is consistent with the fact that health care is a labor-intensive sector characterized at the service delivery level by many small firms with relatively high employment. While direct impacts occur predominantly in health care industries, Medicaid also produces substantial multiplier effects in nonhealth industries through business-to-business transactions (indirect impacts) and consumer purchasing (induced impacts). Industry-by-industry results produced by the IMPLAN model (not reported here for the sake of brevity) indicate that the construction, transportation, wholesale and warehousing, retail trade, finance and insurance, and hotel and restaurant industries in North Carolina each received over $100 million in wages and salaries due to the indirect and induced impacts of Medicaid expenditures in 2003.

How does Medicaid job creation compare to economic development efforts that offer firms incentives to open or expand activities in North Carolina? In a November 9, 2004 press release,[41] Governor Mike Easley announced that North Carolina offered Dell Computer an incentive package of $242.5 million over 20 years to create, directly and indirectly, 8 000 jobs within the state or $30 313 spending per job. By comparison North Carolina state and local governments invested $2.371 billion in Medicaid in 2003, which when leveraged with federal cost share dollars, supported 182 000 jobs or $13 000 in state/local spending per job. Although some Medicaid-supported health care jobs such as physician may pay higher salaries than the average Dell job, and other Medicaid-supported jobs such as hospital custodian may pay less, the average wage/salary of North Carolina health care workers in 2003 was $39 660—similar to the state-average median household income in 2004 of $40 863.[42] Furthermore, Medicaid-supported jobs are widely distributed geographically across the state, whereas the jobs created by specific industrial projects are typically concentrated in a relatively small geographic region.

Much of the labor income and capital income supported by Medicaid is taxable by federal, state, and local governments. The federal government collects personal income, corporate profit, and payroll taxes. There is a comparable set of taxes at the state level. In addition, households pay local property taxes plus state and local sales taxes.[d] Table 2 summarizes tax receipts by governmental entity.

Panel 1 of Table 2 shows that the federal government collected approximately $1.6 billion in taxes as a result of all Medicaid expenditures (by all levels of government) in North Carolina in 2003—most in the form of personal income taxes (53.6%) with another substantial proportion in payroll taxes (41%). Consequently, the federal government recouped approximately 42% of its $3.9 billion in North Carolina Medicaid expenditures. State and county governments contributed $2.365 billion in Medicaid expenditures and collected taxes of $567 million. Consequently, state and local governments recouped approximately 24% of their Medicaid expenditures in the form of tax collections supported by Medicaid expenditures. The larger share of taxes (60.5%) went to the state, principally in the form of personal income (44.6%) and sales taxes (38.6%). State and federal Medicaid funds flowing into each county do not appear directly as line items on the budgets of county governments; they appear only indirectly in the sales tax and property tax revenue lines. Counties and localities realized $224 million in sales and property tax receipts from Medicaid expenditures in 2003, which offset more than half (56%) of their $400 million in Medicaid contributions.

A Policy Experiment: "What if We Gave the Medicaid Money Back to Taxpayers?"

Although the economic impacts of Medicaid spending are large, the economic impacts of spending on this scale would likely be significant if the money were spent on something other than Medicaid. The opportunity cost to society of spending money on Medicaid is that society gives up the economic impacts of spending money in other ways. To investigate the opportunity cost of Medicaid spending, we conduct a policy simulation experiment in which we assume the Medicaid program is shut down, and the federal, state, and local taxes paid by North Carolina taxpayers to support Medicaid are returned to the taxpayers. The taxpayers save and spend the returned funds based on observed patterns in federal consumer expenditure survey data. The expenditure patterns vary by household income level (eg, higher income households save a larger proportion

---

[d] In North Carolina separate sales taxes are levied by the state and local governments.[43] In SFY 2003 the North Carolina state sales tax rate was 4.5% on retail sales (or rental) of tangible personal property, room/lodging/hotel rentals, and laundering services with some exceptions. The North Carolina state sales tax does not apply to unprepared food (eg, groceries) but does apply to prepared food and other items (eg, restaurant meals, food purchased in the deli sections of grocery stores, alcohol, tobacco products). Nor does the North Carolina state tax apply to drugs or medical equipment sold with a prescription. The tax does not apply to insulin or prosthetic devices sold with or without a prescription. Every county may charge an additional 2.5% sales tax on all items subject to the North Carolina state 4.5% tax rate. In addition to general sales taxes, some counties levy additional sales taxes on particular items or activities, such as hotel occupancy taxes. Specific policies vary by county. Hence, the allocation of sales taxes in this table is a rough but realistic estimate.

Table 2.
Economic Impacts of Medicaid Expenditures on Federal, State, and County/Local Tax Receipts: North Carolina State Fiscal Year 2003

	Tax Receipts Supported By		
Government Entity	**Federal Medicaid Expenditures**	**State & Local Medicaid Expenditures**	**Total Medicaid Expenditures**

All Entities	**$1 375 698 880**	**$826 134 734**	**$2 201 833 615**

SOURCE: IMPLAN model calculations.

NOTES: Because of the way data are reported estimates are necessary to apportion sales taxes between state and county governments. For the purposes of this exercise, we assume a state sales tax rate of 4.5% and a local sales tax rate of 2.5%. Under these assumptions the state receives 64% (4.5%/[4.5%+2.5%]=64%) of combined state and local sales tax revenues with counties/localities receiving the remaining 36%.

of each dollar returned). Because most Medicaid dollars are spent on labor-intensive, instate health care services rather than goods imported into the state, Medicaid spending has a relatively large instate economic multiplier effect. By contrast, a large proportion of the typical consumer's spending pays for goods imported into the state (eg, gasoline, food, clothing, entertainment, electronics). If the Medicaid program was shut down, funds returned to taxpayers, and taxpayers allowed to spend these monies according to typical consumer spending patterns, the instate economic impacts of these expenditures would be smaller than the instate economic impacts of Medicaid. In fact, our simulation indicated that employment in North Carolina would fall by an estimated 67 400 jobs and labor income would fall by $2.83 billion if Medicaid funds were returned to taxpayers. The reason for this perhaps surprising result is that most Medicaid dollars are spent on labor-intensive, instate health care services rather than goods imported into the state. In contrast, a far larger proportion of typical consumer spending buys goods and services imported into the state. In comparison to typical consumer spending, Medicaid dollars stay in the state, supporting employment and businesses within North Carolina.

The County Cost Share Issue

The rapid growth in Medicaid payments in recent years has put pressure on county government budgets in North Carolina, causing counties to lobby the state to assume the county portion of Medicaid payments. One issue of concern has been that some rural or less affluent counties may be more reliant on Medicaid and may be paying a disproportionate share of Medicaid costs. Another issue has been that Medicaid funds allocated to residents of a given county may not support businesses and tax collections in that county since residents travel across county lines to access health care services not available in the county of residence. As a temporary measure, the state government agreed in 2006 to cap county Medicaid expenditures.[44] On July 31, 2007, the governor of North Carolina signed into law a measure requiring the state to assume the county portion of Medicaid expenditures.[45] The transfer would be phased in over 3 years beginning October 1, 2007. In partial compensation, counties would be required to give up a portion of their sales tax revenues to the state.

To address the issue of whether some counties may be more reliant on Medicaid, we consider two measures of Medicaid reliance: county Medicaid expenditures[5] as a percentage of county budget[46] in 2003 and Medicaid eligibles[5] as a percentage of county population[46] in 2004. We regressed each of these measures on (1) per capita county income[46] ($1 000s) in 2003; (2) county population[46] (10 000s) in 2003; and (3) the United States Department of Agriculture Economic Research Service (USDA-ERS) Rural-Urban Continuum Codes,[47] 2003, an index of county rural character (larger code numbers indicate a more rural character). County Medicaid expenditures as a percentage of county budget in 2003 are negatively related to per capita county income at the 0.05 level of significance, indicating that wealthier counties spend a smaller percentage of the county budget on Medicaid. County population and USDA-ERS Rural-Urban Continuum Codes are not statistically significant determinants of county Medicaid expenditures as a percentage of county budget in 2003, indicating that rural/urban status does not appear to be a significant determinant of county Medicaid expenditures as a percentage of county budgets. Medicaid eligibles as a percentage of county population, 2004, is negatively related to per capita county income ($1 000s) in 2003 at the 0.05 level of significance. It is also positively related to both county population in 2003 and USDA-ERS Rural-Urban Continuum Codes at the 0.05 level of significance. Hence, wealthier counties tend to have fewer Medicaid eligibles as a percentage of county population while more populous counties and more rural counties have more Medicaid eligibles as a percentage of county population. We conclude that reliance on Medicaid does vary by county type with more affluent counties spending a smaller percentage of the county budget on Medicaid and having a smaller percentage of the population eligible for Medicaid, while more populous and more rural counties have a larger percentage of the population eligible for Medicaid.

To investigate the issue of whether Medicaid funds allocated to residents of a given county actually support businesses and tax collections in the county, we analyze the Medicaid expenditure data by county of health care provider location. The analysis shows that for every North Carolina county, the state and federal government cost share expenditures paid to health care providers located in the county were far greater than the county contribution to Medicaid. For example, relatively populous, urban, and affluent Wake County spent approximately $20 million in local government funds on Medicaid in SFY 2003, but the federal government paid over $200 million in Medicaid expenditures to health care providers located in Wake County. Similar results hold for rural, less populous, or less affluent counties. Even small Yancey County, which spent only $500 000 in local funds on Medicaid in 2003, received over $5 million in federal Medicaid expenditures paid to health care providers located in the county. (Results for all North Carolina counties are available on request from the authors.) One reason that Medicaid expenditures are significant even in rural locations is that a relatively large share of Medicaid expenditures in rural counties goes to nursing and residential care services that are provided in the rural counties themselves. We conclude that even after accounting for Medicaid expenditures that cross county lines, every county in North Carolina has far more state and federal Medicaid money spent in the county than the county itself collects and spends on Medicaid.

Discussion And Conclusions

The rising costs of health care and the appropriate role of government health insurance programs in the health care system are the source of current policy debates. Informed discussion of these issues requires good information on the economic as well as the health consequences of alternative policy choices. The purpose of this study is to estimate the economic impacts of Medicaid program expenditures in North Carolina in SFY 2003 (see Figure 1.D.). In SFY 2003 $6.307 billion in Medicaid program expenditures occurred within the state of North Carolina—$3.941 billion federal dollars, $2.014 billion state dollars, and $351 million in local government funds. Each dollar of state and local government expenditures brought $1.67 federal Medicaid cost-share dollars to the state. The total economic impacts (including direct, indirect, and induced impacts) in North Carolina of Medicaid expenditures in 2003 included (see Table 1):

- 182 000 jobs supported (including both full-time and some part-time jobs)
- $6.1 billion in wages, salaries, and sole proprietorship/partnership income
- $1.9 billion in rents, interest payments, and corporate dividend payments

State and local governments recouped approximately 24% of their Medicaid expenditures in the form of various tax collections on Medicaid expenditures and the economic ripple effects of Medicaid expenditures.

Our unique data set allows us to estimate Medicaid expenditures and economic impacts by health care provider location at the county level. Although we find that reliance on Medicaid does vary by rural/urban and rich/poor county type, the data also show that every North Carolina county received far more in state and federal government cost share expenditures paid to health care providers located in the county than they paid in county-share Medicaid expenditures.

Although Medicaid spending generates large economic impacts, it should be recognized that the Medicaid program diverts spending away from other potential uses that would have generated other economic impacts. In a policy simulation experiment we answer the question, "What would be the net economic impacts of giving the Medicaid money back to taxpayers?" In the experiment we assume that the Medicaid program is shut down, that federal, state and local taxes paid by North Carolina taxpayers to support Medicaid are returned to the taxpayers, and that the taxpayers save and spend the returned funds based on typical consumer expenditure patterns. We find that the instate economic impacts of these expenditures are substantially smaller than the instate economic impacts of Medicaid. In fact, our simulation indicates that employment in North Carolina would fall by an estimated 67 400 jobs and labor income would fall by $2.83 billion. The reason for this perhaps surprising result is that most Medicaid dollars are spent on labor-intensive, instate health care services rather than on goods imported into the state. In contrast, a far larger proportion of typical consumer spending buys goods and services imported into the state. In comparison to typical consumer spending, Medicaid dollars stay in the state, supporting employment and businesses within North Carolina.

It is important to keep in mind that the Medicaid expenditure and economic impact results do not capture the economic value of the improved health and well-being of Medicaid recipients. Furthermore, the results do not capture the savings to society in general of emphasizing preventive care and reducing uncompensated care nor the long-term benefits of promoting wellness. Health insurance like Medicaid provides access to routine medical care, thereby promoting preventive care and timely and appropriate medical interventions and minimizing the necessity of relying on costly emergency services. Medicaid also reduces uncompensated care, which in turn reduces health care providers' need to shift costs to patients with private insurance. Additionally, comprehensive Medicaid services may allow covered adults to obtain or return to employment more quickly. Medicaid services for children— especially Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) services—support both the typical child as well as children with special health care needs. This investment in human capital should improve the capacity of young Medicaid beneficiaries to become productive members of society in the future.

Another caveat is that Medicaid plays a role in supporting the health care infrastructure available to the general population. Medicaid cuts could threaten the financial health of key facilities such as hospitals, or at least shift a larger share of the infrastructure support costs to those with private insurance. Further, to the extent that health care facilities provide amenity effects—such as those associated with living near an ocean—that boost community property values, facility closures could reduce property values. Similarly, a factory may choose to relocate elsewhere if the only hospital in a community closes. These effects are not captured by standard economic impact analysis.

This article poses a basic question: "What are the economic impacts of Medicaid on the North Carolina economy?" Medicaid is a large program with complex implications for its beneficiaries and the communities in which they live. The program is important for the health of many North Carolina citizens. In addition, the economic impacts of the program are substantial and felt statewide from urban research hospitals to rural nursing home facilities. Budgetary costs do not fully capture the economic consequences of Medicaid in North Carolina. This study finds that Medicaid makes a large contribution to state and local economic activity by creating jobs, income, and profit in North Carolina. Any substantial changes to the Medicaid program should be made with caution. **NCMJ**

Accuracy of Self- and Parental Perception of Overweight Among Latino Preadolescents

Valentina Intagliata, MD; Edward H. Ip, PhD; Sabina B. Gesell, PhD; Shari L. Barkin, MD, MSHS

Abstract

Background: *This investigation examines self-perception and parental perception of child body size and factors associated with accurate parental perception of child body size.*

Methods: *Latino at-risk for overweight (AROW) and/or overweight preadolescent children (ages 8-11 years) along with their parents were recruited (N=123 dyads). Children's body mass index (BMI) was measured but not discussed before participants were shown pictures of body sizes and asked to select the image that represented the child's body.*

Results: *The correlation between the child's body size selection and the child's actual BMI was 0.117 (p=0.20) whereas the correlation between the parent's assessment of the child's body size and the child's actual BMI was 0.470 (p<0.001). Logistic regression revealed that only parental education level (≥college) was associated with a more accurate parental perception of their child's body size (OR: 0.11/ 95% CI: 0.01, 0.89) while child's sex, parental BMI, and parental health status were not associated with a perception that corresponded to the child's BMI.*

Limitations: *The sample was drawn from a single community clinic in Forsyth County which serves a large population of newer Latino immigrants in the county.*

Conclusions: *The results indicate that (1) Latino AROW/overweight preadolescent children do not have an accurate perception of their own body size; (2) Latino parents have a more accurate perception of their child's body size with a moderately sized correlation suggesting that their perception of their child's body size is frequently inaccurate; and (3) Latino parents with higher education perceive their child's body size more accurately than less educated parents.*

Accuracy of Self- and Parental Perception of Overweight Among Latino Preadolescents

Interventions for childhood obesity have, at times, been shown to be successful if they include parents.[1,2] But for parents to choose to actively participate in obesity prevention efforts with their children, they must first be aware of overweight in their children and must be concerned about the possible consequences. Erroneous perception of body size may have important health and behavioral implications.

Latino adults have been found to be inaccurate in their perceptions of their own overweight.[3] In a study of low-income Latinas and their children aged 5-7 years, all of the women selected a relatively thin body image as the most desirable and healthy for themselves but preferred a plumper figure for their children.[4] Several studies using multiethnic samples but not breaking results out by ethnicity have shown that parents often fail to identify their children as overweight.[5,6] These findings indicate that Latina mothers may have a more favorable view of childhood obesity and may fail to perceive overweight in their children as problematic. We examined the research question, "Do Latino preadolescents and their parents have similar interpretations of overweight as do medical providers who utilize Body Mass Index (BMI) to make this determination?"

PATIENTS AND METHODS

Participants

Hispanic-American at-risk for overweight (AROW) (BMI ≥85% and ≥95%) and overweight (BMI >95%) preadolescent children (ages 8-11 years) along with one of their parents were recruited from a clinic that serves the greatest number of Latino families in Forsyth County, North Carolina. All patients who met the eligibility criteria (child's BMI ≥85%, child's age 8-11 years, self-identified as Latino, and parent willing to participate with child in the study) were invited to participate. Of the 210 families contacted, 159 families agreed to participate on the telephone, and 123 families provided data.

Measures

We obtained approval for this study from the Institutional Review Board of Wake Forest University Health Sciences. We present baseline data collected at the community-based health center in Winston-Salem, North Carolina prior to any discussion between the patient family and the health care provider. Children's and parents' BMI were measured[7] but not discussed before participants (both adults and children, separate from one another) were shown pictures of child body sizes and asked to select the image that most looked like the child's body. Body size perception was gathered from a picture scale ranging from 1-7 for children where 1-2 was considered by health care providers to be underweight, 3-4 was considered by health care providers to be the ideal body size, 5 was considered to be AROW, and 6-7 was considered to be overweight.[8] This scale is significantly and highly correlated with measured percentage overweight (r=0.79).[8] Additional variables that were collected include the following: (1) educational level of parent (using Census 2000 format);[9] (2) health status of parent (using questions from the Service Utilization Assessment);[10] and (3) parental acculturation (using questions from Marin's short acculturation scale for Hispanics).[11]

Statistical Methods

To assess how accurately Latino preadolescents perceive their body image compared to their parents, we calculated two correlations using Pearson's correlation coefficient: (1) between the child's assessment of his or her body size and the child's BMI, and (2) between the parent's assessment of the child's body size and the child's BMI.

To assess which factors are associated with a more accurate parental perception of body size, we created the variable AGREE. This was calculated by applying a cutoff point of 95% to the measured BMI percentile and classifying those above as overweight. We grouped the parental evaluation scores of 6 and 7 and defined this category as parents perceiving their child as overweight. When the parent's perception matched with the measured classification, the variable AGREE was coded 1; otherwise, it was coded 0. In a logistic regression, AGREE was used as the dependent variable with the sex of the child, education level of the parent (college degree versus no college degree), and self-reported health status of the parent included as independent variables.

RESULTS

In our sample of participating parents, 88% were mothers and 73% were from Mexico (other participants came from Guatemala, El Salvador, Dominican Republic, Columbia, Venezuela, and Nicaragua). Ninety-nine percent of our sample of parents reported that Spanish was spoken at home and with their friends. Moreover, 99% of these adults chose to complete surveys in Spanish. Forty-five percent (45%) of the adults had an education of 8th grade or less; 16% had education up to the 12th grade but not including graduation; 22% graduated from high school; 5% reported some college; 4% reported an a associates degree/technical school; and 8% reported a college degree or higher. Average adult age was 35 years (SD 7.4) and average adult BMI was 33.4 (SD 7.8). Only 17% of adults rated their health as "very good" or "excellent;" 38% reported "good" health; and 45% reported "fair" or "poor" health. Average child age was 9.3 years (SD 1.3). The distribution of female and male children was approximately equal. Average study child's BMI was 25.9 (SD 5.5) indicating that 30% were AROW and more than 60% were overweight.

The correlation between the child's body size selection and the child's actual BMI was 0.117 (p=0.20) whereas the correlation between the parent's assessment of the child's body size and the child's actual BMI was 0.470 (p<0.001). The two correlations were statistically different (p=0.001), suggesting that parents had a more accurate assessment of the child's body size than did the child. While the correlation between parental perception and child's true BMI is statistically significant, we note it is only moderate in magnitude and thus conclude that parental perception of body size is frequently inaccurate.

Table 1 shows the results of the logistic regression. Parent's education was significantly associated with a more accurate perception of the identified obese child (OR: 0.11, 95% CI: 0.01, 0.89, comparing parents with less than a college education to parents with a college education or higher).

Table 1.
Factors Associated with Accurate Perceptions of Child Obesity (N=123 Parent-Child Dyads)

	Odds ratio estimate	95% CI
Child's Sex[1]	0.68	0.30, 1.52
Parent's Education[2]	0.11	0.01, 0.89
Parent's BMI	0.97	0.92, 1.02
Parent's Health Status	1.04	0.67, 1.61

An estimate of higher than 1.0 in the odds ratio indicates an increased odds of agreement between perceived and actual overweight.

1 Reference category: Female

2 Reference category: With college degree

DISCUSSION

In this study, we found that Latino preadolescent overweight children perceived their body size inaccurately while their parents perceived their child's body size more accurately (but still with only a moderately sized correlation, suggesting frequent inaccuracy). Accuracy of parental perception was associated with higher parental educational levels, greater than or equal to a college level education.

Prior work from Killion et al demonstrated that African-American and Hispanic mothers' perceptions of their children's body sizes are often inaccurate for children with BMI > 95%.[12] However, that study only focused on young children aged 3-5 years. Likewise, Olvera et al demonstrated that less acculturated children and mothers identified thinner body sizes than the BMI would indicate.[13] A third of their sample of children were overweight or at-risk for overweight as indicated by the BMI. In our sample of only at-risk for overweight and overweight preadolescents, children were inaccurate in their body size identification, but parents were more accurate in identifying the correct body size for their child. Accuracy of perception was not affected by child's sex as it was in the study by Olvera et al.

The potential factors that create only a moderately-sized correlation between parental perception of their child's body size and actual BMI could be due to many reasons. Among low-income mothers in general, it has been shown that Latino parents do not believe growth charts are useful in defining a child's weight but that physical activity and good appetite are more important markers of health status.[14] Studies of Latino families in particular indicate that these individuals may have different standards for what constitutes a healthy child when compared to the standards of physicians or other ethnic groups.[15] One analysis demonstrated that Mexican-American mothers of obese children selected a "chubby baby" as ideal significantly more often than Mexican-American mothers of non-obese children.[16] From this report, one can infer that Latina mothers may strive to have overweight babies since it is perceived as an ideal body size. Mendoza et al proposes that the discrepancies in perception of a child's health between mother and physician, as revealed in the Hispanic Health and Nutrition Examination Survey (HHANES), may be due to an alternate view of what constitutes good health status in children, "one that is not fully appreciated by traditional measures."[15] In Mendoza's family-community health promotion model, he suggests that Latinos understand good health as the absence of problems that limit functional ability to perform everyday activities.[15]

Health professionals should not assume that defining overweight according to BMI has meaning for all parents. Furthermore, even if a group of people is able to assess body size accurately enough to appropriately apply the term "overweight," there still remains the issue of engendering an understanding that overweight/obesity is an unhealthy state.

Where should we focus future interventions? Jain et al believes that although a discrepancy exists between the views of parents and health professionals regarding the definition of overweight in children, both parties share a general belief that children should be physically active and eat healthy diets.[14] Future interventions should consider that it may be more valuable to focus on these common goals in our efforts towards decreasing the epidemic of childhood obesity.[14]

Limitations

The study was limited due to a sample that was drawn from a single clinic in Forsyth County; therefore, generalizeability may be limited. However, this clinic is one of the predominant clinics providing health care to Latino immigrant families in the county and might offer a glimpse into the less acculturated Latino family. The study involved mostly Latina mothers; it would be interesting to determine whether Latino fathers share similar degrees of body image perceptions for their children. Lastly, future research on Latino families should investigate other factors that enable parents to more accurately perceive their child's body size such as acculturation of the parent and child.

Relevance

Erroneous perception of body size may have important health and behavioral implications. Understanding the mutable factors that reinforce parental ability to see their child's body size accurately is a necessary first step to developing effective pediatric obesity interventions. Consistent with the Health Belief Model,[17] perceived severity of a problem impacts the likelihood that individuals are willing to change their behaviors. In this case, connecting an accurate perception of an overweight child to poor health would be an important first step for Latino parents to promote behavior change to address obesity in their overweight children. **NCMJ**

Newborn Screening in North Carolina:

The Evolution of Policy and Practice

H. Neil Kirkman, MD

Abstract

Newborn screening policies in North Carolina are due to the efforts of skilled and knowledgeable state officials, clinicians, and scientists who are able to develop effective newborn screening procedures. A newborn screening that was developed in North Carolina is the first automated method for diagnosing phenylketonuria. This process was later adopted in many other states. The use of tandem mass spectrometry in newborn screening was also pioneered in North Carolina, and it is being used in an increasing number of states. Newborn screening is more than testing, however; follow-up and specialized care are essential. State-level policies should recognize the multiple links necessary to make newborn screening effective and efficient.

In 1934 Norwegian physician Asbjørn Fölling reported a pair of siblings with a disease we now call phenylketonuria or PKU. Left untreated, PKU usually affects brain development and leads to mental retardation.[1] The disease was soon recognized as an autosomal recessive disorder in which each sibling of an affected child has a 25% chance of being born with the condition. By the early 1960s an infant formula low in phenylalanine was marketed and showed promise, when begun early, of preventing mental retardation. In 1963 Robert Guthrie, a microbiologist at the State University of New York at Buffalo, published a blood test for detecting the disorder in infants soon after birth.[2] The test utilized blood spotted onto filter paper. A punch of the blood-spotted filter paper was placed on agar containing the bacterium *Bacillus subtilis* and a substance that made the bacteria dependent on phenylalanine for growth. Affected infants had a greater zone of bacterial growth around their paper disk than did unaffected infants.

Early Days

Along with concerned parents, Dr Guthrie lobbied the legislatures of various states to mandate the testing of all newborn infants for phenylketonuria. Many states passed the mandate in the 1960s and subsequent events justified the early detection of PKU through newborn screening. At that time, North Carolina was fortunate to have Dr Theodore D. Scurletis as chief of the Maternal and Child Health Section of the State Board of Health. With input from Dr James B. Sidbury, Jr of Duke University; Drs George Summer, John Hill, and Harrie Chamberlin of the University of North Carolina at Chapel Hill; and others, Dr Scurletis urged the governor and legislators to go beyond a mandate and authorize adequate funds for a state newborn screening laboratory in Raleigh. Governor Terry Sanford appropriated $52 000 toward the laboratory in 1964, and the legislature approved continued funding. The laboratory became what is now the Newborn Screening Laboratory in the North Carolina State Laboratory of Public Health. Before testing was mandated in North Carolina, Dr Scurletis recognized the value of informing medical personnel about the importance of screening, and in 1965 he undertook an educational campaign for physicians, nurses, and health department staff. As a result, North Carolina's compliance rate reached 97%, exceeding rates in some states with compulsory testing.

Legislative action benefited North Carolina's newborn screening initiative by providing additional funds that were seriously needed at the time. Funding in North Carolina is influenced by the fact that the Newborn Screening Laboratory has an all-volunteer advisory committee made up of physicians and scientists who are experts in the various disorders being screened and who are from the different North Carolina medical teaching centers. The committee, which includes the parents of affected children and a representative of the North Carolina Pediatric Society, meets several times a year. The practicing physician representative can relay concerns about problems

H. Neil Kirkman, MD, is a Kenan Professor Emeritus in the Department of Pediatrics, Division of Genetics and Metabolism, at the University of North Carolina at Chapel Hill. He can be reached at hnk202 (at) cochill.net or the Division of Genetics and Metabolism, Department of Pediatrics, Chapel Hill, NC 27599-7487.

with newborn screening as well as practice-related details about newborn screening.

North Carolina as a Leader in Newborn Screening Methods

In addition to proposing funding, Dr Scurletis encouraged the use of an automated test[3] for detecting elevated concentrations of phenylalanine rather than Guthrie's bacterial method. The automated test was developed in the early years of automated analysis—an approach now commonly used in laboratory medicine—and seemed more advanced and accurate than the Guthrie test. North Carolina physician-scientists Drs John Hill and George Summer of the University of North Carolina at Chapel Hill created the test. In the early years North Carolina was the only state using this test. It was later adopted by many other states as well as by regions of Canada.

The second major breakthrough in newborn screening also had its origin in North Carolina. In the late 1980s investigators at Duke University, principally Dr David S. Millington and Dr Steve Kahler, began using powerful tandem mass spectrometry (MS/MS) to study blood spots of newborns and to screen for amino acid disorders. Dr Mohamed Rashed of Saudi Arabia developed an electrospray method[4] that allowed samples to be processed more rapidly with MS/MS. After the feasibility of newborn screening with MS/MS was reported,[5] the procedure began to gain general use.[6-8] The International Society of Neonatal Screening awarded their 2006 Guthrie prize to Drs Millington and Rashed. The MS/MS method superseded the automated fluorometric method and is now being used in an increasing number of other states. Since MS/MS screening is a major component of so-called "expanded" newborn screening,[9] North Carolina was once again at the forefront. The MS/MS method can detect a wide variety of inborn errors of metabolism, some of which are so rare they are found in North Carolina infants only once every few years. (See Table 1.) Of the disorders detected by MS/MS in North Carolina, only those having an incidence of 0.5 in 100 000 or higher are individually listed in Table 1. While some disorders are too rare to justify screening for them individually, MS/MS detects them with little additional effort, raising ethical and legal questions about omitting them from screening.[10]

The Issue of Priority

In many states parents vigorously lobby state legislators to authorize screening for a disorder affecting their own child. Such action, while understandable, can result in testing with insufficient regard to cost or benefit. Hypothyroid screening in North Carolina came about in part because a distinguished pediatric endocrinologist, the late Dr Judson Van Wyk, explained the need for hypothyroid screening to his local state representative in 1978. The origin of state funding for galactosemia screening is not clear. But one story is that a bill was introduced by a state legislator after he read an article on the subject while waiting for a haircut. Congenital adrenal hyperplasia can take the potentially lethal salt-wasting form or the less severe virilizing form. Screening for the disorder in North Carolina was initiated by a laboratory manager who had successfully established a screening protocol in a previous position.

The 2006 Newborn Screening Fact Sheets[11,a] from the American Academy of Pediatrics briefly describe the disorders listed in Table 1 (and certain others) and include information on incidence and screening. In North Carolina, as in other states, the introduction of a test has not necessarily correlated with the prevalence of the disorder. Congenital hypothyroidism is over 10 times as common as PKU, also causes preventable mental retardation, and is easier to treat than PKU; however, testing for it was introduced after the PKU test. (See Table 1.) Screening for hemoglobinopathies was limited to infants of African American descent when introduced in 1987, although hemoglobinopathies can be present in other infants. Universal screening did not begin until 1994. Detection and treatment of galactosemia soon after birth can prevent cataracts, liver damage, and death but does little to prevent the moderate developmental disorders that occur. Screening for hearing impairment, which appears to be the most prevalent disorder, is on the basis that early intervention allows the affected infant to develop nearly normal speech, but this claim needs to be confirmed.[11] Figures for North Carolina are not yet known, but national surveys for this test indicate that the false positive rate is high and the follow-up rate is low.[11] For tracking of tests results to occur, a very serious need exists nationally[11] as well as in North Carolina for funding and policies that allow integration of hearing screening with ongoing programs of newborn screening and follow-up.

Prioritizing can be more complex than might be appreciated. As shown in Table I, biotinidase deficiency is rare, yet the extremely low cost of treating this potentially debilitating condition offsets its rarity. Congenital hypothyroidism and PKU have two features in common: both produce mental retardation if untreated in childhood, and both require management through adulthood. Considerations of the vulnerability of the developing brain led to the possibility that the costly phenylalanine-restricted diet of the child with PKU might be discontinued at age 4.[12] Subsequent experience revealed that discontinuing the diet caused the patient with PKU to have irritability, mood disorders, and a risk for seizures. Moreover, it is important for the woman with PKU to have her diet closely regulated during each pregnancy. Since high blood phenylalanine concentrations interfere with development of the brain in children with PKU, it is easy to understand why the same will occur with the brain of a fetus of a women who has a high blood phenylalanine concentrations (even though the infant of a woman with PKU usually will not actually have PKU). Without treatment of pregnant women

Table 1.
Disorders for Which Newborn Screening is Provided in North Carolina in 2007

Disorder	Date testing started in NC	Confirmed cases per 100 000 newborns*
PKU	1966	See MS/MS
Congenital hypothyroidism	1979	49.7[a]
Hemoglobinopathies	1987 & 1994	83.4[a]
Galactosemia, classical	1988	1.6[a]
Galactosemia, variant	1988	3.4[a]
Congenital adrenal hyperplasia	1989	4.3[a]
Hearing impairment	2001	146[b]
Biotinidase deficiency	2004	0.5[c]
Detected by MS-MS	1999	25.6[d]
Amino acidopathies		
PKU		3.7
Hyperphenylalaninemia, not classical PKU		2.3
Citrullinemia		0.6
Organic acidemias		
3-methylcrotonyl-CoA carboxylase deficiency (3-MCC def)		2.9
Glutaric academia type 1		1.1
Methyl malonic acidemia		1.0
Isovaleric acidemia		0.6
Fatty acid oxidation defects		
Medium chain acyl-CoA dehydrogenase deficiency (MCADD)		7.6
Very long-chain acyl-CoA dehydrogenase deficiency (VLCADD)		1.4
Short-chain acyl-CoA dehydrogenase deficiency (SCADD)		1.0
Disorders (12 such) with incidence less than 0.5 per 100,000		3.4

*The following numbers of newborns screened and inclusive dates are from the North Carolina Newborn Screening Laboratory.

a 609,101 and 2002-2006.

b 363,974 and 2004-2006.

c 371,148 and 2004-2006.

d 930,321 and May 1999-December 2006. Of the infants in these MS/MS results, 81% are in the recent report[8] of Frazier, et al

with PKU, the frequency of mental retardation (from maternal PKU) would equal the frequency of mental retardation in people with PKU before newborn screening and treatment was initiated.[13] Thus, the total cost of managing PKU would seem to make it prohibitively expensive, yet the lifetime expense of the diet is less than the high cost of lifetime management of mental retardation or the costs associated with becoming unemployable.

Finally, early detection will not stop the ultimate progression of certain diseases but will provide opportunity to intervene and delay the onset of complications. Early detection also means the expense of unnecessary hospitalization and studies can be avoided. Examples of such diseases include sickle cell disease and cystic fibrosis. Newborn screening for the latter occurs in some states and is under consideration in North Carolina.

