COMMENTARY

The Economic Impact of Prostate Cancer Screening and Treatment

Rachael L. DiSantostefano, PhD, and John P. Lavelle, MB, BCh, FRCSI

Prostate cancer is a significant public health concern. Because of its high incidence and mortality and a lack of consensus on the recommended frequency of screening and the most appropriate treatments, prostate cancer is also characterized by high costs and uncertainty. As a result, there is perhaps no bigger debate in medicine today as far as whether or not there should be widespread screening for prostate cancer and if and/or how to treat early-detected cases.

> *"Whereas the increase in screening detects cancer early and at a potentially curable stage with aggressive treatment, it has also resulted in the overdiagnosis of latent disease and unnecessary biopsies for men with false-negative screening tests."*

The corresponding economic costs of screening, diagnosis, treatment, and follow-up for prostate cancer are not trivial and are expected to increase with the aging of the population and a larger volume of screening. In 1990, the total annual costs to treat prostate cancer were estimated to range from $1.72 billion to $4.75 billion.[1] With the advent of prostate-specific antigen (PSA) screening in the early 1990s, the costs of treating prostate cancer in the United States likely far exceeded this amount, based on trends toward earlier detection and more aggressive treatment. Based on early estimates, the cost of screening increases prostate cancer expenditures by three-to-ten times.[1] The costs of treating prostate cancer in Sweden have been observed to fall within this range, increasing three-fold between 1991 and 2002 (20 million to 65 million euros).[2]

The exponential increase in the volume of prostate cancer screening adds to healthcare costs via the cost of the screening test, follow-up biopsies for positive tests, and treatment (or long-term monitoring) for confirmed prostate cancers. For example, the use of PSA tests increased seven fold, and radical prostatectomies increased six fold between 1991 and 2002 in Sweden.[2] Radiation therapy increased ten fold from 1997-2002.[2] In the United States, similar trends were likely. Between 1989 and 2002, there was a 234% increase in radical prostatectomy in the United States.[1] In 2003, there were 90,328 hospital discharges with the diagnosis of prostate cancer and associated costs of $673 million.[3] While treatment for prostate cancer is expensive, the overuse and/or inappropriate use of diagnostic tests in a manner inconsistent with treatment guidelines significantly inflates costs for disease management.[2] According to the Medicare Current Beneficiary Survey (2002), nearly two thirds of the 17.6 million Medicare beneficiaries received prostate cancer screening.[4] If all Medicare beneficiaries or all men older than 50 (34.7 million in 2000) sought screening, annual costs for the PSA screening test for

Rachael L. DiSantostefano, MS, PhD, is an Assistant Director of Epidemiology at GlaxoSmithKline, where she studies the epidemiology of respiratory diseases. Prior to accepting a position at GlaxoSmithKline, Dr. DiSantostefano was a doctoral student in the Department of Health Policy and Administration, School of Public Health at the University of North Carolina at Chapel Hill, where she studied cost-effectiveness of prostatic diseases. She can be reached at rdisantostefano@nc.rr.com or 104 Ironwood Place, Chapel Hill, NC 27514. Telephone: 919-544-4230.

John P. Lavelle, MB, BCh, FRCSI, is an Assistant Professor in the Division of Urology, School of Medicine at the University of North Carolina at Chapel Hill. Dr. Lavelle can be reached at Lavelle@med.unc.edu and CB# 7235, Chapel Hill, NC 27599-7235. Telephone: 919-966-2571.

one year would approach ~$2 billion assuming Medicare reimbursement (~$50 per test).[5] With costs in the range of a few billion dollars per year (screening, treatment, disease management, monitoring, etc.), costs of a population-based screening program, including disease management, could easily exceed $20 billion within five-to-seven years.

The biggest controversy in prostate cancer research is in the lack of consensus on the value of prostate cancer screening given the test's performance at diagnosing cancer and the inconsistent demonstration of effectiveness of early intervention at improving patient outcomes, including reductions in mortality. Although the existing evidence of effectiveness has improved in recent years, and cost-effectiveness analyses have been increasingly performed, uncertainty about the benefits of treatments in improving patient outcomes remains. A recent systematic review demonstrated that it was difficult to draw conclusions without uncertainty on the benefits of treatment alternatives due to lack of randomized clinical trials. Newer technologies, in particular, were hardest to evaluate given a lack of evidence of effectiveness and a lack of comparison with standard treatment alternatives.[6] Although radical prostatectomy and radiation rapidly replaced watchful waiting for early disease detection with the advent of PSA, there was weak and inconsistent evidence regarding any benefits in terms of improved patient outcomes (including mortality) during this period.[2] One recent study demonstrated lower mortality using radical prostatectomy versus watchful waiting in early-stage disease,[7] but evidence is otherwise weak or inconsistent from other trials, including those with long follow-up.

The lack of consistent or compelling evidence about early detection of prostate cancer showing an improvement in survivorship has not stopped numerous treatments from being rapidly diffused, including aggressive treatments in relatively young men. This is problematic in that aggressive treatments themselves have consequences. For example, after 18 months of follow-up, patients receiving radical prostatectomy in one study experienced significant erectile dysfunction (59.9%) and urinary incontinence (8.4%).[8] Other treatment alternatives result in co-morbidities affecting sexual and urinary function. If these patients experience a long survival period, they must face the psychosocial consequences of treatment-related adverse effects that might not have been necessary if their underlying disease was latent or extremely slow in progressing.

Whereas the increase in screening detects cancer early and at a *potentially* curable stage with aggressive treatment, it has also resulted in the overdiagnosis of latent disease and unnecessary biopsies for men with false-negative screening tests.[9] False positive screening has financial and psychological costs, with about half of men with suspicious screening test results and subsequent negative biopsies reporting worrying "a lot" or "some of the time" about prostate cancer.[10] For men with confirmed prostate cancer, those choosing either watchful waiting or aggressive intervention for early-stage disease must address the implications of their choices, which can result in anxiety, decreased activity level, decreased quality-of-life, adverse effects of treatment, etc. [11]

From an economic perspective, the value of a screening test can be determined by estimating the relative costs and benefits, where benefits of screening can be measured in terms of test performance, unnecessary biopsies, and/or formal cost-effectiveness analyses. Studies that evaluate prostate cancer screening focus primarily on the PSA test. One recent study found that complexed PSA (cPSA)[a] (threshold 2.2 ng/ml) was a better test than total PSA (tPSA) (2.5 ng/ml), with higher sensitivity and specificity and fewer unnecessary biopsies.[12] A cost-benefit study looking at five screening strategies found that cPSA (3.8 ng/ml) was dominant (more costly and less effective), with a threshold of 3.0 ng/ml identifying a similar number of cancers with fewer biopsies than tPSA (4.0 ng/ml).[13]

Using simulations including Markov modeling that simulate the progression of disease to determine the most efficient PSA screening algorithm, the benefits of prostate screening vary by age and were not recommended above age 70, where the competing risk of mortality outweighs the benefit.[14,15] In their Markov model, Ross and colleagues conclude that annual PSA screening (4.0 ng/ml threshold) starting at 50 years of age is dominant (i.e., more costly and less effective) by a biennial screening strategy after tests at 40 and 45 years of age.[16] Screening beyond age 70 required more treatments (and significant additional costs) per person-year of life saved.[14] A second computer model supports screening every two years (4.0 ng/ml threshold), which reduces false-positive and overdiagnosis rates sharply, while catching most cases relative to the more traditional annual screening without any age-specific thresholds.[17] Clearly, additional research to determine the best thresholds for PSA measures (tPSA, cPSA, PSA velocity,[b] etc.) and to determine the utility of other biomarkers in detecting aggressive prostate cancer is critical. If future screening tests can better distinguish latent disease from aggressive disease and minimize false positives, they offer great potential to lower unnecessary expenditures for prostate cancer.

The utility of prostate cancer screening and treatment will be debated for the foreseeable future, especially with the advent of new treatments and the absence of randomized clinical trials. The most common treatments, radiation and radical prostatectomy, might never be compared in a randomized trial for a variety or reasons. PSA is the only real biomarker available today to detect prostate cancer, and it is imperfect. Based on the current economic evidence, routine prostate cancer screening using PSA and subsequent treatment for early-stage disease do not appear to be cost-effective until improvement in patient outcomes, including

---

[a] Complexed PSA is a test measuring the level of PSA that has been complexed or bound with a certain protein (alpha-1-antichymotrypsin) in a patient's blood sample.

[b] PSA velocity is the rate of change in the PSA level over time.

mortality, have been demonstrated. Methods calculating the expected value of perfect information (EPVI is a measure of the cost of making an incorrect decision due to uncertainty) should also be factored into decisions about prostate cancer screening.[18]

Despite its shortcomings, PSA will continue to be used to detect prostate cancer in the absence of a more accurate biomarker. Furthermore, we will continue to treat early-stage prostate cancer aggressively if a patient prefers this to watchful waiting. However, healthcare administrators might give more scrutiny to screening and treatment programs as costs continue to escalate with the aging of the population. With this increased scrutiny, cost containment might include a prostate cancer screening schedule tailored to individuals based on prognostic factors that are still being identified. **NCMedJ**

SPECIAL DATA REPORT

Horse-Related Injuries and Deaths in North Carolina, 1995-1999

Doris M. Bixby-Hammett, MD

Nationally, accidents are the leading cause of death for those under 35 years of age and the fifth leading cause of death among all age groups.[1] Injuries are a serious public health problem, which takes a toll on the health of the population and imposes social and economic costs on society. If the medical community is to prevent injuries and deaths, each activity should be individually evaluated.

This data presented here are based on a study is of equestrian accidents in North Carolina resulting in injury or death. North Carolina has a horse population of 256,270 equines,[2] and many North Carolina citizens use horses for recreation and employment. There are an estimated 70,000 horseback riders in North Carolina. This study compared data from three sources for the years 1995 through 1999: the National Electronic Injury Surveillance System (NEISS)[3] (records for North Carolina), North Carolina Trauma Registry (NCTR),[4] and the North Carolina Medical Examiner's Database (NCME).[5] Records in the NCTR were selected with Ecodes indicating injuries caused by animals.

The age group at greatest risk for all injuries (NEISS), severe injuries (NCTR), and deaths (NCME) are equestrians between the ages of 25 and 44 years of age. Equestrians age 45-65 years are the second highest group at risk of injury. The largest percent of injuries among this age group can be seen in the NCME data, with smaller percentages in the NCTR and the NEISS data. It has been suggested that experience would decrease the number of accidents, but one would expect the equestrians age 25-64 years would have more experience in horse-related activities than younger equestrians.

Fractures represent the highest percent of injury type in the NEISS and NCTR data. The second most common injury in NEISS is contusion and abrasion, but in NCTR, it is laceration. Neurological head injury is the most common cause of death, the third most common injury in the NCTR data, and the fourth most common injury in the NEISS data.

Table 1.
Age Groups from NEISS, NCTR, and NCME Databases, 1995-1999

	NEISS (NC subset)		NC Trauma Registry		NC Medical Examiner	
Age	Count	Percent	Count	Percent	Count	Percent
0-4	2	0.5%	16	3.1%	3	12%
5-14	61	16.4%	68	13.3%	1	4%
15-24	59	15.8%	85	16.6%	1	4%
25-44	172	46.1%	211	41.2%	11	44%
45-64	70	18.8%	104	20.3%	7	28%
64+	9	2.4%	28	5.5%	2	8%
Unknown	0	0%	0	0%	0	0%
Total	373	100%	512	100%	25	100%

According to the NEISS data, the extremities are the most commonly injured body parts, while the NCTR and NCME data rank the head as the most commonly injured. The trunk ranks second in all three databases.

Conclusions

The North Carolina data correspond with national medical studies of horse-related activities in that head injury is the leading injury. Head injuries are the most severe of the injuries in North Carolina, causing 56% of all horse-related deaths. Head injuries can be prevented or reduced in severity by wearing properly fitted and secured American Society for Testing and Materials (ASTM) equestrian standard/Safety Equipment Institute (SEI) certification protective headgear. Other factors that can play a role in injury prevention include: horse selection at the level of the rider, horse and rider conditioning for the activity, instruction from a qualified teacher, no use of alcohol while riding, and proper attire for the activity.

Doris M. Bixby-Hammett, MD, is Board of Director emeritus of the American Medical Equestrian Association/Safe Riders Foundation and a past member and chairman of the Safety Committee, United States Pony Clubs. Recent Trends in Prostate Cancer in North Carolina

Prostate cancer is the most frequently diagnosed cancer in men in North Carolina and in the nation. The objectives of this analysis are to examine recent trends in prostate cancer incidence, mortality, and staging; to examine racial differences in incidence, mortality, and staging; and to compare North Carolina statistics to national data.

North Carolina incidence and mortality data were provided by the State Center for Health Statistics. Incidence rates (cases per 100,000 population) and mortality rates (deaths per 100,000 population) are presented. The rates were age-adjusted to the 2000 United States population by five-year age groups. The incidence and mortality rates were calculated as overlapping three-year rates. For comparison, national incidence (Surveillance Epidemiology and End Results Program, or SEER) and mortality rates (National Center for Health Statistics) are presented.

Figure 1.
Age-Adjusted Incidence Rate (per 100,000)

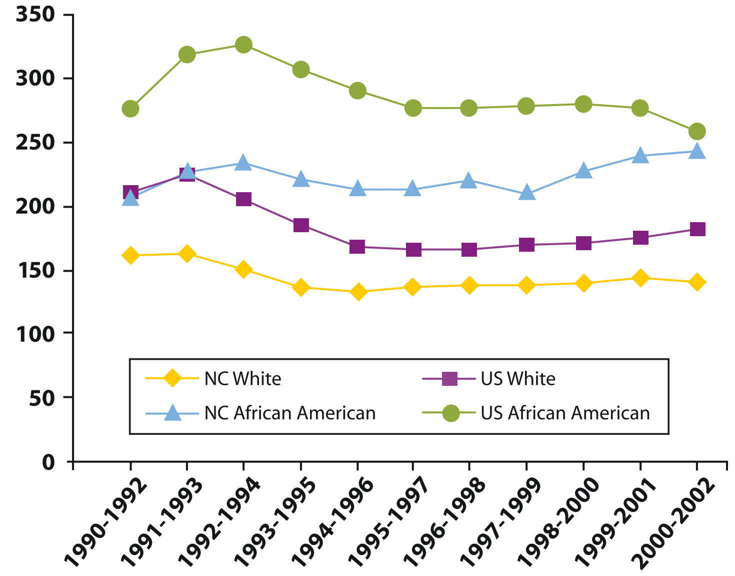

Figure 1 displays trends in prostate cancer incidence. In the last decade, the incidence of prostate cancer in North Carolina has been stable overall. Incidence rates in North Carolina for both whites and African Americans are lower than the SEER national rates. However, according to a second data source, the National Program of Cancer Registries, which includes most of the United States population and, therefore, is more representative of national rates than SEER, in 2002 only North Carolina whites and not North Carolina African Americans had an incidence rate statistically different from the respective national rate. In North Carolina, the incidence for African Americans is approximately 70% higher than for whites (during 2000-2002, 239 per 100,000 versus 139 per 100,000).

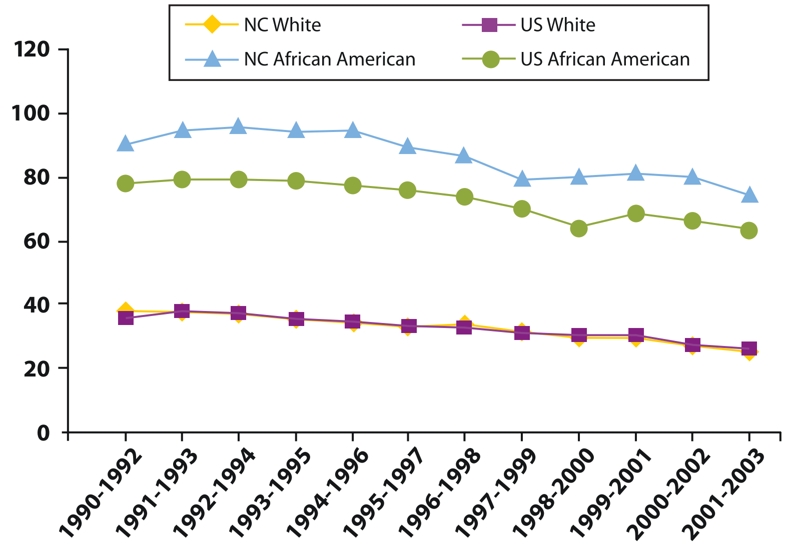
Figure 2 displays trends in prostate cancer mortality. In the last decade, North Carolina mortality rates have been declining. Overall, the North Carolina rate is higher than the national rate. Although whites in North Carolina have the same mortality rate as whites in the United States, African Americans in North Carolina have a higher mortality rate than African Americans in the United States. In North Carolina, the mortality rate for African Americans is almost three times as high as that for whites (during 2000-2002, 74 per 100,000 versus 25 per 100,000).

Figure 2.
Age-Adjusted Death Rate (per 100,000)



There are substantial differences in stage at diagnosis between whites and African Americans in North Carolina. Eighty-two percent of white men are diagnosed with local stage disease, compared to 74% of African Americans. These two groups are equally likely to be diagnosed with regional disease (9%), but African Americans are more likely to be diagnosed with distant disease (7% versus 3%) or for the stage to be unstaged or unknown (9% versus 5%). Later diagnosis contributes to higher mortality.

Interpretation of the incidence data is affected by the introduction and dissemination of prostate-specific antigen (PSA) testing. The advent of this diagnostic tool in the 1980s resulted in an overall increase in incidence rates, followed by a period of stability. Future changes in the use of PSA and other methods of diagnosis will impact trends and differences in the incidence data.

North Carolina African Americans have much higher prostate cancer incidence rates than whites, similar to the pattern seen at the national level. It is unlikely that differences in testing for prostate cancer contribute to this racial difference in incidence, since recent data from the Behavioral Risk Factor Surveillance System (BRFSS), a state-based telephone survey, suggest that North Carolina African Americans and whites have similar rates of PSA testing ever or in the last year.

Declining trends in prostate cancer mortality in North Carolina are encouraging and could be related to earlier detection of cancers by PSA testing or improvements in treatment. The three-fold disparity in mortality between whites and African Americans suggests differences in tumor biology, stage at diagnosis, access to healthcare, or treatment. The prostate cancer incidence rates in North Carolina are lower than those for the United States, while the mortality rates in North Carolina are higher overall than for the nation. This pattern could be due to differences between North Carolina and the nation in case reporting, stage at diagnosis, access to healthcare, or treatment.

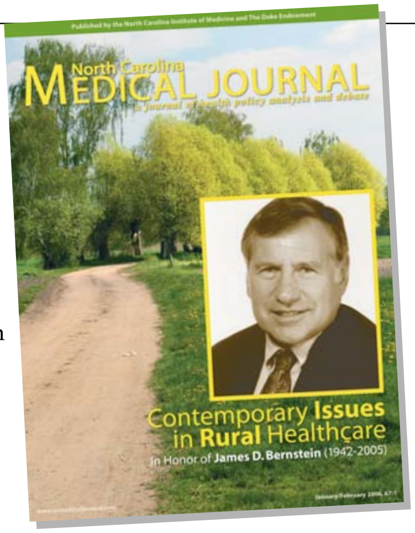
Readers' Forum



To The Editor:

I have greatly enjoyed my issues of the *North Carolina Medical Journal*, but none more than the January/February 2006 issue that honored James Bernstein. He was a remarkable man, and I found Donald Madison's article, in particular, both moving and informative.

The mention in Don's article of the Global Community Health Fellows Program, the brainchild of Bill Stewart, MD, when he was serving as Surgeon General of the United States Public Health Service, brought back memories of that remarkable group of individuals who were selected for the program. My closest contacts among the fellows were Steve Joseph, MD, who later became Health Commissioner of New York City, the Dean of the School of Public Health at Minnesota, and the Assistant Secretary of Defense for Health and Medical/Department of Defense; Merve Silverman, MD, who later became Director of Public Health for the City and County of San Francisco and a national and international leader on HIV/AIDS; and Jim Brown, MD, who was the Director of Student Health Services at the University of California Berkley (UC Berkeley) and one of the founders of the Joint Medical Program at UC Berkeley and the University of California San Francisco. All remarkable individuals and contributors as was Jim Bernstein. Jim was what Tom Oliver and others have called "policy entrepreneurs" who could link problems to solutions to the political process, and do it effectively. That is a rare skill.

Leadership is something a lot of people write about, but few practice with the understanding that Jim had for all the elements of leadership. In Don's article, he describes what we might call "Bernstein's principles" on page 35. Very informative.

The January/February 2006 issue was special because of my high regard for Jim and because Don's article triggered so many thoughts about the evolution of rural health service over the past 40 years, including the critical role played by Jim and his colleagues in North Carolina.

INTRODUCING A NEW LEVEL OF CARDIOVASCULAR CARE
FOR SOUTHEASTERN NORTH CAROLINA

When heart disease affects one person in our community, it affects us all—families, loved ones—our neighbors. Here in Robeson and surrounding counties, we have a high incidence of heart disease. And in the past, treatment options often required traveling outside our community, adding to the stress of an already difficult situation. But now Southeastern Regional Medical Center has teamed up with Duke University Health System to offer a new level of cardiovascular care, right here at home.

Owned by SRMC and managed by Duke, one of the world's most respected names in healthcare, the new Southeastern Heart Center will offer open-heart surgery, cardiac intensive care, and complete cardiac cath and interventional services, all provided in a state-of-the-art equipped facility by a team of highly trained SRMC and Duke physicians.

At Southeastern, we take the health of our community to heart. So we're bringing Robeson and surrounding counties the high standards of Duke, without the drive.

Neighbors caring for neighbors. That's Southeastern Regional.

“Great learning experience! The course offered a whole new world for me. It has helped me make a much needed career change and has given me new confidence as a leader at a local level and I hope a more global level in the future.”

—Shelley Janssen, MD, 2005 Program Graduate

Do you have the skills to be a successful physician leader?

Sign up now for the Fall 2006 Physician Leadership Institute!

Exclusively for physicians

To become a physician leader, you must have a solid working base of leadership skills and abilities—training that most physicians did not receive in medical school.

The primary purpose of The Physician Leadership Institute (PLI), a partnership between The Carolinas Center for Medical Excellence (CCME) and the University of North Carolina Kenan-Flagler Business School, is to provide you with that training.

PLI offers a business-based physician leadership program in four weekend sessions. The sessions are conveniently located in Chapel Hill, North Carolina.

FALL 2006 SESSION DATES

SEPTEMBER 8 – 10 | OCTOBER 6 – 8 | NOVEMBER 3 – 5 | DECEMBER 1 – 3

What you will learn

Financial Management | Negotiations | Problem Solving | Leadership Skills | Conflict Management

Additional benefits to you

No business prerequisites required | Continuing Medical Education credits available

Official certificate upon completion from UNC-Kenan Flagler School of Business | Active Alumni Network

Enroll today!

How a team of heart specialists helped Hugh McColl make the best investment of his life.

When Hugh McColl, the man who changed American banking, learned he needed heart bypass surgery, he chose the team that has outpaced all others for years. He chose the Carolinas Heart Institute at Carolinas Medical Center and the Sanger Clinic's Dr. Mark Stiegel.

Carolinas Heart Institute has a rich and storied history of groundbreaking innovations; some of the finest medical minds in America, and the latest, most advanced technology available – including the new revolutionary *64 Slice CT Scanner*.

Today, Hugh McColl is enjoying the success of his surgery with his usual zest for life. In fact, he calls his choice of care "one of the best investments I ever made."

We know Mr. McColl could have gone anywhere in the world for cardiac treatment. He chose the region's premier team.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, non-profit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Tarheel Footprints in Healthcare

Recognizing unusual and often unsung contributions of individual citizens who have made healthcare for North Carolinians more accessible and of higher quality

Recognizing Shirley Lucey and Virginia Scanlan and the Alice Aycock Poe Center for Health Education

Without the volunteer efforts of many of our state's citizens, North Carolina would not be the envy of so many others. Dozens of the wonderful programs and organizations for which this state is known sprang from the ideas, commitment, and determination of a few individuals who saw a need, convinced others of the feasibility of addressing it, and then led the effort to mobilize the resources to make a valuable initiative possible.

Such is the case with what is now known as the Alice Aycock Poe Center for Health Education in Raleigh, a statewide non-profit organization whose mission is to provide comprehensive programs and resources in healthy lifestyle education for all youth in North Carolina. This wonderful facility offers on-site instruction to more than 5,500 school-age participants each year, coming from many school districts throughout North Carolina. The Poe Center's theatre-style instructional programs are delivered by master teachers to classes of students from across the state who come to the Center for periods of a few hours or a whole instructional day. Classes are conducted in model classrooms, which are exceptionally well-equipped as teaching theaters dealing with: general health, nutrition, physical activity, dental health, drug education, and family life and reproductive health.

The Poe Center was first imagined as filling a need in the Wake County Schools, initially as an exhibit at the old North Carolina Museum of Natural History funded by the Wake County Medical Society Auxiliary. When the new museum was built, space for a health-focused exhibit was limited so members of the Auxiliary started exploring other educational program possibilities. Leaders of the organization decided to visit eight-to-ten free-standing health education centers around the nation to see how these facilities and programs operated and whether this idea might be feasible in central North Carolina. The result was a decision to start raising funds to construct a multi-classroom teaching facility, which could become a resource for all schools and school systems in North Carolina, thus extending the impact of regular classroom instruction on matters related to health and enlivening the content and presentation style associated with this information.

The two individuals who took primary responsibility for conceptualizing the Poe Center's program and for raising the funds to support its implementation, including its physical construction, were **Shirley Lucey** and **Virginia Scanlan**, who served as President of the Board of Directors of the Poe Center in 1987-1988 and 1988-1989, respectively. Ms. Lucey and Ms. Scanlan organized teams of their Wake County Medical Auxiliary colleagues in 1990 to approach dozens of corporate and individual donors, and they worked with area school systems to develop contracts with the Poe Center for the instructional programming that would be offered. Their efforts raised the $3.5 million necessary to build this fabulous teaching/learning facility and are a tribute to their dedication and determination. "Once the first $100,000 was raised, there was no turning back," Virginia Scalan recently recalled. Most of the counties in central North Carolina and beyond have benefited from their efforts as the Poe Center has taken shape. Today, the Poe Center offers programs of instruction for students from some 25 school systems throughout North Carolina, as well as special programs of teacher training, educational programs focused on specific disease and public health issues (e.g., breast cancer, family life, adolescent health, substance abuse, dental health), and active summer programs for children from preschool to age ten. Shirley Lucey recently gave credit to the physician members of the Wake County Medical Society, who collectively donated $1 million of the total cost of building this facility. The footprints of these leading Tarheel volunteers have made a deep impression on the lives and health of North Carolina's children.

Support for Tobacco Control Policies among Youth in North Carolina

Elizabeth Conlisk, PhD, Scott K. Proescholdbell, MPH, and William K.Y. Pan, DrPH

Abstract

Background: *The objective of this research was to examine attitudes toward tobacco control policies among middle and high school students in North Carolina. Specifically, we report data on knowledge of the harmfulness of secondhand smoke and support for restaurant and school-based smoking restrictions.*

Methods: *The statewide North Carolina Youth Tobacco Survey was administered to a representative sample of 3,073 middle school and 3,261 high school students in the fall of 2003. The overall response rate for the middle and high school samples was 77.0% and 77.4%, respectively. Support for tobacco policies was analyzed by smoking status and by knowledge of the harmfulness of secondhand smoke*

Results: *The vast majority of respondents in the middle school (87.6%) and high school (91.6%) reported that secondhand smoke was "definitely" or "probably" harmful. However, less than half of middle school (48.6%) and high school (40.2%) students responded that smoking should be banned in restaurants. Even among the select group of students who had never smoked and who believed secondhand smoke was harmful, support for such a ban was less than 60% at both school levels.*

Conclusions: *Youth in North Carolina are aware of the health risks of secondhand smoke, but are not convinced of the need to restrict smoking in restaurants. These results point to the need for more youth-focused advocacy and education around smoking restrictions, both to reduce youth exposure to secondhand smoke and to solidify voter support for such protections once they reach adulthood.*

Key words: *youth, tobacco control, smoking restrictions.*

Introduction

Over the past 20 years, exposure to secondhand smoke (SHS) has been associated with an increased risk of lung cancer, heart disease, and respiratory ailments in non-smokers and has been estimated to cause approximately 3,000 lung cancer deaths and 35,000 heart disease deaths in adult non-smokers in the United States each year.[1,2] In addition, SHS has been associated with adverse infant outcomes, such as low birth weight and Sudden Infant Death Syndrome, as well as childhood asthma and middle ear infections.[3] As awareness of the health risks of SHS has increased, so has support for policies that restrict smoking in public places such as restaurants, where SHS levels have been found to be two-to-five times higher than levels in the homes of smokers.[4] From 1992 to 1999, support for smoking bans in restaurants increased from 37.5% to 59.8% among adults in Massachusetts.[5] Unfortunately, not all states show majority support for such bans. A recent report compared the results of 20 statewide surveys on attitudes toward tobacco control policies in 2000.[6] In four of those states, less than half of the respondents favored policies to ban smoking in restaurants; support was lowest in North Carolina (44%), the largest tobacco producing state in the country.

As opposed to most adults, today's adolescents are growing up in an era when the risks of SHS are well established and smoking restrictions are not uncommon. Even in North Carolina, local smoking regulations were hotly debated and adopted in more than 100 municipalities/counties before a statewide preemption bill went into effect in 1993.[7] In addition, North Carolina has an active tobacco education and prevention

Scott K. Proescholdbell, MPH, is the Epidemiologist for the Surveillance and Evaluation Team, Tobacco Prevention and Control Branch, North Carolina Division of Public Health. Mr. Proescholdbell can be reached at Scott.Proescholdbell@ncmail.net or 1932 Mail Service Center, Raleigh, North Carolina 27699-1932. Telephone: 919-707-5412.

William K.Y. Pan, DrPH, is Assistant Scientist in the Johns Hopkins Bloomberg School of Public Health, Department of International Health. Dr. Pan can be reached at 615 N. Wolfe Street, Baltimore, MD 21205. Telephone: 410-502-2141.

program in the schools, and more than 80% of middle and high school students responded that SHS was harmful to non-smokers in a 1999 survey.[8] However, it is unclear whether that knowledge translates into stronger support for smoking restrictions among adolescents and whether they might be expected to solidify public support as they come into adulthood.

To our knowledge, few studies have examined attitudes toward tobacco control policies among youth,[9-12] and only two have examined support for smoking bans in restaurants. Albers et al.[11] reported that support for restaurant bans among Massachusetts youth in 2001-2002 ranged between 53% and 61%, depending on the strength of local restrictions on smoking in restaurants. Support was similar among adolescents in metropolitan Ohio, with 56% agreeing that smoking should not be allowed in restaurants without bars.[12] Our report adds to these findings by examining knowledge of SHS risk and support for restaurant bans among middle and high school students in North Carolina where there is relatively low adult support. As support for restaurant bans has been shown to vary by smoking status in adults[8] and youth,[11] data will be reported separately for current smokers and those who have never smoked. Support will also be analyzed by knowledge of the harmfulness of SHS, an analysis not previously reported.

Methods

Data were collected through the school-based North Carolina Youth Tobacco Survey (YTS) in the fall of 2003. Details of the YTS methodology used nationally have been described elsewhere.[13] In brief, the North Carolina Youth Tobacco Survey used a two-stage cluster sample design to produce a representative sample of public middle school (grades 6-to-8) and high school (grades 9-to-12) students. Sampling was stratified by region to assure a balanced representation of schools from the coastal, piedmont, and mountain areas.

The first-stage sampling frame consisted of all public schools (including charter schools) that included at least one grade between 6 and 12. Schools were selected with a probability proportional to school enrollment size. The second sampling stage consisted of systematic equal probability sampling of second-period classes in each school sampled. An average of three second-period classes was sampled per school. All students in the sampled classes were eligible to participate in the survey except those who are routinely exempt from written tests because of language or learning barriers. Participation was voluntary and anonymous, and school procedures for parental permission were followed. The overall response rate for the middle and high school samples was 77.0% and 77.4%, respectively. Non-participation was primarily due to absenteeism. The final sample included 3,073 students from 104 middle schools and 3,261 students from 96 high schools.

The self-administered, 78-item questionnaire included questions on tobacco use, SHS, and attitudes toward tobacco policies. The specific questions asked about SHS are given at the bottom of Table 1. Responses are reported for the total sample and for two subgroups defined by smoking status: current smokers and never smokers. Respondents who reported smoking within the past 30 days were classified as current smokers. Respondents who reported having never smoked a cigarette were classified as never smokers. The comparison of current versus never smokers intentionally omits former smokers to heighten the contrast based on smoking status; hence the number of current smokers and never smokers will be less than the totals reported in the table. All percentages reported are weighted to reflect the likelihood of sampling each student and to compensate for differing patterns of non-response. SUDAAN was used to compute variance estimates and 95% confidence intervals.[14]

Results

Among middle school students, 9.3% (95% CI 7.7 to 10.9) were classified as current smokers and 70.5% (95% CI 66.5 to 74.5) as never smokers. Among high school students, 27.3% (95% CI 24.0 to 30.6) were classified as current smokers and 40.4% (95% CI 36.3 to 44.5) as never smokers.

Middle school students were slightly less likely than high school students to believe that SHS was harmful, although the percentage for both groups was quite high, 87.6% (95% CI 85.3 to 89.9), and 91.6% (95% CI 90.0 to 93.2), respectively) (see Table 1). Current smokers were less likely than never smokers to respond that SHS was harmful, but the percentage that did was still high for both middle school (83.1%, 95% CI 77.3%, 88.9) and high school (85.1%, 95% CI 81.4 to 88.8) students. Less than half of middle school (48.6%, 95% CI 45.8 to 51.4) and high school (40.2%, 95% CI 37.0 to 43.4) students responded that smoking should be banned in restaurants. Support for smoke-free restaurants was much higher among those who had never smoked compared to current smokers: 55.4% (95% CI 51.4 to 58.4) vs. 22.6% (95% CI 15.0 to 30.2) at the middle school level and 58.8% (95% CI 55.0 to 62.6) versus 16.1% (95% CI 11.6 to 20.6) at the high school level. Similar data and trends were observed for the question on personal preference for smoke-free space. Support was much higher for the adoption of tobacco-free policy at schools—91.8% (95% CI 90.4 to 93.2) of middle school students and 75.5% (95% CI 72.5 to 78.5) of high school students favored such policies. Even among current smokers, there was majority support for tobacco-free school policies in both the middle schools (68.8%, 95% CI 60.6 to 77.0) and high schools (51.1%, 95% CI 55.6 to 56.6).

Support for tobacco control policies among never smokers tended to be higher among students who believed SHS was harmful (see Table 2). Still, support for smoking bans in restaurants at the middle or high school level never reached 60%, even among the select group of students who had never smoked and who believed SHS was harmful. Similarly, only 61.4% (95% CI 57.9 to 64.9) (middle school) and 54.2% (95% CI 50.1 to 58.3) (high school) of this select group stated that they preferred to eat in smoke-free restaurants. In contrast, support for tobacco-free schools was considerably higher in this group—96.6% (95% CI 95.6 to 97.6) and 89.7 (95% CI 86.3 to 93.1) for the middle and high school, respectively. Among current smokers,

1 Responded "Definitely yes" or "Probably yes" to the question "Do you believe the smoke from other people's cigarettes is harmful to you?"

2 Responded "Not allowed at all" to the question "In restaurants, to what extent do you think that smoking should be allowed?"

3 Responded "I prefer places where no smoking is allowed" to the question "When you go out to a place with your friends and family, what smoking policy do you prefer?"

4 Responded "Very important" or "Somewhat important" to the question "In your opinion, how important is it that your school district adopt a "100% tobacco-free school policy?"

5 Students who responded that their district was already 100% tobacco-free were omitted from the analysis.

The data collection protocol was approved by the Centers for Disease Control and Prevention and the research protocol was approved by the institutional review board at Hampshire College.

* All includes current, former, and never smokers. Details are only given for current and never smokers.

support for tobacco control policies was associated with SHS knowledge at the middle school level, but the confidence intervals were quite wide. Among current smokers at the high school level, knowledge appeared to have little impact on support for tobacco control policies.

Discussion

This paper is the first to examine support for restaurant- and school-based tobacco control policies among youth in a major tobacco-growing state. The results are mixed. Knowledge is high, with approximately nine of ten middle and high school students reporting that SHS is harmful to non-smokers. These results are comparable to those reported in the 2000 National Youth Tobacco Survey,[12] suggesting that North Carolina youth are as informed about the risks of SHS as youth nationally. Also, approximately nine of ten middle school students and three of four high school students supported the adoption of a 100% tobacco-free policy in their school districts. This latter analysis excluded the 11% (middle school) and 14% (high school) of students who responded that their district had already adopted such a policy, districts that presumably are more supportive of tobacco control measures in schools. Hence, the overall support for such a policy is probably even greater.

Support for bans on smoking in restaurants, however, was much less common. Less than half of students supported such bans, and support was no greater than that reported by North Carolina adults surveyed in 2000 (44%).[6] It is unclear why support among youth is not greater, given the high awareness

1 Responded "Definitely yes" or "Probably yes" to the question "Do you believe the smoke from other people's cigarettes is harmful to you?"

2 Responded "Not allowed at all" to the question "In restaurants, to what extent do you think that smoking should be allowed?"

3 Responded "I prefer places where no smoking is allowed" to the question "When you go out to a place with your friends and family, what smoking policy do you prefer?"

4 Responded "Very important" or "Somewhat important" to the question "In your opinion, how important is it that your school district adopt a "100% tobacco-free school policy?"

5 Students who responded that their district was already 100% tobacco-free were omitted from the analysis.

The data collection protocol was approved by the Centers for Disease Control and Prevention and the research protocol was approved by the institutional review board at Hampshire College.

* All includes current, former, and never smokers. Details are only given for current and never smokers.

of the risks of SHS and strong support for tobacco-free policies in schools (policies which are actually more restrictive as they apply to all tobacco use, and not just cigarettes). This apparent inconsistency could be due to a number of factors. Perhaps youth are aware of the risks of SHS, but do not perceive these risks as serious. Similarly, youth might view restaurants, unlike schools, as voluntary, short-term exposures and not as daily worksites for restaurant staff. Thus, they might not see the need for government regulation of what appears to be a voluntary risk.

It is also possible that these attitudes reflect the hard work of the school-based tobacco control programs, which have focused their advocacy work on the adoption of tobacco-free policies in school districts. These efforts appear to have been successful, both in the overwhelming support among youth for such policies and the tripling of tobacco-free school districts in the past two years—from 15 at the start of 2003 to 45 by the end of 2004. In contrast, less emphasis has been placed thus far on tobacco use in public places, such as restaurants. The results here point to the need for school-based advocacy around this issue as well, both in reducing youth exposure to SHS and helping to solidify voter support for such protections once they reach adulthood.

The percentage of students who prefer to patronize smoke-free restaurants is not much higher than those who support bans. Even among never smokers who are aware of SHS risks, only a modest majority prefers smoke-free space. As with tobacco use itself, knowledge is not sufficient for avoiding risk. This finding supports the innovative work of Albers et al., who examined the acceptability of smoking in restaurants to youth in Massachusetts relative to social norms, as measured by community-level smoking restrictions.[11] While the relationship between acceptability and community-level restrictions was not statistically significant, it was in the hypothesized inverse direction (acceptability declined as restrictions increased), which underscores the importance of social norms in both research and advocacy education at the school level. In this research, we attempted to examine support for tobacco control policies by tobacco-free school status; however, too few districts had implemented such policies at the time of this survey for a meaningful analysis. As we continue tracking support for tobacco control policies in the biannual YTS in North Carolina, we will broaden our analysis to include information about community-level norms as reflected by school-based policies. In tobacco-producing states such as North Carolina, analysis and policy may further benefit from the use of geographic mapping software to target interventions where tobacco use is high. We also encourage the Youth Tobacco Survey coordinators in other states to add questions on tobacco control policies so that such policies can be tracked and responded to nationally. **NCMedJ**

Acknowledgments: This research was supported by the WM Keck Foundation Grant to assist faculty research at Hampshire College (EC). Additional funding was provided by the North Carolina Health and Wellness Trust Fund and the Centers for Disease Control and Prevention through the North Carolina Tobacco Prevention and Control Branch. The authors would also like to thank Sheryl Scott for her many helpful suggestions for this manuscript as well as with the North Carolina YTS questionnaire.

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists who labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina Academy of Physician Assistants, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

North Carolina MEDICAL JOURNAL

POLICY FORUM
Covering the Uninsured

COMMENTARIES

> *"Most of the increase in the uninsured is due to the drop in employer-sponsored insurance. North Carolina experienced a greater loss in employer-sponsored insurance than other states."*

INTRODUCTION

Policy Forum:
Covering the Uninsured

More than 1.3 million North Carolinians have no health insurance, and these numbers are growing more rapidly in our state than in other states. As a result, the overall health of North Carolina suffers—the uninsured experience poorer health and miss more days of work and school; our healthcare institutions face financial strain; and those with insurance pay higher health insurance premiums as costs are shifted. Who are these people—the uninsured? Some may be surprised to learn that 78% of them work full-time jobs or live in a family where at least one person has a full-time job. Not surprising is that many people without insurance have incomes below 200% of the federal poverty guidelines.

To address this problem, the North Carolina Institute of Medicine, in collaboration with the North Carolina Department of Health and Human Services (NC DHHS), the North Carolina Department of Insurance, and the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill, convened a Task Force to study options that would expand health insurance coverage to more North Carolinians. They released their report and recommendations in April 2006. In this issue of the Journal, we highlight some of Task Force's work and provide further discussion through commentaries written by some of the Task Force members and other stakeholders.

The commentaries examine issues faced by: small employers providing health insurance coverage; physicians, dentists, and hospitals providing care to the uninsured, and state government officials who regulate the insurance industry and provide public health insurance via Medicaid. We also include discussions on why healthcare costs are increasing, strategies for controlling these costs, strategies for promoting legislative change, policy options for small employers and high-risk pools, and how the problem of lack of insurance manifests itself among our state's growing Latino population.

The Task Force was chaired by Carmen Hooker Odom, Secretary of the NC DHHS, and Thomas Lambeth, former Executive Director of the Z. Smith Reynolds Foundation. Under their leadership, the Task Force realized it could not develop a plan that would provide coverage for all who needed it, but believed a multi-pronged approach could be developed to help large numbers of the uninsured. They were further guided by the belief that everyone in North Carolina will benefit if more people have health insurance coverage. As more people gain health insurance coverage, they also gain needed access to healthcare and better health. Having healthier citizens in our state will lead to lower healthcare costs and insurance premiums, higher worker productivity, better school attendance, financially more secure healthcare institutions, and, ultimately, a stronger economic future. Ideally, all North Carolinians should have health insurance that meets their basic healthcare needs, but until this is possible, the recommendations found in the Task Force report would help expand coverage to thousands.

We hope this issue of the Journal helps bring greater understanding to a complex and painful problem for our state. North Carolina is fortunate to have a group of stakeholders willing to work together toward a solution. The collaborative efforts of this Task Force increase the likelihood for change and provide hope for new policy and a healthier North Carolina.

ISSUE BRIEF

North Carolina's Uninsured

Pam Silberman, JD, DrPH, Carmen Hooker Odom, MRP, Thomas Lambeth, G. Mark Holmes, PhD, and Kristen L. Dubay, MPP

Most people in the United States have health insurance coverage through their employers. More than 61% of the non-elderly in this state have employer-sponsored insurance (ESI). The connection between health insurance coverage and employment dates back to World War II, when Congress passed the Labor Stabilization Act (1942), which restricted employers from offering wage increases to attract workers. The Act restricted wage increases, but did not limit the use of non-wage benefits. As a result, many employers began offering health insurance as a means of competing for scarce workers. The connection between employment and health insurance coverage was solidified in 1954, when the Internal Revenue Service ruled that employer contributions to health benefits plans were non-taxable benefits to employees. Health insurance purchased outside an employer-based system has never been afforded the same tax advantage.

> *"Workers who are in poor health are less productive, children who are sick miss more days of school, and the growing numbers of uninsured are creating an economic strain on the healthcare institutions that care for everyone."*

While most people obtain health insurance coverage through their employers, this connection has grown more tenuous in recent years. The percentage of non-elderly people with employer-sponsored insurance declined by nine percentage points in North Carolina, from 67.6% (in 1999-2000) to 61.5% (2003-2004). Nationally, there was only a six percentage point decline in employer-sponsored insurance in the same period, from 67.6% to 63.3%.[1] At the same time, there has been a 15% increase in the percentage of people with public coverage in North Carolina (from 17.3% in 1999-2000 to 20% in 2003-04), but this increase has not been sufficient to offset the loss of employer-sponsored insurance. The percentage of people with private, non-group coverage has remained relatively constant over the years.

The decline in employment-based coverage has led to a sharp growth in the numbers and percentage of uninsured. Since 1999-2000, the percentage of North Carolinians without health insurance coverage increased 15%, compared to a 10%

Pam Silberman, JD, DrPH, is President and CEO of the North Carolina Institute of Medicine. Dr. Silberman can be reached at pam_silberman@nciom.org or 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713. Telephone: 919-401-6599, ext. 23.

G. Mark Holmes, PhD, is Vice President of the North Carolina Institute of Medicine. Dr. Holmes can be reached at mark_holmes@nciom.org or 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713. Telephone: 919-401-6599, ext. 24.

Kristen L. Dubay, MPP, is the Project Director for the North Carolina Institute of Medicine. Ms. Dubay can be reached at kdubay@nciom.org or 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713. Telephone: 919-401-6599, ext. 25.

increase nationally. This growth in both the number and percentage of uninsured is not part of the normal ebb and flow of insurance coverage. In 2003, North Carolina experienced the largest increase in both the numbers and percentage of people without coverage in any five-year period in the state's history since 1992. The year 2004 saw a slight rebound in the percent who were uninsured, but in general, there is still an upward trend in the percentage of people without coverage. In 2003-2004, approximately one out of every six people under the age of 65, or 1.3 million people, lacked health insurance coverage in North Carolina. While this problem is not unique to North Carolina, our state appears to have been disproportionately affected by the loss of coverage. The percentage of the state's population without health insurance has grown more rapidly in North Carolina than in most of the other states in the country.

There have been many reasons posited to explain this large increase in the numbers of North Carolina's uninsured. Studies show that the primary reason for the increase in the numbers of uninsured is rising health insurance premiums.[2] The downturn in the economy during the early part of this decade also contributed to the increase in the numbers of uninsured.[3] Extensive job losses in manufacturing and the simultaneous growth in the service sector have contributed to this problem. Regardless of the reason, North Carolina is now faced with more than a million people who lack insurance coverage.

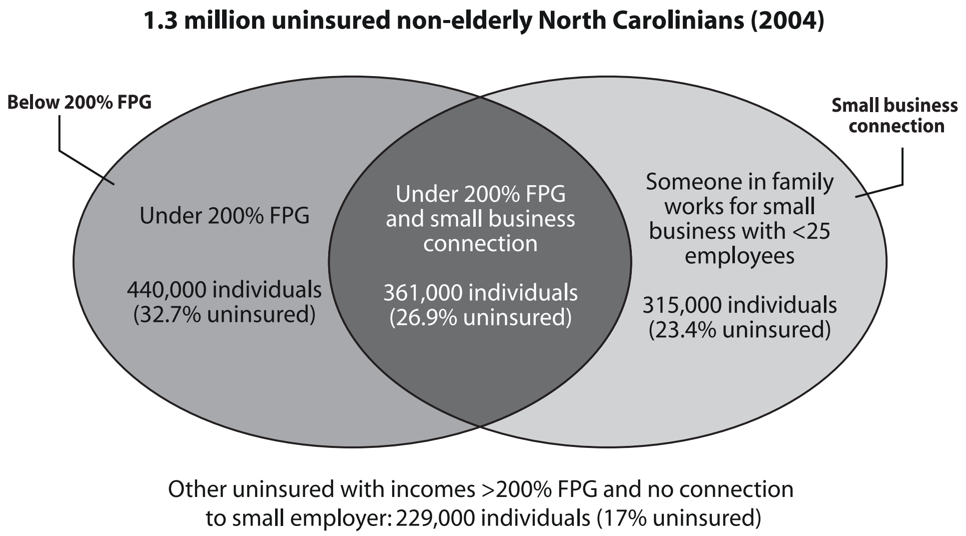
People who lack insurance coverage have a harder time obtaining needed healthcare, and as a consequence, their health suffers. But the rising numbers of uninsured have broader societal implications. Workers who are in poor health are less productive, children who are sick miss more days of school, and the growing numbers of uninsured are creating an economic strain on the healthcare institutions that care for everyone.

In 2004, the North Carolina Department of Health and Human Services (NC DHHS) obtained a State Planning Grant from the United States Department of Health and Human Services, Health Resources and Services Administration to analyze the numbers of uninsured and develop policy options to address this problem. In this effort, the NC DHHS partnered with the North Carolina Department of Insurance (NC DOI), the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill, and the North Carolina Institute of Medicine (NC IOM). As part of the State Planning Grant project, the NC IOM convened a task force to examine options to expand health insurance coverage to the uninsured. This issue brief describes the findings as well as some of the policy options considered by the Task Force. First, the issue brief describes the uninsured and the health consequences from lacking health insurance coverage. The issue brief also presents some of the reasons for rising healthcare costs and concludes with several options to expand coverage and healthcare services to the uninsured.

The Demographics of the Uninsured

In many ways, the uninsured are a microcosm of the state's population. They include workers and the unemployed; wealthy and low-income individuals; and men, women, and children of all races, ethnicities, and ages. Yet, while the uninsured are a broad cross-section of the state's population, there are certain groups that are more likely than others to be uninsured. More than four fifths (83%) of the uninsured fall into one or both of two groups: (1) those having someone in the family working for a small employer (an employer with 25 or fewer workers) or (2) those having a family income less than 200% of the federal poverty guidelines (FPG).[1]

Figure 1.
Uninsured in North Carolina: Primarily Those with Low Income or Employees of Small Firms



A common misperception about why people lack insurance coverage is because they do not work or have no connection to the workforce. In fact, more than three fourths (78%) of the uninsured are in families where someone is working full time, and one third (33%) are in families where two people are working full time. The size of a person's employer workforce is a major determinant of whether or not a person has health insurance coverage. Small firms, particularly those with fewer than ten employees, are far less likely to offer insurance than larger employers (see Table 1). Approximately half (55.3%) of the uninsured, or 776,000 North Carolinians, are employed by or in a family with someone who works for a small firm (with fewer than 25 employees). Connie Majure-Rhett and Kristen Dubay provide further insight into the

Table 1.
Percent of Firms that Offer Health Insurance, by Size of Firm (2002-2003)

Size of Employer	NC	US
Total	53.6%	56.7%
<10 employees	29.4%	36.2%
10-24 employees	67.5%	67.0%
25-99 employees	79.3%	81.7%
100-999 employees	99.3%	94.5%
1000+ employees	98.9%	98.7%

Source: Agency for Healthcare Research and Quality. Center for Financing, Access and Cost Trends. 2003 and 2002 Medical Expenditure Panel Survey – Insurance Component. Table II.A.3.

problems that small employers have in paying for health insurance in their commentary in this issue of the Journal.[4] The type of industry also impacts on insurance coverage as certain industries—particularly construction and agriculture—are less likely than other industries to offer health insurance.

Almost 60% of the uninsured, or 801,000 North Carolinians, have family incomes below 200% FPG, or $38,700 for a family of four in 2005.[5] While most of these individuals are workers, they are less likely than those with higher incomes to work full time, and they are more likely to work in industries that have lower rates of insurance coverage. Even if they are offered coverage, the employees' share of the cost may be too burdensome. The average total cost for employer-sponsored insurance in North Carolina was more than $3,200 per year for an individual employee and $8,200 for family coverage in 2002-2003.[a] The average employee-share of health insurance premiums in North Carolina was $558 for individual coverage and $2,200 for family coverage. Based on these figures, the average employee premium costs for a family living in poverty would be 12% of their gross income, or 6% for a family living at 200% FPG, not including other out-of-pocket expenses, such as deductibles, coinsurance, or copayments. Health insurance premiums are generally more expensive in the non-group market for similar coverage. Thus, individuals who do not have access to employer-sponsored insurance may have to spend more money if they try to purchase a comprehensive policy directly from an insurer. Adam Searing, Project Director of the North Carolina Healthcare Access Coalition, a consumer advocacy group, describes a research-based approach to effective policy advocacy on behalf on the uninsured population later in this issue of the Journal.[6]

In addition to those who have low incomes or work for a small employer, there are other groups that are more likely than the general public to lack insurance coverage. Racial and ethnic minorities have a much greater likelihood of being uninsured than do whites. Approximately 14% of white, non-Latinos are uninsured, compared to 18% of black, non-Latinos and 54% of Latinos. Many people believe that the growth in the Latino population has driven the rise in the uninsured in North Carolina. However, it is generally not the growth in the Latino population—or any racial or ethnic group per se—that drives our uninsurance rates; it is their relatively low income and access to employer-sponsored insurance or public coverage. This subject is more thoroughly discussed by Dr. Holmes in a commentary on page 202 of this issue of the Journal.[7]

Other groups that have a greater likelihood of being uninsured include young adults and those living in rural areas. Young adults ages 18-34 are more likely than those who are older or younger to lack coverage. Approximately 29% of young adults lack coverage, compared to 11% of children under age 18, 15% of those age 35-64, and less than 1% of those age 65 or older. Children are less likely to be uninsured than most adults because they have greater access to publicly subsidized insurance (either Medicaid or North Carolina Health Choice).

People living in rural areas are also disproportionately more likely to be uninsured than those living in urban areas (21% versus 17%, respectively). Given that the uninsured rate varies considerably by age, industry, firm size, and rurality, it is no surprise that the uninsured rate varies markedly across North Carolina. The Running the Numbers section of this issue includes county-level data on the uninsured. The county with the lowest uninsured rate in 2004 was Wake (13.9%), and the county with the highest (Tyrrell) had over double this rate at 28.3%. The demographic and socioeconomic characteristics of the county's population have considerable influence on the likelihood of residents to lack health insurance (see page 235).[8]

Health Effects of Being Uninsured

The uninsured are more likely to report being in fair or poor health, but are less likely to receive needed healthcare services. A rich body of research literature documents the adverse health impact from lacking insurance coverage. The Institute of Medicine of the National Academies did a meta analysis of research studies analyzing the impact of being uninsured (2002),[9] as did Jack Hadley for the Kaiser Commission on Medicaid and the Uninsured.[10] In addition, we have North Carolina-specific data that document the impact of being uninsured on access to health services and avoidable hospitalizations.

Uninsured North Carolinians are much more likely than people with insurance coverage to report healthcare access barriers. The State Center for Health Statistics, within the NC DHHS,

---

[a] The full cost of employer-sponsored insurance—absent any employer contribution—would constitute 36% of the gross income of an individual living in poverty for individual coverage and 18% for a person living at 200% FPG. For a family of four living in poverty, the total cost of employer-sponsored insurance for a family would constitute 45% of their gross income, 22.5% for a family of four living at 200% FPG.

[b] The BRFSS is national health risk survey developed by the Centers for Disease Control and Prevention (CDC) and amended by individual states. It is administered and supported by the Division of Adult and Community Health, National Center for Chronic Disease Prevention and Health Promotion, CDC, and is an ongoing data collection program. All states, the District of Columbia, and three territories participate in the BRFSS.

is a participant in the Behavioral Risk Factor Surveillance Survey (BRFSS)[b] annually, a telephone survey of 15,000 adults across the state. Uninsured North Carolinians in 2004 were more likely to report they had no personal physician or healthcare provider (52%) compared to people who had insurance (13%).[11] They are four times more likely than people with insurance to report that there were times in the last 12 months when they needed to see a doctor, but could not due to the costs (44% versus 11%, respectively). Uninsured people with diabetes were more likely to report that there were times in the last 12 months when they could not afford their testing strips for diabetes due to the costs (49% versus 16%, respectively). Similarly, people without coverage are less likely to obtain preventive screenings, such as mammograms, prostate specific antigen (PSA) screenings, or colorectal screenings, than those with insurance coverage. North Carolina hospital discharge data show that the uninsured are more likely to be hospitalized for preventable conditions than those with private insurance coverage.[12] For example, the uninsured are 50% more likely to be hospitalized for asthma than those with insurance.

The national data also show access barriers similar to what we found in North Carolina. However, national studies have also been able to examine the effect that lack of coverage has on health outcomes. National data show that the uninsured are more likely to delay care and, as a result, be diagnosed with more advanced health problems, such as late-stage cancer. Those with chronic diseases are less likely to obtain the treatment or medications they need to manage their chronic illnesses. And, similar to North Carolina data, national data confirm that the uninsured are more likely to end up in the hospital for preventable conditions. Because of these access barriers, the national Institute of Medicine estimated that being uninsured increases the risk of dying prematurely by 25% over rates for those with insurance coverage.

Lack of insurance coverage affects more than the specific person's health status. The growing numbers of uninsured affect everyone. Children who are sick miss more school days and may have a harder time keeping up with school work. Workers in poor health are less likely to work or may work fewer hours. Research shows that workers with insurance coverage take fewer sick days and have shorter episodes of illness than workers who are uninsured.[13] The uninsured in North Carolina are more likely to report difficulties paying their medical bills, being contacted by a credit agency, and having to cut back on other living expenses—such as utilities, food, clothing, housing, or transportation—to pay for their medical bills.[12] Outstanding medical bills, in turn, are a leading cause of bankruptcy.[14] Further, the costs of providing health services to the uninsured are "shifted" to those with private insurance coverage, leading to higher premium costs. One study suggested that the costs of caring for the uninsured in North Carolina have led to a $438/year increase in employer-sponsored insurance premiums for individuals and a $1,130 increase for families.[15] In addition, the growing costs of caring for the uninsured are creating a financial strain on the healthcare institutions that serve everyone regardless of insurance status. William Pully, President of the North Carolina Hospital Association, describes the financial impact of the rising numbers of uninsured on hospitals across the state in his commentary in this issue of the Journal.[16]

Rising Healthcare Costs Are Leading to the Increased Numbers of Uninsured

Between 2000 and 2004, health insurance premiums have increased 65% nationally, far faster than wages (12.2%) or general inflation (9.7%).[17] These rising premiums are a major contributor to the increasing numbers of uninsured. More than half (55%) of the uninsured surveyed in North Carolina reported that they didn't have health insurance because it costs too much, and another 23% reported that they were out of work or between jobs, which could also make health insurance coverage unaffordable.[11] Similarly, 86% of employers who did not offer health insurance reported in a national survey that high premium costs were an important reason for not offering coverage.[18] Every 10% increase in premiums leads to a 2.5% decline in employers offering coverage, with smaller firms being more responsive to premiums than larger firms.[19]

In order to stem the increasing numbers of uninsured, it is also important to address rising healthcare costs. While there are many factors that lead to increased premiums, the primary driver is the increase in underlying healthcare costs.[c,20,21] We, as a society, are using more healthcare services, while at the same time, the underlying costs of many of these services have increased. The advent of new technology and treatment protocols, changes in overall disease prevalence or changing demographics, the costs of defensive medicine, and underlying labor costs all contribute to rising healthcare costs. One study showed that almost one third of the change in healthcare spending between 1987 and 2000 was attributable to the treatment of five major health problems: heart disease, mental disorders, pulmonary disorders, cancer, and trauma. Half of the increase was attributable to 15 conditions.[22] Many of these health conditions are exacerbated by our lifestyles or lifestyle-related diseases, including obesity, smoking, and problem drinking.[23] Sandra Greene, a Senior Research Fellow at the Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill, provides more information about the reasons for the increased healthcare expenditures in her commentary on page 192 in this issue of the Journal.[24]

Employers have responded to these rising premium costs by

---

[c] One way of determining the extent to which underlying healthcare costs are driving premium increases versus underwriting profits of insurance companies is to compare the premium increases of fully-insured plans versus self-funded plans, as the premium costs in self-funded plans almost exclusively relate to underlying costs of medical claims. Studies that have compared the premium increases to determine the effect of insurance underwriting profits on premiums found almost no effect of underwriting profits between the springs of 2004 and 2005. Underwriting profits did play more of a role on the premium increases in the prior year, when premiums for fully insured plans increased 11.2%, but medical claims expenses only rose 7.4%.[19,20]

shifting more of the costs to their employees, either through higher premiums, deductibles, or other out-of-pocket spending. Between 2000-2005, the employee's share of health insurance premiums increased by 82%, with a 67% increase in family coverage.[25] One fifth of all employers are offering high-deductible plans, which have at least a $1,000 deductible for individuals and a $2,000 deductible for family coverage. Employers have also tied the increased cost-sharing to the services that are contributing significantly to rising healthcare costs, such as inpatient hospitalizations and prescription drug use.

In addition, more employees are now covered by plans that offer case management or disease management for high-cost and chronic health conditions. A small percentage of the population accounts for the majority of spending on healthcare. In 1996, for example, approximately 5% of the population accounted for 55% of all spending on healthcare, and 30% of the people accounted for 90% of healthcare spending.[26] Thus, 81% of employees with employer-sponsored insurance are in plans that use case managers to manage high-cost claims; and 56% of workers are in plans that offer at least one disease management program.[25]

Incremental Reform Efforts

Ultimately, the only way to fully address the problems of the uninsured is to ensure that every person has health insurance coverage. Offering health insurance on a voluntary basis creates incentives for adverse selection. In other words, people who are less healthy and likely to incur healthcare costs are more likely to enroll and pay for health insurance than those who are healthier. Thus, lower participation rates and a population of higher-risk individuals will increase the average cost per eligible.

Nonetheless, it is difficult to achieve universal coverage on a state-level basis; to date, no state has been able to fully insure its population. Further, the Task Force realized early in its deliberations that no single approach to providing universal coverage would gain the support of the different healthcare constituencies. Thus, the Task Force recommended a multi-pronged approach that included market-based reform efforts, private-public partnerships, and public initiatives to expand coverage to more of the uninsured.

The Task Force's priority recommendations focused on five areas:

- Expand the healthcare safety net to provide healthcare services to more uninsured.
- Promote personal responsibility for health to help improve population health.
- Create a lower-cost health insurance product for small employers who have not offered health insurance in the past.
- Develop a limited-benefit Medicaid expansion plan for low-income parents.
- Create a high-risk pool for individuals with pre-existing health problems.

Expand the Healthcare Safety Net

Many people are under the mistaken belief that people can get the healthcare they need, even if they do not have insurance. Under the federal Emergency Medical Treatment and Active Labor Act (EMTALA), hospitals are required to screen and stabilize anyone who seeks care in their emergency department.[d] However, this is not the most appropriate, nor is it the least costly, way for people to receive care. The North Carolina Institute of Medicine Safety Net Task Force examined the availability of safety net organizations that provide primary care services to the uninsured on a sliding-fee scale basis, such as community and migrant health centers, free clinics, public health departments, state-funded rural health clinics, or other non-profits with a mission to serve the uninsured.[27] Private physicians also provide care to the uninsured, often on a reduced cost basis. The Task Force found that these organizations are not available in every county. Statewide, only about 25% of the uninsured received care through a healthcare safety net organization. Further, national studies show that less than half of the uninsured are aware of safety net resources in their communities.[28] Safety net providers are also limited in the care they can provide, as many are unable to provide needed behavioral health or dental health services, specialty care, or access to necessary medications. In this issue of the Journal, Annette DuBard, a primary care physician working at a community health center in Alamance county, describes some of the frustrations and heartbreak she faces as a physician trying to address the healthcare needs of her uninsured patients.[29]

The North Carolina Institute of Medicine Task Force on Covering the Uninsured recognized that its recommendations would not lead to universal coverage for all of the uninsured. Thus, safety net services are needed to ensure that those who continue to lack coverage will have some access to services. **The NC IOM Task Force on Covering the Uninsured recommended that the North Carolina General Assembly increase funding to support and expand the healthcare safety net in order to provide services to more of the uninsured.**

Promoting Personal Health Responsibility to Improve Population Health

Lifestyle choices and lifestyle-related diseases contribute to the rising costs of healthcare. Smoking, heavy drinking, and obesity can lead to chronic health problems and, as a result, increased healthcare costs. For example, obese people have a higher risk of developing diabetes, hypertension, and heart disease. Smokers have a greater likelihood of developing lung cancer or heart disease. Problem drinkers have a higher risk of trauma through falls and motor vehicle accidents, and are at increased risk for pancreatitis and certain types of congestive heart failure. According to 2001 figures, 24% of the United States population is obese, an increase of ten percentage points since 1987.[30] The increased prevalence of obesity alone

---

[d] EMTALA requires hospitals that participate in Medicare to screen anyone who requests treatment at the emergency department, regardless of ability to pay. 42 USC §1395dd.

accounted for 12% of the real per capita healthcare spending growth between 1987 and 2001.

One of the best strategies to reduce the rapid escalation in healthcare spending is to encourage people to live healthier lifestyles. On page 225 in this issue of the Journal, Robert Greczyn, President and CEO of Blue Cross and Blue Shield of North Carolina, presents ideas on how we can control healthcare costs in North Carolina.[31] The incidence of chronic diseases and, over the longer-term, the rate of growth in healthcare spending, could be decreased if people would eat healthier foods, exercise regularly, maintain a healthy weight, and reduce other risky behaviors. Thus, one of the Task Force's recommendations was to focus on improving population health. People have a responsibility to be better stewards of their own health, but society at large can help in that effort. **Specifically, the Task Force recommended that individuals be given the education, support, and resources needed to make informed healthy lifestyle choices; that individuals with chronic diseases be provided the information and access to health services needed to manage their conditions; and that individuals who engage in unhealthy behaviors be expected to pay differential premiums to cover some of the increased healthcare costs of their lifestyle choices. Further, the Task Force recommended that providers, employers, insurers, schools, and government all assist in promoting healthy lifestyle choices and encourage people to participate in evidence-based wellness initiatives.**

Low-cost Health Insurance Product for Small Employers

The Task Force focused on ways to reduce premium costs for small employers, as half of the uninsured have a family connection to a small employer. North Carolina's small-firm employees are less likely to be offered health insurance by their employer than nationally, but those who are offered insurance are more likely to enroll.[32] Focus groups with North Carolina employers, conducted by FGI Research as part of the State Planning Grant, confirmed that employers want to provide health insurance coverage to their employees. "We like to keep our employees healthy so they'll show up for work," noted one focus group participant. However, high premium costs were cited as the major barrier to offering coverage.

The Task Force focused on different ways to reduce premium costs for small employers. One of the primary ways to reduce costs is to reduce the benefits covered or greatly increase cost-sharing. However, there is a tension between offering pared-down benefit plans or plans with such high cost-sharing that the uninsured would find it unattractive, versus expensive plans that offered comprehensive benefits.

The Task Force's priority recommendation was to offer a publicly-subsidized health insurance product that would be targeted to small employers with 25 or fewer employees, sole proprietors, or employees who are not offered health insurance through their jobs. The state would be urged to provide reinsurance[e] to help reduce the premium costs by 30% over what is available in the private market. To further reduce the potential costs to the state, the proposal would be limited to employers who have not offered health insurance in the last 12 months and who also have a low-wage workforce (i.e., at least 30% of the employees earn $12/hour or less). Eligibility for sole proprietors and working individuals would be limited to those who had not had coverage in the last 12 months and who had family incomes less than 250% FPG. This model is based on the Healthy New York model, which has been in operation since January 2001 and now covers more than 100,000 previously uninsured individuals.[33]

The Task Force also recommended that commercial insurers develop tiered benefit plans, which offer very basic healthcare coverage (i.e., generally limited to a specified number of doctor's visits or have caps on hospitalization costs) at the lowest premium, with more comprehensive benefits and reduced cost-sharing available for a higher premium. While these products are unlikely to appeal to a significant portion of the uninsured, they may be attractive to those who are young and healthy and do not foresee the need for comprehensive coverage. Another recommendation from the Task Force was to review the state's small group reform laws enacted in the 1990s, which helped establish a small group rating methodology to stabilize the small group market. The North Carolina Department of Insurance established a work group to examine these laws to determine if there are potential modifications that could increase coverage among small employer groups. Barbara Morales Burke discusses the work of this committee in her commentary in this issue of the Journal.[34]

Limited-Benefit Health Insurance Product for Low-Income Parents

Three fifths of the uninsured have incomes less than 200% FPG. People with low-incomes have difficulty affording coverage, whether through an employer or in the non-group market. Many low-income people are covered through Medicaid or North Carolina Health Choice (the State Children's Health Insurance Program). For example, in March 2006, there were almost 1.2 million people covered by Medicaid and approximately 105,000 children under the age of 19 covered through North Carolina Health Choice.[35] However, because of categorical, income, and resource restrictions, these programs do not cover all low-income uninsured individuals. The United States Bureau of the Census Current Population Survey estimates that Medicaid and North Carolina Health Choice only cover approximately 35% of people living below 100% FPG, and

---

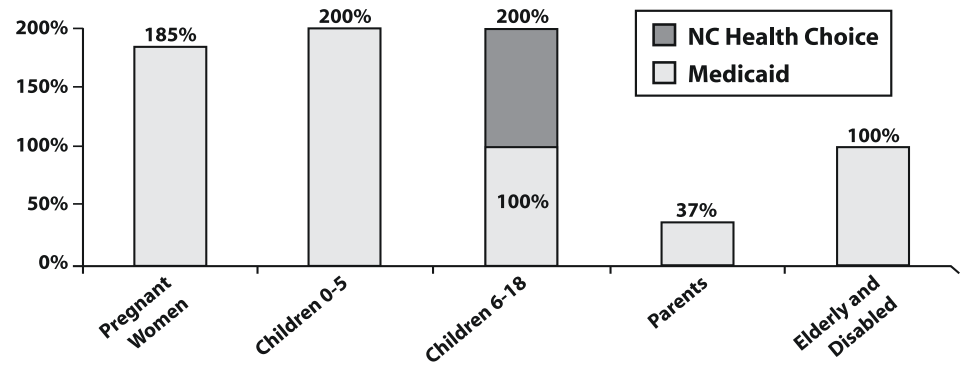
[e] Reinsurance is essentially insurance coverage for insurance carriers. If the annual claims for an individual in the plan reach some predetermined amount, then the reinsurer covers at least some part of the claims above that level. Under the Healthy New York program, the state reimburses private health plans for 90% of the claims costs between $5,000 and $75,000 per individual (called the "reinsurance corridor.") The NC IOM Covering the Uninsured Task Force did not recommend a specific reinsurance corridor, rather it recommended that the reinsurance corridor be set at a level that would result in 30% lower premiums than are available in the private market.

only 20% of those living between 200-200% FPG.[3] In order to qualify for Medicaid, a person must fall into a specified eligibility "category," including pregnant women, children under age 21, parents with dependent children, people with disabilities, or seniors age 65 or older. In addition, individuals must have incomes below a certain income limit; and, depending on the eligibility category, the person may have to meet certain resource restrictions (e.g., amount of money in the bank). Childless adults who are younger than 65 and not disabled will not qualify for Medicaid, regardless of how poor they are.

The Task Force explored different options to expand Medicaid to cover more low-income people. This is a lower-cost option to the state than developing a 100% state-funded program, as the federal government pays approximately 63% of program costs. North Carolina's income eligibility rules are comparable to or higher than many other states for pregnant women, children, older adults, and people with disabilities. However, North Carolina's income eligibility thresholds for parents, which limit their countable income to 37% FPG, are among the lowest in the country (see Figure 2).[36]

The Task Force's top priority for Medicaid expansion was to cover parents and pregnant women with incomes up to 200% FPG. In order to limit the cost to the state, the Task Force suggested that the state seek a waiver of the traditional Medicaid laws to design a more limited benefit package. The limited benefit package would focus on ambulatory care, with incentives for people to participate in disease and case management to help them manage their chronic health problems. Inpatient hospitalization would be limited to $10,000 total/year, and covered individuals would be expected to pay a sliding-scale premium and cost-sharing for the services they receive. Unlike traditional Medicaid, this expansion would not be an entitlement, so the state would have limited financial liability for the coverage. The Task Force decided to focus on Medicaid expansion for parents, rather than children, since the income limits for the working adults are so much lower than for children.

Figure 2.
Medicaid Income Eligibility as Percent of Federal Poverty Guidelines (FPG)



Analysis of the United States Bureau of the Census Current Population Survey (CPS) data suggests that there are tens of thousands of uninsured North Carolinians who currently qualify for Medicaid or North Carolina Health Choice, but are not enrolled.[37] National studies show that many people who are eligible for public programs do not enroll because they do not know about the program or eligibility criteria, or because the complicated eligibility process or stigma attached to the programs deter them from applying.[38,39] The NC DHHS has already done a lot to simplify and streamline the application processes. Yet, the Task Force recommended that more be done to increase outreach and simplify the application process to encourage uninsured individuals who are currently eligible to apply for these programs.

Another way to expand care for the uninsured is through the Medicaid Community Care of North Carolina (CCNC) networks. CCNC is comprised of community-based networks designed to improve the care provided to Medicaid recipients. The 14 regional networks cover 92 of the 100 counties and approximately 670,000 Medicaid recipients. Each network includes primary care providers, hospitals, departments of social services, health departments, and other healthcare providers and provide case management and disease management services to help patients manage chronic or high-cost conditions. L. Allen Dobson, Assistant Secretary for Health Policy and Medical Assistance for NC DHHS, discusses the importance of implementing CCNC cost-saving strategies (i.e., quality improvement, disease management, targeted utilization initiatives) along with providing continued support for the safety net in his commentary in this issue of the Journal.[40]

High-Risk Pool for People with Pre-Existing Health Problems

Ostensibly, people with pre-existing health problems are among those individuals most in need of health insurance coverage, but they often have the hardest time finding affordable coverage. People with pre-existing health problems cannot be excluded from coverage or charged higher premiums if they obtain their coverage through an employer. However, with limited exceptions, individuals who seek coverage in the non-group market can be denied coverage or charged unaffordable premiums. Later in this issue of the Journal, David Moore, past President of the North Carolina Healthcare Underwriters Association, discusses the merits of creating a high-risk pool in North Carolina.[41]

Blue Cross and Blue Shield of North Carolina is the only insurer in the state to offer health insurance coverage to anyone in the non-group market, regardless of their health status. However, premiums vary, based on the age, geographic location, sex, and health status of the individual. The premiums are established to cover the anticipated costs of the group of enrollees—thus, those with pre-existing problems are charged higher premiums than those who are healthy and presumed to use fewer health services. For example, non-group health insurance coverage for a man with significant health problems could cost more than $800/month (for a $1,000 deductible, 30% coinsurance plan), or more than $1,800/month for a 55-year-old man. Premiums for women are generally more expensive, especially if the woman chooses maternity coverage.

Thirty-three states have established high-risk pools to help subsidize the costs of health insurance coverage for people with pre-existing problems. Research suggests that approximately 1% of the non-elderly population has difficulty obtaining insurance due to their health status ("medically uninsurable").[42] The experience from other states suggests that between 10-30% of these individuals may enroll in a high-risk pool, depending on the premium price and whether the state offers additional subsidies for low-income people.[43] Most states cap the premiums charged to individuals enrolled in the high-risk pool to 150% of the standard price charged to healthier individuals. **The Task Force recommended that North Carolina establish a high-risk pool and that the losses from the pool be spread broadly among all insurers, including commercial carriers, third-party administrators, and reinsurance carriers.** Congress appropriated $75 million in grant funds in 2005 to help states offset some of the losses from a high-risk pool.[44] In addition, Congress appropriated another $15 million to provide start-up funds to states, like North Carolina, that have not yet established a high-risk pool.

Conclusion

The problems of the uninsured affect everyone in our state. Individuals stand to benefit by having affordable coverage that enables them to get necessary healthcare services. Providers will gain if there is a source of coverage for those individuals for whom they are already providing some services, but with minimal payments. Businesses benefit by having a healthier, more productive workforce and fewer bankruptcies. The state stands to gain by having a healthier, more competitive workforce and healthier children who are more likely to succeed in school. As more people gain insurance coverage, there will be less uncompensated care. This, in turn, will reduce the need to shift uncompensated costs of serving the uninsured onto people with insurance, which will help moderate rising healthcare costs for those with insurance.

Just as each group stands to gain by expanding insurance coverage to the uninsured, there is a shared responsibility to assist in the solution. Individuals should purchase health insurance when affordable coverage is offered. Employers can assist by offering insurance and helping contribute toward the cost of employee and dependent coverage. Insurers can help by subsidizing the costs of the high-risk pool. Providers can assist by accepting lower reimbursement rates for low-income individuals and small employers who were previously uninsured. And government can assist by helping to subsidize the costs of insurance for those who could not afford coverage in the private market.