State or Commercial Laboratory?

The campaign of Dr Guthrie and concerned parents for mandated PKU testing probably encouraged the screening of newborns to be conducted in state laboratories rather than private laboratories since the bacterial methods required by the original test are used there. In most states this served to prevent the privatization of newborn screening. Private laboratories made an effort in the late 1990s to introduce bills in various state legislatures that would close state newborn screening laboratories and turn the activity over to commercial labs. At the same time the slowness with which many states adopt new screening methods prompted a discussion of the need for a national policy.[14] Directors of state laboratories cannot act independently to regularly update methods and equipment but are often dependent on legislative appropriation and are slowed by bureaucratic red tape. The breakup of communist governments in Europe in the 1990s revealed the inefficiency of government operated services and made a case for privatization. In North Carolina some physicians and parents, unaware of the 1999 incorporation of MS/MS into the state program, sent samples to a private laboratory in another state.

The director of one private laboratory based in another state lobbied the North Carolina Pediatric Society to recommend closing the state laboratory and allowing his lab to do testing (including MS/MS screening) on a broader range of disorders. Members of the Society were unaware that this director had earlier visited Duke University to learn that MS/MS could be used in newborn screening. More critically, his suggested tests included detection of glucose-6-phosphate dehydrogenase deficiency, a disorder for which testing on newborn infants had been found inadvisable 35 years earlier, as was recognized by a member of the Newborn Screening Advisory Committee (appointed by the Newborn Screening Lab directors) who had authored over 20 articles on this subject. It must be conceded, however, that this private laboratory provided 20 months of MS/MS screening under contract during development and confirmation of the MS/MS method in the state laboratory.

Remaining to be proven is whether privatizing newborn screening would result in lower costs. Many states now charge fees to support their state laboratories. In 1991 the North Carolina General Assembly authorized the North Carolina Department of Environment and Natural Resources to charge hospitals for testing. The charge was $10 per initial test in 2002 and $14 in 2005. The funds remain in the department to be used to support the Newborn Screening Program.

Screening and Follow-Up

Since the early days of newborn screening, the Newborn Screening Quality Assurance Program of the Centers for Disease Control and Prevention has been responsible for checking the accuracy of newborn screening laboratories in the United States. In North Carolina the extremely low rate of cases missed through laboratory error is due to the high quality of leadership within the Newborn Screening Laboratory. During many of the earlier years, the laboratory was under the capable direction of Maxine Matheson. As newborn screening became more technically complex, it was apparent the laboratory should be directed by someone board-certified in clinical chemistry, as has been the case for over 20 years.

The importance of an aggressive follow-up program became apparent in the early years of screening when 33 of 37 North Carolina infants detected as having PKU were promptly started on the low-phenylalanine diet. The 4 infants who were not placed on a phenylalanine-restricted diet developed retardation,[15] and several lawsuits were filed against physicians. None of these cases was the result of a laboratory error; all resulted from a breakdown in follow-up. This is in contrast to a national survey that revealed missed cases of PKU and hypothyroidism were more often the result of laboratory error than of failure to follow up.[16]

A system had evolved by 1974 for tracking abnormal results in North Carolina infants and seeing that each infant was either retested or referred for confirmation and treatment. That system was monitored by Elizabeth Moore, Genetic Program Manager of the Division of Maternal and Child Health. In the 1980s, during the period when MS/MS screening was contracted to a private laboratory, it became apparent that difficulty in coordinating follow-up was a potential problem. Another factor contributing to failed follow-up is a change in the physician of record when an infant is discharged from the hospital. A policy was finally established in North Carolina for laboratory staff to directly contact parents if repeat testing had not been obtained. This caused initial and understandable resentment among physicians until missed cases were documented. Despite the great importance of an effective follow-up program, the follow-up component is easily overlooked in funding of newborn screening programs.

The Issue of Who Will Manage Each Disorder

After an abnormal result from newborn screening, the confirmation and management of congenital hypothyroidism and the hemoglobinopathies (eg, sickle cell disease) may occur in many North Carolina medical teaching centers. In sharp contrast, the management of inborn errors of metabolism often requires specialized expertise. The dietary management of pregnant women with PKU, for example, is complicated by the nausea of early pregnancy and the changing metabolism of the pregnant woman. This situation is even more complex than that of the growing infant or child with PKU. Dietary management of many inborn errors of metabolism requires the expertise of a dietitian who has specific training and experience in managing such cases. Underrestriction can result in mental retardation or brain damage; overrestriction can result in death. Moreover, management of maple syrup urine disease, for example, requires regulating blood levels of three amino acids simultaneously.

In North Carolina, all PKU cases, approximately 90% of disorders detected by MS/MS, and certain inborn errors of metabolism are managed at the University of North Carolina at Chapel Hill by a dietitian who has a doctorate degree in biochemistry. This model of centralization also includes Duke University where confirmation and management of certain other inborn errors of metabolism occurs. This centralization is due to the difficulty of obtaining specialized skills in many locations. The disadvantage of centralization is the travel required of patients living elsewhere in the state. To offset this disadvantage, maximum use is made of mailed samples and telephone consultations. Although the Guthrie bacterial test is now seldom used, the method of collecting blood on filter paper (the Guthrie card) is ingenious and is widely used.

Guthrie cards have made newborn screening practical and have allowed North Carolina parents of infants and children with certain inborn errors of metabolism such as PKU to obtain samples for dietary monitoring and to inexpensively mail them to a laboratory. However, the cost of making available to needy families the expensive dietary formula and specialized care they require is a second area that is easily overlooked in funding newborn screening programs. The Guthrie card, incidentally, should not be called a "PKU card;" it is used to test for many more disorders than PKU. Until Dr W. Harry Hannon of the Centers for Disease Control and Prevention intervened in 1996, postal policies to prevent the transmission of HIV could have essentially put an end to newborn screening and subsequent dietary monitoring.

Current and Future Policies

Numerous considerations must be examined in developing policy on newborn screening. Little justification exists for screening for conditions that require no treatment until much later in life. It may be argued that the condition might be later missed, but such failure in later detection is a problem that must be addressed separately. The detection of some disorders must await technical advances that make screening reliable and relatively inexpensive. As newborn screening is extended to detecting more rare or less treatable conditions, testing becomes difficult to defend financially. Perhaps a standard should be applied that is unknown to newborn screening but familiar to other areas of public health. Will the dollars expended for the new screening prevent more grief and suffering than the same amount spent in other ways? Would funds be better directed to immunizations and accident prevention?

About 20% of current test samples need to be repeated because of an inadequate sample or borderline result. The introduction of screening for each new disorder inevitably leads to an increase in the total proportion of false positives, some of which can cause harm. A false positive for hypothyroidism or PKU is not as disturbing as one for galactosemia, which requires an immediate appraisal of whether the infant has septicemia, an early feature of untreated galactosemia. False negatives are still worse. Thyroid deficiency is not necessarily excluded by results soon after birth. Some infants have enough thyroid function to carry them through early infancy but then later become thyroid deficient (especially infants with birth weights under 1 500 g). With extensive transfusions, a condition can be missed when the test is dependent on a blood protein (eg, biotinidase deficiency and the hemoglobinopathies). Physicians can decrease the number of false negatives by considering how the tests are done. High levels of metabolites in the affected infant occur largely after birth. With mothers and babies being discharged very early, a blood sample should always be obtained at discharge with an additional sample obtained by 1 week of age if discharge was before 24 hours. Infants on soy formula or total intravenous feedings cannot be diagnosed as having galactosemia from an elevated blood galactose and therefore require an additional assay.

Present techniques in DNA analysis are unlikely to simplify newborn screening since each disorder often results from any of many mutations. Moreover, the most common type of congenital hypothyroidism does not have a genetic basis. Of very great importance in newborn screening is the changing effectiveness of treatment particularly when early treatment is essential. It is possible that future bone marrow or stem cell replacements, for example, will make additional disorders appropriate for newborn screening. Krabbe disease[17] and severe combined immunodeficiency[18] are two disorders presently approaching this point.

Future policy should reserve decisions about future tests within the staff of the Newborn Screening Laboratory and their consultants. Printed policies for newborn screening can be obtained by calling the Newborn Screening Clinical Chemistry Unit at (919) 733-3937. **NCMJ**

Call for Papers

John W. Williams Jr, MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

The Governor's Initiative to Improve Health Care:
Taking Measure of Medical Care in North Carolina

Charles Willson, MD

Most physicians I know are working longer hours and seeing more patients each day in order to meet the increasing demand for services and to make financial ends meet. We are practicing, as we were trained, to evaluate and treat each patient as an individual with unique complexities and needs. Much of the time, we deliver care that is timely, effective, and highly valued by our patients.

After the last patient of the day has been seen and the billing and paperwork is complete, we often put our feet up on the desk and read our journals and newspapers. Then we hear the drum beats of critics who say that medical care in America is not accessible to all Americans, often falls short of best practice, and sometimes is unsafe. Certainly, with our citizens' health status measuring below many third world countries and our per capita health care spending almost double that of the next most costly country (Switzerland), the question of value is most appropriate.

> *"…I believe that the act of measuring our processes and outcomes will be seen as the pivotal change that led to a safer, higher quality, and more affordable health care system."*

Payers for medical services, employers, insurers, and government are talking about mandating physician reporting of quality measures and outcomes of their care. There is talk of practice profiles, community ratings, and "pay for performance." Implementing best guidelines and generating these reports will require new office resources. Having practiced in a busy pediatric office for 19 years, often seeing more than 40 patients a day, I know how difficult it is to change how we care for patients. My analogy is that changing office processes while seeing your patients is like trying to change your pants while riding a bicycle.

As a leader of the North Carolina Medical Society, I have been privileged to participate in discussions at many venues of how we can improve and document the quality of care we physicians in North Carolina are delivering every day. I am totally committed to the proposition that it is no longer enough to say that our quality is good because we are well-trained, dedicated, and hardworking. However, I see a bicycle wreck coming down the road if physicians are required to report their compliance with best practices to each payer, in different formats and measuring different parameters.

Why not build on the data reporting primary care physicians already do for Community Care of North Carolina, our unique and highly successful case management program for NC Medicaid? Let's develop a system where one report on a care initiative meets the requirements of all insurers in North Carolina (and hopefully the federal Centers for Medicaid and Medicare Services)? Let's give our physicians the knowledge and resources necessary to measure the care they deliver to certain populations of patients within their practices. To meet this vision, a group of stakeholders, led by Governor Mike Easley, has developed a new initiative aimed at improving the quality of health care delivered to all North Carolinians.

For nearly two years, leaders from North Carolina government (the Governor's office), health care providers (the NC Medical Society, the NC Hospital Association), organizations helping practices document and improve their quality (NC Area Health Educations Centers Program, Community Care of North Carolina, the Improving Performance in Practice program), and

Charles Willson, MD, is a former president of the North Carolina Medical Society and a clinical professor of pediatrics at the Brody School of Medicine at East Carolina University. He can be reached at willsonc (at) ecu.edu or Department of Pediatrics, Brody 3E 139, 600 Moye Blvd, Greenville, NC 27834.

insurers (Blue Cross and Blue Shield of North Carolina, the NC State Health Plan, Medicaid) have been meeting to see if we could agree on an approach that would support practice-based physicians in the implementation and measurement of best practices and produce data reports that would be accepted by the payers' *quality* programs. Generous funding from a variety of organizations, including Blue Cross and Blue Shield of North Carolina, NC Medicaid, the NC Health and Wellness Trust Fund, the Center for Health Care Strategies, and the National Governors Associations, has enabled this group to develop the plan and infrastructure necessary for this ambitious objective.

Fortunately, through a grant from the Robert Wood Johnson Foundation, the Improving Performance in Practice (IPIP) program in the Department of Family Medicine at the University of North Carolina at Chapel Hill School of Medicine has been rolled out to selected practices in eastern and western North Carolina. Using agreed upon best practices and hands-on office system analysis by field agents, IPIP provides a model for how this initiative might be implemented throughout our state without disruption of patient care or financial hardship to the practices.

In October 2006, the North Carolina Medical Society House of Delegates adopted a series of recommendations on quality reporting that parallels the American Medical Association policy on pay for performance. These programs must be voluntary, evidence-based, nonpunitive, and transparent and must provide the financial and technological resources needed to support them. A group of physicians in the state of Washington has sued an insurer for using quality data to unfairly channel patients to certain practices. We need safeguards that ensure the data generated by the initiative will not be used by insurers to direct patients to practices based on lower cost rather than higher quality.

As medical historians write about the crisis we face today in American health care, I believe that the act of measuring our processes and outcomes will be seen as the pivotal change that led to a safer, higher quality, and more affordable health care system. Every physician I know wants to practice the highest quality of care, but time and financial resources are limiting barriers. The first step is to measure what we do today. With that knowledge, we can integrate a continuous quality improvement culture within our practices.

In North Carolina, I believe that we are uniquely positioned to develop an honest statewide quality of care reporting program that will be the model for our country. By participating, North Carolina physicians will not only be measuring our care, we will be taking measure of our profession. The result will support my opinion that our physicians truly are the best in the world. **NCMJ**

How to Reach Us

LETTERS TO THE EDITOR

- Our e-mail address is NCMedJ (at) nciom.org
- Our fax number is 919-401-6899
- Or you can send your letter to: *North Carolina Medical Journal*, Letters, 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713
- Please include the writer's full name, address, and daytime phone number. Letters may be edited for clarity or space.

SUBSCRIPTIONS AND GIFTS

- Customer services for subscriptions or gifts can be accessed via e-mail NCMedJ (at) nciom.org or by calling the North Carolina Medical Journal's business and advertising manager, Adrienne R. Parker, at 919-401-6599 ext. 28.

SUBMITTING PEER-REVIEWED ARTICLES

- For instructions on how to submit an article to the *North Carolina Medical Journal*, please visit http://www.ncmedicaljournal.com/guideline.shtml.
- Please send your articles via e-mail NCMedJ (at) nciom.org or mail to: *North Carolina Medical Journal,* Submissions, 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713.

CHANGE OF ADDRESS

- Please send your change of address via e-mail NCMedJ (at) nciom.org or by calling the North Carolina Medical Journal's assistant managing editor, Phyllis Blackwell, at 919-401-6599 ext. 27.

REPRINTS AND PERMISSIONS

- For advertising information visit www.ncmedicaljournal.com/media.htm or contact the North Carolina Medical Journal's assistant managing editor, Phyllis Blackwell, at 919-401-6599 ext. 27; pblackwell (at) nciom.org.

North Carolina MEDICAL JOURNAL

POLICY FORUM

Data and Health Policy

COMMENTARIES

> *"Wherever health policy is determined and by whomever it is made, the goal is to strive for policy decisions that are based on sound North Carolina data because these policies will have greater credence and acceptability."*

INTRODUCTION

Policy Forum:
Data and Health Policy

North Carolina is fortunate to have many rich sources of data that provide a solid foundation for making good policy and practice decisions to improve health and health care. Relevant, timely data and high quality analyses and interpretations provide justification for the development of evidence-based medicine, public health practice, and health policy to improve health in North Carolina.

Recently the role of evidence-based health care has been expanded with the announcement of a new, data-driven initiative from Governor Mike Easley. In April, Governor Easley announced a groundbreaking health care initiative in which insurers, organizations working to improve physician practices, providers, and others will collaborate to ensure North Carolinians receive optimal health care. Clinical as well as claims data are at the very core of the initiative. The goal is to extract information from these data, and the information will be used in innovative ways to promote optimal care through performance feedback and encouragement of best practices.

Despite the wealth of health data in the state, significant health information needs remain. For example, due to small samples, some data characterizing ethnic and racial groups yield imprecise estimates, and data pertaining to patient-practitioner interactions are also needed. Likewise, data representative of small geographic areas and subsets of the population—especially those at risk—are needed so that interventions and limited resources can be best targeted. Relatively new technologies such as electronic health records and geographic information systems are filling these gaps and providing researchers with access to much-needed data.

The issue brief by Sandra Greene, DrPH, discusses the relationship between health policy and data and provides an excellent backdrop for the commentaries. The commentary on the North Carolina Health Professions Data System (HPDS) highlights a prime example of data providing useful information to spur policy action and guide state health planning. Thanks to HPDS data, areas with health professional shortages have been identified and a possible future decline in the ratio of health providers to residents has been detected. As a result, medical schools in the state are expanding their programs, incentives are being offered to increase the number of medical school graduates, and physician retention is being encouraged.

In the run up to the fall 2008 elections, data and information systems are also at the heart of several proposals to improve health care quality and reduce the rapid growth of health care costs. North Carolina has explored the development of coordinated electronic data systems for over 15 years starting with data and information committees that were part of the Health Planning Commission and its successor, the Health Reform Commission. The Planning Commission issued a report in 1996 that formed the basis for a strategic plan for the adoption of statewide standards and systems for electronic medical records and information exchanges. The North Carolina Health Information and Communications Alliance (NCHICA) was subsequently formed to help move that plan forward. The time is now right for taking specific tactical steps toward implementation of a comprehensive health information strategy.

This issue of the *Journal* highlights the work of many organizations and individuals committed to collecting, analyzing, interpreting, and using data to improve health within the state. We hope this issue provides readers a broad understanding of the existing data resources in our state and provokes thoughtful discussion about how to enhance existing data resources, recognize possible synergy among datasets, and identify needs and potential solutions.

Data and Health Policy:

Do We Do Our Best?

Sandra B. Greene, DrPH

Health care policy has emerged among the general public as a priority issue for the November 2008 presidential election. Second only to the war in Iraq, health care and the economy are the domestic issues foremost on the minds of Republicans, Democrats, and Independents polled by the Kaiser Family Foundation.[1] Specific issues of greatest concern are the intertwined problems of cost and the availability of health insurance to provide financial access to care. While some candidates propose sweeping change to address the nation's health care ills,[2] historically the health care system has evolved incrementally through moderate policy reform.

Health care policy positions are formulated at the national, state, and local levels. In the state of North Carolina there are many stakeholders responsible for decision making, ranging from departments and divisions of state and local governments to public and private institutions. Collectively, health care policies impact who is eligible to receive health care, what types of care are available and provided, where facilities and services are located, and who pays the bill. In sum, health policy provides the direction, specifications, and building blocks that define our health care system.

Sources of Data for Health Policy

Data useful for health policy decision making in North Carolina originate from numerous sources. This issue of the *North Carolina Medical Journal* describes what these data are and where they come from and explains how they are or can be used. While some data are collected in a one-time study or survey, the most commonly used sources are collected on an ongoing basis, either mandated by state or federal law or by voluntary submission. The range of data sources includes population-based surveys, patient registries focused on specific diseases or conditions, vital records of births and deaths, workforce databases, electronic medical records, and insurance billing records.

The Behavioral Risk Factor Surveillance System (BRFSS), an example of a population-based survey, was originally developed by the Centers for Disease Control and Prevention to measure health behaviors and use of health care services.[3] It is now in use in all states and the District of Columbia and in this state is conducted by the North Carolina State Center for Health Statistics (SCHS). Paul Buescher discusses this survey and other data collection projects in an accompanying commentary. A sample of North Carolina households is randomly contacted by telephone, and adults in the household are interviewed. Questions cover topics including perceived health status, self-reported health care conditions, availability of health insurance, and respondent's use of health care services including screening. Results are reported on a statewide basis and for individual counties with large populations. Core questions are repeated each year, allowing analysis of trends. Additionally, selected questions are added annually as new policy interests emerge. While the BRFSS focuses on North Carolina adults, a companion survey was recently implemented to gather health characteristics of children. Data collection for the Child Health Assessment and Monitoring Program (CHAMP) began in January 2005.[4]

> *"Assuring that health policy decisions made for the citizens of our state are the best they can be calls for nothing less than data-driven decisions."*

Sandra B. Greene, DrPH, is a senior research fellow and research associate professor of Health Policy and Administration at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill. She can be reached at sandrab_greene (at) unc.edu or 725 Martin Luther King Jr Blvd, Campus Box #7590, Chapel Hill, NC 27599.

The North Carolina State Center for Health Statistics also administers patient registries which focus on specific at-risk populations. The Birth Defects Monitoring Program (BDMP) collects and analyzes information on infants born with serious congenital anomalies.[5] These data are aggregated from multiple sources including hospital medical records, hospital billing data, and vital records. A second registry, described in a commentary by Karen Knight, Paul Buescher, and Walter Shepherd, tracks cancer cases in the state, reporting that is required by law. These data are gleaned from hospital records, death certificates, and in cases where the patient is not hospitalized, by physician report.[6] Another source of health care data collected by the National Center for Health Statistics (NCHS) is vital records. Also mandated by law, these databases include registrations of all births and deaths occurring in the state.[7]

The North Carolina Trauma Registry (NCTR) has collected data since 1987 from state EMS agencies, acute care hospitals, and other providers in an effort to provide quality care for injured patients throughout North Carolina. Michael Thomason writes about NCTR and its coordinated data system in his commentary.

Data on the state's healthcare workforce can be found in the North Carolina Health Professions Data System (HPDS), housed at the Cecil G. Sheps Center for Health Services Research.[8] This system is a collaborative effort with the Area Health Education Centers Program and the independent licensing boards of each participating health profession. Included in the database are over 2 decades of demographic and employment history on physicians, nurses, dentists, chiropractors, and other types of health care professionals. Jennifer King and Mark Holmes speak to the importance of these databases and their uses.

Insurance billing records, also referred to as administrative records, provide a rich source of data for use in health policy decisions. These data originate from 2 primary billing forms: the Uniform Billing-92 (UB-04 after June 1, 2007) used for billing institutional charges and the Health Care Financing Administration (HCFA) 1500 used for billing professional charges.[9,10] Information from these records contain patient-level detail on health care services provided to a covered population including physician and clinic visits, emergency room care, hospitalizations, outpatient prescription drugs, and the charges and payments for those services. These databases also contain information on patients' diagnoses, tests, and procedures. Grouping an individual's claims into episodes illuminates patterns of care that when aggregated across population groups provides a picture of how illnesses are treated and how health care services are utilized.

Insurance billing records are maintained by insurance companies or, in the case of publicly funded programs such as Medicaid and Health Choice, a system administrator. The largest database of this type in North Carolina is maintained by Blue Cross and Blue Shield of North Carolina. The Division of Medical Assistance maintains the second largest insurance billing database which contains claims on all Medicaid eligible recipients. Databases such as these housed by private and public insurers are proprietary, and data from them are generally only available for analysis and use in health policy considerations on an ad hoc basis.

The most detailed information documenting patient care is contained in medical records. These are patient-specific files kept in every health care facility. They contain information on all care provided to the patient including patient symptoms and presenting complaints, information that is not contained on billing records. Medical records also contain results from laboratory tests, screening, and outcomes of treatments and procedures. While medical records have traditionally been handwritten, limiting their usefulness for analysis across population groups, the electronic medical record affords significant opportunities for data aggregation and population-based study. Xiaoming Zeng addresses this potential in his commentary.

The articles in this issue of the *Journal* focus on some specific data sets and their policy context. One data set in particular, the hospital discharge and ambulatory surgery data set, has a history that illustrates how policy can be shaped both by the information extracted from the data and by the data themselves, and how the data used can be shaped by the policy process.

History of the Medical Database Commission

As medical costs rose rapidly in the early 1980s, many legislators, employers, and health policy analysts recognized a need for public information on cost and utilization of health care services. Insurance billing records were viewed as a valuable potential data source. In 1985 the General Assembly created the North Carolina Medical Database Commission with the charge "to establish an information base to be used to improve the appropriate and efficient usage of medical care services, while at the same time maintaining an acceptable quality of health care services in this State. This is to be accomplished by compiling a uniform set of data and disseminating aggregate data, including but not limited to price and utilization data."[11] The Commission began its work in 1986, and 3 years later the first data reports, based on electronic copies of UB-92 records, were released. The reports contained summary information on all discharges from North Carolina acute care hospitals. For the first time, North Carolina had information on hospital discharge diagnoses, procedures, and associated facility charges for the entire population.

Through the early 1990s the North Carolina Medical Database Commission continued to expand its efforts to make health care data available to the public. In addition to enhanced hospital discharge data reports with comparisons of charges among providers and analyses of where patients travel to receive care, it also expanded into ambulatory surgery reporting. All licensed free standing ambulatory surgery centers submitted copies of UB-92 billing forms to the Commission's data processor. Annual reports were developed and released. By 1995 both hospital and ambulatory surgery utilization and charge information were available and widely disseminated.

Not all stakeholders were comfortable with the public availability of the Commission's data. In the 1995 session of the

General Assembly, the North Carolina Medical Database Commission was abruptly eliminated. In its place, the Medical Care Data Act was passed establishing the authority of a state data processor, with oversight of the Division of Facility Services [now the Division of Health Service Regulation (DHSR)], to assume responsibility for the collection and reporting of data.[12] The state data processor chosen for this role was Solucient (now Thomson Solucient). Under the direction of DHSR, a copy of the state databases is housed at SCHS for use by the state medical director, and a second copy is maintained at the Cecil G. Sheps Center for Health Services Research for use in state health planning. During the transition from the Medical Database Commission to the state data processor, 1995 data were not collected. Data collection resumed in 1996 and continues today with ongoing reporting by hospitals and freestanding ambulatory surgery centers. However, the public reporting function that existed under the Medical Database Commission no longer exists.

In 2004 statewide collection of health care data expanded with the collection of data from hospital emergency departments. Mandated by law, all emergency departments are required to report an electronic record of each visit.[13] Reporting is to occur daily. The purpose of this data collection effort is to provide data for public health surveillance and to enable an early warning system of bioterrorism or other public health crisis resulting in patients presenting for emergency care. The North Carolina Hospital Surveillance System, a collaborative project between the North Carolina Division of Public Health, the North Carolina Hospital Association, and the University of North Carolina at Chapel Hill School of Medicine, collects and processes the data from all North Carolina hospitals.[14]

How Do We Use Data for Health Policy?

The policy relevant data sources available in this state are used in a multitude of ways to identify new policy directions, support or change existing policy, or to illuminate health problems that if addressed would improve the public's health. Dianne Enright writes about how data provided by geographic information systems help determine allocation of limited public health resources. David Murday and Elizabeth Corley discuss how philanthropic foundations use health data to identify communities whose needs are aligned with a philanthropy's priorities. Christopher Manfield and James Wilson explore how data are used at the local level by citizens, providers, organizations, and policy makers to improve community health. Mark Massing and Anna Schenck discuss how data are used at The Carolinas Center for Medical Excellence to inform consumers, assist providers, and develop information to improve health policy at the federal and state levels.

BRFSS survey results provide relevant examples of how data sources are used to develop and direct policy. General population prevalence estimates of chronic conditions such as arthritis, asthma, and diabetes are calculated from the survey results. The North Carolina Division of Public Health develops programs to provide technical assistance, resources, and care management tips to reduce illness burden for these conditions.[15-17] Behavioral Risk Factor Surveillance System estimates also are used to measure levels of personal behavior that negatively impact health including smoking, alcohol use, and seatbelt use. Programs are then developed to address these behaviors.[18,19] The continuous data gathering of the BRFSS allows program administrators to evaluate their success in reducing negative behaviors by reviewing subsequent survey results.

In a similar fashion to the population estimates from the BRFSS survey, data from the state's vital records and condition-specific registries are used to develop and monitor health care programs. Infant death rates, for example, are closely monitored as a key indicator of the quality of our health care system. North Carolina's high rate of 8.5 infant deaths per 1000 live births in 2004,[20] compared to 6.8 in the US,[21] directs attention to programs that improve access to and use of prenatal care. Overall population death rates also provide rich opportunities to identify and address health care challenges. County and regional death rates, along with disease specific rates, illuminate program opportunities to reduce disease risk and improve the provision of care for those impacted by disease. An advantage of the ongoing availability of these data sources is that it allows continued monitoring and evaluation of program effectiveness.

Information from the state's workforce database, the Health Professions Data System, is used in a wide array of program and policy development activities. These data show where health professionals are employed and the relative availability of the workforce by county and region. It helps track trends in workforce use and identifies shortages in supply. It also enables determination of the age distribution of those working, allowing estimates of how retirements will impact future workforce availability. All of this information is essential for understanding employment needs and drives policy decisions on training programs required to assure a continued supply of the right discipline and number of health care professionals.[22]

The health planning process in this state is largely data driven as reflected in the annual state medical facilities plan developed by the Division of Health Service Regulation (DHSR) under the direction of the North Carolina State Health Coordinating Council.[23] This plan provides need projections for health care facilities and services as specified in GS § 131E-177 including hospital beds, rehabilitation beds, skilled nursing beds, operating rooms, technology, and medical equipment. Much of the data used in health planning are derived from the annual license renewal application form. These forms are required by DHSR for a facility to renew its operating license. Facilities currently complete a handwritten copy and submit it by mail to DHSR. Plans for electronic submission are underway. The form asks for counts of services provided at the institution with instruction on how services should be defined and counted. It is a lengthy form requiring considerable time and effort to complete. Facilities are generally diligent and conscientious in completing these forms. However, there is no audit function to determine the accuracy of the data submitted, and reporting categories are subject to individual interpretation by the facility completing the form.

Other sources of data used to support health planning are the hospital and ambulatory surgery databases collected by Thomson Solucient under the Medical Care Data Act. The State Health Coordinating Council committees that oversee the development and refinement of methodologies for determining needed facilities and services use these databases to understand how services are currently utilized and to project future use. As an illustration, to determine when additional acute care hospital beds are needed, 4 years of historical hospital discharge data are analyzed. An average annual historical rate of change is calculated for those 4 years. Using this rate of change, coupled with a projection of population growth or decline, a calculation is made to determine how many beds will be needed in a service area 6 years into the future. A comparison of the number of existing beds to the number projected to be needed determines if additional beds should be built. Starting with data on current utilization rates and reflecting recent changes in those rates provides a sound basis for future planning. The advantage of using the Thomson Solucient databases to determine utilization rates, rather than a self-reported number of cases from the provider, is more assurance that each facility is treated fairly by counting past utilization consistently.

Emergency room data collected by the North Carolina Hospital Surveillance System are used by the public health community for surveillance and planning. These data are submitted to the North Carolina Disease Event Tracking and Epidemiologic Collection Tool (NC DETECT) which is a tool for categorizing, analyzing, and reporting the data.[24] These data on nearly 3.5 million emergency department visits annually are available to approved users for population-based studies.[25]

What Additional Data Do We Need?

While there is always the desire for more and better data for policy and decision making, collecting additional data has significant ramifications, particularly if it is new information that would place administrative burden on providers to report. While expanding data collection is a worthy goal, we should carefully choose areas of expansion where the expense and effort can be justified. William Kalsbeek's commentary describes an effort underway at the University of North Carolina to identify gaps in public health information. We should also seek opportunities to make optimal use of the data we have. In this spirit the State Health Coordinating Council recently acted to transition to the use of the Thomson Solucient databases for determining operating room need in North Carolina. The current methodology utilizes self-reported aggregated data on the license renewal application form. Using administrative data will enable counts of individual procedures that are consistent for each provider. This change in methodology will take a number of years to accomplish but will improve the accuracy of the need projections and advance the credibility of the process.

Another initiative designed to make better use of the data we have is the North Carolina Comprehensive Assessment for Tracking Community Health (NC-CATCH). James Studnicki, John Fisher, and Christopher Eichelberger describe the development of this Web-based portal for community surveillance in their commentary.

The Thomson Solucient hospital discharge databases provide comprehensive data for care provided in the state's inpatient facilities. However, the Thomson Solucient ambulatory surgery database contains some gaps, with not all freestanding ambulatory surgery centers reporting as required. There has also been a void in data and information on services provided in hospital emergency departments. The new North Carolina Hospital Surveillance System data may serve to fill this gap if the data are made available to planners and policy analysts.

The biggest gap in available data, however, is in records for care provided in physician offices, clinics, and hospital outpatient departments. While approximately 12 in every 100 persons experience a hospitalization during the year and discharge records are available for these events, each person averages between 3 and 4 outpatient visits per year, and we have no database chronicling these events.[26] Outpatient settings are where most contacts with the health care system occur. If we are to adequately understand what care is provided, where it is provided, to whom it is provided, and for what conditions, there is a need to have data on these visits contained in publicly available databases that can be used for a wide range of planning and policy functions.

Another significant gap in publicly available data is information contained in medical records. To fully understand the care process, it is important to know more than diagnoses and procedures. It is necessary to understand patients' presenting complaints, signs, symptoms, and test results. These data are critical for determining the quality and appropriateness of provided care, for assessing patient outcomes, and for measuring and reducing racial and ethnic disparities in treatment patterns. As more medical records are converted to an electronic status, access to these data will become feasible. However, the challenges to the use of electronic medical records are significant. First, there is no standard acceptable format for a medical record like the standard UB-04 and CMS 1500 forms. Combining multiple formats can be difficult and costly. The second major challenge is finding a vehicle for pulling together medical records from multiple sites including physician offices, clinics, and hospitals. Yet this is necessary to aggregate data for population groups. Overcoming these obstacles would provide rich data for surveillance, research, and health policy.

What prevents us from collecting more expansive data and making it available for use in health planning and policy? Cost is perhaps the most significant deterrent, though there must also be the political will. It is costly to collect large amounts of new data. Extracting data that has already been collected for another purpose is less costly, as electronic processing and data storage costs have declined. Expansion of data collection is not viable, however, on a voluntary basis. Mandated reporting by providers, achieved through legislation, is critical to assure complete reporting.

Where Do We Go From Here?

To improve our ability to make data driven decisions in health policy, we should continually look for additional data sources and make publicly accessible those data sources that already exist for other purposes. In this spirit, the Carolina Cost and Quality Initiative (CCQI) was created. The Carolina Cost and Quality Initiative is a collaborative partnership between the University of North Carolina School of Public Health and the Sheps Center to build, maintain, and oversee the use of administrative databases on health care services provided to North Carolina population groups.[27] The purpose of this project is to promote population-based research on the incidence and prevalence of disease in insured populations, to study patterns of health care utilization and cost of care, and to provide information for informed policy decisions on issues impacting our population's health.

Owners of administrative databases in North Carolina have been invited to partner with the University of North Carolina in this project and to share their data. Two are currently participating, and we expect more to join. The Carolina Cost and Quality Initiative project now houses databases contributed by the North Carolina State Employees Health Plan (SEHP) and the North Carolina Division of Medical Assistance (DMA). As the data owners, SEHP and DMA share data through contractual agreements with the university. Each database contains 5 years of historical claims data, and the data owners have agreed to provide periodic updates to keep the databases as current as possible. University faculty and research staffs are invited to submit project proposals for use of the data. Each project request is reviewed by an oversight committee consisting of representatives of the data owner and of the university; upon approval, data are prepared by CCQI staff for the researcher's use.

The Carolina Cost and Quality Initiative databases include insurance claims for hospitalizations, doctor visits, outpatient surgery and treatments, emergency room use, and outpatient prescription drugs. Patient identifiers are encrypted to protect patient confidentiality and to allow the researcher to track all treatments provided to the same individual. The 2 databases combined represent all health care services provided to approximately 1.5 million persons who are geographically dispersed throughout the state. Such a rich set of data for this large population group provides a significant opportunity for research that can favorably impact health policy decisions in the state. We invite project requests and encourage these databases to be used in this way.

Administrative databases, as useful as they are, do not contain information on the results of tests and procedures. To add this additional level of detail, we must also strive to find ways to use electronic medical records for large population groups. Such an undertaking will require combining files of medical records across providers and facilities and encrypting identifying information to protect confidentiality in the process. Holt Anderson and Gary Bowers discuss health care information exchange across provider groups in their commentary. The resulting databases will be extremely large for a population group, but the advantages from this type of data aggregation in informing policy makers and researchers would be significant.

The potential rewards from increasing data collection and availability will be diminished if we do not simultaneously prepare researchers, planners, and policy makers to use available data sources. Elizabeth Layman, and Debbie Travers and Lawrence Mandelkehr, address these issues in their respective commentaries. We must put a greater focus on data and analytics in university curriculum in the courses and programs that are training our next generation of health care leaders. Health care researchers should be trained in the use of claims data analysis and electronic medical records. Those who are preparing for leadership roles should be trained in data literacy to ask for and expect quantitative assessment of health policy issues in their workplace.

All of us in the health care field must look for ways to work collaboratively towards increased availability and use of appropriate data. Assuring that health policy decisions made for the citizens of our state are the best they can be calls for nothing less than data-driven decisions. And as Marcus Plescia and Jeffrey Engel point out in their commentary, future public health data needs must reflect the foreseen and unforeseen changes in our state. Wherever health policy is determined and by whomever it is made, the goal is to strive for policy decisions that are based on sound North Carolina data because these policies will have greater credence and acceptability. **NCMJ**

COMMENTARY

Electronic Records in Health Care

Xiaoming Zeng, MD, PhD

Health care can be studied from many viewpoints. Using information as the primary way to examine our health care system has lately been on the agenda of national health care policy. Physicians need to process large amounts of data into information to make clinical decisions. Public health practitioners need to aggregate heterogeneous data at population levels to prevent and detect epidemics. Health care policy makers need to use a variety of secondary databases as evidence for policy making. How can we ensure the right health care information is accessible to the right person at the right point in a timely manner? At this moment, the only solution to the question is to digitalize the information and share it on a secure, networked information system. Electronic health records (EHRs) offer one such solution by providing a platform for acquisition, storage, access, analysis, and presentation of health data. Electronic health records systems are touted as one of the keys to a new health care system that provides quality and cost-effective care.[1-6] President George W. Bush set a goal of making the use of electronic health records universal by 2014.[7] Various initiatives have been implemented across the health care spectrum from federal to community-level programs.[8,9] Studies demonstrate the promising effects of EHRs on controlling cost, enhancing quality, and reducing medical errors.[5,10-13]

> *"Electronic health records systems are touted as one of the keys to a new health care system that provides quality and cost-effective care."*

We are currently in a transition period in that many health care facilities are upgrading their paper-based record systems to electronic health records systems. Among the many functions of health records, documenting patient care over time is the most essential. To deliver quality care, providers need timely and accurate data on a patient's current and past medical history which may include findings from physical examinations, laboratory results, insurance, and other sources. This situation is made more complex due to increased life expectancy and the shift of the disease delivery model from acute care to chronic care. More data and information are created in the process of caring for a patient with complex, often multiple, diagnoses. Patients with chronic diseases often visit multiple providers and take multiple medications. It is cumbersome for doctors to go through the process of acquiring data from various sources in order to make the right diagnosis, perform the right procedures, and prevent medical errors. Even if practitioners obtain all of the data, they need enormous logistical and technical assistance in order to link it together.

Data in health care, especially patient-based clinical data, have long been entered and stored on paper. Paper records usually allow practitioners to record information in a semi-structured, free-text format. One weakness of paper records is that the information recorded there can be accessed by only one person at a time at one location. Sharing paper records is cumbersome and cost-inefficient. More importantly, it presents a challenge to aggregate all the data from different sources in order to find patterns which are often used in health policy analysis.

A consensus national priority is to establish a networked EHR system that shares the integrated information of each individual at the point of care. To achieve this goal, a totally automated EHR system is needed at each health care institution. More importantly, these institutions should have the capacity to share information with others. This commentary offers more detailed information about EHRs and their value as a data source for health policy, as depicted by Greene in the issue brief of this journal.

Xiaoming Zeng, MD, PhD, is an assistant professor of health services and information management at East Carolina University. He can be reached at zengx (at) ecu.edu or 4340Q Health Sciences Building, East Carolina University, Greenville, NC 27858.

Definitions

Historically, many terms have been used for the concept of an EHR system.[14] The electronic medical record (EMR) is a term often used interchangeably with EHR. The key conceptual difference between EMR and EHR is the owner and location of the record. Electronic medical records are usually included in a local clinical data repository used to support clinical operations. They are usually owned by an individual health care provider and are often accessible to the patients who are the customers of the health care provider. Electronic health records refer more to an overarching system based on information shared by individual care practitioners regardless of practitioner specialty, type of care (eg, inpatient, ambulatory), or location of care. Electronic medical records are often practitioner-oriented while the EHR is patient-centric and supports coordinated care. More importantly, the concept of EHR goes beyond episodic care in health care facilities by providing not only a comprehensive medical history (when patients interact with practitioners) but including patients' own records of their health status (when patients don't interact with practitioners). So, even an EMR system in an integrated delivery system is not equivalent to an EHR system because it does not contain the entire picture of a patient's health status.

Electronic medical records and EHRs are interrelated. Successful EHRs rely on EMRs as the data providers to construct different segments of the individual's health history. The key for the success of patient-centric EHR systems is for each EMR system to have the capability to share data in an automated and error proof way. Because a patient may have different records located in different EMRs, accurately and efficiently linking all the records together is a challenge because there is no existing centralized patient index. Such sharing is called health information exchange.[15]

To undertake the task of health information exchange, two solutions are being implemented by the Office of the National Coordinator of Health Information Technology. One is to build a national health information network which enables providers to access needed patient-related information. The US government is currently promoting a bottom-up, market-oriented approach by advocating regional health information organizations (RHIOs) as the foundation of a national health information network. Stakeholders within each RHIO will share data with their own selection of network and information architecture. The North Carolina Healthcare Information and Communications Alliance (NCHICA) is coordinating an effort to create a regional health information organization in North Carolina. Sharing data among regional health information organizations will complete the national health information network.

Fully functional regional health information organizations and national health information networks rely on information interoperability, which has a long way to go.[16] The other solution to health information exchange is to let patients manage their own personal health information using tools like personal health records. The American Health Information Management Association defines personal health records as "a collection of important information about your health or the health of someone you are caring for (such as a parent or child) that you actively maintain and update. The information comes from your healthcare provider and from you."[17] It is not necessary to have only the encounter data stored in the personal health record. Ideally, patients also would record data related to their health status such as weight, diet, and exercise routines. A successful personal health record system should have interfaces to all the EMR systems in which patients have data footprints.[18,19] Microsoft recently started a Web-based personal health record that allows consumers to store their health records online and share them with their designated providers.[20]

Electronic Health Records and Health Policy

The advocates of EHRs believe they are integral to controlling the cost, improving the quality, and increasing the efficiency of health care. These benefits are largely at the direct patient care level. There also are important benefits to health policy makers at a system level. As Sandra Greene defined in her issue brief, "health policy provides the direction, specifications, and building blocks that define our health care system." As such, EHRs could systematically be used for quick data collection and policy dissemination in health care.

Electronic Health Records As a Data Source for Health Policy

The EHR has primary and secondary usages. Examples of primary usage of EHRs include informing and supporting direct patient care, management support, financial and administrative processes, and patient self-management. Secondary usages of EHRs include education, regulation, research, public health policy, homeland security, and policy support.

The medical or clinical encounter record, whether in paper or electronic format, is the primary data source in health care because it contains specific data pertaining to a specific patient. Primary data sources, after de-identification and aggregation, are the raw inputs to the secondary data sources that are used in health care policy making. For example, a cancer registry is a secondary data source that collects data related to cancer diagnosis and uses it for monitoring patterns of cancer cases in the US. After a patient is diagnosed with cancer, demographic data, occupational history, and administrative and pathological data will be recorded into a facility's cancer registry. The information is then sent to state and national registries. The process of data collection historically relied on manual chart review and reporting due to the paper-based record environment. In an EHR system, data collection is simplified by querying a well-structured database. Moreover, it accelerates the data transmission from an individual facility to a state or national registry. The National Program of Cancer Registries' Modeling Electronic Reporting Project (NPCR-MERP) is an effort at the Centers for Disease Control and Prevention to enable cancer registries to obtain most cancer data electronically and to produce more complete, timely, and accurate cancer surveillance data.[22]

Electronic health records may not necessarily reduce the burden of data entry; however, they will largely facilitate data retrieval and analysis. For example, drug recalls in the past required nurses to manually review patient charts at one facility to find all patients who had the drug on their medication list. In the electronic health record environment, it would take a fraction of the time to query a database in order to identify these same patients.[23] Because EHR and personal health records systems are patient-centric and health-oriented, they make it easy to collect data that would be hard to collect from paper records. For example, the Behavioral Risk Factor Surveillance System (BRFSS) collects data from telephone surveys. If the BRFSS survey is implemented as data elements in an EHR or personal health records system, the data can be easily collected electronically. Ball and Gold[24] proposed a Health Record Bank model that provided patients the power to share their health data with researchers. This would expand the scope of health policy data collection from clinical care to health status.

Electronic Health Records as a Distribution Vehicle of Health Policy

The other implication of EHR for health policy is that health care providers can be informed of important policy by integrating health policy with EHR systems. The Institute of Medicine of the National Academies defined 8 core functions of EHRs in *Key Capabilities of An Electronic Health Record System: Letter Report:* (1) health information and data; (2) results management; (3) order entry/management; (4) decision support; (5) electronic communication and connectivity; (6) patient support; (7) administrative process; and (8) reporting and managing population health.[25] The functions of administrative process and reporting and of managing population health could be used as the leverage points for implementing health policy at the practitioner's level.

Improvements in health care, once verified, need to be disseminated quickly to individual practitioners to be effective, especially at the point of care. This could consist of reminders generated from guidelines related to preventive public health interventions. Many studies have demonstrated that relevant, integrated reminders in EHR could increase the level of compliance with accepted health care guidelines or policies. Alerts could include important information about disease outbreaks or important medication updates. When available, information could be extended to providers on applicable public health interventions, preventive medicine, or disease management.

In the event of a health event affecting a large population, a key activity of health policy is to notify practitioners and patients about available actions to prevent a disease or reduce its impact at the individual and the community levels. Electronic health records can facilitate such intervention in several ways. First, they can provide decision support that enables the implementation of a public health intervention directed to the patient at the point of care. Additionally, they can be a means to inform clinicians of health policy updates. Ultimately, they can provide necessary education to both practitioners and patients.

As mentioned above, EHRs also offer the opportunity to improve policy compliance by incorporating policies, or rules, into the EHR system. Because each EHR system should have decision support capability, transforming health policies—particularly those for disease prevention and management—to unambiguous knowledge representation modules will systematically standardize treatment of consumers at the point of care. For example, the use of reminders in an EHR system increased the number of mammograms, glycosylated hemoglobin tests, and varicella and influenza immunizations for persons with diabetes.[26]

Many barriers remain on the way to having a universal electronic health records system by year 2014—notably lack of initial financial support, misaligned incentives, and missing business models for sustainable health information exchange.[17,27] The US Department of Health and Human Services has recently started a 5-year project to encourage small and medium-size medical practices to adopt EHR systems by providing bonuses to participating practices that adopt certified electronic health records.[28] There is still a long way to go to before there is an EHR system that can store the entire health history of a patient and provide instant access to those who need the information. Until then, the benefit of electronic health records to health policy will not be fully realized. **NCMJ**

COMMENTARY

Public Health Surveillance Data in North Carolina

Paul A. Buescher, PhD

Data from a variety of sources comprise the public health surveillance system for North Carolina today. The purposes of public health surveillance go far beyond collecting data. Effective public health surveillance ensures that the data are used by health policy makers, state and local public health agencies, and health program managers for effective public health planning, resource allocation, and program evaluation. Surveillance is a core public health function. A number of the 10 national essential public health services involve using data and include the following: monitor health status to identify community health problems; diagnose health problems and health hazards in the community; inform and educate people about health issues; evaluate the effectiveness, accessibility, and quality of personal and population-based health services; and conduct research for new insights and innovative solutions to health problems.

> *"Effective public health surveillance ensures that the data are used by health policy makers, state and local public health agencies, and health program managers…"*

The purpose of this article is to describe the major public health surveillance databases available in North Carolina and present some examples of how these data have been used for education, policy, planning, and evaluation. A number of these databases are housed in the State Center for Health Statistics (SCHS), which is located organizationally in the Chronic Disease and Injury Section of the North Carolina Division of Public Health. Until 1980, the SCHS was named the Public Health Statistics Branch and dealt mainly with vital records data such as births and deaths. It was renamed the State Center for Health Statistics, and its mandate was broadened to include responsibility for a wider range of databases. Even when the SCHS does not produce and house the data, it is responsible for accessing health data from a variety of sources and making it available for health policy and program planning. A number of these "outside" data sets are included in this inventory.

The State Center for Health Statistics consists of about 65 employees organized into the following 5 major work units: Statistical Services, Birth Defects Monitoring Program, Central Cancer Registry, Health and Spatial Analysis, and Operations/Quality Management. The State Center for Health Statistics serves the entire Division of Public Health and also some agencies in other areas of the North Carolina Department of Health and Human Services. In addition to providing data and technical support to health and human services programs, the SCHS produces a comprehensive set of health-related publications and answers thousands of requests for data from a variety of individuals from across the state and the nation. More information about the SCHS and its data products, publications, and services can be found at its Web site at http://www.schs.state.nc.us/SCHS.

The State Center for Health Statistics has a Health Data Query System (http://www.schs.state.nc.us/SCHS/data/query.html) that allows the user to generate custom designed, detailed data reports for deaths, births, birth defects, pregnancies, and population data. In addition, public use data files with individual birth, death, fetal death, and matched birth/infant records for the years 1968-2006 (with complete data file documentation) can be downloaded from the Odum Institute for Research in Social Science Web site (http://www.irss.unc.edu/odum/jsp/content_node.jsp?nodeid=10).

This article is not intended to provide a comprehensive inventory of health data available in North Carolina. We include databases that are (1) used extensively by public health programs for surveillance purposes; (2) statewide in coverage;

Paul A. Buescher, PhD, is the director of the State Center for Health Statistics in the Division of Public Health, North Carolina Department of Health and Human Services. He can be reached at paul.buescher (at) ncmail.net or at 1908 Mail Service Center, Raleigh, NC 27699-1908.

and (3) regularly produced or updated as opposed to special or one-time data collection efforts. In general, we do not include health program databases that contain mainly patient and medical encounter information.

Some of the databases described here can be used only for statewide estimates (this includes most of the sample-based surveys) while many will support production of data at the county level. County-level data are used extensively for community health assessment and other local planning and evaluation efforts. (For information about the North Carolina Community Health Assessment Initiative, go to http://www.schs.state.nc.us/SCHS/about/chai.html.) Usually, data are tabulated by county of residence (regardless of the location of the event) so population-based rates can be produced. Even where the data represent a complete count of events (such as deaths), there may be substantial random error in rates based on small numbers of events. (See "Problems with Rates Based on Small Numbers" at http://www.schs.state.nc.us/SCHS/pdf/primer12.pdf.) Combining several years of data before producing rates or aggregating counties will stabilize the rates by reducing random variability due to small numbers.

MORTALITY DATA

Death Certificate Data

Vital records have been core data for public health surveillance since complete registration began for North Carolina in about 1918. North Carolina law requires that a death certificate be filed for each death that occurs in North Carolina. In addition, there is an interstate vital records exchange agreement where we receive death certificates for all North Carolina residents who died in other states. We combine these data to produce complete mortality data by county of residence. For most chronic diseases and for injuries, we do not have comprehensive morbidity data so death rates are often used to portray rates of chronic disease and injury in the state. *The Leading Causes of Death* publication of the SCHS shows numbers of deaths, unadjusted death rates, and age-adjusted death rates for 20 causes of death by county of residence.[1] For details about the rationale for and calculation of age-adjusted death rates, visit http://www.schs.state.nc.us/SCHS/pdf/primer13.pdf.

Medical Examiner Data

The Office of the Chief Medical Examiner (OCME) investigates all deaths due to injury and violence, those from suspicious or undetermined causes, and deaths not attended by a physician. The OCME collects additional information that is not available from the death certificate data system including alcohol and other toxicology test results and more detailed information on gun type for deaths involving firearms. Approximately 9000 of the 75 000 deaths in North Carolina each year are investigated by medical examiners. Limited medical examiner data can be found on the SCHS web site at http://www.schs.state.nc.us/SCHS/data/medexam. For additional information or further data, contact the OCME at (919) 966-2253.

North Carolina Violent Death Reporting System

The North Carolina Violent Death Reporting System (NC-VDRS) began collecting data in January 2004. The NC-VDRS provides detailed statistics about victims and suspects involved in incidents where intentional violence resulted in death (ie, homicide, suicide, legal intervention). Data also are collected for unintentional firearm deaths and deaths with undetermined manner/intent. The NC-VDRS uses information from multiple data sources (eg, death certificates, law enforcement records, medical examiner reports) to provide a description of circumstances, demographics, relationships between victims and suspects, and weapons. Provisional counts and selected data from the NC-VDRS are typically available within 8 months of the calendar year in which the deaths occurred, and complete data are available within 18 months.

The National Violent Death Reporting System (NVDRS) Web site at http://www.cdc.gov/ncipc/profiles/nvdrs/default.htm provides information about the system, its goals, the data it collects, the states that are funded, and how to access NVDRS data. Requests for North Carolina data can be made to the North Carolina Injury and Violence Prevention Branch at (919) 707-5432.

BIRTH-RELATED DATA

Birth Certificate Data

North Carolina law requires that a certificate be filed for each live birth that occurs in North Carolina. In addition, there is an interstate vital records exchange agreement where we receive birth certificates for North Carolina residents who deliver in other states. We combine these data to produce complete natality data by county of residence. In addition to live births, data are collected for each fetal death (stillbirth) of 20 or more week's gestation. *The Basic Automated Birth Yearbook (BABY Book)*,[1] an annual publication of the SCHS, shows live birth numbers for the state and each county tabulated by a number of characteristics captured on the birth certificate: mother's age, mother's race, mother's education, smoking during pregnancy, month prenatal care began, number of prenatal care visits, birth weight, birth order, and medical conditions of the mother. The State Center for Health Statistics also annually publishes *North Carolina Vital Statistics, Volume 1*,[1] which contains selected live birth and fetal death measures for the state and each county. North Carolina live birth and fetal death data are submitted to the National Center for Health Statistics as part of the national vital statistics system.

Reported Pregnancies

The State Center for Health Statistics combines data on live births, spontaneous fetal deaths, and induced abortions to produce statistics on reported pregnancies in North Carolina.[1] In 2006 there were 127 646 live births, 868 fetal deaths, and 29 430 induced abortions reported for North Carolina residents. Fetal deaths in North Carolina are reportable to the state only if they are 20 weeks or more in gestation, so our pregnancy statistics do not include spontaneous fetal deaths of less than 20 weeks gestation (ie, early stillbirths or miscarriages).

Birth Defects Data

The North Carolina Birth Defects Monitoring Program (BDMP)[2] was formally established by the North Carolina General Assembly in 1995. The BDMP gathers data on infants who are born with serious congenital anomalies (birth defects) diagnosed within the first year of life (approximately 4000-5000 infants per year). Data are collected by trained field staff who systematically review and abstract hospital medical records, supplemented by information from administrative health databases such as hospital discharge data, vital records, and other sources. This intensive method of case ascertainment provides the most complete, accurate, and timely data on the incidence of birth defects thereby enhancing its usefulness to public health programs. The program maintains a central registry with patient-identifying information which is considered confidential under state law.

HOSPITAL-RELATED DATA

Inpatient Hospital Discharge Data

Selected data are collected for each of the more than 1 million inpatient hospital discharges occurring each year in North Carolina. This database is owned by Thomson Healthcare, Inc, and the data are made available to the North Carolina Division of Public Health through a special legislative provision. The State Center for Health Statistics can provide these data to agencies in state government and county public health departments for purposes of improving public health. The State Center for Health Statistics has North Carolina hospital discharge data files for calendar years 1995-2005. Data items collected include age and gender of patient, dates of service, expected source of payment, county of residence, admission source, discharge status, principal and additional diagnoses, E codes, principal and additional procedures, and total billed charges. The Healthcare Cost and Utilization Project (HCUP)[3] of the federal Agency for Healthcare Research and Quality provides national and state-specific data and reports including hospital discharge data for North Carolina. The HCUPnet section provides free or low-cost national, regional, and state-level inpatient hospital statistics.[4]

Ambulatory Surgery Data

The North Carolina Hospital Based and Freestanding Ambulatory Surgery Facilities database contains more than 1.5 million records per year for surgeries performed in an outpatient setting. Approximately 155 facilities in North Carolina are reporting information into this database. The State Center for Health Statistics has recently started receiving quarterly updates of the North Carolina ambulatory surgery data from Thomson Healthcare, Inc, under the same arrangements as for the hospital discharge data. The State Center for Health Statistics can provide these ambulatory surgery data to agencies in state government and county public health departments for purposes of improving public health. Data items received by the SCHS include age and gender of patient, dates of service, expected source of payment, county of residence, principal diagnosis, principal and additional procedures, total billed charges, and detailed charges.

Emergency Room Data

North Carolina is the first state in the nation to establish a comprehensive system for electronic reporting of data by hospital emergency departments. Nearly all hospitals in the state with 24 hours a day 7 days a week emergency departments are reporting into the system and the goal is to have all hospitals reporting in the near future. One use of these data is for the North Carolina Disease Event Tracking and Epidemiologic Collection Tool (NC DETECT) system.[5] NC DETECT currently monitors real-time emergency department data and categorizes visits into syndromes in order to detect unexpected cases and outbreaks earlier in their course than traditional disease-based surveillance would allow.

Since data are collected for all types of visits, emergency department use for chronic disease, injury, or any other health condition can also be monitored. Selected North Carolina emergency department data may be accessed at the North Carolina Emergency Department Database Web site at http://www.ncedd.org.

The State Center for Health Statistics has recently started receiving quarterly updates of the North Carolina emergency department data from Thomson Healthcare, Inc, under the same arrangements as for the hospital discharge data. These data files are comprised of records for more than 3 million emergency room visits per year. Emergency room visits that result in an inpatient hospital admission are not included in the data files received by the SCHS since these visits can be counted from the inpatient hospital discharge data. The State Center for Health Statistics can provide these ER data to agencies in state government and county public health departments for purposes of improving public health. Data items received by the SCHS include age and gender of patient, dates of service, expected source of payment, county of residence, admission source, discharge status, principal diagnosis, principal procedure, and total billed charges.

POPULATION SURVEY DATA

Behavioral Risk Factor Surveillance System

The Behavioral Risk Factor Surveillance System (BRFSS) is a random telephone health survey of adults conducted in every state. It is sponsored by the Centers for Disease Control and Prevention (CDC).[6] In North Carolina, survey estimates are available for the state, major regions, and about 25 single counties. The annual sample size is more than 15 000 adult respondents. The BRFSS[7] collects data on many topics including perceived health status, health insurance coverage, physical activity, asthma, arthritis, smoking, disability, diabetes, overweight/obesity, and cancer screening. The BRFSS survey is revised each year and it includes so-called "core" questions from the CDC which are uniform across all states plus questions specific for North Carolina.

Child Health Assessment and Monitoring Program

The Child Health Assessment and Monitoring Program (CHAMP)[8] is a North Carolina health survey of children ages 0 to 17 years. Data collection for CHAMP began in January 2005. Adult respondents to the BRFSS survey with children living in their households are invited to participate in the CHAMP survey. One child is randomly selected from the household, and the adult most knowledgeable about the health of the selected child is interviewed in a follow-up survey. The CHAMP survey is revised each year to meet the child health surveillance needs of North Carolina. It is a state-level survey with more than 3000 annual respondents and does not provide county-specific information. Data topics include health care access, asthma, mental health, disability, nutrition, physical activity, overweight, tobacco, child safety, and injury.

Pregnancy Risk Assessment Monitoring System

The North Carolina Pregnancy Risk Assessment Monitoring System (PRAMS)[9] is a survey of women who have recently had a baby. The survey is sponsored by the CDC[10] and is currently conducted in 35 states. Birth certificates are selected at random and then a health survey is mailed to the mother; for those who do not respond by mail, attempts are made to complete the survey via telephone. Approximately 1500 PRAMS surveys are completed each year in North Carolina usually between 3 and 5 months after birth. Statewide data for 1997-2005 are available as well as some multiyear regional data. The PRAMS sample size is not large enough to produce county-level estimates. While the major purpose of PRAMS is to collect information about risk factors for poor birth outcomes (information not available on the birth certificate), there also are some topics pertaining to women's health and chronic disease before, during, and after pregnancy.

Youth Risk Behavior Survey

In the spring of every odd numbered year, the North Carolina Healthy Schools project conducts a statewide Youth Risk Behavior Survey (YRBS)[11] among middle school and high school students in North Carolina. The North Carolina YRBS helps assess behaviors in youth that impact their health now and in the future. Topics include violence, personal safety, physical activity, nutrition, mental health, tobacco, drugs and alcohol, and sexual behavior (for high school students only). Estimates are produced for the state as a whole and for major regions of the state. There is also a separate YRBS for the Charlotte area. The YRBS is funded by the CDC and North Carolina data are included as part of a national surveillance system.[12]

Youth Tobacco Survey

The North Carolina Youth Tobacco Survey (YTS)[13] provides an important source of public health data for understanding the scope of the tobacco problem and measuring progress toward overall goals among youth. The 2005 North Carolina YTS is a comprehensive statewide representative sample of more than 6000 middle and high school students. Every other year a core set of CDC[14] tobacco-related questions are asked. In addition, North Carolina adds state-specific questions. In 2005 the North Carolina Tobacco Prevention and Control Branch together with the NC Health and Wellness Trust Fund added questions regarding media, community participation, and secondhand smoke attitudes. The sampling design now generates large enough numbers to produce reliable regional estimates (Mountains, Piedmont, and Coast). North Carolina submits data to the CDC as part of the national YTS sample.

OTHER STATEWIDE SURVEILLANCE SYSTEMS

Newborn Hearing Screening Surveillance System

A Web-based tracking and surveillance database called WCSWeb was developed collaboratively by the Early Hearing Detection and Intervention Program,[15] the Sickle Cell Program, and the State Laboratory of Public Health. It contains data on all infants born in North Carolina since January 1, 2004 and on all infants born in North Carolina with suspected hearing loss since newborn hearing screening was mandated in 2000. Patient information is obtained by either direct data entry by hospital, clinical, or public health staff or transfer of newborn screening data from the State Laboratory of Public Health Laboratory Information Management System (LIMS). With the implementation of WCSWeb, the Early Hearing Detection and Intervention Program is able to provide statistical information on the effectiveness of birthing facility newborn hearing screening programs. In 2006 97% of nearly 130 000 babies in North Carolina who were eligible for newborn screening services received a screening which was reported into WCSWeb. Of these babies screened at birth, 4099 or 3.2% needed further follow-up. Of these 4099 babies, 430 had diagnostic evaluation results reported into WCSWeb and 202 were confirmed with a hearing loss. Regional consultants of the Division of Public Health are making a concerted effort to educate hospitals and physicians on the importance of providing prompt rescreening for infants who do not pass the newborn hearing screening and on the use of WCSWeb to report follow-up results.

Cancer Incidence Data

The North Carolina Central Cancer Registry (CCR)[16] collects data on all new cases of cancer in North Carolina. The data are collected primarily from tumor registries in the larger facilities that submit data electronically and by CCR field staff who abstract cancer case data in smaller facilities. In addition to demographic and diagnostic information, data are collected about the first course of cancer treatment. This is one of the few complete morbidity reporting systems for chronic disease in North Carolina. North Carolina participates in the National Program of Cancer Registries[17] and submits data regularly to the CDC as part of the national cancer incidence database. For more information about the CCR, see the article in this issue by Karen Knight.

North Carolina Nutrition and Physical Activity Surveillance System

The North Carolina Nutrition and Physical Activity Surveillance System (NC-NPASS)[18] provides indicators of body mass index status among children such as overweight, underweight, and healthy weight for each county in North Carolina and for the state as a whole. In the future NC-NPASS will monitor trends in key nutrition and physical activity behaviors such as soft drink consumption, fruit and vegetable consumption, levels of physical activity, and television viewing. The NC Nutrition and Physical Activity Surveillance System may not be representative of the population as a whole since it is comprised primarily of data about low-income children seen in the North Carolina public health-sponsored Women, Infants, and Children (WIC) program, child health clinics, and some school-based health centers. The information on older children (who are not eligible for WIC) is especially underrepresented since it comes from a very select population who receive health care from public health clinics. Information on weight status is available only for children ages 2-18 whose height and weight were measured during a health care visit.

Pregnancy Nutrition Surveillance System

The North Carolina Pregnancy Nutrition Surveillance System (PNSS)[19] monitors the prevalence of nutrition problems and behavioral risk factors among women who are enrolled in public health programs. The NC Pregnancy Nutrition Surveillance System links data from the WIC program and public maternity clinics with birth certificates and fetal death records. The system collects prenatal and postpartum information about these women and outcome information about their infants. The majority of the women in the North Carolina PNSS participate in WIC during either the prenatal or postpartum period. The Centers for Disease Control and Prevention collects and analyzes data from the states for the national PNSS.[20]

Pediatric Nutrition Surveillance System

The Pediatric Nutrition Surveillance System (PedNSS)[19] is a child-based public health surveillance system that monitors the nutritional status of low-income children in WIC and other federally funded maternal and child health programs. Data on birth weight, short stature, underweight, overweight, anemia, and breastfeeding are collected for children ages 0-18 who visit public health clinics for routine care and nutrition services including education and supplemental food. Data are collected at the clinic level and then aggregated at the county and state levels. North Carolina data are sent to the CDC for incorporation into the national PedNSS data.[20]

Communicable Disease Data

HIV and other communicable sexually transmitted diseases (STDs) pose public health risks and thus are made reportable to public health authorities in North Carolina. Most often the cases are reported by physicians to local health departments (as required by law) which then forward the reports to the Epidemiology Section of the North Carolina Division of Public Health. Medical facilities may also report cases, usually through the infection control staff. Persons making these reports are immune from liability for doing so. Laboratory reports are sent to the Epidemiology Section and act as a trigger for investigation and reporting of cases not already in the system. The data on reported cases are used to identify risks and vulnerable populations and to design control measures to limit the spread of these diseases through the HIV/STD Prevention and Care Branch.[21] State- and county-level data are available through the General Communicable Disease Control Branch.[22] De-identified North Carolina data are submitted to the CDC as part of the national communicable disease and HIV/STD surveillance systems. North Carolina is developing a comprehensive electronic disease reporting system called the North Carolina Electronic Disease Surveillance System (NC EDSS) that will replace paper-based reporting of communicable and other diseases between local health departments and the Division of Public Health. Initial deployment of the NC EDSS started in 2007 for tuberculosis, and other diseases are being added.

OTHER HEALTH-RELATED DATA

Medicaid Data

Medicaid is a medical insurance program for low-income North Carolinians. Since the 1980s the State Center for Health Statistics has had a cooperative relationship with the Division of Medical Assistance[23,24] (the state Medicaid agency) that involves sharing data for planning and evaluating public health programs. The North Carolina Medicaid Management Information System captures data on all payments for medical services for adults and children enrolled in Medicaid. This is one of the few data systems available to the North Carolina Division of Public Health that contains information on the complete range of medical services provided to a defined population: inpatient, outpatient, emergency room, physician, dental, home health, nursing home, prescription drug, and hospice services. There is also an enrollment file with information on the characteristics of the Medicaid enrollees. The State Center for Health Statistics strictly protects the confidentiality of these data and produces only aggregate data reports unless specifically authorized in writing by the Division of Medical Assistance to release individual-level data. The State Center for Health Statistics has a limited capacity to meet special Medicaid data needs of programs outside the North Carolina Division of Public Health.

Health Workforce Data

The North Carolina Health Professions Data System[25] of the Cecil G. Sheps Center for Health Services Research has detailed county-level health workforce data including physicians by specialty, dentists, nurses, and many other health provider types. The data system also presents state and county health manpower profiles and will accept special data requests. (See http://www.shepscenter.unc.edu/hp.)

Population Data

Population data[26] are not strictly health data, but population counts are important for assessing caseloads or persons at risk when planning for provision of health services. And population data are used extensively as denominators of health-related rates. The NC State Demographics unit produces population estimates and projections with age, race (White and minority), and gender detail for North Carolina and its 100 counties. In addition, the SCHS publishes reports showing annual state demographer population estimates by county, age, race, and gender.[27] Population estimates from the State Demographics unit also are provided through the SCHS Health Data Query System, which also includes more detailed race and ethnicity breakouts.

LINKING DATA

Linking the records in different data sets can increase the utility of the separate components. After linking, the variables of both data sets become available for joint analysis and cross tabulation. For example, each year the SCHS creates a composite linked birth file[28] which consists of the birth certificate records linked to several health program data files: Medicaid babies, Medicaid mothers, maternity care coordination, Medicaid costs, prenatal WIC, health department prenatal care, and child service coordination. This allows for the tabulation of birth certificate measures by participation in these health service programs.

The State Center for Health Statistics annually links all infant death certificates to the corresponding birth records. This matched file[29] allows analysis of infant mortality by characteristics that are available only on the birth certificate such as birth weight, mother's age, mother's education, mother's self-reported race, smoking during pregnancy, and prenatal care participation.