The problems of the uninsured beg for a national solution; as it is difficult for any state to tackle this problem in a vacuum. However, states should not wait until the federal government acts. Many states are devising creative solutions to expand coverage to the uninsured. Some states are further along in their process than North Carolina and already have low-cost products for small employers and Medicaid programs that cover more of the uninsured. North Carolina can learn from these states and then develop programs that are tailored to the unique needs and strengths of this state. The Task Force's recommendations are a starting point toward this goal, but additional work will be needed in the future if the state is ever to realize the goal of universal health insurance coverage for all. **NCMedJ**

COMMENTARY

Healthcare Costs:

The Engine Driving the Decline in Insurance

Sandra B. Greene, DrPH

The increase in the percent of the population that is uninsured in both North Carolina[1] and across the nation[2] is driven by the increasing costs of health insurance premiums. Nationally, health insurance premiums increased 65% between 2000 and 2004. This rise was more than six times greater than general inflation (9.7%), and more than five times the wage growth (12.2%).[3] The increase in premiums makes it harder for employers to offer insurance to employees and for individuals to purchase healthcare coverage. Research indicates that for every 10% increase in health insurance premiums, the number of firms that offer health insurance to their employees falls by roughly 2.5%.[4]

Most of the increase in health insurance premiums is due to the increase in the underlying costs of healthcare.[5,6,7,8] Healthcare costs increase for a variety of reasons, some due to the increased cost of individual services, some due to greater utilization of services, and some due to changes in overall disease prevalence. This commentary examines trends in personal healthcare spending in North Carolina between 1990 and 2000, changes in unit costs and utilization of different services, and the effects of changes in disease prevalence and demographic changes on healthcare spending. The commentary concludes with how these changes impact health insurance premiums and how employers and individuals respond to rising premium costs.

Total Personal Healthcare Spending in North Carolina (1990-2000)

Data from the Office of the Actuary of the federal Centers for Medicare and Medicaid Services show that North Carolinians spent $31.3 billion dollars on personal healthcare expenses in 2000.[9] Table 1 shows how the dollars were spent and the increases in expenditures by service type between 1990 and 2000 (the most recent data available).

In 2000, more than one third of personal health spending in

Table 1.

Sandra B. Greene, DrPH, is a Senior Research Fellow at the Cecil G. Sheps Center for Health Services Research and Research Associate Professor in Health Policy and Administration at the University of North Carolina School of Public Health and was formerly Vice President for Strategic Information at Blue Cross and Blue Shield of North Carolina. Dr. Greene can be reached at SandraB_Greene@unc.edu or CB# 7590, Chapel Hill, NC 27699-7590. Telephone: 919-966-0993.

North Carolina was spent on hospital care (39%), and approximately one quarter (26%) on physicians and other professional services.[9] These expenditure rates are similar to those at the national level (36% and 29%, respectively) and accounted for more than half of the increase in total expenditures from 1990-2000. Hospital care accounted for 35% of the increase in spending, while physician and other professional services accounted for 25%. However, in recent years, prescription drugs have been one of the fastest growing components of healthcare spending. Prescription drugs accounted for 16% of the increase in overall healthcare spending between 1990 and 2000. As a result, prescription drugs constituted 12% of North Carolina's personal healthcare expenditures in 2000, compared to 8% in 1990.[a,9] Long-term care (home health and nursing care) also constituted 12% of North Carolina's personal healthcare expenditures in 2000, with spending on home healthcare increasing more than 300% since 1990.[b]

Changes in Unit Cost and Utilization of Different Services

Expenditures for healthcare services are a function of two components: price per unit of service and the number of units (amount of services received). Understanding whether the price or use of a service is increasing, or both, can help policymakers determine how to respond to healthcare cost increases. As described in more detail below, an increase in unit costs explains the rising costs of hospital inpatient care, while increased utilization explains the rising costs of hospital outpatient services and technology (particularly imaging). For prescription drugs, there has been both an increase in utilization and unit costs.[10]

Previous efforts to curb rising costs of care have focused primarily on price because it is easier to address what something costs than to manage its utilization. Providers contribute to increased utilization, as changes in technology or treatment protocols lead to increased use of certain services or procedures. Defensive medicine—or ordering unnecessary tests or procedures to prevent a potential malpractice claim—also increases utilization. Consumers' demand for services and medications also contributes to rising healthcare utilization. Controlling utilization is generally more difficult than trying to control costs because the public often views the former as restrictions on accessing needed healthcare.[11] However, recent strategies have designed consumer cost-sharing to influence patient utilization rates. By placing more financial responsibility on consumers, patients may reduce their use of marginally useful or unnecessary healthcare services.[c,12]

Hospital Care

Between 1990 and 2000, hospital spending increased 104% in North Carolina (see Table 1) and accounted for 35% of total growth in personal healthcare expenditures. Hospital spending includes that spent on both inpatient and outpatient services. More recent national data showed that hospital inpatient spending increased 6.2%, while hospital outpatient spending increased 11.3% between 2003 and 2004.[13]

The increase in hospital services expenditures is due primarily to an increase in unit price, rather than an increase in utilization. Nationally, hospital utilization increased only 2.9% in 2004, but hospital unit costs for inpatient and outpatient services combined increased 7%.[13] On a population basis, North Carolinians are spending less time as inpatients than a decade ago. In 1989, North Carolina residents' utilization of inpatient hospital services was 752 days per 1,000 persons, compared to

Figure 1.

---

a Prescription drugs, by themselves, constituted 12.4% of personal healthcare expenditures in North Carolina in 2000; non-durable medical products amounted to another 2.2% of the state's personal healthcare expenditures.[9]

b Long-term care expenditures, unlike most other healthcare expenses, are highly dependent on the payer. Public insurance programs, such as Medicare and Medicaid, account for a substantial portion of total spending on long-term care.

c The most notable work in this area stems from the RAND Health Insurance Experiment conducted in the late 1970s. Utilization was lower in plans that had greater cost sharing, but there was mixed evidence on whether the healthcare services were necessary. Health status for most people was unaffected by their reduced services, but for the sick and poor, health was adversely affected.

only 542 days per 1,000 in 2003.[14] The most dramatic decline in utilization occurred among the elderly population.

By contrast, the cost per day spent in the hospital or per admission is escalating because there are more services, treatments, and procedures provided to patients once they enter the hospital. In addition, as more non-emergent healthcare needs can be treated on an outpatient basis, inpatient utilization for those services decreases, and the more intensive, higher-cost services account for a greater proportion of inpatient services, which raises costs. Further, hospital labor costs for nursing and other healthcare professionals have increased.[15,16]

Costs for hospital outpatient care are also increasing as the result of both higher utilization and greater unit price.[13] This increase is a reflection of more services and procedures, such as biopsies, surgeries, and chemotherapy, which are now safe and acceptable when performed on an outpatient basis. In the past, some of these services would have been performed solely on an inpatient basis. Thus, while outpatient costs have been increasing, some of this increase in utilization helped offset the use of more expensive inpatient services. However, there is not a direct one-for-one correlation between increased use of outpatient services and a decrease in inpatient utilization. Further, unit costs for outpatient care are not as well controlled as costs for inpatient care, where the use of diagnosis related groups (DRGs) or similar prospective payment methods limit charges per admission.[d]

> *"Previous efforts to curb rising costs of care have focused primarily on price because it is easier to address what something costs than to manage its utilization."*

Technology

Greater availability and use of technology are also significant healthcare cost drivers.[17] Radiographic imaging has been one of the most significant technological advances in medical care. X-rays, introduced in 1895, were the first form of imaging. Newer forms of imaging emerging in the late 20th century included computed tomography (CT), magnetic resonance imaging (MRI), and positron emission tomography (PET). The current (2004) cost of a CT scan is more than $1,200, an MRI is generally just under $2,000, and a PET scan costs approximately $2,300.[9]

The availability of freestanding MRI and CT technology is associated with higher utilization and spending on these services.[17] However, the use of these imaging technologies for diagnosis has generally proven to be additive, rather than substitutive. A clinician may first order an x-ray or CT scan and then order another imaging technology, such as an MRI, to confirm or further investigate a suspected malady.[17] Therefore, while a diagnosis may be more accurate, the costs associated with determining that diagnosis are increasing.[18] The latest imaging technology, PET, uses radioactive substances to examine body functions, and it is increasingly used in screening for cancer and heart disease despite professional disagreement over some specific uses of this scanning technique. Between 1970 and 1985, North Carolina had only three PET scanners in the state, located at the largest hospitals. However, since 1985, 19 more PET scanners have been approved, and now all teaching hospitals have at least one PET scanner, and moderate size hospitals are applying for their use. This pattern of diffusion is typical for a new technology and will result in rising costs because of the wider availability of the scanners.

Prescription Drugs

The rising cost of prescription drugs is also a major contributor to increasing healthcare costs. In North Carolina, expenditures for prescription drugs increased 250% between 1990 and 2000 (see Table 1). More recent national data show that prescription drug expenditures increased 47% between 2000 and 2003.[19] Both public and private insurance programs have experienced double digit annual increases in prescription expenses.[20] This increase is due both to rising cost per prescription and an increased number of prescriptions filled.[13]

The rising costs of medications may be explained, at least in part, by the introduction of new medications into the market. The National Institute for Health Care Management (NIHCM) conducted a study of 1,035 new drug applications to the Food and Drug Administration between 1989 and 2000 and found that only 35% contained new active ingredients, while the remainder contained currently available active ingredients.[21] Furthermore, only 24% of the drugs offered clinical improvement. Of all the new drug applications, only 15% were both highly innovative and offered significant clinical improvement. In addition, of the $67.4 billion increase in spending on prescription drugs between 1995 and 2000, only 33% of the expenditures were spent on the pharmaceuticals that offered clinical improvements. This raises questions about the cost effectiveness of the increased spending on pharmaceuticals.

A significant factor in the high utilization of new prescription drugs is direct-to-consumer (DTC) advertising.[22] DTC advertising is a successful marketing tool. Drugs that are heavily advertised experience a significant increase in their use.[23] Yet, there are a

---

[d] Diagnosis related groups (DRGs) is a hospital payment system used by Medicare and many third-party insurers. It prospectively sets the hospital payment based on the patient's primary and secondary diagnosis, surgical procedures, age, sex, and the presence of complications.

number of concerns about such advertising techniques. Advertisements generally contain limited information about side effects and promote expensive brand name drugs over generics. Patients who see these ads may exert pressure on their physicians to prescribe drugs they have seen advertised, and this may lead to use of higher-cost drugs, rather than generic versions. In some cases, this could lead to inappropriate clinical use.

Malpractice

Rising malpractice premiums have been noted as a problem for some physicians in particular specialties and geographic areas. It may also negatively affect patients living in areas where physicians are no longer practicing presumably as a result of high premiums. Malpractice also contributes to rising healthcare costs because it leads to defensive medicine. Physicians may order unnecessary tests or procedures or avoid some high-risk patients, out of fear of potential malpractice liability.[24] While it is difficult to fully quantify the costs of defensive medicine, several recent studies suggest that malpractice costs and malpractice insurance premiums are not primary contributors to the rising costs of healthcare. One study reported that only 7% of the annual increase in healthcare costs can be attributed to litigation and risk management,[25] while another showed that malpractice costs account for a very small proportion of healthcare premium costs.[26]

Changes in Disease Prevalence and North Carolina Demographics

Changes in the prevalence of certain health problems underlie some of the increased use of health services and, consequently, relate to a portion of the increase in national healthcare spending. Healthcare spending is concentrated in a relatively small number of health problems. For example, almost one third of the change in healthcare spending between 1987 and 2000 was attributable to the treatment of five major health problems: heart disease, mental disorders, pulmonary disorders, cancer, and trauma.[29] Approximately half of the increase in health spending was attributable to 15 conditions.

For four conditions, cerebrovascular disease, mental disorders, pulmonary conditions, and diabetes, increased spending was due primarily to an increase in treated prevalence or number of cases.[e] In contrast, the increased cost per treated case was the primary factor underlying greater spending on trauma, pneumonia, infectious diseases, and heart disease. Overall population growth generally accounted for only 20-30% of the changes in healthcare spending for any specific condition.

Certain lifestyles choices and lifestyle-related illnesses contribute to many healthcare problems. Smoking, heavy drinking, and obesity[f] can lead to chronic health problems and, as a result, increased healthcare costs.[27] The growing epidemic of obesity is a major contributor to rising healthcare costs. Obese people have a higher risk of developing certain health problems, such as diabetes, hypertension, and heart disease. According to 2001 figures, 24% of the United States population is obese, an increase of ten percentage points since 1987.[28] The increased prevalence in obesity alone accounted for 12% of the real per capita spending growth between 1987 and 2001. Sturm analyzed self-reported health risk data from a national household survey and compared this to reported inpatient, outpatient, and prescription drug utilization. He found that obesity increased healthcare and medication costs by 36% and 77%, respectively, compared to someone with a normal weight.

Obesity has a much greater effect on the prevalence of chronic conditions than current or past smoking and problem drinking. However, current or past smoking also increased healthcare service costs 21% and medication costs 28-30%, depending on whether the individual was a current or past smoker. Compared to obesity, which increased absolute inpatient and ambulatory care costs by $395 per year, current or ever smoking was associated with a $230 increase, and problem drinking was associated with a $150 increase.[29]

North Carolinians, like Americans in general, are much more likely to be obese than they were even 15 years ago. In 1990, 12.9% of adult North Carolinians were clinically obese; in 2002, nearly one quarter (23.5%) were obese (see Figure 2). This trend in population health, although not a major contributor to the increase in healthcare costs, is generally appreciated by society. Although conventional wisdom holds that the increase in the proportion of the population that is overweight and obese is a major driver of cost trends, other factors outlined above, such as increasing use of technology, are more important.

A recent study found that many obese individuals do not realize they are obese.[29] Over 70% of normal weight individuals accurately identified themselves as such, but roughly 15% of obese people knew they were obese. All groups reported their height and weight equally well. This finding suggests that there is a need to increase awareness in the population of what a normal weight is.

It is a common misconception that our aging population is a major factor in explaining increases in healthcare costs. Adults over the age of 65 years do spend more per capita on healthcare than younger individuals. Therefore, as the overall population ages, healthcare spending also increases. However, the aging of the overall population is modest from one year to the next, so while it may have a long-term impact on costs, it does not significantly contribute to spending increases from year to year.

---

[e] Depending on the condition, the increase in treated prevalence can be due to an increase in epidemiological prevalence of the condition (e.g., diabetes) or to the rate of treatment for a particular condition (e.g., mental health).

[f] In July of 2004, the United States Department of Health and Human Services announced its Medicare coverage policy would treat obesity as an illness. Obesity is defined as having a body mass index (BMI, calculated as weight in kilograms divided by height in meters squared) that is 30 or more.

Rising Health Insurance Premiums and Employer Response

One of the most closely watched measures of changing healthcare costs is the national Mercer/Foster Higgins survey of health benefit costs among public and private employers. This survey represents 600,000 employers with at least ten employees and more than 90 million full- and part-time employees.[g] Figure 3 illustrates changes in the total cost of healthcare benefits from 1988 to 2004. With the exception of a few years of modest increases during the mid-1990s, the cost of health insurance premiums has substantially increased each year since the late 1980s. Healthcare inflation increased at a greater pace than the general rate of inflation. Recently, those increases have moderated, and in 2004, benefit cost increases were 7.5%, down from increases of 10.1% and 14.7% in 2003 and 2002, respectively. While still significantly above inflation, it is the lowest annual increase in five years. However, there is a concern that this recent moderation in benefit cost increases underestimates the true cost escalation in the healthcare system. Rather than increasing premiums, many employers have shifted some of the healthcare costs to employees through increased out-of-pocket expenses, such as deductibles and copays. Figure 3 does not reflect the total increase in healthcare costs because it does not include out-of-pocket expenses.

A 2005 survey of employers by the Kaiser Family Foundation and Health Research and Education Trust indicates that many believe shifting costs to the employee is an effective way to control rising health insurance premiums (see Figure 4). This may be because employers feel they have run out of other viable options. But there could be unfortunate implications for their employees. Past studies suggest that higher out-of-pocket costs do deter utilization, and that individuals are equally likely to forgo necessary care as well as unnecessary care.[30] This is a

---

[g] Another national survey conducted by the Kaiser Family Foundation (Kaiser) and Health Research and Education Trust (HRET) results in somewhat different estimates of premium increases. For example, in 2004, the Kaiser/HRET study showed an 11.2% increase from 2003. This study includes employers with three or more employees. The Mercer Foster Higgins study also includes public programs. These differences in study design help explain the different estimates of premium increases.

Figure 4.
Employers Opinions on the Effectiveness of Different Cost Containment Strategies

*Consumer Driven Health Plans include high-deductible plans with a personal or health savings account.

particularly significant problem for low-income people, who are more likely to forgo necessary care and suffer adverse health outcomes as a result.

Employers are also trying to control rising healthcare costs by managing high-cost claims. A small percentage of the population accounts for the majority of spending on healthcare. In 1996, approximately 5% of the population accounted for 55% of total spending, and 30% of the population accounted for 90% of total healthcare spending. This trend has been consistent over time.

People with chronic conditions are included in the high-cost groups and many employers are trying to manage the high costs of chronic conditions through disease management (DM) programs. More than four fifths of covered workers (81%) are enrolled in plans that use case managers to coordinate the care of persons with high-cost conditions. More than half (56%) of all workers with employer-sponsored health insurance are in a plan with at least one disease management program. Of those covered by disease management programs, most workers are covered by programs that manage diabetes (99%), asthma (86%), hypertension (82%), and high cholesterol (66%).[31] Fifty-two percent of employers surveyed in 2005 indicated that disease management was a very or somewhat effective strategy to control rising healthcare costs,[32] although a review of studies examining the return on investment of disease management programs shows mixed results.[h,33] Given the frequent use of disease management programs in employer-sponsored insurance programs, there is a need for more evaluation of their effectiveness to understand where investments of this kind will pay off.

The Elusive Fix

It is not surprising that employers continue to struggle, with little success, in controlling the increases in their healthcare premiums. The healthcare system—the way it is structured, managed, and reimbursed—is complex. Solutions will be equally complex and can't be unilaterally imposed by any single segment of the healthcare system. Some critics say the problem is that patients and providers alike are too insulated from the costs of goods and services and suggest that plans that more closely align consumer/patient and insurer interests (such as Consumer Directed Health Plans[i]) would increase consumer awareness. Others call for more (or less) competition in the healthcare system to control costs. And others put the blame on lifestyles, and call on all of us to take better care of ourselves to reduce illness and healthcare use. While there may be some truth to all of these observations, our problems are more complex than these convey. It is true we have little competition in the provision of healthcare services, but competition rarely works in healthcare as it does in other sectors of the economy. Two high-cost open heart surgery programs in one community do not result in price competition. And arming patients with price information rarely is useful except for elective care, and then only when assuming there is a choice of providers. Patients usually go where their trusted physician directs them. Once a patient is sick and enters the healthcare system, tests and procedures are ordered *for* them, and there is little a patient can do to control the costs associated with their care. The American healthcare system tends to defer to the professional judgment of the physician as to what tests, procedures, and treatments are necessary to ensure the well-being of the patient. Healthier lifestyles are a laudable goal and should be a focus for employers and employees alike. Yet, the healthiest among us will most likely experience health problems at some point through no fault of their own. And once in the healthcare system, the costs are so great that most individuals need some form of assistance in the form of health insurance to afford their care.

Unfortunately, redesigning the American healthcare system

---

[h] A recent Cornell-Medstat study concluded the jury is still out on whether disease management programs deliver a return on investment. A review of 44 studies analyzing the economic impact of DM programs found mixed results for those targeting depression, diabetes, and asthma, which are the most common diseases targeted. However, those programs targeting congestive heart failure and multiple chronic conditions were more likely to be successful.

[i] The premise of Consumer Directed Health Plans (CDHP) is that there is costly, unnecessary use of healthcare services, and by transferring more responsibility for accessing and paying for care to the individual, cost-effective decisions will be made. CDHPs take multiple forms, and may include high-deductible plans, healthcare spending accounts, and tiered benefit plans.

to resolve these problems is an unrealistic goal. In the early 1990s, the American public soundly rejected the Clinton Plan to overhaul the system. And as the HMO backlash of the late 1990s taught us, Americans have been loathe to accept aggressive utilization review that would eliminate marginally beneficial healthcare services, so addressing the "demand" side of the equation is not likely to be fruitful. An alternative method of limiting the use of expensive healthcare services is to limit the supply of expensive technology. In North Carolina we do this to some extent with the Certificate of Need (CON) program. This is not without controversy and often leads to adversarial relationships as healthcare institutions and physicians disagree on whether a service in a particular community is warranted. As a society, we tend to question the use of expensive technology in the abstract. But most of us would have little difficulty advocating for the service when a loved one has even a small probability of benefiting from an expensive procedure. This disconnect between what is in *society's* and the *individual's* best interest is at the heart of the dilemma. Consequently, our attempts to fix the healthcare system will be limited to modest tampering around the edges of this monstrous system, and from modest reforms, we can only expect minimal improvements. **NCMedJ**

COMMENTARY

Hospitals and the Uninsured:

One Hemorrhage at a Time, Please

William A. Pully, JD

Hospitals' promise to the uninsured: our open-to-everyone doors will never close on you. The bleeding reality: the closing doors of other providers and the narrowing reimbursement streams threaten hospital services, not only for the uninsured, but also for the insured.

North Carolina's safety net hospitals are straining under the weight of the rapidly rising numbers of uninsured and climbing demands and shrinking Medicare and Medicaid reimbursements. In addition to facing higher treatment costs, hospitals today are further stretched when other providers either cannot or elect not to continue services to specific populations. Hospitals are *their* safety net also.

One Hospital's Story

Centered in the state's southeastern coastal plain, Duplin county is agrarian, home to more than 50,000 residents. Agricultural jobs here make up over 16% of the workforce, a rate 23 times higher than the state average. Unemployment has fallen in recent years, but residents vividly recall 2000 and 2001 when the county's 23.1% and 24.8% respective joblessness rate ranked worst and next-to-worst in the state. The county also has one of the state's fastest growing immigrant populations. Hispanics, the majority of whom are uninsured, comprised 15.1% of Duplin county residents in 2000 and 18.6% in 2004, numbers that—like farm jobs—are several multiples higher than the state's 4.7% average.

> *"The combination of these losses has devastated the hospital's financial picture, drowning the $1.5 million excess of revenues over expenses in 2000 under a four-year pool of red ink."*

Duplin General Hospital in Kenansville attempts to serve everyone. Eighty-nine of its 101 licensed beds are staffed and open. Twenty of those are for mental health patients, 20 are for those needing skilled nursing care, and nine are for intensive care patients. The hospital's emergency department welcomes 15,000 visitors annually. The surgery suites see 2,200 cases. The hospital discharges 4,200 patients annually and serves 48,000 outpatient visitors—almost one visit for every county resident each year. A more classic example of a "safety net hospital" does not exist.

Two categories of hospital services reveal distinctly different problems facing this hospital. Duplin General delivers between 600 and 700 babies each year. Obstetrics services seldom cover their costs. The percentage of births from the largely uninsured Hispanic population has mushroomed. In 2001, 33% of births at Duplin General were Hispanic. Births to the Hispanic population surpassed 40% in 2002. Over the past three years, more than half of the deliveries were by Latino mothers.

Meanwhile, Medicare and Medicaid patients are turning to the hospital's emergency department in greater numbers. Physician reimbursement rates that have either declined or failed to keep pace with rising costs are constricting access to primary care for these populations. These older, poorer, often sicker patients turn to hospital emergency departments when other healthcare options are closed. In the past year at Duplin General, Medicare patients accounted for 27% of emergency department visits; Medicaid patients 20%; and self-pay patients—the hospital field's euphemism for the uninsured—counted for 24%.

Similar percentages are setting off alarms all over the state. In the aggregate, North Carolina hospital emergency departments

---

William A. Pully, JD, is President of the North Carolina Hospital Association. Mr. Pully can be reached at wpully@ncha.org or PO Box 4449, Cary, NC 27519-4449. Telephone: 919-677-4221.

saw Medicare visits climb to 24%; Medicaid to 22%; and uninsured to 22%. All three groups' usage of emergency departments grew markedly—Medicare by 11%, Medicaid by 6%, and the uninsured by 10%. Combined, Medicare, Medicaid, and uninsured patients accounted for 2,169,006 of 3,432,486 emergency department visits in North Carolina hospitals last year.

For Duplin General, these numbers reflect not only growth among the county's uninsured population, but rising percentages of patients on Medicaid. The hospital's payer mix is over 40% Medicare, and Medicaid patients have reached or surpassed 20% each of the past five years. The hospital receives just over 85 cents on each dollar of its costs from these federal-state-local partnership payers. In one recent year, Medicaid reimbursement to the hospital was more than $750,000 below the incurred treatment cost for Medicaid patients. Statewide, hospital payments from Medicaid in 2005 fell almost $300 million below hospitals' costs. The estimated Medicare reimbursement shortfall ranges from slightly higher than the Medicaid shortfall to more than double that amount.

And, while government payments falter, Duplin General is seeing its totals for the conjoined twins of bad debt and charity care skyrocket. In 2000, their combination was more than $4 million. Bad debt and charity care totals surpassed $5 million the following year, eclipsed $6 million in 2003 and $7 million in 2004. This year the hospital expects bad debt and charity care to total $7.5 million. Statewide, hospitals provided more than $350 million in charity care in 2005 and estimated that bad debt costs were more than $530 million.

The combination of these losses has devastated the hospital's financial picture, drowning the $1.5 million excess of revenues over expenses in 2000 under a four-year pool of red ink. In 2003 and 2004, the hospital lost $2.2 million and $2.4 million, respectively. The depth of red ink decreased in 2005 before plunging to a loss of more than $600,000 through the first half of this fiscal year.

For Duplin General, the dollars are the easily countable portions of the effects of rising numbers of uninsured patients and inadequate government payments for Medicare and Medicaid patients. Harder to enumerate are the uninsured patients who do not have a family physician, although most will come to the hospital's emergency department for primary care. This inappropriate use overcrowds the facility and frustrates emergent patients, increasing dissatisfaction and fueling more liability cases. The low physician reimbursement rates, combined with climbing liability insurance coverage costs, push physicians away from private practice. The hospital finds itself forced to employ physicians, lose money, cut margins, and eliminate services. Some of the costs get shifted to other payers, making premiums spike and prompting employers to drop coverage for their workers. More people without insurance are the result. Not fixing one problem makes another accelerate exponentially.

The cascading financial woes that attend high Medicare, Medicaid, and uninsured populations push hospital trustees into difficult decisions regarding which services to continue and which to eliminate. Duplin General Chief Executive Officer Doug Yarbrough revealed his hospital has already dropped its physician clinic and its diabetes program. They are now squinting suspiciously at any other non-emergent service that does not cover expenses.

Widespread Misery

Duplin General is neither alone nor the worst case. Consider two measures of utilization for uninsured patients—the percentage of hospital charges in the self-pay category and the percentage of patient days in self-pay. Tracking those measures through general acute care patients and for all patients reveals how remarkably representative of North Carolina hospitals Duplin General is. Responses to the North Carolina Hospital Association's Advocacy Needs Data Initiative Survey indicate that 24 of 103 other hospitals in the state had greater percentages of charges in the self-pay category for general acute care and 32 others of 106 had greater percentages of charges for self-pay across all care. Duplin General is even more mainstream when viewed through the percentage of patient days prism. Forty-nine of 102 other hospitals had greater percentages of self-pay patient days for general acute care and 70 of 105 other hospitals had greater percentages of self-pay patient days for all categories of care.

The impact on a hospital's operating margin from high Medicare, Medicaid, and uninsured percentages is not subtle. In 2003, North Carolina hospitals with these high percentages averaged -0.6% from operations. The year 2004 was drastically worse, with a -3.3% average operating margin. Thanks to voluntary reporting of quality indicators opening access to a full market basket update on Medicare payments, 2005 average operating margins for hospitals with these high percentages were -0.5%. Hospitals with moderate percentages of Medicare, Medicaid, and uninsured patients averaged positive but narrow margins, while hospitals with the lowest percentages of these patients averaged operating margins of almost 5% or greater.

Such widespread misery—brought on by government underpayment for Medicare and Medicaid and government indifference toward the uninsured and those who serve them—jeopardizes care for all North Carolinians. **NCMedJ**

Latinos, Immigrants, and the Uninsured

Mark Holmes, PhD

I have presented data on the North Carolina uninsured a number of times over the past couple years to a variety of audiences. Typically each audience finds a particular point of interest—one audience may ask questions about the low-income uninsured, while another may be interested in the working uninsured—but in almost every situation, one of the first few questions is how either Latinos or immigrants (or both) affect the uninsured rate in our state. This question is not altogether unanticipated. The issue of immigration, legal and illegal, is particularly topical given the tremendous population growth over the past decade and the current political focus. An often cited statistic is that, on a percentage basis, North Carolina's Hispanic population was the fastest growing in the country from 1990 to 2000. Congress's consideration of immigration reform, and the subsequent public demonstrations, has focused national interest on the issue. Based on this widespread attention to immigrants in general, and how they contribute to the uninsured rate in particular, there is a cry for objective evidence. How much of the uninsurance problem *can* be attributed to Latinos and immigrants?

> *"...two thirds of the difference in the uninsured rate among Latinos and non-Latinos can be explained by factors other than being Latino..."*

The simple answer, of course, is that there is no simple answer. Like most topics worth considering, there is no definitive answer and data can be used to support conflicting conclusions on the issue. However, when one examines the constellation of statistics on this issue, there is only one defendable conclusion: although Latinos and non-citizens in general are more than three times as likely to be uninsured than non-Latinos and citizens, other factors are more important causes of the problem.

Popular media coverage often blurs the definition between *Latinos, immigrants, non-citizens*, and *illegal* (or *unauthorized*) *immigrants*. Often, it appears, many people consider these groups identical. In North Carolina, however, 32% of non-citizens are not Latino, and 35% of Latinos were born in the United States.[1] Non-citizens include both those who are in this country legally (i.e., with work, student, or other visas), as well as those in the country without documentation. Although much of the consternation on this issue relates directly to undocumented (illegal) immigrants, most of the data sources on the uninsured contain no information on an immigrant's legal status.[a,2] Thus, this commentary focuses on ethnicity (Latino or non-Latino) and citizenship (citizen or non-citizen). In addition, I limit my focus specifically to insurance coverage. A broader assessment of the costs and benefits of North Carolina's immigrant population is well beyond the scope of this analysis.

Simple Comparisons of Uninsured Rates

It is useful to start with simple comparisons. As often mentioned elsewhere in this issue of the Journal,[3] most analyses of the uninsured consider only the non-elderly, since due to Medicare, less than 1% of the elderly are uninsured. Table 1 presents the uninsured rate by citizenship and Latino ethnicity. Slightly less than 18% of non-elderly North Carolinians were uninsured in 2004, although there are marked differences by

---

[a] One study estimates that 55.5% of North Carolina's Latino population is "authorized."[2]

Mark Holmes, PhD, is Vice President of the North Carolina Institute of Medicine and Senior Research Fellow at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill. He can be reached at mark_holmes@nciom.org or 5501 Fortunes Ridge Drive, Suite E, Durham, NC 27713. Telephone: 919-401-6599, ext. 24.

Table 1.
Uninsured Rate by Ethnicity and Citizenship, North Carolina 2003-2004

	Not Latino	Latino	Total
Non-citizen	21.9%	73.0%	57.7%
Citizen	15.1%	25.2%	15.4%
Total	15.2%	53.6%	18.0%

Source: Current Population Survey Annual Social and Economic Supplement, US Census Bureau and Bureau of Labor Statistics

both citizenship and ethnicity. While 15% of North Carolina citizens are uninsured, more than half of non-citizens are uninsured. Likewise, 15% of non-Latinos are uninsured compared with 54% of Latinos.

The data can also be considered from another perspective. Latinos represent approximately 7% of the North Carolina population, while non-citizens represent 6%. Of the 1.3 million uninsured, however, Latinos and non-citizens are overrepresented: 22% of the uninsured are Latino, and 20% of the uninsured are non-citizens. Of North Carolina's 1.3 million uninsured, approximately 170,000—just over one in eight—were born in Mexico.

Trends

Another way to consider the role of Latinos and non-citizens would be to look at changes over time.[b] In 2000, roughly 13.4% of non-Latinos were uninsured; that grew to 15.0% in 2004, an increase of 1.6 percentage points. That is, examining only non-Latinos, the uninsured rate grew from 2000 to 2004. The uninsured rate for Latinos, however, grew substantially, from 37.8% to 51.8%, an increase of 14 percentage points. Likewise, the number of uninsured increased by more than 200,000 for non-Latinos and roughly 125,000 for Latinos. Given the total increase of 334,290 in the uninsured, the growth in the number of non-Latino uninsured represented 63% of the total increase in the North Carolina uninsured from 2000 to 2004.

Another way to analyze the changes is to try to discern whether the increase in the number and percent of uninsured Latinos is due to changes in the state's demographics (the percent of population that is Latino), or changes in the within-demographic uninsured rate (the percent of citizen Latinos who lack health insurance). Performing this analysis shows that one quarter to one third of the change in the percentage of North Carolinians who are uninsured between 2000-2004 were driven by changes in the population. The remaining two thirds to three quarters are due to uninsured increases within each group. Note that the percent of citizen non-Latinos—93% of the North Carolina population in 2000—who were uninsured increased 1.4 percentage points from 2000 to 2004. Thus, the increase in the uninsured rate in citizen non-Latinos alone was responsible for roughly 1.3 percentage points statewide—almost half the increase in the uninsured rate from 2000 to 2004.

Nationally, states with proportionately more Latino and/or non-citizens have higher uninsured rates. The question, of course, is whether this relationship is a direct result of high Latino/non-citizen populations, or whether Latino/non-citizen individuals have other risk factors making them likely to be uninsured.

Behind the Curtain—Latinos and Immigrants Have Increased Risk Factors for Being Uninsured

Of course, Latinos and non-citizens have other factors beyond their ethnicity/citizenship status that make them likely to be uninsured. For example, both Latinos and non-citizens are more than twice as likely to have incomes below poverty guidelines, and full-time workers are nearly twice as likely to

Table 2.
Single Year Estimates of the Uninsured Population of North Carolina, 2000-2004

	Percent Uninsured			Number of Uninsured		
Year	Non-Latino	Latino	Total	Non-Latino	Latino	Total
2000	13.4%	37.8%	14.8%	839,752	139,940	979,692
2001	14.4%	43.5%	16.3%	960,877	202,401	1,163,278
2002	16.8%	52.2%	19.0%	1,128,732	233,312	1,362,044

[b] The data in Table 2 do not use the two-year averaging used elsewhere in the commentary, so the numbers are slightly different.

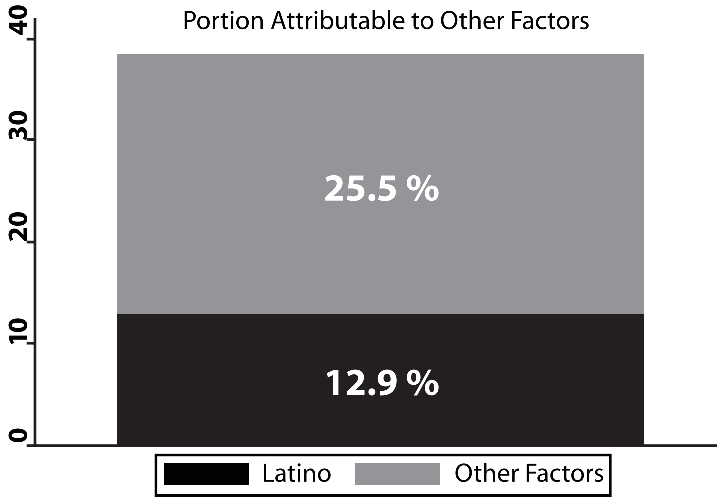
work for a small employer (less than 25 employees). Both low-income and small-employer workers are more likely to be uninsured. Other risk factors for being uninsured are higher among Latino and non-citizen populations. Both groups are much more likely to be male, young adults (25-34), and work in low-coverage industries, such as agriculture, construction, and hospitality.[c,4] In addition, low-income Latinos, especially recent immigrants or people without documentation, are also less likely to qualify for publicly-subsidized insurance, such as Medicaid or North Carolina Health Choice.[d]

After adjusting for the differences in these underlying characteristics, the difference in the uninsured rate attributable to being Latino decreases by 67%, from 38 percentage points to 12 percentage points. In other words, two thirds of the difference in the uninsured rate among Latinos and non-Latinos can be explained by factors other than being Latino *per se*. Similar results hold for citizenship. Note that differences in the rate of being uninsured remain even after adjusting for demographic and socioeconomic differences between the Latino and non-Latino populations.

The Final Answer: A Considerable Contributing Factor, but Not the Largest Driver of the Increase

The evidence, taken in totality, presents a mixed picture. Some statistics in this commentary may seem to prove that Latinos and/or non-citizens are the primary driver of the uninsured rate in North Carolina. Viewed in totality, though, the evidence suggests that other factors, such as socioeconomic status, place of employment, and inability to access publicly-subsidized insurance, may be the factors driving the lack of coverage. The evidence here is consistent with other research, taken from a national perspective, which found that the primary driver of the increase in the uninsured is the increase in health insurance premiums and not changes in demographic or socioeconomic characteristics of the population. One analysis of changes in the uninsured rates of metropolitan areas found that the primary determinant was the increase in the cost of health insurance.[5] Changes in the percent of the metropolitan area residents that were foreign born were generally unrelated to changes in coverage. Another study found that changes in the socioeconomics and demographics of working adults from 1987 to 2002 predict a half a percentage point decrease in the nationwide proportion uninsured. The authors found that the increase in the percent of population that is Latino explained half a percentage point increase in the uninsured rate.[6] A study of immigrants in Los Angeles county found that socioeconomics explained most of the difference in coverage rates between non-native born and native born, but undocumented immigrants remained 16 percentage points more likely to be uninsured after accounting for the differences in employment and other characteristics.[7] The authors claim that extrapolation of their data to national trends suggests that undocumented workers are responsible for about one third of the increase in the number of uninsured adults nationally from 1980-2000. Another study found that nationally white non-Hispanics experienced the greatest increase in the percent of people who were uninsured (1.9 percentage points).[8] The percentage of Hispanics that were uninsured declined 0.3 percentage points from 2000 to 2004. Note the difference in finding from the Gilmer and Kronick article, which underscores the sensitivity of the relationship between the growth in the Latino population and the increase in the rate of uninsurance.[9] Of course, these are national data, which may or may not translate to the specific experience of North Carolina.

Figure 2.
Proportion of Difference in Uninsured Rate between Latinos and Non-Latinos Attributable to Other Factors



Other factors include income, gender, age, working status, industry and employer size. Unadjusted difference is 38.4 percentage points.

---

[c] Other differences exist, including some that cannot be evaluated specific to North Carolina. One study, for example, found that non-citizens were more likely to work at firms that did not offer health insurance.[4]

[d] Federal Medicaid and State Child Health Insurance Laws limit coverage to individuals who meet certain eligibility requirements. To qualify, a person must be either a citizen or an immigrant with certain immigration status who has been in the country for at least five years. Additionally, individuals must meet other categorical and eligibility requirements, such as income or resources. Thus, many low-income Latinos are ineligible to receive regular Medicaid or North Carolina Health Choice benefits, even though they might otherwise meet the eligibility requirements.

The Latino and non-citizen populations of North Carolina continue to increase and are likely to continue growing as they have over the past decade. As we monitor more closely the increasing ranks of the uninsured, the Latino and non-citizen populations will bear closer inspection. Potential policy solutions should be constructed that are cognizant of the large numbers of uninsured who are ineligible for public programs due to their citizenship status. However, the majority of the North Carolina uninsured are non-Latino *and* citizens, so equating "the uninsured problem" with "the immigrant problem" is inaccurate. Addressing the increasing numbers of uninsured is within the realm of our state-level policy capability, and it does not depend on marginalizing our newest North Carolina residents. **NCMedJ**

Health Insurance Coverage:

A Luxury for Most North Carolina Latinos

Javier, his wife and three children moved to North Carolina in June 2000, after Javier lost his job in San Luis Potosí in central Mexico. When first moving to Siler City, Javier worked as a day laborer, doing odd jobs for anyone willing to hire him for a few hours a day. As a day laborer, Javier met the owner of a small landscaping company, and eventually, started working for him full-time. The landscaping business was small, with only four employees, and did not offer health insurance coverage to its workers. Urgent care clinics expected to be paid in cash the day of the visit, and the family doctor in the area charged more per visit than Javier made per day. Javier and his family had no choice but to rely on the emergency room for care.

After six months of working in the landscaping world, Javier found a job at a local poultry plant working third shift. He looked forward to working at a job indoors, where the weather would not impact his ability to earn a living. At this new job, Javier was offered health insurance for his family: $110 a week, $440 a month. However, Javier and his family rely on every penny of his paycheck to buy food and clothing; therefore, not making the purchase of health insurance coverage an option.

Javier's ten year–old son, Gabriel, has asthma, which gets worse in the winter months. In the past few years, the family has learned to manage his asthma. However, a couple of times a year, Gabriel's mother wakes up in the middle of the night to hear Gabriel struggling for air. She offers him chamomile tea and gives him a bath, hoping that the steam will help him breath better. Her remedies help—most of the time. But some times, he continues coughing and struggling for air, even after she has exhausted all of her home remedies. Not knowing what else to do, she takes him to the emergency room, where he receives the care he needs; and she is lectured about the importance of Gabriel using his inhaler on a daily basis. She is too embarrassed to explain to the nurse that without health insurance coverage, unless her husband is given the chance at the poultry plant to work overtime hours every week, his family cannot afford the cost of Gabriel's asthma medication, which is more than $100 a month.

Currently, Javier owes the emergency room over $6,000 in medical bills. For Javier and his family, depending on the emergency room is their only option for medical care. They have learned that even if emergency room visits are expensive, they can make small monthly payments and do not need to have cash on hand. Not being a United States Citizen or a Legal Permanent Resident, Javier's family does not qualify for Medicaid or North Carolina Health Choice, the publicly funded safety net insurance programs for most low-income North Carolina residents. Their family has no safety net; their only hope is that Gabriel will outgrow his asthma. For Javier and his family, like for most low-income families in our state, purchasing private health insurance is not an option, but a luxury they cannot afford. This case, unfortunately, is not an exception, but one that reflects the reality of many Latinos living throughout our state.

COMMENTARY

Caring for the Uninsured:

A Physician's View from the Safety Net

C. Annette DuBard, MD, MPH

Making do without health insurance is an experience familiar to an increasing number of Americans. By now, 13% of non-elderly adults have had at least one gap in coverage during any two-year period. Included among them are a disproportionate number of racial and ethnic minorities and an alarming proportion of the poor. Lack of health insurance typically does not reflect a lack of need for healthcare. On the contrary, the uninsured consistently have worse clinical outcomes and suffer greater risk of premature death than the uninsured.[1] The uninsured share something else in common—a front-row view of the worst our healthcare system has to offer: maldistribution of primary and preventive care availability, fragmentation of services and lack of communication between providers, and the exorbitant price inflation that results from layers of overhead costs and complex payer arrangements.

Inside the Safety Net

I work in the so-called safety net, as a family physician in a federally-supported community health center, where virtually all patients live below 200% of the federal poverty level, and 40% are uninsured. Community health centers pride themselves on providing affordable, comprehensive, patient-centered primary care regardless of a patient's ability to pay. By multiple measures, such clinics provide a quality of care that equals or exceeds that of other healthcare providers, alleviates the health disparities that are plaguing our nation, and reduces overall healthcare costs by decreasing preventable hospitalizations and emergency department use.[2-8] We are only one small piece of the safety net puzzle, which includes health departments and free clinics, hospitals and outpatient teaching clinics, and the countless private practice physicians who absorb much of the cost of caring for the uninsured.

It is a joy to provide a true medical home for patients who are so accustomed to being shuffled around and receiving band-aid solutions for immediate, acute healthcare needs, with no plan for follow-up care beyond "anywhere but here." Uninsured patients who find their way into a stable source of ongoing, affordable, comprehensive primary care must learn a whole new way of interacting with the healthcare system. It becomes possible for them to think beyond immediate concerns, toward long-term approaches to maintaining good health and responsibly managing chronic disease. My vantage point debunks the negative mythology that surrounds the uninsured. I don't feel like anyone is looking for an opportunity to sue me, or wanting "something for nothing." I don't feel a lack of "gratitude." Typically, the more I understand of my patients' lives, the more I respect what they're up against. Nationally, more than 8 in 10 uninsured come from working families. My billing office, which discounts charges based on the patient's income, reports that 90% of our patients pay 100% of what is asked of them.

> *"More than 40% of the uninsured have no regular source of care, and 20% consider the emergency room to be their regular source of care. Almost half have had to postpone seeking care because of cost within the past year."*

C. Annette DuBard, MD, MPH, is a family physician with Piedmont Health Services, Inc. in Burlington, NC. She will complete a preventive medicine residency at the University of North Carolina School of Medicine in June. She can be reached at annettedubard@hotmail.com or CB# 7240, Chapel Hill, NC 27599-7240. Telephone: 919-643-1674.

The Skill Set of Safety Net Providers

The core competencies of my job—what I know of the social, behavioral, and environmental determinants of health, the workings of social services, and the politics of healthcare—I've learned on the job, patient by patient. Taking care of the indigent uninsured requires a skill set that is not measured by any degree, board certification, or compensation system. It requires communication in a language that the patient can understand—for almost half of my patients, that means Spanish. For so many others, it's English at a fifth grade level. It requires a willingness to accommodate to the demands of my patients' lives—their complicated work schedules, frequent changes of address and intermittent phone service, the unpredictable availability of transportation or childcare from a friend or family member—which means working in one more patient at the end of today who didn't show up yesterday and taking on far more than just the "chief complaint" at any visit. It requires agility in pharmaco-economics at the micro level: emptying the grocery sack full of assorted pill bottles and samples or scrutinizing the stack of unfilled prescriptions from the last hospital discharge and starting over based on the amount of cash in the patient's pocket. Which can be substituted with a cheaper alternative? Could we get this one from a patient assistance program? What must be filled today; what can wait until the next paycheck; and what can we do without?

We learn, in the primary care safety net, an alternative way of doing medicine: what you can with what you've got. Expertise in our field requires knowledge of at least two approaches to any diagnostic or therapeutic problem. If you come to me with worsening asthma, or severe headaches, or abnormal liver tests, or infertility, I will flip straight to the section of your chart that tells me whether you have insurance. I will provide you the best care I can, but it will be tailored to your situation—which medications you can afford to try, which tests you can afford to undergo, how likely a specialist is to see you in consultation. I shoulder the knowledge that if my patient has a need that I can't take care of, that need will likely go unmet. So I've learned how to apply dental varnish for children who can't see a dentist. I do office procedures for which insured patients would be referred elsewhere. I work into my rushed visits tidbits of dietary guidance for diabetics who have no access to a dietician and brief counseling for patients suffering mental illness who have no access to a mental health professional. It is not enough.

When the Safety Net Falls Short

When patients' needs extend beyond primary care, my role is to help them navigate the healthcare system outside my doors, which is a challenge for anyone, but a particularly daunting task for those with no buying power (even if, like my patients, they live within 45 minutes of four hospitals, in a region of the state with one of the highest concentrations of specialist physicians). The tertiary medical center will say, "that sounds like something that can be handled at the local hospital," and the local hospital will say, "that sounds more appropriate for the tertiary medical center." For less urgent requests for consultation, any number of barriers may fly up. Patients may be asked to pay in full up front, to arrange an appointment with a financial counselor before a medical appointment can be made, to bring their own interpreter if Spanish-speaking, to send in written information or prior medical records for review and await a phone call if the referral is deemed appropriate. Important and substantial exceptions to this can be identified in every community, but institutional barriers to getting patients to the care they need grow in direct correlation with growth in the number of uninsured and under-insured. Too often, that means patients leave my office with the disgraceful advice: "you'll just have to go to the emergency room the next time it happens (the chest pain, the gallbladder attack, the seizure, the severe headache)."

It's Time for Real Solutions

All this is to say that strengthening the primary care safety net is a good and critical thing, but it will never be a substitute for universal health coverage. Despite federal initiatives that have emphasized expansion of safety net capacity in recent years, healthcare providers serving the uninsured are feeling increasingly strained. The 1.3% increase in total federal spending for care for the uninsured from 2001-2004 pales in comparison to the 11.2% increase in the number of uninsured over this time period.[9] More than 40% of the uninsured have no regular source of care, and 20% consider the emergency room to be their regular source of care. Almost half have had to postpone seeking care because of cost within the past year.[10]

Is it not shameful that in this, the richest nation on earth, 45.5 million people cannot count on access to basic healthcare services? Are we to be proud of our achievements in building the "best medical care in the world" while rationing that care in the most vicious of ways: all for some and none for so many? When I go to work tomorrow, I can expect to see someone whose colon cancer wasn't diagnosed until too late because screening was not available to her. I will see someone who has been disabled by a stroke because he never received adequate care for his high blood pressure and diabetes. I will see someone who keeps missing work or school because of asthma attacks, but cannot afford the medicine that would prevent them. What my patients need is not a safety net, but a healthcare system that makes sense. **NCMedJ**

COMMENTARY

A Perspective on the Dentally Uninsured

M. Alec Parker, DMD

For many fortunate North Carolinians, "access to care" is something that is taken for granted. Through employer-funded benefit plans, many people have dental insurance benefits that help defray some of the costs of dental care for themselves and their families. These dental plans have been especially popular within the benefit packages that are offered by larger companies and corporations as a way to recruit and retain employees. But this trend is changing. As employers seek ways to cut costs, some employees are experiencing cutbacks in their dental insurance coverage. Others are seeing those benefits disappear altogether. Although the loss of dental benefits is not nearly as devastating as the loss of medical coverage, it does create a financial hardship for those who do not have the discretionary income to spend on oral health needs.

Lack of Dental Insurance Affects Vulnerable Populations

In 2000, the United States Department of Health and Human Services published *Oral Health in America: A Report of the Surgeon General*,[1] which found that 108 million children and adults in the United States had no dental insurance—twice the number of Americans who had no medical insurance. And it seems that those who suffer the most as a result of the lack of insurance are the most vulnerable—the very young and the very old. Like any other problem, the first step toward finding a solution is awareness. Unfortunately, one of the most frustrating problems is that those individuals and groups who tend to be at the highest risk for dental diseases seem to be the most overlooked or most unaware. For example, some parents do not recognize the importance of caring for their children's primary teeth because most of those teeth will be gone by the time they are in middle school. They don't realize that they are important not only in the development of proper speech and a healthy self-image, but that they allow the permanent teeth to erupt into proper position. Others do not realize the negative impact that diets high in sugar can have on oral health. Of particular concern is the amount of soft drinks consumed by school-age children. It is alarming to note that 51 million school hours are lost each year due to dental-related health problems.

> *"...one of the most frustrating problems is that those individuals and groups who tend to be at the highest risk for dental diseases seem to be the most overlooked or most unaware."*

Elderly people face a different scenario. Many still harbor the belief that they should expect to lose their teeth as they get older. This belief tends to cause older adults to decrease the number of dental visits for routine preventive care at a time when their dentition is beginning to become more vulnerable. Tooth loss can lead to a multitude of dietary and lifestyle compensations. Many older adults find themselves in nursing homes or other assisted living facilities that can limit their access to dental care within their communities. Although some of these facilities have contracts with dentists to provide dental care to their residents, most utilize the offices of private practitioners to deliver care for those who are healthy enough to be transported. Without access to regular checkups and preventive visits, older adults face an increased likelihood of chronic oral pain resulting from periodontal diseases and tooth loss due to extraction for cases of untreated decay. If left untreated, these dental problems can limit normal daily activities, affect their nutritional intake, alter their level of independence, and complicate other existing overall health issues.

Dental Insurance

In order to understand the impact of being dentally uninsured, it is important to understand that there are some basic differences between dental insurance and medical insurance. One of those differences is that dental insurance plans have traditionally offered financial incentives for patients to seek regular preventive dental care, such as cleanings, examinations, and radiographs. These incentives are built into the reimbursement rates whereby patients receive up to 100% coverage for these diagnostic and preventive services. This encourages patients to visit their dentist regularly so that potential problems can be diagnosed and treated before they become both more complex and more costly. This arrangement works well for both the patient and the insurance company since it saves both parties time and money.

There are three types of dental insurance plans available in the marketplace—traditional insurance, managed care plans, and direct reimbursement. It is important to look at the most common features of traditional dental insurance plans and then see how those features compare with the other types of insurance. First, the traditional plan allows patients freedom of choice when it comes to selecting their dentist. There is no financial incentive for them to choose one dentist over another. Second, most traditional dental insurance plans have an annual maximum benefit. This is usually $1,000 to $1,500 per year for each individual covered by the plan. To further help promote preventive care and to control costs, most plans pay up to 100% of the cost of diagnostic and preventive services. For more routine restorative procedures, such as fillings, most plans pay about 70 to 80%. Reimbursement levels usually drop to about 50% for more complex restorative needs, such as crowns and other prosthetic appliances.

Managed care plans work differently. Insurance companies market these plans in an effort to help control their administrative fees and serve as an alternative to employers who might be looking to lower their premium costs while continuing to provide dental benefits to their employees. The most popular managed care plans being marketed in North Carolina are called "Preferred Provider Plans." Insurance companies seek to assemble a network of providers ("Preferred Providers") who agree to serve the dental needs of those patients whose employers have chosen to purchase the plan for their employees or offer the plan as an individual group purchase option. Managed care plans offer similar incentives to patients by encouraging regular preventive care. They also have annual maximum benefit levels as well as a tiered payment system based on the agreed upon fee schedules accepted by the participating dentist. The cost savings are available to the insurance company by recruiting dentists who agree to accept a fee schedule that is usually discounted 10-to-30% below the prevailing fees within the geographic area. In return for agreeing to discount his/her fees to those within this plan, the insurance company places the dentist's name on a list of their "Preferred Providers." As an incentive for patients to seek care in the office of a "Preferred Provider," they are often offered an additional discount relative to their out-of-pocket co-payments or deductible amounts.

The third, lesser known, type of plan is Direct Reimbursement (DR). This option was developed by the American Dental Association as a self-funded, tax deductible strategy to help employers control escalating premium costs while providing their employees with excellent dental benefits. Unlike traditional plans, there are no monthly premiums for employers to pay since there are no administrative costs built into DR. Employers only pay when an employee utilizes the plan. (Administrative fees charged by insurance carriers can account for up to 25% of the total annual costs of the plan.) Organizations that choose DR have the opportunity to select a dollar amount plan designed specifically for their employees, while setting an annual maximum limit for the year. This allows them to know their total investment for the plan without the worry of increasing premium costs year after year. It is interesting to note that since 1985, DR has experienced only a 2% turnover rate compared to the 10% or higher termination rate within other types of plans. This retention rate can be attributed to the cost-effective, non-networked dental benefits that are appreciated by both employers and their employees. Direct Reimbursement in North Carolina currently has 200+ participating groups covering more than 80,000 people, and it continues to gain market share in this very competitive environment.

Dentists Helping Low-Income Patients without Dental Insurance

For those individuals who are not fortunate enough to have dental insurance benefits and cannot afford to pay the total costs of obtaining dental care in a traditional fee-for-service environment, there are several opportunities for them to obtain dental care. Medicaid benefits are available to many low-income residents of North Carolina. The major barrier with having these benefits is finding a dentist who can afford to provide care given the low Medicaid reimbursement rates. Many counties have dental clinics within their health departments that charge fees on a sliding scale based on household income in an effort to make care more affordable. There are numerous "free clinics" sponsored by local dental societies where practitioners volunteer their time in the evenings or on days off to provide care at no cost. Often dental supply companies donate supplies to help support these charitable efforts. Finally, there are many dentists who provide care at reduced fees for those individuals and families in their practices and in their communities who cannot afford to pay their usual fees.

In addition to these ongoing efforts, there are also other events sponsored by local dental societies and charitable organizations that offer free care by targeting specific populations at different geographic locations throughout the state. For example, the American Dental Association and the North Carolina Dental Society co-sponsor "Give Kids A Smile" on the first Friday in February each year. On that day, each of the 100 counties in North Carolina has an event that provides some type of free dental care to children. Since the program began in 2001, more than 34,000 North Carolina children have received in excess of $3 million in dental care from more than

4,500 dental volunteers. The Duke Endowment and the Kate B. Reynolds Charitable Trust provide financial support for Mission of Mercy Projects scheduled in different locations across our state throughout the year. These are usually two-day events where volunteer dentists set up portable dental equipment in large buildings to provide free care to local low-income residents. It is not unusual for these events to provide free care to several hundred people in a single weekend.

Like any other problem, the first step toward a solution is awareness. The challenge is to effectively educate all of our citizens about the benefits of good oral healthcare regardless of their age or income level. This is especially true for those individuals who are in positions to affect public opinion and public policy. These state and community leaders must be made aware of the overall health risks that are exacerbated by poor oral health habits. If policy makers were aware of the growing body of evidence that suggests a very strong link between oral and systemic health, most would take a more proactive position on assuring that there were mechanisms in place to improve the oral health of our citizens. Improvements in Medicaid reimbursement rates for both children and adults would go a long way in helping to address care to the dental uninsured.

Improving Oral Health Depends on Our Commitment to Dental Care

The real answer to the problem of the low-income dentally uninsured population lies with our society and its degree of commitment to dental care. It is interesting to note that our government provides food stamps to help low-income populations purchase food. Those who are eligible for food stamps can use them at any grocery store to purchase food at 100% of the face value indicated on the food stamp coupons. Also, Medicaid reimbursements for covered *medical* procedures are reimbursed to our medical colleagues at amounts that are equal to 90 to 100% of the Medicare allowable rates. And although progress is being made to increase dental Medicaid reimbursement rates, many procedures continue to be reimbursed at levels less than 50% of their usual costs. At those rates, dentists are losing money each and every time they perform dental procedures for Medicaid recipients. The harsh reality is that society has determined that providing food and medical care for low-income individuals is more important than providing them with dental care. And, until the citizens of North Carolina, and specifically those who serve in our legislature, begin to think differently, we will continue to struggle to find innovative ways to address the dental, emotional, and other health-related problems that low-income individuals experience as a result of those current priorities. **NCMedJ**

Small Employers and the Provision of Small Group Health Insurance Coverage

Connie Majure-Rhett, CCE, and Kristen L. Dubay, MPP

Overview

Employers are the main source of health insurance for North Carolinians. In 2004, more than 60% of non-elderly North Carolinians accessed health insurance coverage through an employer-sponsored health insurance program.[1] However, small businesses are much less likely to offer health insurance coverage than larger business. In 2002 and 2003, only 29% of North Carolina firms with fewer than ten employees offered health insurance coverage, compared to 68% of firms with 10-24 employees, 79% of firms with 25-99 employees, and 90% of firms with 100 or more employees.[2]

One reason that fewer small firms offer health insurance coverage may be due to higher health insurance premiums, on average, for smaller firms. In North Carolina, 2002-2003 the average annual health insurance premium for workers in small firms with fewer than 50 employees was $3,597, compared to $3,206 for firms with more than 50 employees.[3] Small employers, those with 50 or fewer employees, are subject to health insurance rates set by state "small group" rating laws. These laws were modified in the 1990s to reduce the variation in premiums charged to small employers with similar employment characteristics. Small group rating laws are used to spread the health risks of small employer groups across a larger pool of workers. However, despite these laws, small-firm premiums continue to vary widely, and health insurance premiums are still higher on average for small firms than for larger firms.

Reasons for (Not) Offering Health Insurance

Nonetheless, some small employers still feel that it is important to offer health insurance to their employees. Some employers choose to offer health insurance in order to attract the most qualified workers. This may gain importance as our population ages—a serious concern for small employers. Beginning in 2006, for every two "baby boomers" who retire, only one new worker will join the workforce.[4] The decreasing size of the workforce is making the hiring process more competitive for small employers. As a result, the ability to offer a comprehensive benefit package, particularly one with healthcare coverage, is integral to attracting the most talented and qualified employees.

> *"Many workers remain in jobs that might not be their preferred position because of good health insurance."*

Offering health insurance is also connected to worker retention. Many workers remain in jobs that might not be their preferred position because of good health insurance. For example, married men who receive health insurance from their employer are approximately one-third less likely to leave their jobs than married men not receiving health insurance from their employers.[5,6]

A few small employers choose to offer health insurance coverage to employees because the employer would be unable to access affordable insurance for themselves or their own family members in the non-group market due to pre-existing health conditions. Other employers offer health insurance coverage in lieu of providing higher wages. Research indicates that some employees would support that decision. A survey conducted

for *The Wall Street Journal Online's* Health Industry Edition found that more than 60% of adults with employer-sponsored health insurance would prefer no pay increase while maintaining or increasing health insurance coverage rather than receiving a pay increase and a decrease in health insurance coverage.[7]

Nonetheless, employers' desires to provide health insurance coverage often contrast with their financial abilities to afford coverage. There are many reasons that employers choose not to offer health insurance coverage, but the main reason is cost.[8] In addition to the higher average health insurance premium costs for small businesses compared to large ones, small business owners also are often unable to hire a benefits manager and must spend considerable time completing the administrative tasks associated with offering health insurance.[9] Facing annual premium increases, many small businesses shop around for lower prices, compounding the administrative burden imposed on the owners or managers. Finally, in a small business group, a serious health event experienced by a covered worker can also significantly increase the premiums for the group as a whole in the following year, thus making it difficult to continue to offer insurance and maintain participation rates.

Another barrier that small businesses face is minimum participation requirements. Many health insurers require businesses to insure at least 50-75% of eligible employees in order to offer the coverage. Presumably, insurers have this requirement in order to prevent adverse selection into the plan. However, this requirement can be very challenging for small businesses, particularly for those with a high proportion of lower-income workers who cannot afford their share of the insurance premium. There are many small employers around the state who would like to offer coverage, but who cannot because they cannot meet the minimum plan participation requirements.

The Role of Small Businesses in the North Carolina Economy

Small businesses play an integral role in the state's economy. Therefore, everyone stands to benefit from ameliorating the challenges facing small businesses and their employees in their quest to obtain affordable health insurance coverage. In 2003, approximately 74% of private-sector establishments in North Carolina were small businesses with less than 50 employees, and 55% were very small businesses with less than ten employees.[10] Of all employees working in private-sector establishments in North Carolina in 2004, more than 26% of workers were employed by an employer with less than 50 employees, and 11% worked for an employer with fewer than ten employees.[11] Additionally, annual payrolls for North Carolina small firms with less than ten employees accounted for more than $9.5 billion in 2003, and small firms with less than 20 employees accounted for more than $15.8 billion in annual payroll.[12]

Therefore, when small businesses are unable to offer health insurance coverage to their employees, the economic impact is felt across the state. People without health insurance coverage use fewer healthcare services and often end up with health conditions that could have been prevented. As a result, the lack of insurance impacts worker productivity. Workers without insurance have 10% more sick days than those with healthcare coverage.[13] Additionally, some estimates indicate that providing health insurance coverage to those without it increases annual productivity and earnings by 10-30% annually.[14] Nationally, the Institute of Medicine of the National Academies estimated that between $65 billion and $130 billion is lost annually due to the poorer health and premature deaths of the uninsured.[15]

Policy Options for Small Business Health Insurance Coverage

Expanding health insurance coverage across North Carolina for all population groups would be beneficial, but the need for some immediate solutions is particularly acute for small businesses. There are a number of potential policy options at both the state and national levels for expanding health insurance coverage to small businesses. Some of them were highlighted in the North Carolina Institute of Medicine's *Covering the Uninsured Task Force report,*[16] and others have been introduced into the North Carolina General Assembly or in the United States Congress.

The North Carolina Institute of Medicine (NC IOM) Task Force recommendations that would particularly benefit small businesses include: development of a Healthy North Carolina program, implementation of a high-risk pool, expansion of the Medicaid program for low-income parents, and reviewing the impact of the state's small group reform laws. The Healthy North Carolina program would be targeted specifically for small businesses and sole proprietors. It would use government reinsurance to reduce the costs of a new private market health insurance plan for small employers, low-income individual workers, and self-employed individuals previously without health insurance coverage. It is expected that Healthy North Carolina would provide a 30% premium cost reduction over similar plans in the healthcare market, leading to health insurance coverage for approximately 33,500 currently uninsured North Carolinians.

The Task Force also recommended implementing a high-risk pool in North Carolina. There are many individuals with pre-existing conditions who work in or own a small business who would benefit from participation in a high-risk pool. A high-risk pool would control the premium costs of health insurance for individuals with greater health risk factors and take some of them out of the small group market. This could potentially have the effect of lowering the overall market risk and, thus, reducing costs for health insurance coverage in the small group market.

Another Task Force recommendation could benefit workers in small businesses through premium assistance for employer-sponsored insurance. The Task Force recommendation suggests expanding Medicaid to cover parents with incomes less than 200% of the federal poverty guidelines. Through this expansion and an associated waiver from the federal government, Medicaid-eligible parents could use state Medicaid funds to buy into their employers' health plans. As a result, this would help small businesses with low-income workers meet the plan participation requirements of insurance carriers.

Tiered benefit plans were also recommended by the Task Force; however, there is some concern among small businesses regarding the potential this could have for reducing healthcare coverage to "bare bones" plans offering only minimal coverage. Catastrophic coverage is very important to a small business because if a small business owner experiences a serious health event without catastrophic coverage, it could result in the bankruptcy of the entire business. Therefore, unless tiered benefit plans were linked with catastrophic coverage, these plans would not be optimal for small businesses. However, even limited insurance coverage is preferred to none.

North Carolina must also steer clear of supporting association health plans. Association health plans are a way for small businesses to pool their employees to spread health risks across a larger group in order to access lower premiums for health insurance coverage. In North Carolina, association health plans are required to meet the state consumer protection laws outlined by the Department of Insurance, which includes specific mandated services. However, there is a new bill in Congress, S1955 Health Insurance Marketplace and Modernization and Affordability Act of 2006, introduced by Senators Michael Enzi and Ben Nelson, that would enact national standards for regulating and administering health insurance. This bill would favor small group rating laws that lead to larger premium variations charged to small employers.[17] As a result, insurers could avoid offering state-mandated benefits if they offered a benefit plan that includes the mandates covered by the state employee health plans of the five most populous states. As such, insurers offering non-state mandated plans could attract the healthier consumers, thereby increasing the average health risks for the population remaining in health plans with mandated benefits. This could lead to higher premium costs and continued loss of insurance coverage for the smallest businesses and businesses with the highest-risk workers.

At the state and national levels, there are a number of other policy options that could be beneficial to small employers, particularly in the form of tax incentives for businesses that offer and/or contribute to health insurance for their employees. House Bill 20 was introduced into the North Carolina General Assembly in 2005 by Representatives Holliman, Bordsen, Goforth, and Ross. The bill recommends providing a tax credit for small businesses that pay for at least 50% of health insurance premiums for all eligible employees.[18] At the national level, United States Senator Olympia Snowe recently introduced the "Small Business Health Insurance Relief Act of 2006" (S2457), which would provide tax incentives to small businesses offering health insurance coverage to their employees. In particular, the law would offer greater tax credits to the smallest businesses, which have fewer than ten employees, and enable small businesses to offer "cafeteria plans" with non-taxable benefits.[19]

In addition, both the House and Senate of the North Carolina General Assembly have discussed the idea of a Healthy North Carolina model, similar to the one recommended by the North Carolina Institute of Medicine Task Force. In the 2005-2006 Session, the Senate discussed a proposed committee substitute, which focused on a version of the Healthy North Carolina model. The House of Representatives Select Committee on Health also chose a Healthy North Carolina model as one of their recommendations from the full committee, making it eligible for consideration in the 2006 short session.

Every year, small business surveys indicate that health insurance coverage is one of the top issues of concern to North Carolina small business owners. Small businesses need to remain steadfast in their work to find effective and realistic ways to access more affordable health insurance coverage for their workers. Supporting the introduction of the Healthy North Carolina program and a high-risk pool are two of the most important efforts small businesses could make to affect change in the near-term. At the federal level, support for tax incentives could also offer some relief. Small business owners and employees make up more than a quarter of the state's workforce and face much greater challenges accessing health insurance than workers in larger firms. To continue to keep North Carolina's economy strong and supported by this workforce, greater access to healthcare should be made available to small businesses. **NCMedJ**

COMMENTARY

North Carolina High-Risk Insurance Pools

David R. Moore, CLU

Imagine this: You are a 58-year-old man. You have worked all your life, paid taxes, and helped support your family. Two years ago you had a mild heart attack. Your wife has diabetes and high blood pressure. Luckily, you had health insurance through your job that helped you pay for the hospitalization, doctor's visits, and necessary medications for you and your wife. With a new diet, exercise, and the medications, you both are doing well managing your health problems. A little over a year ago, you lost your insurance when your company downsized. You found another job, but your current employer doesn't offer insurance. Your wife also works, but she works for a small employer that does not offer coverage. So, you pay approximately $600/month for continuation coverage (COBRA) for your wife and yourself through your former employer. Last month, you found out your COBRA coverage is about to end. You want to continue to buy insurance coverage, but you were told that purchasing a comprehensive policy with a $1,000 deductible (70% coinsurance) that covers your needed medications would cost more than $4,000/month for your wife and yourself.

All of us know people with health problems; these are the people who most need health insurance. But, have you ever stopped to think about how difficult or expensive it is to buy health insurance if you have pre-existing conditions? As a health and life insurance underwriter (independent insurance agent), I frequently work with families who want to buy health insurance, but have problems because of their past health history or ongoing health problems.

State and federal laws provide some protections for people who have health problems if they work for an employer who offers coverage. Under these laws, people with employer-based coverage cannot be charged higher premiums or excluded from coverage because of their pre-existing health problems. However, these same protections don't generally apply to individuals who want to purchase health insurance in the non-group market. There is currently only one insurer in North Carolina—Blue Cross and Blue Shield of North Carolina (BCBSNC)—that will cover anyone, regardless of their health status. However, the premiums charged are high, because people with pre-existing health problems typically incur greater than average healthcare costs. The premiums charged to people with the most serious health problems may be seven times higher than the premiums charged to a healthy individual. This premium is unaffordable to most families.

Thirty-three other states have established high-risk pools to offer comprehensive health insurance coverage to people with pre-existing health problems. These high-risk pools are similar to high-risk auto insurance. In North Carolina, individuals with poor driving records can purchase automobile insurance—at a higher rate—through the state's high-risk automobile pool. The pool is financed through premiums and an assessment on all of the automobile insurers in the state.

The states that offer high-risk health insurance typically cap the premium charged to families to make the coverage more affordable. Generally, the premium can be no more than 1.5 times (or 150%) of the standard rate charged to comparable healthy individuals.[a] However, because these premiums do not cover the full costs of the healthcare services that the insured high-risk individuals use, states pay for the deficits through assessments on insurance companies, state appropriations, or other means.[b,1] For the last five years, the North Carolina Health Underwriters Association has advocated that North

---

[a] Most states cap the premium at 150% of the standard rate; however, a few states allow premiums to be up to 200% of the standard rate. Health plans typically vary insurance premiums based on the person's age, gender, and geographic location. In a high-risk pool, the 150% cap would be based on a healthy person with a similar age and gender and living in the same geographic area of the state.

[b] Twenty-seven states finance the losses in their high-risk pool through an assessment on insurers. Of these, 11 states provide full or partial tax credits to offset the assessment, effectively shifting the costs back to the state. Seven states have a broad assessment on insurers, including commercial insurance carriers, stop-loss or reinsurance carriers, third-party administrators on a per-person/per-month basis. Two states pay for the losses through a surcharge on hospital bills, and five states use general revenues to fund their losses.[1]

David R. Moore, CLU, is with David R. Moore, CLU and Associates and Past President of the North Carolina Health Underwriters Association. Mr. Moore can be reached at mooreclu@netpath.net or PO Box 1006, Burlington, NC 27216. Telephone: 336-584-3781.

Carolina join the majority of other states and create a high-risk pool to provide affordable coverage to the people with pre-existing health problems.

Two bills have been introduced in the North Carolina General Assembly that would create a high-risk pool: HB 1895 (introduced by Representatives Insko, England, Nye, and Wright, with 28 other co-sponsors) and SB 1681 (introduced by Senator Purcell). The House Select Committee on Health and the North Carolina Institute of Medicine's Task Force on Covering the Uninsured supports similar legislation. While these bills may change as the legislation is debated in the General Assembly, the proposed legislation accomplishes the goal of providing more affordable health insurance to people with pre-existing health problems.

Under the introduced legislation, people with pre-existing health problems would be eligible for the pool if they had been turned down by two insurers due to pre-existing health problems, charged premiums by two insurers with higher rates than offered through the high-risk pool, or offered a health plan by two insurers with conditional riders that exclude coverage for the pre-existing health conditions. Individuals could also qualify if they have specific health problems that were identified by the plan administrators as eligible for coverage, such as HIV/AIDS. Certain other people who do not have pre-existing health problems can also purchase health insurance through the pool if they are unable to find better health insurance coverage in the private market. These include individuals who are guaranteed coverage in the non-group market under the federal Health Insurance Portability and Accountability Act (HIPAA) laws (described previously), or people who lost their insurance when their employer downsized or closed due to the Trade Adjustment Act.

> *"Many of these individuals want to buy health insurance, but can't afford the policies that currently exist."*

Like most other states, the current legislation caps the premium at 150% of the standard rate charged by other insurers offering health insurance to individuals. Rates can be adjusted by age, sex, and geographic variation in claims cost in accordance with established actuary and underwriting practices. In addition, the bills that were introduced would also provide an additional premium subsidy for lower- or moderate-income families to help them afford their health insurance premiums.

The pool would offer several different plans, including Preferred Provider Organization (PPO) plans with different deductibles and cost-sharing levels and at least one high-deductible Health Savings Account plan (HSA).[c] The plans must include at least a $1 million lifetime limit and sliding-fee scale annual limit on out-of-pocket expenses of $2,000-$5,000 based on family income.

This is not the first time that high-risk pool legislation has been introduced in the North Carolina General Assembly. Similar legislation to either establish or study the need for a high-risk pool has been introduced at various times dating back to the 1980s. Historically, the major stumbling block has been the mechanism to finance the uncovered claims costs (e.g., the healthcare costs that are in excess of the premiums collected). Insurance companies have opposed past attempts to finance the uncovered costs through assessments on covered lives. They were concerned that an assessment focused solely on commercial insurance companies, like Blue Cross and Blue Sheild of North Carolina, United Healthcare, Cigna, Wellpath, Fortis, and all other providers of health insurance products in North Carolina, would raise the costs of their premiums, leading more employer groups to self-insure in order to avoid paying the assessment. Provider groups similarly opposed any attempts to cover losses through a provider assessment, arguing that the assessment was nothing more than a "sick-tax" (e.g., tax on sick people). The General Assembly has never been willing to appropriate state funds to finance a high-risk pool.

This year, the legislation is structured differently. Instead of singling out any one group to bear the burden of financing the losses, the legislation spreads the burden across multiple groups. The bill limits provider reimbursement to the Medicare rates, which is lower than what is typically paid through commercial insurance plans. By accepting this lower reimbursement, providers help by lowering overall healthcare costs and therefore, the amount of financial loss to the plan. The proposed legislation also assesses insurers to help pay for the losses. However, unlike past attempts that focused the assessment on commercially insured plans, this legislation calls for a broader-based assessment on commercially insured plans, multiple employer welfare arrangements (MEWAs), third-party administrators (TPAs), administrative service organizations (ASOs), and reinsurers. This helps spread the costs to employer groups that purchase health insurance through commercial insurers, and indirectly, to those who self-insure (by assessing third-party administrators or reinsurers). The legislation also calls for a general appropriation to help subsidize the costs of insurance coverage for lower-income or moderate-income individuals. Congress also appropriated $75 million annually through 2010 to help states offset some of the losses incurred in high-risk pools, and another $15 million to provide

Individuals can withdraw funds from the savings account to pay for healthcare expenses up to the deductible amount.

grants of up to $1 million to help states, like North Carolina, establish a high-risk pool.[2]

> *"The premiums charged to people with the most serious health problems may be seven times higher than the premiums charged to a healthy individual."*

Making health insurance coverage affordable to people with pre-existing health problems is not only the "right thing to do," it is also a smart investment. People who have chronic illnesses or other serious health problems (such as cancer) are more likely than healthier people to need healthcare services. Many of these individuals want to buy health insurance, but can't afford the policies that currently exist. So instead of creating a health insurance product that captures the premium dollars these people are able to afford, we force many people to go without insurance coverage. Without insurance, they are more likely to forgo the care they need to manage their health problems, and their health suffers as a result. Many end up in the hospital with problems that could have been prevented, with no way to pay for the outstanding hospital bills. Large outstanding healthcare bills (often caused by lack of insurance coverage) is one of the primary reasons that people go into bankruptcy.[3] This affects not only the individual family and specific healthcare providers, but other creditors as well. Further, all of us who have health insurance pay higher premiums to help cover the costs of services provided to the uninsured. Thus, by creating an affordable insurance product for those with prior health problems, we both make it easier for these individuals to obtain needed health services in a timely way in an appropriate—and hopefully less costly—setting, but also help capture the funds these individuals can afford to pay for needed healthcare services. **NCMedJ**

Advocating for Healthcare

In 1983, I began a journey that taught me the inadequacies of the health insurance industry. My daughter was born with a birth defect known as microtia. Within 18 months of her birth, my husband became unemployed, and as a result, we lost our health insurance coverage. My husband found employment in North Carolina, and we moved in 1985. During this time, I spent countless hours researching microtia and seeking medical care for my daughter.

In 1989, I finally found doctors who could care for my daughter, and I thought our troubles were over. However, we were quickly denied coverage because she wasn't born on the health insurance plan that we were now under. The reality was that the insurance plan included a clause that exempted all claims for a child with a birth defect unless the child was born under the plan. This was not a pre-existing clause that would give coverage after a period of time, but a clause that prohibited payment at any time for that defect. We chose to fight the claim denial since we had not been able to secure a proper diagnosis for our daughter previously, and the surgery that she needed was not usually done prior to the age of seven years. With the help of our daughter's doctors, we advocated for her care and won our case. Once again, we believed our troubles were over since our daughter was going to receive her much needed medical care. We hoped that this chapter of our life was closing, and life would move on.

As life would have it, in the next few years my husband was laid off from his job again. In a funny coincidence the company he was working for (a small business with less than ten employees) was denied health insurance coverage. One week after his lay-off, the company secured health insurance coverage. Tired of living through unemployment at life's twists and turns, we decided to open our own business. We thought that we had taken control of our own fate, but now we became our own small group seeking health insurance coverage. This presented a challenge all it's own without having the additional difficulty of a child with a congenital defect.

During the ten years we owned our business, we were never able to obtain health insurance for two main reasons:

- The cost was prohibitive—in the mid-1990s, I received quotes for health insurance for our family that were between $800-$1,000 per month.
- We were asked to sign a waiver that stated we would not seek coverage for anything related to our daughter's birth defect.

After our previous experience with insurance claims, we were not comfortable signing an agreement that gave up our daughter's right to coverage for her medical condition, and as a result, we weren't insurable. In the end, we resolved the situation by closing our business. Our overwhelming concerns for our family's health lead us to seek employment with large employers where our daughter's condition would not be a factor in health insurance coverage. We knew we had an overwhelming obligation to our entire family and how devastating a medical emergency could be financially. We went through a difficult transition as we adjusted to less monthly income, but we felt more secure knowing that our children were now protected by a health insurance plan.

Today, we are glad that our situation has been resolved. However, I continue to be greatly concerned about healthcare in the United States and the countless others who are not able to find alternate employment to reconcile issues such as these. Everyday, I hear the concerns of others who are struggling with insurance issues and finding it increasingly difficult to maintain their families' financial and physical health.

COMMENTARY

Insuring North Carolina's Working Poor:
Building the Foundation

L. Allen Dobson, MD

The work of the Covering the Uninsured Task Force of the North Carolina Institute of Medicine and the subject of this Journal forum is extremely timely and focuses on maybe the most important healthcare issue facing our state in decades. Basic affordable healthcare is essential to the health of our state, our citizens, and our economic future. There are no simple solutions, but we must start now building the foundation programs that will allow us to assure all our citizens have access to needed basic healthcare and affordable health insurance in the future.

North Carolina has made great strides over the past decade in providing health insurance for our states poorest children through expansion of our Medicaid and Health Choice programs. Medicaid, while covering over 800,000 North Carolina children and mothers, also serves a vital role in providing care for our 400,000 poor elderly and disabled citizens. Despite recent difficult economic times and severe state budget shortfalls, North Carolina has avoided many of the draconian cuts and eligibility reductions experienced in other states. While North Carolina has not been forced to exercise major cuts to its Medicaid program, controlling Medicaid spending remains a top priority. Through expanding our successful Community Care of North Carolina program statewide and inclusion of the aged, blind, and disabled Medicaid recipients in our clinical management strategies, we can reduce the rate of expenditure growth in the Medicaid program without sacrificing quality or access to needed services. Community Care networks are now well organized regional networks of physicians, hospitals, health departments, and social service agencies charged with developing improved local systems of care for Medicaid recipients focusing on quality, disease management, and targeted utilization initiatives. This public-private partnership between the Department of Health and Human Services and community providers has produced needed savings, slowed the Medicaid growth rate, and improved the quality of care provided to our Medicaid recipients.

> *"As we focus on exploring low-cost options for providing health insurance to more of our citizens, it is important to support and expand the fragile safety net of providers available to our poorest citizens without insurance until coverage is available to all."*

As we focus on exploring low-cost options for providing health insurance to more of our citizens, it is important to support and expand the fragile safety net of providers available to our poorest citizens without insurance until coverage is available to all. Increased funding to these traditional providers, such as community health centers, public health departments, rural health clinics, and free clinics, is needed to help meet the needs of poor citizens. The care of the poor and uninsured, however, can not be left solely to these providers. A coordinated, community system of free care is needed until we are able to provide more of our citizens with affordable health insurance. The success of Project Access in Asheville and the many similar projects across the state, initially funded by federal Healthy Community

L. Allen Dobson, Jr., MD, is Assistant Secretary for Health Policy and Medical Assistance, North Carolina Department of Health and Human Services. Dr. Dobson can be reached at allen.dobson@ncmail.net or 2501 Mail Service Center, Raleigh, NC 27699-2501. Telephone: 919-855-4100.

Access Program (HCAP) grants, illustrates the importance and often unstated role of private physicians in the community safety net. The success of these community efforts to include private primary care access as well as traditional safety net providers in an organized system has successfully expanded the capacity of the system to care for the poor without significant increases in funding. Providing basic primary care through these community-organized systems prevents delay in needed care and often more serious, costly, and unnecessary complications.

This Journal expertly outlines the many options available for expanding affordable health insurance to many more North Carolinians. While the task of covering everyone seems daunting, the recent announcement of the Massachusetts federal waiver approval that creates state-subsidized insurance for low-income working adults and also mandates health insurance for all citizens should illustrate that universal coverage is possible to achieve. Each option presented by the North Carolina Institute of Medicine Task Force on Covering the Uninsured report, *Expanding Health Insurance Coverage to More North Carolinians*[1] is important in providing insurance to different populations of citizens who have no insurance. While Medicaid and North Carolina Health Choice provide health insurance for many of our poorest children, their parents are often uninsured. Childless adults, no matter how poor, have no options for coverage. Many working citizens simply cannot afford the cost of health insurance. It is clear that no one strategy alone will provide for everyone. We must start small, recognizing that there are not sufficient funds available to accomplish the task of full coverage immediately. Long-term success will come from developing programs that also include quality improvement, disease management, and utilization management as important components to assure that the cost of new programs do not grow at a rate that would jeopardize their future. Community Care of North Carolina has shown that such strategies, when implemented locally, can save money while improving quality.

As additional savings are realized in our Medicaid program, it will be important to reinvest some of those savings in building the foundation programs to expand health insurance to all North Carolinians. Building the foundation for providing affordable health insurance for all of our citizens will require a continuing dialog and a strong commitment not only from government, but also businesses, healthcare providers, and citizens. We must start now. It is time for North Carolina step forward to assure healthcare for all of our citizens. **NCMedJ**

Public Policy Options for Small Employer Health Insurance

Barbara Morales Burke, MHA

Despite the fact that fewer people are covered under an employer health plan than have been in the past, employer-based insurance is and likely will remain the cornerstone of our health insurance system for the foreseeable future. Employees of small firms are less likely than employees of large firms to be offered insurance through their job and, as a result, more likely to be uninsured. For example, data from the 2002-2003 Medical Expenditure Panel Survey showed that only 57.2% of employees working in firms with fewer than 50 employees were offered health insurance. Small firms employ a significant portion of North Carolina's workforce, so the lack of insurance among these firms is a serious public policy concern. Policy options aimed at improving our rate of insured among employees of small firms can and should be considered.

> *"Small group regulation cannot be adjusted to produce dramatic change because [it] is based on cost shifting..."*

Before considering these options, it is useful to understand certain aspects of North Carolina's regulation of small group health insurance premiums. Premiums for small employer groups (those ranging in size from self-employed individuals up to firms with as many as 50 employees) are set using a methodology known as "adjusted community rating with rate bands." The "community rate" is the statewide expected per-person annual claims cost for an insurer's entire book of small group business. The "adjusted community rate" is the differentiation in premium costs from the community rate for a particular small group, based on the small group's "case characteristics," which are defined as age, sex, family composition, and geographic location.

Using the community rate creates a substantial subsidy effect on the premiums charged to groups whose members have higher than average medical risk, because the premium rate for all small group insureds, regardless of risk status, is generated from the same starting point. In other words, higher-risk groups benefit from subsidies because the costs are spread across the groups that are less costly to insure. Working from the community rate, each small employer's premium is adjusted to reflect their differences in expected medical costs due to case characteristics and the specific benefit plan chosen. In addition, premiums are permitted to differ—up to 20%—based on the estimated medical risk of the specific group. Thus, North Carolina laws governing small group health insurance premiums reflect a balance of three rating philosophies: a substantial subsidy effect for groups with higher medical risks, full differentiation based on demographics, and limited differentiation based on medical risk.

Potential Changes to Current Small Group Regulation

Small group regulation cannot be adjusted to produce dramatic changes because this regulation is based on cost shifting rather than the underlying healthcare costs that influence insurance premiums. However, some pricing improvements can be achieved through modest adjustments to current law.

Some employers and interest groups advocate for increasing the subsidy effect for the higher-risk employees, while others advocate for reducing the subsidy effect so coverage wouldn't be too expensive for lower-risk employees. A change to our current system will create undesirable tradeoffs at either extreme since it is based on a cost-shifting approach. Because increasing the subsidy effect produced by the rating process shifts more expense to employers and employees who have fewer health risks, fewer employers will be able to afford the higher-cost insurance, and the youngest and healthiest employees offered coverage on the job may decide it is not a good value and opt out. As those with fewer health risks (i.e., the number of those who cost the least insure) leave the market, the community rate

---

Barbara Morales Burke, MHA, is Chief Deputy Commissioner at the North Carolina Department of Insurance. Ms. Morales Burke can be reached at Bburke@ncdoi.net or 1201 Mail Service Center Raleigh, NC 27699-1201. Telephone: 919-733-0433.

rises. Therefore, in reality, increasing the subsidy effect too much would actually produce the opposite of the effect intended—it would inadvertently lead to a lower subsidy effect because there are fewer healthy people in the group to diffuse the costs incurred by those with higher health risks. On the other hand, a rating system that extracts a smaller subsidy from the low-risk groups would increase the likelihood that coverage would become prohibitively expensive for the high-risk groups. Therefore, too great a decrease to the subsidy effect would benefit only the healthiest people and would cause higher numbers of uninsured among less healthy employees. A balance between [these opposing forces] providing a sufficient subsidy effect to help those who cost the most to cover, but not so much subsidy that it drives the low-risk employees out of the market—produces the most beneficial overall results from a public policy standpoint.

The North Carolina Department of Insurance (NCDOI) recently recommended to the North Carolina General Assembly House's Select Committee on Health Care adjustments to the state small group rating laws that would reduce premiums for groups with lower medical risks or certain demographic factors that make them less costly to cover. These changes would result in a modest decrease in the subsidy effect for groups with higher medical risks or certain demographic factors that make them more costly to cover. An additional effect of these changes would be *lowering* premiums or to reducing premium increases for all small groups. This would occur because more lower-risk employees would be able to buy and retain coverage, which would depress the average claims cost and boost the subsidy effect that the community rate has for higher-risk employees. This latter effect is the reason that NCDOI recommends these rating changes.

Some state and federal legislation—most notably bills proposing special treatment for association groups[a]—purport to reduce the high cost of health insurance for small groups. However, these approaches have been flawed due to the fact that they would reduce (or eliminate completely, by fragmenting the small group market) the subsidy effect for higher-cost small employers without providing any offsetting benefit to these groups. Some of these proposals go even further, suggesting the deregulation of association health plans, which would create an un-level playing field within the market and deprive some citizens of consumer protections under state law. As a result, lack of insurance would become an even greater problem for employers whose employees are higher-risk. Association health plans are not a part of the solution for small employers.

New Product Options

New health insurance products may keep coverage affordable for employers who currently offer health insurance coverage to their employees. These products may also appeal to some employers and individuals currently unable to afford to offer or buy coverage. Examples of these products include: high-deductible health plans offered alone or in conjunction with health savings accounts, "limited benefit plans" that cover a certain amount of costs up-front or after meeting a high deductible, and so-called "tiered benefit plans" where an employer contributes toward a base plan with the option for employees to "buy up" to a richer plan. In a few cases, a change to state law would be required to allow these products to be offered or to enable these products to function as intended; in other cases, insurers can and do offer them now.

Proliferation of plans that provide less coverage raises concerns over the financial barriers to obtaining necessary care and whether some employers now offering more comprehensive plans will "trade down." But the reality is, without alternatives, some employers who currently offer coverage may drop it in the future due to cost, and people who cannot afford coverage now will continue not to have any options. A more pressing concern is that these products actually offer value to someone who presently does not have insurance; without value, these products will not even provide incremental improvement in the numbers of uninsured among employees of small firms.

Realistically, alternative products are needed as a part of any multi-pronged approach to sustaining and expanding the small group market. Although tempting from a public policy standpoint, placing limitations on the sale of certain products in an attempt to prevent them from being substituted for more generous coverage is not practical, since there is no way to identify employers or employees who would have to drop coverage due to cost in a future period, but for having the ability to switch to an alternative product. However, requirements can and should be used to preclude the offering of alternative products in a way that subverts small group regulation.

Additional Ways to Subsidize the Cost of Coverage

Because health insurance premiums are simply unaffordable for some employers and employees, additional forms of subsidy may be required to enable some to buy or continue to buy insurance at its present true cost. Attention in our state has focused on tax credits for employers offering coverage and on a program (dubbed "Healthy North Carolina") offering coverage reinsured[b] by the state. Ideas for other, more simple subsidy mechanisms should also be considered.

Tax credits for employers' contributions toward health insurance may help some employers continue to afford offering coverage when they might not otherwise be able to do so. Critics of tax credits rightly point out that credits will reward employers who would offer coverage even without a credit, and therefore are not an efficient use of state funds. Targeted credits, such as credits for employers with lower-paid employees or those not currently offering coverage could be a more effective

---

[a] Association Health Plans are groups of small employers pooling together to self-insure.

tool to contain or decrease the ranks of the uninsured.

The Healthy North Carolina proposal, modeled after an existing program in New York state, would rely upon state-provided reinsurance to reduce the level of premiums that insurers would charge eligible employers and workers for coverage. For this program to work in North Carolina, key differences between this state's and New York's insurance market must be addressed. Funding for the reinsurance needs to be both adequate and reliable in order to have the desired effect on premiums. Premiums and benefits need to appeal to the target population. Eligibility and other program rules need to be set in such a way as to avoid attracting only high-risk groups to the program and also avoid causing erosion of the existing small group insurance market. Even with all of these conditions satisfied, the opportunity to buy health insurance at subsidized rates does not guarantee increased uptake among small employers and employees. However, if there is the will to use state funds for a program such as this, the task of properly structuring it is doable, and the opportunity to thoroughly explore this option should not be passed up.

Addressing the Cost of Medical Care

Although the other policy options discussed here may present some opportunity to reduce the net (or effective) premium costs paid by small employers and their employees, they do not address the primary driver of the cost of health insurance—the cost of the medical care that the insureds receive. Containing the cost of care will entail employing a wide variety of tactics to exploit numerous opportunities for improvement. Chief among these are reducing the amount and level of care needed through promotion of healthy lifestyles, better disease management, and improved treatment protocols. The full impact of initiatives to address these and the other factors fueling the growth of healthcare costs will not be realized all at once or in the short-term. However, tackling medical costs is the only way to achieve meaningful, sustained improvements to the insurance market as a whole.

Conclusion

The small group health insurance market in North Carolina can be improved through a number of policy approaches that can work individually or in combination.

- First and foremost, maintain the basic framework of our current small group regulation. Do not allow or support changes to small group regulation that would fragment the market and benefit only the healthiest workers. This is necessary regardless of any other policies adopted.
- Make adjustments to the details of small group rating law as recommended by the Department of Insurance, in order to realize modest beneficial effects on premiums.
- Allow insurers to offer alternative benefit plans that can help employers continue to afford offering insurance and appeal to some of those employers and employees in the small group market who do not currently offer or buy coverage. Do not allow or encourage products that would undermine the small group market by circumventing small group regulation.
- Use state fiscal policy to subsidize the cost of coverage in order to help employers who currently offer coverage to continue offering it, and enable or encourage employers who are not offering coverage to do so. Target these funds to help those most at risk of having to drop coverage due to cost and those who are the least able to afford insurance today. Make sure that no mechanism used to provide subsidies has a harmful effect on the small group market.
- Implement policy and support specific initiatives to reduce the total cost of medical care provided over the long term.
- Take actions aimed at reducing the numbers of uninsured outside of the small group market that also have a positive impact on small groups. Examples include approving a limited expansion of Medicaid for low-wage workers so that the burden of uncompensated care on all (including the small group market) will be reduced, and establishing a high-risk pool for individual coverage so that removing self-employed individuals (the most risky of all small groups to cover) from the small group market can be considered as an option in the future, and the cost of subsidizing these costly groups can be spread beyond the small group market. **NCMedJ**

---

b Reinsurance is essentially insurance coverage for insurance carriers. If the annual claims for an individual in the plan reach some predetermined amount, then the reinsurer covers at least some part of the claims above that level.

COMMENTARY

Controlling Healthcare Costs:
The Key to Making Coverage Affordable

Robert J. Greczyn, Jr.

Never before in our history have Americans enjoyed such a wealth of healthcare options. The diagnosis, treatment, and cure of illness and disease have rapidly improved in recent history, thanks to groundbreaking research, blockbuster drugs, and technological innovations.

But the seemingly unlimited care and treatment options we have grown to rely on come at a price—to us individually and as a society. For those with health insurance, it takes an increasingly large chunk of each paycheck to cover insurance premiums and medical care. For those without insurance, the cost of their care is left to taxpayers and paying customers, and that burden is growing larger every year.

We're at a point in time in which we can no longer continue business as usual in our healthcare system. As health costs continue their upward march, attention is squarely—and rightly—focused on what can be done to expand access to medical care. The health insurance industry is actively engaged in developing solutions to the growing problem of the uninsured, both in North Carolina and across the nation.

> *"Never before in our history have Americans enjoyed such a wealth of healthcare options."*

The Root Cause

The collective cost of medical procedures, drugs, and devices has risen to the point that the United States now spends 16% of gross domestic product (GDP) on healthcare,[1] which is more than ever before. One reason is demographic: our population is older, with a vast cohort of baby boomers reaching 60 this year. Perhaps more important from a public health standpoint, our society continues to engage in unhealthy living. Poor diet, lack of physical activity, and tobacco use are driving up healthcare costs.

The price we pay for this lifestyle is increased rates of costly chronic illnesses, such as heart disease, cancer, and diabetes. Obesity rates have skyrocketed in adults and in children, with frightening consequences. Once a rarity among children, Type II diabetes (in a simpler era called "adult onset diabetes") is occurring more frequently and condemning children to a life of poor health and increased healthcare costs. We all share in the cost of treating an unhealthy society.

For Blue Cross and Blue Shield of North Carolina (BCBSNC), the unhealthy segment of our membership has a greater impact on our total costs. Our data show that 80% of our costs are driven by only 18% of our members.[2] This puts tremendous pressure on the insurance system, driving premiums up at a faster rate than earnings for employers or their workers. This cost crunch inevitably shrinks the percentage of businesses that offer insurance benefits to their employees. In the end, we cannot broaden access to health insurance without a solid plan for addressing underlying cost pressures in healthcare.

Some say that higher healthcare costs are a good trade-off for getting the best and most up-to-date medical care. We pay more because medical care is so much better, so what's the problem? One of the most frustrating aspects of the United States' cost spiral is that, although we spend more per person on healthcare than any other nation, we are far from the healthiest nation. By various measures, including data from the World Health Organization, the United States ranks about 30th in the world for the health of its people. We don't seem to be getting value from all the additional dollars pouring into healthcare.

Insurers' Response

To address the uninsured problem, the question we must ultimately ask is, "What can we do to stem the tide of rising healthcare costs to make coverage affordable for more people?"

Robert J. Greczyn, Jr., is President and CEO of Blue Cross and Blue Shield of North Carolina. Mr. Greczyn can be reached at bob.greczyn@bcbsnc.com or PO Box 2291, Durham, NC 27702. Telephone: 919-765-7831.

There is no simple answer, and progress clearly depends on individuals, families, insurers, employers, providers, government, public health—all healthcare stakeholders—working together. It will also require a sea change in how we value preventive medicine in relation to more reactive care.

Insurers grapple with how to be involved in this long-term process while still delivering cost-effective insurance products that meet customer needs today. We have to balance investment in new approaches with the likelihood that our customers will see a reasonable return on these investments. Some health promotion efforts accrue benefits to our members immediately. Others take time to realize. Efforts to educate patients with diabetes or asthma, for example, on how to take better care of themselves provide a quicker return by reducing the need for emergency room visits and hospital stays. The payback on heart disease, meanwhile, is more long-term.

One new trend among insurers is the movement to consumer-directed health plans. These plans offer coverage at lower premiums but with higher deductibles, giving consumers more choices in designing and paying for a health plan. One of the most promising aspects of consumer-directed healthcare is Health Savings Accounts (HSAs) that pair health coverage with tax-advantaged savings accounts to pay for medical care. HSAs can also be designed to cover limited preventive health services at no charge.

For the consumer-directed model to succeed, patients will need to not only engage in purchasing decisions—based on information from their physicians, insurers, and other sources—but they'll also need to change their behavior. In our current model, consumers tend to act on what their doctors recommend, with the understanding that their insurer will pick up the tab. The consumer-driven approach says that patients are more in charge of their own care since they have a greater financial stake through higher deductibles, health savings accounts, and other methods of paying for the services provided.

In another change, insurers have found success in helping consumers reduce their costs by promoting the use of generic prescription drugs. Generics are equal to brand-name drugs in active ingredients, yet cost 30% to 70% less.[3] Blue Cross and Blue Shield of North Carolina instituted programs waiving co-payments on generic prescriptions for our members in late 2004 and early 2006, encouraging them to make the switch from brand-name drugs to more cost-effective generic substitutes. Over a three-month period in 2004, BCBSNC members collectively saved approximately $17.6 million in out-of-pocket costs.[3] But there are also long-term benefits: about 22% of members stayed with generics,[3] leading to significant savings in coming years. Our challenge now is to show physicians the value of generics when appropriate for their patients so that the cost advantages can be spread to all patients, not just BCBSNC members.

Additional efforts in North Carolina show promise for a long-term payoff. As the largest health insurer in the state, BCBSNC in 2000 established a foundation to address health needs in North Carolina. Two years ago the Blue Cross and Blue Shield of North Carolina Foundation entered into a five-year, $10 million partnership with the North Carolina Association of Free Clinics to sustain and expand the free health clinic model throughout North Carolina. Funds from the Foundation already have allowed six new clinics to open. By the end of the five-year period, the capacity of free health clinics to serve the uninsured in North Carolina is expected to double.

In another partnership, the BCBSNC Foundation is contributing to the expansion of the Community Practitioner Program run by the North Carolina Medical Society Foundation. The goal of this $10 million grant by the BCBSNC Foundation—which triggered $5 million in matching funds from the Medical Society Foundation—is to help place primary care physicians and nurse practitioners in underserved areas of North Carolina, such as rural areas and inner cities with few medical providers, and keep them there.

Consumer Awareness

One of our challenges is to help make consumers more aware of the true costs of healthcare in today's world. For many, healthcare costs begin with the insurance premium and end with a small co-payment or deductible. This means there is little understanding of the actual costs of physician services, hospital care, or drug treatments.

This disconnect between costs and services undermines market forces that exist in other sectors of our economy. The result is that medical services may be overutilized, or at the very least, that care is not delivered in the most cost-effective way. For example, doctors and patients alike are focused on treating diseases and conditions after they emerge. But there's much less focus on preventive health, counseling, and lifestyle changes that could head off serious health problems before they ever develop.

Enabling consumers to connect costs to medical care could go a long way to helping individuals determine the wisest use of their money. Online services offered by many health insurers, including BCBSNC, let consumers see the costs of various medical services and treatments.

Another method is to measure and present data on the quality of healthcare, which serves dual goals of providing incentives for physicians and hospitals to deliver high-quality care and allowing consumers to see which providers do the best job. As employer-led quality initiatives such as Bridges to Excellence (for physicians) and Leapfrog (for hospitals) gain acceptance, the thinking is that quality incentives will help mitigate rising healthcare costs by shifting the focus to preventive care and reducing the likelihood of costly medical errors and complications.

Beyond educating consumers on the wise use of healthcare benefits, it also must be a primary goal to build awareness of how personal lifestyle choices drive costs in the system. While many Americans understand that an unhealthy lifestyle can lead to obesity, heart disease, and diabetes, few make the leap to connecting increased costs to those lifestyle choices.

North Carolina is facing a growing crisis when it comes to obesity. Obesity-related problems cost North Carolina employers an estimated $3,000 per employee in rising healthcare costs and absenteeism.[3] There is ample evidence in BCBSNC data that overweight individuals have significantly higher medical costs. Still, few individuals seem to make the connection that unhealthy lifestyles cause premiums—including the employee-contributed portion—to rise. While Americans expect the best available care, wide freedom of choice, and access to cutting-edge technology, we often do not take ownership of our own lifestyles.

When it comes to car insurance, the safest vehicle—as judged by accident data—is the least expensive to insure. With homeowners insurance, smoke detectors, burglar alarms, and other preventive devices can help lower your premium. Shouldn't we encourage individuals to show the same respect toward our bodies and our families as we do our possessions?

Collaboration Is Key

While it will be extremely difficult to reduce overall healthcare expenditures and thus increase access to healthcare, by working together we can help slow the rate at which healthcare costs are rising. Although no easy task, this is the key to keeping health coverage affordable.

Insurers can work with providers to develop incentives for preventive care, for example. Employers can work with public officials to design workplaces and communities that encourage physical activity. Health plans can respond to consumer needs by offering coverage designed to fit an individual's specific needs. The list of steps that can make a difference is a long one.

In the end, our challenge goes beyond financial. Reducing cost is a big part of the picture, but it's only a means to an end. The ultimate goal is a healthier North Carolina, one whose residents enjoy longer, happier and more productive lives. By reducing costs—especially for costly chronic diseases—we can also ensure the long-term availability of affordable coverage.

A healthy North Carolina is what it's all about. After all, it's our home. **NCMedJ**

COMMENTARY

Insuring North Carolina's Children

E. Stephen Edwards, MD, FAAP

Quality health insurance for all North Carolina children has been a long-term goal of the North Carolina Pediatric Society (NCPS). Currently 265,000 children under the age of 18 remain uninsured. Two thirds of this number are eligible for either Medicaid or North Carolina Health Choice, the State Child Health Insurance Program. Thus, there are approximately 85,000 North Carolina children who are both uninsured and ineligible for current public insurance programs.

Leaders of the NCPS along with other child advocates and political leaders are exploring options to insure these children. Should there be a state subsidy for children in families with incomes above 200% of the federal poverty guidelines (FPG) or $40,000 for a family of four? If so, should there be a sliding-fee scale, and what should those rates be? At what level should that scale end (300% or 400% FPG)? How could we best assure that there would not be a "crowd out" effect where currently insured children would transfer from private plans to state-offered plans? While the assumption is that co-payments would be required for those above 200% FPG, how much should those co-payments be? Should immigrant children who are ineligible for federal subsidies be offered state subsidies?

One of the most difficult questions involves the benefit package. Currently the benefit package for Medicaid and North Carolina Health Choice is very comprehensive, including preventive healthcare; sick child care; therapy for hearing, speech, and visual problems; and dental and mental health problems. Can we afford that same package for the working poor?

Our state's Enhanced Case Management System has worked well in the Medicaid and North Carolina Health Choice populations to reduce expenditures. It has improved the health of children with chronic diseases, such as diabetes and asthma, while reducing costs by decreasing emergency room and hospital usage. Should that be extended to this new group of insured?

> *"Currently 265,000 children under the age of 18 remain uninsured. Two thirds of this number are eligible for either Medicaid or North Carolina Health Choice, the State Child Health Insurance Program. Thus, there are approximately 85,000 North Carolina children who are both uninsured and ineligible for current public insurance programs."*

Physician fees have to be considered. In North Carolina, Medicaid and North Carolina Health Choice payments for services to children are 95% of Medicare-allowable fees. By national standards this is generous, but with expanded numbers of children covered by the program, will those who care for children be able to stay afloat financially? This will be of special concern if the "crowd out" factor pushes more children from private insurance to the state program. (My impression is that our adult medical colleagues aren't very happy even with 100% of

Medicare-allowable fees.) We certainly don't want to create programs that financially punish healthcare professionals who participate.

And, finally, how do we pay for the system? In Massachusetts, where an individual mandate law has just been signed by Governor Romney, some contend that there is already enough money in the system to finance healthcare for all. This remains to be demonstrated. In North Carolina, at least initially, additional funds would be required from state appropriations. Where would we get those dollars? Are there creative ways to bring more federal dollars to North Carolina by increasing the ceiling for Medicaid and North Carolina Health Choice above 200% FPG?

These are just some of the questions that are being explored by the NCPS and others interested in child health—and they are important questions. These questions could be resolved rapidly if there were indications that we are ready for change. As a society we have committed to nutrition and education for all children. How long can we continue to ignore child health? Data are available to show that uninsured children fail in multiple facets of life, such as missed school days and poor school performance.

We live in the richest society in the world. We tried the employer mandate route in 1990 with the Matsui Bill and in 1993 with the Clinton health plan. There was vigorous objection to both, especially from the business and insurance sectors. Massachusetts has now adopted an individual mandate where each citizen is required to purchase health insurance. We adopt a somewhat similar program for automobile liability insurance. Is the health of our children not more important than our automobiles?

There are obviously some difficult questions of equity and financing involved in health insurance for all children. But a nation that sent men to the moon with a single decade's effort is smart enough and rich enough to provide health insurance for our children. What we lack is not the money, nor the brain power, but the WILL.

If we choose to establish child health as priority, implementation could be accomplished quickly and relatively inexpensively. While the NCPS has focused primarily on child health, I believe that the organization would enthusiastically join any coalition to promote health insurance for all North Carolinians. **NCMedJ**

It's Not the Uninsured, Stupid:

Two Hurdles on the Track to Affordable Healthcare Coverage for All in North Carolina

Adam G. Searing, JD, MPH

Moving North Carolina policy toward affordable healthcare coverage for all requires dealing with two problems ignored by many people and organizations interested in this issue. First, the dominant way stories about lack of affordable healthcare coverage are portrayed in the media is helping to stifle efforts for reform. Contrary to conventional wisdom, so-called healthcare horror stories—far from being helpful in showing the need for reform—focus attention on individuals rather than systemic solutions while insulating political leaders from responsibility. Changing the conversation about healthcare reform isn't enough, however. The second problem lies in irresponsibility on the part of the federal government that has resulted in huge tax cuts aimed largely at the wealthiest Americans, an exploding federal budget deficit, and consequent current and future cutbacks in existing healthcare programs like Medicaid and Medicare. If we can't maintain our current healthcare coverage, the prospect of bringing more people into the current healthcare coverage system is remote indeed.

The Healthcare Horror Story Doesn't Work

A common media tactic used for years when health policy analysts, advocates, policy makers, and others attempt to "address the problem of the uninsured" is to rely on the story of the Medicaid recipient struggling to make ends meet while living with a serious disability, or the mechanic who makes a decent living, but not quite enough to afford health insurance for his family. Advocacy organizations[1] compile "story banks" of these sorts of healthcare failure stories for distribution to reporters. Health policy textbooks highlight the "horror story" illustrative tactic for students.[2] The media actively looks for these sorts of stories and frequently inquires if health clinics, hospitals, doctors, and others know someone without insurance who is willing to tell their story.

The prospect of such healthcare horror stories regularly sparks dread among targeted industries and politicians. For example, filmmaker, Michael Moore, is collecting healthcare horror stories for a new film on the uninsured and America's healthcare system. The pharmaceutical industry is especially worried: "For every horror story Michael Moore produces, we can produce 1,000 success stories, but he's not interested in them," said Ken Johnson, the senior vice-president of the trade group Pharmaceutical Research and Manufacturers of America."[3]

Despite fear from the targeted and enthusiasm from the mobilized, the idea underlying the healthcare horror story—that evoking sympathy with a story of hardship or poverty will translate into support for change in policy—has been shown to be dead wrong. Such stories even have the opposite effect by depressing support for changes in policy and diverting attention from the real problems. After seeing a healthcare horror story, people tend to think of the problem of the uninsured as that particular family's or individual's problem and not a problem that can be solved by government. The focus on the story shifts the focus away from the responsibility of politicians, as leaders of government, to act and address the problem for everyone.

> *"...refocusing media attention from the individual story of the poor uninsured person to the systemic problems that underlie the lack of affordable healthcare should be a top priority."*

The idea that "horror stories" might not be so effective was first raised in the 1980s when Shanto Iyengar and Donald

Adam G. Searing, JD, MPH, is the Project Director for the North Carolina Justice Center's Health Access Coalition. He can be reached at adam@ncjustice.org or PO Box 28068, Raleigh, NC 28068.Telephone: 919-856-2175.

Kinder published *News that Matters*,[4] a critical look at the rise of television news and its effect on policy agenda setting. Conducting multiple experiments they determined that:

> [C]ontrary to much conventional wisdom, news stories that direct viewers' attention to the flesh and blood victims of national problems prove no more persuasive than news stories that cover national problems impersonally—indeed, they tend to be less persuasive. This undermining of agenda-setting may be particularly powerful when viewers in effect blame the victims for the problems that have befallen them. Perhaps visual presentations are generally less persuasive in part because they are so successful as melodrama. Viewers may get so caught up in one family's troubles that they fail to make the connection back to the national condition. Overwhelmed by concrete details, they miss the general point.[5]

Iyengar expanded on this work with more research. In addition to confirming his earlier views, he found that such "episodic framing," or focusing on individual stories and not the bigger picture, also insulated politicians and other public officials from responsibility for fixing the problems. Iyengar writes, "By simplifying complex issues to the level of anecdotal evidence, television news leads viewers to issue-specific attributions of responsibility, and these attributions tend to shield society and government from responsibility."[6] It only makes sense. A story about a family in poverty focuses attention on how to help that particular family, not on the policy decisions that lead to that family being in poverty. Connecting the actions of a politician in Raleigh or Washington to the plight of a particular family is often just too much of a stretch for the average person.

Shifting the Focus: "Sympathy for the Poor" versus "Economic Planning"

More recent research has confirmed and expanded on Iyengar's work. The Ford Foundation has funded extensive research on this topic by the communications firm Douglas Gould & Company.[7] A 2004 survey of 3,205 registered voters compared different "frames" or ways of talking about issues impacting low-wage workers. The "sympathy for the poor" frame, which used the type of classical horror story described above, failed to generate much support for policy fixes. Instead, people felt that the responsibility for solving the problems was incumbent upon the people experiencing the problem.

Researchers then tried what they called the "economic planning" frame. Here they talked about the same problems they had with the "sympathy for the poor" frame, but now they focused on the economy, jobs, and future prosperity. Instead of the horror story, trends and broader influences were used to illustrate the problems. For example, the argument was presented that the nation should not focus on "short-term profits and short-term thinking," but think long-term and "build good-paying jobs with benefits."[8]

The Gould study concluded that moving away from the horror story toward talking about the economy, jobs, trends, and future prosperity significantly increased the public's acceptance of and desire for policy solutions. A recent example of this type of coverage is the wide notice given to retailer Costco for its generous employee benefits, larger contributions to employee health insurance, and low turnover.[9] The theme? Treating your employees well is good for the company, business, customers, and the community.

Other studies involving multiple focus groups, a national study of registered voters, and detailed analysis of news coverage all support the above conclusions.[10-12]

A New Way of Talking about Affordable Healthcare for Everyone

When the predominant way the story of the uninsured is covered in the media is ineffective in building support for policy change, supporters of healthcare for everyone must change their strategy. This means a huge shift in how supporters for change refer to those without health coverage, a change in the examples used to illustrate the need for health coverage, and a relentless focus on the collective responsibility of citizens and government to solve this problem.

First, refocusing media attention from the individual story of the poor uninsured person to the systemic problems that underlie the lack of affordable healthcare should be a top priority. Highlighting solutions is a key part of this effort. Successful collaborations, such as Project Access in Buncombe county,[13] where low-income residents can get comprehensive, affordable healthcare regardless of whether they can afford coverage from work need to be given prominence. Profiles of North Carolina employers who are offering comprehensive healthcare coverage along with decent wages should be used as models. The system is broken—but we have the will and ability to fix it—should be the key message.

Refusing to be drawn into the "find-a-person-without-insurance-to-be-profiled" media trap isn't enough, however. In every story about the lack of affordable health coverage, there should be mention of how this lack hurts the economy, means lack of decent jobs, and imperils future prosperity. To build a strong economy, we need a healthy workforce, and that means everyone needs to be able to see a doctor when they are sick.

We should create jobs in North Carolina, but we shouldn't think short-term. Long-term thinking means creating jobs with good benefits and decent salaries, so people can have a reasonable place to live, connect to their towns and cities, raise their families, and contribute to the future of the community. If families are being driven into bankruptcy by high medical bills that hurts not only them, but our future prosperity. Someone who is bankrupt because of hospital bills isn't going to buy a new car down at the local Ford dealership.

Finally, the way the lack of guaranteed affordable health insurance coverage affects everyone should be made clear. The message here is simple. Why should North Carolinians worry that a job loss or change, a desire to strike out on their own and start a new business, or a sudden disability might mean loss of health coverage for themselves and their families? What kind of economic engine would we unleash if anyone with a great idea could start a business knowing that affordable health coverage was easily available? How many modern-day Wright brothers are trapped between the need to maintain responsible health coverage from their current company and a dream to strike out and invest in their own innovative ideas?

Fixing Federal Budget Problems Is The Second Component Necessary to Advance North Carolina's Health Agenda

Unfortunately, shifting the message and focus to the economy, jobs, and future prosperity will not be enough to move North Carolina toward affordable health coverage for everyone. A huge roadblock remains in the form of the current devastating fiscal irresponsibility of the federal government. For wealthier states, few prospects of new federal funding for health coverage and increasing federal budget cuts limiting federal healthcare money are not as insurmountable. Massachusetts[14]—with a $52,000 annual median income and a low 11% uninsured rate compared to North Carolina's $39,000 median income and 17% uninsured rate—can credibly move toward universal affordable coverage.[15]

This is not so in North Carolina. Too often, supporters of affordable health coverage for everyone shy away from describing just how to pay for the solutions they proscribe. But building an economy where families don't have to worry about losing affordable health coverage is going to cost money. Sure, if we rebuilt the health system from the ground up, we could probably save enough in administrative, paper-pushing costs to bring everyone in. However, as imperfect and wasteful as our current system is, 85% of the population is more or less happily covered under our current system, and the other 15% isn't marching in the streets for radical change.[a,16]

Indeed, the benefits that more expensive medical care brings—stronger communities, healthier workers, and longer lives—are worth paying for. But, before we look to find more money for expanding care, there remains a huge problem. Current federal tax policies mean that we cannot afford the programs we have in place right now, much less to expand them in the future. A top priority of the President and current Congressional leadership is making tax cuts since 2001 permanent. These tax cuts are disproportionately aimed at top income-earners. People with incomes over $1 million will receive a tax reduction of nearly $112,000 this year, while someone in the middle of the income scale can expect only a $748 reduction.[17] Another priority with broad bipartisan support is to balance the federal budget. As the Center on Budget and Policy Priorities points out, those two goals are simply not compatible without cuts that would be unthinkable to many.

The sad truth is that expanding costs for healthcare combined with drastically reduced tax revenues and an exploding federal deficit mean a sharp fiscal squeeze. Add to this the now nearly $10 billion a month being spent on the war in Iraq and Afghanistan (a cost that has risen almost $2 billion a month in the last year),[18] and it's clear the country is heading for a crisis. In fact, realistic estimates of the budget deficit over the next ten years put the federal government in the red by $4.8 trillion.[19] This is simply unsustainable and puts current healthcare programs like Medicare and Medicaid in serious jeopardy.

What Would it Take to Balance the Budget While Preserving the Tax Cuts?

To balance the budget by 2016 while making the tax cuts permanent, policy makers would have to:

Cut Social Security benefits by 45%

Or cut defense spending by 66%

Or cut Medicare by..56%

Or cut every other program except Social Security, Medicare, defense, and homeland security by 32%

Source: Federal Budget Outlook. Budget presentation. Washington, DC: Center on Budget and Policy Priorities. Available at: http://www.cbpp.org/budget-slideshow.htm. Accessed May 24, 2006.

One effect of the federal funding crunch is less money to help states facing tough economic times. Over the last several years, multiple states have enacted large cuts in Medicaid eligibility and benefits in response to the economic downturn. Last year, the biggest health issue debated in North Carolina was the proposed denial of Medicaid eligibility to 65,000 elderly, blind, and disabled residents. Although the state's fiscal fortunes seem to be rising in 2006, the same is not true at the federal level.

This year Congress enacted $39 billion in budget reductions, which will mean more people without insurance and will shift billions in child care assistance and welfare reform costs to the states. For example, North Carolina currently is grappling with an unfunded federal mandate to require a birth certificate from the 1.2 million North Carolinians getting healthcare through Medicaid.[20] Finding birth certificates for over a million people on Medicaid who are overwhelmingly elderly, disabled, or under 18 years old is a Herculean task North Carolina's taxpayers will now be expected to finance. Many elderly African Americans, born in a south with segregated hospitals, will have even more difficulty—their "birth certificate" may only be a notation in the family Bible. Cost savings for the federal government translates into huge budget and human costs at the state level.

It's simple. Any honest talk about major expansions in health coverage for North Carolinians has to start with the federal government getting its own fiscal house in order. Otherwise the healthcare coverage debate in North Carolina for the foreseeable future will be about how to preserve current coverage in the face of gigantic federal cutbacks.

---

[a] Political participation by low-income people (i.e., voting, protesting, contacting legislators, joining advocacy groups, giving campaign donations) is far lower than for people in the middle- and upper-income brackets. This hasn't changed much over the last century.[16]

This political medicine is tough, but necessary, if we want to build a North Carolina economy for the next century where everyone benefits. It will require a balanced, bipartisan approach with strict fiscal rules, reconsideration of ill-advised tax cuts, and an honest assessment of where substantial savings can be made in Medicare and Medicaid spending. This is a contentious process, but some ways to start would be:

- Reinstate "pay-as-you-go" rules that require Congress to pay for all tax cuts and increases in entitlement programs before such tax cuts or increases can be enacted.
- Don't make permanent any tax cuts that are not clearly paid for.
- Rethink tax cuts going to people with annual incomes over $400,000—the top 1% of the population—and devote resulting revenues to reducing the federal budget deficit and strengthening Medicare and Medicaid.
- Revise the Medicare Part D prescription drug legislation to allow the federal government to negotiate directly with drug companies and obtain the lowest possible prices for drugs.
- Invest in research that compares the effectiveness and value of prescription drugs, healthcare procedures, and other health initiatives.

A Positive Outlook for a Strong Future Economy

As our technology becomes more sophisticated, our population ages, and our state population grows, we face a critical choice. A strong future North Carolina economy means good jobs with quality benefits and access to the best and most innovative healthcare that the many medical resources in our state have to offer. A long and healthy life should be attainable for every North Carolinian whether they work in a tourism job on the coast or a research and development job in the Research Triangle Park. A big part of creating the economy and prosperity people want is ensuring affordable healthcare coverage for all. This is an attainable goal, but two necessary steps on the road to reform require rethinking the message around affordable healthcare coverage and demanding true fiscal accountability from the federal government. **NCMedJ**

A Special Thanks

The North Carolina Institute of Medicine (NC IOM) would like to thank each of the Task Force members, steering committee members, and staff for their efforts in creating the Covering the Uninsured Task Force report: *Expanding Health Insurance Coverage to More North Carolinians*.[1]

Task Force members included: **Carmen Hooker Odom, MRP**, Secretary, NC Department of Health and Human Services (co-chair); **Thomas Lambeth**, Senior Fellow, Z. Smith Reynolds Foundation (co-chair); **Rep. Jeff Barnhart**, NC General Assembly; **Andrea Bazan-Manson, MSW, MPH**, President, Triangle Community Foundation; **Mark T. Benton**, Senior Deputy Director and Chief Operating Officer, Division of Medical Assistance, NC Department of Health and Human Services (NC DHHS); **Millie Brown**, Director, Duplin County Department of Social Services; **H. David Bruton, MD**, former Secretary, NC DHHS; **Sonya Bruton, MPA**, Executive Director, NC Community Health Center Association; **Barbara Morales Burke, MHA**, Chief Deputy Commissioner, NC Department of Insurance; **Pearl Burris-Floyd**, Gaston County Commissioner; **Timothy S. Carey, MD, MPH**, Professor of Medicine and Director, Cecil G. Sheps Center for Health Services Research, UNC at Chapel Hill; **J. Keith Crisco**, President, Asheboro Elastics Corp.; **Leah Devlin, DDS, MPH**, State Health Director, NC DHHS; **L. Allen Dobson, Jr., MD**, Assistant Secretary for Health Policy and Medical Assistance, NC DHHS; **Victor J. Dzau, MD**, Chancellor, Duke University Medical Center; **Rep. Beverly Earle**, NC General Assembly; **Allen Feezor, MA**, Chief Planning Office, University Health Systems of Eastern Carolina; **Charles T. Frock**, Chief Executive Officer, FirstHealth of the Carolinas; **Robert Greczyn, Jr.**, President and CEO, Blue Cross and Blue Shield of NC; **Ches Gwinn, MPA**, Co-Chair, NC Health Insurance Innovations Commission; **Billy Ray Hall**, President, NC Rural Economic Development Center; **Sen. Fletcher L. Hartsell, Jr.**, NC General Assembly; **Ann Holton**, Pamlico County Commissioner; **Rep. Verla Insko**, NC General Assembly; **Robert Jackson**, State Director, NC Office, AARP NC; **Connie Majure-Rhett, CCE**, President and CEO, Greater Wilmington Chamber of Commerce; **John B. McMillan, JD**, Manning, Fulton and Skinner, PA; **John Mills**, former Executive Director, NC Association of Free Clinics; **David Moore, CLU**, Past President, NC Health Underwriters Association; **Graham T. Moore, Jr.**, Vice-President of Marketing and Area Operations Manager, APAC-Atlantic, Inc. Coastal Carolina Division; **Aaron Nelson**, Executive Director, Chapel Hill-Carrboro Chamber of Commerce; **Sen. Martin L. Nesbitt, Jr., JD**, NC General Assembly; **Rep. Edd Nye**, NC General Assembly; **Mary Margaret "Peg" O'Connell, JD**, Director of External Relations, The Carolinas Center for Medical Excellence; **Barbara Pullen-Smith**, Director, Office of Minority Health and Health Disparities, NC DHHS; **William Pully, JD**, President, NC Hospital Association; **Sen. William Purcell, MD**, NC General Assembly; **Sen. Tony Rand, JD**, NC General Assembly; **Rep. Karen Ray**, NC General Assembly; **James T. Roberson, Jr., PhD**, Dean, Shaw University Divinity School and Pastor, New Bethel Baptist Church; **Jack Rodman**, President and CEO, NC Business Group on Health; **William Roper, MD, MPH**, Dean, UNC School of Medicine and CEO, UNC Health Care System, UNC at Chapel Hill; **Eric Russman, JD**, Vice President and Executive Director, UnitedHealth Group Center for Affordable Consumer Health, **Randy Rust**, President, Rust Enterprises/McDonald's; **Wanda Sandelé**, Health Director, Craven County Health Department, **Adam Searing, JD, MPH**, Project Director, NC Health Access Coalition; **Stephen T. Smith, JD**, Program Associate, NC Council of Churches; **Russ Stephenson**, President and CEO, Stephenson Millwork Company; **Sen. A.B. Swindell IV**, NC General Assembly; **Judith E. Tintinalli, MD, MS**, Professor and Chairman, Department of Emergency Medicine, UNC School of Medicine; **Lynette Rivenbark Tolson**, former Director of Advocacy, American Heart Association; **Torlen Wade**, Director, NC Office of Research, Demonstrations, and Rural Health Development (ORDRHD), NC DHHS; **Charles F. Willson, MD**, President, NC Medical Society, Clinical Professor, Brody School of Medicine; **Leslie Winner, JD**, Vice President and General Counsel, General Administration, UNC at Chapel Hill; **Rep. Thomas Wright,** NC General Assembly; **Doug Yarbrough, MBA**, President and CEO, Duplin General Hospital, Inc.

Steering Committee Members included: **Anne Braswell**, Senior Analyst, ORDRHD, NC DHHS; **Barbara Morales Burke, MHA**, Chief Deputy Commissioner, NC Department of Insurance; **Matt Canedy, MPA**, Research Assistant, NC IOM; **Kristen L. Dubay, MPP**, Project Director, NC IOM; **Thalia Fuller**, Administrative Assistant, NC IOM; **Sandra Greene, DrPH**, Senior Research Fellow, Cecil G. Sheps Center for Health Services Research, UNC at Chapel Hill; **G. Mark Holmes, PhD**, Vice President, NC IOM and Senior Research Fellow, Cecil G. Sheps Center for Health Services Research, UNC at Chapel Hill; **Jaime Jenkins, MD**, Research Assistant, NC IOM; **Micheala Jones, PhD**, Post Doctoral Fellow, NC IOM; **Adrienne Parker**, Director of Administrative Operations, NC IOM; **Stephanie Poley**, Research Associate, Cecil G. Sheps Center for Health Services Research, UNC at Chapel Hill; **Pam Silberman, JD, DrPH**, President and CEO, NC IOM; **Kristie W. Thompson, MA**, Managing Editor, *NC Medical Journal* and Assistant Vice President, NC IOM; **Torlen Wade**, Director, NC ORDRHD, NC DHHS; **Dennis Williams**, Associate Director, ORDRHD, NC DHHS.

[1] North Carolina Institute of Medicine. Expanding Health Insurance Coverage to More North Carolinians. Durham, NC. April 2006. Available at: http://www.nciom.org/projects/uninsured/uninsuredreport.html. Accessed May 8, 2006.

The Task Force was a collaborative effort of the North Carolina Department of Health and Human Services, the North Carolina Department of Insurance, the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill, and the North Carolina Institute of Medicine. The Task Force was generously funded through a one-year State Planning Grant from the Health Resources and Services Administration of the United States Department of Health and Human Services. The primary staff direction of the overall State Planning Grant Task Force work was the responsibility of Dennis Williams, Associate Director, and Anne Braswell, Senior Analyst, of the Office of the Research, Demonstrations, and Rural Health Development, NC DHHS.

Running the Numbers

A Periodic Feature to Inform North Carolina Healthcare Professionals about Current Topics in Health Statistics

From the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill
http://www.shepscenter.unc.edu

The Uninsured in North Carolina, 2004

Estimating the number of uninsured at the county level is not a straightforward process because there are no direct surveys at the local level. Analysts at the Cecil G. Sheps Center for Health Services Research have used data from the United States Census Bureau's Current Population Survey (CPS) March Supplements from 1995-2005 to create county-level estimates of the numbers of persons under 65 years of age who were without insurance for each year starting in 1999. The maps displayed here summarize the results for 2004.

This estimation process identified the factors associated with being uninsured in the state-level sample then extrapolated those data using full population data for each of the counties. Those data indicate that, in general, people who lack health insurance in North Carolina are more likely to be poor, younger, or employed in small business. These factors, among others, were then used to create local estimates. For example, if 20% of males and 10% of females working in service industry jobs in North Carolina are uninsured, then these rates can be applied to county level employment and age-gender characteristics to generate an estimate of the rate of uninsured in a particular county The complete report, including a listing of counties with numbers and percent of population uninsured, is available at http://www.shepscenter.unc.edu/.

Percent of North Carolinians Aged 0-64 without Health Insurance
Estimates for 2004

Source: Synthetic estimates based on Annual Social Economic Supplement, US Census Bureau, 2004-2005.

Full report available at http://www.shepscenter.unc.edu.

RTN—continued on page 236

RTN—continued from page 235

The maps show that higher proportions of the population in the more rural areas of the eastern part of the state and the northern and southern mountain counties are more likely to be uninsured with a notable "cluster" of high rates in the region including Onslow, Jones, Duplin, Sampson, and Pender counties. The second map indicates that the absolute numbers of uninsured are concentrated in the urban counties. The problem of uninsurance is a statewide phenomenon with rates and numbers showing slightly different effects across the state. Since some areas of the state have lower average incomes or more employees of small businesses, these areas will generally have more uninsured people. Policymakers may wish to focus efforts in areas with particularly low insurance coverage rates. Local healthcare providers may better demonstrate the extent of their need for government and philanthropic support using estimates of local uninsured populations.

Number of Residents Aged 0-64 without Health Insurance

Readers' Forum

To The Editor:

As Chief of the North Carolina Division of Social Services' (DSS) Family Support and Child Welfare Section, I value the commitment and efforts of our university and medical partners and sister agencies in the North Carolina Department of Health and Human Services. We all diligently strive to achieve the safety, permanence, and well-being of children and their families. The commentary written by Dr. Adam J. Zolotor, Dr. Desmond K. Runyan, Ms. Brenda Motsinger, and Ms. Catherine Sanford published in the September/October 2005 volume of your Journal, entitled "Building an Effective Maltreatment Surveillance System in North Carolina" had several points that I agree with and support. One of these is that "coordinated efforts and a variety of data sources from multiple sectors" are critical to developing a child maltreatment surveillance system. The North Carolina Division of Social Services supports this endeavor through participation in the Families Accessing Services through Technology (NC FAST) program. When fully implemented, it will provide for efficient, effective assessment; comprehensive case management; and better evaluation information through its comprehensive outcomes data and capacity to ensure accountability across programs. As a result, I agree that this system will "improve the consistency of data collection and allow data to be compared more easily among counties."

The commentary continues to state that "for each report that is accepted to the department of social services for a family or investigative assessment, the family's needs are now assessed using a standardized risk assessment tool," which leads the reader to believe the use of standardized assessment tools is a new development. The Division implemented the use of Structured Decision Making tools in the county Departments of Social Services on April 1, 2002. These tools were adopted to achieve greater consistency among our child welfare staff in providing on-going safety and permanence for children and families. Our use of those tools over almost four years has guided our case decision-making and helped us better achieve the outcomes of safety, permanence, and well-being of children.

The authors are correct that domestic violence is a risk factor for child abuse. Their statement that "…DSS has recently implemented a policy to accept all reports of witnessed domestic violence for investigation" seems to infer this is new to our system. Our Structured Intake policy guides our intake and screening decisions and became effective June 1, 2003.

We believe that child maltreatment and adult domestic violence often occur together. In September 2004, we established a separate section of our Child Protective Services (CPS) policy manual to provide the specific information and protocol that addresses the intersection of child safety, permanence, and well-being and domestic violence. This policy was developed in collaboration with the state's domestic violence community. It establishes the primary focus of child protection intervention in cases involving domestic violence as the ongoing assessment of the risk posed to children due to the presence of violence in their families. It, in combination with our Structured Intake policy, establishes that the DSS does not accept all reported cases involving domestic violence. A CPS report in which the *only* allegation is domestic violence does not meet the statutory criteria for child abuse, neglect, and dependency.

This article's statement also leads one to believe that workers make CPS assessment case decisions independently. This is not accurate or supported by policy that has guided CPS practice for many years. Policy clearly states, "the CPS assessment case decision must be a shared decision, including at a minimum, the worker and the workers' supervisor or supervisor's designee or staffing team."

I appreciate the authors' efforts in serving children and their families. Without them, and others like them, North Carolina's children would be much less safe than they are today. I am honored to partner with them in our continued collaborative efforts. Thank you for the opportunity to offer some insight on some of our policy and practice points. I am available to answer questions or further explain our CPS system.

fitcommunity

Congratulations to the following for being designated as a Fit Community:

City of Asheville
Town of Chapel Hill
Town of Cramerton
City of Durham
City of Greensboro
City of Mount Airy
Town of Oak Island
City of Wilmington
Pitt County, Honorable Mention

Fit Together, a partnership of Blue Cross and Blue Shield of North Carolina (BCBSNC) and the NC Health and Wellness Trust Fund (HWTF) is pleased to honor these communities.

HWTF Chair Lt. Gov. Bev Perdue and BCBSNC CEO Bob Greczyn congratulate the citizens of these communities for supporting healthy lifestyles.

Nearly 50 North Carolina towns and counties applied to be a Fit Community. Designees are leaders in supporting:
- Physical activity in the community, schools and workplaces;
- Healthy eating in the community, schools and workplaces; and
- Tobacco-use prevention efforts in schools.

How a team of heart specialists helped Hugh McColl make the best investment of his life.

When Hugh McColl, the man who changed American banking, learned he needed heart bypass surgery, he chose the team that has outpaced all others for years. He chose the Carolinas Heart Institute at Carolinas Medical Center and the Sanger Clinic's Dr. Mark Stiegel.

Carolinas Heart Institute has a rich and storied history of groundbreaking innovations; some of the finest medical minds in America, and the latest, most advanced technology available – including the new revolutionary *64 Slice CT Scanner*.

Today, Hugh McColl is enjoying the success of his surgery with his usual zest for life. In fact, he calls his choice of care "one of the best investments I ever made."

We know Mr. McColl could have gone anywhere in the world for cardiac treatment. He chose the region's premier team.

Surgery and science combine to unlock the secrets of diabetes

A partnership between Pitt County Memorial Hospital and the Brody School of Medicine at East Carolina University is at the forefront of bariatric surgery research. In more than 2,500 documented cases, our surgeons have seen patients overcome dependence on insulin and oral therapy in a matter of days. Some patients have required no further medication for as long as two decades.

The confirmation of these findings by surgeons throughout the world has led to a major grant from the Johnson & Johnson Corporation. The grant will help researchers find an explanation for this medical advance and to see if medication can achieve the same result. Dr. Walter Pories, an ECU professor of surgery and bariatric surgery pioneer, and his colleagues will lead a two-year clinical study of adults with diabetes that evaluates insulin sensitivity and glucose metabolism before and after gastric-bypass surgery. For more information on the study, call 252-744-3290.

Working together, Pitt County Memorial Hospital and Brody School of Medicine surgeons have been performing and studying gastric bypass surgery since 1978. To watch a live web cast of bariatric surgery at Pitt County Memorial Hospital or learn more about bariatric surgeons at the Brody School of Medicine and Southern Surgical Associates, visit www.bariatric.uhseast.com.

Blue Cross/Blue Shield of North Carolina recognizes the surgeons practicing bariatric surgery at Pitt County Memorial Hospital as a Center of Excellence

Tarheel Footprints in Healthcare

Recognizing unusual and often unsung contributions of individual citizens who have made healthcare for North Carolinians more accessible and of higher quality

Recognizing Tom Vitaglione, MPH
Senior Fellow, Action for Children North Carolina

(formerly known as the North Carolina Child Advocacy Institute)

Tom Vitaglione, MPH

Anyone who has worked on statewide issues related to child health in North Carolina over the past thirty-five years could not have gone without some contact or communication with Tom Vitaglione. He has played a key role in shaping a host of programs that have made a tremendous impact on the health and well being of North Carolina's children and youth.

Tom chose to start his professional career in North Carolina after receiving his master's degree in public health from Columbia University and spending time in Malawi with the Peace Corps. Over his more than three decades of state service through the Children and Youth Section in the Division of Public Health, his leadership and accomplishments are widely recognized. For example, he was a principal architect of North Carolina's Children's Health Insurance Program (NC Health Choice) and helped to assemble a task force of 75 leading experts with the North Carolina Institute of Medicine to prepare an outline of the proposed program. The result was legislation eventually enacted to extend coverage to over 75,000 previously uninsured children. This number has since been extended by the North Carolina General Assembly to include more than 125,000 children.

Tom was also one of the leaders whose vision created the North Carolina Child Fatality Task Force. He continues to play a strong role as Co-Chair, a position to which he was appointed by Governor Michael Easley. In this role he has brought public, media, and legislative attention to a number of child mortality issues. The Child Fatality Task Force compiles annual statistics on a wide spectrum of risks to child health and safety, then partners with the North Carolina Institute of Medicine and Action for Children North Carolina to release them each year. The *North Carolina Child Health Report Card*, a visual measure of our progress on key health indicators, has been released for a decade thanks to Tom's leadership.

Further, Tom has been a tireless advocate for stricter automobile child restraint laws, for the regulation of child safety in the operation of all terrain vehicles, for graduated driver's licenses, the dangers of home fires for children and infants, the reduction of child exposure to lead, programs to address the problems of child maltreatment and abuse, and the active role of state government in the collection, analysis and publication of child health, injury, and fatality statistics.

Leah Devlin, North Carolina State Health Director, comments that "Tom Vitaglione has always been a fearless champion for improving children's health and well being. He has been a strong leader for many years from within the public health system and he brings that same energy and advocacy in his current role in the private sector. Generations of children and their families in North Carolina continue to be well served by the passionate and committed Tom V."

Since his retirement from state government, Tom Vitaglione has been a Senior Fellow at Action for Children North Carolina. In addition to his role as a Fellow and as Co-Chair of the Child Fatality Task Force, Tom and his wife have found time to invest their energy and talents in developing (and fundraising for) the Malawi Children's Village, a multifaceted program serving more than 3,500 AIDS orphans in 37 villages in the southern region of this small country in East Africa.

Dr. Jonathan Sher, former President of the NC Child Advocacy Institute, had this to say about him: "Tom is the most universally respected and beloved person that I ever have known personally (having only met the Dalai Lama in passing). This is even more impressive given that, as an Italian Catholic from New York City, he started with three strikes against him in the North Carolina of three decades ago. When I grow up, I'd be delighted to turn out just like the real-life Tom Terrific!"

The *North Carolina Medical Journal* is proud to recognize the career and continuing accomplishments of this tireless child health leader in our state. We celebrate our good fortune that Tom Vitaglione chose North Carolina as "home" and thank him for his ongoing efforts on the part of the children of our state.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, non-profit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Feasibility of a Primary Care Intervention to Decrease Oral Antibiotics for Acute Upper Respiratory Tract Infections:

A Pilot Study

Meera Kelley, MD; Mark W. Massing, MD PhD; Joshua Young, BS; Anne Rogers, RN, BSN; Renee Taylor, MPH and Robert Weiser, BA

Abstract

Background: *Antimicrobial resistance in common respiratory tract pathogens is a growing public health threat, especially in the southeastern United States. The excessive use of antibiotics for common infections is a major contributing factor in the emergence of antibiotic resistance. We report results from a multi-site outpatient pilot project in North Carolina to reduce antibiotic prescriptions for acute nonbacterial upper respiratory tract infections (URIs).*

Methods: *Primary care practices were provided education and symptom therapy kits for patients with URIs, as an alternative to antibiotics, in a project to reduce the overuse of antimicrobial therapy. The feasibility of this approach was evaluated with interviews and surveys. A methodology for claims-based evaluation of intervention efficacy in reduction of antibiotics use was developed as part of this project.*

Results: *Of eight contacted practices, four agreed to participate and three participated fully. Physicians reported that symptom therapy kits were useful for patients with URIs and resulted in a meaningful change in antibiotic prescribing behaviors. A claims-based approach is a feasible and promising method to evaluate efficacy in subsequent post-pilot large-scale implementations.*

Limitations: *Due to the small number of outpatient practices and the lack of controls in this pilot study, the efficacy of the intervention in reducing antibiotic use could not be determined.*

Conclusions: *Education combined with symptom therapy kits as an alternative to oral antibiotics is a feasible intervention that warrants additional studies to evaluate the efficacy of this approach in the reduction of antibiotic use for URIs.*

Keywords: *antibiotics, upper respiratory tract infection, outpatient care.*

Introduction

Resistance to antimicrobial agents is a growing public health threat, especially in the southeastern United States.[1-6] Antibiotic overuse contributes to resistance, yet antibiotics are commonly administered to treat conditions such as nonbacterial acute upper respiratory tract infections (URIs) for which they are not proven effective.[7-11]

The American College of Physicians-American Society for Internal Medicine, American Academy of Family Physicians, Infectious Diseases Society of America, and the Centers for Disease Control and Prevention have endorsed a campaign to promote appropriate antibiotic use for the treatment of acute respiratory tract infections in adults. Clinical Practice Guidelines providing evidence-based recommendations have been published.[12] They provide practical strategies for limiting antibiotic use to the patients who are most likely to benefit.

Among the frequently cited causes for antibiotic overuse are physician perceptions of patient expectations, patients' actual expectations, lack of knowledge of the dangers and limitations

of antibiotic therapy, and inadequate communication during physician-patient encounters.[13-17] To maximize effectiveness, interventions to reduce antibiotic use will need to address as many of these factors as possible.

We developed a multi-pronged approach to reduce the outpatient use of antibiotics for URIs that focuses on patient and physician education and understanding while enhancing patient-physician communication through the use of symptom therapy kits. In this report, we describe a pilot project to evaluate the feasibility and uptake of this approach. We report promising findings supporting the need for a large scale study to evaluate the effectiveness of educational interventions combined with symptom therapy kits to reduce the use of antibiotics for URIs.

Methods

Pilot Project Overview

Internal medicine, general practice, and family medicine providers treating large numbers of patients were identified as potential project participants. Of eight invited practices, one practice declined because the physician felt that patients seen at the practice were particularly high-risk and likely required antibiotics for treatment of URIs. Three other practices declined due to time constraints. Of the four practices that entered the project, one failed to complete the intervention because the practice physically relocated and intervention materials were misplaced. Three practices successfully completed the project interventions.

Physicians in four participating practices received a project introduction consisting of training related to antibiotic resistance and current treatment guidelines provided by a physician specializing in infectious disease. Intervention materials provided in January 2002 to each practice included 100 symptom therapy kits, 15 posters, and 10 symptom relief prescription pads. Symptom therapy kits and symptom relief prescriptions offered patients the alternative of symptom control with reassessment in consultation with their physician should symptoms not improve.

Physicians and their staff were contacted routinely throughout the cold and flu season of early 2002 to identify problems and successes related to the project, assess practice adherence with project protocols, and identify the need for additional intervention materials. A formal interview and questionnaire were administered to participating providers in April 2002.

Because this was intended to be a pilot project for the development of the intervention, the number of participating practices was limited and no controls were identified. Thus, intervention efficacy could not be determined. However, in anticipation of a large-scale implementation of the intervention, this project also included a component to develop an evaluation methodology using administrative claims.

North Carolina Medicaid outpatient and pharmacy claims were reviewed to characterize antibiotic use for acute nonbacterial URIs. Methods and results are described in detail elsewhere.[18] Data were provided by the Division of Medical Assistance of the North Carolina Department of Health and Human Services, the administrators of the state's Medicaid program.[19] Pre-intervention analyses of Medicaid claims revealed high levels of antibiotic use, justifying the development of this pilot project to reduce outpatient antibiotic use for acute nonbacterial URIs.

This project was sanctioned by the North Carolina Medicaid program due to its potential to prevent drug-related adverse events, protect public health, and reduce costs. It was approved by the Institutional Review Board of the University of North Carolina School of Medicine.

Interventions

Educational materials were distributed to participating physicians at no charge. Some materials were obtained from the Campaign for Appropriate Antibiotic Use in the Community sponsored by the Centers for Disease Control and Prevention.[20] These included an educational poster for examination and waiting rooms, a prescription pad for symptomatic relief of URIs,[21] and "A new threat to your health: Antibiotic Resistance" pamphlet.[22] Clinical practice guidelines were distributed to all participating practices. These were adapted from "Principles of Antibiotic Use for Treatment of Acute Respiratory Tract Infections in Adults" created by the American College of Physicians-American Society of Internal Medicine.[12] The guidelines included information concerning the syndrome, etiology, course of illness, and treatment recommendations for common adult URIs including nonspecific URIs, acute pharyngitis, acute rhinosinusitis, and acute bronchitis.

In addition to the above materials, The Carolinas Center for Medical Excellence developed a symptom relief kit known to patients and providers as the "self-care kit." This kit consisted of an assortment of items used for education and symptomatic relief in a custom-designed 6x4x1.5 inch box (Figure 1). Each kit cost approximately $6. Providers were encouraged to distribute the kit and other intervention materials, in place of antibiotics, to patients with URIs. Practices were encouraged to distribute these materials to all patients with URIs regardless of insurance status and payer. The kit included a postcard survey returned via mail to assess patients' impression of the usefulness of kit contents. The response rate (2.6%) was too low to be meaningful, and the patient survey results are, therefore, not reported here.

It was recognized that recommended treatment approaches for URIs may differ among professional societies. Although the American College of Physicians guidelines were distributed, the adoption of these guidelines versus others was not specifically requested. The main focus during educational meetings with physicians was to describe and encourage the use of the symptom therapy kit as an alternative to antibiotics when, in the physician's judgment, the likelihood of a bacterial infection was low.

Project Evaluation

Interviews and surveys completed by participating physicians were used to evaluate the feasibility of this approach. The prevalence of filled prescriptions for oral antibiotics following index patient-physician encounters for URIs occurring during baseline (January 1, 2001-March 31, 2001) and intervention (January 1, 2002-March 31, 2002) measurement periods was determined from Medicaid pharmacy claims as a model for the evaluation of a large-scale implementation of this intervention beyond the pilot phase. Antibiotics were identified using the *Physician's Desk Reference and the National Drug Code (NDC) Directory*. NDC numbers for oral antibiotics in the Medicaid pharmacy claims database were obtained from the Multum Lexicon™ database (Multum Information Services, Inc., Denver, CO, 2001). The number of days from the date of the index patient-physician encounter for URIs to the first pharmacy service date for an oral antibiotic prescription was evaluated as a potential indicator of intervention efficacy.

Patient Populations

Patient populations for this project consisted of all adult patients with nonbacterial URIs seen at any of the participating practices. Complete information regarding these populations is not available. Medicaid administrative claims were used for limited practice characterization.

According to our claims-based evaluation protocol, a Medicaid recipient must have had at least one face-to-face outpatient encounter with a family medicine, general practice, or internal medicine physician for acute nonbacterial URIs during the measurement period. Qualifying outpatient physician-patient encounters were identified based on *Current Procedural Terminology (CPT)*[23] and *International Classification of Disease, 9th Revision, Clinical Modification (ICD-9-CM)*[24] codes in Medicaid claims.

In our claims-based evaluation protocol, the conditions and diagnosis codes for acute nonbacterial URIs were acute nasopharyngitis (460), acute pharyngitis (462), acute upper respiratory infections (465.9), acute bronchitis (466.0), and influenza (487.1). Index encounters must have occurred in the baseline or intervention measurement periods. Patients with acute nonbacterial URIs encounters less than 90 days prior to the index encounter were excluded. Patients with chronic respiratory conditions were also excluded: chronic bronchitis (491), emphysema (492), asthma (493), and chronic obstructive pulmonary disease (496). These conditions were identified from claims for outpatient services occurring during an observation period beginning 90 days prior to the index visit. To exclude a patient for chronic conditions, there must have been two or more claims at least six days apart specifying at least one of the chronic respiratory condition diagnosis codes.

Analysis

All analyses were performed at The Carolinas Center for Medical Excellence. Data from physician interviews and surveys were recorded and analyzed using electronic spreadsheets. Our pilot methodology for claims-based evaluation used Medicaid data provided by the North Carolina Department of Health and Human Services Division of Medical Assistance. Statistical and claims analyses were performed using SAS v9.1 statistical software (SAS Institute, Inc., Cary, NC).

Results

Intervention Uptake

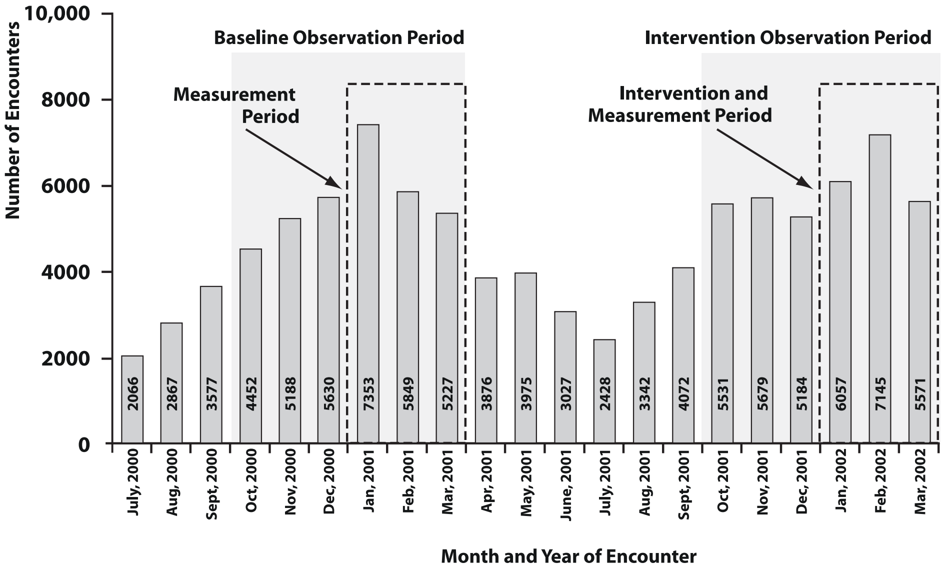
Surveys completed by all participating physicians (n=14) in late April and early May 2002 indicated an overall positive view of project interventions and their effect on prescribing patterns. Results suggest that most physicians frequently felt pressured to prescribe antibiotics. On average, physicians reported that they would prescribe antibiotics for acute nonbacterial URIs 39% of the time before the intervention and 20% of the time after the intervention. All physicians surveyed thought the kits were helpful, and most believed their patients also found the kits useful. On average, physicians reported they had given kits to 44 patients, and about a third of patients who received the kits were enrolled in Medicaid. Posters and printed guidelines were also used by almost all physicians. In contrast, the symptom relief prescription pads were used by less than half the physicians.

Claims-based Findings

A claims-based approach is a feasible method to characterize patient populations and to assess efficacy of this intervention in large-scale studies designed for this purpose. Statewide in the Medicaid population 18 to 64 years of age, there were 98,096 patient-physician encounters for acute nonbacterial URIs from July 1, 2000 through March 31, 2002. These involved 55,614 patients seen by 1,739 providers. The number of encounters varied seasonally, as expected (Figure 2), with the highest monthly counts occurring in January 2001 and February 2002. During the baseline measurement period there were 18,429 encounters involving 14,960 patients and 1,210 providers. During the intervention measurement period there were 18,773 encounters involving 15,439 patients and 1,269 providers. The distributions of specific URIs diagnoses were similar during the baseline and the intervention measurement periods, with approximately 2% of encounters for acute nasopharyngitis; 17-18% for acute pharyngitis; 32-33% for acute upper respiratory infections; 43% for acute bronchitis; and 4-5% for influenza.

The state population was mostly female (78%) and Caucasian

Figure 2.
Number of patient-physician encounters by month and year for acute nonbacterial upper respiratory tract infection among Medicaid recipients 18 to 64 years of age in North Carolina.



(59%). African Americans were the largest minority group (31%). Almost three quarters (73%) were less than 50 years of age. Participating practices differed substantially from the state and among each other with respect to Medicaid patient population size, age, sex, and race/ethnicity composition (Table 1).

In the Medicaid claims analysis for this pilot project, there were 15,628 and 16,020 pharmacy claims for oral antibiotics during the baseline and intervention measurement periods, respectively, in the statewide population of Medicaid patients seen for URIs. Among patients filling an antibiotic prescription for URIs, about 79% of pharmacy claims occurred by the day following the patient-physician encounter, and 84% occurred within 5 days. More than half of the statewide population filled a prescription for antibiotics within 5 days of seeing a primary care provider for acute nonbacterial URIs. The prevalence of pharmacy claims for antibiotics declined slightly, from 59% to 58% statewide, comparing baseline and intervention measurement periods. Rates also decreased in the intervention practices (Table 2). The extent to which these declines were related to the intervention cannot be determined due to limitations in the study design in this pilot study. Nevertheless, these effectiveness measures can be readily determined from administrative claims supporting a claims-based methodology for the evaluation of an efficacy study.

Discussion

Antimicrobial resistance has increased at an alarming rate, both in hospitals and in the community. During the five-year period from 1994–1995 to 1999–2000, penicillin susceptibility decreased from 76% to 66%, and erythromycin susceptibility from 90% to 74%.[25] The overall proportion of penicillin non-susceptible pneumococci within a population-based surveillance program across the United States in 1997 was 25%.[3] The southeastern United States has demonstrated the lowest susceptibility of all regions, with up to one third of pneumococci isolates demonstrating antibiotic resistance.[3,4,26]

The excessive use of antibiotics in the outpatient setting has contributed to the increase in antimicrobial resistance.[5,27] In one study, antibiotics were prescribed for 51% of patients diagnosed with colds, 52% with upper respiratory tract infections, and 66% with bronchitis.[9] The progression of antimicrobial resistance can be reversed. For example, in Finland, nationwide reductions in the use of macrolides resulted in a significant decline in resistance among Group A streptococci.[8]

Table 2.
Percent of patients filling antibiotic prescriptions within 5 days of index encounter for acute nonbacterial upper respiratory tract infection among Medicaid recipients without chronic respiratory conditions during the baseline and intervention measurement periods in participating practices.*

	Intervention Practice % (total Number of Patients with URI)		
	1	2	3
Baseline Period Jan 1, 2001-March 31, 2001	62 (40)	67 (33)	64 (101)
Intervention Period Jan 1, 2002-March 31, 2002	39 (41)	60 (25)	60 (128)

*These descriptive data are not useful for evaluation of intervention effectiveness due to limitations in study design and statistical power.