The State Center for Health Statistics has recently linked the NC-NPASS data described above for adolescents ages 12-18 to the Medicaid paid claims and enrollment data to analyze health care utilization and expenditures by body mass index categories.[30] The Medicaid data alone do not capture any information on body mass index. It was found that adolescents who are overweight and at risk for overweight have higher Medicaid expenditures and that overweight adolescents had a significantly higher incidence of diabetes, asthma, and other respiratory conditions.

USING DATA FOR EDUCATION, POLICY, PLANNING, AND EVALUATION

These public health surveillance data are used extensively for education, policy, planning, and evaluation. A few selected examples include the use of PRAMS data to develop a statewide public education and awareness campaign to reduce the risk of Sudden Infant Death Syndrome (SIDS); the use of Medicaid data, live birth data, and PRAMS data as part of a North Carolina Medicaid Program and Division of Public Health application to the federal Centers for Medicare and Medicaid Services (CMS) to obtain a family planning waiver to extend Medicaid eligibility for family planning and sexually transmitted disease services for men and women up to 185% of the federal poverty level; use of birth defects data to help target and evaluate programs to reduce certain birth defects through the intake of folic acid; and the use of BRFSS survey data by several community-based organizations and health departments to apply for grants, guide intervention strategies, and support policy changes for their initiatives. Data are of little value unless they are used, and use of data in turn provides incentives to increase the quality of the databases. North Carolina is fortunate to have such a wealth of state and local data sources. Additional and ongoing data collection will continue to provide the state with valuable measures for determining appropriate policy interventions for improving the health of individuals and communities. **NCMJ**

COMMENTARY

Geographic Information Systems and Health in North Carolina

Dianne Enright

A geographic information system (GIS) is a powerful tool in shaping North Carolina heath policy and research. A geographic information system is more than a mapping tool; it is defined as a database that is tied to locations in space. However, the true power of a GIS comes from the ability to view many types of data together and to query or ask questions of the data.

There are some challenges in using health data with GIS. First, you must be able to geocode the data or assign a location to it in some fashion. Sometimes this could be simply presenting data that are already aggregated at the city or county level such as rates for a particular cause of death. (See Figure 1.) However, patient- or provider-level data must become geo-enabled. This type of point-level data could be geocoded by either gathering data in the field with a global positioning system (GPS) or through address matching.

> *"…a valuable tool for emergency response, program evaluation, and health research. The geographic information system has proved to be an essential tool to help allocate limited public health resources."*

A global positioning system captures location coordinates that are easily imported into a GIS to display locations. A global positioning system provides very accurate data; however, time must be spent in the field traveling to each location to ascertain specific coordinates. Geocoding at the address level involves matching an address against source data such as a road network that is attributed with existing address ranges. The geographic information system interpolates the position along the road where the address falls and captures the coordinates to display location. Numerous problems can occur with address matching. Mistakes can be made when the address is entered into a data system. In addition, problems can occur with the interpolation, or the source data that the address is compared to could have mistakes. Sometimes a person's current address is newer than the source data's creation date, or the address given simply does not exist and therefore cannot be located. Also, collection of patient data is often done for billing purposes. Many patients report a post office box for mailing purposes, thus the patient's physical residence is not locatable.

The State Center for Health Statistics (SCHS) has been using GIS since 1989 to assist health programs with evaluations, to establish or modify health policy, and to facilitate research. A simple choropleth (shaded) map can provide valuable information obtained by visualizing where in space a health event or problem is occurring. A choropleth, or thematic map, is based on statistical data that have been aggregated to an aereal unit. The maps are then shaded using different degrees of the same color, traditionally displaying the highest values as the darkest shade. (See Figure 1.)

Geographic information system techniques are also used for more sophisticated public health analyses. For example, the SCHS uses the power of GIS to assist in making decisions for nutrition services programs. The Health & Spatial Analysis Unit of the SCHS has been working with the Women's & Children's Health Section (Nutrition Services Branch, North Carolina Division of Public Health) to support decisions about the Child and Adult Care Food Program. The program funds meal reimbursements to family day care homes. The reimbursement for meals served in day care homes is based upon eligibility for tier I

rates (which targets higher levels of reimbursement to low-income areas, providers, or children) or lower tier II rates.[a] After the Nutrition Services Branch approves an application, the family day care homes are located using GIS and then overlaid on a special run of census data. The census data show the percentage of children in poverty to determine the amount of reimbursement the family day care home may receive. (See Figure 2.) Using a different population age, the same type of analysis is applied to the Summer Adult Food Program. These analyses help target where limited funding dollars are truly needed.

Another ongoing project the North Carolina Division of Public Health has been working on for several years is syphilis elimination. New syphilis cases are geocoded and mapped on a quarterly basis in the 6 counties with the highest rates in the state. Each quarter is assigned a different color so the new cases identified throughout the year are easily traced. The staff of the HIV/STD Prevention & Care

---

Branch (Epidemiology Section, North Carolina Division of Public Health) and local health departments use these maps to help reduce outbreaks. Again, by using a GIS to pinpoint where new syphilis cases occur, testing, education, and prevention methods are targeted directly to the neighborhoods where they are needed the most.

Geographic information systems are also becoming a widely used tool in emergency responses throughout the state. Many law officers and paramedics are equipped with GIS and GPS, which allows for real time vehicle routing for personnel to find locations quickly and for dispatchers to manage personnel and equipment. The North Carolina Office of Public Health Preparedness and Response (Epidemiology Section, North Carolina Division of Public Health) is also using this technology to better serve North Carolina residents. The North Carolina Office of Public Health Preparedness and Response is charged with responding to public health emergencies and has developed methods for gathering information from the field using GIS. It is vital to gather information very quickly in a public health emergency or following a natural disaster. Interviewers in the field are equipped with handheld computers that include a GPS. This equipment allows the staff in the field to navigate to interview locales as well as capture the coordinate location of where the interview occurs. Interviewers can use questionnaire forms on the handheld devices to gather required information from the population affected by the emergency or event. The information gathered is associated with the collected location coordinates. All of this information is then uploaded to a central database where it can be analyzed. Reports are shared with multiple authorities to assist in determining needs and allocating resources.

A geographic information system also was used in a recent study of the time spent traveling to health care providers for families with a child having an orofacial cleft. It is important for infants born with an orofacial cleft to receive coordinated treatment from craniofacial centers or teams in the first 2 years of life. For the study, residential addresses of children with orofacial clefts were mapped, and the craniofacial centers were located. Using "closest facility methodology" the most efficient route from the residence to the closest care provider was calculated. By using this analysis method the actual distance and time spent traveling to the closest craniofacial center was estimated (although patients may not always travel to the closest facility or care provider) which is more accurate than using a straight line distance. This analysis was performed again after 2 new proposed locations for craniofacial centers were included where there were previously none. The analysis demonstrated that the addition of 2 new centers would result in an average decrease in orofacial cleft patient travel time of 16 minutes. (See Figure 3.) A geographic information system is a useful tool for evaluating the role that travel distance may play as a potential barrier to accessing health care among children with orofacial cleft and/or other types of birth defects.

The North Carolina Division of Public Health uses GIS for a variety of projects and purposes. It is a valuable tool for emergency response, program evaluation, and health research. The geographic information system has proved to be an essential tool to help allocate limited public health resources. **NCMJ**

NC-CATCH:

North Carolina Comprehensive Assessment for Tracking Community Health

James Studnicki, ScD; John W. Fisher, PhD; Christopher N. Eichelberger, MS

Although the United States invests more resources than any other nation in the world for health, we are far from the healthiest country. In fact, the US languishes in the lower half of industrialized nations for a range of indicators used to measure health status and even trails nations considered to be economically underdeveloped for selected health indicators.[1] Accompanying this disappointing level of overall health status are the enormous disparities in the health of groups defined by race, ethnicity, socioeconomic status, and geography.[2] Despite decades of scrutiny by researchers and health policy analysts and numerous reports and white papers on the subject by prestigious and influential organizations such as the Institute of Medicine (IOM) of the National Academies, these vast differences are pervasive and seemingly intractable.[3,4]

For example, poor White females in Mississippi and in Appalachia experienced declines in life expectancy between 1982 and 2001.[5] Similarly, in North Carolina between 1975 and 2005, despite reductions in absolute rates, Black infant mortality steadily increased from 1.8 to 2.3 times the White rate.

The Measurement Mandate

While the problem of variation in community health status is complicated and has many underlying causes (known and unknown), there is nearly universal agreement that if we are to have any hope of improving it there must be a monitoring system to measure and benchmark community health status in a systematic way. There have been frequent attempts to provide a framework for community health status monitoring systems. The Planned Approach to Community Health (PATCH) developed in 1985 by the Centers for Disease Control and Prevention (CDC) sought to determine root causes and key intervention points for a few selected health issues.[6] In 1991 the American Public Health Association developed the Healthy People 2000 (and later 2010) protocol for addressing a series of defined national objectives.[7] At about this time, the IOM of the National Academies proposed a model for community health improvement that involved an iterative process that cycled through assessment, evaluation, and action phases. The IOM of the National Academies proposed a set of 25 indicators which expanded on the 18 recommended by the original Healthy People 2000 objectives.[8] The National Association of County and City Health Officials and the CDC developed the Assessment Protocol for Excellence in Public Health (APEXPH) which focused on process indicators to determine the internal capacity of public health organizations, and this protocol was later expanded to include other community health organizations.[9] There have been other community health assessment models developed by the hospital industry,[10] state and local government agencies, university research groups, and collaborations of multiple partners. Although these methods vary in their approach to assessment, they all share a common requirement: data. The data required to populate these various methodologies typically include existing secondary sources such as vital statistics (birth and death registration) and the extensive menu of secondary data from the surveys maintained by the National Center for Health Statistics (NCHS). Some of the methods also require

> *"Access to a wide range of data sources is a prerequisite to effective community health status assessment."*

James Studnicki, ScD, is Irwin Belk Endowed Chair in Health Services Research, College of Health and Human Services, at the University of North Carolina at Charlotte. He can be reached at jstudnic (at) uncc.edu or 9201 University Boulevard, Charlotte NC, 28223-0001.

John W. Fisher, PhD, is an assistant professor in the College of Health and Human Services at the University of North Carolina at Charlotte.

Christopher N. Eichelberger, MS, is director of the Software Solutions Laboratory in the College of Computing and Informatics at the University of North Carolina at Charlotte.

primary data collection efforts to provide a perspective on local populations or providers not available in existing secondary data sources.

From Data to Knowledge: The Challenge of Analytics

Access to a wide range of data sources is a prerequisite to effective community health status assessment. Bringing together data from multiple sources, linking and integrating them, and continually updating and maintaining them for useful analysis can be a daunting challenge to even the most capable and resourceful organization. For the typical local community organization, such a task is often beyond their financial and technical capabilities.

The potential of the Internet as a means to disseminate data for health assessment has been recognized, and there has been a rapid increase in the number of states which maintain at least some form of access to health data through the World Wide Web. Although only 10 states reported a Web-based query tool in 2000, by 2006 the number had grown to 27 states.[11] In most cases, the state systems are limited to a static interface which provides prestructured statistics such as death counts or rates organized into preformatted reports. In a few instances, the query menu itself is dynamic and enables the user to make a selection of data sets, statistics, tables, and maps. These systems, however, do not have the kind of multidimensional navigation and analytical capabilities that can be made available with modern online analytical processing software. Therefore, when viewed from the perspective of what is really state-of-the-art given the rapid advances in computational software and Web-enabled applications, currently existing systems demonstrate major limitations. These include unidimensional filtering queries; single grain data without real time "roll up" or "drill down" capability; data set "silos" which are unlinked and nonintegrated; inconsistent definitions across data sets; lack of metadata (ie, data about the data necessary to facilitate the understanding, use, and management of the system); and lack of an imbedded, organized framework for extracting decision support knowledge from the underlying data.

The Community Health Assessment Portal

North Carolina has been one of the most active states nationally in promoting community health status assessment, and counties are required to produce a formal report at least every 4 years. The State Center for Health Statistics maintains a number of databases useful to this process and works closely with Healthy Carolinians in performing assessments and mobilizing multisectored community action. With assistance from a health services research and technical development team from the University of North Carolina at Charlotte, the Division of Public Health (with additional funding from the Kate B. Reynolds Charitable Trust) initiated the development and deployment of a system that will address many of the weaknesses of current systems, thus bringing modern Web-enabled software technology to public health. To this end, the Division of Public Health decided to move beyond merely producing data to actually enhancing the capability to analyze the data more effectively.

The North Carolina Community Health Assessment Portal (NC CHAP) can best be understood as a means to bring the capabilities of business intelligence to public health surveillance, particularly community health assessment. The original innovators in this field used the word "business" in a broad sense as a collection of activities carried on for some purpose such as commerce, science, government, or public health. "Intelligence" is also defined in a general sense as the ability to "apprehend the interrelationships of presented facts in such a way as to guide actions toward a desired goal."[12] Modern business intelligence systems use data that has been gathered into a data warehouse or data mart and also occasionally use transactional or operating data. Using various types of software to support reporting, interactive pivot-table analyses, visualization, statistical data mining, and other technologies and applications, business intelligence systems provide historical, current, and predictive fact-level views of the enterprise in order to support better decision making.

NC-CATCH

As a business intelligence system, the Comprehensive Assessment for Tracking Community Health (NC-CATCH) has the following components:

Data Warehousing. Extant data organized into the data warehouse will include demographic/population data at the census track level (updated annually by a commercial firm); mortality data; birth data; pregnancy data; hospital discharge data; emergency department visit data; behavioral risk factor survey data (regional and county level only); cancer incidence and treatment data; and other miscellaneous social, economic, and health-related data available at least at the county level. The data will be geocoded to the census tract where possible. Access to the various levels of warehouse capability will be through a portal on the Web site of the State Center for Health Statistics.

Methodology. Health is a multidimensional concept, and there is no single perfect measure for summarizing the health status of a defined population. CATCH is a comparative framework that provides a consistent, objective, multidimensional method for organizing and interpreting community health data. Key elements of CATCH include multiple indicators organized into categories (eg, infectious disease, maternal and child); comparisons with peer counties; state values; Healthy People 2010 values and other benchmarking standards; trend analysis for the most recent 3-5 year time period; an objectively derived rank ordered list of community health challenges; and a concise assessment of racial/ethnic health status disparities.[13] The CATCH report, uniformly aggregated for each North Carolina county, will provide a comprehensive starting point from which the relative health challenges and achievements can be understood, and areas requiring further analyses can be identified. The CATCH report includes embedded hyperlinks into the appropriate queries that allow full investigation of the underlying data.

Prestructured Queries. Prestructured queries allow the user more flexibility to choose the variables and dimensions of interest, but the choices are necessarily limited. A user, for example, may want to view infant mortality by race or by county, or hospitalization rates for diabetes by county. Some of these views are precalculated and made available through the portal, but they too are static like the CATCH report. These types of queries are the typical method for supplying information in most states. Another type of query is more active in that the user can select from a few number of dimensions to provide a limited form of query customization. These systems are interactive only to the extent that the user is given a menu of queries to select from. Since the number of possible queries is limited only by available data, the challenge is to provide a menu of queries that satisfy the needs of most users or provide information about the most important problems. Structured queries, however, can never maximize the use of information since they cannot anticipate nor perform all the multidimensional data navigation and analysis necessary to model a complex system such as population health.

Online Analytical Processing. Online analytical processing is a category of software technology that enables users to gain insight into data through fast interactive access to a wide variety of possible views of information transformed from raw data. The NC CATCH user utilizing online analytical processing functionality will be able to calculate and model across dimensions, through hierarchies, and across members; slice subsets for onscreen viewing (eg, organize hospital discharge data by pay source); drill down to deeper levels of consolidation (eg, identify all census tracts with a certain percentage of population in poverty); reach through to underlying detail data (eg, compare infant mortality in different counties by the specific causes of infant death); or rotate to new dimensional comparisons in the viewing area (eg, move from Black/White comparisons to Hispanic/non-Hispanic comparisons of age-banded chronic disease mortality). Online analytical processing truly brings the power of the data warehouse to the user's desktop. Multidimensional analysis makes it easier to navigate the database, and because the data are physically stored in a multidimensional structure, the speed of these operations is faster and more consistent than is possible in other database structures.

A Brief Explanation of the Technical Approach

The principal challenge to presenting consolidated health data consists of identifying the appropriate levels at which to enforce data standards. Raw health data exist in many different forms and formats: plain text documents, images, printed tables, spreadsheets, and databases. Each of these forms is well suited for its particular audience.

Each of these levels is treated separately within the following sections and related to the left-hand side of Figure 1:

(1) The raw health data sources (the small cylinders at the bottom of the figure) were identified at the beginning of the project. Each was defined in terms of format, layout, and meaning. Staff used this information to build small software routines that load a given raw data source into a central database (the large cylinder in the figure). This transaction-level database is the first level of standardization in the project.

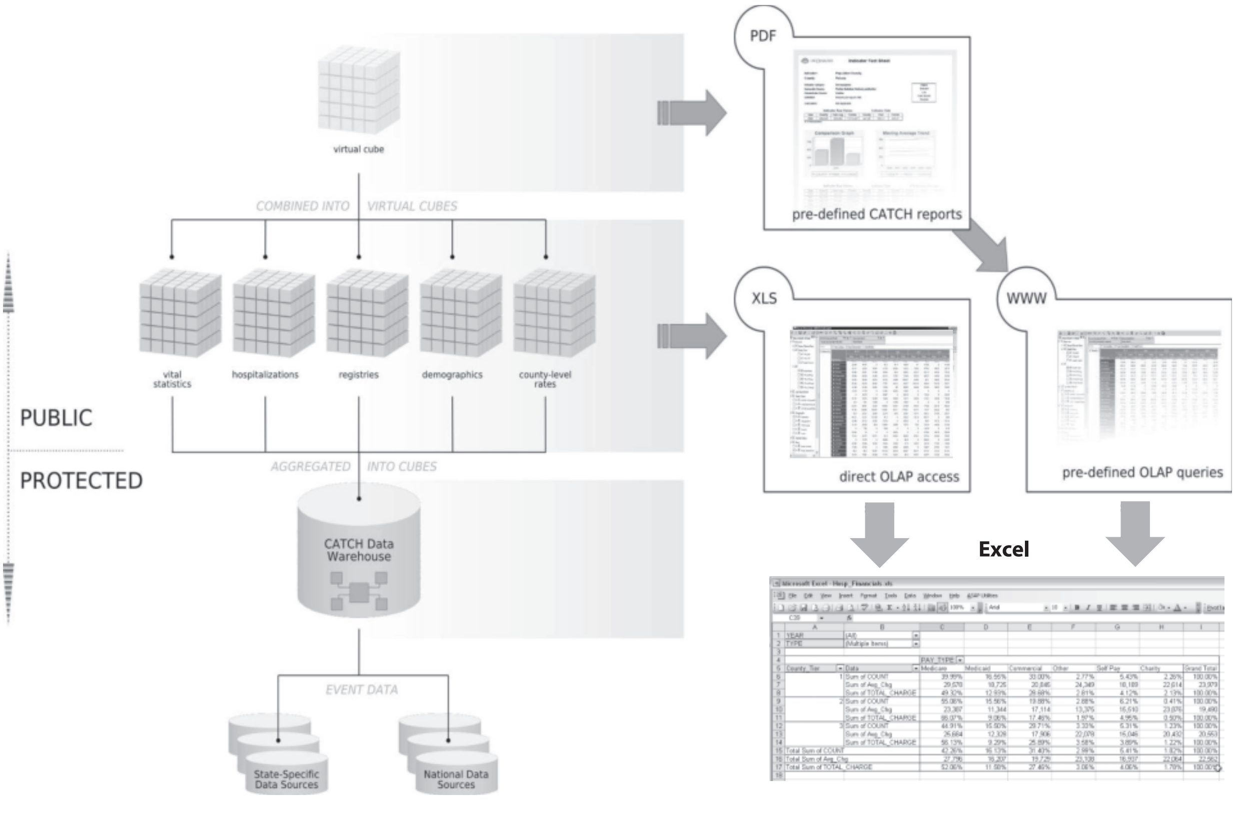
(2) Once the raw data have been loaded into the transaction-level database, a second set of standards is applied to bridge separate sources and construct a series of unified multidimensional data cubes. A data cube is merely a collection of data that has been preaggregated along a given set of dimensions so that every possible combination of dimension values can provide a set of output measures efficiently. In the figure, the data cubes are depicted as gridded boxes in which each small component corresponds to one intersection of dimensions. Typically, we interpret dimensions as X, Y, and Z, but in data cubes the dimensions are more likely to be time, age band, race, sex, cause of death, etc. Identifying the standards that allow for the bridges among data sets, as well as defining the common dimensions and measures that typify the logical cubes, is the second level of standardization in the project.

(3) The logical data cubes themselves can be recombined into virtual cubes (illustrated as translucent, gridded boxes at the top of the figure) providing glimpses into the data that were not previously available. For example, one logical cube is dedicated to the detailed demographics of North Carolina; another cube is dedicated to the deaths that have occurred over time. Combining these 2 cubes into a virtual cube allows us to explore not only the base demographics and the deaths, but rates and age-adjustments across all geographies, years, demographic splits, and causes of death. Identifying the meaningful combinations of logical cubes into virtual cubes is the third level of standardization in the project.

This project seeks to provide 3 levels of access targeted to meet the needs of 3 distinct user communities, differentiated by the trade-off between ease-of-use and analytical flexibility/complexity. These users are served with different views as shown in the right-hand side of Figure 1:

(1) The general public and many senior policy staff are likely interested in the predefined county profiles that are part of the CATCH report (available as a Web page). This use of the commonly used report format provides rapid access to the highest level of aggregation and comparative benchmarks. However, since the report is not a static document but actually contains active hyperlinks, it also

Figure 1.
North Carolina Health Assessment Portal Construction and Interface



provides immediate access to the more detailed underlying data.

(2) These data, of significant concern for county health departments, are accessed through a large set of predefined online analytical processing queries or exploratory reports using both the logical and virtual cubes. Once again, a report-style interface is employed to minimize the technical expertise required to quickly access the desired information. This simplified drill-down capability provides a powerful tool for investigating multidimensional relationships.

(3) At the high end of complexity and flexibility, researchers have access to the lowest level data in the free-form online analytical processing queries. The full range of dimensions is available in a drag-and-drop visual interface for creating ad hoc queries across the entire data warehouse.

Each of these levels serves a specific role in the reporting of health data, and each has an independently maintained set of standards for how data are allowed to participate. These metadata themselves constitute one of the most significant new capabilities of the project. **NCMJ**

COMMENTARY

The Emerging Field of Informatics

Debbie Travers, PhD, RN; Larry Mandelkehr, MBA, CPHQ

The field of health care informatics brings together the various health sciences (eg, medicine, nursing, public health) and other relevant fields including information science, computer science, and cognitive science. The focus of this emerging field is to promote the effective organization, analysis, management, and use of information in health care in order to facilitate optimal health care delivery.[1,2] An important mission of the informatics field is to prepare practitioners to utilize health data for direct care as well as in support of optimal health services organization and delivery, public health surveillance and practice, and clinical research. In this article we describe how the field has developed and how clinicians and health care managers are being prepared to make the best use of data.

> *"As the health care informatics field has developed, there has been recognition of the need to prepare informatics experts in both the clinical and managerial ranks."*

Early applications of information technology in health care began in the 1960s with a focus on financial (eg, generating a bill) and clerical (eg, admission, discharge, and transfer transactions) systems. These systems typically ran on large mainframe computers and produced basic management reports but often lacked the flexibility to produce customized reports. They were organized around generating a bill for a health care encounter as opposed to providing a longitudinal view of patients' health. With the introduction of powerful personal computers and networking technologies in the 1980s came the development of more clinically-oriented computer systems for health care. These systems were also more robust in supporting administrative functions.[3] Early clinical applications included laboratory results reporting and order entry systems; administrative applications included human resources, materials management, and project management systems.

As the field of health care informatics continued to develop, more vendors entered the health care information technology (IT) environment. The health care IT companies offered an expanded array of products including computerized provider order entry, clinical documentation (eg, physician and nurse notes), and specialized systems for areas such as the emergency department, the pharmacy, and the operating room. More recently, the field has grown to include bioinformatics applications which have been developed to manage the large quantity of genomic and other basic scientific data.

During this time researchers began to study the impact of clinical IT systems on the health care delivery system and eventually on patient outcomes.[3] These studies identified best practices and systems for health care IT design, integration with clinical workflow, and implementation.[4] Outcome studies showed the greatest impact on patient outcomes from computerized provider order entry and clinical decision support tools embedded in the IT systems.[5-7] Currently there are many large health care IT initiatives aimed at improving patient outcomes and reducing errors through well-designed decision support applications. Examples of such applications include drug-drug incompatibility alerts to providers during electronic prescribing and the use of standardized order sets.

Debbie Travers, PhD, RN, is an assistant professor in the School of Nursing and adjunct assistant professor in the Schools of Public Health and Medicine at the University of North Carolina at Chapel Hill. She can be reached at dtravers (at) email.unc.edu or Campus Box 7460, Chapel Hill, NC 27599-7460.

Larry Mandelkehr, MBA, CPHQ, is director of Performance Improvement at the UNC Health Care System and adjunct instructor in the School of Public Health at the University of North Carolina at Chapel Hill.

How We Teach People How To Use Data

Formal Informatics Education

Many of the early pioneers in health care informatics came from various clinical and technical fields and learned informatics on the job. Formal degree-granting educational programs in health care informatics began in the 1970s with a variety of foci such as health administration, clinical sciences (eg, medicine, nursing, pharmacy), computer science, bioinformatics, and public health.

National organizations have begun to develop recommendations for health care informatics content in the curricula for various professions. This emphasis on preparing practitioners to address informatics is an outgrowth of recommendations by the Institute of Medicine of the National Academies' 2003 report *Health Professions Education: A Bridge to Quality*.[8] This report was issued partly in response to the Institute of Medicine's 2001 report, *Crossing the Quality Chasm*, which focused on safety and quality of care.[9] In the 2003 report, the IOM recommended 5 core competencies that all clinicians should possess in order to meet the needs of the 21st century health system. One of those 5 is to utilize informatics to "communicate, manage knowledge, mitigate error, and support decision making using information technology."[10] These recommendations have spawned many educational initiatives directed at health professionals including the American Medical Informatics Association (AMIA) 10x10 Program, the goal of which is to train 10 000 health professionals in basic informatics content by the year 2010.[11] Though AMIA is just beginning to delineate core informatics content for physicians, it has partnered with leading academic informatics programs to deliver the 10x10 continuing education programs and short courses in both clinical and bioinformatics. This initiative is using curricular content from existing informatics training programs, distance learning, and other innovative educational strategies to deliver quality education to busy working professionals. A sample of key content from some of the clinically-oriented 10x10 programs is shown in Table 1.

Several of the content areas address preparation of practitioners for utilizing health data effectively including evidence-based medicine, data mining of databases/data warehouses, information integration and knowledge management, and data standards.

The National Library of Medicine (NLM) of the National Institutes of Health began funding medical informatics research training programs in the 1990s and currently funds 20 university-based programs.[12] Their goal is to advance the scientific basis underpinning the informatics field by training researchers. Some of these programs provide tuition and even stipends to health professionals wishing to gain expertise in informatics research. North Carolina participated in a joint Duke University and University of North Carolina at Chapel Hill medical informatics training program in the 1990s, but the formal NLM-sponsored program was discontinued in the early 2000s. Both universities continue to offer various types of education in health care informatics.

Informatics Competencies and Certifications

There are national recommendations for informatics competencies and certifications for many professions including nursing and health management. There is currently an effort to develop similar structures for physicians. The American Medical Informatics Association has received a grant from the Robert Wood Johnson Foundation to establish a subspecialty of applied clinical informatics in medicine which will include a certification process for physicians.[13]

The National Center for Healthcare Leadership has established a set of competencies for graduates of health care management programs.[14] Competencies that are relevant to informatics include data analysis, manipulation, understanding, and ability to explain data.

Specific informatics competencies for nurses are also being developed based on recommendations from the Institute of Medicine of the National Academies.[15] The competencies include skills, knowledge, and attitudes that are clinically-oriented as well as some that emphasize use of data for supporting safe processes of care and metrics for monitoring health outcomes. Nurses can achieve certification in the specialty of Nursing Informatics through successful completion of an examination.[16] Table 2 includes the key content included in this Informatics Nurse certification offered by the American Nurses Credentialing Center.

Table 1.
Informatics Content From Various American Medical Informatics Association 10x10 Programs[11]

Discipline overview, history
Evidence-based medicine
Role of information and technology in improving health care efficiency and quality
Databases, data warehouses, and data mining
Data standards
Decision support
Privacy, confidentiality, and data security
Information integration and knowledge management
Networking and telemedicine
Information system planning and project management
Clinical and administrative information systems
Electronic health records
Computerized provider order entry
Consumer health informatics

Table 2.
Informatics Content For Nursing Informatics Certification

Systems life cycle Systems planning, analysis, and selection
Systems design
Systems implementation and testing
Systems evaluation, maintenance, and support
Human factors (eg, usability)
Hardware, software, and networks
Data standards
Security
Data aggregation, warehousing, and mining
Knowledge generation (outcome probabilities, expert and rule-based systems)
Professional practice, trends, and issues
Models and theories (eg, change theory)

Content areas such as data standards, data aggregation/ warehousing/mining, and knowledge generation address preparation of practitioners for utilizing health data effectively.

Examples of How Data Usage Can Be Taught in Clinical Settings

Increasing the use of data in decision making and driving improvement in busy health care organizations is a challenge on many fronts. Patients are sicker, staff shortages exist in key markets such as nursing and pharmacy, and new regulatory requirements and technology seem to appear at every turn. Incorporating data in applications such as statistical process control via the use of control charts to identify outlier events is a useful strategy but needs to be easily incorporated into the busy clinical environment. Educating clinical leaders, including nursing managers and physicians, to create statistically correct control charts with a spreadsheet is not feasible due to the complexity of the analysis and the different computer skill levels of the managers. Purchasing specialized computer software is expensive and the software often has a long learning curve.

The preferred alternative approach is to simplify the process such that each manager only needs to enter data into a spreadsheet and click a few buttons to create the control chart. The primary educational focus is the use of customized spreadsheet menus which create the charts as well as interpret graphs and develop action plans to improve patient care and operations. The education process focuses on the mechanics of chart creation and then shifts to problem solving and root cause analysis techniques to address the identified issues.

Key elements of the informatics curriculum for public health and health care professions include data definitions, data management tools, data quality, and system selection. The following sections describe these topics in detail.

How Data Are Collected and Managed

Identification of Common Data Definitions Is Essential

It is very common for different individuals or departments to have different definitions of the same data element. Unless everyone is using the same set of data definitions from the beginning, there will likely be errors in data collection, analysis, and conclusions. For example, does the hospital admission date and time occur when the patient arrives at the emergency department or when they are admitted to an inpatient bed? Is the infection rate based on all patient days or only the days on which the patient has a catheter placed? Are children's ages stored in the database in months or years? Are names entered as "John Doe" or "Doe, John?" A lack of planning and agreement on basic information in any of these examples will result in confusion, rework, and lack of useful data.

In addition to agreement on the definition of each data element, the following aspects should be considered and documented:

- *Data elements*. Sufficient data are needed to avoid ambiguity in names. Admission date and inpatient admission date should be distinquished.
- *Description*. Brief but clear descriptions of complaint/ treatment should be understandable by the nonexpert.
- *Numerator and denominator definitions for rates.*
- *Data storage format*. For example, options may include text, number, yes/no.
- *Units of measure*. For example, body temperature may be recorded in Celsius or Fahrenheit.
- *Default value*. To speed data entry time the most common. value for a data element might automatically appear.
- *Is the data element required?*

Tools for Managing Clinical Data

Desktop computers contain a variety of powerful desk tools for data management and analysis. Selecting the best tool or tools for each situation is a key element of the education program. Three common data management and analysis tools available to public health and health care students and professionals are spreadsheets (eg, Microsoft Excel), databases (eg, Microsoft Access), and statistical applications (eg, STATA, SAS).

Spreadsheets are the analytical computer programs with which most people are familiar. They are the easiest to learn and provide both data management and statistical tools and typically have a wide range of capabilities that enable them to be used in lieu of more complicated computer programs. Spreadsheets are relatively intuitive to use and learn, excel in graphically displaying data, provide a variety of statistical functions, and can support up to millions of data values. On the downside, spreadsheets lack strong data validation tools which can lead to data quality issues when entering large amounts of data. The standard spreadsheet data format (2-dimensional table) is easy to create but is inefficient for complex data sets and often results in data redundancy. This redundancy wastes data entry time, increases file size unnecessarily, and creates more opportunities for data entry errors. Finally, spreadsheets can only be updated by one person at a time.

Database programs are less intuitive to learn and use. When properly designed, however, databases can provide very efficient data storage for complex data sets and eliminate the data redundancy inherent in spreadsheets. Databases also provide strong validation and entry tools that facilitate data entry and improve data quality. Database programs allow multiple users to add and update data simultaneously—a key feature for large scale data collection and sharing via a central data repository. Reports can be designed to quickly generate weekly or monthly reports without needing to cut and paste data as when using a spreadsheet. On the downside, databases tend to have fewer tools for statistical analysis or graphing capability as compared to spreadsheets.

Specialized statistical programs provide for extensive analyses of large data sets using a wide range of statistical functions. They provide graphing capability but typically not to the extent of spreadsheets. These statistical programs are the tools of choice when performing analyses for publication which are beyond the basic regression and t-test functions available in spreadsheets. However, these programs do not support the strong data validation, management, and reporting functions common to databases.

A key educational focus emphasizes the strengths and weaknesses of each tool and how to quickly move data between them in order to utilize the benefits of each application without being limited by a program's weaknesses. A typical example of using the programs together might be to use the database for data entry and validation, the statistical program for detailed statistical analysis, and the spreadsheet for graphing the results.

The Importance of Data Quality

No matter how well a spreadsheet or database is designed, it will not be able to serve its purpose if the data it contains are inaccurate or incomplete. Maintaining the quality of data in a spreadsheet or a database requires diligence, planning, and constant monitoring. Clinical managers must be taught to evaluate the quality of data prior to using the data to make decisions.