Results from our pilot project suggest that physicians respond favorably to interventions aimed at reducing antibiotic use for nonbacterial URIs. The symptom therapy kits were especially well received. An expanded study to test the efficacy of this approach could be supported by our findings. Furthermore, the claims-based evaluation methodology created as part of this project appears to be a feasible method to evaluate intervention efficacy in a study designed for this purpose. The availability of Medicare pharmacy benefits starting in 2006 offers the potential for expansion of this evaluation into the Medicare population.

We have reported that the North Carolina Medicaid program paid more than $1.5 million for 33,061 oral antibiotic prescriptions filled for acute nonbacterial URIs from October, 2000- March, 2001.[18] The average prescription cost of $45 during this period well exceeds the $6 cost of the self-care kit. Healthcare payers may find such kits a cost effective alternative to antibiotics. Providers interviewed during the project suggest that, when the kit is offered during outpatient office visits, it serves as a catalyst to foster better patient-physician communications, promotes increased knowledge, and enhances awareness of expectations.

Important strengths of this study include a multi-site implementation, pre-post quantitative evaluations, qualitative evaluations, and the inclusion of diverse patient populations commonly seen by primary care providers throughout North Carolina. The extent to which project practices represent the "typical" North Carolina practice is not known. Characteristics of Medicaid patient populations for some project practices differed substantially from those of the state. This should be considered when evaluating the generalizability of our findings. Patient populations seen in these practices include Medicaid and minority populations common to other practices throughout the state. In this respect, the project practices may share similar barriers related to URI treatment with other practices statewide. A limitation is the low response rate to patient surveys. As a result, the acceptability of this intervention to patients could not be directly determined.

Medicaid claims-based evaluation of efficacy may be limited by several factors. Medicaid patients generally have good access to medications through the program's pharmacy benefit, and information about this access is readily available through the Medicaid program; however, these patients are not necessarily representative of the overall patient population. The effect of interventions cannot be determined for patients not in Medicaid. Our inability to distinguish between patients who were not prescribed medications from those who were prescribed but did not fill prescriptions is another limitation of claims-based evaluation.

In conclusion, our multi-pronged approach to reduce antibiotic use for URIs in the outpatient setting by targeting barriers related to understanding and communication shows much promise. We have found that these efforts are feasible and welcome in outpatient practices. We have also shown that physicians are very receptive to symptom relief kits, especially when combined with patient education. Unfortunately, a statistically rigorous proof of effectiveness was not possible, nor was it our goal, given the limited nature of a pilot project. Nevertheless, it is reassuring to find that antibiotic use rates declined for all participating practices. These findings suggest that an expanded study to test the effectiveness of this approach is warranted. **NCMedJ**

Acknowledgements: The investigators acknowledge and thank participating physicians, their patients, and their staff for making this project possible. We also thank the North Carolina Division of Medical Assistance and its staff for their guidance in project development and for the provision of the Medicaid claims data used for project evaluation. We are grateful to Anna Cook, Senior Associate for Corporate Information at The Carolinas Center for Medical Excellence, for the graphic design of the symptom therapy kits. This project and manuscript (Internal Tracking Number 7SOW-NC-PUB-05-02) was conceived and funded by The Carolinas Center for Medical Excellence, formerly known as Medical Review of North Carolina, Inc.

Public Health News Frames in North Carolina Newspaper Coverage of the 100% Tobacco-Free Schools Campaign? Sometimes

Suzanne DePalma Morrison, MPH; Sonya F. Sutton, MA and Felicia E. Mebane, PhD

Abstract

Objective: *News organizations are an important and influential part of the social environment. They identify certain issues by the extent and nature of their coverage. To help explain what public health policy messages may have influenced school policy decisions, this content analysis provides an examination of newspaper coverage of North Carolina's 100% tobacco-free schools campaign.*

Data Collection Methods: *Researchers searched LexisNexis for articles published in North Carolina newspapers between January 1, 2001 and December 31, 2004 that included variations of "North Carolina tobacco-free schools." Researchers then conducted a descriptive analysis of 138 stories from nine North Carolina newspapers (approximately 4% of all the state's newspapers) and used page placement and story type to examine the level of importance placed on the issue. Finally, frames for and against tobacco-free school policies were tracked, along with the presence of key messages presented by 100% TFS advocates.*

Principal Findings: *The volume of news coverage changed throughout the study period, with peaks and valleys closely associated with external "trigger" events. In addition, a majority of the newspaper articles did not include key public health messages.*

Conclusions: *The results suggest an opportunity for public health experts and officials to work more effectively with local journalists to increase the use (and impact) of public health messages in news coverage of tobacco policies affecting youth.*

Introduction

Tobacco use is a tremendous public health burden in North Carolina, particularly among youth. The results of tobacco prevention research in schools show that school districts with a 100% Tobacco-Free School (TFS) policy in place (one that bans all tobacco use, everywhere on campus, by everyone, at all times) have a lower rate of tobacco use among youth.[1,2]

North Carolina state law prohibits tobacco use inside school buildings, but permits local school boards to establish policies for outdoor tobacco use by students, school staff, and school visitors.[3] In 2000, 90% of North Carolina's 115 school districts had policies that permitted school staff, visitors, and/or students to use tobacco on campus and at school-related events.[4] In response, the North Carolina Tobacco Prevention and Control Branch (TPCB) of the North Carolina Department of Public Health initiated a statewide campaign to encourage all school districts to adopt a 100% TFS policy.[5] This initiative has relied on advocacy strategies to draw attention to the issue and promote public health frames intended to influence how the public and policymakers respond to the proposed policy changes. As of January 2006, 65 districts were 100% tobacco-free.[6,7]

As public health leaders and advocates focus their efforts on 100% TFS policy adoption in the remaining North Carolina school districts, it is important to understand what information on this issue is available to policymakers and to consider the kinds of messages or data needed to inform these debates. The primary aim of this study is to describe whether key public health messages, sources, and data related to 100% TFS policies are being presented in print news media. Following this analysis, recommendations are offered for how existing media advocacy strategies promoting public health messages can be improved

or expanded so 100% TFS policy debates are informed by public health goals and evidence.

An Overview of North Carolina's 100% Tobacco-Free Schools Campaign

North Carolina's 100% TFS campaign was spurred by former Governor Jim Hunt's Teen Tobacco Use Prevention Summit in January 2000. The Summit was organized by state leaders in response to the high tobacco usage rates among North Carolina's youth reported in the 1999 Youth Tobacco Survey.[8] The initiative gained momentum in 2002 with the creation of the 100% TFS Program within the TPCB. In June of the same year, the State Board of Education passed a resolution encouraging, but not requiring, all North Carolina school districts to adopt this policy. Finally, in July 2003, the North Carolina General Assembly passed Senate Bill 583 (SB 583) entitled "Tobacco Use in Schools."[9] This new law joined federal legislation in banning tobacco use in school buildings and gave school districts the authority to adopt 100% TFS policies that are more restrictive than the state law. By December 2005, 57% (65) of North Carolina school districts had adopted this policy. This paper focuses on how some of the key public health messages, sources, and data were reported in newspapers by North Carolina journalists from 2000 through 2004.

The Significance of News Frames in Public Policy Debates

News reports, analyses, and commentaries comprise the principal arenas within which scientific, medical, and public health controversies are defined as public problems and are brought to the attention of decision makers, interest groups, and the general public.[10] News coverage (in print and other media) affects the shape and outcome of health policy debates in two key ways: agenda setting and story framing.

First, agenda setting theory shows that the capacity of the public's or policymakers' agendas is limited.[11] At any time, only a few major issues—out of the hundreds that can be reported each day—are of concern to the general public or policymakers. Journalists' and editors' story selections focus a spotlight on issues that are reported. The spotlight can be enhanced by the relative prominence of placement of news reports.[12-14] By emphasizing some issues with repeated and prominent coverage, the news legitimizes and increases the salience of highlighted problems, leading people to seek solutions for highly visible issues, often to the exclusion of unpublicized ones.[11,15-20] In sum, journalists may influence health policy by highlighting issues and policies that then become more likely than other issues to find a place on the public agenda.

Second, journalists use frames, a central organizing idea or story line, to tie information together or provide emphasis and to quickly convey the essence of an issue.[21] By emphasizing a specific component of an issue or policy solution over another, news frames can influence which considerations are deemed most accessible or most important when the public is making policy choices.[22,23] Frames within news articles provide direction for audiences by assigning relative importance to particular problem definitions, causal interpretations, moral evaluations, or preferred courses of action.[24,25]

Thus, by presenting particular interpretations of problems and policies, issue frames presented in the news can become a key basis for public policy decisions.[26,27] And, once an issue is framed by news coverage, it can be very difficult for policymakers and other interests to shift the image of the issue to another perspective.[10]

Key Research Questions

This analysis evaluates news coverage about 100% TFS policies in North Carolina with regard to agenda setting and framing. The time period, 2001-2004, represents the first key phase of the 100% TFS campaign. This analysis examines the volume and prominence of the North Carolina newspaper coverage of 100% TFS schools as well as the tobacco control frames and messages that were reported.

Methods

This study analyzes newspaper coverage of the 100% TFS issue in North Carolina from January 1, 2001 to December 31, 2004 in major daily newspapers in the state. Reports on this topic were identified by performing a key word search using phrases related to "North Carolina tobacco free schools." We collected all of the reports with the key terms anywhere in the full text of the article from the sources listed for North Carolina in the LexisNexis news archive between November 2004 and February 2005. The resulting nine English language newspapers were from the North Carolina news outlets in the LexisNexis archive and represent 4% of the state's newspapers. Initially, we retrieved and reviewed 192 articles against our inclusion criteria, leaving 138 in our final sample.

Outcomes Measures: General

Each article was coded for the newspaper that published it, the date of publication, and whether 100% TFS was the focus of the report or part of a broader discussion. The inverted pyramid style of journalism calls for the most important information of the article to be placed at the beginning or lead.[28] Consequently, 100% TFS was considered to be the focus when it was mentioned in the headline or lead sentence or discussed in at least one-third of the article. In addition, each story was coded for whether it was a regular news report, a news brief, an editorial or letter to the editor, or commentary. Hard news stories (the regular reports and news briefs) are expected to report the who, what, when, where, and how of a news event with no explicit opinion.[28] A newspaper's editorial page, letters to the editor, or commentary pieces are intended to convey the views or opinions of the editorial board of a newspaper or the author. This variable allows for a better understanding of the sources of the public health frames.

Outcome Measures: Agenda setting

The extent of the 100% TFS coverage was measured by counting the volume of news coverage over the study period. In addition to reporting significant issues more often than other issues, editors and reporters give information they consider important more prominent placement.[29] Because prominent stories are more likely to have an impact on audiences, each article was coded for whether it was published on the front page of the first section of the newspaper, on the front page of the local news section, or in other sections.

Outcome Measures: Framing

A preliminary review of the North Carolina news articles confirmed reliance on two, prominent policy frames on each side of the tobacco policy debates. The primary frame supporting 100% TFS, that tobacco in schools is a children's health problem, uses a public health frame implying that 100% TFS is necessary to provide a healthy school environment. The primary opposing frame, that adults have a right to use tobacco as they see fit, consolidates the argument around infringement on the personal rights of adults who work in schools or attend school functions. Each article was coded for whether it mentioned either of these issue frames.[27,30]

Regardless of the frame through which the story was told, each report was also coded as to whether it contained two messages about tobacco use that are offered as an underlying rationale for 100% TFS policy and are based on public health research. We measured whether the articles included (1) information that secondhand smoke is dangerous to youth and (2) that role modeling of tobacco use by peers and adults is associated with an increase in youth tobacco use. Each article was also coded as to whether specific data, such as youth tobacco use rates, were mentioned.

Coding

Each outcome measure was based on published analyses of news coverage of health or health policy topics and a review of prior debates of tobacco free schools.[27,36-37] A codebook was developed and the coding for each variable was pre-tested. Coding reliability was tested on a 25% probability sample of the population of articles. Coder agreement, calculated as the percentage of agreement between the two coders, was 94% across 54 variables. Data were analyzed using a combination of Microsoft Excel and SPSS software.

Results

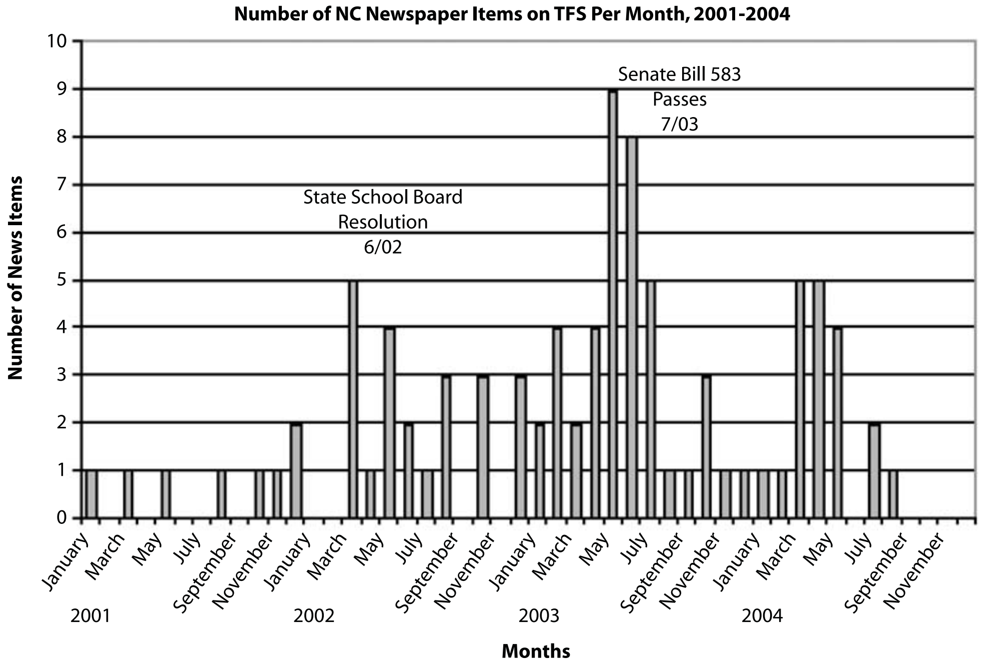
General

A majority of the 138 articles identified in our search came from North Carolina's largest daily newspapers, with the greatest percentage of articles (23%) came from the *Raleigh News & Observer*, which serves the state capital and covers state government issues closely. Eighty-eight of these news items (64%) were focused on 100% TFS in either the headline, lead or at least one-third of the article. Regular news reports accounted for more than half (55%) of the articles analyzed. Thirty-five percent were news briefs and 10% were opinion pieces (i.e., commentary or editorials/letters to the editor).

Agenda Setting

Figure 1 shows that there were several peaks and valleys in the volume of 100% TFS newspaper coverage in the time period. Events such as the State School Board Resolution and the debate and passage of SB 583 are associated with an increase in news coverage. Following these events, the coverage level dropped to previous levels. As another indication of the prominence of these reports, one quarter of the articles appeared on a front page of a newspaper section; 7% appeared on the front page of the entire

Figure 1.
Monthly Distribution of 100% TFS News Items in North Carolina Newspapers, 2001-2004, n = 90



newspaper, and 18% appeared on the front page of the second section of the newspaper, which is usually devoted to local news.

Framing

Slightly less than half (47%) of the news items included at least one of the two dominant policy frames. The children's health frame was used in 33% of the news items, while 19% of the stories framed the issue around individual rights (see Table 1). The messages about dangers of secondhand smoke and the importance of role modeling for school staff were apparent in the coverage. Thirty percent of the reports included the secondhand smoke message, and 28% included the role-modeling message. Fifty-seven percent included neither of these messages.

Table 1.
Distribution of Public Health Policy Frames and Messages in 100% TFS Coverage in North Carolina Newspapers, 2000-2004

Frames	**% of News Items n = 138**
Children's Health	33%
Individual Rights	19
Neither of these	53
Messages	
Danger of second hand smoke and smoking for youth	30
Impact of role modeling on youth	28
Neither of these	57

Discussion

The results of this analysis provide the first systematic description of the extent and content of newspaper coverage of North Carolina's 100% TFS movement from 2001-2004. First, the volume of reports from these newspapers appears to reflect coverage of "trigger" events, such as adoption of the statewide school board resolution on 100% TFS, rather than continued interest in the local processes considering 100% TFS across the state. While this trend is not surprising given journalists' reliance on events as a catalyst for news reports, it also highlights the fact that proponents of 100% TFS will likely have to continue their advocacy campaigns to provide incentives for continued coverage.

Second, the prominence of these stories provides another view of what priority newspapers placed on reporting the 100% TFS policy. Very few (7%) of the 100% TFS articles in this study made it onto the front page of the newspaper. While newspaper coverage is not the only indicator of the public policy agenda, it is an important indicator of how the public perceives an issue.

Several factors may have influenced the extent and prominence of this newspaper coverage of the debate. First, newspaper editors may consider 100% TFS debates a community news story, one more likely to be covered by a local newspaper. Second, debates about 100% TFS in a newspaper's market may not have been controversial and reporters and editors may not have believed they merited attention or prominence in the news coverage. This explanation suggests that advocates wanting to raise the salience of 100% TFS in school districts should spend some advocacy efforts on finding ways to connect 100% TFS to values, consequences, and conflicts that are newsworthy or connect with the communities' top priorities. Getting more front page coverage about 100% TFS could help move this policy onto or up school boards' agendas. Third, reporting on the issue may be especially challenging for North Carolina newspapers. Editors may hesitate to take on a topic that has the potential to alienate some of their readers, for example, those who use or make their living from tobacco. Fourth, there is also a tendency for news items to naturally run out of steam, especially if not refreshed by new information or story lines. Finally, editors may have chosen to feature other tobacco-related stories during the study period, including the proposed tobacco tax and the tobacco buyout.

A third key finding is that although these newspapers' reporters used the children's health issue frame in nearly twice as many articles as the rights frames, a large majority of the articles did not contain this public health frame. These results suggest that public health frames in connection with 100% TFS may not be getting through to news audiences.

This study has several limitations. One drawback of this type of evaluation is the lack of consensus in the broader public health and journalism communities about what constitutes high quality coverage for 100% TFS and related policies. For assessments of news coverage to be most effective, they should be guided by a normative standard incorporating the goals and constraints of news reporting and the information needs of the general public. Further discussion and analysis is needed to determine and apply a policy news reporting standard to tobacco free schools policy coverage.

Another limitation is that the newspapers included are only a small proportion of the newspapers in North Carolina. Because LexisNexis is a key news archive and is often used as the basis for this type of analysis, we believe our findings highlight important insights that warrant further investigation with a more representative sample of North Carolina news. This study points to the need for research that identifies the full scope of reporting on the issue and examines in detail why local journalists report on tobacco-free school policy issues as they do (or do not) and the impact those choices have on local and state level debates.

Finally, though this study reported on the use of data and sources in articles related to tobacco free schools, it did not assess the accuracy or balance of the information presented. News stories that contain inaccurate information or portray circumstances with an obvious bias can result in opinions or views about policies that are misinformed and not truly reflective of public preferences.

Conclusions

Based on these results, additional public relations events and promotions from state leaders may help raise 100% TFS on journalists' agendas. At the same time, providing opportunities for journalists to report proactively, rather than focus on event-driven coverage, may help to increase the number of 100% TFS articles. For example, public health advocates may arrange to meet with reporters and editors to discuss the benefits of the policy to students and school districts. They may provide other reporting angles, such as education, business, or economics, that might broaden its appeal to news audiences and convince reporters that the issue is important because of its statewide scope. Reporting frames that link 100% TFS with other tobacco-related stories, such as those on hospitals, worksites and universities considering a tobacco-free policy, may also help raise the salience of 100% TFS. Finally, for public health framing to gain traction in news coverage, public health advocates should consistently promote several public health angles, including the one that moved public policy in early tobacco control debates, specifically the notion that tobacco kills.

In sum, news organizations have an important role to play in public health policy development in all types of settings, including schools. While news professionals make the decisions about how to write a story, advocates and public health leaders who work with journalists can help inform and shape the views of the public and policymakers. For the 100% TFS policy, improved news coverage could help the issue garner more attention from North Carolina residents and policymakers. **NCMedJ**

ARTICLE

Skin Problems Related to the Occupation of Commercial Fishing in North Carolina

William A. Burke, MD; David C. Griffith, PhD; Christopher M. Scott, MD and Eric R. Howell, MD

Objective: *Commercial fishing is one of the most dangerous professions with many of the occupational health problems related to the skin. This study elucidates the types of occupational skin disorders that occur in commercial fishermen in North Carolina.*

Study Design/Settings: *Booths were set up offering free skin cancer screenings at various seafood festivals, a "blessing of the fleet" event and commercial fishing shows, which were located throughout eastern North Carolina from 2002-2004. When commercial fishermen were screened, they were asked about significant skin problems that they had experienced and were related to their occupation. They were specifically asked about their history of (1) cancerous and precancerous skin lesions, (2) eczemas, (3) superficial fungal infections, (4) bacterial infections of the skin, (5) traumatic injuries related to the skin, (6) bites and stings, (7) shocks from fish, and (8) skin problems related to environmental extremes.*

Results: *Eighty-one North Carolina watermen were screened: seven of the fishermen (9%) had at least one basal cell carcinoma, five (6%) had at least one squamous cell carcinoma, and no melanomas were detected. Many occupationally related skin disorders were noted on the historical survey, and some of the more dangerous of these included traumatic injuries related to fishing equipment, cutaneous cancers, fish bites, infections, stingray injuries, and man-of-war stings.*

Limitations: *The sample population was comprised of volunteers, which limits generalizability, and some diagnoses were established retrospectively.*

Conclusions: *There are a wide variety of skin disorders among commercial fishermen in North Carolina and healthcare professionals should be aware of these when working with watermen.*

Key Words: *Fishermen, fishing industry, occupational health, skin diseases.*

Introduction

North Carolina is usually ranked amongst the nation's top ten seafood producing states and has approximately 4,000-7,000 active full-time commercial fishermen harvesting catches from its 4,000 miles of marine and estuarine shoreline.[1-3] Situated where the cold-water Labrador Current meets the warm tropical waters of the Gulf Stream, North Carolina waters offer an especially wide and diverse variety of seafood.

Commercial fishing is well-known to be one of the most hazardous of all occupations.[4] A significant proportion of work-related health problems in this industry affect the skin.[5,6] The skin of fishermen is often exposed to high levels of wetness; to a variety of potential cutaneous pathogens; to estuarine and marine flora and fauna that can bite, sting, shock, or otherwise cause contact/irritant skin reactions; to multiple types of traumatic injuries; and to extremes of heat and cold.

Currently, very little data exist related to cutaneous diseases in the workforce of watermen in our region. The commercial fisherman is usually a stoic, independent, and hard-working individual who is often distrustful of institutions such as medicine.[7] As such, watermen often don't seek medical attention for perceived minor skin ailments. In addition, many can't afford to see a physician even for more serious problems due to a lack of personal funds as well as often having no health insurance.

The purpose of this study is to gather data about cutaneous problems related to the occupation of commercial fishing in North Carolina. In addition, an effort was made to educate the watermen and their families about some of the well-known risks of their occupation as well as some preventive measures.

William A. Burke, MD, is Professor, Division of Dermatology,Brody School of Medicine, East Carolina University. He can be reached at burkew@ecu.edu or Department of Internal Medicine-Dermatology, Brody Medical Science 3E117D, Greenville, NC 27858. Telephone: 252-744-2555.

David C. Griffith, PhD, is Professor and Research Scientist, Institute for Coastal and Marine Resources, East Carolina University.

Christopher M. Scott, MD, is Resident, Division of Dermatology, Brody School of Medicine, East Carolina University.

Eric R. Howell, MD, is Resident, Division of Dermatology, Brody School of Medicine, East Carolina University.

Materials and Methods

From 2002-2004, multiple seafood festivals, commercial fishing shows, skin cancer screening sessions, and a "blessing of the fleet" event, all taking place in eastern North Carolina, were attended by our faculty group at ECU (see Table 1). At these events, a booth offering free skin cancer screenings to all interested individuals (including commercial fishermen) was set up. While the vast majority of people who presented themselves for screening were not watermen, those who were fishermen (and who agreed to a short survey) were questioned about their previous history of skin problems related to their work in commercial fishing. A skin examination of their scalp, face, ears, neck, and upper extremities was performed by an experienced board-certified dermatologist. Impressions of clinical lesions were recorded, but biopsies were not done.

Table 1.
List of events/places where screenings and study took place.

Event Attended	Date(s)	# Fishermen Screened
North Carolina Commercial Fishing Show (New Bern, NC)	February 23-24, 2002	20
Engelhard Seafood Festival (Engelhard, NC)	May 18, 2002	6
Blessing of the Fleet (Hobucken, NC)	June 15, 2002	7
Swansboro Mullet Festival (Swansboro, NC)	October 12, 2002	0
Mill Creek Oyster Festival (Mill Creek, NC)	November 2, 2002	2
Carteret Skin Cancer Screening (Beaufort, NC)	February 18, 2003	6
North Carolina Commercial Fishing Show (New Bern, NC)	February 22, 2003	12
North Carolina Commercial Fishing Show (New Bern, NC)	February 28, 2004	19
Pitt County Memorial Hospital/ECU clinics (Greenville, NC)	various, 2002-2004	9
Total		**81**

The survey instrument was designed by the authors and included the current skin cancer screening results as well as the historical information related to previous skin problems the dermatologist obtained through interviewing the participating fishermen. This information included previous personal histories of precancerous and cancerous skin lesions, eczematous (including allergic) conditions, superficial fungal infections, bacterial infections, traumatic injuries, bites and stings, fish shocks, and problems related to environmental extremes. In addition, questions were asked related to demographics, including zip code of the domicile, age, sex, full-/part-time work; where they fished (inshore/offshore/both); and whether they had insurance. Skin phototype[8] (ranging from skin type I through skin type VI) was also assessed by the dermatologist. A person with skin type I has extremely fair white skin that never tans and always burns with even minimal sun exposure. In contrast, an individual with skin type VI has very dark brown skin that pigments extensively and almost never burns. The research protocol was approved by the East Carolina University Brody School of Medicine Institutional Review Board.

IV – VI	0	(0)

* includes 13% over 65 on Medicare

Results

A total of 81 North Carolina commercial fishermen were screened, a sample representing approximately 1-2% of all licensed watermen in the state. All of the watermen who presented to the researchers and were asked to participate in the study consented to the survey. Background information collected on these individuals is summarized in Table 2.

These fishermen lived from as far north as Moyock

(Currituck County), North Carolina to as far south as Southport (Brunswick County), North Carolina (see Figure 1). A summary of the clinical data is listed in Table 3.

Figure 1.
Map of Eastern North Carolina Showing Hometowns (dots) of Fishermen Participating in this Study.

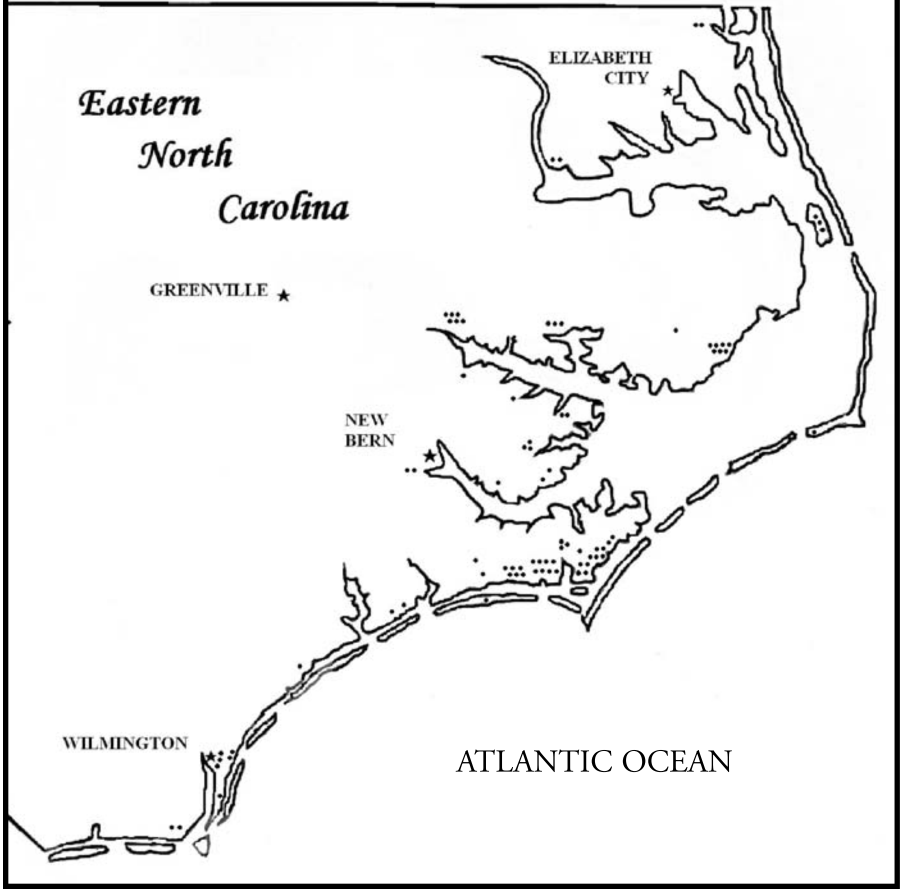

Table 3.
Clinical data on the 81 commercial fishermen in this study.

Skin Problem	# Fishermen in "Live" Screening	# with History of Problem
Actinic Keratosis	49 (60%)	27 (33%)
Actinic Cheilitis	12 (15%)	1 (1%)
Basal Cell Carcinoma	7 (9%)	15 (19%)
Squamous Cell Carcinoma	5 (6%)	7 (9%)
Malignant Melanoma	0 (0%)	3 (4%)
Eczema		30 (37%)
Superficial Fungal Infection		24 (30%)
Bacterial Infection		47 (58%)
Traumatic Injury		25 (31%)
Bites/Stings		69 (85%)
Fish Shocks		12 (15%)
Heatstroke/Frostbite		0 (0%)

Cancerous/Precancerous Skin Lesions

Of the 81 fishermen screened, only one (1%) had skin type I (fair-skinned white individual who burns extensively and never tans), 76 (94%) had skin type II (fair-skinned white individuals who usually have lighter hair and blue eyes and who burn easily and tan with difficulty), and four (5%) had skin type III (average white individual with darker hair and brown eyes who burns moderately, but tans well). Forty-nine (60%) of the fishermen had a total of 269 precancerous actinic keratoses. Individuals had between 1 and 45 actinic keratoses, Of these individuals, one had skin type I with the remainder having skin type II. Twelve watermen (15%) had actinic cheilitis (all skin type II). Seven fishermen (9%) had a total of 14 basal cell carcinomas (one with type I skin and six others with skin type II). Five fishermen (6%) had a total of seven squamous cell carcinomas (all skin type II). There were no malignant melanomas found in the limited skin screening in this group of watermen.

Twenty-seven (33%) of the fishermen reported a previous history of having been treated for actinic keratoses, and one (1%) had previously diagnosed actinic cheilitis. All of these men had skin types I and II, and their average age was 58 (range = 40-79). Fifteen (19%) reported having had a total of 28 basal cell carcinomas. The mean age of these watermen was 59 (range = 48-79) and all had skin type II. Seven (9%) of the 81 total fishermen reported having had ten squamous cell carcinomas. The mean age of those reporting a previous history of squamous cell carcinomas was 64 (range = 48-79), and all had skin type II. Three (3.7%) of the overall group gave a history of having had malignant melanoma. All of them had skin type II, and their mean age was 63 (range 59-72).

Eczemas

A total of 30 fishermen (37%) reported a history of "eczema," with hand eczema and eczema of the forearms accounting for all of these cases. It was generally reported by the fishermen that the problem was worse in the winter months. Although there may be others, three of this group reported having had rashes that suggested a history of an allergic contact dermatitis: one who was allergic to rubber/latex gloves, one who reacted only when handling shrimp, and one who reacted only after handling squid.

Superficial Fungal Infections

Of the entire group of watermen studied, 24 (30%) gave a history of having had superficial fungal infections. The majority of them gave a history of "athlete's foot" (tinea pedis), with others giving a history of hands, legs, groin, and nails being involved (often combined with their feet). One individual gave a history of a fingerweb "fungus infection" when working in gloves, and this was likely due to *Candida* (erosio interdigitale blastomycetica).

Bacterial Infections

Commercial fishermen are exposed to many disruptions of the epidermal barrier to skin infections due to the minor cutaneous traumatic injuries in their day-to-day work in handling fish/crustaceans with spines, sharp shells, pinch injuries, and fish bites. A total of 47 fishermen (58%) described having had a bacterial infection that was serious enough to warrant seeking medical care, and many of them described multiple episodes.

The largest numbers of cases of infection were described by individuals as "fish poison," "shrimp poison," "crab poison," or "scallop poison," and were reported by 25 fishermen (31%). These are common names for the usually transient and self-limited cellulitis known as erysipeloid due to the organism, *Erysipelothrix rhusiopathiae*. True cases of erysipeloid may, however, be difficult to sort out from fish envenomations in this historical study. Many fishermen reported not seeking medical attention except for the most serious episodes of erysipeloid, and yet, *Erysipelothrix rhusiopathiae* can disseminate and cause endocarditis as well as other sequellae.[9]

The next most common infection where medical attention was sought was abscess formation in eight fishermen (10%) and cellulitis in seven fishermen (9%). These infections were often related to a puncture wound (fish/crab/shrimp spine or splinter injury) or a laceration (crab pinch, fish bite or other traumatic injury).

Three (4%) of the fishermen reported seeking medical attention for cases of *Mycobacterium marinum* infection. This slow-growing aquatic organism causes granuloma formation in tissue with a tumorous or verrucoid lesion enlarging over many weeks to months and usually following (and at the site of) a traumatic injury to the skin.

Other less common infections requiring medical attention were folliculitis (two fishermen; 2%) where the infection was occurring under or at the margins of rubber gloves, and an acute paronychia infection of a proximal nail fold (one fisherman; 1%). One fisherman (1%) also reported that he had been treated for the infestation commonly known as "creeping eruption" or "catworms" (cutaneous larva migrans).

Traumatic Injuries

Most fishermen laughed when initially asked about traumatic injuries to the skin: "It happens every day," they answered. However, when asked about the more serious traumatic injuries to their skin where medical attention should have been sought, 31% reported in the positive. Lacerations, skin avulsions, severe puncture injuries, and crush injuries (with injury to the skin) related to boats or boat equipment occurred in eight fishermen (10%). Injuries ranged from a hatch falling, a hand crushed between two boats, a bulkhead injury, a fall on the boat, and a drill bit injury while working on the boat, to a hand caught in a boat's steering chain with loss of digits/fingertips. Lacerations, skin avulsions, or crush injuries (with injury to the skin) due to the larger fishing equipment were reported to have occurred to nine fishermen (11%). Injuries ranged in this category from a trawl door falling on a foot, a net dropping on a foot, winch injuries, block injuries, a crab pot-pull injury, a gill-netter pulley tearing a waterman's hand open, to lacerations from metal oyster gear equipment. Serious fishhook lacerations/injuries occurred in five fishermen (6%) with these occurring most commonly in the offshore/finfish fishermen. Serious knife laceration injuries occurred in three watermen (4%), and serious, deep lacerations from an oyster shell injury occurred in one fisherman (1%). Several of the fishermen reported more than a single serious traumatic event.

Bites and Stings

Virtually all of the commercial watermen interviewed were very familiar with the day-to-day exposure to minor fish bites, crab pinch injuries, shrimp spine injuries, minor jellyfish stings, minor shell cuts, minor fish stings, etc. Out of the 81 total fishermen interviewed, there were only 12 who reported never having had what they would consider a "significant" or "serious" bite/sting related to their occupation.

Serious or extensive exposure to jellyfish stings was the most common exposure occurring in 22 individuals (27%). Nettles falling from nets led to extensive and severe stings in some individuals. Indeed, 21 fishermen (26%) reported being stung by jellyfish in the eyes with temporary blindness, "blistering" of the eyes, severe conjunctivitis, and pain/edema causing temporary ocular closure. Nine fishermen (11%) reported at least one serious sting by a Portuguese man-of-war. One individual reported such a severe sting to his chest and face that he "went into shock." He recovered without medical attention as he was offshore and couldn't get to a medical facility.

Potentially one of the most severe and common sting injuries to which commercial fishermen in North Carolina are exposed is from the stingray. The injury usually occurs on the limbs, and these injuries account for many of the visits to doctors' offices in this occupational group. Twenty-six (32%) of watermen surveyed reported at least one stingray sting (range 1-13 stings). Fifteen (19%) had suffered multiple stings. Smaller sting injuries were referred to as "pin cushion" stings whereas the larger lacerations, deep puncture injuries—injuries with retained spines or those leading to infection—were those requiring medical attention.

Serious puncture injuries necessitating extraction or causing infection from fish fins/spines/bones or crab/shrimp spines/ "prongs" occurred in 16 commercial fishermen (20%). Severe fish stings (other than those due to stingrays) were reported in five individuals (6%), with the more severe stings reported due to the spiny dogfish and sea catfish.

Fish bites can also lead to severe injuries, and the more severe injuries were reported by ten watermen (12%). In North Carolina, fish reported to cause these more severe bite injuries included sharks, barracuda, mackerel, and bluefish.

Severe crab pinch injuries were more common in the inshore fishermen and were reported by nine commercial watermen (11%). These resulted in lacerations that required suturing, resulted in tendon exposure, or were crush injuries.

Fish Shocks

Some fish have specialized cells known as electrocytes, which are capable of producing an electric current strong enough to shock individuals coming in contact with them. Fish known to cause electric shocks in North Carolina waters include the stargazer (Family Uranoscopidae) and torpedo ray (Family Torpedinidae). Eleven fishermen (14%) reported shocks from stargazers and one (1%) from a torpedo ray. There were no serious sequellae, and only transient anesthesia and paraesthesias were noted.

Environmental Extremes

Fishermen often continue to work in extremes of heat, cold, and wetness. No cases of "immersion foot" were reported. There were also no cases of heat stroke although two reported "heat prostration" (with loss of consciousness in one). There were also no cases of frostbite reported, although two watermen reported frostnip injury.

Discussion

Skin cancers as well as precancerous lesions have been shown to have an increased incidence in commercial fishermen and have been found to be correlated with age and fair skin types.[10] In addition, actinic cheilitis and squamous cell carcinoma of the lip have also been shown to have a high incidence in this occupational group.[11] Sun-protective clothing, sunscreens (PABA free, waterproof, at least SPF 15), lip balm containing sunscreens, and wide brimmed hats will all lower the potential for skin cancers in watermen. It must be emphasized that even "waterproof" sunscreens will wash off with the extremes of wetness and perspiration that occur in fishermen, and frequent reapplications are needed.

A history of eczematous rashes was commonly reported by our study group with the majority fitting into the category of irritant/xerotic/atopic with only a few having allergic contact dermatitis. Allergic dermatitis to latex/rubber products is well known,[12] as are allergic reactions to seafood.[13,14]

Exposure to wetness, humidity, and perspiration likely explains the high incidence of superficial fungal infections in commercial fishermen. Interestingly, in a previous study of watermen (in Germany), there was an even higher preponderance of tinea infections than that reported by the fishermen in our study.[15]

Fishermen are occupationally subject to infections not commonly seen in persons working in terrestrially-based occupations. In addition to the more usual Staphylococcal or Streptococcal infections, aquatic organisms such as *Vibrio* species, *Aeromonas hydrophila*, and *Pseudomonas*, need to be considered when treating infections in these individuals. Very serious and life-threatening infections due to *Vibrio vulnificus* and *Aeromonas hydrophila* need to be considered in fishermen who have liver disease, are immunosuppressed, or who have chronic diseases, such as kidney failure or diabetes.[16]

Traumatic injuries to the skin in commercial fishermen were often due to the vessel, fishing equipment, or knives/hooks. Deeper as well as crush injuries may need radiologic evaluation as well as consultation with a surgical sub-specialist, both of which are often hard to arrange at the time these injuries occur among watermen.

Bites and stings were a common injury to the watermen in our study, and treatment of these injuries usually depends on the type of injury incurred. If spine/foreign body retention is possible, a radiologic examination may reveal it, and a surgical consultation should be considered. Consideration of antibiotic coverage and attention to tetanus prophylaxis is also warranted.

Fishermen in our study were the recipients of shock injuries from both the stargazer and torpedo ray. These fish can deliver shocks anywhere from 14 to 220 volts depending on the species.[17,18] No serious complications are generally noted in these injuries and no treatment is usually indicated.

Working in the hot summer heat without taking sufficient breaks, coupled with insufficient fluid intake, historically accounted for the few cases of heat prostration in our study. No cases of frostbite were recorded in this study, but prolonged exposure to cold without protective clothing/gloves accounted for the two cases of frostnip noted. It is recommended that protective survival suits be carried on commercial fishing vessels as they may be life-saving in the event of a vessel capsizing or sinking.

Conclusions

It is easy to conclude from this study that North Carolina commercial watermen are exposed to a large variety of risks to their skin including: (1) high levels of ultraviolet rays of sunlight causing development of cancerous and precancerous skin/lip lesions; (2) traumatic injuries from fishing equipment, boats, boating repairs, as well as sharp spines/shells in sea critters; (3) skin irritants and allergens, wet/dry cycles, and chapping cold exposure that all can lead to eczematous conditions; (4) wetness, humidity, and sweaty conditions leading to cutaneous fungal infections; (5) traumatic injuries to the epidermal barrier to infection as well as exposure to a variety of aquatic pathogens leading to bacterial infections, including life-threatening ones; (6) bites, stings, and shocks from marine fauna that can, at times, be severe; and (7) extremes of wetness, heat, and cold potentially leading to injury.

The most serious concerns raised by this study include the high incidence of skin cancer, especially melanoma, where 3.7% of North Carolina watermen surveyed had a history of this potentially metastatic and life-threatening form of skin cancer (as compared to a lifetime risk of 2.2% in white males in North Carolina[19] or the typically accepted 1.3% in the general population in the United States[20]). Other concerns about skin cancer relate to the high numbers of uninsured watermen, which can lead to delays in seeking medical attention.

There are several concerns when interpreting the results from this study. First, with the exception of the skin cancer screening of this group, the study is largely retrospective, relying on memories of events by the fishers themselves. The results are not proven by biopsies, microscopic tests or cultures, but rely on visual recognition and historical claims. One could make the argument that many of the accounts are embellished and magnified. However, in the opinion of our group, this is probably not a significant factor and, if anything, the stoicism and fierce independence of these individuals lends them to tend to diminish and belittle even potentially life-threatening events.

Second, some of the fishermen talked of other peers who had life-ending infections or severe disabling traumatic injuries. Obviously, the individuals who had these events were not able to present themselves for our study. Indeed, watermen coming to festivals and events likely represent the healthier and higher end of the financial spectrum of watermen. We could observe many out working in the sounds during these festivals/shows. Finally, since the commercial fisherman in our region tends to be an independent individual, lacking in finances or insurance to pay for medical care, and at times distrustful of the healthcare system, many fishermen probably did not present to our booth for a screening. It was often the spouse of a waterman who coerced him over to our booth to get screened for concerning lesions. As the participants in this study were volunteers, it is unclear whether the data collected here can be extrapolated to the entire population of watermen.

In conclusion, we have presented a study of 81 commercial fishermen in eastern North Carolina who have had a large variety of cutaneous problems related to their occupation. While this group of watermen has had severe economic pressures in recent decades, they have unique healthcare needs. Concerning issues in this group of North Carolina workers include: (1) the need for affordable health/disability insurance; (2) first aid/emergency supplies on vessels; (3) protective gear and equipment for fishermen; and (4) better access to healthcare (including specialty access) in rural fishing communities. As the economy becomes more global with its concomitant local economic pressures on this group of watermen, a more global approach both to fishing regulations and fishing safety should be pursued. **NCMedJ**

INTRODUCTION

Policy Forum:
Confronting the Problems of Overweight and Obesity

Most of us have had the embarrassing (and sometimes horrifying) experience of seeing photographs of ourselves taken some 25 or 30 years ago, only to realize that "back then" we were but a mere fraction of our present body size and shape. We wonder "What happened?" When this experience occurs just after end-of-year holidays, it can be the stimulus for numerous resolutions to address these parts of our personal lifestyles in the effort to return to a shape and size we once were.

In recent years, those of us who have devoted our lives and careers to the health and health-related professions have become increasingly aware, as have all who are exposed to the national news media, that Americans (and North Carolinians) collectively are gaining weight at an alarming pace. Recent analyses of data from the National Health and Nutrition Examination Survey (NHANES) indicate that as many as 17% of U.S. children and adolescents are overweight and 32.2% of adults are obese. Others have estimated that as many as 65% of American adults are either overweight (BMI of 25-29.9) or obese (BMI of 30 or higher). And, it is the velocity of these increases which is of even greater concern. Most of us have seen the maps produced by the Centers for Disease Control and Prevention (CDC) which, when rapidly viewed in sequence, seem to show the nation becoming "heavier" with each successive picture.

There is some good news in that the rate at which average weight in our population has been increasing over the six-year period from 1999 to 2004 is somewhat lower for women than for men, children and adolescents. From the perspective of most highly respected organizations and individuals in the field of public health, we are facing a substantial "epidemic" of overweight and obesity in this country, and North Carolina is a state where these trends are most evident.

There have been efforts to "account for" and "explain away" some of the extent, if not the likely health consequences, of these trends. One paper gaining substantial interest this past year, by Flegal and colleagues, argues that obesity, as a cause of death is far less significant than many have estimated. But the fact remains, that the percentage of our population who meet the criteria for overweight and obesity has increased significantly, and we know that there are health and healthcare costs associated with these trends.

The *North Carolina Medical Journal* has assembled in this issue a number of commentaries addressing various aspects of this epidemic in an attempt to underscore the significance of these trends for our state and our healthcare arena. We are grateful to all our contributors, particular Dr. Don Bradley of Blue Cross and Blue Shield of North Carolina, who has provided the overview Issue Brief. We are also pleased that three of our state's largest private philanthropies (The Duke Endowment, the Kate B. Reynolds Charitable Trust, and the NC Health and Wellness Trust Fund Commission) have each contributed descriptions of programs and initiatives they have funded to assist in addressing these issues. We are also pleased that some of the authors in this issue bring important "national" perspectives to bear on these topics. We appreciate the contributions of Steven Reinemund, CEO of PepsiCo and LuAnn Heinen of the National Business Group on Health, as well as Donald Hensrud of the Mayo Clinic, who have helped us put many aspects of these trends into a broader perspective.

We are aware that there are those who have resisted the use of the term "epidemic" to describe the trends we highlight in this issue of the Journal. But, few can argue that these trends are not occurring, and at an alarming pace. Addressing these issues will require the concerted efforts of healthcare professionals and healthcare organizations, voluntary organizations, employers, public schools, and local civic organizations. We hope that these commentaries will help illuminate the many ways in which these problems can (and are) being addressed in our state.

The Epidemic of Overweight and Obesity:
A Challenge to Medicine, Public Health and Public Policy

Don W. Bradley, MD, MHS-CL

The National Institutes of Health (NIH) and National Heart Lung and Blood Institute (NHLBI) define adult overweight as a body mass index (BMI) between 25 and 29.9, and adult obesity as a BMI greater than 30.[1] By those definitions, the United States is in the midst of a dramatic obesity/overweight epidemic with data being quoted from a variety of perspectives and timeframes. North Carolina is representative of national trends, with the Behavioral Risk Factor Surveillance System (BRFSS) reporting 52.3% of adults as overweight or obese in 1995 and 62.6% in 2005.[2] The prevalence of overweight amongst children (6-11 years) and adolescents (12-19 years) rose from 11% to 19% and 11% to 17%, respectively, between the 1988-1994 and 2003-2004 National Health and Nutrition Examination Surveys (NHANES).[3]

In this issue of the *North Carolina Medical Journal*, staff of the NC State Center for Health Statistics have provided recent data on the extent of the overweight and obesity epidemic in our population,[4] along with data on trends in the behaviors of youth putting them at risk of these conditions.

Some critics argue that not everyone who has a BMI >25 is overweight, that the health and economic impacts of overweight/obesity are greatly exaggerated,[5] and/or that all the hype about the obesity epidemic is a ploy by the weight-loss industry, pharmaceutical companies and some researchers to create business.[6] Actually, their arguments have some validity, which suggests several caveats as the reader "digests" the following diverse compendium of well-reasoned articles by a distinguished set of authors.

First, the critical issue is control of obesity's comorbid conditions, not weight per se. A singular focus on weight or BMI misdirects both clinician and patient regarding the importance of lean versus fat body composition or distribution of fat. BMI is a correlate, though not a direct measure of body fat and fat distribution. Rather, weight/BMI should be considered a vital sign, giving the practitioner an objective, but non-specific metric that relates to potential underlying conditions.

Two commentaries in this special issue of the *North Carolina Medical Journal* offer specific advice to clinicians regarding how discussion of overweight and obesity can be handled in the context of conventional clinical encounters with patients with or at-risk for these conditions. The first of these by Dr. Donald Hensrud of the Mayo Clinic in Minnesota outlines a broad, but specific, approach to how these issues may be addressed as part of clinical practice routine.[7] The second, a sidebar commentary by Dr. Suzanne Lazorick of the NC Division of Public Health, gives further illustrations of how BMI and other related measures can be integrated with normal practice procedures.[8]

> *"It is much easier to maintain a healthy weight (and lifestyle) than it is to remediate unhealthy eating and sedentary habits. For this reason, a key focus should be prevention and treatment of childhood obesity."*

The underlying conditions of importance include diabetes, hyperlipidemia, hypertension, coronary artery disease, osteoarthritis, obstructive sleep apnea, gall bladder disease, asthma, depression, and some cancers (e.g., colon and breast).

Simply removing body fat by abdominal liposuction will not significantly improve metabolic parameters such as insulin

Don W. Bradley, MD, MHS-CL, is Executive Medical Director, Blue Cross and Blue Shield of North Carolina. He can be reached at don.bradley@bcbsnc.com. Telephone: 919-765-4003.

sensitivity and lipid concentrations.[9] More recent evidence suggests visceral fat has a far greater impact on obesity-related metabolic disease.

Second, lifestyle change, not weight loss, is critical. Enduring weight loss requires sustained behavioral change, with or without pharmacologic support. It is those lifestyle changes—lower and improved caloric intake and increased physical activity—that impact obesity comorbidities. Multiple authors note that loss of as little as 5-10% of body weight through lifestyle changes improves metabolic parameters of diabetes and cardiac risk factors.[10,11]

Third, successful treatments of obesity-related conditions will require a different medical paradigm than is in place now. Given the need for ongoing support for lifestyle changes, obesity should be considered a chronic condition, followed by clinicians using an integrated, multidisciplinary Chronic Care Model.[12] The model is described in more detail later, and presumes involvement of the patient, the clinical team, decision support and information systems, and the community.

Fourth, prevention rather than treatment is the preferred method to deal with obesity-related conditions. It is much easier to maintain a healthy weight (and lifestyle) than it is to remediate unhealthy eating and sedentary habits. For this reason, a key focus should be prevention and treatment of childhood obesity. The complexity of prevention-oriented initiatives addressing the problem of overweight and obesity are described more fully by Jennifer Hastings and her colleagues from NC Prevention Partners in this issue of the *North Carolina Medical Journal*[13] and by Drs. Leah Devlin and Marcus Plescia of the NC Division of Public Health.[14] Dr. Alice Ammerman and colleagues from the UNC Center for Health Promotion and Disease Prevention describe the extent and the problems of addressing the epidemic of obesity among NC's racial and ethnically diverse population.[15]

Impact

Caveats given, North Carolina is in the midst of an epidemic of obesity-related conditions. Mirroring the 53% increase in obesity over the last 10 years, the self-reported prevalence (BRFSS-NC) of diabetes, elevated cholesterol, and hypertension has increased 89%, 52% and 41%, respectively, over the last ten years (see Figure 1). Notably, obesity is more prevalent in eastern North Carolina over the last four years (see Figure 2), and the rate is increasing more quickly than in the rest of the state. If comorbid conditions follow the rates of obesity, then one may assume they are more prevalent down east.

Figure 1.
North Carolina BRFSS 1995-2005 Obesity and Related Comorbidities

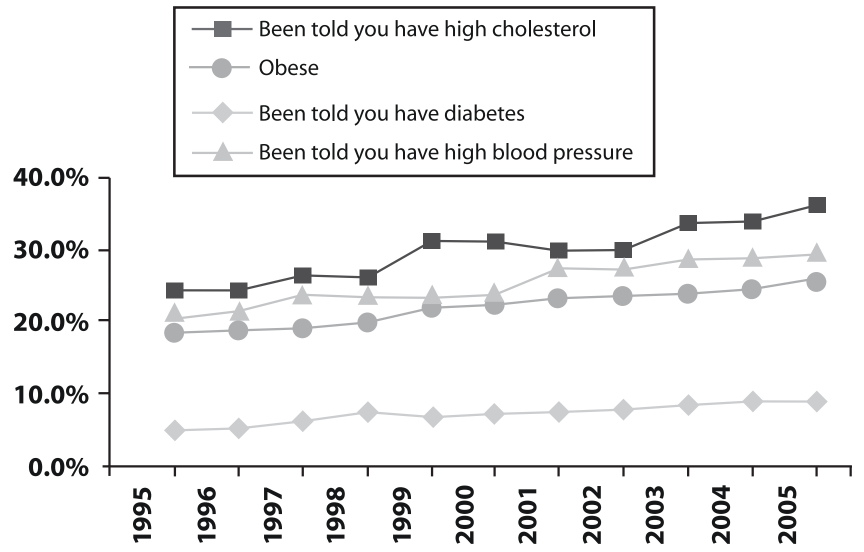

Figure 2.
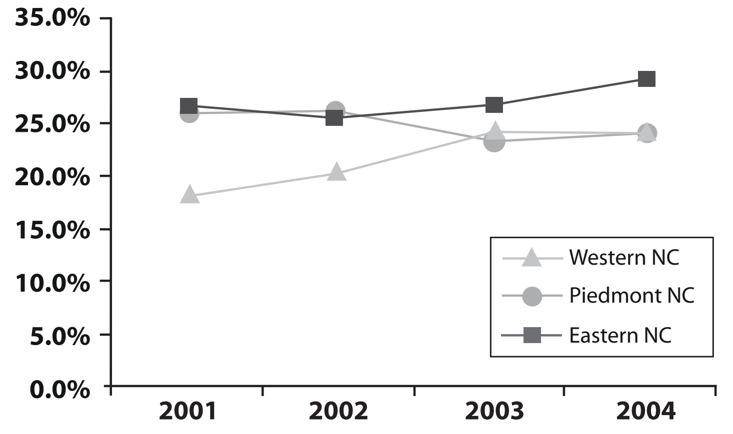
North Carolina BRFSS 2001-2004 Obesity by Region



This increase in obesity-related chronic illness creates a significant burden for North Carolina primary care practitioners because care for chronic illness requires more time and practice resources than treatment of acute illnesses, especially if the conditions are not well controlled. Ostbye, et.al.[16] estimated that a 2,500-patient primary care practice caring for 10 chronic diseases (seven of ten related to obesity) per national practice guidelines would require 3.5 hours a day if the conditions were well controlled. If the chronic conditions were not well controlled, then the estimated time increased by a factor of 3, or 10.6 hours a day. Add to the practicing physician's day another 7.4

hours a day to deliver nationally accepted (and recommended by the US Preventive Services Task Force) preventive care guidelines,[17] and the primary care practice would need to stay open 18 hours per day, not including any acute care visits.

Even if practices chose to remain open 24 hours a day, it is abundantly clear that it is difficult to deliver all recommended care for chronic conditions. McGlynn[18] estimates that only 45% of recommended care is provided for diabetes, 49% for hyperlipidemia, 57% for osteoarthritis, 65% for hypertension, and 68% for coronary artery disease.

The quality issue identified by McGlynn is not caused by the obesity epidemic, but it is certainly exacerbated by it. Fortunately, there are sources of assistance for overweight or obese patients to whom physicians can make referrals when needed. These are described by Dr. Kathryn Kolasa and colleagues in this issue of the *North Carolina Medical Journal.*[19]

Obesity is a Chronic Condition

The Institute for Healthcare Improvement (IHI) advocates the Chronic Care Model developed by Wagner and colleagues at the Group Health Cooperative of Puget Sound[20] as a paradigm for delivering care for chronic conditions including obesity comorbidities (www.ihi.org). This paradigm focuses on productive interactions between a well-informed, highly motivated patient and an integrated, multidisciplinary healthcare team that anticipates patient needs and addresses them not only during individual physician visits, but also at individual or group meetings with other healthcare team members, outbound phone calls, emails, or mailings, and referral to a variety of informational resources.

Obesity treatment requires that the patient be supported in making self-management decisions based on his/her current preferences and readiness to change. The goal is to have the patients assume primary responsibility for their own health and hopefully make healthy clinical and lifestyle choices. The healthcare system should include incentives for patients (and physicians), adequate reimbursement for necessary services, and accurate, accessible, relevant and timely information that the patient and doctor can use to make decisions, and information systems that automatically remind providers and patients what services are needed and when.

The context for interactions between the patient and the healthcare system in the Chronic Care Model is the community, and it plays a significant role in the management of obesity-related conditions. Obesity is impacted by the quantity, quality and cost of food available, marketing and packaging of food, the safety and availability of environments to be physically active, competing priorities for time to be active (e.g., school curriculum, television/video games/internet "tube time", work and sleep), cultural and faith-based ethnic beliefs regarding body habitus, physical activity and eating behaviors, and regulatory and legislative mandates.

Payors (employers, insurance companies, Medicare and Medicaid) have historically been reluctant to cover treatment of obesity because of controversy regarding evidence that obesity directly contributes to medical and business costs, the lack of evidence that treatment is effective, and the lack of demonstrable short-term financial return.

The data shown above speak to the impact of obesity (as a marker of sub-optimal nutrition and physical activity) on medical conditions.

The Evidence is Mounting

Fortunately, there is a mounting body of evidence that the Chronic Care Model is effective in managing obesity-related conditions such as diabetes,[21,22,23] and emerging literature suggests that obesity itself is amenable to treatment.

One well-designed study, for instance, suggests that specific meal replacement as a mechanism to reduce caloric intake was effective in attaining and maintaining modest weight loss over four years.[24,25] Another systematic review[26] recommends dietary, physical activity, and behavioral approaches. And recently, preliminary studies suggest sleep deprivation plays a role in obesity.[27,28]

In addition, the magnitude of preventable disease attributable to obesity is increasingly well documented.[29,30] Thompson and Finkelstein estimate that 5% of all medical spending is attributable to obesity, and that the average annual medical spending for obese patients is 26-39% higher than for normal weight adult patients. This is consistent with Blue Cross and Blue Shield of North Carolina data (2003), which showed 32% higher medical expenditures for obese patients.

At issue from a financial perspective is the belief of some employers and insurers that they will not recognize a return on investment for obesity treatment, especially with younger employees/members. As a chronic condition, the medical sequelae of poor nutrition and lack of activity do not become apparent for several years. Some payors are concerned that they may pay for expensive treatment (especially bariatric surgery), only to have the patient leave their employ or plan well before reduced medical expenses are realized.

In this issue of the *North Carolina Medical Journal*, Drs. Eric Finkelstein and Derek Brown of Research Triangle Institute address the reasons why private sector organizations are reluctant to invest in obesity prevention and treatment for their employees.[31] But, commentaries by Steven Reinemund, CEO of PepsiCo,[32] and LuAnn Heinen of the National Business Group on Health,[33] point out the way in which American business and industry have undertaken to address these issues as matters of concern to their consumers and their own employee populations.

More recent and sophisticated economic models[34] confirm that time required to break even and possibly realize a financial benefit of bariatric surgery is considerable, estimated at five years. Strategies to mitigate the prolonged return on investment time, though, may include incentives to use centers of excellence for bariatric surgery, employee cost sharing, and incentives to retain the patient with the employer or insurance plan after surgical intervention. Further evolution of economic models will help influence payor coverage decisions for treatment of obesity. Of note, Medicare recognized obesity as a condition (eligible for reimbursement) in 2003, and began limited coverage for bariatric surgery in 2006. In this issue of the North Carolina Medical Journal, Dr. Walter Pories of East Carolina University's Brody School of Medicine, one of the pioneers in bariatric surgery in the U.S., offers a detailed overview of current progress and efficacy in this mode of treatment for morbid obesity.[35]

The key to ongoing reimbursement for the treatment of obesity will be the results of studies and pilot programs currently being launched. A variety of stakeholders are involved in these efforts, including the Centers for Disease Control and Prevention, the North Carolina Health and Wellness Trust Fund, the State of North Carolina, public school systems, private insurers and foundations, and employers. We are fortunate to be able to include in this issue of the *North Carolina Medical Journal* descriptions of programs addressing the childhood obesity epidemic by Paula Hudson Collins of the NC Department of Public Instruction[36] and Lt. Governor Beverly Perdue on behalf of the NC Health and Wellness Trust Fund Commission.[37]

The physician's role in combating the obesity epidemic is multi-faceted and critical. As the most trusted source of medical information, the doctor can identify, assess, and make recommendations for prevention and treatment of obesity and obesity-related conditions. Efforts by Blue Cross and Blue Shield of North Carolina to give physicians (and their patients) access to the best medical and behavioral therapies for addressing the problem of overweight and obesity are described in this issue of the *North Carolina Medical Journal* by Blue Cross and Blue Shield Senior Vice President Robert Harris.[38]

Within a Chronic Care Model, he/she may not provide direct behavioral counseling or nutritional advice, but extends medical legitimacy to other healthcare team members (nurses, nutritionists, trainers, counselors, community programs, on-line programs, health plan programs, etc.). The primary care practitioner helps coordinate and direct care, especially if the patient has (and many patients do have!) multiple chronic conditions. The physician should seek multiple communication channels to work with patients, including printed materials, referral to on-line resources, group sessions, inbound and outbound phone lines, and e-mail. The practice should keep patient registries for chronic conditions, automate care reminders, and track clinical performance.

A proactive physician may work outside the office setting, collaborating with the school system, faith-based or community organizations, or government-sponsored programs.

Of no small importance, physicians can model healthy behaviors, including demonstrating healthy nutrition in the office, being physically active in a public manner, and maintaining a healthy weight. Modeling health behaviors not only increases physician credibility with patients, but provides insight into the practicalities and options being recommended to the patient.

Finally, physicians can serve as potential advocates for public policy change, planning for active communities, and changes to employer-based programs. The more evidence-based the advocacy, the more powerful it is.

Since obesity is as much of a social issue as it is a medical issue, the role of stakeholders outside the healthcare system cannot be underestimated. Several North Carolina initiatives are described in this issue of the *North Carolina Medical Journal*, and are excellent examples of the multi-pronged approach that is needed to stem the rising tide of obesity as a population health issue. Among these are programs supported across North Carolina by The Duke Endowment[39] and the Kate B. Reynolds Charitable Trust,[40] the NC Health and Wellness Trust Fund Commission, and the national program of the Robert Wood Johnson Foundation based in Chapel Hill known as "Active Living by Design."[41] Since the backgrounds and needs of North Carolinians are unique (as they are in any state), and there does not appear to be any approach that has demonstrated superior results, it is highly appropriate that multiple initiatives be undertaken. What is critical, however, is to coordinate separate efforts as much as possible, and to carefully document outcomes so that we know where best to invest resources going forward.

Federal assistance for combating obesity is directed primarily through the Federal Trade Commission (marketing and advertising, particularly to children and adolescents), and the Food and Drug Administration (food labeling).[42] The Federal Trade Commission is mired in technical complications in identifying and regulating advertising to children,[43] while the Food and Drug Administration has had somewhat more success in promoting food labeling. We in North Carolina must recognize that federal efforts are but one more piece of an extensive medical/social/economic puzzle. **NCMedJ**

Overweight and Obesity:

A Clinician's Perspective

Donald D. Hensrud, MD, MPH

In recent years, much has been published in the medical and lay literature on overweight and obesity. The most current United States data show that in 2003-2004, 32.2% of adults were obese and 66.3% were overweight or obese.[1] The increasing prevalence over the past three decades, the associated disease comorbidities, and the attributable healthcare costs of obesity have been well documented. Various etiologic factors for the relatively recent increase in weight have been described, many of which involve a permissive environment that promotes a sedentary lifestyle and increased energy intake. For these reasons, obesity is one of the major public health challenges the United States is facing.

If overweight and obesity are a public health problem, does it not require a public health solution? What can healthcare providers do in their office to make a meaningful impact on a problem that affects two-thirds of their adult patients? Compounding the challenge to clinical treatment of overweight and obesity are the limited appointment time and reimbursement available to most clinicians. While the impediments to effective treatment of obesity are real, healthcare providers can stimulate individual and collective changes in their patients by following a specific, efficient, and systematic plan. Listed below are elements of a general plan to treat overweight and obesity for the busy clinician.

1. Perform a Brief Assessment

A. Classification

Measure height, weight, and waist measurement (or estimate by inspection) and determine body mass index (BMI) from a table or by calculation. Review the established comorbidities from obesity that are present (Table 1). Health risks, and therefore the need to lose weight, increase with increasing BMI, increasing waist measurement, and a greater number of established comorbidities (Table 2).[2] The initial classification of obesity can help guide treatment recommendations.

Table 1. Medical Comorbidities of Obesity

Type 2 diabetes mellitus
Hypertension
Dyslipidemia (high triglycerides and low HDL cholesterol)
Cardiovascular disease
Coronary artery disease
Stroke
Congestive heart failure
Nonalcoholic fatty liver disease (steatosis, steatohepatitis, cirrhosis)
Respiratory diseases
Obstructive sleep apnea
Obesity-hypoventilation syndrome
Asthma
Restrictive lung disease
Many cancers
Osteoarthritis
Cholelithiasis
Gastroesophageal reflux disease (GERD)
Gynecologic abnormalities
Infertility
Abnormal menses
Venous stasis
Skin problems
Intertrigo
Cellulitis
Increased risk of complications during surgery or pregnancy
Increased overall mortality

Donald D. Hensrud, MD, MPH, Divisions of Preventive Medicine and Endocrinology. He can be reached at hensrud.donald@mayo.edu or E17, Mayo Clinic, Rochester, MN 55905. Telephone: 507-538-1703.

B. Patient Readiness

Is the patient interested in increasing their efforts to lose weight? If not, just providing a brief motivating message and educational material may be all that can be accomplished at this time. Administering treatment recommendations will probably not be effective. Questions based on the stages of change model can be used to help determine patient readiness. Examples of patient readiness questionnaires are available, some of which target general readiness,[3] while others focus on specific diet and physical activity habits.[4]

Table 2.
Classification of Overweight and Obesity.[1]

			DISEASE RISK	
	BMI[2] (kg/m2)	Obesity Class	Low Waist Cir	High Waist Cir[3]
Underweight	< 18.5		-	-
Normal	18.5 – 24.9		-	-
Overweight	25.0 – 29.9		Increased	High
Obesity	30.0 – 34.9	I	High	Very high
	35.0 – 39.9	II	Very high	Very high
Extreme obesity	≥ 40	III	Extremely high	Extremely high

1 The Practical Guide to the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults. NIH Pub. No. 00-4084, 2000. Available online at: http://www.nhlbi.nih.gov/guidelines/obesity/practgde.htm/, accessed July 10, 2006.

2 Body mass index (BMI) can be calculated as wt(kg)/ht^2(m), or wt(lb)x703/ht^2(in). Tables of weight, height, and BMI are also available.

3 High waist circumference is defined as > 40" in men and > 35" in women

C. History

Much of the medical history and weight-related assessment of obesity can be performed most efficiently with a written questionnaire. The items listed in Table 3 are relevant to the assessment of obesity and may influence treatment recommendations. A questionnaire based on these items can be prepared, tailored to the physician's practice, and administered to patients undergoing assessment for weight management. If it is not possible to provide a questionnaire to patients ahead of time, asking a few brief questions, even in a busy practice, can provide a reasonably good snapshot of baseline diet and activity habits (Table 4).

2. Order Appropriate Laboratory Studies

Consider obtaining a fasting blood glucose, lipid screen, TSH, and AST. Further testing should be guided by the clinical evaluation. For example, if there is a history of snoring with possible apneic periods or overnight oximetry, an appointment in a sleep disorders center should be obtained.

3. Use a Positive Approach

This is an area that is often under appreciated and difficult to document, but can be extremely important. Patients are often discouraged by lack of results in weight management. Physician recommendations can have a strong influence on patient behavior. The physician can prepare the patient by providing motivation and encouraging a positive attitude when initiating and following through on weight loss efforts. A typical approach toward weight management is to go 'on a diet', which is often overly restrictive, has a negative connotation, and is therefore likely to be temporary. On the other hand, people often say they feel better when they are more active. By focusing on the beneficial aspects of lifestyle changes in diet and physical activity, weight management efforts are more likely to be enjoyable, sustainable, and effective.

4. Determine a Tailored Plan

The plan for weight loss should be individualized based on the initial classification of obesity and factors in the patients' history. The aggressiveness of the approach should be guided by the degree of obesity and number and extent of comorbidities. All patients should initially receive specific recommendations for diet, physical activity, and lifestyle behavior changes. If there is no response to initial therapy, some patients may be candidates for pharmacotherapy or possibly surgery (Table 5), in addition to continuing efforts with lifestyle therapies. Physicians should obviously be familiar with medications to treat obesity if they are going to use them. Referrals for possible surgery should be made to medical centers experienced in this modality.

The plan for weight loss should include specific treatment recommendations for diet, physical activity, and lifestyle changes. Suggestions for dealing with individual challenges of managing weight that were uncovered in the assessment should be included. Rather than overwhelm someone with too much to address, a few main items can be targeted. For example, if eating at restaurants occurs frequently, a plan for making appropriate choices as well as monitoring of calorie intake should be developed. Encouraging patients to use problem-solving techniques can help them confront challenges more effectively. First, the problem is identified. Barriers to change followed by benefits to change can be written down. Potential solutions to the problem can then be explored, and a specific plan for addressing the problem designed. Goals should be determined (see below) and follow up appointments arranged.

5. Outline a Dietary Program

Many different dietary plans and programs are available including low carbohydrate, low fat, counting calories, meal replacements, very-low calorie diets, and popular diets, of which some have little basis in known physiology. The

Table 3. Items to Assess in the Medical and Weight History for Evaluation of Obesity.

Medical History
Comorbidities of Obesity
Medications and dietary supplements (some medications, e.g., corticosteroids, some antidepressants, and others may adversely affect weight)
Family history of obesity
Weight History
Reasons/expectations for weight loss
Available support
Previous methods of weight loss and results (including why results were not successful)
Potential barriers to weight loss and maintenance (time, finances, established habits, physical limitations)
High School graduation weight, minimum and maximum adult weight
Periods of increased weight gain (e.g., pregnancy, smoking cessation, stressful life periods)
Current (and past) diet
Triggers to eating
Current (and past) exercise and general activity
Type, frequency, and duration of exercise
Amount of nonexercise activity
Factors the patient believes are responsible for weight
Binge eating, purging, laxative or diuretic use

approach used should be practical, enjoyable, healthful, and sustainable. If tracking calories are used, an initial goal of 1,000 to 1,200 kcal/day for women and 1,200 to 1,600 kcal/day for men can be recommended.[2] Increasing the intake of low energy dense foods including vegetables and fruits can lower overall energy intake, yet maintain bulk that contributes to satiety.[3] Including foods such as whole grains and small amounts of unsaturated fat while restricting saturated fat, refined carbohydrate and processed foods can help promote health while managing weight. This approach is also consistent with other dietary guidelines recommended to decrease the risk of chronic diseases. Specific areas to target that have been identified as contributing to increased caloric intake or obesity are portion control, skipping breakfast, eating away from home—particularly fast food, and consuming refined carbohydrate, particularly sugar.[5]

6. Incorporate Exercise/NEAT

Increasing total energy expenditure can be accomplished through increasing exercise and non-exercise activity thermogenesis (NEAT). Patients should be encouraged to start a regular aerobic exercise plan slowly, yet gradually and progressively increase the frequency, duration, and intensity of exercise, in that order. Patients may need individual instructions from a physical therapist or other qualified healthcare provider on the appropriate exercises based on their fitness level and physical limitations.

While exercise is the most efficient way to burn calories, the potential for increasing total energy expenditure is just as great by increasing NEAT throughout the day. Many people exercise an hour or two of the 168 hours in a week. Increasing NEAT may increase total energy expenditure more than exercise, because of the multiple opportunities available in the rest of the waking hours of the week. Lists of potential activities and strategies are available,[3] but the bottom line is any activity is good activity. The more excuses people can make to get activity during the day by performing activities such as walking during a work break or parking farther from a destination (instead of 'taking the shortcut'), the better chance they'll have at managing weight.

7. Formulate Realistic Process Goals

The goal in weight loss is obviously a lower weight. However, many people focus too much effort on this outcome goal and not how to reach that goal. This is analogous to having a goal to make $100,000 without putting sufficient thought and effort into a plan on how to make it. It's been reported that the vast majority of people have unrealistic outcome goals for weight loss,[6] which eventually results in frustration, abandonment of efforts, and regain of any weight that was lost.

Process goals help to focus on the day-to-day activities that result in weight loss and, more importantly, sustaining that weight loss over time. Goals should be SMART—specific, measurable, attainable, realistic, and trackable. Examples of SMART process goals include eating one more serving of vegetables daily or starting to walk 10 minutes four times per week (and increasing by one session and 5 minutes per session each week to a goal of 40 minutes 6 times per week).

Challenges and problems should be expected and a plan to deal with them should be utilized, using problem-solving techniques. For example, everyone hits a weight plateau eventually. Two basic options for addressing this are to further increase physical activity or decrease calorie intake. If it is not possible to implement further changes in these areas that are sustainable, then continuation of current lifestyle habits is much preferred over

Table 4. Brief Questions to Assess Diet and Physical Activity Habits.

Diet
What do you eat in a typical day for breakfast, lunch, dinner, and snacks?
How much meat and how much vegetables and fruits do you eat in a typical day or week?
How often do you eat outside the home?
Physical Activity
How much exercise do you get in a typical week?
How much physical activity do you get in a typical day?

> *“The most current United States data show that in 2003-2004, 32.2% of adults were obese and 66.3% were overweight or obese.”*

stopping existing efforts and regaining weight.

Self-monitoring is an important aspect of adherence to change and achieving goals. People who keep diet and activity records are more likely to manage weight successfully.

8. Provide Resources

Time is limited in the office setting. Verbal recommendations should be supplemented by a written recommendations and resources such as office handouts, pamphlets, or a book. In addition, there are many websites related to weight loss, some of which are interactive, but the quality may vary. Telephonic coaching is becoming more popular. Patients should generally be referred to a Registered Dietitian who can take the time to obtain a detailed dietary history, provide education and recommendations, and follow patients over time, often in a group setting. Reputable commercial weight management programs can follow people over time and provide social support. For patients with significant behavioral issues related to weight management such as binge-eating disorder, referral to a Clinical Psychologist is indicated.

9. Arrange Follow up

Ongoing follow up is important in that it can help maintain motivation and provide an opportunity to ask questions, give feedback, refine recommendations, and revise process goals. Patients often appreciate the support and accountability a follow up visit offers. Patients can follow up in various ways and with different types of people. Similar to the rest of the plan, follow up should be tailored to the individual.

10. Outcome Measures

A comprehensive lifestyle modification program may result in weight loss of approximately 10% in 16 to 26 weeks.[7] While weight loss is an obvious primary objective, success can be defined in many additional ways. Long-term weight maintenance after weight loss is more important than rapid, short-term weight loss followed by weight regain. Inches lost and body composition changes are important intermediate markers. Improvement in the comorbidities of obesity and quality of life are important additional goals that can be realized. These goals can result from weight loss and from sustained health-promoting lifestyle changes in diet and physical activity, independent of weight loss.

Barriers to Clinical Treatment of Obesity

In addition to genetics and the environment, barriers to effective implementation of the clinical plan outlined above can be due to patient, healthcare provider, and health system factors. Patients often don’t appreciate the strength of the connection between their obesity and health comorbidities. In fact, patients who are overweight or obese often don’t recognize themselves or their children as such.[8] In addition, many people have tried to lose weight, often with an ineffective approach, and realize the difficulty of losing and maintaining weight loss. Healthcare providers are not exempt from challenges with managing their own weight and have experienced how difficult it is to achieve lasting weight loss in their patients. In addition, healthcare providers may not have adequate training or resources to help them adequately treat obesity. Insurers do not generally reimburse for obesity as a diagnosis. An exception to this is Blue Cross Blue Shield of North Carolina, which has instituted a plan for addressing obesity as part of a healthy lifestyle program that covers a limited number of office visits for physicians and registered dietitians, as well as pharmacotherapy when indicated.[9] Further education for healthcare providers and patients, implementation plans to treat obesity and document outcome, and resources to support these efforts are needed.