It is always faster and more efficient to prevent inaccuracies or incomplete data during the data entry process than it is to find and fix problems after the damage is done. Several strategies can improve the quality of data in a database. Proper design is the first step to preventing data quality problems. Most computer programs contain standard features to prevent data entry errors such as selecting the type of data that can be stored in a particular location. For example, if the database requires entry of a date in a certain location then the entry of an invalid date would be prevented. Assigning range limits prevents entry of invalid data while requiring the entry of a value prevents incomplete data. Required fields should be used carefully, however, as requiring the entry of too many values may introduce bad data if users become frustrated with a lengthy data entry process. Involving data entry personnel early in the development of a database improves the data entry process and tools and reduces the potential for errors.

Data users should understand how the data they are using are defined. This is particularly important if the data are being used secondarily, and it is not possible to influence how the data are entered. For example, there are two federal data standards for information regarding race (eg, American Indian or Alaskan, Asian or Pacific Islander, Black or White) and ethnicity (eg, Hispanic or Non-Hispanic).[17] However, many health care organizations collect only one combined field, and it is not possible to accurately determine the race or ethnicity of their patients.

If a spreadsheet or database contains bad data, auditing the data may be an option to identify or correct errors.[18] Range checks can identify values that are too large or too small, and sample calculations can identify invalid or missing entries. Although auditing will often find a majority of bad data present in a program, it is always better to prevent the bad data from being entered in the first place.

System Selection Issues

Clinicians and managers should participate in the selection of clinical information systems whenever possible, and they should be prepared to consider data needs during the selection process. This issue should be included in the curricula of health informatics programs; however, the focus of systems selection is often weighted heavily toward clinical issues. While issues such as user friendliness and integration with the clinical workflow are important considerations in the selection of clinical information systems, data management issues should also be kept in mind. The quality and availability of data for use on the back end is important in order to facilitate other uses of routinely collected health data such as benchmarking, quality improvement, research, and surveillance. Vendors should be questioned about the types of reports that are available from these systems as well as the option to customize reports, export data for use with other computer applications, or run ad hoc reports locally rather than having to request the data from the vendor.

As the health care informatics field has developed, there has been recognition of the need to prepare informatics experts in both the clinical and managerial ranks. There also is a need to educate nonmanagers in basic informatics content. Professional and educational organizations are working to address these needs through formal educational programs as well as the development of competencies and certifications. While the various educational programs, competencies, and certificates continue to be developed, it remains to be seen how widely adopted these initiatives are at present. Clinicians and managers would be wise to take a proactive approach to acquiring health care informatics knowledge and skills in order to make the best use of data for direct care as well as in support of optimal health services organization and delivery, public health surveillance and practice, and clinical research. **NCMJ**

COMMENTARY

The Role of Data at The Carolinas Center for Medical Excellence

Mark W. Massing, MD, PhD, MPH; Anna P. Schenck, PhD, MSPH

Few organizations rely more heavily on data than The Carolinas Center for Medical Excellence (CCME). CCME is not a health care provider but rather a developer of data-driven services that enable providers to deliver the best possible care to their patients. CCME's existence depends on its ability to make complex data meaningful and relevant to the health care concerns of its customers. The CCME offices in Cary, North Carolina, and Columbia, South Carolina, house a diverse staff of more than 100 skilled health care and information technology professionals. Many of the physicians, nurses, health services researchers, epidemiologists, statistical analysts, quality improvement specialists, medical record abstractors, coding specialists, and information technology specialists employed at CCME were trained at and are affiliated with the major academic and medical centers of the Carolinas.

CCME uses data to influence health policy and health care delivery in hospitals, skilled nursing facilities, outpatient practices, home health agencies, and other medical settings. Data that are meaningfully summarized and reported can influence policy through their effects on clinical decision makers responsible for health care quality and costs. The internal organization of CCME is oriented around 4 major market areas: federal programs and services; state programs and services; physician and community services; and research. Below we describe the data assembled at CCME and how they have been used in these market areas to influence clinical decision makers and to improve care.

> *"CCME's existence depends on its ability to make complex data meaningful and relevant to the health care concerns of its customers."*

Federal Programs and Services

The primary activity of CCME's Federal Programs and Services Division is the Quality Improvement Organization (QIO) contract with the Centers for Medicare & Medicaid Services (CMS). As the QIO for both North and South Carolina, CCME is responsible for assuring quality of care for nearly 2 million Medicare enrollees. The QIO program is the product of the federal government's evolving need to contain costs and provide appropriate care in the Medicare program. It developed from antecedent programs formed shortly after the creation of Medicare in 1965. These earlier programs focused on hospital-based utilization control and physician peer review. Data from administrative claims and medical records were used to identify physicians providing substandard or unnecessary care. The focus was on outliers with little emphasis on improvements in the general population of providers. In response to recommendations of the Institute of Medicine of the National Academies in 1990,[1] the emphasis of Medicare quality assurance changed from case-specific punitive and regulatory action toward a population-based approach focusing on clinical decision making, outcomes, and professional capacity building to improve care. Now the QIO works collaboratively with health care providers in virtually all settings to collect and use data describing health outcomes and overall patterns and processes of care. QIOs analyze and review complex data from many sources to create meaningful information that guides clinical decision makers.

The collection of data and the dissemination of information

Mark W. Massing, MD, PhD, MPH, is director of outpatient and community services at The Carolinas Center for Medical Excellence. He can be reached at mmassing (at) thecarolinascenter.org or 100 Regency Forest Drive, Suite 200, Cary, NC 27518.

Anna P. Schenck, PhD, MSPH, is director of research at The Carolinas Center for Medical Excellence.

derived from data to health care consumers and clinical decision makers is a major activity of CMS and QIOs. In 2000 Jencks and colleagues[2] described national- and state-level rates on a series of clinical performance indicators for care provided to Medicare enrollees in the hospital and outlined the intended expansion of a system to monitor care provided in nursing homes and home health agencies. In the 2 Carolinas, CCME has worked with 173 hospitals, 479 nursing homes, and 235 home health agencies to improve quality as measured though data collected and made publicly available on government websites. The data are publicly reported in an effort to produce incentives for increased quality and reduced costs by creating market pressure from informed consumers and increased competition among providers.

The publicly reported quality measures for Medicare patients in hospitals include 24 care processes and 2 outcome measures.[3] (See Table 1.) Data sources for the hospital measures include clinical and administrative records. Nineteen quality measures are used to monitor nursing home care[4] and 12 indicators are used to monitor home health care.[5] (See Table 1.) Both the nursing home and home health quality measures are created from standardized patient level assessments.

The DOQ-IT (Doctor's Office Quality-Information Technology) program supports the adoption and effective use of information technology in the outpatient setting.[6] Participating outpatient medical practices may voluntarily report patient-level health care data captured from electronic health records to a clinical data warehouse administered by CMS. The DOQ-IT program has assisted 104 medical practices in North Carolina and 61 practices in South Carolina with selection, implementation, and use of electronic health systems. CMS is currently redirecting QIO physician support activities from implementation of electronic systems to effective use and central reporting of electronic data.

As a Quality Improvement Organization, CCME uses a data-driven approach to assist with Medicare-related activities, making use of enrollment databases, Medicare service claims, selected clinical information from medical record abstractions, and setting-specific quality measure data. With the capacity to link data for patients across settings and across files, CCME can create population-based maps showing variation in care by geographic location and can assess quality of care by demographic characteristics. Data can be aggregated to the county, facility, or single provider to assess quality of care. CCME uses Medicare data to identify the need for policy or clinical interventions at the local or state level.

This approach is illustrated by the trend reports CCME sends to nursing homes in the Carolinas every quarter. (See Figure 1.) The example shows almost 3 years of trended data and provides the facility the ability to compare its progress in improving care (in this case, reducing the number of residents in restraints) with that of the state and the nation. CCME creates thousands of facility level data reports every year to share with North and South Carolina health care providers.

Clinical data will grow in importance and volume as medical practices implement electronic systems. These systems will provide the raw data needed to support public reporting and pay-for-performance initiatives. Considering that as many as

Table 1.
Measures Assessing Quality of Care for Medicare Enrollees

Patient Population	Beneficiaries	Source(s) of Data
Hospitalized Heart Attack Patients	■ Percentage of patients with aspirin within 24 hours of arrival ■ Percentage of patients with aspirin prescribed on discharge ■ Percentage of patients with beta blockers prescribed on discharge ■ Percentage of eligible patients with ACE inhibitor prescribed at discharge ■ Percentage of smokers offered cessation counseling at discharge ■ Percentage of patients with fibrinolytic medication within 30 minutes of arrival ■ Percentage of patients with percutaneous coronary intervention (PCI) within 90 minutes of arrival	Hospitals submit specific data elements to clinical data warehouse about care provided to heart attack patients using the patient record as the data source
	■ 30-day risk adjusted mortality rates among enrollees hospitalized for heart attack	Medicare claims and enrollment informations
Hospitalized Heart Failure Patients	■ Percentage of patients with evaluation of left ventricular systolic function ■ Percentage of patients with left ventricular systolic dysfunction who are prescribed ACE inhibitor or ARB ■ Percentage of patients provided with discharge instructions ■ Percentage of smokers offered cessation counseling at discharge	Hospitals submit specific data elements to clinical data warehouse about care provided to heart failure patients using the patient record as the data source
	■ 30-day risk adjusted mortality rates among enrollees hospitalized for heart failure	Medicare claims and enrollment information

Patient Population	Beneficiaries	Source(s) of Data
Hospitalized Pneumonia Patients	■ Oxygenation assessment ■ Initial antibiotic timing ■ Pneumococcal vaccination ■ Influenza vaccination ■ Blood culture performed in the emergency department prior to initial antibiotic received in hospital ■ Appropriate initial antibiotic selection ■ Smoking cessation advice/counseling	Hospitals submit specific data elements to clinical data warehouse about care provided to patients with pneumonia using the patient record as the data source
Hospitalized patients receiving selected surgical procedures	■ Percentage of patients who receive prophylactic antibiotic within 1 hour prior to surgical incision ■ Percentage of patients who have prophylactic antibiotics discontinued within 24 hours after surgery ends ■ Percentage of patients who receive a prophylactic antibiotic that is recommended ■ Percentage of patients who have an order for recommended venous thromboembolism prophylaxis ■ Percentage of patients who receive appropriate treatment to prevent blood clots within 24 hours prior to or 24 hours after surgery	Hospitals submit specific data elements to clinical data warehouse about care provided to patients undergoing selected surgical procedures using the patient record as the data source
Nursing home residents in home for extended stay	■ Percentage of residents given influenza vaccination during the flu season ■ Percentage of residents who were assessed and given pneumococcal vaccination ■ Percentage of residents whose need for help with daily activities has increased ■ Percentage of residents who have moderate to severe pain in past week ■ Percentage of high-risk residents who have pressure sores in the past week ■ Percentage of low-risk residents who have pressure sores in the past week ■ Percentage of residents who were physically restrained in the past week ■ Percentage of residents who are more depressed or anxious in the past month ■ Percentage of low-risk residents who lost control of their bowels or bladder in the past 2 weeks ■ Percentage of residents who had a catheter inserted and left in their bladder in the past 2 weeks ■ Percentage of residents who spent most of their time in bed or in a chair in the past week ■ Percentage of residents whose ability to move about in and around their room got worse in the past week ■ Percentage of residents with a urinary tract infection in the past month ■ Percentage of residents who lost too much weight in the past month	Minimum Data Set (MDS) Repository The MDS is a patient level assessment conducted by nursing homes on residents at regular, specified intervals.
Nursing home residents in home for short period of time	■ Percentage of residents given influenza vaccination during the flu season ■ Percentage of residents who were assessed and given pneumococcal vaccination ■ Percentage of residents with delirium in the past week ■ Percentage of residents who had moderate to severe pain in the past week ■ Percentage of residents with pressure sores in the past week	Minimum Data Set (MDS) Repository The MDS is a patient level assessment conducted by nursing homes on residents at regular, specified intervals.

Patient Population	Beneficiaries	Source(s) of Data
Medicare enrollees receiving home health care	■ Percentage of patients who get better at walking or moving around ■ Percentage of patients who get better at getting in and out of bed ■ Percentage of patients who have less pain when moving around ■ Percentage of patients whose bladder control improves ■ Percentage of patients who get better at bathing ■ Percentage of patients who get better at taking their medicines correctly (by mouth) ■ Percentage of patients who are short of breath less often ■ Percentage of patients who stay at home after an episode of home health care ends ■ Percentage of patients whose wounds improved or healed after an operation ■ Percentage of patients who had to be admitted to the hospital ■ Percentage of patients who need urgent, unplanned medical care ■ Percentage of patients who need unplanned medical care related to a wound that is new, is worse, or has become infected	Outcome and Assessment Information Set (OASIS) The data come from comprehensive patient assessments conducted by home health agencies at regular, specified intervals

75% of physician practices do not use electronic medical records,[7] it is clear that most clinical data currently reside on paper where they are difficult to access and use. A major policy challenge involves the removal of barriers and the creation of incentives for physicians to adopt electronic systems, to undertake the expensive migration of data to these systems, and to fully integrate electronic systems into practice and care management.

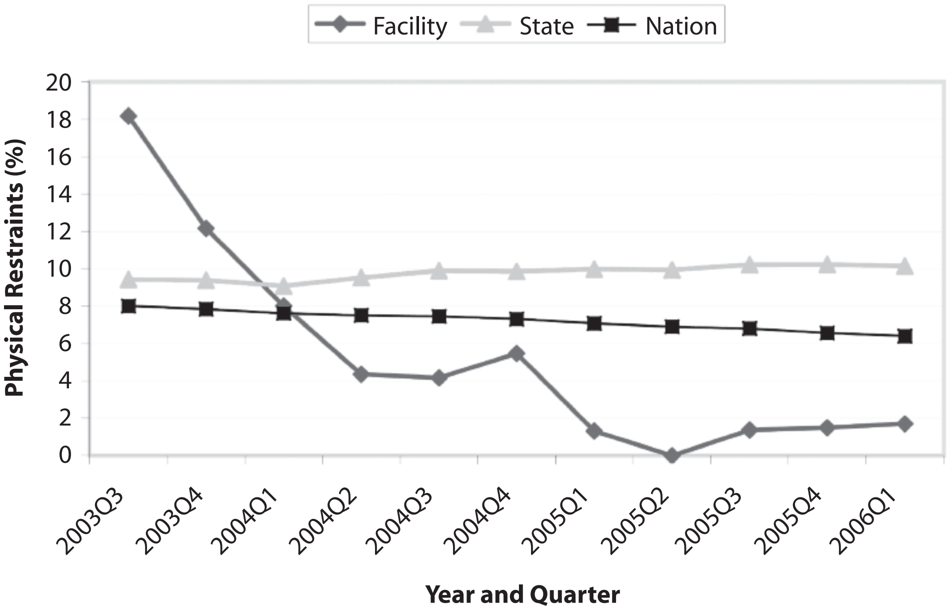
State Programs and Services

Programs conducted by states are another important source of health data used by policy makers to reduce costs and improve health outcomes. The Medicaid program administered in North Carolina by the Division of Medical Assistance (DMA) of the state Department of Health and Human Services rivals the federal Medicare program in terms of population and costs. About 1 out of every 5 North Carolina residents were served by the Medicaid Program in 2006 (1.7 million persons in total) at costs exceeding $11 billion.[8]

Data available through state programs include sociodemographic information for eligibility and enrollment, administrative claims for reimbursement of services, and limited, but growing, clinical information used for quality improvement and disease management. State health data are typically collected and maintained by a variety of agencies and contractors. Identifying, linking, and fully utilizing these fragmented data sources constitute a major challenge. But the rewards are great because these data are a rich and often underutilized source of information.

CCME has extensive experience in the use of state health data through its contracts and collaborations with a number of state agencies. A good example of how CCME has worked with DMA to expand the use of state health data relates to the Community Alternatives Program for Disabled Adults

Figure 1.
Example of Trend Report for Residents in Restraints Sent to a North Carolina Nursing Home



(CAP/DA).[9] This program reimburses eligible disabled adults for home-based care as an alternative to more expensive nursing facility care. CCME collaborated with CAP/DA consultants to create its Automated Quality and Utilization Improvement Program (AQUIP) that allows the state to assess the health status of its home-based clients in a manner similar to the way they would be assessed at nursing facilities. AQUIP captures client information and assessment data from the state and from county case managers and uses their data to assess the need for services and to examine variations in quality and costs. It also allows for the comparison of this population with institutionalized patients. AQUIP offers an example of how existing state health data can be used for multiple purposes.

About 1 in 5 North Carolina Medicare beneficiaries is enrolled in Medicaid. These dually eligible persons qualify for Medicaid due to disability or extreme medical or financial need. As a group, they are more likely to have complex health conditions that are difficult and expensive to treat.[10] Improving health outcomes and reducing costs is challenging in this population. Contributing to the challenge is the fragmentation of their health data between the federal Medicare system and the state Medicaid administrative agencies.

Evaluating the cost and quality of pharmacologic therapy in the treatment of chronic diseases such as diabetes and heart failure is especially problematic in the dually eligible population. Prior to the implementation of the Medicare Part D pharmacy benefit in 2006, state Medicaid agencies administered pharmacy benefits for dually eligible clients. Thereafter, the pharmacy benefit for the dually eligible was federalized and rolled into the Medicare Part D program.[11,12] Due to limitations imposed by the Medicare Modernization Act, Part D administrative claims data have been generally unavailable to Medicare contractors, state agencies, and health services researchers. Efforts to contain costs, reduce errors, and improve outcomes associated with pharmacotherapy have been limited by restricted access to these data.

Despite these data challenges, CCME has collaborated with DMA in projects that combine Medicare and Medicaid data to better understand and improve health care outcomes in their client populations. Medicaid data were used to evaluate the effectiveness of a CCME quality improvement project to reduce the use of antibiotics for nonbacterial respiratory tract infections.[13,14] CCME data abstractors collected clinical care information from outpatient medical records in a statewide heart failure quality improvement project involving Medicaid and private managed care.[15] In this project, clinical data from the medical records were linked to administrative claims data. In an ongoing project, CCME has linked Medicare and Medicaid administrative claims data for the dually-eligible population with heart failure in North Carolina and South Carolina to better understand and improve heart failure care in this high-risk population.

Billings and Mijanovich in a recent Medicaid study[16] demonstrated that given sufficient data it is possible to identify populations at high risk for future adverse health outcomes. The same data can be used to focus prevention efforts on persons most likely to benefit and to enable administrators to predict costs and make the business case for prevention. Medicare and Medicaid offer 2 of the few comprehensive data sources to capture the complete health experiences of large populations as they transition through the medical system. Combining and linking these data offers even greater opportunities to understand and improve health care effectiveness while containing costs.

Physician and Community Services

CCME provides a number of data-intensive services to support physicians and other health care providers in clinical decision making and quality improvement. Each addresses a fundamental need to get the right data, understand what the data mean, and act appropriately on the data.

Community Health Care Coordination

The impact of fragmentation of the health care system and its data on patient care, costs, and quality is substantial. Patients with complex medical conditions frequently obtain care from multiple settings and from different providers within settings. The task of identifying and linking patient data in different formats across diverse settings and providers can be daunting. Legislation designed to protect patient privacy creates further barriers to data sharing. This makes cross-setting data use difficult if not impossible. The failure of data to travel with patients as they transition through health care settings contributes to inefficient and uncoordinated health care. This can lead to increased costs, lower quality, and poorer health. CCME recognizes that effective health care requires a community approach to care coordination. To that end, it is developing community-based projects to promote cross-setting care coordination through information exchange and patient-centered care.

Care Management Support

Although the widespread adoption and implementation of electronic systems is an issue of central concern, there is a growing realization that the next major challenge will be the use of electronic health data to support effective care management and public health. CCME has found that the full capabilities of electronic health information systems and the data they generate are greatly underutilized. The availability of electronic data is the prerequisite to transformational system change, but it does not guarantee it. The lack of expertise and resources to understand and act on electronic data are a major barrier to achieving the substantial improvements in health outcomes and efficiencies that they promise. CCME is addressing this need through support services that enable providers to translate data into actions that measurably improve patient outcomes, enhance satisfaction, and demonstrate savings and revenues consistent with a business case for quality.

Physician Leadership and Education

The volume of data is growing much faster than the ability of physicians to understand and act on it. Recent advances in information technology provide data at levels not conceived of when most physicians were receiving medical training. Health care providers now have additional requirements to understand and use these data in routine patient care. There is a great need to enhance the skills of health care providers in the use and interpretation of data. There is also a need to develop data-driven physician leaders who are comfortable with a rapidly evolving data environment that guides clinical decision making and informs health policy. A major objective of CCME's Physician Leadership Institute is to enhance skills in the use of data to inform and support physician leadership.[17]

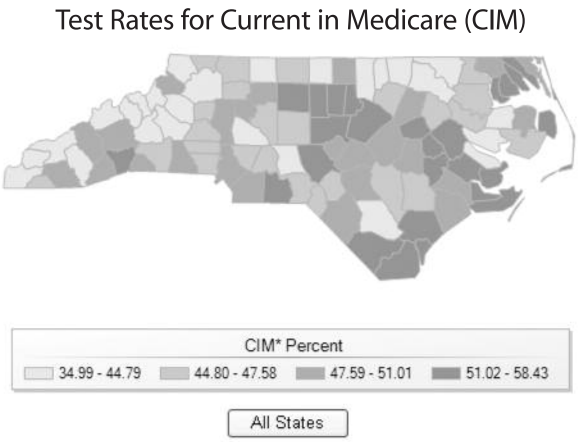
Research

The Research Division of CCME has 3 areas of focus: developing improved ways to measure quality and effectiveness of care, monitoring quality of care, and evaluating approaches to improve quality of care. The development of improved measures is crucial to the improvement in quality. Quality measures not only need to be scientifically sound (eg, valid and reliable), they must also be feasible and responsive to changes in care. CCME research focuses on the development of measures that meet these criteria. It has become an accepted tenet of quality improvement professionals that "if you don't measure something, you can't improve it!" Thus, monitoring care is a vital function of any quality organization. CCME routinely monitors the quality of care for Medicare enrollees as part of the QIO contract. It extends the power of quality monitoring to state and local organizations by hosting a Web-based surveillance report on Medicare which includes enrollment information, utilization statistics, and quality of care measures.[18] Monitoring care undoubtedly leads to identification of opportunities to improve care. CCME research in this area focuses on assessing the effects of policy or system changes and evaluating interventions to change provider or consumer behaviors.

The Palliative Care Quality Measurement Project provides an example of measurement development research conducted by CCME. Under contract from CMS, CCME was asked to identify and develop new quality measures for hospice and palliative care. CCME researched existing quality measures and identified a subset of measures for further consideration. We gathered data on 140 potential measures from other organizations and directly from care providers for measures that had not previously been tested. The project resulted in a set of 34 quality measures that technical experts agreed were appropriate for hospices to use in internal quality improvement. The results of this project were shared with CMS and made available to providers on the MedQIC website.[19]

Our Web-based report on colorectal cancer screening in the Medicare population illustrates the type of research CCME conducts to monitor care.[20] Figure 2 displays geographic variation in the proportion of Medicare enrollees in North Carolina who have had the recommended colorectal cancer testing. Lighter areas of the map represent the areas of the state with lower levels of adequate colorectal cancer testing—areas where interventions to increase screening are needed. Since 2000 CCME has, under contract with CMS, monitored test use rates for the national Medicare population. The data in the Web-based report have been instrumental in the inclusion of colorectal cancer screening in the next QIO contract, which will require QIOs in all states to work towards improving colorectal cancer testing.

Figure 2.
Colorectal Cancer Testing in the Medicare Population in 2005 (Rates per 100 Medicare Enrollees)



Conclusion

It is only when data are turned into information that the full power of data-driven solutions can be leveraged. At CCME we are working to develop the information that will help improve health policy at the federal and state levels; inform consumers so they can take a more active role in both selecting their own care and improving the care in their communities; assist providers in improving their care delivery systems; and educate physicians and providers on the patterns, problems, and opportunities to improve the health and health care of the population as a whole. We invite readers to join us in these efforts. **NCMJ**

Shaping Health Workforce Policy Through Data-Driven Analyses:

The North Carolina Health Professions Data System

Jennifer King; Mark Holmes, PhD

There is growing concern among North Carolina's policymakers that the state's supply of health professionals may not be adequate to meet future demands. Decisions about whether to enact or change policies directed at training, recruiting, and retaining health professionals affect a wide range of stakeholders and can be the source of contentious debate. For example, an important proposal considered by the North Carolina General Assembly in the 2007 legislative session was the development of a new dental school. The House Select Committee on Health Care Subcommittee on Healthcare Workforce reviewed extensive data analyses describing the supply of dentists.

The ability of legislators, legislative staff, and policy makers to understand, consider, and debate pressing issues and potential policy solutions depends on their access to ready sources of rich data and researchers who can work with the data to objectively present the analyses. One such resource in North Carolina is the North Carolina Health Professions Data System.

In partnership with the North Carolina Area Health Educations Centers (AHEC) Program and 12 state licensing bodies, the North Carolina Health Professions Data System (HPDS) maintains licensure files for 20 health professions and has continuous data for most of these professions dating back to 1979. Through consistent annual reports, analysts are able to monitor the supply of health professionals and detect new trends as they emerge. Further, interested stakeholders frequently use the HPDS data when debates about workforce issues surface. Finally, workforce policy experience has enabled HPDS analysts to identify emerging issues in the supply of unlicensed health professionals that are important to health care delivery as well as to the health of the state's economy.

> *"...state policy makers have recognized that the objective analysis available from the HPDS uniquely informs North Carolina policy makers and helps ensure that public policy on health workforce issues is based on the best available evidence."*

The North Carolina Health Professions Data System

The NC Health Professions Data System contains a broad array of information on a variety of licensed health professionals. In 2006 the HPDS included data on 20 different licensed professions. (See Table 1.) The inventories include physicians and nurses as well as professions with fewer members such as podiatrists and occupational therapy assistants. The NC Health Professions Data System annually produces the "Orange Book," an annual report of the state of North Carolina's health professions as well as maps depicting the supply of professionals across the state. Administratively located within the Cecil G. Sheps Center

Mark Holmes, PhD, is co-director of the Program on Healthcare Economics and Finance at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill and vice president of the North Carolina Institute of Medicine.

Table 1.
Professions Included in the 2006 NC Health Professions Data System Data Files

Physicians	Chiropractors
Primary Care Physicians	Occupational Therapists
Physician Assistants	Occupational Therapy Assistants
Nurse Practitioners	Optometrists
Certified Nurse Midwives	Podiatrists
Registered Nurses	Practicing Psychologists
Licensed Practical Nurses	Psychological Associates
Dentists	Physical Therapists
Dental Hygienists	Physical Therapist Assistants
Pharmacists	Respiratory Therapists

for Health Services Research, the HPDS is supported by the North Carolina Area Health Education Centers (AHEC) and the University of North Carolina at Chapel Hill Office of the Provost. Consistent with the university system's increasing commitment to community engagement, the HPDS routinely provides communities with local health professional data; these data are used for multiple purposes such as grant applications and local government priority setting. North Carolina residents highly value the HPDS as a resource; in 2007 the HPDS responded to over 200 data requests from the public.

The data available in the HPDS legally remain the property of the licensing boards that provide the data to the HPDS under a joint agreement allowing HPDS analysts to use the data for research and public policy purposes but restricting use of the data to very specific applications. This agreement maintains the security and privacy of the data. Available data in the system vary widely depending on the specific profession and the license renewal form. Although other data sources provide data on North Carolina's supply of some health professions, these sources typically contain less information, are updated in a less timely manner, or contain only a sample of professionals.

Monitoring Trends

By monitoring annual changes in the supply of health professionals in the state and in comparison to national trends, HPDS analysts are able to identify trends that merit special attention. For example, based on data from 2000 to 2004, researchers became concerned that North Carolina's past experience of robust growth in physician supply relative to population was slowing. This realization prompted the North Carolina Institute of Medicine (NC IOM) to convene a year-long task force to examine the state's physician supply and recommend options to address the projected shortage.

Using the HPDS data to examine the supply and practice characteristics of physicians, physician assistants, nurse practitioners, and certified nurse midwives, researchers developed a model that projected the future supply of providers relative to the projected growth in North Carolina's population. Figure 1 shows this projection from 2004 to 2030.

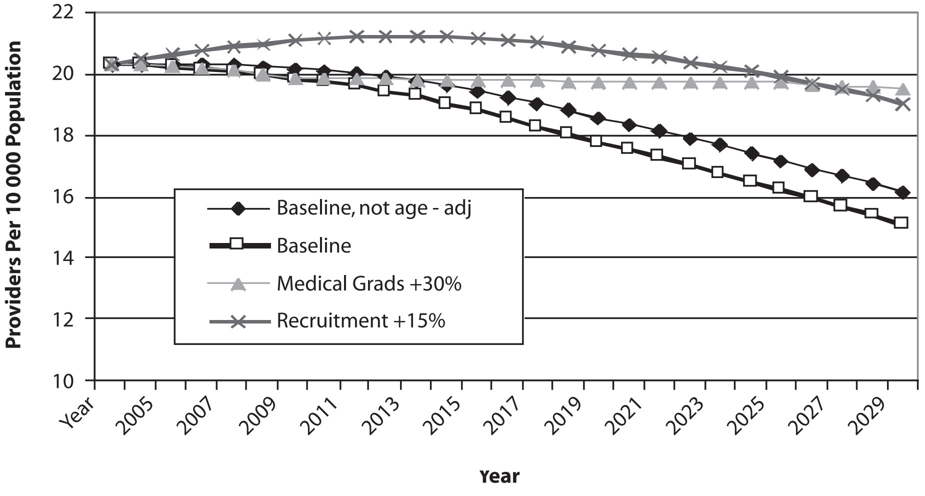
The model incorporated historical migration and retirement patterns available from the HPDS data and projected the effect of different policy options (eg, increasing the number of medical graduates, recruiting more physicians from out of state, increasing productivity through new models of care). The model allowed the NC IOM to test the impact of a variety of policy scenarios on provider supply. The model revealed that, if nothing changes, the state will face a decreased supply of providers in the near future.

Without the long, uninterrupted, historical time series of physician data, the model's ability to project supply would have been more limited. Tom Bacon, DrPH, director of the North Carolina AHEC Program, and a member of the NC IOM task force, described the importance of regular monitoring of supply (February 2008), "With so much attention to workforce policy, it is critical to develop comprehensive data on the location and practice patterns of all types of health care practitioners if we aim to resolve our pressing needs. More fundamentally, without a rich data source on health care practitioner supply, we might not even be aware of the problems."

Informing Workforce Policy Debates

The HPDS is also frequently called upon by institutions or groups when they wish to make the case for a new policy or

Figure 1.
Projected Provider Supply, North Carolina: 2004-2030



Source: North Carolina Health Professions Data System and the North Carolina Institute of Medicine.

educational program, or when an issue related to health professionals surfaces in public debate. Data from the HPDS are readily available and equally accessible to stakeholders on all sides of issues; thus, there is no need to undertake expensive one-time studies.

For example, in recent years analyses based on the HPDS have been used to inform debates and proposals regarding:

- New schools of pharmacy, dentistry, and optometry
- The supply of psychiatrists in the context of state mental health reform
- The retention of medical students and residents trained in North Carolina
- Changes in health professionals' scopes of practice
- The effect of malpractice rates on the supply and distribution of obstetric care providers
- The designation of health professional shortage areas
- The supply of health professionals from underrepresented minority groups

Data are also frequently used by researchers and the press to investigate issues related to the distribution, cost, and quality of health care services in the state.

Highlighting New Areas of Workforce Research

In recent years, the HPDS has expanded its workforce analysis capacity to focus more on allied health—a sector of the health care industry that currently faces labor shortages and is likely to grow in the future. The HPDS contains licensure data on dental hygienists, physical therapists, physical therapy assistants, occupational therapists, occupational therapy assistants, and respiratory therapists. However the majority of the allied health workforce is not licensed and assessing the supply of these unlicensed workers can be especially challenging.

To address this challenge, the HPDS has begun an Allied Health Job Vacancy Tracking Project that tracks vacancies through newspaper and online advertisements. While not a definitive measure of demand, the project has proven useful in identifying professions facing acute shortages as well as important differences in the demand for allied health professionals among the state's 9 AHEC regions.

The HPDS allied health workforce research has drawn the attention of state policymakers who are looking for ways to address manufacturing, textile, and furniture job losses in North Carolina. Allied health jobs represent not only a large and increasingly important employment sector in the state but an engine for economic growth as well. Between 1999 and 2005 allied health employment in North Carolina grew much faster than total health care employment and total employment. (See Table 2.) Over 69% of the total job growth in the health care sector between 1999 and 2005 was due to growth of allied health jobs.

Recognizing the growth potential of allied health employment, state policy makers in the Office of the Governor, the legislature, and the Departments of Health and Human Services and Commerce are collaborating with HPDS staff, the state's community college and university systems, health care employers, and industry to develop innovative ways to transition unemployed individuals into allied health jobs. The hope is that these efforts will reduce workforce shortages, increase access to health care services, and improve the economic outlook in the state's neediest counties.

Table 2.
Total, Health Care and Allied Health Employment, North Carolina

	1999	2005	% Growth (1999-2005)
Total NC Employment	3 801 670	3 809 690	0.2%
Health Care Jobs	251 550	302 270	20.2%
Allied Health Jobs	***76 590***	**111 630**	**45.8%**

Source: Occupational employment statistics. State cross-industry estimates: 1999-2005. U.S. Department of Labor, Bureau of Labor Statistics Web site. http://www.bls.gov/oes/. Accessed June 28, 2006.

Note: Allied Health Jobs are also included in the Health Care Jobs category.

Hawley Truax of Governor Easley's Policy Office called the data "crucial" in developing the allied health sector strategy (February 2008). Again, the discovery was somewhat serendipitous, once HPDS staff initially identified the rapidly increasing number of allied health professionals in the data. When this was brought to the attention of the Office of the Governor the strategy quickly developed.

The North Carolina Health Professions Data Systems as a "Neutral" Data Source

Researchers and policy makers in other states have watched what North Carolina has accomplished with its HPDS and have sought out advice and guidance on building their own systems. For example, HPDS staff have assisted North Dakota, Florida, and Missouri in developing similar systems and have offered advice to researchers in at least 6 other states. Other state policy makers have recognized that the objective analysis available from the HPDS uniquely informs North Carolina policy makers and helps ensure that public policy on health workforce issues is based on the best available evidence. Advocates representing opposing sides of an issue will often cite the same HPDS data and interpret it slightly differently. This is a subtle, yet profoundly complimentary statement on HPDS's reputation in the public policy community—opposing sides may disagree on what the data mean, but few disagree with the quality of the data. In public policy debates, access to a neutral, unbiased data source is the most important tool for building solutions. Without it, public policy may be based on the volume of the argument rather than the quality of the data, and the outcomes may be far less useful than hoped for. **NCMJ**

COMMENTARY

Community-Level Data

Christopher J. Mansfield, PhD; James L. Wilson, PhD

Health-related data are used at many geographic and political levels by individuals and groups for a multitude of purposes. The focus of this paper is on what and how data are used at the local level, for what purposes and by whom, as well as some of the unique challenges and methodological manipulations involved. Examples of common and unique uses of data and the analytic challenges involved are included.

Health-related data are typically used at the local level to describe populations in terms of demographics, economics, social and environmental conditions, disease prevalence, births, causes of deaths, health behaviors, and available health care resources. They may also be used to characterize access to health services and the use and cost of such services. The data are generally secondary, ie, obtained from another agency that specified form and content without local user input. The data may come from the US Census (eg, income, housing, education), the state and federal vital statistics system (eg, births, deaths, communicable disease incidence), disease registries (eg, cancer incidence, prevalence), or national or state surveys (eg, Behavioral Risk Factor Surveillance System). Other sources may be agencies responsible for Medicaid, Medicare, licensing and regulation, environmental protection, education, commerce, agriculture, transportation, highway safety, or law enforcement. With increasing technology and governmental investments in data collection, there is a wealth of data available, but they may not be readily useful to or easily analyzed by the local user.

Local Users and Uses

The users of health-related data at the community level in North Carolina might be local chapters of voluntary health organizations (eg, American Heart Association, American Lung Association), Healthy Carolinians groups, hospitals, health departments, health care providers, professional associations, academic institutions, news media, governmental agencies, elected officials, and individual citizens interested in their own health or the health of their family and community. Typical purposes for data use include community diagnosis, program planning, policymaking, advocacy, justification of requests for resources, and program evaluation. The purposes may be categorized within the 3 core functions of public health (ie, assessment, policy development, and assurance)[1] and within the 10 Essential Public Health Services.[2,3] The core functions and essential services are related and provide a useful typology of the various uses. (See Table 1.)

> *"The fundamental purpose of using data at the local level is to inform and empower citizens, health providers, and policy makers to take actions to improve community health."*

These core functions and resource allocation decisions should be guided by empiricism and rational analysis, ideally leading to the greatest good for the greatest number. Good decisions depend on good information. Data, however, are not the information. They are the raw material of information. Data must be refined to become information, and information must then be turned into knowledge that is then diffused and understood before it can lead to action. Data are useful only if transformed into information about problems that can and should be solved and put in the hands of people able and willing to solve them. Because problems identified and prioritized at

Mansfield, PhD, is a professor in the Department of Family Medicine in the Division of Community Health and Preventive Medicine and director of the Center for Health Services Research and Development at East Carolina University. He can be reached at mansfieldc (at) ecu.edu or Building N, Physicians Quadrangle, East Carolina University, Greenville, NC 27858.

James L. Wilson, PhD, is associate director of the Center for Health Services Research and Development at East Carolina University.

Table 1.
Uses of Data at the Local Level in Relation to 3 Core Functions of Public Health and the 10 Essential Public Health Services

Assessment

1. Monitor health status to identify community health problems
2. Diagnose and investigate health problems and health hazards in the community

Policy Deveopment

3. Inform, educate, and empower people about health issues
4. Mobilize community partnerships to identify and solve health problems
5. Develop policies and plans that support individual and community health efforts

Assurance

6. Enforce laws and regulations that protect health and ensure safety
7. Link people to needed personal health services and assure the provision of health care when otherwise unavailable
8. Assure a competent public health and personal health care workforce
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services
10. Conduct research for new insights and innovative solutions to health problems

the community level are often the ones most likely to be solved, data may be most useful when applied at the local level.

There is a history of community action for health improvement in North Carolina from the Comprehensive Health Planning Councils of the late 1960s, through the Health Systems Agencies from the mid-1970s to mid-1980s, to a public health community diagnosis and planning process that began in the mid-1970s and continues today. In the mid-1990s, the North Carolina Department of Health and Human Services began to require local health departments to submit legislative priorities for funding requests and encouraged the local departments to base their priorities on a community diagnosis process to be conducted every 4 years. Local planning was bolstered in the late 1990s by the establishment of the Governor's Task Force for Healthy Carolinians and the Office of Healthy Carolinians which developed the state's health plan called *Healthy Carolinians 2010*.[4] It was aligned with the federal *Healthy People 2010*[5] blueprint and contained goals and objectives with quantified benchmarks and targets. The Healthy Carolinians initiative embodied the first 5 of the 10 Essential Services under the functions of *Assessment* and *Policy Development* listed in Table 1 above. It encourages local health planning with small grants and "certification to communities who have broad-based community partnerships which represent the needs of the disadvantaged and whose mission is prevention based."[6] As certification requires a community assessment, the communities and staffs of the local public health departments, who are principal partners, are some of the most active users of health-related data. They are guided by a Community Health Assessment Guide Book[7] and an online County Health Data Book,[8] the contents of which are described in the commentary by Paul Buescher. As local communities *monitor health status to identify community health problems*, they typically examine data on mortality, communicable disease prevalence, pregnancy rates, and birth weight. However, the Healthy Carolinians approach goes beyond typical health statistics. They may also look at population demographics, education and socioeconomic conditions, and behaviors that contribute to health. The Centers for Disease Control and Prevention's Behavioral Risk Factor Surveillance System (BRFSS), a statewide telephone survey conducted annually in North Carolina, is an excellent source of data on risk factors, but there are only 22 counties with samples large enough for statistical generalization, and the complex sampling strategies require special statistical procedures for valid description.[9] Local groups frequently conduct their own behavior and opinion surveys but often do so with small convenience samples from which valid generalizations cannot be made. The community assessment and planning process also includes an evaluation of community resources (ie, asset mapping). Healthy Carolinians partnerships are now certified in 78 of the state's 100 counties.[10]

Health workforce data are particularly useful. Historically, inventories of physicians and other providers have been used in requests for designation of Health Professional Shortage Areas (HPSAs) which may bring federal and state resources to build and staff community health centers. These data, combined with information on local and regional health disparities, are constantly used to *inform, educate, and empower* policy makers, *mobilize partnerships to identify and solve health problems*, and *develop policies and plans*. They have been effectively employed to justify the need for medical and dental schools at East Carolina University, the Area Health Education Centers Program, and expansion of curricula and enrollments in the state's medical, nursing, and allied health schools. Other frequent users of health workforce data at the local level are hospitals, community health centers, Area Agencies on Aging, and voluntary health organizations. They *develop policies and plans that support individual and community health efforts* and use data on health resources for *linking people to personal health services*. Physician directories and community service inventories are very valuable data assets. Local public health departments, hospitals, and academic institutions are interested in local data for their roles in *assuring a competent workforce* and in *evaluating the effectiveness, accessibility, and quality of personal and population-based health services*. Academic institutions use local data to *conduct research for new insights and innovative solutions to health problems*. While there is a rich array of secondary data, they may not be appropriately defined or available in a form for valid and ready application at the local level.

Focusing the Data on Specific Regions and Communities

Professional policy analysts and knowledgeable policy makers at the state or federal level may be able to refine or transform data easily into information and to act on it. Users at the local level may be challenged. Technical expertise not withstanding, a number of problems may exist at the local level. The variables in data collected by a state or state-level agency may not have been chosen or measured to answer local questions. The geographic level of observation and measurement may not be appropriate. The county is a common level of aggregation for most health and health resource data but health problems and community planning efforts do not always follow county boundaries. Local users may need to lump or split the data for multi-county or partial-county analyses. Census data are obtainable down to the census block but analysis may require that they be lumped together. When data are from statewide samples, sample sizes at the county level may not be large enough to draw statistically significant conclusions, particularly when describing smaller population subgroups (eg, Hispanics or American Indians) by gender and age group. When county level data are large enough to split, more specific locations within a county may not have been collected or available. Another problem is that the time frames of data in standard reports may not be useful. Single-year data may not have enough observations; multiple-year data (particularly rates) may occlude trends. The needs of community-level data users, contexts, and relevant issues vary widely, as do their analytic capacities. The challenge for local users is to get simple patterns to emerge without torturing the data, the analysts, or the end users. The data must be clean, of sufficient size, and amenable to simple analysis for information to emerge and be seen, not through statistical smoke, but in clear graphic displays and then stated in simple sentences. A few examples of unique uses and challenges are useful.

Variable Must Be Redefined

A planner at a local health department wants to look at leading causes of death for people under age 75 in her county, but available reports do not provide mortality rates for that specific age group. She suspects that for those under age 75 cancer rather than heart disease is the leading cause of death. She asks colleagues at the local university to analyze recent death file data. They aggregate death certificate data (available from the Odum Institute[11]) into a 0 through 74 age group and recalculate mortality rates by race and gender. Her hypothesis is confirmed and community attention will be focused on cancer prevention and treatment.

Longer Exposure in Taking the Data Snapshot

A Healthy Carolinians group wants to develop programs to address obesity in the county. BRFSS data are available, but sample sizes in single years are too small to show any statistically significant differences between the county and the state. A custom analysis reassembling the raw data into a 5-year period to provide a larger sample shows there is in fact a higher body-mass index for the county population than the rest of the state. They will use the information in a grant application.

Produce a Moving Picture Instead of a Snapshot

Elimination of health disparities is a goal of *Healthy Carolinians 2010*. Halfway through the decade, how are individual counties doing in relation to this goal? By analysis of single-year data as a 25-year time series, trends may become apparent at the county level.

Gerrymandered Health Statistics

Data geocoded at the county level are not adequate to define phenomena that do not respect county boundaries. Local communities would certainly be interested in the health impacts of a flood, tornado, or toxic discharge—events likely to cross governmental boundaries. So also might we be interested in the relative health of one political jurisdiction to another. How, for instance, does North Carolina's Third Congressional District differ from the First Congressional District in terms of mortality? By political design, the First Congressional District contains 17 whole counties and 6 partial ones. The Third District contains 9 whole counties in addition to 6 partials, split from the First District. Demographically, the First District is 54% nonwhite versus 22% nonwhite for the Third. Mortality data are coded in public files only at the county level so important health statistics are not available at the congressional district level, which is an unfortunate disconnect between democracy and public health. Mortality rates for congressional districts can be estimated, however, by applying race- and/or age-specific rates to populations in census blocks weighted by race and age proportions and then aggregated up to the district.[12] The race and age proportions are known accurately at the census-block level. Indeed, that information was used to create the politically gerrymandered districts. For example, the estimated mortality rate (2000-2004, age-adjusted) for the total population of the First District is 1039 deaths per 100 000 population versus 966 for the Third District. The estimated rates could have considerable political significance and lead to advocacy for resources to address health disparities. This kind of analysis is not difficult, but it does require powerful computing. The same methods can be used to calculate mortality rates for state legislative districts. Similarly, we can lump together data about populations affected by natural and manmade disasters. This could be very useful in disaster planning, management, and recovery.

The fundamental purpose of using data at the local level is to inform and empower citizens, health providers, and policy makers to take actions to improve community health. There are methodological challenges in refining, redefining, repackaging, and analyzing the data, but with available technology, programs to train local users, and community-campus partnerships for technical assistance, these challenges can be overcome. State agencies and academic institutions can provide training and expertise in survey design and sampling, statistical analysis, interpretation of data, and cartographic presentation of information. We can and should improve how we collect and disseminate data for local users. Death and health-related data should be geocoded and available for analysis—with privacy safeguards—at the smallest community level whenever possible. One of the objectives of *Healthy People 2010* (23.3) is the "development of data systems that use geocoding to promote use of geographic information systems (GIS) at all levels."[5] Realization of this objective would allow local users flexibility to define neighborhoods and communities in more appropriate ways and to show their elected representatives the problems, needs, and resources of their "designer districts." We should develop dynamic, electronic public health data systems that allow users to define queries in terms of units of analysis, levels of aggregation, and combinations of variables of interest at the community level. The systems should be customizable, current, convenient, and collaborative. **NCMJ**

COMMENTARY

Using Health Data to Focus Philanthropy on Critical Needs

David E. Murday, PhD; Elizabeth A. Corley, MA

In early 2003 The Duke Endowment began planning for a special grant program for early childhood health issues with an emphasis on preventive care and services. During the first phase of the proposed program, grant projects in North and South Carolina were expected to target critical primary health care access issues that affect specific child health outcomes in those states.

The Duke Endowment was concerned that a competitive request for proposals would place communities with high needs but fewer resources at a disadvantage. To avoid this, the Cecil G. Sheps Center for Health Services Research at the University of North Carolina Chapel Hill and the Center for Health Services and Policy Research at the University of South Carolina were asked to assist the Endowment in determining the specific areas in their respective states with access-related health problems for children. The centers were asked to provide data-based answers to the following questions:

- Where are the documented areas of unmet need for children's primary care services?
- What do key people in those areas see as the most important barriers to accessing services and the most important activities needed to improve access to child health care services?
- What improvements in the health status of children can be expected if access to child health care services improves?

This article describes the efforts in South Carolina to answer these questions and support the Endowment's efforts to target the program in communities with the highest needs.

> *"...health data can be used to help a foundation identify communities whose needs are aligned with the philanthropy's priorities."*

Background

Access to health care is not equal for all children who need it. Prior research in South Carolina examined hospitalization for ambulatory care sensitive conditions as an indicator for access to primary care and found regional disparities.[1] Ambulatory care sensitive conditions are medical conditions for which children who receive appropriate and timely primary care are less likely to need emergency or inpatient care.[2] Examining 1995 data from the statewide inpatient hospital discharge database maintained by the Office of Research and Statistics of the South Carolina Budget and Control Board, the 10 highest ambulatory care sensitive conditions for pediatric admissions were bacterial pneumonia; asthma; dehydration; gastroenteritis; severe ear, nose, and throat infections; convulsions; kidney/urinary infections; cellulitis; diabetes; and immunization-preventable conditions. Access to primary care was the strongest factor affecting these admissions—children without a primary care physician were 9.5 times more likely to be hospitalized for a preventable problem than children with a primary care physician. Other demographic factors such as race, income, and insurance coverage were also significantly associated with ambulatory care sensitive conditions hospitalizations.[1] These results were consistent with findings from other research on the topic.

David E. Murday, PhD, is director of the Center for Health Services & Policy Research at the Arnold School of Public Health at the University of South Carolina. He can be reached at murday (at) sc.edu or 730 Devine Street, Suite 112, USC Arnold School of Public Health, Columbia, SC 29208.

Elizabeth A. Corley, MA, is consultant for Health and Demographics at the Office of Research and Statistics of the South Carolina Budget and Control Board.

There are 3 types of barriers to access of primary care services:

- Structural barriers are related to the number, type, concentration, location, or organizational configuration of primary care providers.
- Financial barriers restrict access. After reviewing evidence about financial and nonfinancial barriers to health care access, the Institute of Medicine of the National Academies determined that health insurance coverage is the major determinant of whether children have access to health care.
- Personal and cultural barriers such as language, attitudes and beliefs, social support, and education may inhibit people who need medical attention from seeking it, or once they obtain care, from following recommended treatment guidelines.

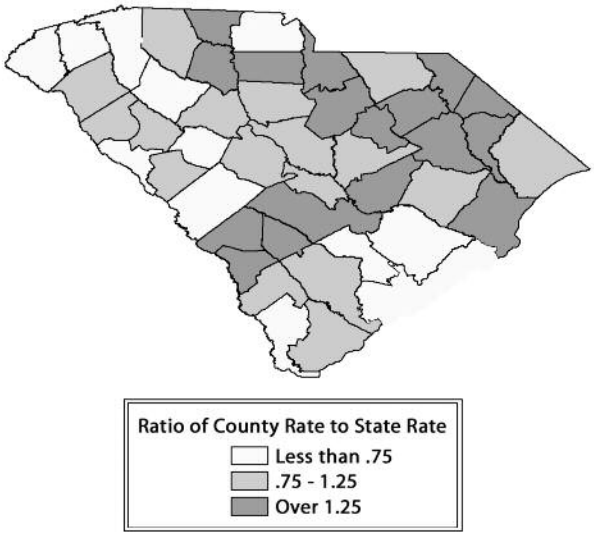
Geographic Information System Maps

Building on the prior work in South Carolina, researchers at the South Carolina Center for Health Services and Policy Research collaborated with the SC Office of Research and Statistics staff to examine several factors that could be used to identify specific areas of the state with access-related health problems for children. Within 2 months, geographic information system maps were generated (counties were grouped into those within 25% greater than or less than the statewide average and those lower or higher than this range) and counties were compared on a number of characteristics:

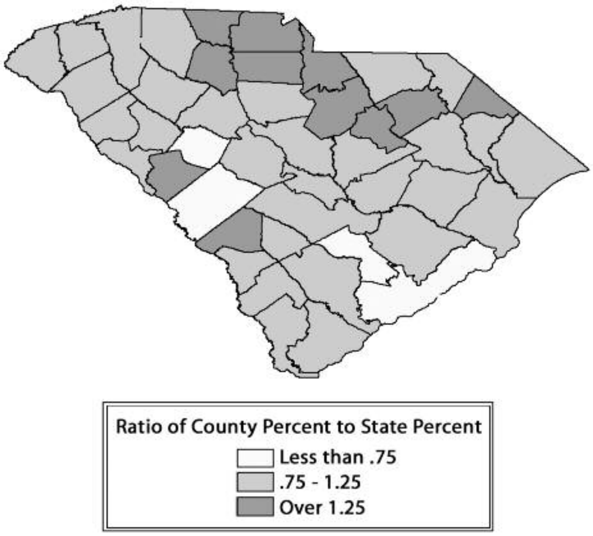
- All ambulatory care sensitive conditions and most common ambulatory care sensitive condition hospitalizations for persons under age 18 by
  - o Rate of ambulatory care sensitive condition hospitalizations per population.
  - o Percentage of ambulatory care sensitive condition hospitalizations as a percentage of all hospitalizations. (This adjusts for differences in overall utilization among counties.)
  - o Differences by payer.
- All ambulatory care sensitive conditions and most common ambulatory care sensitive condition emergency room visits for persons under age 18. (The same comparisons were used as above.)
- Rate of pediatric primary care health professionals per population under age 18 for each primary care service area.
- Percent of population with less than a high school education. (Used as a proxy for socioeconomic status.)

Maps for ambulatory care sensitive condition hospitalizations and emergency department visits used FY 2002 data; the darker counties were more than 25% above the statewide average and the lighter counties were more than 25% below the statewide average. The map for primary care physicians used 2001 data; the darker counties were more than 25% below the statewide average and the lighter counties were more than 25% above the average. So darker counties were likely to be areas with access-related problems for children. (See Maps 1-6.)

Map 1.
Rate of Ambulatory Care Sensitive Condition Inpatient Discharges



Map 2.
Ambulatory Care Sensitive Conditions as a Percentage of Inpatient Discharges



Potential Intervention Sites

Using the geographic information system maps, 9 potential target counties were identified. Based on past involvement by The Duke Endowment and the availability of hospitals eligible for Endowment grants, 4 potential intervention sites were chosen. Table 1 presents some comparative data for these sites and for a county with similar demographics but a much lower ambulatory care sensitive conditions hospitalization rate.

Over the next 2 months, Center for Health Services and Policy Research staff conducted a series of key informant interviews with 6 to 8 key people in each of those communities

Map 3.
Ambulatory Care Sensitive Conditions as Percentage of Emergency Department Visits

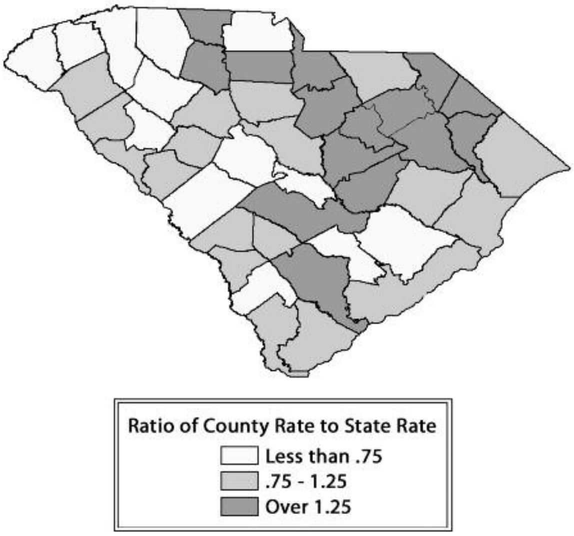
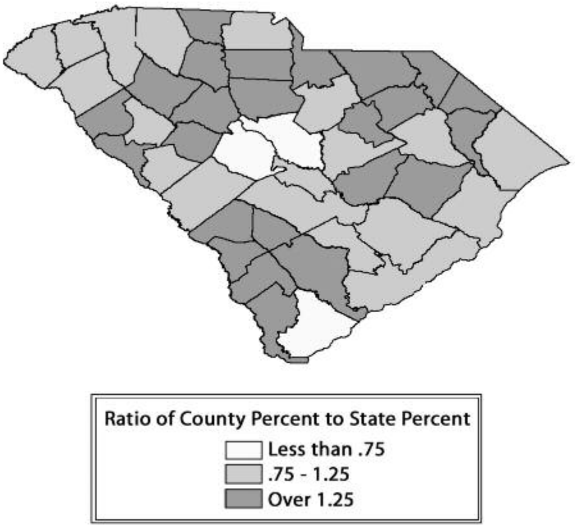
Rate of Asthma Inpatient Discharges



Map 5.
Percentage of the Population with Less than a High School Education



Map 6.
Primary Care Physicians per 10 000

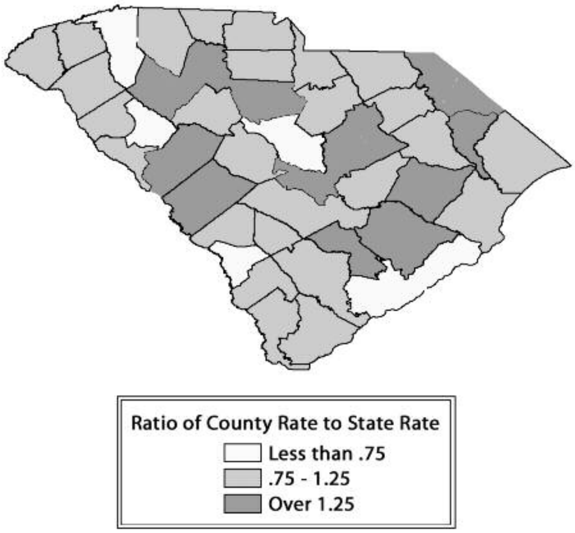


Table 1.
Actual Versus Expected Ambulatory Care Sensitive Condition Discharges, FY 2002

County	Actual	Expected, if at rate of:	
		Statewide Average	Laurens County
Dillon	309	90	65
Kershaw	425	145	106
Lee	120	56	41
Union	174	77	56

to identify the probable reasons for the higher rates. Key informants included hospitals administrators, health department staff, school nurses, community health centers staff, pediatricians, and other stakeholders. Individual reports were created for each community. Tables 2-5 summarize the common findings.

Forum for Potential Grantees

Similar geographic information system analyses and qualitative research were occurring in North

Table 2.
Major Child Health Problems

Asthma, allergy, upper resiratory infections
Obesity, nutrition
Diabetes
Mental health problems
Developmental delay
Teen pregnancy
Children presenting much sicker
Dental problems
Child abuse/neglect
Urinary tract infections/sexually transmitted diseases
Otitis media
Premature births

Table 3.
Barriers to Primary Care for Children

Transportation
Parental perception of importance of care
Lack of providers (especially Medicaid)
Lack of coordination, long waits, lack of follow-up
Family constraints: finances, job, child care, health coverage
Illiteracy
Poverty/working poor
Lack of care, translators, advocates for Latinos
Lack of awareness, outreach, advocacy

Table 4.
Common Needs

Transportation, including resources for non-Medicaid
Early periodic screening, diagnosis, and treatment resources, perhaps provided by school nurses
Spanish interpreters, outreach coordinators, advocates
Fund for non-Medicaid clients for prescriptions
Outreach, screening, education, coordination, advocacy, public awareness
Primary care centers
Physicians, nurse practitioners, nurses
More family support services/school nurses
Psychiatrists, therapists

Table 5.
Common Strengths

Caring, committed, and creative individuals working with and on behalf of children
Organized networks, interagency groups
Belief in collaboration to meet the critical needs of children in their communities
Strong "finger-on-the-pulse" awareness of needs of children in the communities
History of successful grant partnerships

Carolina. Staff from both states then assisted The Duke Endowment staff in developing a forum for potential grantees held in early summer 2003. Teams from each potential target county attended with the goal being for the attendees to consider the data for their areas, then consider interventions to improve access to primary care that The Duke Endowment would be willing to fund. The forum provided an opportunity for Endowment officials to explain in detail the concept of this funding initiative and for prospective target grantees to understand the proposal process. A key agenda item included data presentations by researchers from both state organizations that highlighted the specific data analyses and informant survey results for each of the target areas. Ample time was allotted for target area representatives to brainstorm with their respective research organizations regarding some of their ideas for improving access in response to the data presented and to suggest additional data that might enlighten their proposal processes.

The Duke Endowment Funded Projects

As a result of the forum and further technical assistance, 3 of the 4 target counties in South Carolina developed proposals that were subsequently funded by The Duke Endowment and implemented in early 2004. The proposals varied widely in their approach to addressing access to primary care.

- The Union County proposal emphasized postnatal home visits by public health nurses to link new parents to a variety of services. Some services were directly related to access (eg, linking infants to medical homes, education about recognition of health problems, and appropriate use of ER) while others were not related to access (eg, family planning, education on caregiving and injury prevention).
- In Dillon County, the proposal focused exclusively on children with asthma with the goal of reducing the burden of asthma in the county. Improving access to primary care for these children was just one of several different strategies to address asthma related problems.
- The Lee County proposal's stated purpose was "to reduce identified barriers to health care access" with strategies directly related to improving access such as referral, case management, establishment of medical homes, education regarding appropriate and timely use of the health care system, and resource development.

Follow-Up Data

Since, with expected implementation delays, the projects did not begin until 2004, the earliest expected effects of the programs would be visible in state fiscal year 2004-2005.

Discussion

This case example illustrates how health data can be used to help a foundation identify communities whose needs are aligned with the philanthropy's priorities. The relationship between access to primary care and hospitalizations for ambulatory care sensitive conditions is clearly established, and qualitative data can be used to identify specific needs, barriers, and strengths. The combination of these data can help communities consider the comprehensive nature of a problem and suggest strategies that reflect the community's resources and priorities.

This case example also illustrates the limitations of health data. Health data is but one factor a community will consider in determining its most important needs and the strategies to address them. The postnatal nurse home visiting program in Union County had been reduced due to budget cuts; restoring the program was a community priority even if it was only indirectly related to access to primary care. In Dillon County, data on high hospitalization rates for children with asthma (an ambulatory care sensitive condition) reinforced ongoing community concerns about children with asthma. As a result, strategies for improving access to primary care were focused on this limited population and other strategies were not related to access at all.

Tables 6-8 present data on pediatric admissions for ambulatory care sensitive conditions for each county during the 3 years before and 3 years after implementation. In terms of actual admissions, each county shows a substantial decrease from the 3-year average before implementation to the 3-year average after implementation–from 152 to 97 admissions per year in Union, from 264 to 156 in Dillon, and from 126 to 84 in Lee. However, since the statewide average was also decreasing over the same period, not all of those reductions can be attributed to the grant initiatives. **NCMJ**

COMMENTARY

The North Carolina Trauma Registry

Michael H. Thomason, MD, FACS

Unintentional injuries are the leading cause of death in North Carolina and throughout the United States for ages 1 to 44, with medical expenditures of $117 billion each year.[1,2] Optimal care of seriously injured patients requires an organized and coordinated approach by emergency medical services (EMS), hospitals, and other health systems. The Office of Emergency Medical Services (OEMS) is the lead agency for coordinating trauma care in North Carolina and began designating individual trauma centers in the 1980s.[3] The Trauma System Act of 1993 enabled development of an inclusive statewide trauma system with every acute care hospital required to affiliate with 1 of the 7 newly created Regional Advisory Committees (RACs). Each RAC is led by a regional Level I or Level II trauma center[a] and is expected to develop regional treatment protocols, transfer guidelines, and programs for education, training, and performance improvement.[4] Unfortunately, the legislation which created the trauma system and RACs was an unfunded mandate, so efforts to build and support it to date have been voluntary and the establishment of an integrated, inclusive trauma care system has been incomplete.

> *"The goal of the coordinated data system is inclusion of all state EMS agencies, acute care hospitals, and other providers in an organized, multidisciplinary, data-driven structure to provide optimal quality care for all injured patients throughout North Carolina."*

The North Carolina Trauma Registry (NCTR) was created in 1987 as a cooperative effort between the state's trauma centers and OEMS to facilitate the collection of consistent data on all injured patients admitted to the trauma centers. Each of the 11 trauma centers in North Carolina (6 Level I, 3 Level II, and 2 Level III) are required to collect and submit data using NTRACS (National Trauma Registry of the American College of Surgeons) software. Over 250 data points are collected on each trauma patient, with standard data definitions provided in a data dictionary which is regularly revised and updated. Since 1994 the registry has collected data on more than 200 000 patients treated at North Carolina's trauma centers.[4]

Data from the registry has been a resource for many scientific publications over the past 20 years, including those focusing on the evaluation of care and outcomes of specific injuries, causes of injury, impact of injury prevention equipment such as seat belts and motorcycle helmets, and in other benchmarking and outcomes studies. The NCTR Research Review Committee and Publications Committee oversee access to registry data and assure that resulting publications are accurate and maintain confidentiality of the patients and hospitals. However, since state law only mandates data submission by designated trauma

---

[a] Level I and II trauma centers provide comprehensice care for trauma patients, and serve as regional resource centers. Level III centers provide initial stabilization of injured patients, with transfer to Level I or II centers for those patients with more complex or critical injuries.

Michael H. Thomason, MD, FACS, is the medical director of the F.H. "Sammy" Ross, Jr. Trauma Center at the Carolinas Medical Center in Charlotte, NC. He can be reached at michael.thomason (at) carolinashealthcare.org.

centers, the registry does not currently provide a population-based profile of injured patients cared for in more than 100 acute care hospitals throughout the state.

The impact of the NCTR on health policy decisions has thus been somewhat limited. Several databases currently contain information on injured patients throughout the state, including the NCTR, PreMIS (the EMS prehospital database), and NC DETECT (the North Carolina Division of Public Health database which is updated daily with information from all emergency department visits to hospitals in North Carolina). These various databases must be linked to provide a comprehensive profile of injury in North Carolina, and efforts are currently underway to do so. If successful, this will create a registry, maintained and administered by OEMS, with accurate and accessible data to support ongoing evaluation of the evolving trauma system with benchmarking for performance improvement and outcomes research, injury prevention, and public health planning. The goal of the coordinated data system is inclusion of all state EMS agencies, acute care hospitals, and other providers in an organized, multidisciplinary, data-driven structure to provide optimal quality care for all injured patients throughout North Carolina. **NCMJ**

COMMENTARY

Transforming Care in the Physician Workplace Through Electronic Data Exchange

Holt Anderson; Gary Bowers

In 2007 total national health expenditures were expected to rise 6.9%—2 times the rate of inflation. Total spending was $2.3 trillion in 2007 or $7600 per person. Total health care spending represented 16% of the gross domestic product (GDP).[1] Health care spending in the US is expected to increase at similar levels for the next decade reaching $4.2 trillion in 2016 or 20% of GDP.[1] (See Figure 1.)

A study by the Congressional Budget Office, *Technological Change and the Growth of Health Care Spending*, published in January 2008 estimates that the percentage of GDP spent on health care will grow from 16% in 2006 to over 20% within a few years due to the aging population and growth in chronic care expenditures, and if left unchecked, will approach 49% of GDP by 2082.[2] (See Figure 2.)

> *"The danger of missing information is increased with the dispersal of care among multiple specialists serving patients with a variety of chronic conditions."*

Figure 1.
Real Spending on Health Care in Selected Categories, 1965 to 2005 (Trillions of 2005 dollars)

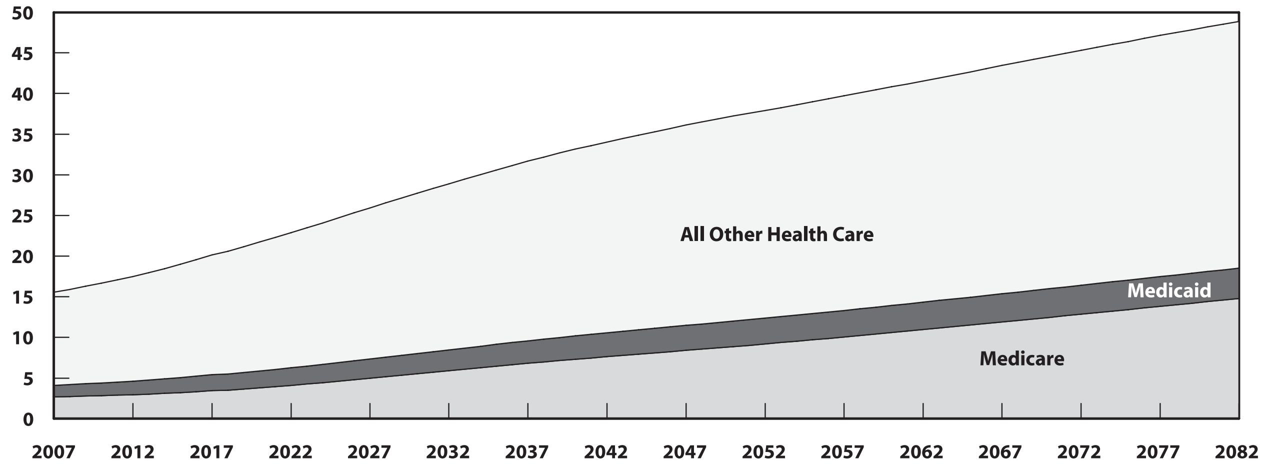
Holt Anderson is executive director of North Carolina Healthcare Information and Communications Alliance, Inc. He can be reached at holt (at) nchica.org or PO Box 13048, Research Triangle Park, NC 27709-3048.

Gary Bowers is executive director of the Western North Carolina Health Network.