Table 5.
Treatment Options for Obesity.[1]

	BMI				
Treatment	**25-26.9**	**27-29.9**	**30-34.9**	**35-39.9**	**≥40**
Diet, physical activity, and behavior therapy	with comorbidities	with comorbidities	Yes	Yes	Yes
Pharmacotherapy		with comorbidities	Yes	Yes	Yes
Surgery				with comorbidities	Yes

1 The Practical Guide to the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults. NIH Pub. No. 00-4084, 2000. Available online at: http://www.nhlbi.nih.gov/guidelines/obesity/practgde.htm/, accessed July 10, 2006.

Conclusion

The causes of the recent rise in the prevalence of overweight and obesity are multiple, diverse, collectively powerful, and pervasive. Multidisciplinary action with interventions from government, academia, public health, private industry, and healthcare institutions will be necessary to reverse the rising trend in obesity. The healthcare providers' office is one part of this massive effort and while efforts by clinicians may not solve the problem of obesity, they may help many individuals to improve not only their weight, but their health and quality of life. **NCMedJ**

The Public Health Challenge of Obesity in North Carolina

Leah Devlin, DDS, MPH and Marcus Plescia, MD, MPH

Obesity is one of the most important public health issues of our time. Just as infectious diseases threatened the health and well being of communities in the early 20th century, chronic diseases are now the greatest threat of the 21st. The risk factors for obesity, physical inactivity and poor nutrition have begun to approach the public health impact of tobacco use.[1] The resulting rise in chronic diseases that is directly attributed to these three risk factors threatens to undo much of the progress made to improve health in the last century and worsen existing health disparities. At no other time in our history have we had the majority of our population affected or threatened by an epidemic; over 67% of American adults are overweight.[2]

As with any public health epidemic, we must take aggressive steps. Progress in containing infectious disease epidemics of the past occurred when epidemiologists shifted focus from identifying afflicted individuals to resolving the underlying environmental causes of infectious outbreaks by ensuring adequate access to clean water supplies and appropriate disposal of sewage. The same approach must be taken with obesity. While physical inactivity and poor quality dietary practices are the immediate causes of obesity, our society must shift from a focus on individual responsibility and look to the root factors in our societal environment that have led to this unprecedented increase.

Responsible public health practice is based on population-based surveillance and the use of evidence-based interventions. Much can be learned from our experience with tobacco control. After evidence emerged that tobacco use could best be controlled through societal and environmental approaches, interventions were implemented to make the product less available, more expensive, and less appealing. Rates of tobacco use and worksite exposure to second-hand smoke are now declining across the nation, including in North Carolina.[3,4] Evidence-based approaches for obesity are also emerging. Using the same approach as the *Guide to Clinical Preventive Services*,[5] *The Guide to Community Preventive Services*[6] has convened a scientific committee to review the evidence for effective community-based interventions (www.thecommunityguide.org). In 2005 the national Institute of Medicine (IOM) convened an expert task force to make recommendations on how to control childhood obesity based on scientific reports, review of previously successful public health campaigns, and expert testimony.[7] The recommendations of these two expert groups (the US Preventive Services Task Force and the CDC Task Force on Community Preventive Services) require complex approaches to impact obesity in multiple sectors of our society. An emphasis is placed on policy and environmental change as more efficient and sustainable approaches than focusing solely on personal responsibility.

> *"The risk factors for obesity, physical inactivity and poor nutrition have begun to approach the public health impact of tobacco use."*

Eat Smart, Move More...North Carolina is an ambitious statewide initiative to encourage healthy eating and physical activity wherever people live, learn, earn, play, and pray. The North Carolina Division of Public Health provides staff support and funding for the Eat Smart, Move More leadership team, a

Marcus Plescia, MD, MPH, is Chief, Chronic Disease and Injury Section, Division of Public Health, NC Department of Health and Human Services. He can be reached at Marcus.Plescia@ncmail.net or 1915 Mail Service Center, Raleigh, NC 27516. Telephone: 919-707-5203.

group of over 100 public and private partners. The focus of the initiative is on seven evidence-based strategies:

- reducing time spent watching television;
- increasing physical activity;
- increasing fruit and vegetable consumption;
- decreasing sugar-sweetened beverage consumption;
- decreasing portion sizes of foods and beverages;
- preparing and eating more meals at home; and
- breastfeeding.

Consistent with national recommendations, Eat Smart, Move More…North Carolina is a comprehensive, multi-level initiative to effect policy and environmental change across the state, within organizations and among communities and to support interpersonal and individual changes in health behavior.

Across the State: Public Policy and Social Norms

An educational campaign through television, radio, and print presently targets mothers aged 25 to 54 with all seven Eat Smart, Move More messages. The campaign is running currently in the Raleigh-Durham and Charlotte media markets, and will expand statewide in the late fall. The re-designed Website, *www.EatSmartMoveMoreNC.com*, was re-launched in January 2006 with a new consumer-focused Website, MyEatSmartMoveMore.com. The Website features tools and resources for professionals, news tips for journalists and helpful information for individuals trying to make simple lifestyle changes.

Based on the work of the North Carolina Health and Wellness Trust Fund Obesity Study Group, legislation was passed in the 2005 session to implement nutrition standards for school meals and vending machines as well as a state Board of Education policy to make physical activity mandatory for grades K through eight. North Carolina has recently been identified as a national leader for its use of federal Preventive Health and Health Services Block grant funds to support policy and environmental change interventions through every local health department in the state. Local progress in effecting such change has been well documented. Legislation has been introduced this year to fund a community grants program to make neighborhoods, towns, and cities more pedestrian friendly. In August 2006, the NC Division of Public Health will host an obesity summit in collaboration with the Trust for America's Health with the goal of committing prominent leaders to support a public policy approach to obesity prevention and control.

Organizations: Policies and Environments

The Health*Smart* Worksite Wellness Tool Kit has been developed for state employee worksite wellness committees in collaboration with the North Carolina State Employee's Health Plan. Employee groups across the state have been trained in how to organize an effective committee to develop policies and resources that will improve nutrition, physical activity, tobacco cessation, and stress management among the state employee workforce. A demonstration project has been started in the Department of Health and Human Services. Policy and environmental changes in the Division of Public Health include availability of healthy vending machine snacks, a stairwell project, local walking routes and a breastfeeding room.

Eat Smart: North Carolina's Recommended Standards for All Foods Available in School and Move More: North Carolina's Recommended Standards for Physical Activity in School are curriculums available to all school districts and have been implemented at varying levels to incorporate healthy eating and physical activity in the academic environment.

A partnership with the North Carolina Cooperative Extension Service provides preschools with *Color Me Healthy*, a nutrition and physical activity education program for four to five year-olds that has been implemented in 5,500 child care centers across North Carolina. Through the use of color, music, and exploration of the senses, *Color Me Healthy* teaches children that healthy food and physical activity are fun. The Nutrition and Physical Activity Self-Assessment for Child Care (NAP-SACC) is a pilot intervention in child care centers aimed at improving nutrition and physical activity policies and practices. Center staff complete self-assessments and receive consultation on improving the center's feeding and physical activity programs. This program will be expanded statewide in the coming year.

African American Churches Eating Smart and Moving More: A Planning and Resource Guide is designed to create healthy eating policies and physical activity programs among church congregations. This tool builds on the existing Black Churches United for Better Health program and is helping churches form wellness committees, start walking clubs, and institute healthy food potlucks. Statewide train-the-trainer workshops are helping interested church members become agents for change in their church communities.

Communities: Policies and Environments

All local health departments receive capacity funding for health promotion efforts focused on policy and environmental change. Local Physical Activity & Nutrition Coalitions (LPANs) promote physical activity and healthy eating opportunities at the community level. Currently, 68 out of 100 North Carolina counties have an LPAN, usually as a subcommittee of their Healthy Carolinians partnerships.[a] These coalitions initiate and coordinate local programs and interventions to increase opportunities for physical activity and healthy eating. Coalitions are encouraged to focus on policy and environmental approaches. *Winning with ACEs! How You Can Work Toward*

---

[a] Healthy Carolinians, a network of public-private partnerships representing public health, hospitals, schools, churches, businesses, community members, and elected officials, address North Carolina's 2010 health objectives through a collaborative planning process.

Integrating A Focus on Overweight and Obesity in Clinical Practice: Practical Suggestions

The U.S. Preventive Services Task Force found good evidence to support assessment of Body Mass Index (BMI, weight in kilograms divided by the square of height in meters) of all adults when primary care visits occur. The task force recommended that if BMI is greater than 30, healthcare providers should arrange for, or provide, intensive counseling about nutrition and physical activity.[1]

Measuring BMI

Accurate BMI measurement requires an office *system* that supports regularly obtaining accurate heights and weights (e.g., shoes off, stadiometer, calibrated scale) and includes one of the easy-to-use tools to calculate and record the BMI (e.g., table, wheel, website, PDA, or by hand calculator). Making room for these measurements in the routines of a busy primary care practice requires special attention to staff orientation and the scheduling of intake procedures.

As a practice routinely begins to document BMI for all of its patients, it is important to plan or identify appropriate patient follow-up recommendations depending on the results obtained from these measures. One very simple office protocol is shown in Table 1, but this can be modified to a practice's particular level of counseling ability and local resources.

Table 1.
Basic Office Protocol Based on Patient BMI Calculation

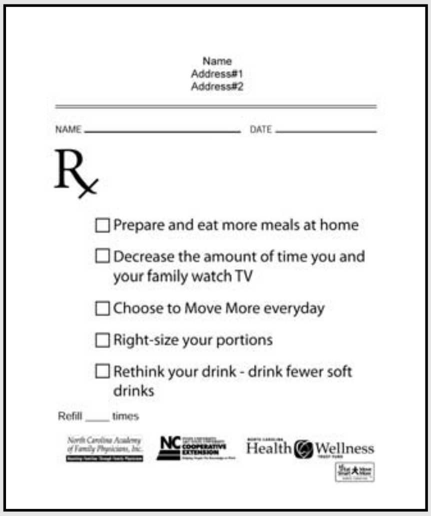
BMI Result	Action Plan
Underweight BMI < 18	• Communicate the BMI result, • Schedule follow up for further work-up as indicated
Healthy 18 < BMI < 25	• Communicate the BMI result, • Reinforce healthy behaviors
Overweight BMI = 25-30	• Communicate the BMI result, • Provide introductory counseling, • Plan follow up
Obese BMI > 30	• Communicate the BMI result, • Schedule any appropriate lab work, • Plan follow-up for more intensive counseling or refer for further intervention

Introducing Brief, Targeted Counseling about Nutrition and Physical Activity

With access to the Internet, a great place to start is the newly redesigned website: *www.eatsmartmovemorenc.com*. This site includes an entry portal that takes one to a site for professionals that includes a drop-down menu of downloadable, ready-to-use tools. There are several handouts for patients that provide practical strategies to address each target behavior in the Eat Smart Move More program. Office staff could prepare a few packets ready for specific issues, or customize packets that will best fit specific patient populations. Although handouts by themselves are not likely to be effective, they do facilitate discussion of a patient's motivation to make changes and focus on one or two behaviors that they may be most successful at changing. If available time does not allow for personalized messages at each visit, it may be best to focus on one behavior at a time for several weeks, and simply discuss that issue with all patients, with a goal over a year of reaching many patients with different, but important, messages.

Another way to reinforce behavior change messages is the "Big Five Prescription Pad" available as a customizable pdf from the tools menu. (Figure 1) This tool can be used as a take-home prescription for patients to emphasize the behaviors discussed, or perhaps to contract with them on 1-3 behaviors on which they may agree to focus after the visit. The key is not to overwhelm the patient with what may appear to be expectations of sweeping changes that must be made all at once, but support them in the idea they can target their efforts to selected issues.

Figure 1.
Example Blank "Big Five Prescription" Pad, modifiable PDF available at www.eatsmartmovemorenc.com/



Name
Address#1
Address#2

NAME ______________ DATE ______________

℞

☐ Prepare and eat more meals at home

☐ Decrease the amount of time you and your family watch TV

☐ Choose to Move More everyday

☐ Right-size your portions

☐ Rethink your drink - drink fewer soft drinks

Refill ____ times

Additionally, a computer for patient education use in the office can be an advantage, and it can be set to this site for easy patient access.

More ideas

If the goal is to provide more than the simple handouts discussed above, an individualized, but still brief, tool is "Starting the Conversation," available for a modest price through NC Prevention Partners (*www.ncpreventionpartners.com*). This tool can be completed by the patient while waiting for the provider. The tool helps illustrate to both patient and provider which behaviors may be problems and provides suggestions as to how to support the behavior change which can be reinforced by the provider. Therefore, this easy to use, brief, "handout" also serves as an *interactive*, individualized counseling tool.

Active Community Environments (referred to as the ACEs Guide) is a tool specifically developed to help community coalitions promote changes in community design that make opportunities and facilities for physical activity more available and accessible.

Funding for specific physical activity and nutrition programs has been available through the Eat Smart, Move More…North Carolina Community Grants program, which has funded approximately 15 counties each year for the past six years to implement evidence-based programs in their communities. These grants, together with grants from the Kate B Reynolds SELF project, and the Fit Together Initiative of the NC Health and Wellness Trust Fund and Blue Cross and Blue Shield of NC (both programs described elsewhere in this issue of the *North Carolina Medical Journal*) provide resources for communities to adopt evidence-based policies and practices that improve access to and increase opportunities for healthy eating and physical activity in various settings.

Interpersonal and Individual: Lifestyle Changes

Families Eating Smart and Moving More is an interactive curriculum offered in communities and through physicians' offices to help families find simple solutions to eat more nutritious meals and be more physically active. Community health professionals and para-professionals use this formal curriculum to teach families the skills to eat more meals at home, make healthy food choices when eating out, incorporate exercise in their everyday routine, and watch less television.

Traditional public health programs also promote healthy lifestyles. The Women, Infants and Children (WIC) program serves over 230,000 individuals across North Carolina to assure that pregnant women and infants have access to healthy foods. WIC nutritionists instruct families about good nutrition and promote breastfeeding. Recent expansion of the North Carolina School Nurse program has provided opportunities to identify children who are overweight and counsel their families about healthy physical activity and nutrition practices.

Future Directions

Obesity is a complex problem that will require complex solutions. Changing the societal and institutional factors that have contributed to this problem will also require strong political will and the investment of significant resources. Three areas need particular attention if we are to continue to make progress.

1. Statewide capacity for health promotion.

Competitive grants for community-based obesity prevention have increased significantly over the last few years from a variety of North Carolina funders. Interest in preventive interventions remains high among local philanthropies. However, recent reductions in federal funding have decreased the baseline level of general health promotion funding that has traditionally been made available to every local health department in the state. This may ultimately undermine the capacity of local health departments in lower wealth counties to pursue competitive funding, resulting in increased geographic disparities within the state. The North Carolina Public Health Improvement Plan from the Public Health Task Force 2004 is now being updated for 2006. The plan recommends a health promotion coordinator in every local health department to assure a basic level of health promotion capacity across the state.[8] State and local funding strategies must be identified to reach this goal.

2. Social Marketing to Change Social Norms

Community-wide campaigns are evidence-based approaches to increase physical activity when combined with local interventions.[9] This is an integral component of the Eat Smart Move More…North Carolina initiative and local and regional efforts have shown that these campaigns have great promise in North Carolina communities. The Centers for Disease Control and Prevention's *Best Practices for Comprehensive Tobacco Control Programs* recommended spending between $1.00 to $3.00 per capita on tobacco prevention and control public education campaigns to obtain a meaningful result.[10] Applying this same formula to a comprehensive obesity prevention campaign would cost the state a minimum of $8.25 million. While this is a significant sum, it represents only 1.2% of the $600 million annual cost to the North Carolina Medicaid program that has been attributed to the treatment of obesity related illnesses.[11]

Land Use and Transportation Policy

The connection between land use, transportation policy, and physical activity is one of the most compelling evidence-based opportunities to impact obesity.[7] Much of the current effort to create better infrastructure for physical activity has focused on regional and local programs. Efforts should also focus on transportation policy and planning at the state level. Assessments of traffic performance and environmental impact must be prepared for most transportation projects. Assessments could also be required to document the impact of state and local transportation plans on pedestrian access and potential use. Less than four percent of North Carolina students currently walk or ride a bicycle to school one or more days per week.[12] Safe routes to school projects have been implemented in other states by assessing and improving sidewalks and road crossings. Similar projects should be developed and funded across North Carolina. Placing greater priority on pedestrian and bicycle improvements in the State Transportation Improvement Plan would increase resources available to fund local projects. However, transportation changes will not be effective without supportive land use changes. People are more likely to walk or ride a bicycle if popular destinations can be reached safely and efficiently. Local land use planning is highly variable, and often dismissed or ignored. Efforts should be made to set land use planning performance standards across the state and local health departments must begin to be more involved in the planning process.

The complexity and multi-dimensional nature of the overweight and obesity problems will require a multitude of approaches and collaborative efforts across multiple sectors of society. Using the framework of the Eat Smart, Move More…North Carolina initiative, NC public health agencies and programs are working closely with foundations, media and policy makers, business and industry, schools and preschools, faith-based organizations, communities, and individuals to reverse the rising rates of obesity in North Carolina. We must continue to focus our efforts and resources on this important public health problem. Public health is a public responsibility. **NCMedJ**

The Clinical Nutritional Implications of Obesity and Overweight

Kathryn M. Kolasa, PhD, RD, LDN; Kay Craven RD, LDN; Sarah Henes MA, RD, LDN and Catherine Sullivan MPH, RD, LDN, IBCLC, RLC

Introduction

It can be argued that our unstated national policy, until recently, has been that a person's weight is his/her "personal responsibility." Until 2005, the unspoken philosophy of our Dietary Guidelines was to encourage consumption of the variety of our national food supply. This policy coupled with limited, if any, reimbursement for non-pharmacological and non-surgical obesity treatments remain a major deterant for adults and children in receiving appropriate preventive and treatment counseling. Only recently has obesity been recognized as a disease that has both medical and economic sequelae.

Adults, too, report that they know "what to do" but just don't do it.[1] However, there is little evidence that Americans know how to estimate their caloric need or select a health promoting diet. Only one third of Americans report obtaining nutrition advice from physicians and even fewer (13%) receive counseling from a nutrition professional.[2] The American food supply is very complex, and stereotypes and myths of "healthful eating" are pervasive.[1] That shouldn't be surprising considering consumers receive most of their nutrition information from the media.[2] And though the United States government publishes evidence based dietary guidelines, it has virtually no budget for their promotion. As a result, few Americans have the knowledge, skill or motivation to embrace a diet that is health promoting and leads to a healthy weight. Nutrition knowledge alone does not guarantee healthy eating behaviors, but consumers cannot make informed food choices without it. Nutrition professionals have the education and experience to aid adults and children in developing eating plans that are personally satisfying and health promoting. For this paper, "nutritionist" refers to a licensed dietitian/nutritionist (RD/LDN).[3]

> *"Only recently has obesity been recognized as a disease that has both medical and economic sequelae."*

Additionally, RD/LDNs contribute to the nutrition education of physicians and other care providers. They work in coalitions toward environmental and policy changes to improve opportunities for physical activity and healthy eating.

Nutrition Education of and by the Physician

Nutrition and obesity education of medical students, residents and practicing physicians is uneven but generally inadequate.[4-6] The specialty of Family Medicine has led the way by requiring nutrition training.[4,5] As an example, medical students and Family Medicine residents at the Brody School of Medicine at East Carolina University (ECU) analyze their personal diets, learn to routinely include nutrition assessment in their history taking, practice counseling overweight patients with standardized patients, develop a relationship with a skilled clinical dietitian, and learn evidence based guidelines for treatment of

Kolasa, PhD, RD, LDN, is Professor and Section Head, Nutrition Services and Patient Education, Departments of Family Medicine and Pediatrics, Brody School of Medicine at East Carolina University. She can be reached at kolasaka@ecu.edu or 600 Moye Blvd, Suite 4N-70, Greenville, NC 27834. Telephone: 252-744-5462.

Kay Craven, RD, LDN, is nutrition specialist at the ViQuest Center, Greenville, NC.

Sarah Henes, MA, RD, LDN, is the Healthy Weight dietitian for the ECU-UHS Pediatric Healthy Weight Research and Treatment Center, Greenville, NC.

Catherine Sullivan, MPH, RD, LDN, IBCLC, RLC, is Assistant Clinical Professor and nutrition specialist, Department of Family Medicine, Brody School of Medicine of East Carolina University, Greenville, NC.

overweight. Unfortunately, the inclusion of nutrition and obesity training in North Carolina medical schools is not assured. This led the Fit Families North Carolina Study Committee to recommend that "North Carolina based medical schools should teach the basic principles of prevention including the benefits of healthful eating and physical activity, the importance of breastfeeding, and how to effectively counsel people to change health behaviors as part of the core curriculum."[7]

Kahn[6] suggested that even if medical students receive good training, their interest and enthusiasm for nutrition assessment and counseling rapidly diminishes if they do not receive reinforcement from their clinical house officers and faculty mentors. It seems paradoxical that primary care physicians agree that providing nutrition counseling to their patients is their responsibility, even when they are not entirely comfortable and confident with the advice they give for life style change.[4] Kahn confirms that few take advantage of CME opportunities.[6] Too often we observe physicians who have embraced the concept of evidence-based practice for their specialty but either are unaware or ignore nutrition evidence when counseling patients. Physicians need to determine the nutrition and obesity prevention and treatment messages they have the time and skill to provide to their patients. They should follow practice guidelines (not dietary fads or trends) that include practices such as annually monitoring weight of patients, plotting the BMI of children on growth charts, measuring waist circumference, encouraging the DASH diet for patients with pre-hypertension, pre-diabetes, or metabolic syndrome. Physicians who choose to counsel their patients about weight should be guided by the National Heart, Lung and Blood Institute (NHLBI) guidelines.[8] Tools for office practice developed by NHLBI Nutrition Academic Award are available at http://www.nhlbi.nih.gov/funding/training/naa/products.htm. "Practical Advice for Family Physicians to Help Overweight Patients" describes implementation of a systematic and practical approach to management of obesity in practice.[9] Physicians who find time, reimbursement or skill as barriers to providing this type of care, can still serve their patients by reinforcing the messages of the North Carolina Eat Smart Move More campaign which are to: 1) decrease sugar-sweetened beverages, 2) decrease TV time, 3) prepare and eat more meals at home, 4) decrease portion sizes, 5) increase physical activity, 6) increase fruits and vegetables, and 7) breastfeed your baby (www.myeatsmartmovemore.com).[10] They should refer their patients to an RD/LDN or to a weight loss program that conforms to the North Carolina safe weight control program regulations.[3]

Referral to Weight Control Programs.

The Federal Trade Commission's "Voluntary Guidelines for Providers of Weight Loss Products or Services" encourages consumers to protect themselves from programs that do not adhere to standards.[11] North Carolina seeks to further protect consumers from unsafe weight loss programs by requiring annual review of programs, which are not provided by an RD/LDN. The regulations require that the client's level of health risk should be identified as low, moderate, high, or inappropriate for participation in a weight loss program. Patients at "low risk" can obtain nutrition education about the Dietary Guidelines for Americans and the Food Guide Pyramid from health educators and nurses. Patients of higher risk require physician clearance and a nutrition prescription and consultation from an RD/LDN. Key features of the standards include: 1) the program should not promise weight loss in excess of the safe two pounds per week; 2) plans should have at least 1,000 calories per day; adequate protein (0.8-1.8 grams/kilogram of goal weight) and no less than 100 grams carbohydrate/day; 3) participants receive nutrition education that encourages permanent change; 4) a maintenance component is provided; and 5) appropriate staff is available. Any supplements should not exceed 100% of the Recommended Dietary Allowances and neither formula products nor appetite suppressants should be used with low risk clients. Although these regulations became effective in 1995, the North Carolina Board of Dietetics/Nutrition has very limited resources for promotion or enforcement. Complaints can be filed with the Board at www.ncbdn.org.

Referral to a Licensed Dietitian/Nutritionist (RD/LDN).

There is adequate evidence that weight loss can be achieved with a variety of dietary approaches.[12] The RD/LDN has the education and skill to assist patients with the selection of an approach that not only leads to a healthy weight but is health promoting. The RD/LDN can assist patients with the most difficult aspect of weight loss treatment—adherence. North Carolina has licensed nutrition professionals[3] since 1991. The Dietetics Practice Act is to protect the citizens of North Carolina from harmful nutrition practices. Anyone who holds a valid license from the North Carolina Board of Dietetics/Nutrition can legally practice in the state. Additionally, those who are exempt (e.g., doctors, physician assistants, nurses, dentists, dental hygienists and psychologists) from the Act (NCGS 90-368) can offer nutrition education, but cannot use the title "registered dietitian," "licensed dietitian" or "nutritionist."[3] Additionally, federal, state and local government employees, herbalists, and weight control service providers are among those who are exempt as a function of their employment (e.g., sales person in a health food store). In 2005, Blue Cross Blue Shield of North Carolina (BCBSNC) invited about 700 North Carolina RD/LDNs to become credentialed and listed in their provider network (www.bcbsnc.com). The weight loss interventions offered by these RD/LDNs are guided by "Adult Weight Management Evidence-Based Nutrition Practice Guidelines."[13] Recently BCBSNC began reimbursing up to four doctor's office visits and up to 6 credentialed RD/LDN visits for weight assessment and counseling to adults enrolled in their "Healthy Lifestyle Choices."(www.bcbsnc.com/health-wellness/mhp/healthylifestyle.cfm) Although the reimbursement is very modest, the action by BCBSNC is a laudable first step to improving access for weight management services.

North Carolina RD/LDNs in partnership with BCBSNC have launched a study to evaluate the cost and clinical outcomes of Medical Nutrition Therapy (MNT) provided by RD/LDNs.

Physicians can assist by referring patients to this 24-month prospective study. There already are published trials demonstrating lifestyle change occurs with intensive therapy. For example, the Diabetes Prevention Program (DPP) trial[14] showed that nutrition and physical activity interventions were superior to pharmacological interventions. In that study, participants had multiple interactions with nutrition professionals including culturally sensitive training in diet, exercise, self-monitoring, goal-setting, and problem-solving as part of a 16-session core-curriculum. Monthly individual or group sessions, phone or mail contacts were provided. Unfortunately, the significant barrier to translating the DPP findings into real life practice is the lack of reimbursement for this intervention and lack of willingness or inability of the patients to pay for these services.

Facilitating a Successful Referral to the Dietitian.

RD/LDNs report that the success of their patients, including their "show rate" for MNT visits, is dependent on the physician setting strong expectations. This should not be the "referral of last resort" that occurs only after medicines have been maximized. Physician need to tell patients the dietary intervention is integral to their treatment and is best provided by a nutrition specialist. The RD/LDN will tailor the dietary prescription to the patient's lifestyle and preferences. Physicians who inform their patients that they will monitor progress increase the patient's likelihood of success. And when the change occurs, the physician needs to note changes and as appropriate adjust medications. Physicians can explain that the cost of the consultation, if not reimbursed, is reasonable and will more than likely save the patient time and money in planning healthy eating and reducing medications. A directory of RD/LDNs can be found at www.eatright.org/find.html. While consumers can refer themselves to a dietitian they are best served when their physician offers the opportunity.

The Special Case of Medical Nutrition Therapy for Gastric Bypass Patients.

Since most third party payers began requiring a nutrition assessment prior to gastric obstructive procedure (GOP) the opportunity for RD/LDNs to counsel GOP patients has dramatically increased. The authors of this paper provide assessment and counseling to patients from multiple surgical practices. At the pre-surgical assessment, some patients are well informed. Others see the surgery as a quick fix or "magic pill". The RD/LDN helps the patient understand the mechanisms of the surgery and its short and long term impact on both nutritional and overall health. Some surgical candidates have attempted many weight loss programs, but many have not experienced a structured nutrition intervention. While traditional diet and exercise programs may not be sufficient to help most morbidly obese patients, some lose significant weight and elect not to pursue surgery. Unfortunately, the requirement for the pre-GOP nutrition assessment is often without reimbursement, contributing to wide variations in the comprehensiveness of the MNT patients receive. Since little is known about the natural history of nutrient status and eating habits of these patients, it is prudent for all GOP patients to have access to MNT both pre- and post- their gastric obstructive procedure . Many GOP patients who were not provided MNT peri-surgically, self refer to an RD/LDN when weight re-gain begins, about two years post-surgery. Currently clinical experience rather than evidence guides most nutrition recommendations made for GOP patients.

Surgery remains the most effective means currently available to induce and sustain substantial weight loss in these morbidly obese patients, however, experience suggests that too few patients have the opportunity, while they are gaining the excess weight, to receive the MNT they need about portion sizes, calories, carbohydrates, fat, and protein. In addition to lack of reimbursement, barriers include lack of physician referral as well as physicians' negative attitudes about potential success.

The Special Case of Treating Children, Adolescents, and Their Families.

Children, adolescents, and their families would benefit from assessment and nutrition intervention by a RD/LDN. In the absence of national guidelines in 2004, RD/LDNs associated with the Pediatric Healthy Weight Research and Treatment Center at ECU developed a seven visit MNT protocol (www.ecu.edu/pedsweightcenter). Pitt Memorial Hospital Foundation funding supported a dietitian providing MNT in eight pediatric and family medicine offices. A retrospective chart review of 129 at-risk or overweight youth who received multiple sessions with the RD/LDN was completed. It typically took four visits, over five months, for patients to make lifestyle changes impacting their BMI. Strategies such as increasing the number of days of physical activity, reducing the number of times eating out per week, increasing servings of fruits and of vegetables, decreasing consumption of fried foods, and reducing total amount of sweetened beverages consumed made a difference. These changes resulted in a decrease in BMI. To some, the effect size appears small, but those children who had abnormal laboratory values for lipids or blood sugar generally normalized them.

Based on experience with more than 800 overweight children, single visits seem to be of limited value. At least one visit is needed to "sell" the patient and family that eating healthy and being physically activity is for everyone in the household, including part-time care providers like grandparents and "weekend parents." The RD/LDN empowers the family to set realistic goals. The patient is told in follow up that the RD/LDN will provide a structured plan and non-judgmental support. We are surprised by the prevalence of emotional eating by children. Youth who are singled out in their family often "sneak" "hoard" or "binge" on restricted foods. Our first strategy is to help the family switch from sugar sweetened beverages (e.g. sweet teas, colas, kool-aid and juices) to sugar free drinks, plain and flavored water, and low fat milk. Much work is needed in this area as families often only switch from one sugar sweetened beverage to another without instruction. It is particularly important to help pre-teens and teens become accountable for their food and beverage choices through skill building including label reading, portion size recognition, and recognition of internal hunger cues.

The challenge remains that medical nutrition therapy for overweight children is not reimbursed, except at health departments. In 2005, The North Carolina Study Committee for Childhood Overweight/Obesity proposed that "the State Health Plan, Medicaid, Health Choice and Special Health Services should include coverage in North Carolina to include prevention and treatment services for children, youth, and their families who are overweight or at risk for overweight, and to allow RD/LDN practicing in both public and private settings to be reimbursed for medical nutrition therapy."[7]

There are many different lifestyle change programs to help parents and children with weight management. However, a systematic literature review found that the limited evidence conclusions about the effectiveness of these interventions was not conclusive.[15] It is not clear what criteria should be used to call a group weight management program for youth "a success."

We find that youth taking part in the eight to ten week, age specific programs at ViQuest Center—Greenville (www.uhseast.com) have varying outcomes. In 2005, 68% of the school age participants maintained or reduced their BMI percentile for age. But these results vary from session to session, in no predictable way. Defining success, providing appropriate follow-up, and making these programs affordable to overweight North Carolina youth remain unresolved challenges for those providing group classes.

Moving Outside the Clinical Setting: Environmental and Policy Changes to Support Healthy Eating

More than a skilled clinician and a motivated patient is required to achieve lifestyle changes that support healthy weights. Environmental and policy changes are needed to make it easier for people to make healthy food choices. North Carolina has a variety of plans available to allow citizens to begin to make these changes. Healthcare providers and persons in healthcare leadership positions should review these plans and identify objectives that can be incorporated into their own work and community environments.

The North Carolina Division of Public Health has championed the development of plans and tools to address obesity including "Moving Our Children to A Healthy Weight"[16] as well as "Blue Prints for Changing Policies and Environments in Support of Healthy Eating and Physical Activity."[17] North Carolina published achievable standards for all foods available in schools.[18] North Carolina's plan to prevent obesity and reduce chronic diseases is expected in August, 2006. The North Carolina Health and Wellness Trust Fund (HWTF) supported the development of recommendations to address Childhood Obesity in its Report of the Fit Families' Study Committee.[7] HWTF, also, in partnership with Blue Cross Blue Shield of North Carolina has tools for healthier weight and lifestyle at www.fittoghernc.org.

The experts note that solutions to the obesity epidemic need to be "local." The Eat Smart Move More web site (www.eatsmartmovemorenc.com) includes a catalogue of success stories. Nutrition education resources in North Carolina's rural areas are limited. Food Literacy Partners Program (FLPP) is an example of a successful program where RD/LDNs in Pitt County have trained more than 240 community volunteers who share their new health and food literacy with others at schools, churches, clinics, health fairs, and other events. Most graduates, who are required to provide 20 hours of community service in return for the free training, report changing their own food choices and finding themselves talking about nutrition to their families, friends and co-workers. Finding the resources to sustain successful local nutrition education initiatives like FLPP remains a challenge.

Bottom line

North Carolinians have limited access to evidence-based food and nutrition information to help prevent or treat overweight and obesity. RD/LDNs are uniquely qualified to train others to provide nutrition education and to deliver medical nutrition therapy directly to patients.

Physicians can find a dietitian by using the Blue Cross Blue Shield of North Carolina list of credentialed dietitian or Find A Dietitian at www.eatright.org. **NCMedJ**

Tipping the Scales of Prevention Advocacy with $10,000 and a Notebook

Jennifer Hastings, MS, MPH; Meg van Staveren, MPH, RD; Rachel Bikoff; Julie Knaack, RD and Meg Molloy, DrPH, MPH, RD

A nationwide glance reveals that North Carolina has some of the best health insurance coverage and benefits for obesity. Examples include health coaching and lifestyle improvement programs offered by the State Health Plan of North Carolina; reimbursement and tools for primary care providers to address obesity, nutrition counseling, and weight loss medications through Blue Cross Blue Shield of North Carolina; and medical nutrition therapy for children and adolescents provided through the NC Division of Medical Assistance. Unfortunately, more than 1.3 million nonelderly people in North Carolina lack health insurance coverage, and these resources are not available to them.[1] Furthermore, access to these policies and resources in other settings are critical in the fight against obesity and overweight.

NC Prevention Partners' (NCPP) collaboration with the Kate B. Reynolds Charitable Trust addressed this issue in five low-income community health centers (CHC) throughout the state. Over the last three years, this partnership enabled NCPP to work closely with these CHCs to establish systems to improve health. In addition, this funding along with funds from the NC Division of Public Health facilitated the creation of the *Prevention Rx* system for healthcare clinics, the *NC Good Health Directory*, and the *Starting the Conversation* series. With these tools, the CHCs have built strong, sustainable systems, including those that support nutrition and tobacco cessation in their communities.

Imagine a community health center has been given a check for $10,000 to be used over two years. With this money, they've hired a part-time, 15-hour a week nutritionist. Then, imagine the funding disappears or comes to an end. Would the nutrition program be gone, too? This amount of money, given to one CHC, helped to start an effective nutrition counseling program. Thanks to system-level changes the CHC made, the program is still in operation and is now sustainable even after the funding period ends.

Here is what one CHC did. First, the CHC hired a part-time dietitian to counsel both patients and staff. However, the CHC did not just hire a nutritionist for the life of the grant. Instead, to be able to retain the services of a nutritionist after the grant, they began filing for reimbursement for the nutrition services they offered. The nutritionist worked closely with the billing and coding departments to set up a system to reduce the number of rejected claims. In addition, she worked with the CHC's staff providers to educate them about the services she

> *"If the familiar adage, 'An ounce of prevention is worth a pound of cure,' was restated using units of time, it might read as: 'A brief preventive healthcare intervention can add up to years of quality, healthy living.'"*

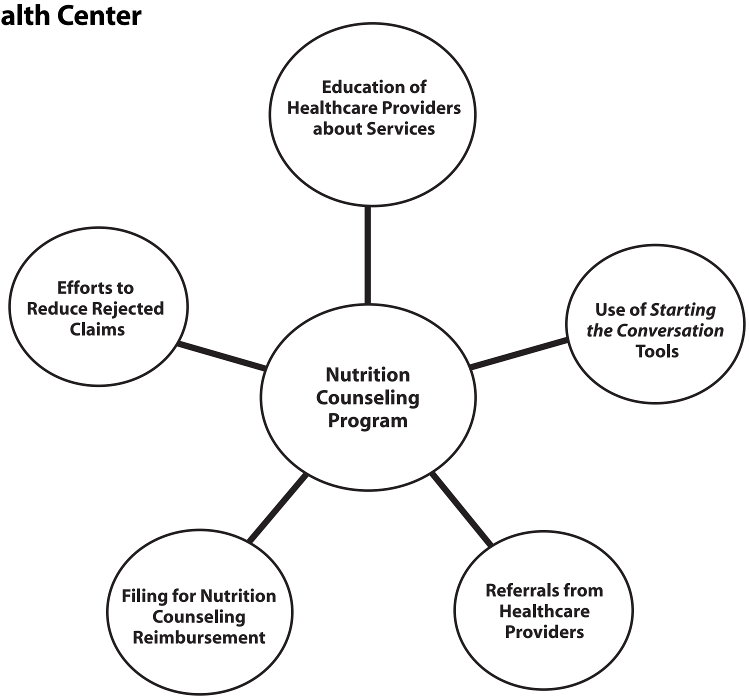
Meg van Staveren, MPH, RD, is Physical Activity & Nutrition Coordinator, NC Prevention Partners.

Rachel Bikoff, MPH, was an intern at NC Prevention Partners.

Julie Knaack, RD, is an intern at NC Prevention Partners.

Meg Molloy, DrPH, MPH, RD, is Executive Director, NC Prevention Partners.

Figure 1.
Sustainable System for Nutrition Counseling at the Community Health Center



offered and to increase patient referrals. These system-level changes, as seen in Figure 1, are critical components of the CHC's ability to impact obesity and overweight in the local community.

Many motivated health professionals attend trainings to learn about how to combat obesity and chronic disease. Unfortunately, many of the notebooks and resources provided often return to offices only to sit unused on bookshelves. What made the difference for the community health center described above was that the nutritionist and other staff who attended the Prevention Partners *Prevention Rx* training session made it a priority to use those resources and newly-aquired tools and skills. A measure of their nutrition program's success can be seen in the number of patients helped—nearly 400 in less than two years. One patient seen during that time had been obese for years and was able to lose over 100 pounds, dramatically improving her quality of life.

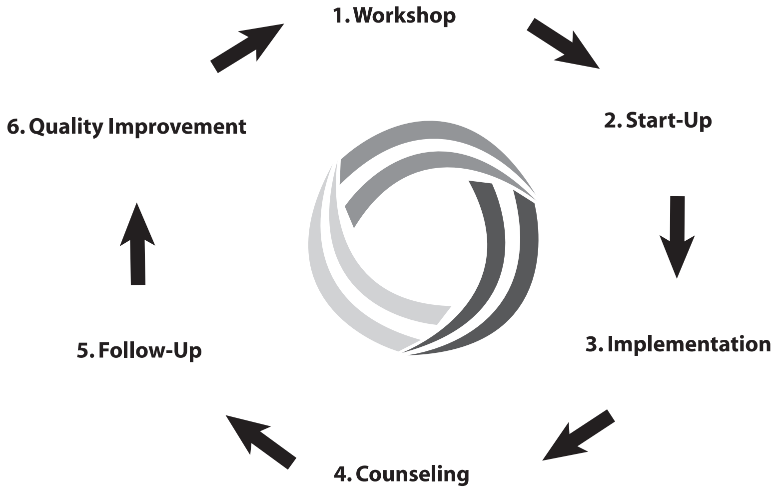
This story exemplifies the way NC Prevention Partners approaches problems in public health. We want the notebook to come off the shelf. We look for ways to make it easier for individuals to do simple things like make good food choices, receive preventive healthcare, and find support for healthy behaviors. We focus on system, policy, and environmental changes because, as Malcolm Gladwell, author of *The Tipping Point: How Little Things Can Make a Big Difference*, states,[2] "Human beings and their behavior are highly-sensitive to their environment." The environments highlighted in this article are healthcare settings, schools, and worksites.

Where People Receive Healthcare

If the familiar adage, "An ounce of prevention is worth a pound of cure," was restated using units of time, it might read as: "A brief preventive healthcare intervention can add up to years of quality, healthy living." NC Prevention Partners created the *Prevention Rx* system to facilitate the process of routinely addressing physical activity, nutrition, and tobacco use in healthcare interactions. As shown in Figure 2, *Prevention Rx* workshops give healthcare providers working in any setting the necessary tools, resources, and skills to do this.

Through the one-day workshop, healthcare professionals learn how to use the *Starting the Conversation* series—tools that help providers conduct brief screening and counseling for nutrition, physical activity and tobacco. In addition, information is provided about modifying patient history forms, documenting prevention encounters, and filing for reimbursement. Finally, an on-line referral database called the *NC Good Health Directory* gives providers a collection of local resources to which they can refer their patients. *Prevention Rx* is a healthcare office system that takes the guesswork out of how to help patients practice healthy behaviors, such as those that support a healthy weight.

Figure 2.
The *Prevention Rx* System



Where People Learn

There has been substantial controversy surrounding the nutrition and physical activity environment in the school system. Along with the recent release of the "School Foods Report Card" from the Center for Science in the Public Interest, there has been a strong push for national and state system-wide changes. Reaching children through schools is logical because children spend so much time there. However, differences between school systems at the local level mean that policy or programmatic changes need to incorporate flexibility to allow for district specific adaptations. It is these smaller modifications that will tip the local scales in favor of a generation of healthier youth.

Since 2004, North Carolina has taken a step forward in addressing the health of children through "Eat Smart: North Carolina's Recommended Standards for All Foods Available in Schools," and "Move More: North Carolina's Recommended Standards for Physical Activity in Schools." Additionally, national legislation now requires schools participating in any reimbursable meals program to develop district-level wellness policies by the start of the 2006-07 school year.

NC Prevention Partners' *Zone Health* pilot program, supported by GlaxoSmithKline Community Partnerships, provides schools with toolkits to take local policies from the notebook to practice. Recognizing that obesity is a multi-factorial problem, *Zone Health* guides schools through an assessment of their school health environments and policies. Through the program, schools receive assistance and resources to make changes and to begin drafting quality prevention policies to support the health of their students and staff. Once their policy development is complete, schools are given training and tools to do ongoing evaluation and policy revisions. Even schools that have completed and adopted wellness policies at the school level can benefit from the *Zone Health* program because it allows them to assure the steps they have taken are comprehensive and meet or exceed district-level policy requirements.

The *Winner's Circle Healthy Dining Program* is another collaborative initiative between NC Prevention Partners, local and state public health and school leaders. This program offers tools and training for schools to promote healthy foods and beverages on their campuses using the *Winner's Circle* purple star and gold fork logo. One of the organizational goals for DPI set by the Section Chief of Child Nutrition Services is for all NC elementary schools to implement the *Winner's Circle* program. Eventually, middle and high schools will also be targeted for *Winner's Circle* implementation. This will help schools meet the health and nutritional policies detailed in the state publication, "Eat Smart: North Carolina's Recommended Standards for All Foods Available in School." Since 2002, eighty-one NC Local Education Areas (LEAs) have received *Winner's Circle Healthy Dining Program* training through the NC Division of Public Health (DPH) and the NC Department of Public Instruction (DPI). To date, *Winner's Circle* has been implemented in approximately 1,600 schools.

Schools participating in the *Winner's Circle* program develop their own promotional campaigns to engage and encourage students to think about healthy eating. The schools also have the flexibility to adapt the program to their school-community culture by selecting from a variety of *Winner's Circle*-qualified foods and beverages to include in their offerings. Any food substitutions can be incorporated over time to avoid potential financial losses from a complete system overhaul. In addition, incremental meal service modifications will lead to well-balanced menus and will tip the scales for obesity prevention in North Carolina.

Where People Work

The typical American spends well over half of his or her life at work, establishing the work environment as a significant factor in individual health. For example, access to nutritious foods at work can increase the likelihood that healthy food choices are made; physical activity incentives for employees can increase the likelihood that employees are more active; and health insurance options that include covered physical activity and nutrition benefits can help overweight and obese employees reach and maintain a healthy weight.

Every year, medical care and lost productivity from obesity, poor nutrition, physical inactivity, and tobacco use cost employers an average of $5,000 per employee.[2] To help businesses improve employee health and reduce healthcare costs, NC Prevention Partners created the *Prevention 1st Challenge*. One of the goals of this program is to facilitate the creation of policies and environments that support individual health in worksites throughout the state.

The *Challenge's* main tool—the *Prevention Audit*—provides businesses the opportunity to assess their physical activity, nutrition, and tobacco use policies and environments. The audit and resulting *Prevention Report Card*[3] can then be used to identify priority issues and to assist in the development of a strategic prevention plan to create policies and environments that support employee health. The *Prevention 1st Challenge* can similarly be used by counties. County health directors and Healthy Carolinian coalitions can use their county *Prevention Report Card* to create awareness and leverage support from their local and state public policy makers and community leaders.

Be an Advocate

All of these programs require that simple changes in policy and environment are made. Taken together, these changes can significantly influence obesity and overweight. Using the premise of Gladwell's book that, "little things can make a big difference," it stands to reason that in public health, simple changes and actions will determine whether we win or lose the fight with obesity and overweight in this state. Advocacy is about doing something and doing something that makes sense. In his book, Gladwell[2] mentions three factors that drive social change. They are:

- **The Law of the Few**—Exceptional people who spread the word through social connections, energy, enthusiasm, and personality.

- **The Stickiness Factor**—Simple changes that can make a big difference in how much impact a message makes.
- **The Power of Context**—Human beings and their behavior are highly-sensitive to their environment.

With these three factors in mind, imagine if just 10 readers of this journal—that's 0.03% of the *North Carolina Medical Journal's* readership—made simple changes that led to sustainable system-level changes in their clinic, school or place of work. Now, like the clinic in the vignette above, imagine that each of those system-level changes affected 400 people over two years. Even with less than 1/10 of a percent of the journal's readership causing these small changes, as many as 4,000 of the overweight or obese individuals living in this state could be helped.

As the CHC in the vignette showed, tipping the scales in favor of prevention could start with as little as $10,000 and a notebook.

What else can we do? Be an advocate for sustainable systems in North Carolina to support healthy weight and consider the many additional opportunities described in Table 1. **NCMedJ**

Table 1.
Advocacy Opportunities for Addressing Obesity

☐ Strengthen your own clinic, hospital, school, or work environment by establishing the *Prevention Rx* system and linking with other resources in your community. Support one another, benefit from the expertise and experience of those around you, and avoid re-inventing the wheel.

☐ Advocate for local policy changes in your community's schools and work sites. Advocate for increased availability of quality resources in your area to help people reach and maintain a healthy weight. Consider volunteering with a local task force or as a speaker to the school board.

☐ Advocate for state and federal policy changes to support improved nutrition and increased physical activity in schools and communities.

☐ Publicize resources and programs available in your area and share your success with others around the state on the *Healthy County Profile* (located under Quick Links) at www.ncpreventionpartners.org.

☐ Find and use local physical activity and nutrition resources in the *NC Good Health Directory* at www.ncgoodhealthdirectory.com, and submit resources not found there to let others know what is available in your area.

☐ Visit the *Preventive Benefits Watch* (located under Programs at www.ncpreventionpartners.org) to learn about what preventive benefits are offered for physical activity, nutrition, and obesity by the private and public NC health insurers. North Carolina is the only state in the nation that makes this information publicly available, thanks to all of the health plans voluntarily sharing and annually updating their preventive benefits profiles and to the NC Division of Public Health, NC Department of Health and Human Services.

☐ Attend a training session to obtain the tools and skills to implement *Prevention Rx*, *Winner's Circle*, *Zone Health*, or the *Prevention 1st Challenge*. For current offerings, go to www.ncpreventionpartners.org.

Active Living by Design

Active Living by Design (ALbD), a $15.5 million national program supported by the Robert Wood Johnson Foundation (RWJF), was launched in late 2001. Located in Chapel Hill and part of the North Carolina Institute for Public Health at the UNC School of Public Health, ALbD helps communities increase physical activity and healthy eating through changes in community design, policies, and promotions.

In late 2003, twenty-five diverse partnerships from across the nation were selected from 966 applicants to receive $200,000 grants and technical assistance over five years to implement comprehensive initiatives to increase physical activity in their communities. More recently, 12 of these partnerships received an additional $50,000 over eighteen months to pilot test approaches to increase access to healthy foods for children in low-income neighborhoods.

ALbD provides technical assistance through a team of project officers and a comprehensive learning network. Like the partnerships they support, the ALbD project team includes representatives from a variety of disciplines, including public health, health policy, city and regional planning, parks and recreation, nutrition, and communications.

Community partnerships implement five strategies that address the social-ecological influences on physical activity and healthy eating: preparation, promotions, programs, policies, and physical projects. This "5P community action model" provides the intervention framework for each of the partnerships. Evidence of the effectiveness of these strategies can be found in various studies, many of which were summarized by the US Task Force on Community Preventive Services, which recommends interventions with informational, behavioral, environmental and policy approaches.

Now midway through their initiatives, the ALbD community partnerships are making excellent progress. While it is too early to measure long-term behavior change, it is clear that community changes already are occurring. Partnerships have amended development ordinances and approved new street design standards, created trails and greenways, implemented social marketing campaigns to increase awareness of opportunities for physical activity, changed school policies regarding recess and lunch menus, established new community gardens and bicycle recycle programs, and more. In addition, during their first two-and-one-half years the ALbD partnerships have secured or leveraged additional funding equal to over sixteen times that of RWJF's initial investment in their communities.

In an effort to continue to test and replicate the 5P approach, ALbD is working with a variety of other organizations across the country. For example, ALbD is providing technical assistance to local partnerships in Minnesota for community engagement and assessment addressing active living. Funded by Blue Cross and Blue Shield of Minnesota, ALbD anticipates that these partnerships will eventually build a vision and principles for active living into their communities' comprehensive plans.

Closer to home, ALbD also provides technical assistance to counties and municipalities funded through the North Carolina Health and Wellness Trust Fund's Fit Community initiative and to rural communities through Blue Cross and Blue Shield of North Carolina Foundation's Fit Together grant program.

Through these comprehensive efforts, ALbD and local partnerships are collaborating in neighborhoods, communities, counties and regions across the United States to combat the nation's epidemics of physical inactivity and poor nutrition.

For more information on ALbD, go to: www.activelivingbydesign.org.

Sarah Strunk, MHA, is Director, Active Living By Design National Program Office. She can be reached at sarah_strunk@unc.edu or 400 Market Street, Suite 205, Chapel Hill, NC 27516. Telephone: 919-843-3122.

Coordinating School Efforts to Help Address the Obesity Epidemic in North Carolina

Paula Hudson Collins, MHDL, RHEd

While the world is getting flatter, Americans—especially our young people—are getting rounder. According to Thomas Friedman, New York Times columnist and author of *The World Is Flat*,[1] America is working in a globally competitive world in which the field is increasingly "flat" or equally competitive for all developed nations. With everyone seeking an advantage, the terms "lean and mean" take on even greater significance. Healthy workers are more productive, learn more effectively and cost less in the long run than unhealthy workers. Research indicates that there is a positive link between healthy students and greater academic gain. This ultimately leads to a healthier and more competitive workforce.

The causes of the "rounding of America" are well known. Some of the culprits include the sedentary use of technology for learning, shopping as recreation, greater access to fast food, cola consumption, a "quantity is quality" attitude about food, less time and safe space available for exercising, and over-scheduled families relying on multiple remote controls. Could schools unintentionally be culprits as well? With a wide array of vending machines, little time scheduled for physical activity and even less time for students to choose and eat a healthy lunch, they may also be culpable. Even students who want to be healthier during the school day, often encounter unintentioned obstacles.

> *"Healthy workers are more productive, learn more effectively and cost less in the long run than unhealthy workers."*

Today, educators are being asked to prepare students to successfully compete in a world that many adults could not have imagined. In response to this challenge, a wide range of educators, advocacy groups and businesses are enthusiastically emphasizing strategies focused largely on assessments of student academic performance and teacher effectiveness. With this framework in place, it is no surprise that our schools have become environments, for students and teachers alike, of the over-tested and over-stressed! It is time to utilize our educational resources to provide a winning strategy for healthy students in an even healthier school environment.

The best way for schools to address the obesity epidemic is to work in a coordinated effort to do what they do best… educate! Former United States Senator William Cohen from Maine said, "It is clear that children must be healthy to be educated and they must be educated to be healthy." While this might appear to be the old chicken or the egg quandary, we must address learning to be healthy and being healthy to learn, simultaneously. A school health program that effectively addresses students' health improves their ability to learn.

North Carolina is fortunate to be one of 23 states in the nation to receive competitive funding from the Centers for Disease Control and Prevention to promote Coordinated School Health Programs (CSHP) at the state and local levels. The model promotes eight components of a healthy school with school professionals working together to address health issues. The model combines their collective wisdom, experience, and efforts in order to provide the greatest benefit to the students.

According to Marx, Wooley, and Northrop, authors of *Health is Academic*,[2] the recognized template for establishing a Coordinated School Health Program, each of the eight components described below contribute to students' health in unique ways and at the same time, they enhance each other. A Coordinated School Health Program (CSHP) includes:

- Comprehensive School Health Education
- Physical Education
- School Nutrition Services
- Healthy School Environment
- School Health Services
- School Counseling, Psychological and Social Services

Paula Hudson Collins, MHDL, RHEd, is Senior Advisor for Healthy Schools in the North Carolina Department of Public Instruction. She can be reached at PCollins@dpi.state.nc.us or 6349 Mail Service Center, Raleigh, NC 27699-6349. Telephone: 919-807-3859.

- School-Site Health Promotion for Staff
- Family and Community Involvement in Schools

Comprehensive School Health Education focuses on the health information, strategies, and objectives taught to students. This classroom-based education addresses the physical, mental, emotional, and social dimension of health; develops health knowledge, attitudes, and skills; and is tailored to each age level. It is designed to motivate and assist students to maintain and improve their health, prevent disease, and reduce health-related risk behaviors. Typically, North Carolina elementary students receive health instruction taught by their classroom teacher in lessons often integrated into other subjects. Time for health instruction is in competition with other equally important and tested subjects during the elementary student's day. In middle school, grades six to eight, students receive health instruction from certified health and/or physical education teachers in a variety of ways. Health and physical education are referred to as Healthful Living and students usually receive health instruction in the classroom setting, alternated with physical education held in the gymnasium or other activity facility or athletic fields. In high school, students have one Healthful Living unit graduation requirement, which is typically half health and half physical education. Over 95% of high school students complete the Healthful Living graduation requirement in the ninth grade. The Healthful Living Standard Course of Study guides the grade-level objectives utilizing national standards and health methods and theory. While health has its own discipline, health objectives are frequently integrated into other subjects such as examining the nutritional composition of the foods in a foreign culture through a social studies class, plotting a graph of the number of steps recorded on a pedometer in math class, reading a book about an unhealthy rabbit in language arts or discovering the effects of a compromised immune system due to HIV infection in a biology class. The North Carolina Department of Public Instruction has written the Balanced Curriculum Document to assist educators in pacing and balancing time to allow them to teach the entire curriculum. The Healthful Living Standard Course of Study is available at www.ncpublicschool.org.

Physical Education is planned, sequential instruction that promotes lifelong physical activity. It is designed to develop basic motor skills, sports skills and physical fitness as well as to enhance the students' mental, physical, social and emotion abilities. Physical activity is a behavior that is cultivated and includes a variety of activities, with the focus on being active. The Centers for Disease Control and Prevention suggests a minimal requirement of 60 minutes of moderate to rigorous physical activity each day for optimal health. In North Carolina, students receive 30 minutes of daily physical activity during the school day as required by the Healthy Active Children Policy. This policy suggests that elementary schools should consider the benefits of having 150 minutes of physical education weekly and that middle schools should move toward having 225 minutes of Healthful Living education per week. The Healthy Active Children Policy is available at www.ncpublicschools.org/State_Board.

School Nutrition Services focus on the integration of nutritious, affordable and appealing meals, nutrition education, and the creation of an environment that promotes healthy eating behaviors for all children. Some people are quick to criticize the school lunch program as contributing to childhood obesity. However, reimbursable lunches meet USDA recommended guidelines for nutrients and while pizza is still served, it is made on whole-wheat crust with turkey sausage and low fat cheese. Continually problematic are the vending machines and à la carte food sales used to supplement necessary operating costs for the school lunch program. In North Carolina, great strides continue to be made to offer more fresh fruits, vegetables and healthier meals in a cost effective manner.

Healthy School Environment addresses the physical, emotional, and social climate of the school. It is designed to provide a safe physical plant, as well as a healthy and supportive environment that fosters learning. In North Carolina, the healthy schools environment deals with a range of issues from providing a tobacco-free, weapon-free, bully-free, vending-free, mold-free campus to one which addresses health disparities and equal learning opportunities for all students. A school environment where adults are role models of good health and active behaviors and where students feel safe, provides one strategy to help fight childhood obesity.

School Health Services include preventive services, education, emergency care, referral and management of acute and chronic health conditions. It is designed to identify and prevent health problems and injuries as well as to care for students. In North Carolina, health services are provided through school nurses, school-based or school-linked health centers, and local health departments, hospitals and many community health partners. Collaborative work between schools and public health agencies has proven to be tremendously successful in addressing the obesity epidemic. No one agency can or should try to address this issue, alone.

School Counseling, Psychological, and Social Services include activities that focus on the cognitive, emotional, behavioral and social needs of individuals, groups and families. It is designed to prevent and address problems, facilitate positive learning and healthy behavior and development. In North Carolina, there is a tremendous need for increased access to mental health services for students. Research indicates that many self-esteem issues and mental health concerns contribute to overeating and depression.

School-Site Health Promotion for Staff includes assessment, education and fitness activities for school faculty and staff. It is designed to maintain and improve the health and well-being of school staff, who serve as role models for students. In North Carolina, numerous staff wellness programs are conducted in school systems. When students see their teachers participating in a walking program, choosing healthy foods and teaching about the benefits of a healthier lifestyle, it helps to eliminate the "do is say, not as I do" hypocrisy. Further, a healthy, engaged faculty is more productive and misses fewer days of work.

Family and Community Involvement in Schools creates partnerships among schools, families, community groups, and individuals. It is designed to maximize resources and expertise in addressing the healthy development of children, youth, and their families. Efforts to involve families in their child's education has proven to contribute to the child's overall school success. Likewise, students who learn about healthy lifestyle choices at school but go home to a setting with differing choices are often conflicted. Teaching the child to be healthy can impact family health practices, particularly if the family understands and reinforces what the child is taught.

On any given school day, as part of a Coordinated School Health program, a student battling obesity will have access to a collaborative system of resources for assistance. He will receive decision-making information during a health education class, learn a life-time skill in physical education, and be able to select and eat a nutritious meal in the school cafeteria. He, along with his family, will have the opportunity to talk with the school counselor or social worker and meet with the school nurse to discuss health options as part of a Child and Family Support Team. He will interact with teachers who are good health role models and are actively taking care of their own mental and physical health as part of the staff wellness program. He will be challenged to learn in a safe and healthy school environment and will have the opportunity to participate in an after school fitness group co-sponsored by the school and a community agency. He will function in an opportunity rich environment, which links health and academics and is designed for overall student success.

The Coordinated School Health Program is supported through 115 district level School Health Advisory Councils, which are required by the Healthy Active Children Policy and championed by the Local Education Area School Health Coordinator.

A complete overview of the Coordinated School Health Program and supporting resources is available at www.nchealthyschools.org.

Reversing the obesity epidemic requires a long-term, well-coordinated approach to reach young people where they live, learn, and play. Schools have an important role in helping to address childhood obesity. Schools provide a safe place in which to apply what is learned, encourage the development of healthy behaviors, and foster understanding of how health impacts overall student success. After all, Health is Academic! **NCMedJ**

Yes, Virginia, Bariatric Surgery Works, and It Is Safe

Walter J. Pories, MD, FACS

About two weeks ago it happened again. A friend stopped me in the hall of the hospital and asked me if there wasn't something we could do for his patient, a young but massive woman with diabetes, crippling arthritis and hypertension, now on 11 medications. When I asked if he had considered bariatric surgery, he recoiled at the suggestion and told me, in no uncertain terms, that the gastric bypass "doesn't work" and "it's far too risky."

It's time to set the record straight.

A Few Facts

Let me start this brief review of bariatric surgery with a few facts with which most physicians will readily agree:

- ***Obesity is epidemic.*** Two thirds of the American population are overweight or obese with even higher proportions in the African American and Hispanic populations. Twenty three million Americans have a Body Mass Index (BMI) greater than or equal to 35, exceeding their ideal body weight by about 100 pounds; 8 million, equal to the population of North Carolina, have BMIs greater than or equal to 40. Of even greater concern is the exploding prevalence of obesity among young people. More than one million children and adolescents are severely obese—many with type 2 diabetes.
- ***Severe obesity is a disease.*** It is not a moral failing or a punishment for some sin. While we do not know the cause of this recent epidemic, many factors have been implicated including genetics, viral infections, change in the national diet, portion sizes, high sugar drinks, availability of food, decreased activity, loss of physical education programs in schools, coin machines in public places, lack of sidewalks, lack of security in neighborhoods, etc. The fact is that we do not know why obesity has overtaken this nation in 20 years with the ferocity of an infectious plague. To blame it on afflicted individuals is unfair and cruel.
- ***"Morbid" is an appropriate descriptor for severe obesity.*** Virtually all patients with BMIs greater than or equal to 40 have at least one co-morbidity (i.e., a deadly disease associated with severe obesity). The list is long because obesity afflicts every system: diabetes, hypertension, cardiac failure, asthma, metabolic syndrome, pulmonary failure, hiatal hernia, deep venous thrombosis, pulmonary emboli, hernias, pseudotumor cerebri, stress incontinence as well as cancers of the breast, colon, prostate, and intestine. Early deaths are common among the mordibly obese.

More Facts that May Be a Bit Surprising

- ***Morbid obesity does not respond to diets, exercise, behavioral modification or even drugs*** in the long run. As long ago as 1991, the National Institutes of Health Consensus Conference on the Surgery of Obesity[1] concluded that surgery is the only effective treatment for patients who exceed their ideal body weight by more than 100 pounds. Non-operative approaches are ineffective, expensive, and not worth the effort.
- ***The BMI is not a good measure of adiposity.*** There are major differences in adiposity, i.e. the percentage of fat in the human body, depending on gender, muscle mass, mass, and ethnicity.[2] The problem is that most consider a high BMI a measure of adiposity, but it is not; it is merely an indicator of mass, thus able to represent muscle or fat. Selecting the

> *"Type 2 diabetes is no longer a hopeless disease. Diabetes can, for the first time, be fully reversed with bariatric surgery with a prolongation of life."*

Walter J. Pories, MD, FACS, is Chief of the Metabolic Institute and Professor of Surgery, Biochemistry, Sport and Exercise Science at the Brody School of Medicine, East Carolina University. Dr. Pories can be reached at pories@aol.com or 600 Moye Boulevard, Greenville, NC 27834.

BMI of 35 as the critical index for surgical care is not based on fact. An Asian woman with a BMI of 32 has as much risk for co-morbidities as her Caucasian counterpart with a BMI of 35. We use the BMI because it is clinically efficient and correct most of the time, but we need to be aware of its serious limitations. With Tanita scales[a] and dual energy X-ray absorptiometry (DEXA)[b] becoming more widely available, we may be able to focus on adiposity and the co-morbidities as better indicators.

Some Facts that May Seem Unbelievable

- *Bariatric surgery can produce durable weight loss.* A series of 602 morbidly obese patients were studied at East Carolina University (ECU) for up to 16 years after they underwent gastric bypass operations, with a 95% follow-up These patients maintained a mean weight loss of 106 lbs. This long-term weight loss has now been confirmed by other centers.[3]
- *Type 2 diabetes is no longer a hopeless disease.* Diabetes can, for the first time, be fully reversed with bariatric surgery with a prolongation of life. At ECU, we documented that 83% of our diabetic patients enjoyed a full remission of the disease with a sharp reduction in mortality.[4] This work has also been confirmed around the world.[5] One of our patients has now remained euglycemic (normal glucose levels) for over 23 years following a gastric bypass even though she required 90 units of insulin at the time of surgery. The explanations for the rapid remission prior to significant weight loss are not clear, but it appears to be indirectly related to the contact of the small bowel with food [i.e., the less food and the greater the exclusion of gut, the more complete the remission (see Table 1)].[6]
- *Bariatric surgery reduces the mortality from diabetes.* Two reports document that severely obese patients who undergo bariatric surgery live longer than those who don't. MacDonald,[7] based on the experience at ECU, reported a mortality of 1% per year in those who underwent bariatric surgery versus 4.5% per year in a group of people who were scheduled for surgery, but cancelled at the last minute. Christou,[8] following analysis of the results in the Canadian health system document,[9] concluded that bariatric surgery reduced mortality risk by 89%.
- *Most of the other co-morbidities of morbid obesity also resolve following bariatric surgery.* The exact figures are not available, but reports suggest that asthma, pseudotumor cerebri, stress incontinence, and cardiac failure due to fatty infiltration cardiomyopathy clear in almost all patients. Hypertension is alleviated in about half of bariatric surgical patients. Arthritis is not reversed, but the loss of weight can produce marked improvement in function. Seeing a wheel chair-bound patient progress to a walker and then a cane and finally a free gait is not unusual. Although patients enjoy a period of euphoria during the first year or two after the surgery, whether emotional disorders improve long-term is not clear.

Finally, Some Really Startling Facts

- *Diabetes clears before there is significant weight loss.* Obesity may be a contributing factor, but the cause of the type 2 diabetes appears to lie within the molecular mechanisms within the gut. The islets, long blamed for the problem, are most likely innocent, overworked bystanders. Bariatric surgery has opened exciting areas for research into our most serious chronic diseases.
- *Bariatric surgery may become the treatment of choice of type 2 diabetics who are not obese.* Bypassing the duodenum and proximal jejunum in lean, genetically diabetic rats prevents the development of the disease without loss of weight.[10] Similarly, Arguelles and his colleagues in Mexico,[11] recently reversed diabetes in a small series of non-obese patients with a stomach sparing bypass of the proximal foregut.
- *Bariatric surgery is as safe as cholecystectomy* and far safer than most major operations when the procedures are performed in "Centers of Excellence." Based on the experience of 55,000 patients reported by 106 Centers of Excellence in their applications to the American Society for Bariatric Surgery (ASBS) and the Surgical Review Corporation (SRC), the operations were performed with a 90-day mortality rate of 0.35%, about the same as cholecystectomies.[12] In

Table 1.
Weight Loss, Resolution of Diabetes, and Operative Mortality after Four Bariatric Surgical Operations (n = 22,094 patients; 2738 citations 1990-2002; Buchwald et al)

	Restrictive Operations		Restrictive and Malabsorptive Operations	
	Gastric Banding	Gastroplasty	Gastric Bypass	Duodenal Switch
Excess weight loss	47.5%	68.2%	61.6%	70.1%
Resolution of diabetes	47.8%	62.2%	83.6%	97.9%
Operative mortality	0.1%	0.1%	0.5%	1.1%

[a] Tanita scales use impedance technology to determine body weight and composition including assessments of Fat Mass, Fat Free Mass, Fat %, Total Body Water and BMI in one step

[b] Dual-energy x-ray absorptiometry (DXA or DEXA) densitometry is today's established standard for measuring bone mineral density and bone loss. Measurement of the lower spine and hips are most often done. More portable devices that measure the wrist, fingers or heel are sometimes used for screening, including some that use ultrasound waves rather than x-rays.

Table 2.
Mortality Rates Following Common Operations in United States Hospitals

	Aortic Resection	Coronary Artery Bypass Graft	Craniotomy	Esophagectomy	Pancreatic Resection	Pediatric Heart Surgery	Hip Replacement
# of Hospitals	2485	1036	1600	1717	1302	458	3445
National Average Mortality Rate (%)	3.9	3.5	10.7	9.1	8.3	5.4	0.3
Average Hospital Case Loads	30	491	12	5	8	4	24

Source: Dimick JB, Welch HG, Birkmeyer JD. Surgical mortality as an indicator of hospital quality. *JAMA* 2004;292:847-851

contrast, Table 2 shows Dimick's review of the outcomes for other common operations in the United States[13] after only 30 days: aortic resection 3.9%, craniotomy 10.7%, esophagectomy 9.1%, pancreatic resection 8.3%, and pediatric heart surgery 5.4%. Only hip replacement, with its mortality rate of 0.3%, is as safe as bariatric surgery when performed in Centers of Excellence.

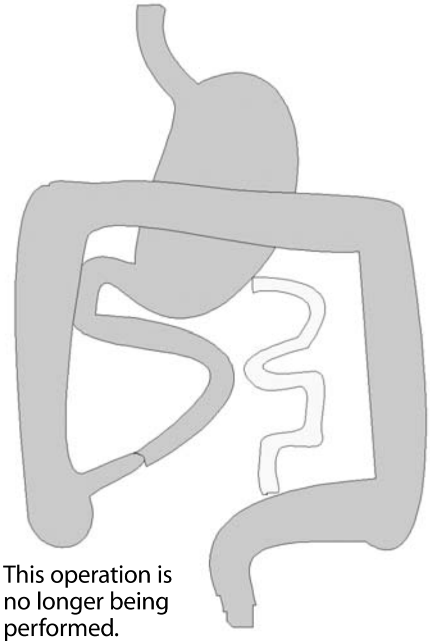
The Bariatric Surgical Procedures

Bariatric surgery is designed to produce weight loss by (1) reducing intake and/or (2) interfering with digestion and absorption.

The Intestinal Bypass, a Purely Malabsorptive Operation

The *intestinal bypass*, shown in Figure 1, although no longer performed, was important in its recognition that obesity could be a serious enough problem to warrant surgical intervention. The operation excluded the majority of the jejunum and ileum from contact with food, leaving only 14 inches of jejunum and four inches of ileum in the intestinal conduit. The excluded gut was turned into a diverticulum to empty into the colon. The operation induced significant weight loss through its interference with small bowel function, but the procedure was abandoned due to its serious long-term effects, including liver failure, kidney stones, mineral imbalances, and severe protein deficits, perhaps due in part to overgrowth of bacteria in the excluded segment. Unfortunately, more than 30,000 of these operations were performed before the operation was abandoned.

Figure 1.
Intestinal Bypass



This operation is no longer being performed.

Purely restrictive operations

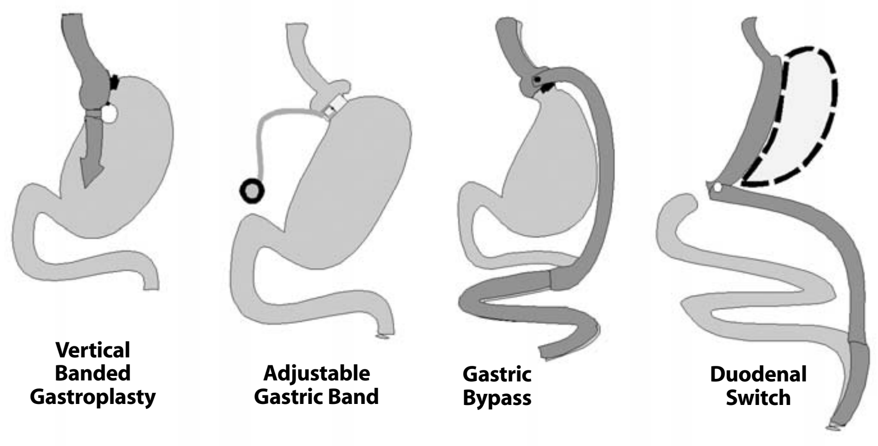
The *vertical banded gastroplasty* and *adjustable gastric banding* are two similar operations that induce weight loss solely by restricting intake. The vertical banded gastroplasty has been replaced almost totally by the adjustable gastric band, a far less traumatic and equally effective operation that consists of placing a bracelet-like band to create a golf ball-sized pouch. The advantage of the procedure is that the size of the stomach can be adjusted by changing the fluid volume of the balloon lining of the band through the subcutaneous port.

Combined restrictive and malabsorptive operations

The *gastric bypass* and the *bilio-pancreatic bypass with duodenal switch* are two operations with both restrictive and malabsorptive components. The gastric bypass supplements the actions of a small proximal gastric pouch with exclusion of the distal stomach, duodenum, and proximal jejunum from contact with food. The "duodenal switch" allows the patient to eat more because the entire lesser curvature of the stomach is maintained as a tube, providing a larger gastric pouch. This requires bypassing a significantly longer segment of the small bowel in addition to the resection of most of the stomach.

Of all of these operations, only the duodenal switch is not reversible.

Figure 2.
The Currently Accepted Bariatric Operations in the United States



The two operations on the left are restictive; the two on the right include a malabsorptive component.

Outcomes after Bariatric Surgery

A *comparison of the outcomes* of adjustable gastric banding, vertical banded gastroplasty, gastric bypass, and duodenal switch based on a meta-analysis of the bariatric surgical literature from 1990-2002 is shown in Table 1. The data are not quite fair since the experience with the adjustable gastric band was limited. More recent experience has shown that this newer procedure will also achieve excess weight loss in the 60-65% range after three years. In general, however, operations that combine restrictive and malabsorptive components, such as the gastric bypass and the duodenal switch, produce more weight loss and higher remission rates of diabetes, but with somewhat higher mortality rates.

Short-term complications after bariatric surgery are similar to other abdominal procedures (i.e., anastomotic leaks, bleeding, stenosis, and intestinal obstruction) and probably less frequent. They are, however, more dangerous in the morbidly obese with their co-morbidities and limited immune response. Anastomotic leaks, for example, require immediate attention because even short delays in repair and drainage may lead to fatal sepsis. A remarkable indicator of the safety of the surgery is that pulmonary emboli, though uncommon, now represent the most common cause of death.

The most serious *long-term complications*, however, are nutritional. Bariatric surgical patients require vitamin and mineral supplementation for life, including a broad multivitamin and mineral preparation, such as two Flintstone chewable vitamins tablets per day plus calcium. Menstruating women may require additional iron. Some patients also require vitamin B12 supplementation. Women in the child-bearing years are strongly urged not to become pregnant until their weight stabilizes, usually a period of 18-24 months after the bariatric surgery. If pregnancy ensues during this period, the mothers should be treated as high risk with special attention to meeting nutritional needs. Unfortunately, some patients refuse to comply even with these simple requirements with disastrous results, including full-blown cases of kwashiorkor, beri beri, pellagra, pernicious anemia, and Wernicke-Korsakoff neuropathies. Other long-term complications include bowel obstruction due to internal hernias or adhesions, functional problems with the band or reservoir, arrhythmias, and pulmonary emboli.

Patient Selection

According to the National Institutes of Health, the American Society of Bariatric Surgery, and the Centers for Medicare and Medicaid Services, patients should be offered bariatric surgery if they meet the following indications:

1. Have a BMI greater than or equal to 35 with significant co-morbidities, such as diabetes, hypertension, severe arthritis, cardiac failure.
2. Have a BMI greater than or equal to 40.
3. Are 18-65 years of age.
4. Have no unresolved issues regarding alcohol or substance abuse, depression, and/or other emotional problems.
5. Have acceptable surgical risk.
6. Have a full understanding of the procedure with realistic expectations.
7. Agree to life-long follow-up.

Most bariatric surgeons also require a strong family support system. Strong disagreement from a spouse or relative should be resolved prior to undertaking this elective surgery.

Insurance Coverage

Even though bariatric surgery is the only effective therapy for morbid obesity, many carriers still refuse to cover the procedures. We are fortunate in North Carolina that Blue Cross Blue Shield, Medicare, and Medicaid provide reimbursement if the operations are performed at Centers of Excellence certified by the ASBS or the American College of Surgeons. Other carriers are also becoming more responsive through pressure from employers and the realization that they can incur significant savings in reduced healthcare costs following bariatric surgery.

A Final Word

Bariatric surgery is a major medical advance. Finally, severe obesity, diabetes, hypertension, crippling arthritis, stress incontinence, sleep apnea, and pseudotumor cerebri are no longer hopeless conditions. With operations that last less than two hours and with hospital stays of two-to-four days, patients can regain a level of health and function previously thought impossible.