Figure 2.
Projected Spending on Health Care as a Percentage of Gross Domestic Product, 2007 to 2082 (Percent)



Source: Congressional Budget Office.
Note: Amounts for Medicare are net of beneficiaries' premiums. Amounts for Medicaid are federal spending only.

The fiscal impact of these increases in overall spending for health care in relationship to limited growth in tax revenues or corporate profits will force choices that may accelerate the number of uninsured and underinsured individuals and increase pressure on reimbursements to practitioners, hospitals, and other related services. Often cited reports including those from the Institute of Medicine of the National Academies such as *To Err is Human* and *Crossing the Quality Chasm* highlight the human and economic costs of inefficient and paper-based care and encourage a swift movement to electronic health records and secure electronic health record exchange.[3,4] Work is being done by the North Carolina Healthcare Information and Communications Alliance (NCHICA) and others to build an economic business case that will support the transition to electronic health records in the practice setting where the cost and change in work flow have deterred adoption up to this point.

The Role of Quality in Improving Health Care Safety and Outcomes

The North Carolina Medical Society established the Quality of Care and Performance Improvement Committee to examine the relationship between better information management and practitioner job satisfaction and improvements in the quality of care provided. Evidence is emerging that practitioners who use electronic health records keep their patients healthier through built-in structured reminders and avoid mishaps by using electronic prescribing with automatic drug-to-drug interaction checking.[5] The current system of prescribing and dispensing medications in the United States has widespread problems with safety and efficiency. Experts predict that a shift to electronic prescribing (e-prescribing) systems could avoid more than 2 million adverse drug events annually, of which 130 000 are life-threatening.[6] E-prescribing also has enormous potential to create savings in health care costs through reduction of adverse drug events and in improved workflows. One recent study estimated the potential savings at $27 billion per year in the United States.[7]

By design, practitioners also are in a better position to take advantage of incentive programs such as Bridges to Excellence and increased reimbursements from Medicare. The Bridges to Excellence North Carolina initiative is one that encourages the use of electronic health records in practitioner offices to improve health care for partner health plan members. In North Carolina the Bridges to Excellence program provides funds to practices that are certified by the National Committee for Quality Assurance as having certain electronic and process capabilities and that serve members of health plans whose employers have subscribed to the Bridges to Excellence program. This program is showing participating employers that employees served by physicians who have electronic health records are healthier, have chronic conditions better under control, and have fewer trips to emergency departments. In turn, the health plan saves money, providing the business justification for paying incentives to physicians using electronic health records.[8]

Better and More Timely Information at the Point of Care Drives Quality

Lack of timely and reliable information about a patient has the effect of slowing accurate diagnosis and treatment. Such a delay can be frustrating for physicians and dangerous for patients, especially if knowledge about allergies and medications is not available when prescription orders are being entered. The danger of missing information is increased with the dispersal of care among multiple specialists serving patients with a variety of chronic conditions.

In a recent request for proposals, the Agency for Healthcare Research and Quality stated that the burden of providing treatment and supportive services for individuals with complex health care needs continues to increase.[9] In 2000, 60 million Americans had multiple chronic conditions, and it is projected that this will rise to over 81 million by 2020.[10] Yet care for these patients is often fragmented across multiple settings and across providers—with limited or no communication or coordination and no sense of overarching responsibility. Patients often do not seek services until there is some crisis in their condition, a crisis that may have been avoided had they sought care earlier or if their care had been better coordinated. Also, these transitions in care are often accompanied by changes in a patient's functional status which may further complicate future care needs.[9]

Information management is key to addressing these issues because it provides physicians with better and more organized information which saves them time and achieves better diagnoses and treatments (and healthier patients). Furthermore, the time saved can translate into more patients served. While there is a steady increase in the numbers of practitioners and practices adopting electronic health records, the cost and required workflow changes present barriers to many practitioners. However, a business case is being made for overcoming these barriers as peer practitioners show evidence of the benefits of electronic health records and payers begin to offer incentives for their use.

Health Information Exchange Networks

As more practitioners adopt electronic health records, additional issues arise. Of primary concern is the ability to share information collected across provider groups as needed to serve patients. As such, hospitals and health systems are building referral networks in their communities to connect radiology, labs, and pharmacies through community health information exchange (HIE) networks. In order for these networks to succeed, they must address a number of issues including data compatibility and privacy. Following a 2004 Presidential Executive Order, the US Department of Health and Human Services established the Office of the National Coordinator of Health Information Technology (ONC). The Office of the National Coordinator was tasked with facilitating privacy and security, developing and recommending standards for certification of applications, harmonizing codes, and building a "network of [community] networks, that will enable most Americans to have an electronic health record by 2014."[11]

Sixteen hospitals in western North Carolina have been recognized as leaders for their early implementation of a community HIE network which is called WNC Data Link. Their vision was to create a network to connect all of the regional hospitals to enable the sharing of electronic longitudinal records for patient care. Through WNC Data Link authorized physicians can quickly access patient lab results, medications, radiology reports, discharge summaries, histories and physical examinations, and other information from any hospital in the region via the Internet. WNC Data Link has become particularly valuable as patients transfer between hospitals and also in emergency departments where immediate access to patient information is vital. The next phase of this initiative will link physician practices and other providers to this network.

North Carolina has a number of unique capabilities and organizations that can lead the transformation from an inefficient, paper-based system of care to a high-quality environment that enhances the practice of medicine, improves efficiencies and outcomes, and makes our state even more attractive for business. NCHICA is being recognized nationally for its past and current activities as described below.

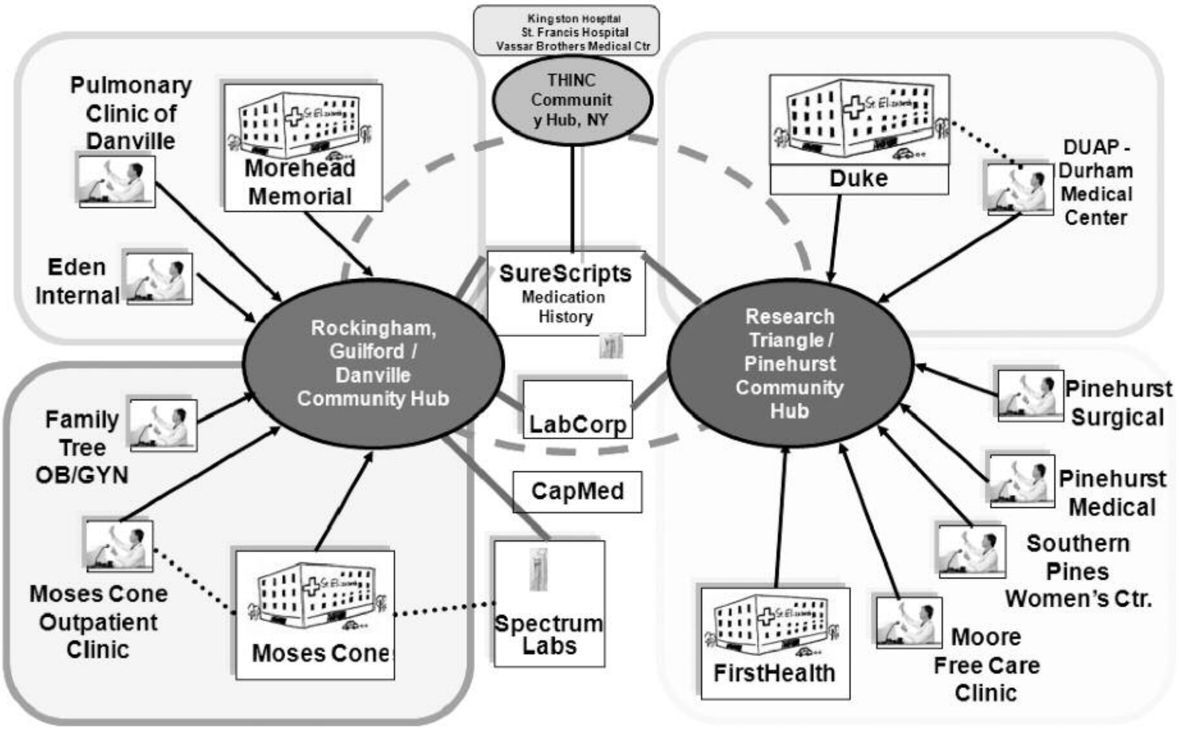
1. **North Carolina is involved in national efforts to transform health and care through the North Carolina Healthcare Information and Communications Alliance (NCHICA).**

NCHICA was formed in 1994 by Executive Order of the Governor of North Carolina as a nonprofit organization with a mission of "improving health and care in North Carolina by accelerating the adoption of information technology and associated policies."[12] NCHICA fosters collaboration among all sectors of health and care and works on policy and technology solutions that enable secure health information exchange.

North Carolina has received significant funding for 2005-2008 to participate in national efforts to develop better laws and regulations that enable exchange for treatment purposes. At the request of the Office of the Governor, NCHICA applied for and received a contract from the Agency for Healthcare Research and Quality (AHRQ) and the Office of the National Coordinator for Health Information Technology (ONC) to study business practices, laws, and regulations that have the effect of impeding the exchange of electronic health information that is required for treatment purposes.[13] Among the barriers revealed by the study, the most prominent was confusion over the Health Insurance Portability and Accountability Act (HIPAA) and the labyrinth of state and federal laws and regulations governing consents and privacy. After a legal analysis was completed, a legal work group developed recommendations for solutions and how changes might be implemented. North Carolina and 33 other states collaborated on this phase of the work that concluded at the end of 2007. In the next phase, underway in 2008, North Carolina will collaborate with other states in the development of intrastate and interstate consents and interorganizational agreements that will enable the secure exchange of information in a consistent manner that takes into consideration concerns over liability and standards.

Another major project involves North Carolina and a select group of states in the development of policies and technologies to support 2 phases of the Nationwide Health Information Network (NHIN): Architecture Prototypes and Trial Implementations. North Carolina participated in the development of the Architectural Prototype of the NHIN in 2006 and early 2007. This development was led by IBM with a subcontract to NCHICA. This phase included participation by the organizations shown in Figure 3.

Figure 3.
Nationwide Health Information Network, Phase 1



Source: North Carolina Healthcare Information and Communications Alliance, Inc.

As communities continue to build their own HIE capabilities, the challenge will be to connect neighboring communities, regions, and states. The vision is for this network to eventually become nationwide and possibly worldwide. It is clear that the best business case for greatest value can be made for the community HIE network where over 90% of all traffic will occur. Less justifiable is the cost to construct and maintain a cross-continental capability that would be rarely used. However, if the "network of networks" is constructed for clinical exchange on the local level, the connections and security capabilities would be useful for national and regional activities such as public health and claims/payments that cross community boundaries. Figure 4 graphically displays how a locator and switching service might be established to serve multiple communities in a region. The connections in a nationwide "Network of Networks" are represented in Figure 5.

2. **The North Carolina Health Information Exchange (NC HIE) Council was formed to develop consensus strategies and actions that will keep North Carolina on the forefront of health information exchange efforts.**

The NC HIE Council was formed in 2007 as a consensus-building body of knowledgeable individuals representing the leading sectors of health and care in North Carolina. The Council includes representatives from the following:

- North Carolina State Health Director or designee
- North Carolina State Chief Information Officer or designee
- North Carolina Consumer Advisory Council on Health Information
- North Carolina Medical Society
- North Carolina Hospital Association
- North Carolina Nurses Association
- North Carolina Health Information Management Association
- North Carolina Association of Pharmacists
- North Carolina Health Departments
- North Carolina Office of Emergency Medical Services
- North Carolina Association of Free Clinics
- North Carolina Division of Medical Assistance
- North Carolina Division of Mental Health, Developmental Disabilities, and Substance Abuse Services
- North Carolina Association of Health Plans
- Health Information Exchange
- Private-sector behavioral health organizations
- Long-term care/nursing homes
- Laboratory service providers
- Radiology service providers
- NCHICA CIO Roundtable
- At-large members appointed by NCHICA Board of Directors

Figure 4.

Figure 5
Nationwide Health Information Network, Architecture

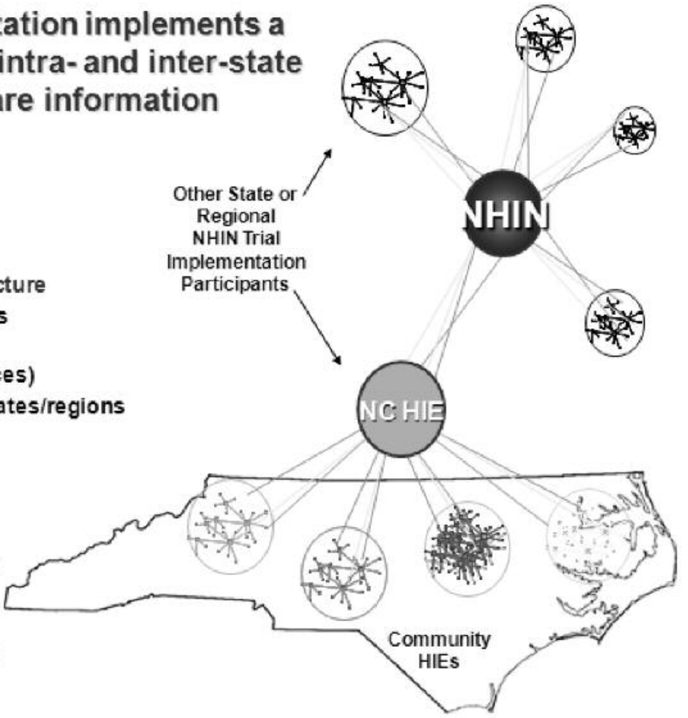
The NHIN Trial Implementation implements a "network of networks" for intra- and inter-state exchange of healthcare information

NC HIE

- Convener, Educator, Facilitator
  - Privacy/security framework
  - Standards/reference architecture
- Incubator for piloting new concepts
- Utility for Foundational Services (e.g., EMPI, Record Locator Services)
- NHIN compliant linkage to other states/regions

Community HIEs

- Encourage EHR adoption and "last mile" connectivity
- Develop real-time patient summary and data aggregation capabilities
- Provide training and education
- Engage non-provider stakeholders (payers, employers, public health)



Source: North Carolina Healthcare Information and Communications Alliance, Inc.

It is the mission of the NC HIE to enable the timely and secure exchange of electronic health information among its authorized members for the purposes of:

- Improving the quality of health and care provided to individuals in North Carolina.
- Improving the efficiency of the health care system in North Carolina.
- Enhancing patient safety in North Carolina.
- Improving the overall health of North Carolina's residents.

The NC HIE Council will develop policies and procedures that facilitate these objectives and may contract with one or more health care information service providers to operate a health information exchange network to fulfill this mission.

3. **The North Carolina Consumer Advisory Council on Health Information was formed in response to privacy concerns.**

In 2006 NCHICA established the North Carolina Consumer Advisory Council on Health Information in response to consumer concerns regarding privacy and the move to electronic health records with the attendant ability to share personal information across networks. These concerns connect broadly with the vision of a national and international capability to move information to any point on the globe. The Council is expected to become informed about both North Carolina and national initiatives and to advise NCHICA on policy and technology matters.

4. **A series of regional town meetings will be held in the spring and summer of 2008 to inform North Carolina residents of NCHICA efforts and how they can become engaged in the process.**

At the urging of its members, NCHICA will undertake a series of educational town meetings in various regions of North Carolina in the spring and summer of 2008. NCHICA representatives will share information about state and national initiatives and solicit feedback regarding local priorities that will help shape future efforts. Expected attendees are physicians and nurses, hospital administrators and chief information officers, business and political leaders, and other individuals interested in increasing health information exchange to improve quality of care and to positively impact the cost-effectiveness of the health system in North Carolina. This is particularly important as we balance the increasing demand for services with the limited resources to pay for those services.

The future looks bright for transforming health and health care practices in North Carolina from the inefficient, paper-based environment of today to the advanced electronic systems of tomorrow. Such a transformation will support health professionals in their delivery of high-quality care to their communities and will elevate North Carolina into a position of national leadership. **NCMJ**

COMMENTARY

Training Health Care Personnel to Work with Health Care Data

Elizabeth Layman, PhD, RHIA, CCS, FAHIMA

The Institute of Medicine of the National Academies (IOM) has recognized since the early 1990s that the United States needs an electronic health record system.[1-3] An electronic health record system is the keystone of the US Department of Health and Human Services' overarching initiative to increase the use of health information technologies in the health care sector. Two IOM reports, *To Err Is Human: Building a Safer Health System* and *Crossing the Quality Chasm: The IOM Health Care Quality Initiative*, particularly encouraged the migration to electronic health record systems.[4,5]

Underpinning the requirements for health care data are the recommended 8 core functionalities and 6 key capabilities of electronic health record systems.[3] A brief review of selected core functionalities and key capabilities suggests the extensive scope of health care data that is needed. For example, health information and data is a core functionality. Data associated with health information are patient or client demographics, facility and provider identification, encounter dates, admission and discharge dates, disease and service codes, clinical notes, problem lists, and medication lists. Decision support is another core functionality. Limited examples of health care data needed for decision support are warnings and contraindications for medications, out-of-range values for laboratory tests, and reminders for interventions and screenings. Reporting and population health management is another core functionality. A few examples of health care data needed for this management include specimens, procedures, results, laboratory identification, patient's temperature, outbreak data, adverse event reports, and registry data.

> *"Effective use of health care data means that health care personnel, health care organizations, and health care systems have real-time information about the health of individuals and of populations…"*

The 6 key capabilities describe what electronic health record systems should be able to do. The first key capability is longitudinal collection of data for and about individuals. Thus, electronic health record systems should be able to assemble the health care data about an individual across the span of that individual's life from all the sites of health care delivery. Examples of these sites include hospitals, physician offices, health departments, pharmacies, fitness centers, student health services, radiologic centers, dental offices, ophthalmologic practices, mental and behavioral health centers, rehabilitation units, and skilled nursing facilities. Related to longitudinal collection is interoperability, another key capability. Interoperability allows linkages among providers. Through these linkages, providers are able to exchange data. For example, dental offices can check insurance eligibility and benefits. Another important capability is that electronic health record systems allow authorized users to access individual and aggregate data. Thus, in addition to supporting clinical decision making at the point of care, electronic health record systems allow policy makers to analyze aggregate data. The key capabilities, therefore, support the delivery of integrated health care to individuals and to populations.

The variety, sources, and uses of health care data indicate the complexity of the training effort that is needed. After training, health care personnel should be able to transform individual health care data elements into information and information into knowledge. With knowledge, the health care sector can

Elizabeth Layman, PhD, RHIA, CCS, FAHIMA, is professor and chair of the Department of Health Services and Information Management at East Carolina University in Greenville, North Carolina. She can be reached at laymane (at) ecu.edu.

promote high standards, interoperability, and effective use of health care data.

High standards of care are represented by evidence-based practice. Evidence-based practice can be the use of medical and health knowledge in external referent systems or the use of standards promulgated by the professional associations and oversight entities. One key capability of electronic health record systems is the ability to connect to external knowledge such as drug references, clinical laboratory tests manuals, and anatomical references. For health care organizations, an example of a high standard of care is assuring that providers have complete health records upon which to base diagnosis and treatment. Evidence-based practice may also be supported by clinical guidelines and quality measures. For example, the National Quality Measures Clearinghouse sponsored by the Agency for Healthcare Research and Quality lists quality measures by professional association/developer, disease/condition, treatment/intervention, and measure.[6] These measures are data driven. The mortality rate for acute myocardial infarction per 100 discharges requires data on diagnostic codes, discharge status, and numbers of discharges. In addition, to put the rate in context, data on numbers of transfers, on length of stay, and on risk factors are also needed. In another example, the Centers for Medicare and Medicaid Services has process measures that require data to calculate median time from arrival at a hospital to the administration of fibrinolytic agents in patients with ST segment elevation and to calculate the percent of patients with acute myocardial infarction who have a history of smoking cigarettes and who receive smoking cessation counseling during the hospital stay. Thus, health care data can support quality improvement when the data are available in real time at the point of clinical decision making as well as retrospectively when they are available for analysis.

Interoperability is based on messaging standards or data exchange standards for information systems. These standards enable health care data to be exchanged and used among information systems across multiple sites of care. Many organizations have been involved with the development of these standards, and a lack of coordination has impeded interoperability. Examples of standards include Health Level 7 (HL7); clinical medical vocabularies such as the Systemized Nomenclature of Medicine, Clinical Terms (SNOMED-CT), Logical Observation Identifiers Names and Codes (LOINC), and the Unified Medical Language System (UMLS); and Digital Imaging and Communications in Medicine (DICOM). E-prescribing has been made possible by the National Council for Prescription Drug Programs (NCPDP) standards. The American National Standards Institute (ANSI) has developed messaging standards for the exchange of financial and administrative transactions. The ASTM (formerly American Society for Testing and Materials) has created many standards for electronic health record systems in the areas of health data security, record content, and the continuity of care record. Recently, a working group of the American Health Information Community has been very active in recommending and testing interoperability specifications (IS).[7] Functional electronic health record systems are dependent upon the coordination of these many standards.

Effective use of health care data means that health care personnel, health care organizations, and health care systems have real-time information about the health of individuals and of populations and that they have this information when they need it and in formats they can easily understand. For example, when opening the record of a patient with diabetes, the endocrinologist has immediate access to HbA1c values both as raw data and as a line graph. Moreover, if the patient was hospitalized in another state, the HbA1c values from the out-of-state hospital stay have automatically flowed into the physician's record. In terms of effective use of health care data at the organizational level, the medical group to which the endocrinologist belongs can aggregate the data for its patients with diabetes. In another example, health care data will flow—when authorized—from the hospital to the home health agency or from the rehabilitation center to the durable medical equipment vendor. At the system level, effective use of health care data would allow policy makers, administrators, and analysts to project demand, supply, and distribution of health care personnel. Generally, effective use of health care data also requires that health care personnel, health care organizations, and health care systems can manipulate the data to create knowledge about individuals' and populations' health at any point in time as well as over time.

Within health care organizations, the key health care personnel needing initial training are physicians, nurses, information service technicians, and clerical personnel. Physicians and nurses generate the volume of health care data. Information service technicians could anticipate report structures if they understood secondary uses of health care data in accreditation, regulation, and reimbursement. Training clerical personnel would enhance the accuracy of data entry. This training could be received in many formats including continuing education at conferences, on-site sessions in education departments of health care organizations, online continuing education from universities, and formal classes at community colleges and universities.

According to a recent report, 1000 public health informaticians and 1000 public health executives with informatics leadership training are needed in the health care system by 2010.[8] A public health informatics officer would be placed in each state health department. The authors of the report recommend both continuing education and formal education.

Nationally, several training and educational opportunities exist, many of which are online. The American Medical Informatics Association (AMIA) is developing a certification for physician clinical informaticians.[9] Under a grant from the Robert Wood Johnson Foundation, the AMIA is also developing a core content document and a draft set of training requirements for a physician subspecialty in applied clinical informatics.[9] Additionally, in order to generate sheer numbers, the AMIA has the "10x10" initiative or 10 000 clinical informaticians by the year 2010.[10] Under this initiative, universities, professional medical associations, and the AMIA itself are offering single and multiple courses to expand the knowledge of electronic health records, health care quality, exchange standards, public health informatics, and bioinformatics. Examples of initiatives include the Centers for Disease Control and Prevention two-year fellowship in public health informatics[11] and the Technology Informatics Guiding Education Reform (TIGER) Initiative which aims to make informatics a nursing competence.[12] The establishment of these initiatives represent current efforts to prepare health care personnel to use health care data.

In North Carolina, several options exist to train people to work with health care data. First, North Carolina has a well organized and robust system of Area Health Education Centers (AHECs). A search of the statewide calendar identified an offering entitled "health information on the Internet."[13] The AHECs also offer online courses. Second, North Carolina has an extensive community college system. This system offers individual courses on health care data or one-year certificates and associate degrees in fields that use and manage health care data. Community college offerings are both face-to-face and online. Finally, campuses of the University of North Carolina system offer individual courses and baccalaureate, masters, and doctoral degrees in health or medical informatics. Some of these offerings are also online.[14] While these examples focus on systems in North Carolina, other states have similar systems.

A 2006 joint report of the American Health Information Management Association and the AMIA identified 2 levels of competence for health personnel, as both health information users and health information specialists.[15] Physicians and nurses are the prime health information users, while other users include health administrators, policy makers, and regulators who make decisions based on the data. Reimbursement specialists at a health insurance company are also health information users and use the data to determine whether to pay a claim. Health information specialists comprise health information managers, applied clinical informaticians, and information technology resource managers. These personnel work to assure the integrity of the technological infrastructure and the quality of the health care data. For example, they work to ensure the security of off-site storage and the accuracy of coded data. The competence required of these health information specialists and health information users depends upon the support available to them and the independence of their use of the health information.

Competence involves both breadth and depth of knowledge within domains. General domains include biomedical sciences; health care delivery system; information and communication technologies; information management planning; electronic health information systems; data standards; data privacy, security, and confidentiality; data analysis and outcomes (decision support, accreditation, regulation, accountability); and leadership. Minimal educational foundations needed to work with health care data include biomedical sciences, health care delivery systems, information and communication technologies, and regulations and accreditation standards. Health informaticians such as public health informaticians or nurse executive-informaticians would need knowledge across the 4 general domains. Dependent upon the discipline of the health personnel member, additional content areas could include classifications, nomenclatures, terminologies, and taxonomies; epidemiology; health law; organizational behavior and management; and research and statistics.

Within all the domains, the extent of expertise depends upon the role of the health personnel member. For example, a telehealth communications specialist setting up the connection between a local physician at an assisted living center and a tertiary care center needs to know the definitions of the sites in the continuum of care so he or she will know what assisted living centers and tertiary care centers are. On the other hand, an inspector from the North Carolina Division of Health Service Regulation not only needs to know all the sites of care but also all the regulatory requirements for each of those sites. Determining how wide and how deep people need to be trained will require ongoing study and review by professional associations and academic disciplines as electronic health records develop and spread throughout the continuum of care.

Promoting high standards for quality through interoperability and effective use of health care data are compelling reasons to train health care personnel to understand how to use health care data. Current health personnel need training through continuing education, and future health personnel need training in their basic and academic preparation. A sustained effort is needed to achieve the long-term goal of a data-prepared workforce. **NCMJ**

COMMENTARY

Do We Have All of the Public Health Information We Need in North Carolina?

William D. Kalsbeek, PhD

Much of the progress in public health at the national, state, and local levels has depended on information about the populations that are served. Indeed, successes in dealing with susceptibility to infectious disease, injury, tobacco use, dental disease, and other major health issues of the past century have occurred because of the availability of objective scientific evidence to inform the development and affirmation of steps in the right direction. This evidence has also served as a signal to halt misguided steps and thus winnow out ideas that have proven to be ineffective. But science has only played a partial role in advancing the health of the population. Some decisions have been made based on anecdotal evidence, political expediency, and organizational inflexibility to change. A 1988 Institute of Medicine of the National Academies panel further noted that in reality, many program and policy decisions in public health are made as a reaction to the pressure of hot-button issues and organized interest groups.[1]

This article first examines the role of information in public health decision-making and then touches on some steps to assure that future decisions affecting the health of North Carolina's citizens will be made with the best information available. By implication, I suggest that continued progress towards improving the health of North Carolinians will be made most expeditiously by having the best population-based data systems available.

Data and Information in Decision Making

Within the past 10 years several practitioners and academic researchers have proposed more formal frameworks for integrating the use of objective evidence in public health decision making.[2-5] The adoption of this notion in practice has come to be called evidence-based public health (EBPH), which Ross Brownson and colleagues have defined as "the development, implementation, and evaluation of effective programs and policies in public health through application of principles of scientific reasoning including systematic uses of data and information systems and appropriate use of program planning models."[2]

Three "tools and processes" recommended for EBPH involve using data gathered from those who are affected by decisions. *Risk assessment* requires data on public exposure to harmful physical and chemical agents, *economic evaluation* weighs the cost of a population-directed intervention against the impact on those to whom the intervention is directed, and *public health surveillance* involves a continuing effort to profile relevant health-related behaviors, exposures, and outcomes in the general population.

> *"…continued progress towards improving the health of North Carolinians will be made most expeditiously by having the best population-based data systems available."*

Surveys and administrative records are 2 common sources of data for EBPH. A survey involves systematic data collection by having respondents complete a specifically designed questionnaire. These respondents are usually selected from a carefully chosen sample to reflect a broad cross-section of the studied population. Administrative records contain data that are recorded as an inherent part of a health-related process that affects a selective part of the population (eg, those who have visited a hospital, are Medicare beneficiaries, are members of a managed health

William D. Kalsbeek, PhD, is director of the Survey Research Unit and a professor in the Department of Biostatistics in the School of Public Health at the University of North Carolina at Chapel Hill. He can be reached at bill_kalsbeek (at) unc.edu or 730 Martin Luther King, Jr. Blvd, Suite 104, Chapel Hill, NC 27599-2400.

care organization, or have a particular disease). Administrative data are less expensive to use when they are available as a data source, but surveys are more adaptable to specific needs since the questionnaire and sample designs are based solely on the information needs the survey is intended to meet. Sometimes administrative data are used to improve the quality or reduce the cost of surveys.

However having appropriate data is not sufficient for EBPH to work since "data" and "information" are related but not equivalent concepts. There are two types of data: *micro data* and *macro data*. *Micro data* are bits of information about individual members of a population such as what a survey respondent reports as the status of his or her private health insurance coverage (ie, covered or not covered). These member-specific data may be used to form *macro data* for the population as a whole or for important geographic or demographic subgroups—for example, the percentage of persons in Bertie County who are covered by private health insurance. Data become *information* when findings from macro data provide answers to questions that are raised in making decisions. For instance, to deal with access to health insurance we may need to know which counties in North Carolina have the lowest private insurance coverage rates or if private insurance coverage is statistically associated with personal employment status. Answering questions that arise during decision making requires the technical ability to work with micro data as well as the ability to interpret macro data findings. Thus the mere existence of micro or macro data does not imply that we have the information we need.

Information must also be scientifically valid to be useful in decision making. The right kind of data and the resources to produce information are needed to create credible information about the general public. For example, estimating the rate of private health insurance coverage from a sample of those who have visited doctors' offices would produce invalid findings if those seen by a doctor are more likely to be insured than those who are not seen by a doctor. In this context resources are ultimately the financial wherewithal to assure that those using the data will be familiar with the statistical methods needed to transform micro data into the kinds of macro data that will inform decision making.

Gathering useful micro data, particularly in public health surveillance, must therefore follow well-established principles of survey practice.[6] The wording of questions used to produce micro data items must be appropriate for the type of macro data that are needed, samples must be representative and large enough to meet established standards, and the statistical estimation approach used to produce macro data findings from micro data items must properly take into account how the sample was chosen.

Data and Public Health Information in North Carolina

The capacity to create data and produce public health information from them is well-established in North Carolina. The State Center for Health Statistics (SCHS) in the Division of Public Health has a long history of effectively compiling and reporting data from all births and deaths as part of the state's vital registration system. The State Center for Health Statistics also compiles data from other targeted sources of health data including case registries, hospital and emergency room visits, and reported pregnancies. The SCHS collects and disseminates data from the following 3 sample surveys of all North Carolinians in specific age ranges:[7]

- *The Pregnancy Risk Assessment Monitoring System (PRAMS).* An annual mail-plus-telephone survey of about 2400 recent births on childbirth, maternal behavior, and morbidity. PRAMS is conducted in collaboration with the national Centers for Disease Control and Prevention (CDC).
- *The Behavioral Risk Factor Surveillance System (BRFSS).* An annual telephone survey of 15 000 to 17 000 persons 18 years and older that covers various topics on health promotion and disease prevention. BRFSS is also conducted jointly with CDC.
- *The Child Health Assessment and Monitoring Program (CHAMP).* An annual telephone follow-up survey of 3000 BRFSS households with children under age 18 years covering topics on child health and development.

The paper by Paul Buescher in this issue of the *Journal* more fully describes each of the SCHS data sources. The Survey Research Unit (SRU) at the University of North Carolina (UNC) at Chapel Hill School of Public Health has also conducted many important health-related telephone surveys of North Carolina citizens in recent years. These studies have covered a broad range of topics including back and neck pain, health care utilization, domestic violence, youth labor injury, and oral cancer.[8] Staff from the SRU have also assisted the SCHS and the CDC to develop and refine the designs for many of the surveys they conduct.

Are There Unmet Information Needs?

Clearly the statewide surveys conducted by the SCHS and the SRU have addressed a wide range of health topics and population groups—to the point that one might suspect that the state has all the public health data it needs. I am skeptical of this notion, however, since a closer look at the designs of these surveys reveals the potential for gaps affecting important parts of public health practice. For example, while the BRFSS sample is sufficiently large to produce a wide variety of acceptably precise estimates at the state, regional, and county levels, it does not currently include topics like health insurance coverage, food insecurity, and cancer prevalence. Moreover, sample sizes in the PRAMS, CHAMP, and SRU surveys are too small to provide estimates for most local areas like counties and municipalities. Even the largest national health surveys conducted by the National Center for Health Statistics and the Agency for Healthcare Research and Quality are of little help to North Carolina's health professionals since they generally do not have samples of sufficient size or design to produce statistically useful findings at either the state or local levels. Local area macro health data findings in North Carolina are therefore currently limited to topical estimates that can be produced with acceptable precision from BRFSS, and to county-level findings that are generated from the vital registration system and other sources of health-related micro data aimed at specific population subgroups in the state.

Efforts are now underway to determine if information needs are being met by those working in various sectors of the public health system in North Carolina.[a] The specific goal of a detailed assessment being conducted by the UNC Chapel Hill Department of Biostatistics, in conjunction with the North Carolina Division of Public Health, is to identify gaps in public health information by asking the state's users of public health data what their unmet information needs are and by determining which of these needs are being met, or could be met, by currently available data and resources. During this assessment, health professionals in the state's public and private sectors will be asked to report the kinds of public health information they have needed for their practice and research activities but have not had available. The discovered information needs will then be compared against the data available from existing sources, and each information need that cannot be met by existing data and/or resources will be considered an "unmet" need.

What If There Are Unmet Information Needs?

Several possible findings could emerge from this assessment of the need for public health information. One is that we have all the information we need and that no action is required. This would be the ideal outcome of course, but perhaps it is not the most realistic one to expect. Indeed, the assessment may conclude that we lack the data we need, that we lack the resources to turn data into the information we need, or both.