Even so, patients who have undergone bariatric surgery, although significantly healthier, cannot be considered "normal" without potential problems. Long-term follow-up for malnutrition, especially the thiamine, niacin, B12, calcium, and iron is essential. Rarely, patients may also develop internal hernias, bouts of hypoglycemia, and other metabolic problems. In such cases, patients are encouraged to call a bariatric surgeon or someone familiar with these complex patients. **NCMedJ**

Addressing Disparities in the Obesity Epidemic

Alice Ammerman, DrPH, RD; May May Leung, MS, RD and David Cavallo, BA

Disparities In Overweight and Obesity Rates

As with so many health problems in the United States today, individuals who have been the most marginalized by society and can least afford the consequences of poor health are often the most likely to be overweight or obese. Currently in the United States, with over 65% of the population affected, it is the norm to be overweight or obese.[1] Among some ethnic groups, this proportion rises to three quarters, with approximately 76% of Black and Mexican-American adults overweight or obese.[2] Disparities exist among youth as well, with 37% of Mexican-American and 35% of Black youth already overweight or at risk, compared to 33.5% of Caucasians.[2] Obesity rates are also rising in the young American Indian population, with an estimated obesity prevalence of 22% for boys and 18% for girls.[3]

Disparities In Lifestyle Behavior and the Environment

Racial, ethnic, and income disparities are not limited to body weight. Low income and minority groups are more likely to be physically inactive, consume a less healthy diet, live in neighborhoods with limited healthier food options or exercise opportunities, and work in jobs that provide limited support for healthier lifestyle behaviors.[4,5] Minority adolescents engage in consistently higher levels of sedentary activities, such as television viewing and playing of video/computer games.[6]

Food Access and Availability

In contrast to more affluent communities, those with a greater proportion of ethnic minority residents often have about 30% fewer supermarkets and grocery stores that carry high quality, fresh fruits and vegetables and affordable healthy foods such as whole grains, low-fat dairy, and meats.[7,8] Given limited access to supermarkets, families living in these communities are more likely to purchase food from local corner stores or bodegas where the price of fruits and vegetables is generally higher and the quality lower than in standard supermarkets.[9] At the same time, fast food restaurants tend to be highly accessible in low-income and minority neighborhoods.[5] Among African Americans in North Carolina, higher fast food consumption has been associated with obesity, higher saturated fat intake, lower consumption of fruits and vegetables, and low self confidence in healthy meal preparation.[10]

The Built Environment

Access to parks, gyms, and other opportunities for exercise has been shown to correlate with higher levels of physical activity.[11,12] Affordability as well as distance and transportation availability are factors that effect access and may put lower income individuals at a disadvantage in terms of opportunities to be active.[13,14] Heavy traffic, inadequate street lighting, unleashed dogs, and high crime rates are other factors in the built environment that may decrease physical activity for both adults and children.[15-18] Again, many of these factors are more likely to be a problem in lower income neighborhoods.

Societal vs. Personal Responsibility and Adverse Psychosocial Impact of Obesity

Despite the many environmental obstacles to good nutrition and adequate physical activity, low income and minority individuals living in these environments are often blamed for making poor personal dietary choices and favoring sedentary behaviors. In fact, the debate rages about whether the obesity epidemic will be most effectively addressed through personal responsibility for nutrition and physical activity behaviors or through community-level change. While most would argue the answer lies in a combination of the two, there is increasing interest in environmental and policy level change as an approach that has potential to combat ethnic and income disparities related to access to healthy food and opportunities for physical activity. While not

sufficient to reverse the rates of obesity, the easy availability of healthy, affordable food, and safe opportunities for exercise would make it easier for individuals who face many life challenges to make better choices regarding lifestyle behaviors.

Once overweight, children may be less likely to participate in sports or recreational activities and frequently experience problems with peer acceptance in school.[19-21] With obesity, the risk of experiencing psychosocial problems such as depression, poor self-esteem, and poor quality of life are also present, especially in a society that stigmatizes obesity.[22,23] These factors can serve to further marginalize the poor and persons of color, thereby helping to perpetuate the obesity cycle. Interventions to address obesity in minority and low-income communities must carefully avoid adding or exacerbating the stigma of obesity given an already long list of negative characterizations of these individuals and their communities. Kumanyika has stated this well, “Raising awareness and concern about obesity may render people in communities of color less satisfied with themselves and less able to cope with one more thing for which we cannot yet offer a good solution. This is a reason for serious reflection as we go forward.”[24]

> *“...the debate rages about whether the obesity epidemic will be most effectively addressed through personal responsibility for nutrition and physical activity behaviors or through community-level change.”*

Cultural norms may serve to both buffer the adverse psychological impacts of obesity and perpetuate the health-related problems. There appears to be greater aesthetic tolerance among some minority groups for body types that are heavier than what is portrayed by the popular media as most fashionable.[25] The positive side of this is that women, in particular, are not held to an unrealistic and nearly unachievable standard that can create lifelong internal conflict between the pleasures and comfort of food and the desire to achieve a body image deemed flattering. On the other hand, the relative absence of such pressures may “give permission” to maintain a weight that contributes to long-term chronic disease and poor health outcomes.

There is substantial evidence of an association between poverty and obesity.[26-28] It is a source of confusion to many, however, that someone of limited means could be overweight and simultaneously food insecure, or hungry.[29] This apparent paradox may stem from historical evidence that those who could afford adequate food were generally the wealthy and the more “portly.” Harder to grasp is the current situation with the relatively low cost of high calorie, low nutrient dense food, such as foods containing high fructose corn syrup sweeteners and many forms of hydrogenated fats used in processed foods, compared to the high cost of whole grains, fruits and vegetables, and lean meats.[28] This leads to a form of malnutrition where overall the diet is “calorie dense,” as opposed to what is recommended by nutritionists as “nutrient dense,” referring to a higher ratio of vitamins and minerals to calories. A southern staple, collard greens, for example, are “nutrient dense”, particularly when seasoned *without* fatback, as they are packed with nutrients, but have few calories.

The Southern Diet and Agricultural Tradition

The often-maligned southern diet may be more associated with region and income than ethnicity. Though often referred to as “soul food,” the traditions of fried chicken, corn bread, pinto beans, and greens are often shared across lower income whites, blacks, and even acculturated American Indians in North Carolina and the southeastern United States. Latino immigrants bring new healthier food options such as salsa, while sharing or adopting some of the less favorable southern dietary practices such as seasoning with meat fat and consumption of fast food. While often high in animal fat, the traditional southern diet has many health-promoting elements, including garden vegetables, pinto and other dried peas and beans (an excellent high fiber, lower fat protein source), and buttermilk (a low-fat cultured milk product that remains after the butter has been removed). Despite the tradition of large family meals and tables overflowing with a wide variety of food, southerners, like many others, are substituting convenience, take out, and fast food for home cooked meals. As a result, families prepare and eat fewer meals together. Some studies have shown that the children of families who eat home-prepared meals together are less likely to face problems with obesity and may experience other benefits such as enhanced school performance.[30,31] Rather than always finding fault with the traditional diet, southerners would be better served by slight refinements (e.g., seasoning collards and pinto beans with onions and garlic, instead of fat back) rather than abandoning it for processed and packaged foods consumed away from home and on the run.

Considering the calorie expenditure side of the obesity equation, North Carolina has traditionally been an agricultural state. In addition to the potential benefit of providing homegrown produce, an agricultural lifestyle involves hard physical labor. With the advent of more mechanized farming and agribusiness, and with fewer individuals tending their own crops or livestock, agricultural jobs can no longer be seen as a significant source of physical activity for North Carolinians. In fact, many rural North Carolinians spend significant time commuting to more urban areas for work but continue to live in communities with very limited access to opportunities for physical activity. Even walking for exercise is difficult with few parks and no sidewalks along high speed rural roads.

Overcoming Disparities with Community-based Approaches

Not only are low-income and minority individuals more likely to suffer from the causes and consequences of obesity, interventions and policies designed to curb the obesity epidemic may differentially benefit those who suffer least from the problem. Individual-level interventions often require payment for health counseling, purchase of specialty foods, and access to exercise equipment or facilities. Blue collar worksites are less likely to have flexible scheduling or exercise equipment to facilitate increased physical activity while on the job. Similarly, vending machines and snack bars are probably more common than cafeterias with healthy food options.

Thus far, local policies and environmental change have primarily benefited those living in newer or wealthier communities. For example, ordinances requiring sidewalks are applied to new developments, and new parks, walking trails, and bike lanes are often added in more suburban communities. Likewise, environmental changes such as walking and biking trails are more likely to be effective when located in communities where personal safety concerns are limited.

Population or community-level policy and environmental interventions take a more "upstream" approach and consider multiple factors, such as politics, economics, socio-cultural factors, and the built environment. Ethnically-inclusive interventions that have been shown effective often prioritize coalition building and extensive community input in the early phases of development and implementation. This approach increases buy-in and focuses on the mobilization of social networks, use of local resources such as lay health advisors and community health workers, and tailoring of culturally-specific messages.[32-34] Some research suggests that minority populations and communities with strong histories of interdependence for survival purposes may respond better to interventions that build on social support and community norms rather than a focus on individual education and behavior change.[32]

Future Research Directions and Public Health Priorities

Careful thought is needed regarding research priorities to address health disparities and the obesity epidemic. While not addressing all ethnic groups, AACORN (the African American Collaborative Obesity Research Network) was formed to "stimulate and support greater participation in framing and implementing the obesity research agenda by investigators who have both social and cultural grounding in African-American life experiences and obesity-related scientific expertise."[35] This group has proposed a number of research priorities that have broad potential to address health disparities and obesity. Their suggestions range from determining the extent to which lifestyle behaviors associated with obesity are influenced by ethnically-targeted marketing, to understanding more about differential health effects of obesity across ethnic and racial groups.[35] Also important to consider in framing a research agenda is the history of exploitation and resulting distrust of the research and medical communities.[32] In order to successfully address the obesity epidemic, researchers and practitioners must continue to challenge themselves to think broadly and deeply about the causes and consequences of access, behavioral, environmental, policy, and health outcome disparities among low-income and minority populations. **NCMedJ**

Empowering Consumers and Employees to Lead Active, Healthy Lifestyles

Steven S Reinemund

Few health issues facing America today generate the same galvanizing concern as obesity. In the course of the last few years, those who work in, and around, the business of healthcare have begun to share an understanding of both the scope of the problem, and the sense of urgency needed to address it.

But the consequences of obesity have moved well beyond the healthcare industry. Whether as a consumer, an employer, a healthcare provider, insurer or policy maker, this critical health issue is shaping everything from how we eat to how we move. And food and beverage companies, in particular, understand their responsibilities for finding solutions. In short, obesity has become everyone's business.

Understandably, everyone wants quick solutions that work. Where America struggles today is in finding effective answers for a complex problem that has been in the making for decades. Not surprisingly, even a daily scan of news media shows there are as many opinions on how to address obesity as there are people and industries to sponsor them.

For PepsiCo, the solution starts with a fundamental belief in energy balance—the balance between calories consumed and calories expended through activity. It's a simple idea in concept, but how it works is as unique to an individual as a set of fingerprints. From the kinds of foods consumers eat to the kind of incentives that can motivate physical activity, the solution ultimately is specific to each of us.

That's why—while there are many different public policy solutions being proposed and implemented—we believe the solutions that will work best are those that meet consumers where they are, providing them with the information, the tools, and the motivation to change.

There are things companies like PepsiCo can do to make sure our marketing practices help consumers clearly understand the choices they're making. For example, PepsiCo launched its Smart Spot symbol in 2004, the first-of-its-kind designation that makes it easier for consumers to identify PepsiCo products that can contribute to healthier lifestyles.

But in addition to making it easier to find these choices, what consumers really need is a wider range of healthier foods and beverages they really want to eat and drink. And they need those foods and beverages to be marketed in a way that encourages and motivates them to adopt a healthier lifestyle. That's something we definitely know how to do as a company.

With brands like Tropicana, Quaker, Gatorade, Aquafina and Frito-Lay's Baked! products, we're continually expanding our portfolio to offer more foods and beverages that can play a role in healthier lifestyles. And to be transparent, it's not only the right thing to do for consumers; it's the right thing to do for our business.

> *"...we believe the solutions that will work best are those that meet consumers where they are, providing them with the information, the tools, and the motivation to change."*

In fact, in 2005, our Smart Spot-eligible product revenues grew more than two-and-one-half times faster than the rest of our portfolio, and we're seeing the same growth trends this year. So in essence, PepsiCo's efforts to find solutions are about putting our resources squarely at the intersection of business and public interests.

That includes taking some big steps to improve the healthfulness of our existing products. In 2004, PepsiCo's Frito-Lay

Steven S Reinemund, is Chairman and CEO, PepsiCo, Inc. He can be reached at steve.reinemund@pepsi.com or 700 Anderson Hill Road, Purchase, NY 10577. Telephone: 914-253-2000.

business was the first food company and the largest-to-date to eliminate trans fats from its products. This action equates to removing 55 million pounds of trans fats from the American diet. In 2006, Frito-Lay made the move to reduce saturated fats in Lay's and Ruffles potato chips by more than 50 percent by switching to NuSun sunflower oil, a heart healthy oil. By converting to NuSun sunflower oil, nearly 60 million pounds of saturated fats are removed annually from the American diet.

We've also partnered with the U.S. beverage industry and government and health officials to find solutions. In partnership with a respected health advocacy organization formed by the American Heart Association, the William J. Clinton Foundation, and Arkansas Goveror Mike Huckabee, PepsiCo and other industry members developed a school vending policy in May 2006 aimed at providing lower-calorie and/or nutritious beverages and limiting the availability of soft drinks in schools. Moving forward, we are equally committed to continue working with industry, government, and health officials on snack and food choices in the nation's schools—important work that is taking place in the coming months.

But there's more work to be done in, and for, our schools. To help educate kids about energy balance, PepsiCo and America On The Move—a national on-line program dedicated to helping individuals, families and communities make positive changes to health and quality of life—developed a lesson plan called Balance First. This program already reached three million elementary students in 2004. In 2005, we continued to distribute the lesson plans to elementary schools. And in partnership with Discovery Education, we've distributed the Balance First program to 15,000 middle schools in the United States—virtually every middle school in the nation.

We're also passionate about motivating our own employees to adopt healthier lifestyles. We have to be. Healthy employees are a priority for us—our company's success depends on the day-to-day well-being of our people.

PepsiCo is a very "people-intensive" and people-dependent business. In North America, for example, the majority of our products are manufactured, sold, delivered, and merchandised on store shelves for our retail partners entirely by our own employees. Together, our team produces and delivers more than 500 different products to over 435,000 outlets of every description—supermarkets, mass merchandisers and club stores, gas stations, convenience and drug stores, restaurants and hotels and other food service accounts, and so on. In the United States alone that requires dawn-to-dusk efforts from 27,000 manufacturing and distribution employees and 22,000 salespeople. They all work together effectively as one incredible business machine.

Keeping those people on the job and in good health isn't a nice-to-do—it's a must-do, and we've been at it for many years. In fact, PepsiCo had one of the nation's first on-site health facilities in the 1960s, and continues to pioneer health benefits decades later that promote healthcare choice for our employees.

Those programs certainly help us manage healthcare costs and provide great tools for employees. But to address today's health needs for our people, we knew we needed to take a quantum leap. Like many employers, we recognized an increasing opportunity to invest in keeping our associates well. So, in 2004, we launched HealthRoads, an innovative health program for PepsiCo employees that's focused on taking action and changing behavior.

Essentially, HealthRoads is a highly accessible, simple, confidential, and personalized health program using an interactive web tool. It's based on the idea of customizing information and programs to each PepsiCo associate, starting with the voluntary and confidential completion of a Health Risk Assessment to identify individual needs.

Every quarter we launch new fitness or nutrition programs to generate added excitement. We have experts who reach out to employees with specific health risks and engage them in developing healthier habits. We provide tools that are integrated with our benefits to help employees make good purchasing decisions. And all of the HealthRoads programs include incentives to provide that little extra boost that many participants need.

Clearly, there isn't a one-size-fits-all solution, nor is there a single initiative that will solve the issue of obesity. If anything, there is more evidence than ever that the only way to make a real difference is by pulling many different levers, tapping the expertise of many partners, and working both sides of the energy balance equation.

There has never been a bigger need, more attention and more consumer knowledge coming together around obesity than there is today. The real opportunity is harnessing our collective resources, and showing consumers the way to healthier habits. We can do that with simple and consistent messages, with products and programs that make improving lifestyles easier, and with marketing that motivates consumers to take charge of their health by capturing their imaginations. **NCMedJ**

Obesity in (Corporate) America:
Large Employer Concerns and Strategies of Response

LuAnn Heinen, MPP

The epidemic of obesity in America has been likened to "a massive tsunami heading towards the shoreline".[1] Employers understand very well that they and their employees finance healthcare in the United States, either directly through the purchase of employer-sponsored healthcare or indirectly as corporate and individual taxpayers for publicly provided care. If the obesity tsunami strikes with the gale force predicted, employers will see financial and human capital effects even greater than those they now face. An expected proliferation of new treatment options will further challenge cost and quality management efforts.

A Familiar Problem

Compared to five years ago, employees are paying 64% more in healthcare costs today and employers are paying 78% more.[2] As health costs dramatically outpace economic growth, both private and public resources are reallocated to cover this burgeoning expense. The high cost of healthcare limits job growth and wage increases, leads to higher numbers of uninsured Americans, and diverts resources from other social needs, such as education, which, along with healthcare, is critical to ensuring a competitive workforce in years to come.

Employers, as purchasers of healthcare, try to (1) stem the growth in spending on healthcare and (2) ensure they are paying for quality. It is a terrible truth that while United States healthcare expenditures are out of control, we are still not receiving care commensurate with established quality standards more than about half the time.[3] Of the multitude of strategies deployed by employers over the years for dealing with these quality of care issues, some of the more enduring include: disease management and health improvement programs, employee cost-sharing and plan design changes to limit or restrict coverage, information and incentives for employees to manage their own health, and strong support for the National Committee for Quality Assurance's HEDIS (Health Plan Employer Data and Information Set) performance measures and other quality purchasing initiatives. Newer pay-for-performance incentives also appear promising.[4]

Current Game Plan: Health Improvement

Increasingly large self-insured employers, especially those with high employee retention, see their challenge as *population health management*. The argument that trends in health spending can be managed by improving employee (and dependent) health status appears to hold. Employers therefore are focused on reducing the number of health risks (e.g., high blood pressure, unhealthy weight gain, high cholesterol, sedentary lifestyle, poor diet, high stress, etc.) across their population in an effort to flatten the cost trend. Such health improvement/risk reduction efforts often co-exist with "disease management" programs targeting individuals with diabetes, back pain, heart disease, etc.

> *"The bigger the bite healthcare takes out of corporate profits, the higher healthcare falls on the CEO and CFO priority list."*

Employers work with health plans, consultants, and vendors to develop and execute their own population health strategy. Typically an analysis of medical claims data and health risk appraisal (HRA) biometric information sets the stage. Sometimes employees are surveyed to determine their priorities. Specific programs are purchased from health plans or other companies to address priority areas; program cost and intensity are tied to an expected financial return. Financial incentives for employees/dependents are commonly used to encourage participation.

LuAnn Heinen, MPP, is Director of the Institute on the Costs and Health Effects of Obesity, National Business Group on Health, Washington, DC. She can be reached at heinen@businessgrouphealth.org. Telephone: 952-842-6524.

Evidence that this may be working comes from published literature on return-on-investment from well designed health promotion programs.[5] In addition, employee benefits consultants have shown that companies identified as "best performers" (i.e., experiencing the lowest medical cost trend) are disproportionately found to be early adopters of aggressive health improvement programs.[6]

Ultimately, however, these efforts to improve population health may be swamped by the increasing numbers of obese individuals and the corresponding, exponentially increasing, healthcare costs. Unless employers can "turn the tide," costs are more likely to escalate than flatten.

Senior Leadership Response

The bigger the bite healthcare takes out of corporate profits, the higher healthcare falls on the CEO and CFO priority list. The magnitude of expense affects global competitiveness (for example, think of the $1,500 added to the price of every GM car to cover healthcare). It also can directly impact earnings per share (EPS), as in the Fortune 500 company whose CEO reported a drop of $0.19 in EPS due to an overage in healthcare expenses (i.e., the amount actual expenses exceeded the healthcare budget in a year).

More and more companies, with top leadership support, are intensifying their efforts to:

- Define a strategy based on company data and consistent with corporate culture to improve employee health, establishing appropriate goals and measures.
- Communicate with employees and dependents about why healthy weight and healthy lifestyle improvements are a win-win opportunity, using corporate branding and messages tied to business goals.
- Provide tools and incentives to help employees and dependents understand their own health risk profile and start to improve their personal health risks.
- Create a supportive work environment, including healthy on-site dining, vending and catering for employees as well as opportunities for physical activity at work and on the employee's own time.
- Develop a benefit plan that, consistent with company resources, reflects the importance of a non-sedentary, non-smoking, healthy-weight workforce.

Companies who are engaged in these activities may apply for the National Business Group on Health's *Best Employers for Healthy Lifestyles* awards. Platinum, Gold and Silver award levels recognize large employers who have implemented robust health and wellness programs at the worksite; 57 awards have been made in the first two years of the program. Examples of Platinum winners include: Aetna, Florida Power & Light, IBM, Johnson and Johnson, Pitney Bowes, and Union Pacific Railroad.

Overweight and Obesity Compound the Problem

It is well documented that overweight and obesity are important drivers of healthcare costs both today *and* tomorrow. Physicians provide (and employers finance) care for more cases of diabetes, hip, knee and back problems, cancer, heart disease, high-risk pregnancy and many other conditions due to the prevalence of obesity, especially severe obesity, and its complications. One study attributed 27% of private insurance spending increases between 1987 and 2001 to obesity.[7]

In addition, obesity itself is beginning to be treated as a disease with drugs, surgery, and behavior therapy in various combinations. We have seen only the tip of the proverbial iceberg to date. *Treated prevalence* is growing rapidly, and along with this growth in treated prevalence, significant cost increases are expected (similar to the increase in costs for treated hyperlipidemia when widespread use of cholesterol-lowering medications became the standard of care). Although per case costs are high, it is the treated prevalence that drives the total cost, according to Thorpe's work in the privately insured market.[8]

For example, a large employer (35,000 employees) in the northeast discovered that 85% of its employees are overweight or obese, with only 15% currently at a healthy weight. It is not a stretch to assume that half of the 85% (14,875 employees) might qualify for a new weight loss drug expected to receive FDA approval in late 2006. Imagine the economic impact of putting even 14,875 employees on a new prescription drug at an estimated $1,800 per person—nearly *$27,000,000 per year*, for a drug that is prescribed indefinitely.

The provider community views the epidemic of obesity as a tremendous opportunity; from this perspective, the "unmet need" is pressing. Because fewer than five percent of obese Americans are now receiving surgery, drugs and/or behavioral therapy for obesity, the remaining 95% of the obese patient population—some 58 million people—can be seen to represent "unmet need." If even a fraction of those millions begin receiving obesity care, the costs can be staggering, given the high cost of treatment per patient (for new drugs in the pipeline, surgeries such as the lap band and gastric bypass, and others still in development) and, especially, the vast number of potentially eligible patients.

Arguments will be made that obesity surgery cures diabetes, and that the return on investment is such that the treatments achieve breakeven in a few years' time. It's likely that some treatments will prove cost-effective for *some* patients, but in many cases coverage is requested without standardized treatments or patient selection protocols.

The Challenge

Increasingly, employers recognize that *everyone* needs weight management. Those (often younger) employees with healthy BMI levels (<25) need to be encouraged and supported to maintain their health. Those in the overweight-to-obese category (BMI 25-35) are candidates for various types of weight loss programs (group support, individual coaching, medically supervised, etc.). And those in the over-35 BMI category need individualized plans and are, potentially, candidates for surgical treatment.

Historically very little insurance coverage has been provided until patients reach a BMI of 35 or greater and present with co-morbidities. Today, however, employers are asked to cover everything from Weight Watchers at Work to gastric bypass surgery with subsequent excess skin removal. Given the importance of weight management at lower and moderate BMI levels, as well as in the pediatric population, employers are reevaluating their benefit plans and coverage policies.

Evidence-based benefit design is the goal, and offers the best answer to the question: Which obesity treatments should be covered? Even partial coverage would help assure quality standards and allow employees to benefit from network pricing in every category (outpatient pharmaceuticals, behavioral therapy/lifestyle management, bariatric surgery). But how can the already-burdened employer-sponsored health plan take on a new category of expense that, given the prevalence of the problem, is likely to increase medical spending so significantly? In any case, employees will need to brace for even more cost-sharing and the likelihood of much higher cost-sharing, or no coverage, for high-cost services related to health problems associated with individual lifestyle choices. **NCMedJ**

Why Does the Private Sector Underinvest in Obesity Prevention and Treatment?

Eric A. Finkelstein, PhD and Derek S. Brown, PhD

Introduction

Over the past several decades there has been a rapid rise in the prevalence of obesity. Currently, 65% of adults are either overweight or obese, an increase from 46% in 1976-1980 and 56% in 1988-1994.[1] These increases in obesity rates have spurred corresponding growth in the prevalence of several diseases, including type 2 diabetes, cardiovascular disease, hypertension, osteoarthritis, several types of cancer, gallbladder disease, and sleep apnea.[2]

As a result of the increase in obesity and related diseases, medical expenditures attributable to obesity have also ballooned. We have estimated that complications from obesity now cost the United States medical system over $93 billion per year.[3] Costs in North Carolina alone exceed $2 billion annually.[4] In addition to medical expenditures, obesity results in greater absenteeism and reduced worker productivity. For example, female employees with a BMI over 40 miss roughly one week more per year on average than female employees of normal weight.[5] Including both medical expenditures and increased absenteeism, the costs of obesity at a firm with 1,000 employees are estimated to be $277,000 per year.

The dramatic increase in prevalence and costs of obesity has captured unprecedented attention by the media. According to the North American Association for the Study of Obesity (NAASO), the number of obesity-related articles appearing in United States newspapers and newswires has more than tripled in the last five years, from approximately 8,000 articles in 1999 to almost 30,000 articles in 2004. National, state, and local governments have also increased efforts to inform the public about the consequences of obesity and strategies for obtaining a healthy weight (e.g., the *Healthy Lifestyles and Disease Prevention Initiative*, a part of the U.S. Department of Health and Human Services' *Small Steps* program). Despite the attention of policymakers and the media, most employers and insurers have taken little action to fight obesity.

Why have insurers and employers been reluctant to aggressively pursue obesity treatment and prevention strategies? One answer—which is not without merit—is that few proven long-term weight loss and weight maintenance interventions exist. However, even as these strategies are developed and refined, our research suggests that employers may be reluctant to adopt them. In this commentary, we provide an economic perspective on the behavior of employers and insurers in fighting obesity and highlight three key points that reveal why obesity prevention and treatment efforts are likely to be underprovided by the private sector.

> *"Employment-based health insurance, combined with the transient nature of the United States workforce, further reduces the incentives to invest in obesity treatment, even among firms who may have a high prevalence of obesity in their employed/enrolled populations."*

The three primary factors behind the private sector's under-provision of obesity treatment and prevention are the chronic

Eric A. Finkelstein, PhD, RTI International and RTI-UNC Center of Excellence in Health Promotion Economics. He can be reached at finkelse@rti.org or 3040 Cornwallis Road, Research Triangle Park, NC 27709-2194. Telephone: 919-541-8074.

Derek S. Brown, PhD, RTI International and RTI-UNC Center of Excellence in Health Promotion Economics.

nature of obesity-related diseases that tend to accrue later in life, the fragmented nature of healthcare financing in the United States, and the high rate of job mobility of employees. The implications of these factors can be discerned from the following figure, which shows the increase in costs attributable to obesity for each age between 18 and 75, based on data from the nationally representative 2001-2003 Medical Expenditure Panel Survey (MEPS):

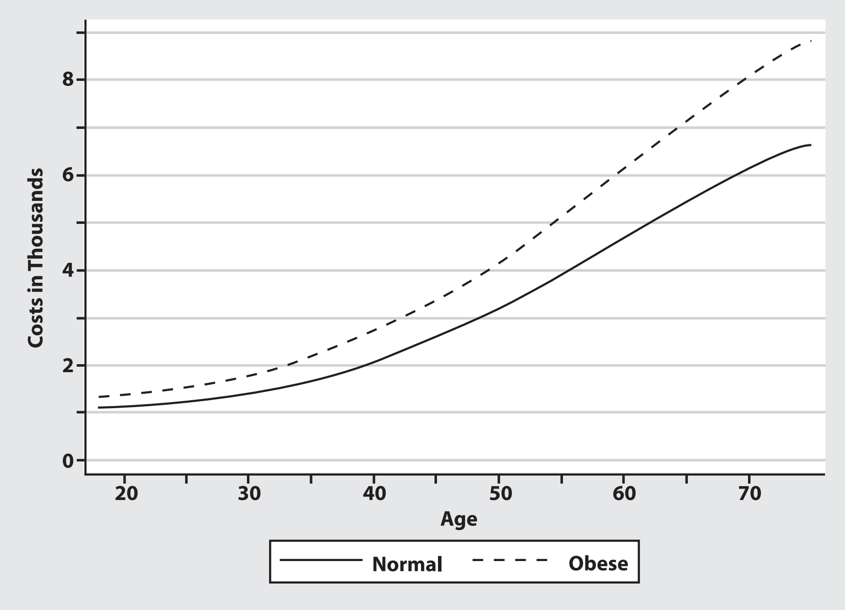
1 **Firms have little financial incentive to invest in obesity treatment for younger obese individuals who have not yet developed costly complications.** Although the prevalence of obesity is growing rapidly among youth and young adults, the date in Figure 1 show that the medical costs of a young obese individual are similar to those of a normal weight individual of the same age. The risk of type 2 diabetes and other obesity-related diseases is greater among overweight youth and young adults, but the MEPS data reveal that these conditions are relatively rare among this group. In fact, the annual medical costs for an obese individual do not become statistically greater than the costs for someone of normal weight until they reach their early to mid 30s. Because overweight and obesity is not especially costly among younger populations, firms have little financial incentives to invest in obesity prevention and treatment for them.

2 **Employment-based health insurance, combined with the transient nature of the United States workforce, further reduces the incentives to invest in obesity treatment, even among firms who may have a high prevalence of obesity in their employed/enrolled populations.** One may argue that focusing solely on current costs of obesity is short-sighted. In practice, however, firms rarely look to benefits beyond five years when considering investments in employee wellness. Individuals in today's economy tend to switch jobs roughly every four to five years.[6,7] Employers also switch insurance carriers intermittently; most employees will not remain with the same employer or insurer for more than a few years. As a result, a firm that pays most of the initial costs of obesity treatment will not garner the long-term benefits of improved health, including reduced medical expenditures and increased productivity—a future firm will instead. As a result, the incentive for firms to invest in obesity prevention and treatment is diminished, leading to reduced offering of such benefits.

3 **The existence of the Medicare program further reduces private sector incentives to invest in obesity treatment.** Even organizations that are able to keep their populations enrolled for long periods of time, such as public sector employees, are unlikely to adequately invest in obesity prevention and treatment because of the existence of the Medicare program, which assumes responsibility for primary health insurance coverage for most Americans once they reach age 65. The chronic nature of obesity-attributable diseases implies that a significant percentage of the costs of obesity occur after age 65. In fact, the figure reveals that of the roughly $58,000 cost of obesity incurred between the ages of 18 and 75, 38% accrued after age 65.

As retiree health insurance benefits become increasingly rare, firms are less likely to take the costs of obesity after age 65 into account when determining the optimal amount to invest in obesity treatment. For example, suppose a medical treatment was available for a one-time cost of $40,000 that guaranteed that an obese individual would have the same medical cost profile as someone of normal weight for their entire life (assumed to be to age 75). Assuming a 0% discount rate (money today has the same value as money in the future), a firm that considers an individual's entire cost profile would invest in this technology for its captive obese population. However, if firms only consider the time period up to age 65, the cost of the treatment technology is greater than the $36,000 in savings (62% of $58,000) that would accrue to the firm, and therefore firms are unlikely to make this investment.

Figure 1.
Annual Medical Expenditures for Normal Weight and Obese Employees in the 2001-2003 Medical Expenditure Panel Survey



Discussion

In summary, the chronic nature of obesity-related diseases, employment-based health insurance, the high rate of job mobility of today's workforce, and the existence of the Medicare trust fund reduce the incentives of the private sector to invest in obesity prevention and treatment. For these same reasons, there is also likely to be an underinvestment of research into effective employer-based obesity intervention strategies because of concerns that the private sector might be unlikely to finance them even if proven effective.

It should be noted that while these factors reveal that firms are likely to underinvest in obesity prevention and treatment, the increasingly high prevalence and costs of obesity suggest that the profit maximizing level of obesity prevention and treatment is positive and growing. As noted earlier in this edition, Blue Cross Blue Shield of North Carolina (BCBSNC) has committed a substantial amount of resources toward obesity treatment and is optimistic that their investment will pay off in terms of improved health and reduced costs. Given the high prevalence of obesity in their enrolled population and the fact that tenure in their plan is relatively long compared to the rest of the industry, it makes economic sense that they are one of the few private sector insurance plans to offer expanded benefits for obesity prevention and treatment. In fact, they remain one of a shrinking number of health plans that provide coverage for gastric bypass surgery, a high cost procedure that many employers/insurers have opted not to cover. Other firms will look to BCBSNC for feedback concerning the costs, cost-effectiveness, and budgetary implications of their coverage decisions. If they are able to show that their investments result in improved health and reductions in future—but not too distant—expenditures, other insurers are likely to follow their path.

Given the issues presented above and the increasing national prevalence of obesity, BCBSNC and other insurers should also pursue development and marketing of innovative health plans that are structured to keep individuals enrolled in the plan for long periods of time so the investment in prevention and treatment can be recouped by the plan. Although not directly addressed above, firms might also consider incorporating financial incentives for individuals to make personal investments aimed at maintaining their health. For example, a few firms offer premium discounts or rewards to employees who maintain or move towards a healthy BMI or who meet other health criteria.[8] These reductions in premiums may be worth the investment to an employer/insurer that can keep their captive population healthy and enrolled in the plan long enough to recoup the investment.

Given the abundance of affordable high calorie foods, the sedentary nature of modern lifestyles and most occupations, and the reliance on technology to accomplish everyday tasks, a majority of Americans find it increasingly difficult to maintain a healthy weight. Employers and insurers have an opportunity to implement strategies to help them maintain and improve health, but in a competitive marketplace, they will do so only to the extent that it serves the best interest of the firm. As a result, halting the obesity epidemic may require a substantial deviation from the current approach of healthcare financing in the United States. **NCMedJ**

The Payer Perspective:
Blue Cross and Blue Shield of North Carolina's Approach to the Obesity Epidemic

Robert T. Harris, MD

The health and cost impacts of overweight and obesity have been well documented over the past several years. Rates of obesity and overweight have increased within the United States at an alarming pace, as have rates of bariatric surgery, type 2 diabetes, and healthcare costs associated with weight-related illnesses. In North Carolina, 23 percent of adults are classified as obese and an additional 36 percent are overweight. The rate of adults who are overweight has doubled over the past 20 years, and the number of overweight teens has tripled during the same time period.[1] Studies have shown that as body mass index (BMI) increases, healthcare expenditures increase with costs being 25 percent higher in people with a BMI of 30 to 35, and 44 percent higher for people with a BMI greater than 35.[2]

> *"In North Carolina, 23 percent of adults are classified as obese and an additional 36 percent are overweight. The rate of adults who are overweight has doubled over the past 20 years, and the number of overweight teens has tripled..."*

Preventive health has long been a focus of Blue Cross and Blue Shield of North Carolina (BCBSNC), and the company is committed to working with members and healthcare providers to combat obesity and excessive weight. In designing our comprehensive approach to this issue, we faced a number of challenges including member lifestyles and perceptions, traditional health plan design, and provider time stresses and reimbursement practices. However, the early results of our comprehensive, evidence-based approach are promising and provide hope that collaborative approaches may make a long-term difference.

Background

Traditionally, health plans have excluded coverage for weight reduction services, except for bariatric surgery when it is deemed medically necessary. Coverage exclusions have included physician assessment, counseling or medical management of weight issues, weight loss medications and weight loss programs. The reluctance to cover services has been attributable to several factors: no clear benefit models; few programs tracking long-term outcomes; frequency of weight gain; and no strong evidence of success with more traditional medical approaches such as case management, physician supervision (without the support of a structured nutrition, physical activity and behavior change program) or drug therapy (without concurrent behavior change).

In a 2003 survey of HMO and PPO members, Blue Cross and Blue Shield of North Carolina found 55 percent of its adult members were overweight or obese. The survey also pointed to startling perception gaps among members—Nearly one-third of overweight members believed their weight was "just right," and many were unaware of the extensively documented health impact of obesity. An analysis of claims data associated with these members found that obese member costs were 32 percent higher than those of normal weight members, and overweight members' costs were 18 percent more. Overweight and obesity accounted for $83.1 million in medical costs in 2003 for BCBSNC.

Robert T. Harris, MD, is Senior Vice President, Health Care Services & Chief Medical Officer, Blue Cross Blue Shield of North Carolina. He can be reached at robert.harris@bcbsnc.com or PO Box 30016, Durham, NC 27702-3016. Telephone: 919-765-4332.

The survey also found that only 57 percent of obese members and 32 percent of overweight members reported being advised by their doctors to lose weight within the past 12 months. At the same time, a report from the United States Preventive Services Task Force[3] found that patients who were advised to lose weight were more than three times as likely to drop pounds as those who didn't discuss weight with their doctors.

BCBSNC had recognized for some time that North Carolinians were struggling with growing waistlines, and over several years had initiated a number of community and member-specific strategies. But with fresh claims and member survey data in hand, BCBSNC clearly identified the need for a more comprehensive and innovative approach to a complex problem. This approach would have the goal of decreasing the prevalence of obesity among the commercial BCBSNC membership through physical activity, healthy eating, weight control and safe and effective treatment.

Effective Solutions

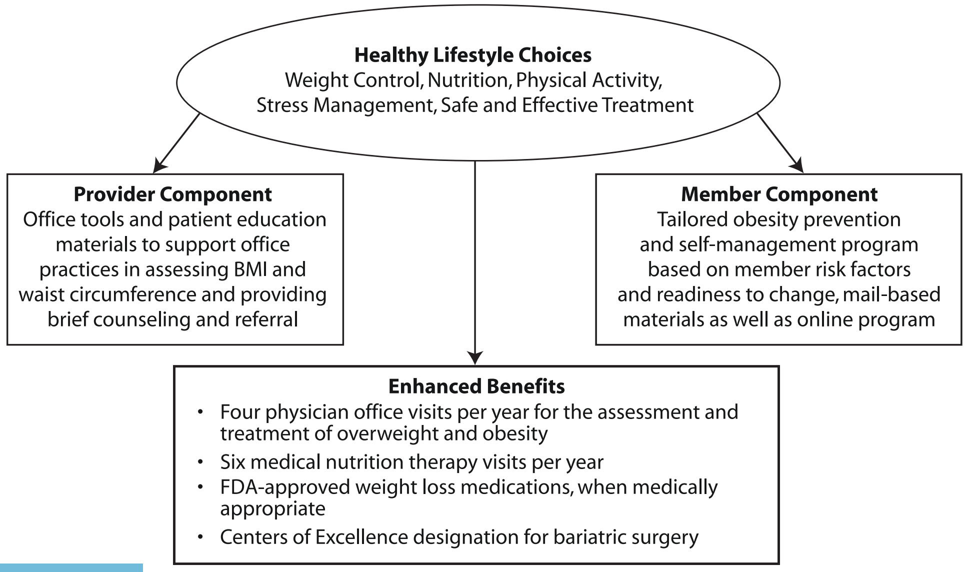
The National Institute of Health's National Heart, Lung and Blood Institute issued an evidence-based report in June 1998, which provided clinical guidelines for identifying, evaluating, and treating overweight and obesity in adults.[4] This report provides a comprehensive literature review of randomized controlled trials, evidence statements, and recommendations for what determines a successful weight loss regimen. The panel concluded that weight loss and weight maintenance therapy should employ a combination of low-calorie diets, increased physical activity, and behavior therapy. Behavior therapies include self-monitoring of eating and physical activity, stress management, stimulus control, problem solving, contingency management, cognitive restructuring, and social support. Additional relevant recommendations include:

- Treatment of an overweight or obese person must incorporate a two-step process—medical assessment followed by treatment. Medical assessment includes determination of the degree of obesity and overall health status. In addition, providers should assess patient motivation to enter weight loss therapy and readiness of the patient to implement the plan.
- The initial goal of weight loss therapy should be to reduce body weight by approximately 10 percent from baseline. Significant health improvements can be achieved with this modest level of weight loss. With success, further weight loss can be attempted, if indicated.
- Weight loss drugs approved by the United States Food and Drug Administration (FDA) may be used as part of a comprehensive weight loss program including diet and physical activity for high-risk patients. Drugs should never be used without concomitant lifestyle modification. Continual assessment of efficacy and safety is necessary and should only be continued if the drug is efficacious.
- Weight loss surgery is an option for carefully selected patients with clinically severe obesity when less invasive methods have failed. Surgical patients should be monitored for complications by multidisciplinary teams.

Blue Cross and Blue Shield of North Carolina's Strategy

In 2004, BCBSNC launched Healthy Lifestyle Choices,^{SM} a comprehensive set of health improvement services developed to prevent and reduce obesity. BCBSNC conducted extensive literature reviews on what is most effective in the prevention and management of obesity and solicited input from national experts, physician advisors and BCBSNC members in the development of the program. In addition, a baseline member survey and formative evaluations provided key guidance in project development. Healthy Lifestyle Choices includes a member self-management program, a physician toolkit to support clinician evaluation of weight and treatment of obesity, and enhanced benefits covering physician assessment, medical nutrition therapy, and FDA-approved weight loss medications for long-term treatment of obesity (when medically appropriate). These new services are standard benefits available to members enrolled in BCBSNC's HMO, PPO and individual products.

Figure 1.
Components of BCBSNC's Healthy Lifestyles Choices^{SM} Program



Physician Component

As part of the Healthy Lifestyle Choices program, BCBSNC developed toolkits to aid physicians in the assessment of weight and the treatment of obesity. Two different toolkits were developed, one specifically addressing assessment and treatment of adult overweight and obesity and the other for pediatric patients and their parents. BCBSNC piloted these toolkits with 200 of the highest volume primary care practices. The toolkits include: BMI wheels for the assessment of body mass index, retractable tape measures for the assessment of waist circumference, patient and parent education tear sheets, NHLBI practical guidelines for assessment and treatment of obesity, pocket cards outlining practical guidelines in a brief stepwise manner, removable patient stickers with reminders for BMI and waist circumference assessment, and "get up and move" posters for pediatric offices.

Enhanced Benefits

As part of Healthy Lifestyle Choices, and to support physicians' appropriate assessment and treatment of obesity, BCBSNC examined and adopted benefit changes. Physicians reported that they needed both the tools and the time for the assessment and treatment of obesity. Reimbursement would allow for dedicated time and appropriate follow-up care. In addition, physicians acknowledged the value of nutrition counseling for members if they needed extra support. BCBSNC worked closely with a Physician Advisory Group to establish a reasonable benefit structure that would encourage assessment and monitoring, while discouraging inappropriate utilization such as "physician weight loss clinics" springing up in offices across the state. New benefits include:

- Coverage for four physician office visits and related testing for the evaluation and treatment of obesity per benefit period.
- Six medical nutrition therapy visits for members enrolled in BCBSNC's Healthy Lifestyle Choices program. Copayments and coinsurance are waived to encourage utilization.
- Coverage of FDA-approved weight loss drugs for the long-term treatment of obesity—coverage requires prior authorization from BCBSNC, and the member must be enrolled in the Healthy Lifestyle Choices program.

The above benefit changes were approved by the North Carolina Department of Insurance and are part of the standard benefit package offered by BCBSNC.

BCBSNC is credentialing licensed, registered dietitians to be included in the BCBSNC provider network. Credentialed dietitians are listed in the online BCBSNC provider directory, which allows both physicians and members to easily locate an in-network dietitian in a particular area of the state.

In addition, BCBSNC announced the establishment of a network of Centers of Excellence (COE) for bariatric surgery in July 2004. Seven facilities, including 12 bariatric surgeons across North Carolina, are included in the network. The COEs are listed in the BCBSNC provider directory, which can be found online at bcbsnc.com.

Self-management program

The Member Health Partnerships^{SM} Healthy Lifestyle Choices program is free to eligible members and provides educational materials and self-help tools. BCBSNC proactively identifies and invites members with specific diagnoses such as hypertension, dyslipidemia and metabolic syndrome (conditions that can significantly benefit from dietary changes, increased physical activity and weight management) into the program. Members can also self-refer. Members do not need to be overweight or obese to join; however, more than 85 percent of program participants both need and want to lose weight. Materials are customized to the member's individual health status and readiness to make lifestyle changes. Members complete a short health assessment survey as part of the enrollment process to determine health risks and needs. As part of the Healthy Lifestyle Choices program, a member receives customized mailings over a six-month period. Materials include a personalized health feedback report (based on survey results), a lifestyle diary, step counter, interactive online tools, condition-specific materials, and a quarterly newsletter.

The Results

BCBSNC was the first major health insurer in the country to make coverage available for doctors to talk specifically to their patients about how weight affects their health. The Healthy Lifestyle Choices program is helping participants achieve a healthier weight and engage in lifestyle changes that can prevent serious health problems. Since its inception, 9,296 BCBSNC members have actively engaged in the Healthy Lifestyle Choices program. Early program results are promising. The following results reflect self-reported, pre-post survey data following the first six months of the program:

- 47% of participants who reported wanting to lose weight lost an average of 9.5 pounds.
- 14% lost 10 pounds or more.
- 46% of participants lost an average of 0.86 inches around their waist.
- 70% of participants in the Hypertension Stage I/Stage II categories moved to a lower hypertension severity category (e.g. Prehypertension or Normal categories).
- 13% of participants in the Prehypertension category lowered their hypertension severity to Normal.
- 46% of participants reported an increase in days of exercise. On average, members increased their days of exercise by 0.64 days.
- 90% of program participants were satisfied or very satisfied with the program.

Future process and outcome measures of the program will include:

- Utilization and costs (pre-post against a similar cohort of non-participants)
- Incidence of type 2 diabetes onset

- Provider assessment of BMI and counseling
- Utilization of various program components
- Program return-on-investment

BCBSNC is currently collaborating with the American Dietetics Association and the Blue Cross and Blue Shield Association to conduct an in-depth analysis of the effectiveness of the medical nutrition therapy component of the program.

BCBSNC gained solid recognition as an industry leader, willing to work collaboratively with doctors and other healthcare professionals for the good of its members to offer an obesity solution. Others have publicly recognized this effort:

> *"The move will probably become a model for other insurers and private companies," said Morgan Downey, executive director of the American Obesity Association, a Washington Advocacy group. "It is very comprehensive and unprecedented…"*
>
> —The Washington Post

> *"Other insurance companies and health plans and employers will be watching this very closely."*
>
> —Helen Darling,
> President, National Business Group on Health

> *"This program represents a direction that a lot more health insurers could pursue. Clearly, BCBSNC is making a serious commitment of resources to support its members in their efforts to manage their weight."*
>
> —William Dietz, M.D.,
> Director of the Centers for Disease Control and Prevention's Division of Nutrition and Physical Activity.

BCBSNC remains committed to working with members and providers over the long term and to refining our approach based upon our results, emerging medical literature, and best practices. Successfully combating obesity and overweight are one of the leading challenges of our entire healthcare system, akin to the anti-tobacco campaigns that began in the last half of the 20th century. Winning this battle is crucial to moderating healthcare costs, sustaining the viability of our healthcare system, and maintaining the economic vitality and quality of life of our state and nation. **NCMedJ**

SPECIAL ARTICLE

The Kate B. Reynolds Smoking Education Lifestyle Fitness Improvement Program:

Preventing and Reducing Chronic Disease in Low-Income North Carolina Communities

Margaret L. Sauer, MS, MHA; John H. Frank, MBA; J. Lloyd Michener, MD; Susan D. Yaggy, MPA and Truls Østbye, MD, PhD

Seven of every ten Americans die from chronic disease. Uncontrolled chronic diseases result in premature disability, diminished functional status, and diminished quality of life. They account for more than 75% of medical care expenditures.[1] The effects of chronic disease can be prevented or controlled by changing three health behaviors: smoking, poor nutrition and physical inactivity.[2]

North Carolina consistently ranks poorly on these behaviors. More 60% of adults in NC are overweight or obese, and the prevalence of obesity and overweight is greater in minority populations. Only 37.6% of NC residents receive the recommended amount of physical activity,[3] and 22.6% of adults smoke.[4]

The Kate B. Reynolds Charitable Trust launched the SELF Improvement Program in 2001, offering to fund community-based organizations and their local partners to reduce and prevent chronic disease in low-income North Carolina residents. The Trust's goals were to change the perception of chronic disease and its complications from inevitable to preventable, develop sustainable collaborative community-based services to increase physical activity, improve nutrition, and curb or eliminate tobacco use. SELF Improvement built on the understanding that health promotion strategies that incorporate multiple interventions based in the community have been more successful than those targeting individuals.[5,6]

The Trust committed $10 million to SELF Improvement and contracted with the Department of Community and Family Medicine, Duke University Medical Center, to administer the program. The Trust and the Duke team established an advisory board to review the requests for proposals and select grantees to be funded. SELF Improvement represented the largest and longest single commitment by the Kate B. Reynolds Charitable Trust in its history.

> *"More than one million North Carolina residents have received information on improving nutrition and physical activity, and on smoking cessation."*

Project Selection

The Request For Proposals (RFP) targeted traditional health organizations as well as non-traditional organizations, such as

Margaret L. Sauer, MS, MHA, is Clinical Associate and Director of Health Promotion/Disease Prevention Programs, Division of Community Health in the Department of Community & Family Medicine, Duke University School of Medicine. She can be reached at sauer004@mc.duke.edu or 2914, Durham, NC 27710. Telephone: 919-681-3086.

John H. Frank, MBA, is Director of the Healthcare Division, Kate B. Reynolds Charitable Trust, 128 Reynolda Village, Winston-Salem, NC 27106-5123. Telephone: 336-723-1456.

J. Lloyd Michener, MD, is Professor & Chair, Department of Community & Family Medicine, Duke University School of Medicine.

Susan D. Yaggy, MPA, is Assistant Professor and Chief of the Division of Community Health in the Department of Community and Family Medicine, Duke University School of Medicine.

Truls Østbye, MD, PhD, is Professor, Department of Community and Family Medicine, Duke University School of Medicine.

United Way and Parks and Recreation Departments. Per the Trust's indenture, projects had to serve low-income North Carolina residents. The RFP requested collaboratively developed, multi-level, community-based interventions to improve nutrition, physical activity, and prevent tobacco use. Applicants were asked to document active involvement of the target population in program planning, willingness to submit data and participate in ongoing program evaluation, commit to attend statewide meetings to review progress, share lessons learned, and engage in mutual problem solving.

Selected Projects

All projects applied community-based models to help low-income, underserved North Carolinians change their lifestyles to prevent and reduce chronic disease. Each project built on the resources and characteristics of its region and culture, and each was unique in its approach to prevention of chronic disease. Each project targeted the community at multiple levels, using a variety of strategies. While not strictly categorized, projects have been organized by primary target audience as described below.

Schools

Illustrative school-based projects have targeted and attempted to change health behaviors in students, teachers, parents, and staff, modified how meals are prepared for children, and altered the tools teachers use to deliver a "standard" curriculum.

- In Dare County, PEER Power, a partnership between the Health Department and the schools, high school students were trained as peer health educators to help other elementary and middle school students learn the importance of physical activity, smoking cessation, and good nutrition.
- In Swain County, the Health Department partnered with schools and the town of Bryson City to improve the nutrition of children as well as other residents. The program replaced fryers with ovens in the school cafeterias and built a community walking trail. Physicians distributed medication without charge to help participants stop smoking.

Community

Community-based projects offered participants a mix of services designed to complement local culture and resources. Key strategies included: shopping and meal preparation on a budget, walking trails, individual nutrition and physical activity advice, and group classes.

- In Wake County, Strengthening the Black Family, Inc., organized activities through community leaders in three Wake communities. Families learned to prepare nutritious food that is culturally appropriate for African-American participants with a limited budget. The program also provided group physical activity and health screenings.
- Triangle E, located in Duffyfield, is a low-income, historically African-American neighborhood in New Bern. Churches convened Action Teams to assist the project, the Craven County Health Department provided health screenings, and the City's Parks and Recreation Department provided nutritional counseling and physical activity. The program was integrated in the long-range strategic plan for the city and officials expanded the program to all city employees.

Healthcare

Healthcare projects shifted the focus from providing care in hospital/clinic-based settings, to neighborhood settings more accessible and better able to meet community members' needs.

** Statewide, focusing on the four highlighted counties

Projects addressed barriers including; transportation, insurance coverage, language, culture, and access to primary care providers.

- In Alamance County, Elon University, Alamance Regional Medical Center, Alamance Community College, Centro La Communidad, International Family Clinic, and Piedmont Health Services collaborated on "SALSA" (**S**alud **L**atina, **S**alud de **A**lamance). Alamance Community College taught English to Latinos using a curriculum to reduce and prevent chronic disease. Exercise training centers were established in churches under the supervision of Elon University's Exercise Physiology Department.

Faith-Based Organizations

Faith-based projects ministered to the whole person (body, mind, and spirit). These projects tailored their strategies to recognize the effect of behavior and lifestyle, social and political conditions, spiritual and emotional states, economics, and environmental conditions on health.

- The Faith and Health Initiative of the General Baptist Convention of North Carolina, headquartered in Durham, is based in four of North Carolina's poorest counties: Granville, Franklin, Vance and Warren. The initiative included 88 churches with more than 19,000 members. This project trained 136 lay leaders to serve as Faith and Health Advocates to motivate and mobilize church members to improve their diet and increase their physical activity. The program provided congregational education and nutritionally appropriate food choices at church events. Many participating churches established walking trails on their grounds.

Implementation and Ongoing Technical Assistance

A critical part of SELF Improvement was the development of partnerships with state agencies to provide additional technical assistance. The North Carolina Department of Public Health offered grantees ongoing support to develop sound nutrition programs, increase participants' physical activity, and decrease smoking. This partnership assured that SELF Improvement would complement not duplicate state-funded efforts.

Grantees developed detailed action plans with community partners to guide their work, delineating project activities, partner roles, costs, and timelines. Grantee partners were involved in the creation and implementation of the plan. These documents became the navigational road maps for the project and required endorsement by the "community," the Duke Management Team, and the Trust.

Data Collection

The Duke Management Team developed a comprehensive database to evaluate and record project activities/outcomes centrally, and to help grantees manage their projects. Questionnaires were developed using questions adapted from the Behavioral Risk Factor Surveillance System (BRFSS) and the Youth Risk Behavior Surveillance System (YRBSS). Program participants completed surveys describing changes in nutrition, physical activity and smoking behavior. Project teams recorded the amount and types of services provided in each community. Grantees submitted information quarterly to the Management Team for review and follow-up as needed.

Technical Assistance

To help grantees monitor progress and identify areas of weakness, the Duke Management Team created a quarterly score card system for each project. Score card reports provide a graphic display of progress toward each project's target goals and objectives outlined in the original proposal, including accomplishments, participation, and health behavior outcomes. Conference calls were conducted quarterly with each grantee to review progress and propose improvements.

Some projects struggled with gaps in leadership and staff turnover. The Management Team asked the Duke Center for Non-Profit Management, which provides classes in communities throughout North Carolina, to create a Certificate Program in Healthcare Leadership for the grantees. The new Certificate Program in Nonprofit Management provided opportunities for grantees to improve their management and leadership skills through local classes. As of June 2006, 23 staff members from 14 projects are enrolled in the Certificate program; one staff member completed the program; and two are enrolled in master's degree programs.

Results

SELF Improvement aimed for and achieved a broad reach across the state. More than one million North Carolina residents have received information on improving nutrition and physical activity, and on smoking cessation. More than 25,500 residents have engaged in individualized health promotion activities, including health assessments, counseling, classes, and case management. Combined outreach efforts from these programs have been extensive. Some of the outcomes in the most successful programs, which are far in excess of the overall program numbers below, will be the subject of future publications.

Tables 1 and 2 give an overview of participants' characteristics and the overall results from the 15 projects' interventions for nutrition, physical activity, and tobacco cessation. Data are not available for all participants, but overall, adults reduced BMI, increased physical activity, improved nutrition, and a small number stopped using tobacco. Increases in youth physical activity and nutrition were reported for the first two follow-up visits after administration of the baseline questionnaire. More detailed analysis of youth BMI will continue, although valid BMI data were not available for all projects.

Lessons Learned

The SELF Improvement Program just completed its fifth and final year of funding. Important lessons have been learned:

1. Lifestyle changes take time. The Kate B. Reynolds Charitable Trust found it useful to have offered grantees a five-year period in which to mobilize and integrate local resources and craft appropriate services.

Youth Participant Characteristics and Aggregate Results for 15 Projects 2001-2006

Participant Information		(n=16,901)
Age		Mean: 8.9 years 93% K-5th grade
Sex		
- Female		49%
- Male		51%
Race		
- African American		55%
- White		38%
BMI (At baseline-based on z-scores)		
- Normal Weight		54%
- Overweight		18%
- Obese		26%
Moderate physical activity		
(all assessments: 43,645)		
Changes in days per week performing moderate physical activity (from baseline)		Mean: 2.7 days/week
1st Follow-up visit	(n=5,972)	+0.2 days
2nd Follow-up visit	(n=4,281)	+0.6 days
3rd Follow-up visit	(n=3,287)	+0.9days
Tried Smoking		
(all assessments: 10,713)		14.0%
Change in smoking status (from baseline)		
1st Follow-up visit	(n=5,939)	
2nd Follow-up visit	(n=4,277)	No change in youth smoking status
3rd Follow-up visit	(n=3,288)	
Fruit intake		
(all assessments: 15,691)		Mean: 45.9 times/month
Increase in fruit intake (from baseline)		
1st Follow-up visit	(n=5,964)	+0.3/mo.
2nd Follow-up visit	(n=4,281)	+0.2/mo.
3rd Follow-up visit	(n=3,288)	0.2/mo.
Vegetable intake		
(all assessments: 15,037)		Mean: 41.1 times/month
Increase in vegetable intake (from baseline)		
1st Follow-up visit	(n=5,966)	+0.5/mo.
2nd Follow-up visit	(n=4,279)	+0.5/mo.
3rd Follow-up visit	(n=3,288)	- 0.5/mo.

program leadership in local communities were motivational and improved core management capacity.

5 Overall, projects struggled to find connections to local medical practices. Although two projects built strong connections with practices, a sizable gulf exists between medical practice and community-based chronic disease prevention programs. Community agencies and medical practices need to partner with one another to effectively treat/prevent chronic disease. As practicing physicians struggle to help their patients make difficult changes in their lifestyle, it is worth remembering that doctors and patients are not alone, and that in many communities, help is already available.

6 Extensive training to help projects develop sustainability strategies helped grantees learn to think beyond the "next grant." Several grantees have found ways to generate income to sustain their services to under-resourced people outside of additional grant funding.

7 Creating and managing data was difficult for many grantees, although extensive and ongoing technical assistance helped. Electronic databases for all program activities enabled the Management Team to generate score cards to coach and supervise grantees so improvements could be made.

The SELF Improvement program has created a foundation upon which North Carolina communities can model effective interventions to reduce and prevent chronic disease. **NCMedJ**

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists who labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina Academy of Physician Assistants, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

Eat Smart, Move More **Health Tip**

Tame the Tube–and Get Moving

Many of us say we don't have time for physical activity, yet we spend 3 to 4 hours in front of the TV. Not only are we inactive while watching television, we often snack on high-calorie foods at the same time. Trade TV time for physical activity. Walk or bike with your family after dinner. By planning TV time, you'll have more time for physical activity.

For more tips on how to tame the tube where you live, learn, earn, play and pray, visit

Pediatric Healthy Weight Case Management

A Project Supported by the Duke Endowment

James Cox, MSW, ACSW and Peggy Sessoms, RD, LDN

The Pitt County Memorial Hospital (PCMH) Pediatric Healthy Weight Case Management Program (PHWCMP) is a multifaceted initiative supported through a grant from The Duke Endowment to address the epidemic of childhood obesity in Pitt County. The goal of the PHWCMP is to develop effective strategies that will reduce premature morbidity and the risk of premature mortality associated with "at-risk for overweight" and "overweight" children ages two to 18 years. The primary focus of the program is to inform children, families, and the community that the epidemic of childhood obesity is not an *appearance* issue, rather it is a *health* issue with life-long medical implications. The three interrelated components of the program include: interdisciplinary case management, care standardization, and social marketing.

Multidisciplinary case management is not a new concept for the management of chronic illness; however, the utilization of an interdisciplinary case management team is an innovative approach to the management of the complex issues related to childhood obesity. The PHWCMP interdisciplinary team consists of nursing, nutrition, and social work and depends upon input from the child's physician and other community partners.

Both at the beginning and throughout the duration of the PHWCMP intervention, *Readiness to Change* and *Quality of Life* surveys are administered to patients and their families. These results, along with a assessment of psychosocial, medical, nutritional, and physical activity needs are used to develop individualized treatment plans. The case manager develops and implements the treatment plan in partnership with the child, parent or guardian, and physician. Clinical case management services are provided in a variety of innovative settings including; homes, schools, medical clinics, the workplace, the community health office, and other community-based settings.

The PHWCMP is relationship-based and family-focused. To have success in dealing with the complex issues associated with childhood obesity (e.g. psychosocial, behavioral health, medical co-morbidities), the establishment of a long-term trusting relationship between patient, family, and case manager is essential. Each child and family member is encouraged to participate in "STARTING POINT," a ten-week program that provides the foundation for case management and healthy lifestyles changes. The curriculum focuses on helping families understand about childhood obesity by including information on behavioral health, nutrition-related, medical conditions, and physical activity. The goal is to move families through different levels of interventions, addressing barriers that may prevent them from making changes. The case manager implements a treatment plan recognizing that the child's and parent/guardian's participation is key to the success of the intervention. Each of the clinical case managers is responsible for their individual case load, but also relies upon the professional expertise of their interdisciplinary team members in order to provide comprehensive services to each referral.

Convincing families that childhood obesity is a chronic health issue is the focus of the social marketing campaign. In order to more effectively address this barrier, 500 families were surveyed. Focus groups were conducted in local day care centers. The information collected was incorporated into a social marketing campaign. This campaign utilizes television, print materials, and the internet to share information about childhood obesity with the public. The website will also be used for some case management with enrollees. A major component of the campaign focuses on the use of Body Mass Index (BMI) grids as screening and tracking tools. BMI "wheels," specific to the pediatric population, have been developed and shared with healthcare providers. The wheels are an important tool in the effort to standardize care and to help track the health status of children. A media campaign to educate the public about BMI is under development.

Childhood obesity has reached epidemic proportions locally and nationally. Given the complexity of the issue, the development of creative and innovative approaches is vital. Strategies developed have the potential to be replicated on a larger scale. The utilization of an interdisciplinary case management model, enhanced through implementation of social marketing and care standardization efforts, is a unique approach in addressing issues related to childhood obesity. **NCMedJ**

James Cox, MSW, ACSW, is Coordinator, Pediatric Healthy Weight Case Management, Department of Community Health, Pitt County Memorial Hospital in Greenville, NC. He can be reached at: jrcox@pcmh.com. Telephone 252-847-4610 (office) 252-561-9539 (pager).

Peggy Sessoms, RD, LDN, is Clinical Case Manager, Pediatric Healthy Weight Case Management in the Department of Community Health, Pitt County Memorial Hospital.

Fit Families NC:
A Study Committee on Childhood Obesity

A Project Supported by the NC Health & Wellness Trust Commission

Lt. Governor Beverly E. Perdue

Childhood obesity is a growing problem with a startlingly simple solution: get kids to eat healthier and engage in more physical activity. While all segments of society have roles to play in fighting obesity, state government has a unique responsibility. Thanks in large part to contributions made by a project of the NC Health and Wellness Trust Fund Commission (HWTF), North Carolina has stepped forward to make change happen.

HWTF was created in 2000 by the General Assembly to receive one-quarter of North Carolina's share of the Master Settlement Agreement payments. Its Commissioners were charged with addressing the health needs of vulnerable and underserved populations and with developing a comprehensive, community-based plan to improve the health and wellness of the people of North Carolina.

The HWTF's core plan focuses on grants for state and local programs and multi-media campaigns to address: teen tobacco use, prescription drugs for seniors, medication assistance, health disparities, and obesity.

In 2003, the Commission unanimously voted to establish a study committee on childhood obesity called *Fit Families NC.* HWTF Commissioner Dr. Olson Huff, Senator William Purcell, and Representative Verla Insko agreed to lead this effort.

They were tasked with helping HWTF better understand the causes of childhood obesity and, more importantly, to develop practical recommendations for addressing this growing health concern in North Carolina. Committee members were strategically selected to represent broad diversity, both professionally and geographically.

To accomplish its objectives, the Study Committee took a multi-pronged, balanced approach that considered lessons learned from other states, and created a forum for *all* stakeholders to be heard. The inclusive nature of *Fit Families NC* included representatives from public health, business, education, academia, faith-based organizations and more.

During 2004-2005, the Study Committee held seven public hearings throughout the state that covered pertinent topics. Recommendations were received during the year-long study committee process and organized into two action areas: (1) Legislative Policy Proposals and (2) Proposals for State and Local Agencies, Organizations, Trade Groups etc.

The following policies directly resulted from *Fit Families NC* recommendations:

Revision of the State Board of Education's Healthy Active Children policy

- The State Board of Education voted unanimously to adopt a daily 30-minute physical activity requirement for all students, K-8. The first state in the nation to pass such a policy at the State Board level. This requirement will be implemented in the 2006-2007 school year.

School Nutrition Standards legislation (House Bill 855 – Sponsored by Rep. Verla Insko)

- Establishes a statewide nutrition standard for all school meals, a la cárte items, beverages, and the After School Snack Program in elementary, middle and high schools.
- Decreases foods high in total fat, trans-fat, saturated fat and sugar.
- Increases foods containing fruits, vegetables, and whole grain products.

School Vending Standards legislation (Senate Bill 961 – Sponsored by Sen. Bill Purcell)

- Bans soft drink and snack vending sales in elementary schools altogether.
- Prohibits sale of sugared carbonated beverages in middle schools and restricts soft drink sales in high schools.
- Requires that by 2006-2007 school year, 75% of snacks in middle and high schools have no more than 200 calories per package. The consensus work of *Fit Families NC* to develop this recommendation led the American Beverage Association to adopt a national voluntary policy that honors the provisions of this legislation.

While these policies are far from a solution to childhood obesity in North Carolina, each is an important step in the right direction. HWTF and *Fit Families NC* continue their work to ensure proper implementation of these policies, while remaining steadfast in our goal to make North Carolina's kids the healthiest in our nation.

For more information on the Health and Wellness Trust Fund or Fit Families NC, visit www.HealthWellNC.com.

Lt. Governor Beverly E. Perdue, Chair, NC Health and Wellness Trust Fund Commission. Telephone: 919-733-6137.

Obesity and Overweight in North Carolina: Prevalence, Trends, and Risk Factors

Obesity and overweight are serious and increasing health problems in North Carolina and in the United States. According to the Behavioral Risk Factor Surveillance System (BRFSS) survey data for 2005, 24% of adults in the United States are obese. Although a national and North Carolina health objective for the year 2010 is to reduce the prevalence of obesity among adults to less than 15%, current data indicate that the situation is worsening rather than improving. While the prevalence of overweight among adults in North Carolina remained stable from 2000 to 2005 at 37%, obesity increased from 22% in 2000 to 26% in 2005 (NC BRFSS).[1] This increase in prevalence raises concern because of the implications for the future health of North Carolinians.

People who are obese are at increased risk for heart disease, high blood pressure, diabetes, arthritis-related disabilities, and some cancers. In addition, the prolonged illness and disability associated with many chronic diseases decrease the quality of life for millions of Americans. Much of the chronic disease burden is preventable.

Even more disturbing is the rapid increase in overweight among children and youth. Nationwide, the prevalence of overweight has more than tripled in adolescents from 5% in 1980 to 17% in 2004, and has more than doubled in children ages 6-11 from 7% in 1980 to 19% in 2004.[2] These trends are important to monitor because overweight children and adolescents are more likely than those of normal weight to become overweight or obese as adults,[3] and therefore be more at risk for associated chronic diseases.

Using data from the North Carolina Youth Risk Behavior Survey (YRBS), Table 1 shows consistent increases from 2001 to 2005 in the percentages of middle school and high school students who were overweight and at risk of overweight.

Table 1.
Prevalence of Overweight and At Risk for Overweight Among Middle and High School Students, 2001 and 2005 North Carolina YRBS

	Middle School		High School	
	2001	**2005**	**2001**	**2005**
Overweight	13%	16%	13%	14%
At Risk for Overweight	16%	18%	14%	16%

The Child Health Assessment and Monitoring Program (CHAMP) is a new tool in North Carolina that will help monitor child health status and identify child health problems, including overweight. Implemented in January 2005, this statewide representative survey gathers data from parents or caretakers of children ages 0-17. According to the 2005 baseline data, 12% of children and adolescents ages 0-17 are at risk for overweight and 16% are overweight.

Physical inactivity and poor diet are associated with overweight and obesity, as well as with heart disease, cancer, diabetes, and stroke. North Carolina BRFSS data for 2005 show that 58% of adults failed to meet recommended physical activity standards. Twenty-six percent of adults reported having no leisure time physical activity at all. North Carolina YRBS data indicate that 30% of high school youth spend less than 20 minutes per school day being

RTN—continued on page 330

RTN—continued from page 329

physically active, and that 26% are physically active less than 20 minutes per weekend day. The recommended time is a minimum of 60 minutes per day.

North Carolina 2005 BRFSS data show that 77% of adults consumed less than the recommended five fruits and vegetables per day. Table 2 shows consumption of fruits and vegetables in children and youth as reported in the 2005 North Carolina YRBS and CHAMP surveys. Seventy-three percent of high school students reported that they consumed less than the recommended minimum of three servings of vegetables on a typical day and 47% consumed less than the recommended minimum of two servings of fruit. The CHAMP data, which are reported by parents or caretakers, show similar results for high school age children (ages 14-17). Seventy-four percent of all children ages 0-17 did not consume the recommended three servings of vegetables, while 37% did not consume the recommended level of fruits.

Table 2.
Consumption of Fruits and Vegetables in NC Children and High School Students

	YRBS	CHAMP	
	High School	Ages 14-17	Ages 0-17
< 3 vegetables / day	73%	76%	74%
< 2 fruits / day	47%	51%	37%

The CHAMP survey includes questions about sugar-sweetened beverages and hours of television viewing, two behaviors also associated with overweight. Parents or caretakers reported that 39% of children ages 0-17 drank two or more servings of sweetened beverages such as soda pop, sweet tea, fruit punch, Kool-aid, sports drinks or fruit drinks on a typical day. For adolescents ages 14-17 it was 56%. Fifty-three percent of children ages 0-17 were reported to watch television for two or more hours per day. For adolescents ages 14-17 it was 61%.

Both CDC and the national Institute of Medicine[5,6] have recognized that we cannot "fix" these problems by education alone, expecting individuals to change behaviors by themselves. Individual changes in behavior must be supported by changes in policies and environments in settings where people make everyday decisions. Information about public health efforts to address these issues can be accessed at http://eatsmartmovemorenc.com.

Readers' Forum

To The Editor:

I would like to commend the contributors, editors, and publishers of the *North Carolina Medical Journal* for their last issue, "Covering the Uninsured." Few subjects are more important to our state's future than the exploding cost of healthcare and the more than 1.3 million uninsured North Carolinians. This problem is clearly not unique to our state, but it is one of many areas in which federal leadership is sorely lacking. As Adam Searing of the North Carolina Justice Center's Health Access Coalition rightly noted, there is little likelihood of major federal action until Washington puts its fiscal house in order.

If we are going to make a serious statewide effort to significantly reduce the number of uninsured North Carolinians, as I believe we should, then the expertise and knowledge of our state's leading healthcare and health policy experts must be leveraged. Doctors, hospitals, political leaders, insurance companies, and employers must join together to achieve the innovation, cooperation, and diligent work that such an initiative will require.

The alarming facts about the health of the uninsured alone should cause moral outrage. In almost every measurable health outcome, they fare worse than the insured. A number of contributors also demonstrated how everyone suffers when so many people are uninsured. School attendance and worker productivity decline, state costs for Medicaid and indigent care grow and divert resources, insurance premiums increase, our healthcare institutions face growing financial strains, and small business is stifled. All of this combines to drag down our state's economic growth.

Dr. Sandra Greene of the Cecil G. Sheps Center for Health Services Research at UNC-Chapel Hill provides a valuable analysis of the rapidly growing healthcare costs that cause insurance premiums to increase. There are many steps we can take to rein these costs in and expand coverage by making it more affordable.

Patients and insurers can help by participating in and creating new initiatives to promote generic drugs, preventive medicine, and increased consumer information and choice. The promotion of healthy lifestyles is one of the best long-term investments our state can make. I have been pleased to work with *Be Active North Carolina* to encourage physical activity and healthy living. As a member of the State Board of Education, I also led the effort to require daily physical activity in our public schools. Healthy habits must begin at a young age because healthy children perform better in the classroom and live longer and more productive lives.

North Carolina Hospital Association President William Pully is right that hospitals need help with reimbursement rates and a higher percentage of insured patients. I am happy to report that recently passed legislation supported by the Hospital Association and my office now allows public hospitals to invest funds via the State Treasurer's office. This will increase returns, decrease investment costs and provide additional financial resources. Hospitals and doctors are also suffering from higher malpractice premiums that lead to defensive medicine and threaten healthcare access, particularly in rural areas. It is imperative that all North Carolinians have the highest quality of healthcare available in their community. We must find solutions that preserve the rights of patients, end the waste of excess procedures, and improve access.

At the state level, our leaders must find new ways to immediately expand access to healthcare. The April 2006 report by the *North Carolina Task Force on Covering the Uninsured* convened by the North Carolina Institute of Medicine offers a number of good policy recommendations. I strongly agree that small businesses need help, as their employees are more likely to be uninsured and the obstacles they face are particularly difficult.

I also want to encourage our experts to consider bigger and bolder ideas for systemic change. While the policies working in other states might not always be feasible here, the inspiration for unique North Carolina solutions might be found anywhere. Massachusetts' new bipartisan legislation that requires all residents to purchase health insurance is a great example. Illinois recently passed legislation that will provide health insurance for every child. And a number of states are examining enhanced benefit accounts that incentivize weight management, smoking cessation and other healthy habits.

We need real leadership and innovation—here in North Carolina—to examine these kinds of big ideas and to take much-needed action on behalf of our families. To this end, I hope all of you will continue the dialogue that has been started on these pages and I thank all of the authors for their informative articles.

Richard Moore
Treasurer
State of North Carolina
Raleigh

To The Editor:

The May/June 2006 issue of the *North Carolina Medical Journal* included a thorough assessment of North Carolina's problems with people uninsured for healthcare. The authors made multiple points as to why the situation is detrimental to our state. The articles were timely and well done.

I would emphasize three basic parameters of our healthcare system that reflect a sad situation that affects all of us:

(a) Healthcare costs have progressively increased and we are spending far more per capita for healthcare than any other nation.
(b) The percentage of our population which is uninsured has risen progressively, now close to 1.5 million people in North Carolina.
(c) By various parameters measured by the World Health Organization, we show poor results, with our ranking 30th to 37th in the world for quality of healthcare.

Our technological advances have been remarkable, but we remain inconsistent with delivery of basic healthcare to our citizens. We need some degree of health insurance for all North Carolinians, but our per capita income is low by comparison with other states, and we have a larger percentage of people with no health insurance. Currently we cannot afford comprehensive healthcare for all persons, but we can take some steps to diminish the problem. Here are steps I think worthy of policy consideration:

(a) An adjustment in taxes that would enable individuals to pay premiums for health insurance with "before-tax" dollars.
(b) Tax credits that would encourage small employers to provide health insurance to their employees and their families.
(c) State government involvement in reinsurance underwriting to aid employers who might be self-funded for their health insurance.
(d) A consolidation of risk for high-risk individuals, such as was recently passed by the NC House of Representatives, but disapproved by the Senate. This measure would be a significant step toward affordability of health insurance by people who are not included in group insurance.

If these changes could occur, the benefits would include:

(1) Lower healthcare insurance premiums resulting from: (a) Less cost shifting in pricing by providers to recoup some of the expenses for care of the uninsured from those with insurance, (b) less utilization of the emergency department which is far more expensive for non-emergencies than care through a personal physician, and (c) less frequent in-patient admissions.
(2) Less days absent from school for children with a primary care physician.
(3) Increased productivity resulting from less time away from work.
(4) Earlier detection and more effective management of chronic problems and risk factors before disabling disease develops.
(5) Less frequent bankruptcies and emotional trauma for families with overwhelming medical bills in the face of no health-insurance.
(6) Less strain on healthcare providers and institutions as they strive to provide safety net care.

All of us in North Carolina, including those with health insurance and those who manage businesses, should push for improvements in our system that would be greatly enhanced if more people had some degree of health insurance coverage resulting in better access to more timely medical care.

Robert H. Bilbro, MD, FACP
Raleigh Medical Group

To The Editor:

Thank you for the interesting and thought provoking issue of the *North Carolina Medical Journal* of May/June 2006, on the topic of "Covering the Uninsured." Given your statistics, it appears more than four million North Carolinians do have some form of health insurance.

While some of the content in the various articles pertains to the mentally ill, the lack of specific attention is a glaring omission of your issue. How many of the four million plus who are covered have no, minimal or discriminatory coverage for mental illness?

All of the patients of a free psychotherapy clinic in Raleigh, where I served as Medical Director, lacked health insurance as well as permanent housing. One of the criteria for admission to the clinic was that applicants have no commercial insurance, Medicare or Medicaid, regardless of whether there was specific mental health coverage. During the 10 year life of the clinic we saw and treated hundreds of patients. Almost as many people with health coverage, but without mental health coverage were turned away. Over the course of treatment a large majority of patients acquired permanent housing and/or some form of health insurance, making them ineligible for our services and so were referred to private medical practitioners.

It is interesting your issue does pay specific attention to the dentally uninsured, also frequently not included by insurers and a major problem.

Evidence is clear that mental illness is a major health problem and a significant factor in many of the 15 conditions to which is attributed half of the increase in healthcare spending, including heart disease, obesity, smoking and problem drinking.

Raleigh, NC

To The Editor:

The March/April 2006 issue of the Journal included an excellent policy forum series on prostate cancer. One article in particular prompted me to ask a question. PSA and digital rectal examination are the key tests for detecting this disease. It is noted in several places in the forum that PSA may be affected by the patient's age, race and the presence of prostatitis, benign prostatic hypertrophy, and/or prostate cancer. Since there are so many men who could serve as the various reference groups for this test, why could we not have reference ranges specific for age, race and presence or absence of these disease states? This would, it seems, make the interpretation of a result much more definitive for a given patient.

Richard A. Dickey, MD
Hickory, NC

The Issue Brief Author Responds:

The issue of age and race-specific PSA reference ranges is an excellent one. Because PSA is a prostate marker and not a prostate cancer marker, many conditions influence the PSA value and its dynamics in individual patients. Many studies have reviewed the issue of age, race and inflammation and suggested reference ranges are reported in the literature.[1-5] Because these data are derived from large screening populations, no valid values have been agreed upon for absolute age- or race-related cut-offs. Indeed the lowest suspicious value has declined from 4.0 in the early PSA era to as low as 2.5 in the 21st century.[5]

A more accurate method of evaluating patients is, however, the rise in PSA over time or PSA velocity. While the exact PSA velocity values remain controversial, a rise of approximately 0.7 ng/dl per year is a good starting place.[6] The most important issue is regular screening of men over age 40 especially if they have a strong family history or are African American. Regular PSA levels will allow the physician to create a slope of PSA rise, and if that slope is associated with rapid PSA velocity, the physician can pursue a biopsy diagnosis of prostate cancer.

Surgery and science combine to unlock the secrets of diabetes

A partnership between Pitt County Memorial Hospital and the Brody School of Medicine at East Carolina University is at the forefront of bariatric surgery research. In more than 2,500 documented cases, our surgeons have seen patients overcome dependence on insulin and oral therapy in a matter of days. Some patients have required no further medication for as long as two decades.

The confirmation of these findings by surgeons throughout the world has led to a major grant from the Johnson & Johnson Corporation. The grant will help researchers find an explanation for this medical advance and to see if medication can achieve the same result. Dr. Walter Pories, an ECU professor of surgery and bariatric surgery pioneer, and his colleagues will lead a two-year clinical study of adults with diabetes that evaluates insulin sensitivity and glucose metabolism before and after gastric-bypass surgery. For more information on the study, call 252-744-3290.

Working together, Pitt County Memorial Hospital and Brody School of Medicine surgeons have been performing and studying gastric bypass surgery since 1978. To watch a live web cast of bariatric surgery at Pitt County Memorial Hospital or learn more about bariatric surgeons at the Brody School of Medicine and Southern Surgical Associates, visit www.bariatric.uhseast.com.

Tarheel Footprints in Healthcare

Recognizing unusual and often unsung contributions of individual citizens who have made healthcare for North Carolinians more accessible and of higher quality

Recognizing Samuel D. Cranford, Jr.
Asheboro, North Carolina

Samuel D. Cranford, Jr.

North Carolina hospitals, like so many voluntary and non-profit organizations in/outside the healthcare arena, depend for their governance and administrative leadership on the service of community members who give of their time and talents as hospital trustees. Hospitals are, for the communities they serve, important economic engines of community growth and development, and most are major employers in their respective counties. Lay trustees of these institutions bear an enormous responsibility for assuring the long-term stability of these institutions, and they help to shape the vision of hospital senior management regarding how these institutions can grow and continue to meet the increasing need for more, and more advanced, healthcare services and technology in the years ahead.

In this issue of the *North Carolina Medical Journal*, we are pleased to recognize the efforts of one of North Carolina's most outstanding hospital trustees, **Samuel D. Cranford, Jr.**, of Asheboro, who has served for over 30 years as a Director and member of the Executive Committee of Randolph Hospital, Inc., a private not-for-profit hospital in that community.

Sam Cranford is a well-known and highly regarded business executive. He served as President and Treasurer of a family owned ladies hosiery manufacturing company, Asheboro Hosiery Mills, Inc, until the family made the decision in 1998 to close the manufacturing plant in response to a shrinking market for its products. Since that time he has been actively engaged in other textile and clothing manufacturing businesses, as well as in the commercial and residential real estate business in Asheboro and surrounding areas. Sam Cranford has applied his business experience and skills in service to the greater Asheboro area by serving as the President and majority owner of a development company that negotiated Asheboro's first private housing unit for older adults, as well as other development efforts. He has served as Vice Chairman of First American Savings Bank and a director of First Peoples Savings and Loan, eventually helping to lead that organization to becoming the largest savings institution in the state of North Carolina. He was a board member of First National Bank & Trust and a founding board member and member of the executive committee of Bankers Trust of North Carolina (now a part of BB&T Corporation).

Like a number of trustees of North Carolina's community hospitals, Sam Cranford has a long history of volunteerism in his community. He was a founding member and officer of the YMCA of Randolph County; past president of the United Way of Randolph County; past president of United Way of North Carolina; past chairman of the Adolescent Pregnancy Prevention Coalition of North Carolina; and past president of Randolph Fellowship Home, non-profit organization offering emergency shelter and food assistance. He is past president of the Rotary Club of Asheboro and a former District Governor of Rotary International. For all of these voluntary activities, he has received the Distinguished Service Award of Randolph County and selected by the North Carolina Jaycees as one of five Outstanding Young Men of our state.

Because of his long tenure as a hospital trustee, his extensive business experience, and his numerous types of experience in serving the health and human services needs of his community, Sam Cranford was appointed by Governor Easley as a member of the State Health Planning Commission, for which he served as co-chair of the Preventive Health Subcommittee. The North Carolina Institute of Medicine asked him to serve as a member of its Task Force on the North Carolina Nursing Workforce and in this capacity he brought to the Task Force years of experience as a hospital trustee in dealing with these complicated professional and educational issues.

The President of Randolph Hospital, Robert E. Morrison, offered these comments: "Sam Cranford is an exceptionally valuable member of our board of directors. He has the ability to hear and see a number of different perspectives on a single issue, to ask challenging questions that others might not consider. He has served as one of our directors for many years, and he has had statewide health planning and policy experience on many levels. He is also committed to continuing education. Paid directors of large corporations rarely put so much energy into knowing their industries. Sam does it as a volunteer. Through these experiences he has become an expert in many of the most fundamental aspects of healthcare. Sam's attitude always has been to see where we are now, to start there, and see what it would take to get us to the next higher level. He is a champion of improvement. This attitude, plus his congenial manner and intellect have made him a valuable member of the leadership team in Randolph County and North Carolina generally."

For all of these many accomplishments, and for his steadfast and continuing role in his community and statewide in support of community-based healthcare services and facilities, as well as for his vision of *what might be possible* if healthcare systems were to operate with greater effectiveness and efficiency, the *North Carolina Medical Journal* is proud to recognize Samuel D. Cranford, Jr., and all hospital trustees, who have served us so well.

The University of North Carolina Hospitals (UNC-H) is calling for applications to a:

Residency in General Preventive Medicine/Public Health at UNC Chapel Hill
(Commencing July, 2007)

The resident will:
1. In the academic year, undertake a Master's Degree in Public Health at UNC, and
2. In the practicum year, pursue research and practicum rotations in a variety of clinical and public health settings.

Graduates will be board eligible in Preventive Medicine.

Applications will be made to both the Preventive Medicine Residency (deadline November 1) and to the UNC School of Public Health (deadlines vary by department, but begin around January 1).

Applicants must have completed an internship year in a primary care specialty in an ACGME-accredited program; be a U.S. citizen or permanent resident; have completed medical training in an LCME-accredited medical school; possess a current certificate from the Education Commission for Foreign Medical Graduates (if applicable); and have a valid medical license in the United States.

For information on the preventive medicine residency and how to apply, please see:
http://www.med.unc.edu/wrkunits/2depts/soclmed/PREVENTIVEMED/PrevMedHomePage.htm
For further information, please contact
Deborah Porterfield, MD, MPH, Residency Director at
porterfi@email.unc.edu or (919) 843-6596.

U.S. AIR FORCE
CROSS INTO THE BLUE

NO ONE GOES THROUGH MEDICAL SCHOOL TO PRACTICE INSURANCE.

Remember graduating from college and passing your MCATs, then spending the next four years of your life getting through classes like clinical epidemiology, neurology and radiology so you could practice medicine? Today's financially driven managed care environments make having a practice difficult. Hurrying patients in and out of the office to make a quota and going into negotiations to prescribe treatments that don't coincide with a patient's policy aren't practicing medicine. We'd like to prescribe a solution: Move your profession to the United States Air Force. Get back to what's important — practicing medicine. To request more information, please visit our website at AIRFORCE.COM or give us a call at 1-800-423-USAF.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, non-profit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

Key Attributes of Health Ministries in African American Churches:

An Exploratory Survey

Lori Carter-Edwards, PhD, Yhenneko B. Jallah, MS, Moses V. Goldmon, EdD, J.T. Roberson, Jr, PhD, and Cathrine Hoyo, PhD

Abstract

Background: *Church leaders are considered instrumental in the successful implementation of church-based health programs. However, it is unknown which program attributes they perceive as important and which program attributes exist in their congregations.*

Objective: *To explore the perceived importance and existence of health ministry-related attributes in predominately African American churches.*

Methods: *Cross-sectional survey, with a convenience sample of 98 registered church leaders attending a conference on health and spirituality in Raleigh, NC. Attendees were asked to complete a brief survey assessing perceived importance (very important vs. somewhat or not important) and existence (yes vs. no) of 20, health ministry-related attributes in their churches. Percent perceived as very important, percent existence, and their differences were assessed for each attribute.*

Results: *Seventy-two (73.5%) of the attendees completed the survey. Attributes perceived as very important were: displaying health information in churches (73.6%); hosting health fairs for church members (72.2%); pastoral, church-based Internet access (70.8%); willingness to receive foundation funding for activities (66.7%); and incorporating health messages in Sunday bulletins (65.3%). For each of these program attributes, there was a gap between the proportion rating them "very important" and existence of the attribute in their own congregations (range diff in %: -8.3 to -22.2).*

Limitations: *Lack of generalizability due to sample selection and homogeneity.*

Conclusions: *Among leaders surveyed, despite perceived importance, attributes did not exist for all. Future studies should evaluate whether attributes considered important by church leadership parallel an increase in the development and maintenance of health program activities, and are associated with congregation health behaviors and health outcomes.*

Key Words: *health ministry; African Americans; perceptions; churches*

Introduction

There has been an increased interest in African American churches as conduits for health information and program outreach to help prevent or reduce the burden of chronic diseases.[1,2] However, little is known about church attributes or infrastructures used to carry out health outreach and services to church congregations and their surrounding communities. Outreach services are typically conducted through health ministries, defined as special missions that integrate faith and health for their members and the communities they serve.[3] Health ministries are integral to the overall ministry of the church, and are organized to address health needs through activities and information dissemination related to spiritual, emotional, social, and physical health and wellness. They may be of particular importance to community-based health programs since millions frequently go to churches to find help for coping with life.[4]

Lori Carter-Edwards, PhD, is a Senior Investigator at the Institute for Health, Social and Community Research at Shaw University. She can be reached at loriedwards@hughes.net. Telephone: 919-599-6643.

Yhenneko B. Jallah, MS, is a biostatistician in the Center for Biostatistics and Data Management at the Institute for Health, Social and Community Research at Shaw University.

Moses V. Goldmon, EdD, is Director of the Research in Ministry Institute and Assistant Professor of Education in the Shaw University Divinity School.

J.T. Roberson, PhD, is Dean of the Shaw University Divinity School.

Cathrine Hoyo, PhD, is Assistant Professor in the Department of Community and Family Medicine at the Duke University Medical Center.

Despite the existence of church-based health ministries, little is published about them, including their characteristics, structures, or effectiveness. Even less is known about them in African American churches. Most literature on health ministries and their functions has been in the area of parish nurse programs. The recorded history of a health ministry model through the work of parish nurses dates back to 1836 in Kaiserwerth, Germany.[4] Rev. and Mrs. Fliedner established the "Deaconness" movement where, by 1900, over 25,000 trained nurses representing religious organizations served the ill in communities in Europe, the US, Egypt, Russia, and Hong Kong.[4]

Today, parish nurse programs continue to provide services to churches and local communities. Their success is largely dependent on church leadership. Pastors play key roles in the development and maintenance of parish nurse programs. If pastors are not interested, there is little hope for implementation.[4] However, for pastors who endorse such a program, they provide support by: assisting in the selection of congregation members to serve on a task force; helping the group bring the message to the congregation; helping to select and contact other pastors in the community who might be interested in such a program or collaboration; and providing the project with a strong biblical foundation for whole-person healthcare.[4] Once pastors select the parish nurse program leader, a health cabinet, typically comprised of the pastor, parish nurse, and other lay members, is formed to assist individuals and families in improving and maintaining their own health and that of their community, through worship, education, support networks, recreation, and fundraising.[4,5] Roles, needs, and challenges may differ across churches based on size,[6] location,[7] and program mission.[4]

As with these parish nurse programs, lay leaders and staff are key to the successful implementation of health programs in African American churches.[8] Such programs will exist only if pastors and their church leaders perceive them to be essential, efficacious in reducing disease risk, and consistent with the church mission.[9] However, it is not known whether attributes similar to those identified as essential in traditional parish nurse programs exist in health ministries in African American churches.[10] Furthermore, it is unknown what church leaders perceive to be important attributes for a health ministry, or whether these characteristics exist in their own congregations. This exploratory study describes the perceived importance of church-based health ministry attributes in a sample of leaders of predominantly African American churches, and the extent to which perceptions of importance diverged from reported existence of these attributes in their respective churches.

Methods

Study Sample

The study population was a convenience sample of 98 pastors, other ordained clergy, or lay leaders in predominantly African American churches in NC who were registered attendees of the 2004 Third Annual Health Enhancement through Medicine and Spirituality (HEMS) Conference, held in Raleigh, NC. This assembly was a collaborative effort between the Shaw University Divinity School, the oldest historically black university in the South, and the Old North State Medical Society, based in Durham, NC. The conference theme, "Building an Effective Ministry of Health and Healing," emphasized church accountability for the community's welfare and the need for collaboration between churches, academia, and other institutions to address African American health problems through effective outreach programs. The analysis sample included the 72 attendees (73.5%) who filled out an informed consent and health ministry assessment survey. The study's protocol and informed consent form were approved in 2004 by the Institutional Review Board at The University of North Carolina at Chapel Hill School of Public Health.

Health Ministry Assessment Survey

A health ministry assessment survey was administered to conference attendees and included questions on: respondent demographics (age, gender, marital status, and annual household income); church characteristics (respondent roles, denomination, church size and location); and the perceived *importance* and *existence* of 20 health ministry attributes in the church or congregation represented by the respondent. Since no scale to date has been published that captures parish nurse program or health ministry attributes, the HEMS conference organizers compiled an exploratory list of health ministry attributes based on literature on parish nurse programs,[4-6] church-based studies,[2,9-14] and attributes deemed important based on the conference theme of leadership, outreach, and collaboration (e.g., technological attributes for collaboration and outreach). Attributes were grouped into four areas: *leadership and staffing* (leadership decisions, appointments, personnel roles, responsibilities, and expertise, and working relationships with other church groups that may impact behaviors related to chronic disease [e.g., the kitchen committee's food choices and preparation practices]);[4-6,10-14] *function* (activities that may be conducted by a health ministry, whether part of the church health infrastructure or through outreach);[4-6,9] *technology and funding* (characteristics associated with Internet access for quick acquisition of health ministry-related information as well as information on capital development and fundraising);[4-6,15] and *collaboration* (research partnerships with academic institutions and local community organizations, such as health agencies, outreach programs, and foundations).[1,5]

For each attribute, respondents rated the *level of importance* (very; somewhat; not at all) and current *existence* in their church (yes; no; don't know). It was anticipated that the number of potential respondents would have been no greater than 100, which represented the approximate number of persons who pre-registered for the conference. Thus, for importance, a three-level, rather than a standard five-level, response category was created to minimize potentially small cell sizes in the analysis. Existence measured an individual respondent's perceived existence of the attribute in the church of which he/she was a member. To maximize anonymity of respondents, data were not collected on the name of church; so more than one respondent may represent some churches.

Variable Measurement and Analysis

Sample demographics and levels of importance and existence of health ministry attributes were evaluated. The proportion of attendees for which each attribute was very important (versus somewhat important and not at all important) and corresponding level of existence (percent existence among the entire analysis sample) are reported. McNemar's test of differences in proportions was used to compare differences in percentages of importance and existence of the 20 attributes. Where attributes were rated as very important, Fisher's exact test was used to evaluate individual effects of clergy status (pastor and other clergy vs. non-clergy or laity),[4,5] geographic location (urban vs. rural),[7] and church size (300 members (large) vs. <300 members (medium and small)).[6,17] It was hypothesized that the percent difference in attribute importance and existence would differ for: clergy and non-clergy members of urban compared to rural churches; and for larger versus smaller or medium-sized churches.

Results

Of the 72 respondents, 43 (59.7%) were women (Table 1). Approximately 39% of the sample were clergy (senior pastors or associate ministers). Most were members of large Baptist churches located in urban communities.

Among the 20 attributes (Table 2), the display of health information at the church was the attribute most frequently rated as very important (73.6%). Other attributes ranking high in importance were: hosting health fairs for members (72.2%); pastoral access to the Internet (70.8%); willingness to receive foundation funding for activities (66.7%); and incorporating health messages in Sunday bulletins (65.3%). The pastor leading the health ministry and making all of the decisions was perceived as being the least important (25.0%). A higher proportion reported an attribute as being important than existent in their churches for 18 of the 20 attributes. For the five most frequently rated as very important, the difference in percentage between existence and importance ranged from –8.3% to –22.2%. For all 18 attributes, differences in percentages between existence and importance ranged from –5.5%, where the health ministry is headed by a healthcare professional (p=0.359) to –27.8%, where the health ministry has a system for keeping track of the church members' health status or specific health indicators (p<0.001).

Limited associations of clergy status, church geographic location, and church size on existence of the 20, health ministry attributes were found; therefore full results are not shown. More clergy than non-clergy perceived access to the Internet as very important (p=0.02). More leaders from larger than smaller churches identified hosting community health fairs as very important (p=0.01). Urban compared to rural leaders perceived having a health professional head the health ministry as very important (p<0.001).

Table 1.
Sample Demographics (N=72)

Characteristics	N (%)
Gender	
% Male	21 (29.2)
% Female	43 (59.7)
Missing	8 (11.1)

[a] Baptist includes: National Baptist Convention of America, National Baptist Convention USA, Inc., National Missionary Baptist Convention of America, and Progressive National Baptist Convention, Inc.

[b] Other Denomination includes: African Methodist Episcopal, African Methodist Episcopal Zion, Christian Methodist Episcopal, Church of God in Christ, and other denominations.

Discussion

In this exploratory study, display of health information was deemed most important, emphasizing, as in other studies, a continued interest in health information dissemination and education in African American churches.[9,11] The other attributes considered most important by at least 65% of the sample were in the areas of function/technology and funding. Reasons these particular attributes may be considered most important is that they can reach a large number of people at one time and/or open up financial and collaborative opportunities for gathering and using information to help sustain church-based or church-sponsored health programs.[16,17] For attributes considered least important, findings reveal that research may be less of a priority for health ministries than practice (as indicated through functional attributes). In addition, despite the recognized importance of pastoral approval before implementing a health ministry leadership structure,[1,4,5,18] this sample may be comfortable with church members, rather than the pastor, making daily decisions and fulfilling the responsibilities of a health ministry. This may be a necessity for pastors since their multiple commitments to their own families, congregations, and colleagues can make additional time commitments to such activities challenging.[19]

Table 2.
Differences in Existence and Perceived Importance of Health Ministry Attributes (N=72)

Attribute	Attribute Area	% (N) Exist[b]	% (N) Very Important[a]	Difference in %[c]	p-value[d]
1. Church displays health information (pamphlets)	Function	65.3 (47)	73.6 (53)	-8.3	0.359
2. Church hosts health fairs for members	Function	58.3 (42)	72.2 (52)	-13.9	0.064
3. Pastor has access to Internet at church	Technology and Funding	63.9 (46)	70.8 (51)	-6.9	0.109
4. Church is willing to receive foundation funds for its health ministry	Technology and Funding	52.8 (38)	66.7 (48)	-13.9	0.013
5. Health messages/announcements are in Sunday bulletins at least once per month	Function	43.1 (31)	65.3 (47)	-22.2	0.006
6. Church hosts health fairs for the community	Function	38.9 (28)	63.9 (46)	-25.0	<.001
7. Health ministry uses biblical scripture with members	Function	52.8 (38)	62.5 (45)	-9.7	0.442
8. Pastor appoints member to be head of the health ministry	Leadership and Staffing	65.3 (47)	58.3 (42)	7.0	0.664
9. Pastor incorporates health messages in sermons monthly	Function	44.4 (32)	58.3 (42)	-13.9	0.286
10. Church has earmarked funds specifically for health ministry	Technology and Funding	30.6 (22)	58.3 (42)	-27.7	0.002
11. Church is willing to receive government funds for its health ministry[e]	Technology and Funding	45.8 (33)	58.3 (42)	-12.5	—
12. Health ministry works with the kitchen committee	Leadership and Staffing	34.7 (25)	56.9 (41)	-22.2	0.007
13. Health ministry is headed by a healthcare professional	Leadership and Staffing	51.4 (37)	56.9 (41)	-5.5	0.359
14. Church has separate 501c3 for outreach ministries	Technology and Funding	31.9 (23)	56.9 (41)	-25.0	<.001
15. Members have access to Internet at church	Technology and Funding	27.8 (20)	48.6 (35)	-20.8	<.001
16. Health ministry has system for keeping track of members health	Function	19.4 (14)	47.2 (34)	-27.8	<.001
17. Church participates in research with local community organizations	Collaboration	31.9 (23)	47.2 (34)	-15.3	0.011
18. Church participates in research studies with universities	Collaboration	23.6 (17)	41.7 (30)	-18.1	0.013
19. Health ministry occasionally provides members transportation to physicians office or health centers[e]	Function	23.6 (17)	37.5 (27)	-13.9	—
20. Pastor leads ministry and makes all of the decisions	Leadership and Staffing	36.1 (26)	25.0 (18)	11.1	0.122

[a] Percentage is computed as ([number very important/total n of 72 respondents] x 100).
[b] Percentage is computed as ([number exist in the church/total n of 72 respondents] x 100).
[c] Difference in % is an absolute difference computed as (%exist - %very important).
[d] Two–sided exact p-value obtained from McNemar's test of difference in proportions of perceived very important and exists within the church.
[e] No statistics computed due to missing or zero values in cross tabulation table.

For most of the attributes, the proportion of the sample perceiving them as very important was greater than the proportion reporting the attributes existed in their churches. These findings, coupled with their attendance at the HEMS conference, whose theme focused on health ministries, reflect a potential interest to increase these attributes. Additionally, significant differences between perceived importance and existence across all four attribute categories imply that characteristics for effective health ministry service and outreach may be multi-dimensional.[20] Formal assessment of functional activities, technological access, and collaborative partnerships may lead to an increase and improvement in the churches' attributes and help shape and implement effective church-based interventions in the future.

Limitations

There are limitations to this study. The convenience sample of predominantly Baptist conference attendees limits the generalizability of the findings. Another limitation is lack of information on both the church attended and whether an established health ministry existed in their churches. It is possible that more than one respondent attended the same church, hence a clustering (or inter-correlation) in responses. Non-response is another limitation. Some attendees (24%) did not complete the survey, raising the concern that respondents may have different perceptions or prevalence of existence of these health ministry attributes than non-respondents. Additionally, some who filled out the survey did not complete all of the demographic questions, making it difficult to determine whether the results would have been different by clergy status, urbanity, or church size. Despite these limitations, the study's findings are useful for generating hypotheses about key attributes and their implementation in predominantly African American churches.

Conclusions

Churches represent the oldest institution among African Americans.[21,22] Compared to other organizations, they are typically better able to disseminate information within the wider African American community,[1,20,22] and are also associated with an increased likelihood of positive healthcare practices.[23] This exploratory study represents new evidence on health ministry attributes in this sample of church leaders. Further understanding of these and other attributes, including how well they operate and are implemented, and whether they parallel an increase in the development and maintenance of health ministry program activities, will provide valuable information for designing subsequent church-based observational studies and interventions and assessing improvement in congregation behaviors and health outcomes. **NCMedJ**

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists who labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina Academy of Physician Assistants, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

POLICY FORUM

Sexually Transmitted Diseases (STDs): Persistent Epidemic, Unspoken Topic, Missed Opportunities

> *"STD and HIV programs remain highly controversial, lack strong public approval, are significantly underfunded, and are frequently fractured at service delivery points."*

INTRODUCTION

Policy Forum:

Sexually Transmitted Diseases (STDs): Persistent Epidemic, Unspoken Topic, Missed Opportunities

One of the characteristic aspects of public health, but one rarely the focus in the lay media coverage of the field, is the persistence of some of the problems to which public health has devoted significant attention over its long history. Sexually transmitted disease is one of these categories of public health issues, as Dr. Steven Cline, Deputy Director of Public Health of the NC Department of Health and Human Services, has pointed out in his Issue Brief, which never seems to "go away." Despite the existence of numerous programs to screen for these conditions, to trace the sexual contacts of those diagnosed, or to educate our population, especially those at highest risk, of the dangers of these diseases and how they may be prevented, the incidence and prevalence of these diseases remain a matter of constant concern across our state and the nation as a whole.

One would have thought that the discovery of acquired immunodeficiency syndrome (AIDS) and the risk associated with the human immunodeficiency virus (HIV) would have cast such a wide alarm that public awareness of the dangers of unprotected sexual encounters would have had the effect of significantly reducing both the incidence and the prevalence of these conditions. As the papers in this issue of the *North Carolina Medical Journal* indicate, sexually transmitted diseases (STDs) remain one of the most difficult and demanding of the public health challenges in our state. Yet, the good news is that when we devote appropriate financial support and public commitment to the effort, change is possible.

Despite the enormity of the epidemic of STDs, the worldwide (though periodic) media attention to the spread of HIV/AIDS, and the impact of the several varieties of sexually transmitted diseases among many different segments of our population, only scant or passing attention seems to be given to these issues in discussions of community public health, in legislative deliberations of funding for essential public health programs, or in the curricula of our public schools where human reproductive and sexual health issues could be addressed.

In this issue of the Journal, we have invited persons who have led the effort of our state and local public health and education agencies in confronting the problems of STDs to describe the problems faced in this area, as well as some of the programs and initiatives they have sponsored to address these problems. It is not always either easy or straightforward to determine the incidence or prevalence of each of the types of STDs reportable in our state, as Lynne Sampson describes in her Running the Numbers section. But, as Drs. Arlene Sena and Marcia Hobbs point out, screening technologies for most STDs have greatly improved in recent years. Dr. Peter Leone describes current science and best practice for the detection and clinical management of acute HIV infection and makes the case for early intervention by healthcare professionals to prevent the spread of this disease. We are fortunate that Dr. P. Frederick Sparling, one of the nation's leading specialists in infectious disease research, has contributed a brief overview of the prospects for vaccines to protect and prevent these diseases in the future.

Given the fact that nearly half of all newly diagnosed STDs (including HIV) in our state occur among adolescents between the ages of 15 and 24, there is an urgent need for additional attention to these issues through our public schools. North Carolina is one of the states where concerted action with regard to STDs appears to be most urgently needed. It is alarming to read, as one can in Dr. Cline's Issue Brief, that of the 28 US counties reporting over 50 percent of the nation's primary and secondary syphilis cases in 1998, five of these counties were in North Carolina! Special attention to the efforts in two of these counties (Guilford and Robeson) among sex workers are described in this issue, but one can see from reading these accounts just how complicated and frustrating these efforts can be.

We hope by bringing more attention to these issues through these pages that we can see in the year ahead a renewed commitment to address the difficult challenge of STDs in our state and our communities where these problems are most evident.

Gordon H. DeFriese, PhD
Editor-in-Chief

Sexually Transmitted Diseases:
Will This Problem Ever Go Away?

J. Steven Cline, DDS, MPH

One of the oldest professions in the world may also be related to one of the oldest public health problems in the world—sexually transmitted diseases. In 2005, more than 18 million new cases of STDs (sexually transmitted diseases) were reported in the United States, with 54,500 cases in North Carolina alone. While these diseases are of epidemic proportion, we actually see surprising little about them in the media and we talk about them even less. A 1997 national Institute of Medicine report stated that "sexually transmitted diseases (STDs) are hidden epidemics of tremendous health and economic consequence in the United States. They are hidden from public view because many Americans are reluctant to address sexual issues in an open way and because of the biological and social factors associated with these diseases."[1] According to this report, in 1995 the United States had the highest rates of curable STDs in the developed world, with approximately 12 million new cases of STDs annually, three million of them occurring among teenagers. Little public outcry has been heard since then and little progress has been made in the last ten years.

> *"Why can't we make this problem go away?"*

Historically, it is easy to accept that STDs were a problem before we even understood the germ theory of how infections are spread. Similarly, in 1918, at the time of the Spanish flu epidemic, infections such as influenza and STDs were common, but not commonly understood. However, now the United States has the most advanced healthcare system in the world, a wide variety of powerful antibiotics, modern infection control practices, and a multitude of tried and true methods individuals can use to prevent STDs. Most sexually transmitted diseases and conditions are entirely preventable and many curable. Obviously, this is not just a problem of healthcare. As a practicing public health professional in North Carolina and a parent to four teenagers who are soon to enter the "at risk" population, I consider this to be unacceptable.

Why can't we make this problem go away?

The Problems Presented by STDs

STDs are transmitted through unprotected sex with someone who has the disease. Since many STDs are asymptomatic, STDs are frequently transmitted by persons who unknowingly are infected. Any person who is sexually active or who becomes sexually active is at risk.

In North Carolina, there are nine sexually transmitted diseases or conditions that are reportable to state and local public health agencies. They include: chlamydia, gonorrhea, syphilis (all stages and types), chancroid, granuloma inguinale, hepatitis B, HIV/AIDS, lymphogranuloma venereum (LGV), and nongonococcal urethritis (NGU). Historically, North Carolina has experienced consistently high rates of syphilis, gonorrhea, chlamydia, and HIV/AIDS when compared to other states.[2] There are also a number of sexually transmitted illnesses such as human papillomavirus (HPV) that are not reportable in North Carolina. The "Running the Numbers" department of this issue of the *North Carolina Medical Journal* includes a discussion authored by Lynne Sampson describing the problems of drawing inferences about the prevalence of STDs from available reportable data.[3]

There are 30 known strains of HPV, some strains causing no symptoms, others causing genital warts, and still others that cause cervical cancer. HPV is a leading cause of cervical cancer in the United States. It is believed to be implicated in an average of 300 cases of cervical cancer reported in North Carolina each year. The Centers for Disease Control and Prevention (CDC) estimates that over 50 % of sexually active adults will acquire HPV at some point in their lives.[4] Genital herpes is also common, but not reportable. An estimated 45 million cases of genital herpes, primarily caused by type 2 herpes simplex virus (HSV-2), occur each year in the United States,[5] but few states require reporting of these cases. Other STDs not reportable in North Carolina include trichomoniasis and bacterial vaginosis.

J. Steven Cline, DDS, MPH, is the Deputy State Health Director in the Division of Public Health, NC Department of Health and Human Services. He can be reached at steve.cline@ncmail.net. Telephone: 919-715-6733.

Table 1.
North Carolina Reportable Sexually Transmitted Diseases, 2005

	Sex			
	Male	Female	Unknown	Total
Chlamydia (lab-confirmed)	5,481	25,702	0	31,183
Gonorrhea	7,529	7,546	0	15,075
Syphilis				
Primary Syphilis	81	15	0	96
Secondary Syphilis	135	43	0	178
Early Latent Syphilis	127	88	0	215
Late Syphilis	80	71	0	151
Late Latent Syphilis	34	25	0	59
Late Syphilis w/symptoms	0	0	0	0
Neurosyphilis	0	2	0	2
Congenital Syphilis	5	5	1	11
Syndromic Diagnoses				
Nongonococcal Urethritis (NGU)	5,318	n/a	0	5,318
Mucopurulent Cervicitis (MPC)	n/a	24	0	24
Pelvic Inflammatory Disease (PID)	n/a	382	0	382
Other STDs				
Chancroid	5	0	0	5
Granuloma Inguinale	1	3	0	4
Lymphogranuloma Venereum (LGV)	3	0	0	3
Opthalmia Neonatorum (gonorrhea)	0	0	0	0

Undiagnosed and/or untreated STDs contribute to the higher than average rates of infant mortality and preterm births in North Carolina and are a leading cause of infertility across the country. Other common, yet serious, medical implications of STDs include such things as syphilitic meningitis, neurosyphilis, chronic hepatitis, cirrhosis, liver cancer, endometritis, and even death. Despite advances in healthcare, HIV infection remains a fatal disease. We're not just talking about a curable STD rash, but serious infections with serious potential consequences for individual and community health.

According to data collected by the HIV/STD Prevention and Care Branch of the Division of Public Health, over 54,500 new STDs were reported in North Carolina in 2005. These included 11 cases of congenital syphilis and 1,806 new cases of HIV disease. Specific disease trends vary by disease and from year-to-year. Some STDs, such as gonorrhea, have actually declined over the last ten years while the number of reported chlamydia cases has increased among 20 to 29 year olds. It is important to note that screening for chlamydia has increased in publicly-funded clinics over the past several years, and in May of 2004 the State Laboratory of Public Health began using a more sensitive screening test. This likely accounts for the increase in detected cases. Hepatitis A, B and C, often not appreciated as STDs, accounted for an additional 1,100 STD case reports in 2005. STD screening and reporting varies from provider-to-provider, therefore performing a statewide STD trend analysis can be challenging.

The high rates of STDs affecting North Carolina are typical across the predominantly rural South. For the past decade, southern states consistently led the nation in reported cases of syphilis, chlamydia, gonorrhea, and new AIDS cases.[6] In 2002, the CDC reported that seven of the states with the highest AIDS case rates in the nation were located in the South. Similarly, in 2000, all of the states with the highest rates of gonorrhea and nine of the top ten states with regard to infectious syphilis were in the South.[7] These trends are still true today. The direct and indirect human and economic costs associated with these diseases in the rural South have been well documented by state and national organizations, public health experts, and healthcare researchers. Higher rates in the South are influenced by differences in the racial and ethnic distribution of the population. These differences are linked to higher rates of poverty and the availability and quality of healthcare services.[7] STDs, including HIV/AIDS, disproportionately and unacceptably affect persons of color, particularly across the South. Poverty, access to quality healthcare (including prevention services and education), cultural factors such as the lack of trust for the healthcare system, and social stigma are all strongly linked to high rates of STDs and HIV/AIDS among persons of color.

CHALLENGES: Why Is This So Difficult?

Missed Opportunities

There are two myths that are prevalent in North Carolina. The first is the belief that STDs, including HIV, only happen to people who do bad things or make bad choices. The second is that only the people who have these conditions are directly affected by them. These beliefs, whether openly expressed or quietly implied, keep individuals from seeking rapid treatment for themselves and their sexual partners. The fear of being stigmatized, and the lack of awareness about the true risks of acquiring an STD, keep the epidemic alive in our communities.

The false assumptions about who is at risk for HIV/STD infections affect screening and counseling practices of public and private healthcare providers. While STD and HIV screening and counseling are a regular part of the standard of care in local public health departments and community health centers, it is normally not a part of routine screening in many private practices.

For example, one North Carolina study found that among primary care providers in Wake County in 1997 less than 25% offered routine screening for chlamydia, despite the fact that this disease is the most frequently reported bacterial STD and one that is easily treated.[7] Preventing and treating STDs is also critical because of the strong evidence that a person with a STD is more likely to acquire HIV infection, and if an individual is co-infected, they are more likely to transmit their HIV infection to others.[8] Early diagnosis and treatment of STDs is a critical public health strategy to reduce the spread of new HIV/AIDS in both the public and private healthcare sectors. CDC just released new guidelines to strongly encourage that HIV screening become a regular and routine part of all healthcare settings in this country.

Access to Care and Cultural Competency

Access to care and the ability to provide culturally-appropriate health services are inextricably tied together. Traditional barriers to care, such as being un- or under-insured, lack of transportation, lack of providers in many rural areas, and inconvenient hours of operation are common for most health services, and certainly impact STD care as well. But, even if patients are able to seek care in their communities, the issues of stigmatization, confidentiality, and cultural differences make STD care particularly challenging for providers and patients.

Adolescent Sexual Health

Nearly half of all the new sexually transmitted diseases and HIV infections occur in youth between the ages of 15 and 24. Adolescents are at increased risk because of their risk-taking behaviors and lack of awareness about HIV/STDs. In 2005, North Carolina high school students participated in the 2005 Youth Risk Behavior Survey (YRBS) that assessed the behaviors that put them at risk for various health problems. These behaviors included diet, exercise, tobacco use, and sexual behavior.[9] The results revealed that 50.8 % of all high school students and 63% of high school seniors self-reported that they had experienced sexual intercourse. Eight percent of students reported having sex before the age of 13. In four of the five risk-taking categories examined, the percentage of North Carolina adolescents engaging in risky sexual behaviors was greater than the national average.[9]

The debate about how North Carolina should address these alarming statistics is strongly mixed. While most people believe that parents/guardians and schools should play a strong role in educating our young people about HIV/STD and teen pregnancy prevention, there is conflict about what the prevention messages should be, how often they should be taught, and at what ages. The role of public education in meeting the challenges of the STD epidemic is the focus of the commentary in this issue of the *North Carolina Medical Journal* by Sherry Lehman.[b]

The North Carolina General Assembly enacted the Abstinence Until Marriage Law in 1995 which instructs the State Board of Education about what to include in the health curriculum taught in North Carolina public schools. The Healthful Living Standard Course of Study sets the goals and objectives by grade for human sexuality education for North Carolina in accordance with the Abstinence Until Marriage Law. This law promotes "abstinence only" education in grades 7 through 12. Many people are concerned that sexually active adolescents are not being provided with all the information they need to reduce their risks of getting a STD or HIV infection. Still others argue that the only message North Carolina teens should get in school is that abstinence is the only absolute way to prevent getting these diseases. They believe that talking about other risk reduction methods (i.e., condom use) is not appropriate. This is a critical conversation for North Carolina. We need to seriously examine this question in light of the fact that many adolescents are having unprotected, high-risk sex and experiencing high rates of STDs, including HIV, not to mention unplanned adolescent pregnancies. In early 2002, North Carolina uncovered a previously unrecognized HIV outbreak among young adults attending college or linked to students attending college. This outbreak received national attention and it supports the notion that North Carolina's young adults are not hearing (or paying attention to) our HIV/STD prevention messages.

Racial and Ethnic Disparities

Syphilis—Syphilis disproportionately affects minority communities in North Carolina. Rates for African Americans, American Indians/Alaska natives, and Hispanics are many times higher than for corresponding white groups. A complex combination of healthcare access, poverty, racism, and the composition of sexual networks produces this disparity in syphilis rates. In 2005 rates among African American males were four times higher than among whites. Hispanic rates were two times higher than for whites. Racial disparities in male syphilis rates have improved slightly over the past five years due in part to decreasing syphilis rates in minorities generally, and increasing rates among white men. Syphilis rates among all women regardless of color have declined dramatically over the past five years from 10.5 cases/100,000 in 2001 to 3.4 cases/100,000 in 1005. There has been a modest improvement in the disparity between white and black female rates as well. In 2005, the early syphilis rate for African American women was approximately 10.5 times the rate for white women. By 2005, African American female rates had declined to approximately 8.5 times the rate for white females.[2]

Unfortunately, North Carolina continues to suffer from cases of congenital syphilis. In both 2004 and 2005, eleven infants were born to mothers who had active or inadequately treated cases of syphilis, the majority of whom were African American. This is down from previous years (21 infants in 2003, 15 in 2002, and 19 in 2001), but remains unacceptably high. Six of the eleven women in 2004 did not have any prenatal care (PNC) prior to delivery and an additional three had less than five total PNC visits. Women who do not receive adequate PNC services often miss opportunities for screening. According to the North Carolina Pregnancy Risk Assessment Monitoring System (PRAMS) survey for 2003, 18.4% of North Carolina mothers reported a barrier to receiving prenatal care services.[11] Younger mothers and those of African American or Hispanic race/ethnicity were most likely to report barriers to prenatal care.

Gonorrhea—There is some good news in that severe racial disparities in gonorrhea incidence rates are on the decline among males. In 2001, rates among African American males were 32 times the rates for white males. The disparity decreased to 22 times higher in 2005. Disparities among females have remained relatively steady, with African American female gonorrhea rates 10 to 14 times higher than rates for white females over the five-year period.

Chlamydia—Racial disparities in female chlamydia reports have remained stable over the past five years (2001-2005), with seven-to-eight times more cases reported among African American females and three-to-five times more cases among American Indian/Alaska Native and Hispanic females.

HIV/AIDS—An estimated 29,500 persons were living with HIV or AIDS in North Carolina (including persons who may be unaware of their infection) as of December 31, 2005. In 2005, the rate of HIV infection for non-Hispanic blacks (61.4 per 100,000) was more than seven times greater than for non-Hispanic whites (8.6 per 100,000). The rate of infection for Hispanics (24.1 per 100,000) was almost three times greater than for whites, and the rate of infection for American Indians (20.6 per 100,000) was over twice the rate for whites. The highest rate of HIV infection in 2005 was among African American non-Hispanic males, at 88.6 per 100,000. This was more than six times more than white non-Hispanic males (14.4/100,000). The greatest disparity observed in 2005 was for African American non-Hispanic females, with a rate of HIV infection (37.3 per 100,000) that was over 12 times higher than for white non-Hispanic females (3.0 per 100,000).

NOTEWORTHY SUCCESSES: What is Working?

Despite the challenges, North Carolina has made progress on several important fronts. The following section describes several efforts that are showing positive results in reducing the rates of these diseases.

STD Services in Local Health Departments

In North Carolina, all 100 local health departments offer free and confidential STD and HIV/AIDS services. Many community, academic, and faith-based organizations also offer STD and HIV/AIDS screening and counseling. Faith-based organizations have been very successful in some communities in linking persons into care and prevention services, or in offering some HIV/STD screening. North Carolina academic and research partners have continued to play enormous roles in developing best practice models and keeping STD and HIV/AIDS on the radar screen nationally. North Carolina was the first state to implement an acute HIV screening program, which allows for the detection of HIV in individuals even before they have had a chance to mount an antibody response.[12] Peter Leone describes these efforts in a commentary in this issue of the *North Carolina Medical Journal.*[13] Successful North Carolina interventions are the subject of a subsequent article by Evelyn Foust in this issue of the *North Carolina Medical Journal.*[14]

Syphilis Elimination

In 1998 CDC reported that over 50% of all the United States primary and secondary syphilis cases were reported from just 28 counties. Five of those counties were in North Carolina, a number greater than for any other state. The counties were Forsyth, Guilford, Mecklenburg, Robeson, and Wake. Many of these cases occur among sex workers in these communities. To assist in addressing the evident need, CDC awarded the North Carolina Division of Public Health additional funding to participate in the National Plan to Eliminate Syphilis.[15] Due to the efforts of NC's local county health departments, community-based organizations, and state disease intervention staff, early syphilis now has been reduced by 69%. North Carolina has been able to demonstrate that community-based interventions, combined with traditional approaches, are effective in reducing STDs.

Commentaries by Merle Green and Jonathan Lucas of Guilford County and by Melissa Packer, April Oxedine, and Karen Woodell of Robeson County in this issue of the *North Carolina Medical Journal* describe the extensive, community-based efforts required to address the epidemic of syphilis among NC sex workers.[16,17]

Vaccines Against STDs

In May of 2001, the Food and Drug Administration (FDA) licensed a combined hepatitis A and B vaccine (Twinrix®) for use in persons over the age of 18. Currently, the vaccine is available at almost all (96%) of the local health department STD clinics across the state. The vaccine is administered as a three-dose series. This project was started in 2003 by HIV/STD Prevention and Care Branch staff in collaboration with the State Immunization Branch. Healthcare providers were educated about the importance of this new combination vaccine and strongly encouraged to offer the vaccine to everyone over 18 years of age who is seen for an STD visit. Targeted risk factors include HIV positive status, Hepatitis C virus positive status, injecting drug use, men who have sex with other men, anyone having a male sex partner, and incarceration. Based on utilization from January through June of this year, it is estimated that approximately 5,600 persons will be vaccinated. Frederick Sparling, a distinguished infectious disease scientist from the University of North Carolina at Chapel Hill, addresses the prospect for vaccines to prevent STDs in this issue of the *North Carolina Medical Journal.*[18]

In June of 2006, the first vaccine for human papillomavirus (HPV) was recommended by the Advisory Committee on Immunization Practices for use in the prevention of cervical cancer caused by four of the HPV types. The HPV types included in the vaccine (Gardasil®) are responsible for approximately 70% of the cervical cancers and 90% of genital warts. Currently the vaccine is recommended for 11-to12 year-old girls, but it can be used in girls as young as 9 years old and up to age 26 at the provider's discretion. It is recommended for girls/women who have not been immunized against HPV. Ideally, immunization would be provided before sexual activity begins, since it will be ineffective if the individual has already been exposed to an HPV type covered by the vaccine. The vaccine is not effective as a treatment for existing HPV, genital warts, cervical cancers or precancers.

The Center for HIV-AIDS Vaccine Immunology (CHAVI) is a major component to the Global HIV Vaccine Enterprise. In July 2005, the National Institute of Allergy and Infectious Diseases (NIAID) awarded the CHAVI grant to a consortium of investigators from Duke University, Beth Israel Deaconess Medical Center, the Dana-Farber Cancer Institute, the University of Alabama-Birmingham, and Oxford University. Dr. Barton Haynes at Duke University is the CHAVI principal investigator and the consortium consists of a group of investigators who are well known as having made significant scientific contributions to HIV vaccine design and to the current basis of knowledge of HIV transmission and infection. The initial research focus will be on understanding the host immune response in the acute stages of infection. Other lead investigators in North Carolina include David Goldstein of Duke University and Myron Cohen of the University of North Carolina at Chapel Hill.

Screening Pregnant Women for HIV

Since 1994, there has been a requirement that pregnant women be offered testing for HIV as a part of regular prenatal care. The North Carolina Administrative Code was modified in 2003 so that all pregnant women would be tested unless they specifically declined such testing. This "opt out" approach to prenatal testing is very effective at promoting testing for women who have prenatal care; however, it does not improve testing for women who do not receive routine prenatal care. The benefit of prenatal testing, especially when combined with the program for acute HIV screening, is undeniable. In the North Carolina State Laboratory of Public Health (SLPH), in addition to the typical HIV antibody testing, patient lab samples are screened for the presence of genetic material (RNA) that would indicate possible HIV infection prior to the development of antibodies. This is innovative new testing technology that is discussed in greater detail in a subsequent article by Arlene Sena and Marcia Hobbs in this issue of the *North Carolina Medical Journal*.[19] Since the implementation of the acute HIV screening program through the SLPH, five pregnant women have been identified with acute HIV infection. These women were tested as the rule requires, and under the previous testing algorithm would have been told they were negative. They would likely have progressed through pregnancy and delivered HIV-exposed infants. Given the likely 25-30% vertical transmission for mothers who are not provided prenatal antiretroviral therapy, it is probable that at least one of the babies would have been infected. However, since the woman's HIV infection was determined and all were provided appropriate prenatal antiretroviral medication, all five babies have been determined not to be infected.

Jail Screening

As part of the Syphilis Elimination Project (SEP), syphilis screening was initiated in the seven county jails in the six SEP counties (Durham, Forsyth, Guilford, Mecklenburg, Robeson, and Wake). Inmates are given counseling on syphilis and other STDs and blood is collected for screening by a nurse or trained phlebotomist. Data collection began in 2002 and analysis shows that the screening is highly effective in identifying new cases. From 2002 to 2004 the program screened 20,552 inmates (17.5% female). There were 742 seropositives, which yielded 121 new cases of syphilis. Screening female inmates seems to be of particular value because they are more likely to be seropositive (8.11% compared to 2.65% for males) and more likely to be new cases (0.97% compared to 0.51% for males). The effort to address the STD epidemic among incarcerated populations is described by Lynne A. Sampson in this issue of the *North Carolina Medical Journal*.[20]

Conclusions

Despite the undisputed impact of STDs, and how much we have learned about how to treat and prevent them, North Carolina public health authorities still struggle to ensure that STD/HIV prevention and control strategies remain high priorities in both private and public healthcare clinics. Most sexually transmitted diseases and conditions are preventable and many curable. However, the establishment of routine screening, and successful prevention and education programs are challenged by lack of resources and public awareness.

Sexually transmitted diseases are a serious problem in North Carolina that won't go away. This is the case of a traditional public health problem that the traditional way of thinking will not solve. Societal attitudes, false beliefs, fears, and our inability to talk honestly and openly about sexual behaviors are getting in the way. STDs are not reserved for a small subset of our society. STDs are equal opportunity infections. The bottom line is that infection with either HIV or another STD is a risk for any sexually active individual. Early education and risk reduction counseling for all sexually active individuals is a must, regardless of age. Routine screening and counseling for these diseases should be the standard of care for all patients in all healthcare settings.

STD and HIV/AIDS programs at the state and local levels remain highly controversial, lack strong public approval, are significantly underfunded, and are frequently fractured at service delivery points. With a father who is a public health professional, my own children have heard this sad story all too often. The risks they face are real and the consequences of ignoring them can be fatal. We can, and we MUST, do better. **NCMedJ**

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

Current and Best Practices for Testing of Sexually Transmitted Diseases

Arlene C. Sena, MD, MPH, and Marcia Hobbs, PhD

Effective diagnosis and treatment of infected persons is a critical component of sexually transmitted diseases (STDs) prevention and control. STD diagnostic methods that are sensitive, rapid and inexpensive are ideal for testing of individuals presenting with genitourinary symptoms and screening of asymptomatic individuals in high risk populations. Fortunately, recent advances in STD diagnostics have provided nucleic acid amplification tests (NAATs) with increased sensitivity compared to older tests and rapid "point-of-care" (POC) tests, with quick turn-around time for results. However, despite their ability to improve best practices for STD management, NAATs and POC tests have not been widely adopted into public and privately funded practices. This may in part be due to barriers ranging from the cost and complexity of some of these methods to unfamiliarity with application of these new technologies for the testing and screening of at-risk patients.

> *"A recent national survey of physicians, in which the majority practice in private clinics, reported that fewer than one-third routinely screened men or women (pregnant or non-pregnant) for STDs."*

Although federal resources for the control and prevention of STDs are primarily distributed to state and local health departments, the National Health and Social Life Survey reported that STDs are frequently treated in private practice settings.[1] Therefore, consideration of the ideal STD testing methods to use in the apparently low prevalence populations evaluated in private clinics is as crucial as application of these technologies in high prevalence populations presenting to STD clinics and emergency rooms.

New STD Diagnostic Methods

Currently available NAATs for Neisseria gonorrhoeae and Chlamydia trachomatis are based on new technologies, including polymerase chain reaction (PCR), DNA strand displacement assays (SDA), or transcription-mediated amplification (TMA) using vaginal, cervical, urethral or first-void urine specimens (Table 1).[2] Self-collected vaginal swabs may also be used in settings where physical examinations are limited for women.[3] Diagnosis of gonorrhea and chlamydia was previously reliant on cultures, enzyme immune assays (EIA), and non-amplification DNA probe assays to detect these organisms. The use of NAATs is now considered the "gold standard" for C. trachomatis; however, despite the availability of NAATs for gonorrhea, culture remains in widespread use since it allows assessment of antimicrobial susceptibility which is currently unavailable with amplification tests. Combination NAATs are available for N. gonorrhoeae and C. trachomatis using a single patient specimen,[4] which is advantageous among high-risk populations in light of the frequency of co-infections with these pathogens. However, NAATs are not approved for detection of gonorrhea or chlamydia in rectal or pharyngeal specimens.

NAATs also hold promise in the future for diagnosis of other STDs. PCR and TMA for Trichomonas vaginalis are more sensitive than culture for diagnosis of trichomoniasis in

Arlene C. Sena, MD, MPH, is Associate Professor of Medicine, Division of Infectious Diseases at the University of North Carolina at Chapel Hill, NC and is Medical Director of the Durham County Health Department, Durham, NC. She can be reached at idrod@med.unc.edu. Telephone: 919-966-2536.

Marcia M. Hobbs, PhD, is Associate Professor of Medicine, Microbiology and Immunology at the University of North Carolina at Chapel Hill, NC.

Table 1.
Common STD Syndromes, Most Likely STD Etiologies and Performance Estimates of Selected Available Diagnostic Technologies [2,4,7,10-13]

STD Syndrome	Most Likely STD Etiologies	Available Diagnostic Technologies	Estimated Sensitivity (%): Specific (%)*
Vaginitis/ cervicitis	Trichomonas vaginalis	Wet mount microscopy	30-60; 100
		Culture	80-90; 100
		Rapid antigen test	78-83; 98-99
	Chlamydia trachomatis	Enzyme immunoassay	53-76; 95
		Direct fluorescent antibody	80-85; >99
		Probe hybridization	65-83; 99
		Polymerase chain reaction (cervical)	90; 99
		Strand displacement assay (cervical)	93; 98
		Transcription-mediated amplification (cervical)	94; 98
	Neisseria gonorrhoeae	Culture (Thayer-Martin)	80-95; 100
		Probe hybridization	93-96; 99
		Polymerase chain reaction (cervical) (urine)	92; 100 65; 100
		Strand displacement assay (cervical) (urine)	97; 98 -100 85; 99-100
		Transcription-mediated amplification (cervical) (urine)	99; 99 91; 99

		Transcription-mediated amplification (urethal) (urine)	95; 98 97; 99
	Neisseria gonorrhoeae	Culture Probe hybridization	As above
		Polymerase chain reaction (urethral) (urine)	97; 97 94; 100
		Strand displacement assay (urethral) (urine)	99; 92-100 98; 93-100
		Transcription-mediated amplification (urethral) (urine)	99; 98 97; 100
	Trichomonas vaginalis	Culture	50; 100
Genital ulcers	Herpes simplex virus	Culture	73-100; 100
		Type-specific ELISA serology	81-100; 96-99
		Rapid antibody test (HSV-2)	93-96; 95-98
		Polymerase chain reaction	98-100; 98-100
	Treponema pallidum	Non-treponemal tests	78-86; 98
		Treponemal tests	87-100;
		Rapid antigen tests	70-88; 100
		Enzyme immune assay	71; 98

* Ranges for test performance of the diagnostic technologies reflect broad differences in reference standards and patient populations.

both men and women, but these molecular tests are available only in clinical research settings.[5] PCR and TMA assays have been developed for Mycoplasma genitalium, which has been recently established as a case of non-gonococcal urethritis (NGU) in men, but the future clinical application of these tests is uncertain.[6] For the evaluation of genital ulcer disease, a PCR for herpes simplex virus (HSV) has enhanced performance over viral isolation with culture, but is not yet approved by the Food and Drug Admininistration (FDA) for testing of genital specimens.[7] A multiplex PCR test for HSV, Treponema pallidum (syphilis), and Haemophilus ducreyi (chancroid) has been developed and continues to be investigated for clinical application.[8]

For human papilloma virus (HPV), there is a commercially available signal-amplified nucleic acid assay and PCR to detect high-risk HPV types associated with cervical cancer.[9] These HPV DNA tests are currently being considered for cervical cancer prevention (along with the Pap smear) including primary screening for high-grade lesions among women >30 years of age. They are not intended to assist in the diagnosis of external genital warts which are primarily associated with benign HPV types.

There are several STD rapid tests which have the advantage of immediate diagnosis in clinics serving both high- and low-prevalence populations. For T. vaginalis, a POC test that uses an immunochromatographic capillary flow (dipstick) assay to detect parasite antigens in vaginal specimens can provide results in 10 minutes.[10] Compared to culture, this rapid test for trichomoniasis has a sensitivity and specificity which is superior to wet mount microscopy (Table 1), but is only approved for use in women. Rapid syphilis tests have also been introduced using an immunochromatographic strip with finger-stick or whole blood to detect antibodies to T. pallidum antigens.[11] However, these tests would be reactive in all patients with prior syphilis, which limits their potential use for testing or screening in low prevalence clinic populations.

There are several new serologic tests for diagnosis of syphilis and HSV that are worth noting. Recently, an immunoglobulin G (IgG) EIA has become available as a diagnostic test for syphilis.[12] This test, which detects treponema-specific antibodies, has the potential to be automated and produces an objective result without requiring confirmation (unlike the reactive plasma reagin [RPR] or other non-treponemal tests). Clinicians now have a choice of several type-specific HSV antibody tests based on the glycoprotein G antigens of HSV-1 and HSV-2.[13] These serologic tests in an enzyme-linked immunosorbent assay (ELISA) format can be used to supplement culture and physical examinations to confirm a clinical diagnosis, to diagnose a person with unrecognized infection, and to manage sexual partners of persons with genital herpes. In addition, rapid POC tests for HSV-2 antibodies (not HSV-1) using capillary blood or serum are also available and can provide results within six minutes.

Current Practices for STD Testing

Unfortunately, publicly-funded STD clinics in North Carolina that evaluate large numbers of patients with suspected STDs have limited access to these advanced technologies for routine STD testing and screening. Currently, evaluation of vaginitis still relies on insensitive wet mount microscopy for diagnosis of candidiasis, bacterial vaginosis, and trichomoniasis. While a urethral Gram stain is typically performed in the evaluation of NGU, pathogens other than C. trachomatis, including T. vaginalis and M. genitalium, are not usually tested for in men. Testing for gonorrhea and chlamydia still rely on culture or DNA hybridization probes in many public clinics. Targeted screening for chlamydia is frequently performed based on age or gender due to limited funds. Initial testing for syphilis consists of the non-treponemal tests, which require confirmation at the state laboratory (which recently switched to the IgG EIA for T. pallidum for confirmatory testing). Some local public health department laboratories have the capability to perform stat RPRs with available results in 15 minutes and darkfield microscopy for direct visualization of treponemes. Diagnosis of HSV or HPV is often based on clinical presentations, since HSV viral cultures that can be sent to the state laboratory are usually reserved for atypical lesions.

Emergency rooms and private clinics may be better able to use newer technologies for detecting bacterial STDs, including gonorrhea, chlamydia, and syphilis. However, a national survey of physicians conducted in 2002 found that only 1.3% and 1.8% of clinicians used newer urine-based tests for gonorrhea and chlamydia, respectively, although these tests are less invasive and more acceptable to patients.[14] In general, there is little to no information in the literature on the use of newer diagnostic methods for the other bacterial and viral STDs in these clinical settings.

Although some emergency rooms that serve a large number of high-risk patients in urban areas have been reported to have a high prevalence of STDs like gonorrhea ranging from 1.7-11.0%,[15] screening rates in these settings are typically lower than in other settings. A recent national survey of physicians, in which the majority practice in private clinics, reported that fewer than one-third routinely screened men or women (pregnant or non-pregnant) for STDs.[14] The survey found that screening rates among non-pregnant women ranged from 20-35% and were slightly higher for pregnant women at 30-32%. Physicians in the survey who saw male patients rarely screened for syphilis, gonorrhea or chlamydia.

Opportunities for Best Practices

With the increasing availability of improved technologies for STD diagnosis, including highly sensitive and rapid tests, we now have the opportunity to improve current practices for STD testing and screening in various clinical practices as well as non-traditional settings. However, the costs and complexities of the NAATs for gonorrhea and chlamydia are barriers to their widespread application, especially in STD clinics with limited funding or small private practices without access to advanced laboratories. Although they are less sensitive than NAATs, POC tests may be more affordable and easier to implement. Positive results from these tests eliminate the need for a return visit and increase treatment rates; therefore, POC tests should be strongly considered, especially in the diagnosis of T. vaginalis and HSV-2 infections which are the most common STDs.

Public STD clinics clearly need access to sensitive molecular diagnostic tests for gonorrhea and chlamydia among all high-risk patients, including men. However, N. gonorrhoeae cultures would still be useful in cases of persistent infections in order to test for antimicrobial resistance. T. vaginalis testing should become routine in both men and women using culture or rapid antigen tests; wet mount microscopy alone is clearly suboptimal for organism detection. Use of the HSV type-specific serology and the POC test for HSV-2 could greatly enhance the diagnosis and management of patients with atypical lesions as well as their sexual partners. The availability of the multiplex PCR test for detection of T. pallidum, HSV, and H. ducreyi would assist in the differential diagnosis of genital ulcers which are frequently seen in these clinics.

STD management in emergency rooms and private clinics could be optimized with the use of urine-based NAATs for N. gonorrhoeae and C. trachomatis and POC tests for T. vaginalis and T. pallidum for testing of symptomatic persons. Utilization of POC tests that can be performed in less than 30 minutes in the emergency room or a doctor's office would allow rapid diagnosis and treatment without a need for subsequent follow-up appointments.

Emergency rooms and private practices present an opportunity for targeted STD screening among asymptomatic at-risk patients, who can be easily determined by adding a brief sexual history as part of their clinic encounters. Adolescents, substance abusers, and persons who report multiple sexual partners should be strongly considered for screening, at least for the bacterial STDs using non-invasive molecular assays or POC tests. The positive predictive values of NAATs , like that of all diagnostic tests, is reduced in low prevalence populations with a greater potential for false-positive tests. However, their increased sensitivity compared to culture make NAATs particularly useful in detecting asymptomatic infections among persons with lower organism burdens.Although STD screening of sexually active women should be prioritized, screening of high-risk asymptomatic men for the most common STDs is important to prevent transmission of undetected infections to their sexual partners.

Approximately 1.3 million cases of bacterial STDs (gonorrhea, chlamydia, early syphilis) were reported in the United States in 2004, and roughly 47,000 cases were reported in North Carolina in 2005.[16-17] In 1994, the total costs for the most common STDs and their sequelae, including pelvic inflammatory disease and adverse pregnancy outcomes, were estimated to be approximately $10 billion dollars annually.[18] The epidemiologic and biologic associations between STDs and HIV infection underscore the importance of STD management as an HIV preventive strategy. We need to prioritize funds and efforts towards increased utilization of the newer STD diagnostic tests in public and privately-funded practices to maximize the detection, treatment and prevention of these highly prevalent infections and their subsequent complications. **NCMedJ**

Public Health Approaches to North Carolina's STD Epidemic

Evelyn M. Foust, CPM, MPH

The National Vision

The Institute of Medicine's Committee on Prevention and Control of Sexually Transmitted Diseases in their 1997 report The Hidden Epidemic, *Confronting Sexually Transmitted Diseases*, concluded that an effective national system of STD Prevention did not exist.[1] As they discussed gaps, new approaches and collaborations, they developed the following vision statement to guide their work:

"An effective system of services and information that supports individuals, families, and communities in preventing STDs, including HIV infection, and ensures comprehensive, high-quality STD related health services for all persons."[1]

This vision recognizes that successful STD prevention systems must insure individual and community participation, and coordination of related programs. While identifying and commiting adequate local and statewide resources and support to implement STD programs are critical, successful STD programs are built upon collaborations which involve a wide variety of stakeholders.

Components of North Carolina's STD and HIV programs are frequently cited as national models. North Carolina's STD and HIV programs are a mix of traditional and community-based approaches. This mix, combined with strong program-to-program collaborations and strategies, have strengthened our collective ability to prevent the spread of STDs, including HIV/AIDS, despite our serious funding challenges.

Traditional Collaborations That Work: Local Health Departments And Disease Intervention Specialists (DIS)

Communicable disease programs, like STD programs, are primarily designed to protect the public health by identifying and treating infected individuals and by notifying and (when appropriate) treating exposed partners, households, networks, or all the above. The confidential nature of this work is protected by law. North Carolina confidentiality provisions are specific and are designed to both prevent the inappropriate release of medical information pertaining to infected and exposed individuals and to protect the public health by allowing for the release of information under specific circumstances. There is a delicate balance between protecting the rights of individuals and protecting the public health.

Traditional "shoe leather" epidemiology starts with timely disease reporting by diagnosing physicians and/or laboratories. North Carolina has a strong public health system and an even stronger commitment to supporting local public health authorities. North Carolina public health law and rules provide local health departments with clear authority and responsibilities pertaining to the reporting and investigation of communicable diseases. North Carolina is fortunate to have a local health department presence in all 100 counties. This presence helps insure that North Carolina public health laws are followed by individuals infected with and /or exposed to a communicable

"...North Carolina relies on partnerships and collaborations to advance STD prevention work. Often the best examples of model STD practices are those that pull traditional providers and community-based partners together."

disease (through enforcement of control measures) and in conjunction with physicians, hospitals, labs and community providers through whom diagnosis and treatment of people with STDs are available. Local health departments also provide confidential medical and counseling services that include STD and HIV disease diagnosis, treatment, referral, partner notification, community outreach and health education.

For STDs like syphilis and HIV/AIDS, local health departments often use Disease Intervention Specialists (DIS) to find persons who are infected and bring them to treatment, or find and notify partners that they may have unknowingly been exposed to a STD. Local health departments are often assisted in the performance of their investigation and control responsibilities by the state's HIV/STD Prevention and Care Branch Field Services staff. The state DISs are located regionally and are trained by the state and/or the Centers for Disease Control and Prevention (CDC) to work with local authorities, private providers, community-based organizations, and hospitals to insure that persons newly diagnosed with syphilis and/or HIV/AIDS understand their diagnosis, are referred to care, and are given appropriate counseling and control measures. These staff also provide confidential partner notification services and often draw blood samples in the field to assist the partner in determining their health status. In 2005, 15% of the named partners exposed to HIV and 20% of the named partners to syphilis-infected individuals who were notified by state DIS were newly infected with HIV or syphilis, respectively. Given the rurality of our state, a mobile DIS workforce is critical.

A Community-Based Collaboration Model that Works

"Cape Fear Regional Bureau For Community Action, Closing The Gap" Program
Jail-Based Strategic HIV/Syphilis Prevention and Support Project
Cumberland County North Carolina

Background and Morbidity

The Cape Fear Regional Bureau for Community Action was founded by Ashley Rozier II and is one of the oldest grassroots HIV/AIDS/Substance Abuse street outreach, community-based organizations (CBOs) in North Carolina. Since 1989, the Bureau has provided prevention counseling, testing and referral services for HIV/AIDS, STDs, substance abuse, hepatitis and many other chronic needs to African Americans, as well as high-risk minorities and the disenfranchised, in the Cumberland County Cape Fear Region. In the NC 2004 HIV/STD Epidemiologic Profile, Cumberland County ranked 6th among the state's 100 counties for cumulative reports of HIV disease (1983-2004) with 1,246 cases. In Cumberland County, African Americans represent only 39% of its population, but an alarming 75% of HIV cases. Additionally, African Americans represented 63% of chlamydia cases, 79% of gonorrhea cases, and 70% of early syphilis cases in 2004.

In January 2006, after collaboration with local and state partners, the Bureau, the Cumberland County Sheriff and the Cumberland County Health Director initiated the "Closing The Gap" program. This program offers traditional jail screening and a community outreach component. Bureau staff are trained to conduct HIV/syphilis counseling and testing and target incarcerated men and women. HIV/STD education and testing is offered on Friday, Saturday and Sunday evenings from 7:00 pm to 11:00 pm. HIV and syphilis blood specimens are processed through the Cumberland County Health Department and test results are provided to the client regardless of whether they are still incarcerated. Those inmates testing positive for HIV and/or syphilis are interviewed for partner notification purposes and are given relevant referrals. This program focuses on 1) early identification of HIV and syphilis, 2) linking clients to appropriate medical care and prevention services, including identification and enrollment of high-risk women in prenatal care programs, and 3) supporting positive clients in adhering to treatment regimens and in adopting and sustaining HIV risk reduction behavior.

Exceeding Their Goals

From January 1-June 15, 2006, the Bureau tested 821 inmates for HIV, of which three HIV-positive cases were identified. For the same time period, 824 inmates were tested for syphilis and six new cases were identified. Seventy-nine percent of those tested for HIV were post-test counseled. All positive HIV and syphilis clients were referred for medical care/treatment, partner notification services and case management services.

In addition to the work within the detention facility, the Bureau has an active outreach program that includes testing in Fayetteville at 110 1/2 Gillespie Street (main office), local bars/clubs, field/street outreach, and in Hoke County. From January 1-June 15, 2006, 137 persons were tested for HIV, of which three HIV-positive cases were identified. For the same time period, 132 persons were tested for syphilis and two new cases were identified. All positive HIV and syphilis clients were referred for medical care/treatment, partner notification services and case management services.

Two Program-To-Program Collaborations that Work

A. Hepatitis A and B Vaccination Program
State Immunization Branch and HIV/STD Prevention Care Branch

In 2002, hepatitis A rates increased dramatically in five North Carolina counties (Wake, Forsyth, Guilford, Mecklenburg, and Robeson). A 4.5 fold increase in the number of men self-reporting recent sexual contact with men was noted when compared to the average over the 1997 to 2001 time period. The increase was largely attributable to men who have sex with men (MSM) activity, especially in white males in the 25-44 age groups. In terms of hepatitis B, it is well-known that it is a sexually transmitted disease, 100 times more infectious than HIV. Unvaccinated adults who engage in unprotected sex with multiple partners are especially vulnerable to this vaccine-preventable disease.

Based on data indicating high rates of hepatitis infection, a statewide strategy to prevent and control hepatitis A and B infection through vaccination was needed. CDC offered grant money to programs designed to increase vaccination rates in high-risk populations. After applying for and receiving funds from a CDC grant, the Immunization Branch made the decision to purchase, a combination hepatitis A and B vaccine, under the trade name Twinrix.® This vaccine is manufactured and distributed by GlaxoSmithKline Biologicals. Through a limited pilot project in 2003, adults at high risk for both hepatitis A and B, including those infected with hepatitis C, were targeted for vaccination.

The HIV/STD Branch staff in collaboration with the Women's and Children's Health Section (WCHS) Immunization Branch, announced the availability of state-supplied hepatitis A and B vaccine to all local health departments effective January 2, 2004. This project continues as an ongoing routine vaccination opportunity. Considered a standard of care, hepatitis A and B vaccine is available statewide to high-risk adults served in health department STD clinics. Since the beginning of the calendar year 2006, administration of hepatitis A and B vaccinations at local health departments has increased (see table below). Communicable disease nurses at the health departments have received correspondence, verbal encouragement to use the vaccine and consistent education about the importance of offering/administering the vaccine from both the hepatitis B and C coordinators. The nurses are strongly encouraged to offer the vaccine to all unvaccinated patients over 18 years of age who are seen in their STD clinic. Targeted risk factors include HIV positive status, HCV positive status,

IDU (Intravenous Drug Users), MSM, MSP (Multiple Sex Partners), and past incarceration. High vaccination coverage will reduce transmission of hepatitis A and B infection in the community by immunizing persons at highest risk for infection.

The Branch Quality Assurance, Training, and Development Team (QATD) regularly conducts site assessments at local health department HIV/STD clinics to assess the uptake of hepatitis A and B vaccinations at the sites. Future plans are to increase the focus on increasing initial acceptance and completion rates of vaccine.

B. *Chlamydia and gonorrhea-screening programs targeting high-risk adolescents entering Assessment and Treatment Planning Centers*

Background

Asymptomatic chlamydia and gonorrhea infections are common among both adolescent males and females and are especially high for those entering detention facilities. According to the CDC STD Surveillance 2002 Special Focus Profile "STDs in Persons Entering Corrections Facilities:"

- The positivity for chlamydia and gonorrhea among women was higher in juvenile facilities than in adult facilities. Among adolescent women entering juvenile detention facilities, the median positivity for chlamydia was 15% (range, 1.5% to 28.9%); positivity was greater than 10% in 17 (71%) of 24 facilities reporting data.
- The median positivity for gonorrhea among women entering juvenile facilities was 4.9% (range, 0.5% to 13.0%); positivity was greater than 4% in 11 (73%) of 15 juvenile facilities. The median positivity for chlamydial infection among men entering juvenile facilities in 30 counties was 6.6% (range, 0.9% to 13.0%).

To address this issue in North Carolina, the HIV/STD Prevention and Care Branch is working in partnership with the Department of Juvenile Justice and Delinquency Prevention (DJJDP) to implement an STD screening program targeting high-risk adolescents entering two state-level Assessment and Treatment Planning Centers. The program reaches adolescents entering one Youth Development Center for Females (approximately 100/year) and one Youth Development Center for Males (approximately 500/year). Center medical staff collect demographic information (age, race, gender) and urine samples for gonorrhea and chlamydia screening using an FDA-approved NAAT testing procedure.

Status

Testing was initiated in October, 2003 for males and females entering the two Youth Development Centers. As of June 31, 2006 the project has screened 1,257 (1,071 males and 186 females) between the ages of 13 and 17. Of those screened, 138 (103 males and 35 females) tested positive for chlamydia and 19 (eight males and 11 females) tested positive for gonorrhea. All of those who tested positive were treated in accordance with NC treatment recommendations and were counseled on risk reduction behaviors to

Table 1.
Total Doses of Hepatitis A and B Vaccines Ordered by 93 Local and Regional Health Departments

2004	15,695	(includes pilot project period)
2005	13,685	
2006 January-June (actual)	8,395	
2006 Estimated total (projected)	16,790	
Using the above numbers and the assumption that all vaccine recipients have received or will receive the required 3-dose series,* it can be estimated that the following number of clients were/will be vaccinated:		
2004	5,230	
2005	4,529	
2006	5,600	(Estimated total for the year)

*NOTE: Many clients received at least one or two more doses of vaccine than estimated. All received the first dose of the vaccine, but the percentage of those returning for their 2nd and 3rd doses is usually around 25% and 5%, respectively.

prevent future infections. This model program is a great example of the benefit of adding routine STD screening to programs serving at-risk adolescents. These young people can be treated quickly and the likelihood of complications such as epididymitis, infertility and pelvic inflammatory disease are greatly reduced.

As can be seen from the above examples, North Carolina relies on partnerships and collaborations to advance STD prevention work. Often the best examples of model STD practices are those that pull traditional providers and community-based partners together. The best example of this is North Carolina's Syphilis Elimination Project.

The Syphilis Elimination Project (NCSEP) began in 1998 with CDC funds given to the HIV/STD Prevention and Care Branch to reduce the levels of syphilis in North Carolina, which has had one of the highest primary and secondary syphilis rates in the United States. The NCSEP program is comprised of six counties: Durham, Forsyth, Guilford, Mecklenburg, Robeson and Wake. Through this program, each county hired a Syphilis Elimination Coordinator devoted to syphilis elimination activities, conducted an evaluation project and convened a community task force to develop a syphilis elimination plan unique to their county. Each county conducts syphilis outreach and education, screening of high-risk persons, jail screening programs, establishes and supports condom distribution centers, and conducts social marketing. A crucial element of syphilis elimination is the partnership formed between CDC, the state, county health departments and community-based organizations (CBOs). CDC in fact made collaboration with CBOs a requirement and thirty per cent of the CDC grant award was designated for use by community-based organizations.

North Carolina has made substantial progress toward controlling syphilis since the inception of the Syphilis Elimination Project (NCSEP) in 1998. Since that time infectious syphilis in North Carolina has declined by 62% and the state rate has dropped from 9.6 to 3.2 in 2005. In 1998 North Carolina led the nation in the number of counties reporting infectious syphilis cases, and was the only state in the nation with five of the twenty-eight counties reporting more than 50% of the nation's morbidity of infectious syphilis. In 2005, only one North Carolina County (Mecklenburg) remains on the National listing of the top counties with syphilis. The NCSEP program has been successful because of the partnership between community-based organizations, local healthcare providers and local/state health staff. This partnership supported the use of locally tailored, innovative strategies and "after hours" screening in non-traditional venues.