Finding that North Carolina lacks important public health information will hopefully prompt a search for new ways to expand or enhance the state's existing data systems. Concluding that the data exist but that we need to boost the state's capacity to create information will mean that creative new ways must be found to make better use of existing data. Fortunately, some effort in this direction is already underway. Faculty from the UNC Charlotte Department of Health Behavior and Administration are currently creating an online, user-friendly data warehouse that will offer visitors the ability to more fully use data from existing SCHS surveys and other sources.

In the event that more health data are needed, recent experiences in California may be useful to North Carolina. California's assessment of its health information needs in the late 1990s concluded that it lacked both data and resources and that a significant expansion in its information production capacity was necessary. This expansion led to the creation of a new statewide survey of all Californians called the California Health Interview Survey (CHIS) to supplement the state's relatively small BRFSS.[9]

One remarkable feature of the CHIS is its strong commitment to data dissemination, an activity for which roughly 25% of its budget is earmarked, according to Dr E. Richard Brown, director of the University of California at Los Angeles (UCLA) Center for Health Policy Research and principal investigator of the CHIS. The CHIS not only makes its micro data files and macro data findings readily available to its many user constituencies, but it also actively promotes the widest possible use of CHIS data through a user-friendly online query system and a series of data user workshops that have been developed especially for nontechnical health professionals at the local level.[10]

Data from the CHIS come from a periodic telephone survey of all major age and race-ethnicity groups, with total sample sizes in its first three 2-year cycles ranging from about 42 000 to 56 000 households.[10] Its design was developed following a "community-based participatory research" model in which key features are made to directly accommodate the information needs of the diverse set of geographic and demographic constituencies that the CHIS serves.[11] The result was a survey design of sufficient size, breadth, and dexterity to make its data both easily accessible and sufficient to produce high-quality statistical estimates down to the local level and for each of California's major demographic subgroups. While some of the survey topics in the CHIS overlap with the BRFSS, many are unique to the CHIS, especially in the areas of health insurance coverage, employment, income, and public program participation. Support is likely to continue beyond the current (fourth) cycle of the CHIS since the impact of its data in the state and beyond has been considerable.

The CHIS has become the main source of state and local public health information in California. Its users have included policymakers, advocacy groups, philanthropic foundations, hospitals, health care organizations, and state and county public health agencies. One illustration is typical of the dozens of documented ways that the CHIS has made a difference in the health of Californians.[12] A research and consulting firm used CHIS data to estimate the number of uninsured children in San Luis Obispo County including those who could have enrolled in existing health insurance programs but did not. Data from CHIS were also used to estimate the cost of covering all children in the county, thus paving the way for a program initiative to cover more children.

To assure that high quality health information is there to guide the future of public health in North Carolina two questions should be considered in the near term: Is the state poised to produce all of the health information it will need and, if not, what remedial steps should be taken? Findings from the needs assessment study in progress will help to answer the first of these questions, but if the second must be addressed as well, finding a meaningful answer will require the state's information users to agree on a solution that could require major enhancements in the state's health data infrastructure to get us where we need to be.

---

[a] Besides North Carolina and California, continuing work groups have been formed in Illinois, New York, New Mexico, and Texas to examine and/or expand their health data and information infrastructures. Several other states are in the process of establishing efforts to do this.

COMMENTARY

Into the Future:
Public Health Data Needs in a Changing State

Marcus Plescia, MD, MPH; Jeffrey Engel, MD

Population-based health data are the driving forces of good public health. Health surveillance, program evaluation, and research data provide the scientific basis for public health decision making at every level of the public health system, and each of the 3 core functions and 10 essential services of public health rely on these data systems to meet their objectives.[1] Recent information technology advances have improved the scope and quality of public health data sources, many of which are described in this issue of the *North Carolina Medical Journal*. As we move forward, our state faces a number of challenges and opportunities in assuring a continued strong public health data system.

> *“Public health plays a leadership role in health information exchange initiatives with the private health care sector and could serve as a neutral party in the oversight and governance of North Carolina’s emerging electronic health data systems.”*

Communities determine much of the North Carolina public health agenda. Community health assessments guide local health departments and community coalitions in identifying emerging health problems and in prioritizing needs. Communities want local data that can be easily understood both by public health professionals and community leaders. A web-based system is currently being developed to provide these data to communities in a highly accessible format that includes comparisons to peer counties.

One of the biggest problems facing smaller communities in developing their priorities is the lack of sufficient numbers from which we can draw conclusions. County-specific data in rural areas can present methodological challenges for certain conditions that are uncommon but highly visible (ie, infant mortality). Rates and indicators developed from statistical analyses can become unstable if the case counts are small. Where there are small denominators, one or two cases can change rates dramatically. One approach that would help with this situation is to allow specific data for small counties to be aggregated across years or geographic areas that are more meaningful to local citizens and state policymakers. For example, North Carolina’s Behavioral Risk Factor Surveillance System (BRFSS) currently provides county-specific data annually by oversampling the state’s 20 most populous counties. The survey could be expanded to oversample every county annually, but the expense would be considerable. Less expensive solutions include oversampling a few large counties annually and oversampling all others in staggered 4-year cycles. Alternatively, the surveillance system could oversample a larger geographic unit such as a region or legislative district.

Our traditional definition of the local county as the population denominator for rates in public health is outdated. In a state with growing urban populations, generalized county data ore often applied to disparate groups; socioeconomic and demographic characteristics vary considerably across urban counties with individual urban neighborhood populations as large as the total

Marcus Plescia, MD, MPH, is chief of the Chronic Disease and Injury Section in the Division of Public Health, North Carolina Department of Health and Human Services. He can be reached at marcus.plescia (at) ncmail.net or 1915 Mail Service Center, Raleigh, NC 27699.

Jeffrey Engel, MD, is North Carolina state epidemiologist and chief of the Epidemiology Section in the Division of Public Health, North Carolina Department of Health and Human Services.

population of many rural counties. There are often demands for data relevant to different areas; for example planning occurs at the municipal level but also for hospitals and health facilities that serve urban and suburban neighborhoods or target only the medically underserved across multiple boundaries. Data are often available by ZIP codes or other small geographic units. Analyses within and across these arbitrary boundaries are often necessary. Geographic information systems technology presents the opportunity for focused assessments of data using multiple levels of geography to define communities and has been used increasingly to understand the needs of urban and rural areas. Geographic information systems can analyze geographic data that use addresses of locations that are frequently not included in public health datasets. In order for community health assessments to document and meet the needs of underserved and special populations, future data systems must collect address data and define protocols that allow small area analyses while protecting individual privacy. Urban health departments should include such analyses in their assessment and planning efforts.

Just as infectious diseases threatened the health and well-being of communities in the early 20th century, chronic diseases and injuries are now the greatest threat of the 21st.[3] With rapid increases in rates of childhood obesity, chronic illness also has become an urgent reality for our children and youth. The majority of chronic diseases are caused by modifiable behavioral risk factors. The North Carolina Behavioral Risk Factor Surveillance System has one of the largest sample sizes in the nation and provides the majority of information on adult health behaviors and local data for the state's most populous counties. Comparable data are needed for children and youth. North Carolina's recent implementation of a Child Health Assessment and Monitoring Program demonstration project provides surveillance data for a wide range of child health and health behavior areas and should be fully funded and expanded. Given the significance of emerging child health issues, more aggressive surveillance systems are warranted. An anonymous school-based system to measure body mass index in randomly-sampled children would provide useful information to better quantify and monitor childhood obesity patterns, guide interventions, and support research in the school-based setting. A child maltreatment surveillance system should be expanded beyond surveillance of only the most severe cases documented by the state medical examiner's office. This would provide better indicators of at-risk children and provide opportunities to track and evaluate preventive interventions.

Racial and ethnic health disparities have emerged as a public health and civil rights priority issue at the national and state level.[4] African Americans comprise more than 20% of North Carolina's population,[5] and in the last census decade, the Latino population in North Carolina grew 394%, from 76 726 in 1990 to 378 963 in 2000.[6] State surveillance of health disparities is primarily limited to birth, death, and behavior survey data. The North Carolina Minority Health Report Card depends solely on these limited datasets. It is well-established that quality of health care services plays a significant role in health disparities.[4] Self-reported race and ethnicity data are accurate and reproducible, and a number of states have mandated hospital reporting of these data. Medicaid, Medicare, and the State Children's Health Insurance Program collect race and ethnicity data from enrollees. North Carolina data on health care utilization among racial and ethnic minorities are limited. Only 55% of North Carolina hospital discharge data currently have complete race and ethnicity fields. With the exception of Medicaid and Medicare, North Carolina insurers do not routinely collect data on enrollees' race and ethnicity. Race and ethnicity reporting must be improved among all North Carolina health care providers and the Minority Health Report Card should be expanded to include utilization and quality of care indicators.

Individual medical records are rapidly moving from being paper-based to electronic and are an important emerging source of public health surveillance data. Electronic health records (EHRs) represent an interconnected system of electronic health care information encompassing medical records of care from multiple provider networks. EHRs contain data essential for public health practice such as notifiable diseases and conditions, chronic disease management, and preventive measures such as immunizations. Exchange of health information between the electronic health record and public health systems such as cancer registries, immunization registries, and reportable disease surveillance systems offers the potential for rapid and synchronized reporting of public health events. This has obvious implications for emergency preparedness and response as well as for improving mandated reporting of routine conditions such as sexually transmitted diseases and lead poisoning.

Robust health information exchange between public health entities and electronic health records requires some unified set of policies to guide information managing organizations; currently the federal government is promoting this coordination through regional health information organizations (RHIOs). Confidentiality, use of a limited data set with patient identifiers, and sharing of health data among entities that are normally in competition are the main reasons regional health information organizations need authority granted to them by elected officials. Many states have enacted or are considering legislation to establish separate authority for public-private collaboration and regional health information organization formation.[7] Public health plays a leadership role in health information exchange initiatives with the private health care sector and could serve as a neutral party in the oversight and governance of North Carolina's emerging electronic health data systems.[8]

In addition to the challenges of governance over health information exchange, an unprecedented need exists to enhance the skills of the public health workforce in the area of informatics and emerging public health data systems. It is estimated that the immediate (2008) demand for skilled public health informaticians is 1000 positions nationwide.[9] Unique skills are needed to manage public health information systems, to turn complex data into useful information, and to develop the business plans and systems needed to assure financial sustainability. New systems such as the applications of a Public Health Information Network (including disease and laboratory reporting systems, immunization registries, and health alert systems) will require sophisticated expertise to manage the systems, and those who use these systems at the local level will require informatics training to facilitate usage. Undergraduate, graduate, and certificate training programs in the new science of public health informatics should be established at North Carolina educational institutions.

North Carolina is fortunate to have a strong system for health surveillance and health assessment at the state and local level. The last decade has brought significant increases in public health data, technology, and emerging public health issues. Federal resources have helped meet a number of these demands, but the state must implement new policies and expand data systems to remain a public health leader as we move into the future. **NCMJ**

COMMENTARY

Cancer Surveillance and Its Use to Reduce Cancer Burden in North Carolina

Karen L. Knight, MS; Paul A. Buescher, PhD; and Walter L. Shepherd, MA

The North Carolina Central Cancer Registry (CCR) is the state agency that collects data and produces statistics on the burden of cancer among North Carolinians. The CCR works closely with the North Carolina Comprehensive Cancer Control Program to plan and evaluate programs that address prevention, early detection, treatment, and survival. This article describes the history and purpose of the CCR, mechanisms of cancer reporting and processing, and uses of cancer data in cancer surveillance, program planning and evaluation, and research.

History and Operation of the North Carolina Central Cancer Registry

The North Carolina General Assembly established cancer as a reportable disease in 1945 for the purpose of population-based cancer surveillance. The North Carolina Central Cancer Registry was formed after the General Assembly provided funding in 1985 to collect information on the incidence of cancer among North Carolina residents to compile relevant statistics and to support "public health work."[1] Funding is also provided through a cooperative agreement with the Centers for Disease Control and Prevention (CDC) through the National Program of Cancer Registries (NPCR) which funds central cancer registries in 45 states, the District of Columbia, and 3 United States territories.

The CCR is a unit of the State Center for Health Statistics (SCHS) in the Chronic Disease and Injury Section of the North Carolina Division of Public Health. (Paul Buescher, PhD, director of the SCHS, reports in this issue on other public health surveillance databases.) The CCR works closely with other units in the SCHS such as the Vital Statistics Unit to monitor mortality trends and the Survey Unit to monitor screening and prevention behaviors. The addition of prevention, screening, and mortality data to incidence information (which includes stage at diagnosis and treatment) provides a more complete assessment of cancer burden. For instance, a shift to an earlier stage at diagnosis for a highly treatable cancer, such as colon cancer, should correspond with a declining mortality rate in the following years.

> *"The Central Cancer Registry is structured to ensure complete, timely, and high quality production of cancer incidence data for use in cancer control and research."*

The CCR is structured to ensure complete, timely, and high quality production of cancer incidence data for use in cancer control and research. Standards for reporting are set by the North American Association of Central Cancer Registries (NAACCR), of which the CCR is a member. The CCR also collaborates with other standard-setting organizations including the NPCR, the National Cancer Institute's Surveillance Epidemiology and End Results (SEER) program, the American College of Surgeons Commission on Cancer, and the American Cancer Society.

Consistent standards across central cancer registries make meaningful national statistics and comparisons possible across

Karen L. Knight, MS, is the unit manager of the North Carolina Central Cancer Registry in the State Center for Health Statistics in the Division of Public Health, North Carolina Department of Health and Human Services. She can be reached at karen.knight (at) ncmail.net.

Paul A. Buescher, PhD, is the director of the State Center for Health Statistics in the Division of Public Health, North Carolina Department of Health and Human Services.

Walter L. Shepherd, MA, is the director of the North Carolina Comprehensive Cancer Program in the Chronic Disease and Injury Section in the Division of Public Health, North Carolina Department of Health and Human Services.

states and regions. Cancer control and research programs can trust the sources of these data when measuring outcomes in different populations. To that end, NAACCR provides evaluation for certification of central cancer registries, and the CCR submits data each December for this purpose. The CCR has achieved NAACCR certification for every diagnosis year since 1997. The cooperative agreement with CDC through the NPCR also sets additional guidance and goals for the CCR, with the CCR submitting data for evaluation and incorporation into United States statistics each January.

Completeness of Reporting

Complete ascertainment of cancer is the first priority of the CCR. This ensures accurate detection of disparities in incidence. The legislation that established the registry requires that all health care facilities that diagnose or treat cancer report to the CCR within 6 months of diagnosis. Reporting sources include hospitals, freestanding surgery and radiation centers, physicians' offices, pathology laboratories, nursing homes, and hospice agencies. Reportable conditions include all malignancies except *in situ* cancers of the cervix, and includes benign brain and central nervous system tumors. Because the CCR is a public health entity, reporting to the CCR is exempt from the Health Insurance Portability and Accountability Act of 1996 (HIPAA).

Information collected about each case includes demographics of the patient at time of diagnosis including name, Social Security Number, race, ethnicity,[a] date of birth, and address, as well as information about the diagnosis including cancer site, histology, stage and grade, and first course of treatment. Over 90% of the data are reported via the CCR's secure Web-based database. CCR staff members assist small facilities and physicians' offices with reporting.

Changes in Cancer Reporting

Ten years ago almost all cancers were diagnosed and treated in hospitals, the primary source of cancer reporting. As more, large physician practices and freestanding chemotherapy and radiology centers have opened, cancers are being diagnosed and treated more frequently outside the hospital setting. Cancers such as prostate, melanoma, leukemias, and lymphomas are most often diagnosed at physicians' offices. Cancers of other sites such as breast and colon are often treated at small facilities with chemotherapy or radiation, without the patient being admitted to a hospital. To ensure that diagnosis and first course of treatment data are completely ascertained, CCR resources have been devoted to recruiting physicians to report cases although many of these small facilities do not have the trained staff or resources to adequately report the needed information.

Electronic reporting of cancer is necessary in order to make use of the electronic medical record and to promote efficient use of scarce resources. For example, electronic pathology reports are linked with the current database to identify cases not previously reported. CCR staff then use the information provided in the pathology report to partially abstract the case and contact the ordering physician to complete the case information. This process not only increases immediate reporting and identifies facilities that may be underreporting, but also identifies physicians' offices for recruitment and reduces the information needed from those offices.

In 2007 the General Assembly passed legislation to fund a Cancer Research Fund to be administered at the University of North Carolina (UNC) at Chapel Hill.[2] The administrators of the fund have been consulting with the CCR and Comprehensive Cancer Control Program for ways to support these programs as they relate to cancer research. Identified areas for partnership with the registry include enhancing cancer treatment data and enhancing geographic information systems to study patterns of care.

Accuracy of CCR Data

Data quality standards include accuracy and consistency of case abstraction and occurrence of few missing data items. This ensures that the data are appropriate for analysis and reporting. When a case is reported to the CCR, the data fields must pass a standard set of data requirements, and 90% are reviewed by certified tumor registrars (CTRs).[3] If a case for the same person has been reported previously by other facilities, CTRs determine if the case is a subsequent "primary" diagnosis or a "multiple primary." If the case has been reported previously by other facilities, the best information is selected from each report and a consolidated record is maintained for analytic use. The rules for consolidating records are standardized by NAACCR. Staff conduct routine quality control audits to identify common errors and follow up to provide training for reporting facilities.

Professional certification is provided by the National Cancer Registrars Association, and reporting facilities are strongly encouraged to hire CTRs for data collection and reporting. There is a nationwide shortage of CTRs, making recruiting difficult for both reporting facilities and for the CCR.[4] Recruiting new people to the rewarding work of cancer registration is necessary to ensure high quality cancer data.

Cancer Prevention and Control Activities and Data Use in North Carolina

The first major steps taken to address cancer prevention and control in North Carolina began in the mid-1940s through the joint efforts of the North Carolina Medical Society and the American Cancer Society, and resulted in the passage in 1945 of House Bill 786 which authorized the establishment of the Division of Cancer Control as part of the State Board of Health.[5] In 1957 the first Governor's Cancer Commission was

---

[a] The only ethnicity captured is Hispanic.

created and continued to exist in some form for the next 2 decades. Several ad hoc study committees followed. Finally in 1992, former Senator George Daniel and the late Representative Nick Jeralds helped to create a study commission that resulted in 1993 legislation creating the North Carolina Advisory Committee on Cancer Coordination and Control.[6] The Advisory Committee has continued its work since then. Two 5-year State Cancer Control Plans have been developed and disseminated (1996-2001, 2001-2006). A third 5-year plan was put on hold while transitioning to a new, continually evolving "living cancer plan," which began to be distributed for public review and comment in the fall of 2007. The current plan can be found on the cancer control Web site at http://www.nccanceradvisory.com/cancerplan.shtml.

The purpose of the State Cancer Control Plan is to examine the burden of cancer in North Carolina and develop a set of goals and objectives. The goals and objectives are associated with strategies for adoption and implementation by public and private organizations, thus creating a blueprint for action.

In addition to mortality and Behavioral Risk Factor Surveillance System (BRFSS) data compiled by the State Center for Health Statistics, the Advisory Committee relies heavily on the work of the CCR to determine the extent of cancer risk and burden, to provide baseline measures for establishment of targets, and to provide the basis for measurement of progress towards meeting the goals. The following describe some of the ways cancer data have been used along the continuum of cancer control:

Prevalence Estimates. The CCR has partnered with UNC to statistically model the state's cancer prevalence. This will be the first time cancer prevalence statistics will be available for North Carolina.

Prevention. Cancer incidence data can be used to target prevention educational messages to subpopulations. Several years ago, the CCR was involved in strategic planning for tobacco control by helping to target populations. In 2007 the CCR worked with the Advisory Committee's Melanoma Task Force to identify areas in the state with high melanoma incidence at younger ages to support efforts at addressing tanning bed use.

Early Detection. Each year the CCR links the incidence data with data from the state's Breast and Cervical Cancer Control Program to identify missed cases and to determine the stage at diagnosis for cases detected through the program.

Treatment. The CCR has worked with researchers from Wake Forest University to link both breast and colorectal cancer data with Medicaid paid claims data to evaluate access and quality of care across the state. Currently, the CDC's Breast and Prostate Patterns of Care study is being conducted by 8 states, including North Carolina, to better understand disparities in cancer treatment and potential barriers to treatment.

Survivorship. Several research studies using CCR data have examined quality of life issues among cancer survivors. Contacting patients can be difficult for these studies since physician notification is required and often physician information is not reported or the physician at time of diagnosis is no longer relevant. New standards in reporting physician information will be in effect for 2008 diagnoses, remedying the first issue.

This year, the CDC negotiated an agreement with the Social Security Death Index and the National Death Index to make these data available to central cancer registries for follow-up and calculation of survival statistics. Survival statistics currently in widespread use are produced by the National Cancer Institute's SEER program which follows all patients until death. Although the CCR links incidence data with North Carolina death records each year, many deaths are missed because patients move and die out of state. By linking incidence data with these additional data resources, the CCR will be able to produce its own survival statistics for the first time, which will be a helpful tool for physicians, patients, and researchers.

Other Uses of Cancer Data in North Carolina

More broadly, data use activities include investigating patterns in cancer incidence and mortality across subgroups of the population, responding to citizens' concerns regarding cancer in their communities, supporting research addressing the causes and outcomes of cancer, and supporting the planning and evaluation of prevention, early detection, and survivorship studies in cancer control. Examples of recent projects are provided to illustrate the variety of ways cancer incidence data are used to address the cancer burden in North Carolina.

Routine Surveillance. Each year the CCR examines the data across the state, evaluating trends over time, racial and geographic disparities, and patterns in stage at diagnosis. The CCR also produces annual reports of cancer incidence statistics and provides more detailed statistics upon request. The latest cancer incidence statistics by race, gender, and county are available on the State Center for Health Statistics Web site at http://www.schs.state.nc.us/SCHS/CCR/. Refer to the section "Availability of Data" in this article for information on how to obtain additional data.

Response to the Public. The CCR responds to citizens' concerns about cancer in their communities by providing opportunities for education about the causes of cancer, how to reduce risk factors, and cancer screening. The CCR also works with the Occupational and Environmental Epidemiology Branch in the Division of Public Health to investigate possible links between exposures in the community and incidence of cancer. However, because there is often a long latency period between a carcinogenic exposure and a cancer diagnosis, it can be difficult to find such associations.

Support of Cancer Research. The CCR works with researchers across the state and the nation to study the causes and outcomes of cancer. There are currently 32 studies in which the CCR is directly involved or releases data for epidemiologic research. Many studies ask the CCR to link incidence data to external data sources. Examples include linkages with Medicaid data in order to look at differences in treatment, as well as linkages with cohorts of employees to study links between occupational exposures and cancer. The Agricultural Health Study, funded by the National Cancer Institute, the National Institute of Environmental Health Sciences, and the US Environmental Protection Agency, has linked information with the registry data in North Carolina and Iowa for the past 15 years to study the effects of a farmer's diet, physical activity, and exposure to pesticides on the incidence of cancer.

Researchers studying the causes of cancer and treatment choices of cancer patients often need to contact patients soon after diagnosis in order to enroll them into studies. Through a partnership with the University of North Carolina's Lineberger Cancer Center's Rapid Case Ascertainment (RCA) Core, the CCR is one of a few state central registries that offer this service for epidemiologic research to research institutions across the state. These university staff members represent the CCR and obtain pathology reports from hospitals within a few weeks of diagnosis. Current and recent studies using RCA include the role of diet and genetics in racial disparities in prostate cancer, risk factors and access to care for colorectal cancer, level of screening mammography in communities, risk factors for ovarian cancer, and risk factors and quality of care for meningioma, a common brain tumor.

Availability of Data

Cancer incidence data by gender, race, and county are provided in reports on the State Center for Health Statistics Web site at http://www.schs.state.nc.us/SCHS/CCR/. Additional aggregate statistics are available by request. A version of cancer incidence statistics that can be queried online is expected in 2008. CCR staff members consult with requestors to assure the best information is provided to address the research or program questions. Some aggregate statistics, in combination with information from other sources, may provide enough information to identify a patient. To mitigate the potential identification of individuals, aggregate counts are released only when there are 5 or more cases per cell of a table. If the number of cases is fewer than 5, the director of the State Center for Health Statistics must approve the data release. If patients are to be contacted for epidemiologic research, the Advisory Committee for Cancer Coordination and Control is consulted for review of the request.

Requests for aggregate statistics not available on the Web site can be obtained by contacting the statistical staff at the CCR at 919-715-7289.

Future of Cancer Surveillance in North Carolina

High quality population-based cancer surveillance data are important for understanding the causes of cancer, detecting demographic and geographic differentials in cancer incidence, and tracking changes in cancer treatment and health care utilization. Projects slated for the next few years to improve our cancer surveillance data include an increase in electronic reporting from pathology laboratories and physician offices, survival analysis, and increased analytic capacity for linkages with external data sources for research. In 2007 the CCR migrated its database management system to California's system, which has a greater capacity to support these projects. Increased electronic reporting in the future will allow the CCR to more efficiently provide data for studies that require patient contact soon after diagnosis and will also increase the ascertainment of cancer cases for cancer control. **NCMJ**

Comment from The Duke Endowment:
The Importance of Data for Grant Making

M. Tina Markanda, FACHE, MBA, MSPH

The mission of The Duke Endowment is to improve lives and communities in the Carolinas. It seeks to achieve this through efforts dedicated to supporting higher education, health care, rural Methodist churches, and children's services. In support of this mission, the Endowment seeks to make an impact that can be demonstrated by quantitative, measurable outcomes for funded projects.

In 2002 The Duke Endowment began a unique collaboration to identify and target "high risk, high need" communities with regard to access to primary care for children with key child health problems. The goal in identifying these communities was to target them for project funding for increasing access to primary care services for children. It is well-documented that primary care services for children are critical to child development. Further, research indicates that children who are poor, minority, and uninsured often do not receive appropriate primary care services.

The Duke Endowment partnered with the Cecil G. Sheps Center for Health Services Research at the University of North Carolina (Sheps Center) and the Center for Health Services and Policy Research (CHSPR) at the University of South Carolina in conjunction with the South Carolina Office of Research and Statistics (ORS). The Sheps Center and CHSPR dedicated significant effort to a multifaceted analytical evaluation to identify high risk, high need communities in each state. The process required accessing and evaluating data from various existing databases and data systems (eg, hospital discharge data, Medicaid claims data, census data, State Health Plan data, North Carolina State Center for Health Statistics data, North Carolina Child Advocacy Institute data, Geographic Information Systems data) to identify communities where ambulatory care sensitive condition rates indicated the highest health risks for children. Ambulatory care sensitive conditions are medical conditions such as asthma and pneumonia that can be managed in an outpatient setting, thus avoiding the need for emergent care in the emergency department or inpatient hospital. Unnecessary emergent or inpatient care can adversely impact both short-term and long-term child well-being. Therefore, managing these conditions can lead to improved child well-being and reduce health care costs. In addition to monitoring variance of rates at this macro level, individual grant recipients also monitored data related to hospital utilization, emergency department services, and other appropriate project-centric indicators at a local level.

This identification of high risk, high need communities allowed the Endowment to focus grant funds on specific communities where it would be possible to apply collaborative interventions and monitor their impacts. Those identified communities were invited to apply for grants to improve access to primary care for children. Of the 8 communities identified, 6 were selected to participate in the program.

Throughout the course of the grant, project leaders have continuously monitored project-specific indicators related to program implementation. Simultaneously, they have monitored variance in county and state ambulatory care sensitive condition rates reported by the Sheps Center, CHSPR, and ORS. As a result, the grantees have been able to proactively test implementation strategies and monitor impacts using ambulatory care sensitive condition data as a gauge. If implementation does not impact outcomes, then grantees can modify strategies as needed. Without this data, monitoring impact would be difficult.

Using this approach of demonstrable impact has been very effective and will serve as a model for future initiatives. As The Duke Endowment continues to focus even more strongly on impact-related grants, partnerships with organizations that can analyze local- and state-level data such as the Sheps Center and CHSPR will continue to be essential from two perspectives. First, grant funds can be targeted to specific communities facing particular health-related challenges and those communities with the greatest needs. Second, both grantees and The Duke Endowment will be able to continuously monitor progress and thus evaluate the impact of interventions to improve the health of citizens and communities in North Carolina and South Carolina.

M. Tina Markanda, FACHE, MBA, MSPH, is a program officer at The Duke Endowment. She can be reached at tmarkanda (at) tde.org or 100 North Tryon Street, Suite 3500, Charlotte, NC 28202-4012.

Readers' Forum

To the Editor:

As published in the journal *Annals of Internal Medicine*, the American College of Physicians (ACP) and the American Pain Society (APS) convened a multidisciplinary panel of experts to perform a systematic evidence review and develop guidelines in the evaluation and management of low back pain. Spinal manipulation was recommended as the only proven non-pharmacologic, non-invasive means of treatment for acute low back pain. Additionally, spinal manipulation was recommended in the care of sub-acute and chronic low back pain.[1]

In the United States, it has been estimated that direct health care costs attributable to low back pain are in excess of $26 billion per year.[2] Indirect costs including associated disability, administrative activities, and lost productivity have been found to generate a societal financial burden of 7 to 8 times greater than direct costs.[3,4] Stewart et al[5] reported $61.2 billion in losses due to lost productivity related to spinal complaints during a one-year period.

The goal of evidence-based protocols is to provide clinicians with practice guidelines based on the best evidence available; to make recommendations based on that evidence; to inform clinicians of when there is no evidence; and, finally, to help them deliver the best health care possible.[6] The ACP/APS spinal manipulation guideline reflects an opportunity to improve health care outcomes through medical and chiropractic inter-professional patient comanagement. The implementation of this guideline may necessitate a paradigm shift in decision making that will cause physicians to insert chiropractic referrals into their algorithms of care.

Medical practitioners should consider the training necessary to attain a chiropractic doctorate. In North Carolina, chiropractors must achieve a baccalaureate degree, complete chiropractic school, and pass national board and licensing examinations. In the United States, 16 accredited chiropractic university programs require a minimum of 4200-5500 hours of combined core science and clinical coursework. Some chiropractic schools are affiliated with medical hospitals, providing chiropractic interns clinical rotations and invaluable clinical experience.[7,8]

Some chiropractors undergo additional postgraduate training to attain advanced subspecialty board certification. Chiropractic colleges provide postdoctoral training in orthopedics, neurology, sports injuries, nutrition, rehabilitation, radiology, industrial consulting, family practice, forensics, pediatrics, and applied chiropractic sciences.[9]

It is important to recognize that medical schools now provide chiropractic course electives and clinical rotations in chiropractic offices. Major medical universities such as the Duke University School of Medicine, the University of North Carolina at Chapel Hill School of Medicine, and the Albert Einstein College of Medicine actively participate in these programs.[10]

In light of the economic impact and morbidity associated with low back pain, it is imperative for physicians to consider the evidence-based guidelines put forth by the American College of Physicians and the American Pain Society. As substantiated by available data, medical and chiropractic interdisciplinary collegiality is now reasonable, appropriate, and in the best interest of patients and our society.

Spotlight on the Safety Net

A Community Collaboration

Kimberly M. Alexander-Bratcher, MPH

Safety Net Survey and Web Site
www.nchealthcarehelp.org

A new and essential safety net resource for North Carolina will be launched this spring. The Web site, www.nchealthcarehelp.org, will provide a unified resource for locating safety net services throughout the state. As such, it will be an invaluable tool for improving access to health care services for the millions of uninsured and underserved people in North Carolina. Health care providers, patient advocates, and consumers will be able to search the database-driven website by service type, county, insurance status, and patent eligibility criteria.

Evolution of the Safety Net Web site

In 2004 with funding from the Kate B. Reynolds Charitable Trust, the North Carolina Institute of Medicine (NC IOM) convened the Healthcare Safety Net Task Force to examine safety net services in North Carolina. The Task Force developed recommendations to expand and strengthen the service capacity of safety net providers. A group known as the Safety Net Advisory Council (SNAC) grew out of the Task Force. With support from the Blue Cross and Blue Shield of North Carolina Foundation, the SNAC developed a web-based survey to collect and house information from the state's safety net organizations.

Through the survey, safety net organizations provided contact information, physical location, services offered, hours of operation, eligibility criteria (if any), forms of payment (eg insurance, sliding fee scale), and whether they were accepting new patients. Additional data were collected on the number of patients, patient visits, and the percentage of uninsured patients. To date more than 200 health care safety net organizations have participated in the survey. Safety net organizations can enter or edit their information at any time on the Web site (www.nchealthcarehelp.org). This spring, information gathered through the survey will be made available to the public at www.nchealthcarehelp.org. Another benefit of having access to these data is that they will provide an estimate of the number of uninsured individuals in North Carolina who are accessing health care through safety net organizations and help identify areas within the state with the most unmet need.

The Safety Net Web site is the result of the combined dedication of health care safety net organizations, foundations, and many other groups to improve the health of North Carolinians. To learn more about the Web site, visit www.nchealthcarehelp.org.

Examples of Safety Net Organizations in North Carolina

- Community Care of North Carolina practices
- Federally certified rural health clinics
- Federally qualified community health centers
- Federally qualified migrant health centers
- School-based and school-linked health centers
- Hospital outpatient clinics and centers
- Project Access programs
- Public health departments
- Free clinics
- State funded rural health centers

LOSING WEIGHT NEVER FELT SO GOOD

Now you can start living a happier, healthier life!

LAP-BAND patient Lisa lost 140 pounds and found a happy, healthy life.

For millions of people, losing weight—and keeping it off—seems impossible. Thanks to the LAP-BAND® System, you can finally take control of your hunger and transform your life.

We now offer the LAP-BAND procedure, the least invasive weight-loss surgery available in the United States. The LAP-BAND System is a tool that helps control your hunger and support your unique weight-loss needs.

THE LAP-BAND SYSTEM ADVANTAGES

- Least invasive, safest surgical option
- No stomach stapling or intestinal re-routing
- Only adjustable surgical option for customized weight loss
- Completely reversible
- More than 150,000 procedures performed worldwide

If you are 100 pounds overweight and are ready to win back your life and regain your health, contact us for more information on the LAP-BAND System solution.

LAP-BAND®
SYSTEM

The Preferred Choice for the Surgical Treatment of Morbid Obesity

---

SOUTHEASTERN
REGIONAL
MEDICAL CENTER

For seminar dates and to register, please call: 910-735-8984
Meet Dr. Barry Williamson, general surgeon who will perform lap banding.

As with any surgery, there are specific risks and possible complications associated with the LAP-BAND surgery. Talk to you doctor to determine if you are a candidate for the LAP-BAND System.