SYNERGY

Definition

(1) SYNERGISM; broadly: combined action or operation (2) a mutually advantageous conjunction or compatibility of distinct business participants or elements (as resources or efforts).[2]

North Carolina's approach to effective implementation of programs and activities designed to impact HIV/AIDS and other sexually transmitted diseases is one rooted in the synergistic character of our programs. Our activities are designed to draw upon the strength of other similar program activities, both at the local as well as at the state level. The Division of Public Health is a full partner with our local health departments as well as community-based organizations and providers. The HIV/STD Prevention and Care Branch recognized several years ago that in order to effectively address the burgeoning HIV and STD impact on communities in our state, it was necessary to form partnerships with key leaders and stakeholders in those communities and to provide resources as well as mentoring to improve delivery of services. Together we are stronger than we are alone. **NCMedJ**

Responding with Treatment to Those Acutely Infected with HIV:

No Time to Lose

Peter Leone, MD, MPH

Acute HIV infection (AHI) refers to the brief period after HIV infection when HIV RNA first appears in the blood, but before HIV-specific antibodies are detectable. Individuals with AHI have increased HIV transmissibility due to the increased viral load in both blood and genital secretions, making it critically important for prevention of secondary HIV transmission.[1] While some patients with acute infection have a viral syndrome (known as acute retroviral syndrome or primary HIV), the mild and non-specific nature of acute retroviral syndrome complicates effective screening.[2] A significant barrier to diagnosis of AHI is the non-specific nature of the signs and symptoms associated with the acute retroviral syndrome. Unless a clinician entertains the diagnosis in the differential and orders an appropriate diagnostic test, the diagnosis will be missed. It is vital to have clinicians consider AHI in young adults with fever and diffuse lymphadenopathy and that clinicians also know to include a viral-specific test and not just an HIV antibody as diagnostic tests. Methods to incorporate HIV RNA screening of all HIV antibody negative bloods for testing populations may reduce the number of missed diagnoses for AHI. Specimen pooling and nucleic acid amplification methodologies have proven to be a feasible and effective method of acute HIV infection screening of at-risk populations such as individuals seen in Sexually Transmitted Disease clinics, Emergency Departments, and at other locations where HIV testing is routinely provided or individuals at risk for HIV infection may seek care.[3]

> *"Early HIV therapy presents a potential window of opportunity to improve immune function and slow the progression to AIDS, and more trials are underway now to determine the clinical benefits of early HIV therapy."*

Diagnosing AHI is of benefit at the level of the individual patient and at the level of the general public as part of HIV disease control efforts. Early HIV therapy presents a potential window of opportunity to improve immune function and slow the progression to AIDS, and more trials are underway now to determine the clinical benefits of early HIV therapy.[4,5] Transmission of HIV is principally driven by the quantity of the HIV inoculum in either blood or genital secretions. This brief period of extremely high HIV viral load and uncontrolled viral replication in AHI last for less than eight weeks. Therapy with ARV can precipitously drop the serum and genital secretion viral load and potentially render the individual "non-infectious" should the viral load drop below detection. Brief interventions that alter HIV high-risk activities for even a brief period of time can tremendously reduce the transmission of HIV among discordant partnerships. Additional public health benefits of early intervention include epidemiologic information about incidence rates in communities,[6] case clustering,[7] information on trends in drug resistance,[8] identification of high risk periods and places,[9,10] molecular characterization to better define core populations and sexual risk,[11] identification of marginalized and otherwise hidden high risk groups,[12] and a unique opportunity to disrupt active HIV transmission networks.

Peter Leone, MD, MPH, is Associate Professor of Medicine in the Division of Infectious Disease, University of North Carolina School of Medicine. He can be reached at peter_leone@med.unc.edu. Telephone: 919-843-0724.

The Period of Acute HIV Infection

The kinetics of HIV transmission and diagnosis has profound implications for disease control efforts. Both the biological progression and behavioral characteristics leading to AHI exacerbate the risk of secondary HIV transmission (Figure 1). As higher viral loads correlate to greater risk of HIV transmission, the increased viral burden in blood and genital secretions associated with AHI increase the probability of transmission.[1,23] "Look-back" studies investigating transmission rates,[24] case series showing rapid secondary transmission,[25] and prospective sero-discordant couple studies[26] all strongly suggest a greater likelihood of transmission per sex act during acute HIV infection. Our own data from the North Carolina AHI program (STAT) suggest transmission of HIV during acute infection occurred >1:13 to 1:18 unprotected coital acts. Beyond the increased risk of transmission from an individual with AHI, the partners subsequently infected during this period are also at an increased risk of transmitting HIV, creating a chain of secondary transmission among core populations.[27]

Figure 1.
AHI and Symptoms

- **49-89% "Symptomatic" within 3 Months**
  (Schacker TW, et al., AIM 1996 125:257-264)
- **Symptoms**

	Schacker	Kinloch-de Loes	NCSTD
Fever	93%	87%	48%
Fatigue	93	26	37
Pharyngitis	70	48	30
Headache	55	39	26
Rash	–	–	15
GI Symptoms	–	–	37

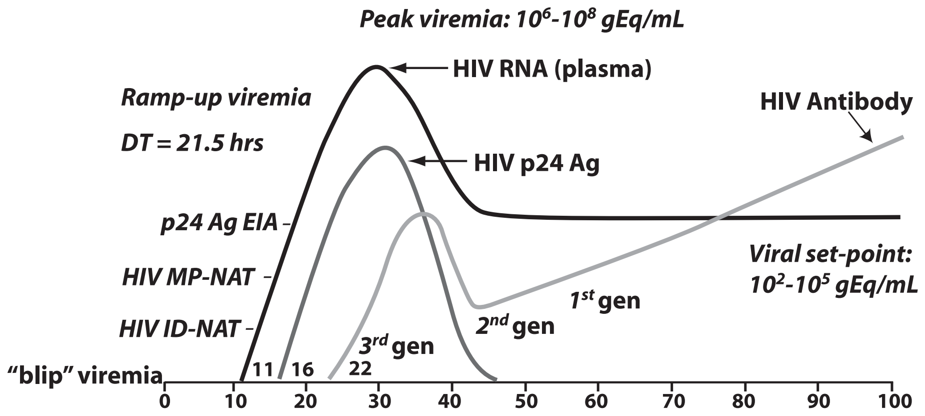
In addition to this heightened biological risk of HIV derived from increased viremia among specific populations, increased behavioral risk has also been suggested during the AHI. Studies analyzing men who have sex with men (MSM) who recently seroconverted revealed behaviors during the period of acute HIV infection which likely facilitated HIV transmission, and declined soon after diagnosis.[20] This behavioral component of HIV risk is independent of viremia, but importantly seems to correspond to a similar period of high-risk behavior. Recall bias interferes with locating active HIV transmission networks since it tends to increase as time elapses from sexual encounter.[28] Finding individuals with AHI at the earliest time following infection is a matter of urgent public health and individual importance.

A recent publication described the epidemiologic and clinical characteristics of a cohort of patients with AHI who were followed prospectively. This represented nearly three percent of all new HIV infections diagnosed during a seven-year time period. The symptoms were nonspecific, with only fever and asthenia being nearly universal (98% and 86% respectively).[30] Prior studies suggest symptoms of an acute retroviral syndrome occur in 40-90% of patients.[13] Our own experience in North Carolina found that 70% of individuals developed an acute retroviral illness, but that less than 50% had symptoms at the time of diagnosis. Anecdotally, even when patients have presented to clinicians with signs and symptoms of the acute retroviral syndrome, the diagnosis was either never considered or the wrong HIV diagnostic test was ordered. Clearly there is a need to educate clinicians concerning the subtle presentations of AHI and consideration given to appropriate diagnostic testing and follow up. Barriers to the initiation of universal HIV testing must be addressed in settings for which clinicians have been hesitant to order HIV testing. Such settings include emergency departments and urgent care settings where clinicians have been reluctant to order HIV tests, let alone screening for AHI with HIV viral load testing, due to lack of reimbursement for counseling, an inadequate referral base for HIV care and the requirements for HIV post-test counseling.

The development of symptoms is associated with high-level viremia and the initial immune response to HIV. Much is unknown regarding the prognostic significance of the acute retroviral syndrome, but the severity of illness may reflect difficulty of the host immune response to control viral replication and has been correlated with a more rapid progression of disease.[13] Sued, et al., provide further support for this conclusion with the more rapid progression of disease reported in those who did not receive ART (42.3% vs. 12.3%).[30] It is, for this reason, disturbing that the percentage of individuals starting on ART decreased during the observed period from 79% to 49%. The high rate of dyslipidemia and lipodistrophy may be attributable to the choice of ART or reflect a "defect" in the host immune response with poor response to viral replication since the majority of the individuals in the cohort had an acute retroviral syndrome.

The timing of HIV diagnosis is central to subsequent public health response and preventing unknowing transmission of HIV. Depending on the threshold used for a true positive, nucleic acid amplification testing (NAAT) used for acute HIV surveillance can be positive within the first week of infection. Some third-generation ELISA tests may be positive as early as three weeks following HIV infection, compared to the two weeks needed for positive p24 antigenemia (Figure 1).[29] The sensitivity of assay used to detect either HIV or HIV-specific antibody response is only one factor in diagnosing acute HIV. The frequency of repeat HIV testing in high-risk groups will also impact the ability to diagnose individuals during the AHI period. Clinician awareness of the presentation of AHI as well as a high index of suspicion is also critical since detectable antibodies levels may not be present at the maximal height of viremia and the onset of symptoms. Appropriate clinical history, such as sexual risk factors, reported intravenous drug use, coupled with physical signs and symptoms of an acute retroviral illness, should prompt the ordering of appropriate diagnostic tests with either a NAAT HIV RNA or HIV p24 assay (Figure 2). Sued and colleagues looked for evidence of AHI in this high risk population and therefore were able to recognize and diagnose AHI. We can and must do better in considering AHI in all sexually active young adults who present with a non-specific mononucleosis-like illness.

Figure 2.
HIV Viremia During Early Infection



The University of North Carolina Hospitals recently implemented routine HIV RNA screening of all HIV ELISA antibody negative or Western Blot indeterminate blood as a way of reducing clinician oversight of AHI. When used with specimen pooling, HIV NAAT offers a sensitive and specific method for detection of acute HIV infection before the period of greatest transmissibility.[3] North Carolina's STAT program illustrates how acute HIV surveillance is critically time-dependent. During the period November 2002 to September 2006, 78 patients from 110 public counseling and testing sites were RNA positive and antibody negative. During this same period, over 90 community-identified cases of AHI were referred into the North Carolina STAT program. Finding individuals with acute HIV infection and their recent sexual partners provides insight about HIV sexual networks at the leading edge of the epidemic. From a public health perspective, the evidence to support increased HIV transmissibility during acute infection justifies closely related case finding and prevention activities.

Conclusion

The clinical presentation of AHI is, at best, non-specific and can closely resemble a host of other "viral-like" illnesses. A history of recent unprotected sexual intercourse or injecting drug use, coupled with characteristic signs/symptoms, such as fever, rash or lymphadenopathy, should alert clinicians to consideration of the diagnosis. Education of clinicians and patients concerning acute retroviral syndrome and access to frequent HIV testing is critical for identification of AHI.

Closing the window period between acquisition and diagnosis of HIV infection via routine acute HIV infection screening is a major public health opportunity that demands further study and consideration. Case interviewing needs to be better connected to HIV prevention, given what we know about the increased HIV transmissibility associated with acute HIV infection. In most parts of the world, physicians fail to diagnose acute HIV infection, case interviewing is underutilized, and disease control based on acute HIV surveillance remains a theoretical benefit. Since the increased HIV transmissibility associated with acute HIV infection is supported by North Carolina's STAT program[3] and transmission data, identifying acute HIV infections and tracing their partners should be further considered. Analyzing the high-risk people/places/periods involved in active HIV transmission needs to be considered in other locations, as a complementary strategy alongside the sensitive-to—less-sensitive HIV testing. Despite support from the CDC and work in the field, routine detection of acute HIV infection and case interviewing has not yet been broadly applied.

Some have persistent doubts about acute HIV-centered testing and disease control. Limitations to the proposed approach include higher testing costs, NAAT test performance issues, and a requisite for venous blood draw. In addition, the need for follow-up Western Blot confirmation for presumably positive clients makes delayed testing less desirable in settings where acute healthcare alone is provided. Rapid HIV testing can be coupled with screening for AHI should the rapid test prove HIV antibody negative. Rapid HIV testing and AHI screening are not mutually exclusive propositions. Given the increased uptake associated with rapid HIV testing, the longer follow-up and potentially greater refusal of blood draws required for acute HIV screening, strategies to incorporate AHI screening seems justified. North Carolina's STAT program has shown that identification of acute HIV infections and disease control can be implemented on a very large scale while preserving test performance and low cost. Sued and associates demonstrate an additional approach by prospective following of high-risk groups with the hope of recognizing AHI. Even with the increased cost and potentially higher refusal rate associated with either strategy, the public health advantages demand further study and consideration of these new approaches. With five years of ongoing increases in the new diagnoses of HIV among North Carolinians, new approaches for prevention must be encouraged. We are clearly missing most cases of AHI. Approximately 60% of all new diagnoses of HIV occur in the private medical sector. It is imperative that an extensive education campaign for AHI be instituted for clinicians and new partnerships for follow-up and referral links for AHI cases be strengthened at the state and local health department level. These activities should also be implemented with simultaneous education of high-risk HIV communities, such as men who have sex with men (MSM) and injecting drug users so that healthcare is sought with the first presentation of AHI signs and symptoms.

Extensive public health experience with syphilis control suggests that disease control-focused epidemiologic investigations linked to active transmission among core high-risk groups may be a more effective public health approach to HIV control than merely recommending universal HIV testing. While traditional HIV surveillance systems provide broader estimates of overall HIV incidence, such surveys are very unlikely to adequately sample either populations that deny high-risk behaviors or high morbidity areas to provide the type of detailed information essential to stopping active transmission networks.

Acute HIV infection detection and disease control systems allow clinicians and public health authorities to get a more detailed and comprehensive understanding of the when, where, why, and who of new HIV infections. Routine detection of acute HIV and disease control offers a new blueprint for organizing HIV testing, bringing HIV acquisition and diagnosis closer, and expanding potential prevention programs. Several lines of evidence support a new paradigm of acute HIV detection and disease control, but more investigation and further replication are necessary. **NCMedJ**

Responding to the Epidemic of STDs through Public Education and Community Intervention

Sherry Lehman

In 2005, 50.8% of high school students in North Carolina had engaged in sexual intercourse according to the Centers for Disease Control and Prevention (CDC), Division of Adolescent and School Health's Youth Risk Behavior Survey (YRBS). While this is a relatively new statistic, teen pregnancy rates and the prevalence of chlamydia and gonorrhea among teens demonstrates that youth in North Carolina have been involved in risky sexual behaviors for a long time. In 1995, the state legislature recognized this fact and took steps to get the schools involved in HIV/STD and teen pregnancy prevention.

Prior to 1995, there were no state statutes or state school board policies that dictated what local school systems should teach regarding sexuality education in the classroom. In 1995, the legislature amended the Basic Education Statute 115C-81 to require abstinence until marriage for HIV/STD prevention as the expected standard for all school-aged children. The North Carolina State Board of Education used the statute as a guide to update the Healthful Living Standard Course of Study, which mandates age-appropriate learning objectives on sexuality education. The amendment of the statute and the course of study created conflict and controversy and changed the way sexuality education was taught in North Carolina.

Overnight, school systems became leery of letting health education teachers teach information about condoms and birth control. Masturbation, abortion, and sexual orientation became taboo subjects for discussion in the classroom. The great tragedy of the transition was that school systems were interpreting the state statute too conservatively and safer sex education was deleted from the scope of knowledge provided to students.

Recognition of the misinterpretation has been a slow, but steady progress has been made. Informed educators from the Department of Public Instruction and the North Carolina Comprehensive School Health Training Center have provided ongoing workshops to local school boards, school administrators, health teachers, community health educators, and parents on the accurate translation of the guidelines. Primary concepts of the workshops include: (1) the allowance of the statute and the mandate of the course of study for seventh and eighth grade health teachers to teach the effectiveness and failure rates of condoms and other birth control methods; (2) the right for parents to opt their students out of the sexuality portion of the Healthful Living curriculum without penalty (or prejudice) to the student; (3) the right of the local school system to go beyond the scope of the statute and hold a public hearing to approve teaching comprehensive sexuality education, which could include classroom demonstration of condoms; and (4) the primary difference between the statute and the course of study (and holding a public hearing) rests with the ability to demonstrate condoms in the classroom. Despite the fact that the statute is known across the state as the "abstinence until marriage" law, the statute allows for great flexibility in teaching an "abstinence plus" curriculum.

The North Carolina Comprehensive School Health

> *"Making A Difference is an abstinence-based middle school curriculum that has been aligned with the Healthful Living Standard Course of Study, and when implemented with fidelity has demonstrated positive behavior change in adolescents."*

Sherry Lehman is HIV Prevention Program and Policy Consultant, North Carolina Department of Public Instruction. She can be reached at slehman@dpi.state.nc.us. Telephone: 919-807-3860.

Training Center provides professional development to school systems or community-based organizations that want evidence-based HIV/STD prevention curricula that meet the state statute *and* the course of study requirements. *Making A Difference*[1] is an abstinence-based middle school curriculum that has been aligned with the Healthful Living Standard Course of Study, and when implemented with fidelity has demonstrated positive behavior change in adolescents. *Successfully Teaching Middle School Health*[2] and *Successfully Teaching High School Health*[3] are two manuals produced by the professional organization, North Carolina Association for the Advancement of Health, which provides six-step lesson plans for every health learning objective, including HIV/STD and teen pregnancy prevention. Staffs of after-school programs and community-based programs, which are not held to the terms of the statute or the course of study, may receive training in such evidence-based curricula as *Focus on Kids*[4] and *Making Proud Choices*.[5] All of the above curricula are highly interactive and promote communication, negotiation, and refusal skills that delay the initiation of sexual intercourse and stress the importance of abstinence.

With the appropriate teacher training, North Carolina can have highly effective health education in the classroom. However, several issues jeopardize the future of school health education. The high stakes pressure of adequate yearly progress and student achievement is forcing health education out of the school day with the need for remedial math, reading, and writing time. The recent Healthy Active Children state board policy, which requires 30 minutes of daily physical activity in elementary and middle schools, is placing an emphasis on physical activity, sometimes at the expense of health education. Without an end-of-course test for health education there is no accountability for the teaching of health, and specifically HIV/STD and teen pregnancy prevention, in the classroom. It is the responsibility of parents and the greater community to advocate for appropriate school health education and disease prevention. Without the watch-dogs of community involvement, the sexual risk-taking behaviors of North Carolina youth may put them in the cross hairs of HIV/AIDS. **NCMedJ**

Opportunities for Addressing the STD Epidemic through Interventions Targeted to North Carolina's Incarcerated Populations

Lynne A. Sampson, MPH

The prevalence of sexually transmitted diseases (STDs) among inmates of jails, prisons, and juvenile detention facilities is many times higher than among the general population. Surveillance projects at the Centers for Disease Control and Prevention (CDC) have found high rates of chlamydial infection, gonorrhea, and reactive syphilis serology among inmates entering both adult and juvenile correctional facilities (Table 1).[1] The Bureau of Justice Statistics also reports that 1.8% of male prison inmates and 2.6% of female prison inmates in the US are infected with HIV.[2]

The association of STDs with incarcerated populations should not, however, imply that the infections were acquired in prison or jail. Although transmission can occur within such facilities, it is not common. Rather, correctional settings represent a unique opportunity to access populations that have a high risk for STD infections and offer screening, treatment, and education.

Why Are Incarcerated Populations at High Risk?

The risk of acquiring sexually transmitted infections has long been associated with illicit behaviors, such as prostitution and drug use. This pattern is especially true for syphilis and HIV infection which have occurred in similar populations since the earliest days of the HIV epidemic. Studies of HIV-infected populations have documented high rates of incident syphilis infection[3,4] and syphilis studies have established HIV infection as a consistent risk factor.[5-8] Syphilis and HIV have both been found to be associated with trading sex for drugs or money,[9-11] use of illegal drugs,[9-14] and a history of incarceration.[6,14] These risks are, in themselves, related as prostitution and drug possession/sale are among the most common reasons for arrest.[15]

Jail Versus Prison Settings – Implications for Screening Programs

Because STDs are highly prevalent in incarcerated populations, screening programs to identify new infections have been proposed and/or implemented in jails and prisons across the United States. Inmates are generally screened upon entry to the facility and receive treatment and/or referrals for any STDs detected. Screening in jails and prisons each has different goals and benefits, therefore it is important to distinguish the difference between these two types of institutions.

> *"...correctional settings represent a unique opportunity to access populations that have a high risk for STD infections and offer screening, treatment,*

Jails are locally operated (city or county) and serve to house persons arrested and awaiting trial as well as those sentenced to short terms of generally less than one year. The average inmate stays in jail for less than two days,[16] most posting bond and awaiting trial outside jail. In North Carolina, only about 23% of the jail population at any given time is serving sentences; the remainder are pre-trial detainees.[17]

Because most jail detainees are housed for only a matter of days, conditions are crowded and opportunities for inmate recreation are limited, decreasing the opportunities for sexual contact (and ongoing transmission) within the institution. In

---

Table 1.
Median Prevalence of Sexually Transmitted Diseases among Populations Screened in US Correctional Facilities, 2004.

	Males		Females	
	Median %	Range %	Median %	Range %
ADULT				
Chlamydia	10.2	0.7 – 30.0	7.2	1.2 – 22.7
Gonorrhea	2.6	0.0 – 33.8	3.0	0.0 – 8.4
Syphilis	2.7	0.2 – 5.9	5.3	0.0 – 19.0
JUVENILE				
Chlamydia	5.8	1.0 – 27.5	14.0	2.4 – 26.5
Gonorrhea	0.8	0.0 – 18.2	4.5	0.0 – 16.5
Syphilis	0.5	0.0 – 2.4	0.7	0.0 – 5.1

Source: CDC STD Surveillance 2004[1]

such settings, STD screening programs serve as community-level screenings, reaching a population that often has limited contact with other healthcare services and screening opportunities. The net benefit of such programs is very much to the non-incarcerated community to which the detainees return.

Prisons are generally under state or federal control and are designed to house inmates sentenced to terms of one year or longer. Essentially all prison inmates will have spent some time in jail before trial, sentencing, and finally entering prison. Screening for STDs in these settings has very different functions: to maintain the health of the inmate population while they are in custody and to prevent ongoing transmission within the facility. Inmates benefit directly from detection and treatment of their disease. Upon release, the benefit transfers to communities where the risk of infection from a newly released inmate is decreased.

STDs in North Carolina Correctional Facilities

The prevalence of STDs among North Carolina's incarcerated populations is difficult to assess because few screening programs currently exist. In 2005, 256 cases of sexually transmitted diseases were reported from the state's correctional facilities (Table 2). These data should be viewed as an extremely low estimate of the true number of STD cases among incarcerated populations in North Carolina. Most reported cases are likely to be the result of sick inmates seeking care. Since the most prevalent reportable STD (chlamydia) is asymptomatic, most cases are not detected unless a screening program is in place. Inmates entering Department of Corrections (prison) custody are screened for syphilis. HIV testing is also offered on a voluntary basis. Screening programs in jails are far less common.

There are also some reporting issues associated with this data. Internal surveillance audits at the Branch have found that some STD reports listed as coming from county health departments were actually cases detected through the local jail. This occurs sometimes when a jail is not able to provide treatment on site and inmates are temporarily transferred to the local health department for care. The STD case report may be filled out at that time and come in to the Branch as a health department case. This bias does not appear to be present in reports coming from prison facilities.

Expansion of STD screening programs, especially in jails and juvenile justice settings, would likely detect a large number of cases of treatable STDs and contribute to decreases in ongoing transmission in the community. The HIV/STD Prevention and Care Branch has two major screening efforts underway that can provide a model for future programs.

Juvenile Justice Screening in North Carolina

Since October of 2003 the HIV/STD Prevention and Care Branch of the North Carolina Division of Public Health has partnered with the State Laboratory of Public Health and the Department of Juvenile Justice and Delinquency Prevention (DJJDP) to provide STD screening in several long-term facilities. Females at the Samarkand Facility and males at C.A. Dillon are screened upon entry for chlamydia, gonorrhea, and syphilis. In 2005, 371 young men were screened. Of these, 40 (10.8%) were found positive for chlamydia and two (0.5%) were positive for gonorrhea. The problem is even more pronounced among young women. Out of 48 screened in 2005, 10 (20.8%) tested positive for chlamydia, and two (4.2%) tested positive for gonorrhea. All of the juveniles were immediately treated for their infections. No cases of syphilis were detected.

The HIV/STD Prevention and Care Branch hopes to secure additional funds to allow for expansion of this program to additional facilities within DJJDP.

Syphilis Elimination Jail Screening in North Carolina

In 1998 CDC found that over 50% of reported primary and secondary syphilis cases in the United States came from just 28 counties. They launched an extensive campaign called the Syphilis Elimination Effort (SEE) in 1999 in response. North Carolina had five counties on that list, more than any other state, and has expanded the program to include six counties.

As part of the enhanced surveillance objective of SEE, North Carolina has instituted syphilis screening in seven jails in all six of the SEE counties. Several counties began screening in the early project years (1999-2001). However, it was not until 2002 that good data collection and evaluation procedures were put into place. By September 2002, all seven jails were screening for syphilis and collecting data for evaluation. Two of the jails also added HIV testing to their programs. Data from 2002-2004 indicate that 98% of inmates who agree to having their blood drawn for syphilis testing also agree to having an extra tube drawn for HIV testing. During that time period the project identified 47 HIV-positive inmates (out of 4,655 screened) of which 25 were new reports.

From 2002-2005, the jail screening program tested 25,069 detainees for syphilis (20,311 males and 4,758 females). Overall, 932 inmates tested reactive and of these, 156 new cases of syphilis were identified (20 primary & secondary, 55 early latent, and 81 late syphilis). Females were more likely to be reactive than males (8.2% vs. 2.7%) and more likely to be a new case (1.2% vs. 0.5%). Female cases were also more likely to be primary, secondary or early latent (60% vs. 41% for males). In addition to greater rates of case detection, screening female inmates has a major additional benefit in that treatment can prevent possible cases of congenital syphilis.

Table 2.
Sexually Transmitted Diseases Reported in North Carolina, 2005

	Males			Females		
	All Cases	Corrections		All Cases	Corrections	
	N	N	%	N	N	%
Chlamydia	5,481	36	0.7	25,702	37	0.1
Gonorrhea	7,529	36	0.5	7,546	12	0.2
Early Syphilis*	343	22	6.4	146	18	12.3
HIV Disease**	1,308	79	6.0	498	16	3.2

Source: NC HIV/STD Prevention and Care Branch

* Early Syphilis = Primary, Secondary, & Early Latent Syphilis (<1 year duration)
** HIV Disease = First report of HIV infection, regardless of stage (includes some cases first reported as AIDS cases)

The Syphilis Elimination jail screening project has been fruitful in identifying 156 previously undiagnosed cases of syphilis and 25 new cases of HIV infection. Undoubtedly many others were also identified through partner notification and contact tracing of those jail cases. The North Carolina Syphilis Elimination team has used the results of the evaluation to adjust our screening by increasing our emphasis on female inmates. We plan to continue syphilis screening in the jails and hope to expand the HIV screening component to additional jails.

Policy Recommendations

Due to the high prevalence of sexually transmitted diseases among incarcerated populations, correctional settings provide a unique opportunity to reach a group of people at high risk and provide testing and treatment for their infections. Such programs benefit the inmates themselves, who may otherwise have poor access to healthcare, and the communities to which they return. This is particularly true for jail screening programs because detainees are often released within a matter of days. Expansion of the existing syphilis and HIV jail screening programs should be a major policy goal. Addition of chlamydia and gonorrhea screening to adult jail screening programs would likely detect a large number of cases and should also be explored. Younger populations are highly affected by these two STDs and special effort should be made to expand chlamydia and gonorrhea screening in juvenile correctional settings. **NCMedJ**

Guilford County's Syphilis Elimination Program:
People Stopping Syphilis Today (PSST)

Merle Green, MPH, MBA, and Jonathan Paul Lucas, MPH

Similar to many of the nation's mid-sized communities, Guilford County, North Carolina (including Greensboro) is battling a growing number of health-related social challenges. Guilford, the state's third largest county, is constantly looking for ways to decrease the number of sexually transmitted infections (STI) in its community that proudly houses eight institutions of higher learning and over 100 public primary and secondary schools. Guilford has battled growing numbers of syphilis cases, one of the state's leading causes of disease and disability. Until three years ago, NC had the highest rate of syphilis in the nation, and Guilford was highest in the state, for nearly a decade.

In 1997, Guilford County's largest cities, Greensboro and High Point, had the disturbing recognition of leading the nation in the rate of syphilis infection. With this news came a determined effort to battle this health issue and turn these numbers around. Health Educators and Disease Intervention Specialists from the local health department knew that one of the keys to any successful behavior change intervention should begin with buy-in from the affected communities. They also knew that matters of human sexuality were often met with secrecy and the attitude that "good boys and girls don't talk about that." With little time for changing human nature in this southern town, the local human service workers joined in an effort to respect the "privacy" attitude of the local community, while aggressively tackling this growing public health threat.

> *"In other words, when the planning was driven by the community, we experienced more success than we did when the agency staff made plans and then took them to the community to buy into."*

One of the initial interventions was to convene and host a community coalition. The coalition was then charged with two ambitious goals. These goals were to lower HIV infection rates, and eliminate syphilis by the year 2010.

The coalition named itself People Stopping Syphilis Today (PSST) in order to candidly acknowledge the southern "manners" under which they would be forced to operate. PSST sought and was awarded funding in 1998 from the North Carolina HIV/STD Prevention and Care Branch of the North Carolina Department of Health and Human Services. The Branch had successfully secured community targeted funding through a grant from the Centers for Disease Control and Prevention (CDC), and subsequently awarded mini-grants to local communities. As it continues to exist today, PSST is a partnership that is organized and led by the Guilford County Department of Public Health (GCDPH), but depends heavily on local residents and other local human service agencies and non-profit groups to staff and manage the many activities aimed at reducing HIV and eliminating syphilis infection.

Coalition participants include public service organizations, community based organizations (CBOs), churches, concerned residents, and non-profit health organizations. After learning about best-practice models across the nation, the group realized that the most effective strategies to lower rates of HIV transmission and eliminate syphilis were intensive "street outreach" to offer

Jonathan Lucas, MPH, is a Community Health Educator at the Guilford County Department of Public Health. Telephone: 336-641-7777.

free counseling and referrals, expanded testing services, and community education programs.

Lessons Learned, Strategy Change

After operating with mixed results for about seven years, the organizers noticed that their successes appeared to be heavily weighted in favor of the interventions that involved less agency intervention, and more direct planning and implementation by local grass roots workers. In other words, when the planning was driven by the community, we experienced more success than we did when the agency staff made plans and then took them to the community to buy into. With these data in mind, PSST purposely began to evolve into a program that was completely community driven. In 2004, community members developed and administered a community demonstration project named the Rapid Ethnographic Community Assessment Process (RECAP). In collaboration with the Centers for Disease Control and Prevention (CDC), this assessment was conducted quickly, required little money, and asked communities at risk their opinions on how best to solve the syphilis epidemic in Guilford County. The assessment identified three key groups who were at highest risk for syphilis and HIV infection. The target groups identified were (a) people who use crack cocaine, (b) people who exchange sex for money or drugs, and (c) the customers of people who exchange sex for drugs or money.

Targeting At-Risk Groups

Building on the work of the assessment, the PSST program began to target local Commercial Sex Workers (CSWs) as a core group at risk for the transmission of HIV and other sexually transmitted infections (STIs). A review of public health records and confidential patient interviews confirmed high HIV and syphilis infection rates as well as large numbers of sexual partners among CSWs. The interviews also confirmed that a large majority of the CSWs are often poor, homeless, young, have a history of childhood abuse, and are likely to be drug or alcohol dependent. These issues are common among CSWs across the nation.[1] A study of childhood trauma and adult prostitution behavior by Merrano, Hatch, Zule and Desmond found that emotional and physical abuse were significant factors in predicting increased risk of prostitution.[2] In a study of juvenile and adult women who were street prostitutes, two-thirds were sexually abused, and, of those abused, 70% felt that the abuse affected their decision to become a prostitute.[2] Drug-addicted people may turn to commercial sex work to earn money to pay for the high cost of illegal drugs.[1] Many homeless youth have no education or means of support, and rely on commercial sex work for survival.[3] Attention to the more immediate concerns of food, housing, and addiction often takes priority over future concerns of HIV and syphilis infection.[3] A cross sectional interview-based survey of seventy-one CSWs found that rates of STIs were nine to 60 times higher than for people in the general population.[3]

To prevent HIV infection among CSWs, it is essential to address the context in which sex work is transacted, as well as the specific practices of the CSWs. Placing the major burden for HIV and syphilis prevention on CSWs themselves may not be the most effective tactic.[4] Men who solicit CSWs play a major role in transmitting disease to their other sex partners and thus into the general population. As such, the clients of sex workers are an important target group in direct STI prevention programs. The regular partners, or non-commercial partners, of CSWs and their clients are another important core group for HIV and syphilis prevention programs to target.

Building Relationships with the Sex Worker Community

PSST collaborates with CSWs to educate their customers and their colleagues (other CSWs) about the signs, symptoms, and prevention of STIs. Outreach workers walk the streets Tuesdays through Fridays and as needed on weekends (in conjunction with special testing events) to educate CSWs, their customers and drug dealers on safer sex practices. Outreach workers also focus on peer education. They spend time educating community gate-keepers and preparing them to educate other community members. Outreach teams provide condoms, personal lubricants, other personal safety products, and written materials about STIs. They discuss the syphilis and HIV epidemic with those they encounter, and provide individual risk reduction counseling to concerned community residents. Outreach workers also provide testing for syphilis and HIV at the request of community members. Outreach staff make referrals to a variety of social service agencies when appropriate. Providing such street outreach eliminates many of the barriers that people have to accessing healthcare, including transportation, childcare, and fear of being recognized at a public clinic.

PSST has set up six fixed sites for testing throughout the county in neighborhoods identified by morbidity maps and deemed "hot-spots" for HIV and syphilis infection. These locations have heavy drug traffic and are often frequented by CSWs. PSST sponsors or assists with about 50 special neighborhood screenings a year in locations with high syphilis morbidity rates to target these individuals who exchange sex for drugs or money. These events are done in collaboration with several other community-based organizations (CBOs), and public and private health organizations. At these events, STI testing is offered along with a number of other medical services that include, but are not limited to, blood pressure, glucose, cholesterol and dental/vision screening. Food and other incentives are provided at these community events. Community members assist with planning, advertising, and implementation of these health clinics. Often, community members alsoprovide food for these events. Services provided are always free, so cost is never a barrier for individuals receiving medical care at these events.

Behaviors that increase some women's risk of HIV commonly put them at risk of being incarcerated. As such, female detainees in the prison system often have STIs and/or are at risk for infections.[5] In a sexual behavior and drug use survey done at the Cook County Department of Corrections in Chicago, researchers collected data on 940 women.[5] Of those women interviewed 27% had two or three partners in the past year and 27% had more than four partners. Between 32% and 74% had not used protection in the last year and one third had traded sex for money or drugs.[5]

Collaborations Between Public Health and Law Enforcement Agencies

With this information in mind, PSST works with law enforcement agencies to reach CSWs and the customers of CSWs through education, screening, and treatment. Representatives from the sheriff's department, Prison Health Services, and city police departments serve on PSST. Officers have agreed to discuss the risk of STI infection with people they arrest, especially those arrested for soliciting CSWs. This increases awareness about the HIV and syphilis epidemic in Guilford County and increases access to education about STIs as an interruption to behavior that could lead to disease transmission. PSST also collaborated with law enforcement to produce an educational video for inmates. The video was designed by inmates and discusses syphilis in "street language." The video is shown to arrestees at booking and also to individuals who are waiting for arraignment.

HIV and syphilis testing is another important component of the collaboration with local law enforcement. Guilford County Detention Centers (GCDC) consistently report more syphilis and HIV than any other reporting location in Guilford County. In spite of the overcrowding county facilities are experiencing, medial personnel in detention centers still manage to provide testing to detainees. Arrestees are screened for tuberculosis when they are booked and the syphilis elimination program offers syphilis and HIV testing at that time as well. Unfortunately, due to overcrowding and understaffing, the nursing staff in detention centers could not provide adequate syphilis and HIV testing. To cover this gap, PSST provides syphilis and HIV testing in the jail through a unique partnership with the Sickle Cell Disease Association of the Piedmont (SCDAP). SCDAP employees provide testing and risk reduction counseling at booking and in the jail pods. GCDC nursing staff also offers the test at 14 days when they perform a standard physical. SCDAP provides weekly educational sessions to inmates about STIs. This partnership increases the likelihood that inmates get tested and treated before they are released back into the community.

The Benefits of the Collaborative Model

Guilford County has had a long history of using the community coalition model as a way to address health problems affecting county residents. PSST has been no exception, and the syphilis elimination program is one in a long line of programs successful at increasing access to care in Guilford County. PSST is a success because of its flexibility and service providers' willingness to listen to those individuals served by the program. Guilford was the first county chosen by CDC to conduct a community assessment (RECAP) around syphilis and one of the first to conduct a strategic planning process, which was accomplished entirely by PSST. Many other high morbidity areas have replicated the assessment and planning process. Guilford County remains one of the few places that have gone beyond the assessment process by creating and implementing a strategic plan based on community input at every stage. The result has been better access to quality care for Guilford County's most disenfranchised citizens. **NCMedJ**

Syphilis Elimination in Robeson County:
Challenges of Addressing the Problem among Sex Workers

Melissa Packer, BS, April Oxendine, BS, MEd, and Karen Woodell, BS

All Is Not Fair with the My Fair Lady Project

In 2004, the Robeson County Health Department received funding through the North Carolina HIV/STD Prevention and Care Branch to implement the highly ambitious My Fair Lady Project, a comprehensive three-year project targeting STD reduction through prostitute rehabilitation.

Greeted with great expectations, the project was the first of its kind funded by the state. With a goal of reducing the occurrence of HIV and other sexually transmitted diseases by decreasing the number of commercial sex workers, My Fair Lady made headlines with local, state, and national media coverage.

The project focused on three key components: *recruitment, rehabilitation and reintroduction*. Commercial sex workers were to be recruited into the program, extensively rehabilitated, and then reintroduced into their former environments with the new skills necessary to encourage positive behavior changes among their past peers.

Unfortunately, despite the media hype and high expectations, the My Fair Lady Project has documented only limited success in reducing sex trade activity in Robeson County. Several distinct and interrelated social problems have led to the near demise of the once ambitious undertaking. With less than one year remaining in the three-year grant, organizers are uncertain of their new directions and whether funding for projects of this nature will be awarded to the Robeson County Health Department in the near or distant future. However, one certainty remains: interventions targeting commercial sex workers must continue in Robeson County.

> *"Commercial sex workers were to be recruited into the program, extensively rehabilitated, and then reintroduced into their former environments with the new skills necessary to encourage positive behavior changes among their past peers."*

Substance Abuse and Mental Health Issues Create a Revolving Door For Peer Outreach Sex Workers

In the first two years of the project, two former commercial sex workers failed in their extensive rehabilitation attempts. These aspiring peer educators and their public health mentors struggled to disentangle the interwoven issues of substance abuse and mental health problems. The most positive phase was the recruitment process, with an initial panel of eight qualified candidates to select from.

The substance abuse challenges faced by sex workers in Robeson County are comparable to those documented in rehabilitation programs across the nation. Studies show that almost all women working in prostitution use drugs and alcohol heavily. Many start using these substances or increase their usage in order to deal with the stress and emotional

Karen Woodell, BS, is Syphilis Elimination Coordinator, Robeson County Department of Public Health in Lumberton, NC.

issues of the trade. Others begin to prostitute themselves to fund their drug habits or those of their partners or family members.[1]

State-employed Disease Intervention Specialists working in Robeson County identified the predominant drug of choice for the local commercial sex worker as smoked crack cocaine. Since crack cocaine appeared in urban areas in the United States in the mid-1980s, reports have suggested that crack smokers may be at increased risk of sexually transmitted diseases (STDs), including infection with HIV, because they have multiple sex partners, trade sex for money or drugs, and rarely use condoms.[2] Consistent with the majority of sex workers in Robeson County, smoked crack cocaine was the drug of choice for the two unsuccessful program participants. One of the participants had been substance-free for 14 months and the other had abstained for five months. Prior to employment with the project, both had experienced recurring relapses. One of the women had once led a substance free lifestyle for a five-year period prior to an unfortunate setback. Despite repeated attempts to redirect the paths of these two women, both were released from their duties. This clearly demonstrates the intractable nature that some substance abuse problems present.

Research indicates that cocaine use is the most common drug problem of patients entering treatment for illicit drug use. According to the 1999 Drug Abuse Treatment Outcome Studies (DATOS) funded by the National Institute on Drug Abuse (NIDA), about three-fourths of all admissions to non-methadone treatment programs in the United States are for cocaine dependence.[3] In a national sample from 55 treatment programs, the problem severity of patients at admission was found to be directly related to cocaine relapse in the year following discharge. Treatment retention also was a significant predictor among moderate-to-high problem groups. Among highest severity patients, 90 days or longer in residential programs was needed to improve outcomes. Cocaine treatment outcomes in the year after discharge indicated that 52% relapsed to drug use with 23% going back to "weekly" cocaine use, 19% to "occasional" cocaine nd 10% to "other drugs." Another 4% had alcohol problems and 11% re-entered treatment without relapse. Overall, 67% had problems during the follow-up period.[3] Having discussed that the first two peer educators relapsed during their course of employment, it should also be noted that both had completed inpatient treatment programs less than 90 days in duration.

Aside from drug addiction, one of the participants suffered from bi-polar disorder. Poor compliance with prescribed medications resulted in excessive absenteeism and lack of communication with project coordinators and community-based partners. Multiple interventions were initiated over an extended period, but each proved unsuccessful. Despite her progressively poor performance, this participant initially exhibited remarkable energy and charisma in her public relations efforts. Her communications skills were considered a "plus" for this "first of its kind" project and garnered a wealth of media attention. Her uninhibited approach to public speaking was applauded by all audiences, both lay and professional. It is unfortunate that she was unable to continue progressing, due to stressors encountered on her road to rehabilitation.

Currently, coordinators, in partnership with Palmer Prevention, a local substance abuse prevention center, have recruited two new peer outreach candidates. The director of Palmer Prevention was actively involved in the recruitment efforts of the project. Though grant funds will soon cease, coordinators anticipate closing the My Fair Lady Project on a more positive note. Like the two former Fair Ladies, both new recruits have a history of smoked crack cocaine addiction. And, reminiscent of the first two, they also have a limited duration of "clean time". Strikingly different are their candid communications concerning fears associated with returning to their former work environments as peer educators. Considering their vulnerability as well as the experiences of their predecessors, project coordinators anticipate consistent supervision during all community outreach activities.

Another variation in strategy involves the primary agency where the participants will report daily. Based upon past experiences and the issue of drug relapse, project coordinators have opted to station the two new employees at Palmer Prevention, rather than the health department. Initially, the health department had elected to "outstation" the My Fair Lady peer educators. This was considered the best approach due to confidentiality concerns, as well as media and public scrutiny. When attendance and performance issues spiraled out of control, the faith-based community partners regretfully suggested the workers move back "home" to the health department.

Now back on track with their original concept, coordinators predict the new linkage with Palmer Prevention will support closer monitoring of the rehabilitation and recovery outcomes of both young women. Improved results are highly anticipated; however, existing grant funds are insufficient to pay for clinical substance abuse counseling.

The project's conclusion may be inevitable, but the capacity of the My Fair Lady Advisory Council has grown significantly. The Council is a diverse group with representation including community, faith-based groups, law enforcement, substance abuse counselors, and the Lumbee Tribal Government. The panel offers a wealth of expertise to the project. Organizers predict group sustainability and support of local interventions long after the My Fair Lady Project has ended.

Project Challenges beyond Drug Addiction and Mental Health Problems

Aside from the aforementioned issues, the My Fair Lady Project has faced some additional challenges. Insufficient funding for full-scale implementation has proven a major obstacle. Increased funding is needed to address the full range of problems commercial sex workers (CSWs) face, both on and off the streets, especially for programs staffed and managed by peers. Drug treatment, housing, child care, and skills training for CSWs are essential. Better healthcare services are needed for CSWs, including diagnosis and treatment for STDs/HIV, care for injuries due to violence, and mental health care.[5]

When the My Fair Lady Project proposal was submitted in 2004, the total original funding request was $480,271, which would have funded a 15-member outreach team over a three-year grant cycle. In the original model, the proposed outreach team included a full-time project coordinator, two rehabilitated commercial sex workers/peer educators during the first year, and the extensive rehabilitation and addition of 12 new peer educators by the conclusion of the project in year three.

The original My Fair Lady Project targeted an audience of 126 known commercial sex workers in Robeson County (as documented in 2004 by state Disease Intervention Specialists stationed in Robeson). The project extended to include some 500 individuals within the periphery of services available through partnering agencies.

Grant reviewers favored the project's novelty, but due to budget constraints the project was awarded a total of $90,000 total with $30,000 awarded per year over a three-year period. Resisting the inclination to decline partial funding, health department staff and their community partners downsized their approach. Without funding for a full-time project coordinator, project oversight fell upon the department's existing Syphilis Elimination Coordinator. And, with insufficient funds to recruit, rehabilitate and reintroduce 14 former commercial sex workers, the "novel approach" was reduced to just two peer educators. Only one peer educator's salary was to be paid from the My Fair Lady grant. The second educator would be recruited by the first paid employee and connected with the rehabilitation and education necessary for skilled employment.

Despite the fact that both of the original women succumbed to their former drug addictions, the project was initiated as planned. The first Fair Lady participant recruited the second who was enrolled in the Certified Nursing Assistant Program at the local community college at the time of her dismissal due to drug relapse. The costs of her tuition and books were covered by grant funds.

Effective Supervision of Dual Projects Proves Difficult

Though the Syphilis Elimination Program and the My Fair Lady Project share a common goal, single supervision of double duties has proven disadvantageous. Newly rehabilitated substance abusers and commercial sex trade workers lacked the self-assurance needed to return to their old environments without consistent public health companionship. Frequently, the Syphilis Elimination Coordinator was unable to accompany the peer educators in their daily street outreach activities, due to her full-time job obligations.

Another setback to successful implementation involved staff training. A deficient budget prohibited training using the Real AIDS Prevention Project (RAPP©) intervention model. RAPP© is a community mobilization program designed to reduce risk for HIV and unintended pregnancies among women in communities at high risk by increasing condom use. This intervention relies on peer-led activities, including: outreach/one-on-one brief conversations with brochures, referrals, and condom distribution; small group safer sex discussions and presentations.[4]

Lessons Learned

As previously detailed, Robeson County public health officials and community partners have learned valuable lessons regarding recruitment, rehabilitation, and reintroduction of former CSWs. Project shortfalls should not be viewed as failures, rather they should guide the course for those seeking to reduce the occurrence of HIV and other sexually transmitted diseases through decreasing the number of commercial sex workers. **NCMedJ**

A Vaccine for Genital HPV:

A Time to Rejoice!

P. Frederick Sparling, MD

In this issue of the journal, Dr. Steven Cline discusses in his Issue Brief the newly licensed and approved vaccine "Gardasil" for human genital papilloma viruses (HPV) types 16, 18, 6 and 11, produced and marketed by Merck.[1] The vaccine requires three parenteral injections over six months, and is expensive ($360). It is approved by the FDA for use in females ages 9-26. A similar vaccine is in development by GlaxoSmithKline, and may be presented for approval in a year. This is an exciting development because HPV types 16 and 18 are the principal causes of cancer of the cervix, accounting for about 70% of such cancers in the developed world and about 60% in less well developed areas of the world. HPV types 6 and 11 are responsible for about 90% of benign genital warts. Clinical studies of the Merck vaccine were about two years in duration, long enough to document remarkable protection against persistent infection and the early cytological changes (cervical intraepithelial neoplasia, or CIN-II and III) that are the prelude to cancer.[2] The clinical studies were limited to women ages 15-26 but studies of immunogenicity in girls 9-15 show the vaccine is equally immunogenic in children. It is extremely likely that the vaccine will prevent HPV 16 and 18 associated cancers that typically follow persistent HPV infection by many years. The Glaxo vaccine consists of only HPV types 16 and 18 only, but appears equally efficacious in preventing incident HPV infection by the type strains in the vaccine, and seems to provide durable immunity at least up to five years.[3]

It has been clear for decades that cervical cancer is associated with sexually transmitted diseases. Extensive basic and clinical research finally narrowed the cause down to the minority of HPV infections in which HPV DNA integrates into host DNA, persisting for years, down-regulating two important tumor suppressor genes, and eventually leading to cancer. Most incident HPV infections clear due to immune responses in less than two years, but persistent infection is dangerous.

How the Vaccine Works

The vaccine is composed of a combination of viral-like particles (VLPs), made up from recombinant HPV protein L1 prepared from each of types 6, 11, 16 and 18. Protein L1 self-assembles into an empty viral capsid (VLP), and lacking any other viral proteins or DNA, is entirely safe. Conformational L1 epitopes are expressed in the VLPs, undoubtedly important to the vaccine's efficacy. The vaccine is quite immunogenic, and stimulates an antibody response that blocks initiation of infection. Remarkably, the vaccine was almost 100% effective in the clinical trials in prevention of infection by the covered types of HPV, but has little effect against most other HPV types. It also has no effect on already established infection. The Glaxo vaccine, which uses a different adjuvant, also results in a cellular immune response against the vaccine strains and a few very closely related HPV types, and may have limited effects against a few other HPV types.[4]

> *"Public acceptance of this vaccine should help pave the way for acceptance of other STD vaccines, when they become available."*

When Must Vaccination Take Place?

The question is, will the HPV vaccines be accepted and widely used? For them to be effective, they must be used before women acquire HPV, which happens soon after onset of sexual activity. Sexual activity often commences in adolescence,

P. Frederick Sparling, MD, is Professor and Chairman Emeritus of the Departments of Medicine and Microbiology at the University of North Carolina at Chapel Hill, and Professor of Medicine at Duke University Medical Center in Durham. He can be reached at zman@med.unc.edu. Telephone: 919-843-8598.

whether parents approve or not. Some have worried that a vaccine for a sexually transmitted disease will only serve to promote sexual activity among the young and susceptible. A recent meeting of the Centers for Disease Control and Prevention's (CDC's) Advisory Committee for Immunization Practices (ACIP) recommended widespread deployment of the vaccine in school aged girls 12 and older, and noted that it may be used in girls as young as nine, so as to prevent acquisition of HPV before onset of sexual activity. Clearly this is crucial, since the vaccine has no therapeutic activity for established infection, and must be used before exposure to the virus. This recommendation was hailed by most public health authorities, and the stage is set to find out just how well the public accepts this new vaccine.

Remaining Questions

Many questions about the HPV vaccine remain, including how it can be deployed in populations in the United States, and especially abroad, who are unable to afford its cost. How durable is the immune response? Will booster immunization prove necessary? Will women continue to undergo regular Pap smear testing, which will be necessary because all HPV types associated with cancer are not included in the vaccine? Although the vaccines appear very safe, will large scale use reveal rare and unanticipated side effects? Will use of a vaccine that includes HPV types 6 and 11 lead to use in men, to prevent socially unacceptable, visible genital warts? Will use in men have an impact on their female sexual partner's risk of acquiring genital HPV? On the longer range horizon, can other vaccines be developed that are effective against established HPV infection?

What about the Prospects for Vaccines to Prevent Other STDs?

The triumph of this development effort, culminating a huge effort by scientists across the globe for well over 20 years, raises the question of whether other vaccines for STDs are imminent. Unfortunately, the answer is "no" with perhaps one exception. A huge effort to discover a vaccine for HIV has been entirely fruitless to date. Although there is a bit of experimental evidence that a vaccine for syphilis might be possible, basic research demonstrating antigenic variation of a key surface protein is one of many arguments that a vaccine will be difficult to discover and even more difficult to develop. Gonorrhea and genital chlamydia have stirred only a modicum of vaccine interest, and the results have not been encouraging. The gonococcus is a master at immune evasion and perhaps also immune suppression, and a few small efforts to develop a vaccine have failed completely. There is no enthusiasm among pharmaceutical companies for development of such vaccines, in part because of their difficulty and expense of development, and also undoubtedly because of market considerations. That is unfortunate, because gonorrhea and chlamydia are common diseases in much of the world, with significant sequelae, and in the case of the gonococcus at least, resistance to antibiotics is spreading rapidly.

The one bright spot on the horizon is herpes simplex virus (HSV). This common and debilitating disease, the cause of so much angst in the pre-HIV era, is still very common. It is one of the major causes of genital ulcers that promote the sexual transmission of HIV. A recombinant surface glycoprotein D is undergoing an extensive phase III trial against genital HSV. Early results showed promise in prevention of disease in women who were seronegative for both HSV-1 and HSV-2, although there was little or no effect in women previously exposed to the virus, or in men.[5]

Challenges Ahead

We should rejoice in the advent of a vaccine for HPV. One hopes that concerns of social conservatives about the possible effects of a vaccine for a sexually transmitted disease on sexual behaviors will not limit use of the vaccine, and that means to pay for the vaccine in those who most need it will be found. Recent evidence suggests both the HPV vaccine and a potential HSV vaccine will be widely acceptable to adolescents and their parents.[6] Public acceptance of this vaccine should help pave the way for acceptance of other STD vaccines, when they become available. The HPV vaccine is the second vaccine to enter clinical use that prevents an important human cancer, joining the hepatitis B vaccine. **NCMedJ**

What North Carolinians Can Expect from the Healthcare System:

Eleven Things Learned During a "Special" Month of Residency Training

Harriett Ravenel Purves, MD, MPH

Most days, residency overwhelms me. To begin with, I am constantly reminded of how much I still have to learn. Despite the years of college and medical school and two years of residency, there are always questions I still cannot answer. Then, there are the long workdays. And, while they are admittedly not as long as they used to be, they proceed at a frantic pace. I almost wish I were allowed to stay in the hospital longer so I could just slow things down, but I am expected to complete my work within an average of eighty hours per week and I am gently scolded when I don't. And finally, there's everything in between—running to code blues, reassuring worried families, returning calls from nurses, social workers and pharmacists, documenting all of the above into the medical record.

Occasionally, during my "good" months, I can get past the hectic days and the intellectual insecurity, but I am left with something equally unsettling. When I have the luxury of time to think about my profession—what I do and the system within which I do it—I am overwhelmed again. I began thinking harder about my profession earlier this year when my father got sick. He was admitted into the hospital twice. He represents a truly fortunate patient—he is well-insured, well-educated, even medically-trained (though he gave up clinical medicine long ago) and he had excellent outcomes. Yet, through two hospitalizations, and weeks of recovery, he had just as much trouble navigating the healthcare system as patients like my non-English speaking, poorly-educated patient from Honduras. It made me wonder: how can this be?

The more I thought about it, the more I wanted an answer. My father's illness came up in conversation with other physicians and I kept prodding them for ideas. My colleagues had plenty of examples of the mysterious ways in which the healthcare system works (or fails to work). I decided to investigate further. As part of my second year training, I had a really good month, a "special" month (as it appeared on my web-based residency schedule) coming up. These special months are built into training to allow residents to pursue research, design a focused rotation or work in another city or country. So, for my special month, I set about to ask and answer my question: "How can this be?"

> *"My colleagues had plenty of examples of the mysterious ways in which the healthcare system works (or fails to work)."*

I phrased the question in general terms. I asked, "What can North Carolinians expect from the healthcare system in the coming years?" I emailed the question to different healthcare professionals I thought would have strong opinions on the matter. I asked them to meet with me to discuss their thoughts. I also asked them to suggest reading material and the names of other people who might be willing to talk with me. The response surprised me. Almost everyone I asked agreed to sit down with me for thirty minutes—which inevitably turned into an hour. They were extremely generous with their time and gave me a lot to consider.

Among the people I interviewed were department chairs, heads of professional societies, health services researchers, public health employees, and primary care physicians. Each person I interviewed had a different perspective, but there were overlapping themes. Though many were pessimistic about the state of the

---

Harriett Ravenel Purves, MD, MPH, is a third-year resident in medicine and pediatrics at the University of North Carolina Hospitals in Chapel Hill. She can be reached at hpurves@unch.unc.edu. Telephone: 919-599-1652.

healthcare system, I was inspired by the thoughtfulness of their answers and the glimpses of hope I found in each interview. I chose eleven ideas that came from the interviews to write about in this article. Because I realized it would be impossible to attribute each point to a single interview, I have thanked the interviewees collectively at the end. But what I learned did not come solely from my conversations with them; I must also acknowledge and thank my father, who has recovered completely and is in good health; the rest of my family, who provide me with plenty of fodder; and my patients, who bravely put up with the healthcare system in the face of illness and who have taught me the most of all.

1. The Healthcare System is Broken.

I am sorry to say that the word "broken" was used most often to describe the healthcare system during my special-month discussions. Other words often used to describe the healthcare system: complex, unpredictable, chaotic, fragmented, flawed, inaccessible, out-of-control, and worst-in-the-world. (Some of the people I interviewed were more pessimistic than others.) I am sure there are some out there who think things are just fine with healthcare, but I suspect those people work in some subsection of healthcare that has managed to remain unaffected by the larger system. And, I am sure some healthcare workers actually make a point of avoiding the larger system—those who have gone into "concierge medicine" where they explicitly spend more time with patients and often accept only cash payments so as to avoid the reimbursement systems. Everyone I spoke with, however, works under the umbrella of the larger healthcare system and they had plenty of stories to back up their use of the word "broken."

I came into the month with my own stories about the shortcomings of today's healthcare system—my stroke patient who needs physical therapy, but cannot find anyone to provide it because she is uninsured; my hepatitis C patient who does not qualify for a liver transplant because of her weight, but can't afford any weight-loss programs; my newborn baby diagnosed prenatally with abnormal kidneys, but whose parents never followed up because of transportation issues.[1] In some cases, I blamed myself as much as the system for these shortcomings. I should be able to work around these obstacles. Surely I could find a physical therapist who would do pro bono work if I looked hard enough. And there must be some way to help my hepatitis C patient lose weight without a costly program. Maybe, with experience, I will learn all the tricks required to get around these system roadblocks.

But the people I interviewed, despite their experience, had as many frustrations as I did. One pediatrician who works at one of the very few clinics that provides care for a large number of Spanish-speaking patients told me that the hospitals in the area refer almost exclusively to her clinic when Spanish-speaking patients need primary care. That means she and her partners get almost all of the newborn babies from the local hospitals born to Spanish-speaking patients. So their appointment book fills with newborn and well-baby appointments (since babies need far more visits in the first year of life than their later years). With all the well-baby appointments, there is not much room left for "sick" visits. So, when a child who is an established patient of her clinic gets an ear infection, instead of being able to make an appointment for an $85 clinic visit, he may wind up in the emergency room where his parents will likely get charged as much as $600.

To make things worse, if that child is uninsured his family will be responsible for the full amount. If the child is insured (by an insurance company with a negotiated rate for its beneficiaries), on the other hand, the hospital may accept as little as $200 as payment in full from the insurance company.[2] What's more—and to add to the potential complexity of this hypothetical example—the child with the ear infection may get antibiotics as treatment or he may get a prescription for antibiotics and recommendations about when to fill it or his parents may get reassurance and be asked to follow-up in a few days. All three options are acceptable under the AAP (American Academy of Pediatrics) guidelines regarding treatment of acute otitis media.[3]

While this example highlights the unpredictable and inefficient way things happen, at least the child will get treated. There are plenty of places in the world where healthcare is not even an option. Most everyone I interviewed qualified their (horror) stories about the healthcare system by saying that it is still possible to get good healthcare in the United States. In fact, depending on the medical problem, you may be able to get some of the best care in the world. Even if your illness is routine, there are doctors who go above and beyond to make things happen in spite of the system. Within the broken system, there are success stories and I heard some during my conversations, just not as many.

2. In Order to get Good Care, You Need to know How to Work the System.

As I mentioned in my introduction, my father got sick earlier this year. He had high fevers and did not feel well at all. Eventually, when he could no longer work (the ability to work being his and many patients' measure of health) he went to an urgent care clinic. It was a Saturday, and his primary care office was not open. From Urgent Care, he was sent to the hospital emergency room. No one there could figure out exactly what was wrong with him, but he appeared seriously ill and, much to my family's relief, he was admitted to the hospital. There were not many clues to go on, but in rather short order, his doctors discovered he had a liver abscess, ultimately of unknown etiology. He underwent CT-guided drainage and started on a long course of intravenous antibiotics. His story falls into the category of a "success story." Before he left the hospital, in a moment I try to remember when I'm deep in the grunt-work of residency, he told the attending physician, "You saved my life."

He never complained about the care he received, but there were plenty of bumps on the road to recovery. At home, when his drain stopped working, he asked me who he should call. The system has changed a lot since he was in medical school and he didn't know who was "in charge" of his outpatient care.

I asked him where his doctors had scheduled him to follow up. He had an appointment in the infectious diseases clinic, so I suggested he call there. Fortunately, he works at the same institution where he got his care and he knew the infectious diseases attending physician who was assigned to his case. He paged the attending to let him know about the blocked drain and another CT was arranged to see if the abscess had drained completely.

I wonder what would have happened if he'd called the office number and had to go through the secretary and nurse. It might have worked out, but it helped that he could go straight to the person who could make things happen. Even when patients are not connected in the traditional sense, they sometimes get lucky and make connections. One of my patients, for example, has figured out that the hospital operator will page me directly if she calls during business hours. I am not sure if she says something special—I would think more patients would call me this way—but she always gets a hold of me. Many more patients, I am afraid, are getting the run-around…endless automated messages; unhelpful, overburdened secretaries answering their calls; appointments made months in the future. Even when I decide to make some of the phone calls myself—to make a subspecialty appointment, for example—it seems I'm just as likely get the run-around. (And, from what I hear around the hospital, it doesn't seem to change even when you are an attending.)

I spent a lot of time during my special month pondering what it means to have "connections" and how people have learned to "work the system." The examples I came up with reminded me of the time I've spent in developing countries. In my travels, I found that having connections is sometimes the only way to get anything done—not just in health matters. Realizing that working the healthcare system in the United States is not that different from making more mundane things happen in the third world made me wonder how long will it be before the overburdened secretaries start accepting bribes to get people seen sooner. If things don't change, it might not be too long until the equivalent of a healthcare black market emerges in which the only way to get things done efficiently is to go around the official system.

3. In America, Healthcare is a Commodity.

In all of my interviews, the topic of healthcare inevitably turned, at some point, into a conversation about business and economics. No matter what your perspective, discussing our healthcare system inside a capitalist framework is inevitable. For better or for worse, it is impossible to separate the humanitarian aspect of caring for the patient from the financial aspect. In medical school, I learned from one preceptor that I should not ask about a patient's insurance status because it should have nothing to do with the way I would treat them. That made sense to me; I shouldn't treat a patient any differently based on his/her ability to pay. A few years later, though, I learned from another preceptor—this time at a community health center—that she essentially asks all her patients about finances. Though she had found an indirect way of getting that information—by asking, "How do you get your medicines?" She didn't want patients to think she might treat them differently if they did not have insurance, but she also wanted to make sure they had a way of getting the medicines she prescribed. That made sense to me as well; what is the point of prescribing something that the patient has no hope of getting? It comes back to the same question: who is going to pay?

Healthcare as a commodity has some strange effects on our practice of medicine. One physician described the "perverse incentives" generated by the healthcare market. The business goal is, "to get as many procedures done as quickly as possible." Maybe, we decided, if you are an aesthetic dermatologist, this philosophy makes sense. Both you and your patients would benefit from the increased number of procedures. In most instances, though, the goal of "throughput"—getting patients through the system and generating the highest number of procedures—may not be such a good idea…especially if you can't be sure how much your procedures actually benefit your patients. And knowing which patients will benefit from which procedures is not as straightforward as I once thought. It takes time to investigate a patient's history and to decide, given his specific circumstances, if he should go through with a certain procedure.

What may appear to be an obvious answer to an obvious problem is not always clear. For example, if a patient has blockages in his coronary arteries, surgery to bypass those blockages seems the obvious answer. Having done two months of adult cardiology as a resident, it came as a shock to me that some physicians argue, based on existing evidence, that very few people should undergo coronary artery bypass grafting.[4] The argument is that bypass grafting may not really change how long a patient lives and, there are significant risks associated with bypass operations. I can appreciate this argument because I have now seen many instances where the effects of treatment ended up being worse than the disease. Debates like this one make me question the interventions I advocate on a daily basis in the name of cure. Depending on my mood, I start to wonder if I am accomplishing what I set out to do—that is, am I helping people? Or am I just an unwitting cog in a system set up to generate money? The business aspect of medicine certainly adds several degrees of complexity to the system.

On the other hand, if it weren't for the business of medicine we wouldn't have some of the state-of-the-art treatments that make a real difference to certain patients. Plus, using a business framework to improve healthcare has proven useful again and again. Many quality improvement plans, for example, are based on business concepts utilized by car manufacturers and air flight controllers to obtain higher quality. One such concept is that variation is a sign of poor quality. Collecting and analyzing data about variation within a business is critical to the process of improvement.[5] Hence the innumerable guidelines now published on a variety of disease entities, which are meant to reduce variation in the practice of medicine. So, treating healthcare as a commodity and the healthcare system as a business has its advantages. In fact, after thinking more about it, I realized that maybe we need to convince more patients to think of health itself as a commodity.

4. Patients Don't Desire Health the Same Way They Desire an Ipod.

For most people, health is an abstract concept. When we are healthy, health is something we almost never think about. We are not actively seeking health in the same way that we might seek the latest MP3 player or flat-screen TV. It surprises me when I meet patients who plan their lives around staying healthy, people who, for years on end, exercise daily and eat the recommended number of vegetable servings, etc. The occasional patient may simply be wired that way, but most people don't make dramatic lifestyle changes until actually experiencing illness in one way or another. I have a patient who finally quit smoking when his wife was diagnosed with lung cancer, for example. The female rap star, Missy Elliott, worked to lose a significant amount of weight after her doctor told her she had high blood pressure. Fear of illness can be a tremendous motivator. But can we motivate "well" people to actively seek health?

One pediatrician I interviewed said that if she taught in the elementary schools, she would make every child bring in a family tree that included medical histories of each relative. She would use the trees to talk about why the children should want to control their cholesterol and weight. I'm afraid that even a family tree might still be too abstract. Studies examining the use of smoking prevention and cessation techniques with kids found that seeing pictures of atherosclerotic aortas and smoke-blackened lungs scared some children into healthy lifestyles, but not the majority of them.[6] Another pediatrician talked about showing pictures from an era gone by to the young parents who don't want their kids to be immunized—pictures of when children were devastated by vaccine-preventable diseases. He thought it might change their minds. But if direct visual examples don't work for kids, I'm not sure they will work for their parents.

So how do we motivate people to actively seek health? And if we decide that scaring people about the prospect of illness is the most effective technique we have, are we willing to accept the consequences of instilling those fears? Acting on fears may backfire in ways that are difficult to predict as the example in the next section points out.

5. People Avoid Changing Jobs for Fear of Losing Health Insurance.

The fact that people stay in jobs because of wage-related benefits is not a new observation. It's probably been as true for workers in the distant past as it is now. But the trend is more worrisome now because, these days, business relies more heavily on the flexibility of the workforce. If workers are reluctant to move into new positions—positions available to them presumably because they have skills that could be put to effective use—jobs for skilled workers remain unfilled and our economy is less efficient. There is good reason to think twice before leaving a job that has health insurance: fewer businesses are offering health coverage and even if a new job promises insurance, it will likely cost you more.[7]

Another problem with new employer-based health insurance is that its benefits may not kick-in right away. Since we know that insufficient insurance can end up costing the system more money, waiting for benefits to kick in must cost the system, too. As an example—my own insurance. Until this year, medical residents in my training program were not eligible for the Family Medical Leave coverage (or the equivalent) until they had been working at the hospital for at least one year.[8] Accordingly, first-year residents in the past may have consciously delayed childbearing. I recognize that there are many other reasons a woman might delay childbearing; but, for some, this was probably an important one. I can imagine that for the unlucky individual, waiting a year could mean the difference between fertility and infertility. And that could mean the difference between a straightforward pregnancy/delivery and a more complicated, expensive pregnancy and delivery. During my special-month interviews, I realized that the link between jobs and insurance is increasingly problematic.

6. Big Business will Lead the Way to Reform.

Wal-Mart has been the target of much criticism about its benefit programs, specifically its healthcare benefits.[9] In 2004, it was even the target of an advertising campaign to drum up support for California's Proposition 72, legislation that would have expanded healthcare coverage in that state. The ads criticized Wal-Mart for not offering affordable healthcare to its employees. The company decided to get involved in the debate.[10] Healthcare expenditure is a big deal for all large corporations—not just because it costs them money, but also because healthy workers are more productive than sick ones. Because of this, more companies are joining the debate about who should pay for healthcare. Some companies, like Chrysler, have publicly supported universal, national health coverage.[11] Others have an interest in keeping the healthcare system more or less the way it is.

Big corporations spending a significant amount of money on healthcare for their employees should have an interest in reform. But, I would expect insurance and pharmaceutical companies, whose profit margins depend on the money spent on healthcare coverage—to support the status quo. I learned, however, during one of my interviews, that Dr. Jean-Paul Garnier, the Philadelphia-based CEO of GlaxoSmithKline (GSK), supports a national healthcare system. What he proposes would cover catastrophic care and help cover people who are between jobs or whose employers do not provide coverage.[12] I suppose that having more people insured—even if it only includes bare-bones coverage—would free up more of a patient's income to pay for his medicines. This could explain why Garnier would be in favor of such a plan. And maybe it is wise to advocate for this plan before another type of plan—one that would allow the government to get big discounts on GSK pharmaceuticals, for example—comes up for debate.

Still, his support of some type of national healthcare system suggests that there is a will on the part of big business (and there is certainly the power) to lead the way to reform. So, we had better make sure big business's way jibes with what physicians and other healthcare professionals want. Accordingly, several of the people I interviewed stressed the importance of allying ourselves (in the medical profession) with business. North Carolina has worked hard to attract big business to the state. Now that big business is here, maybe we should work harder to align our goals on issues that affect us both equally—issues like healthcare.

7. Technology has Increased Costs and Caused Physicians to Specialize.

During my special month, the theme of technology came up just as much as the theme of business. "It used to be that premies born before a certain gestational age just died," one pediatrician reminded me. Technology has changed that. Now we keep babies alive who spent just over half the usual time in their mothers' wombs. And many of them (depending on your perspective of what percentage constitutes "many") grow up with no measurable deficits. Not long ago, one of the ER nurses told me that she is a former 27-week premie. "They told my parents I would be blind, but I see just fine. They also told them there could be mental delays…the jury's still out on that," she joked. Thanks to ventilators that can pump air into their fragile, tiny lungs in just the right way, these babies are much more likely to survive. Likewise, it is not just "any pediatrician" who helps them make it into childhood. Most often, it is a neonatologist, a specially trained pediatrician, who understands those ventilators inside and out, among other things.

It is hard enough to keep abreast of the new technologies available in a single field such as neonatology; it is impossible to keep abreast of all fields in medicine. There are a few souls who appear to know everything (there is one sitting in every morning report I have ever been to), but they must not sleep or eat. No normal human being can keep up with all the information out there. More commonly, and more understandably, I meet specialists who know everything there is to know about their specialty, but may not have kept up in other areas.

A specialist is responsible for knowing a limited set of diagnoses, treatments and management guidelines. A primary care physician, on the other hand, may not have to learn new technologies, but has to keep track of all the guidelines to make sure that the patient is getting the recommended care—whether it comes from the primary care physician or from the specialist. The primary care physician has to coordinate and synthesize the care from a multitude of specialists who may be working with a single patient. That task requires intense organization, clear communication and quite a bit of time and patience. As a resident, I respect the power of technology and the knowledge of specialists, but I also have newfound respect for primary care providers.

8. Physicians Don't Go into Primary Care Because They Dread It.

It finally dawned on me why residents, as a rule, dread going to clinic. Most residents spend a half-day a week in clinic. The rest of the time we are in the hospital. The outpatient world operates differently and it requires a separate skill set. I cannot speak for all residents, but my visits to clinic are just frequent enough to make me painfully aware of my inadequacies. Give me the eighty-year-old Alzheimer's patient who has been rejected by every nursing home in the tri-county area and I will find placement. Give me the new-start dialysis patient and I will make sure vascular interventional radiology places a permcath before the day is out. But, give me an otherwise healthy young woman with sinus problems and I am clueless. I am never quite sure of my role when caring for my clinic patients. How much should I do for them? How much should I expect them to do for themselves?

One internist explained the problem to me this way, "With inpatient medicine, there's a sense of control. If you're in the medical ICU you can control a patient's blood pressure, his breathing, his blood sugar. With outpatient medicine, you have no control. You don't know if a patient will take the medicine you've prescribed or go for the mammogram you scheduled. It's a psychological issue." By psychological, he meant that, in the hospital, you have a completely different mindset and it's hard to turn it off and on. While the rewards of outpatient medicine seem greater (I cannot describe how great I felt when my first patient told me she quit smoking because of something I said to her), the frustrations also seem greater (I also cannot describe how guilty I felt when I failed to prevent my obese, diabetic patient with coronary artery disease from going into the hospital each time—seven times in the past year). The same physician who told me about the psychology of control reassured me, "You have to realize that there are 10-15% of patients who won't do well…even if you're Sir William Osler and Mother Theresa all in one."

9. Doctors Can Make a Difference.

If you have gotten this far, despite all the discouraging news, relax…here comes the uplifting part. Several of my interviewees reminded me that doctors do make a difference. We may learn tomorrow that for the past twenty years we have been treating [insert any number of disease processes here] all wrong, but we will likely still make a difference to the patient suffering from that disorder just by supporting him/her through it. I think it means a lot to a patient simply to learn about what ails him/her—it gives him more control. For the families struggling with a loved one compromised by illness, doctors can also offer great comfort. Many have written about the patient-doctor relationship and, though I will not dwell on it here, despite the chaotic system in which we work, I came away from my special month convinced doctors can and do make a difference.

10. We Need to Get Smart, Old People Energized.

This piece of advice came from a newcomer to North Carolina who told me that the fastest growing population in our state is the one made up of older adults. This surprised me since my background includes work with the Latino population and a commonly touted fact is that North Carolina has the fastest growing Latino population in the country. The latter fact may be true, but the elderly population is larger and growing at an even faster rate. The baby boomers are aging into this population and elders from other states are migrating to North Carolina. Of course, not every person over "retirement age" is retired. And the working elderly population may be one of the most respected and influential groups in the state. It also happens to be a group that relies more heavily on the healthcare system.

To add to this idea, I would say that we need to get smart, old doctors energized. I don't mean to offend and reader with my choice of wording—I only say it this way to point out that there is a fair number of retired physicians in North Carolina's older population. And who better to advocate for change than those who are intimately familiar with the provision of healthcare? Retired doctors (in my mind) have "special months" one after the other. So they might have time to push legislators on these issues. And I would like to issue a challenge to them to complain.

The same person who spoke to me about the retired population —a Yankee—remarked how little North Carolinians seem to complain. For example, if more people of my father's generation started to make a stink about the hoops they jump through to get an appointment or prescription drugs, change might happen sooner. After thinking about this more, the thought of driving to the nearest retirement community (there is one less than half a mile from my house) to encourage elders to complain crossed my mind. But all good (and "special") months come to an end. Before I knew it, I was back in the hospital most of my waking hours. Starting a movement did not appear feasible anymore. Fortunately, I had come up with another way to do something that I can do even on my bad and even really bad months.

11. Participate in Professional Societies.

There were mixed opinions about this advice, but more of the people I interviewed supported it than not. Part of my motivation in designing my special month stemmed from my growing obsession with choosing a career path. Without explicitly using the words, the question, "What should I do with my life?" came up implicitly in every interview. I tried to explain my general goals to see if the interviewee would come up with a specific job description. One physician swiftly diagnosed me, "You have the same disease I do. You want to change the world." I have been accused of this in the past and even been mocked for it. It may be naïve, but I still have hope.

Before my special month, I believed that a single, carefully chosen job would allow me to accomplish my divergent and unwieldy goals, which include knowing everything I possibly can about internal medicine and pediatrics, becoming a trusted doctor for a wide range of patients, staying in touch with healthcare trends and policies, and maintaining a balanced lifestyle. Again, I freely admit the naivete behind this belief. Fortunately, this last piece of advice may have saved me, particularly with regard to staying in touch. There just may be a way to step back and keep abreast of what is happening generally in medicine and the healthcare system—even, when I spend every fourth night in the MICU or, later, when I become an attending…namely, participating in an organized group of my professional peers.

For the past two years, I have shamelessly deleted the email invitations to local meetings of the different state and local medical societies because I thought it would take away too much of my prized free time. But I am going to try a meeting or two because I realized during my special month that contact with other people interested in the challenges of the healthcare system—importantly, outside of the hospital and clinic—reenergized me. I may not have found all the answers during my special-month interviews, but I was inspired and motivated by the thoughtfulness of the excellent clinicians and thinkers who spoke with me. I hope to have many chances to continue the conversations we started. **NCMedJ**

Acknowledgements: The people I interviewed all contributed significantly to my month and to my education in general. I am truly grateful. In alphabetical order, they are: John Buse, Chief of the Division of Internal Medicine and Clinical Epidemiology, UNC-CH; Timothy Carey, Kenan Professor of Medicine and Director, Cecil G. Sheps Center for Health Services Research, UNC-CH; Darren DeWalt, Assistant Professor of Medicine, UNC-CH; Robert Gutman, Durham Nephrology Associates; Nortin Hadler, Professor of Medicine and Microbiology/Immunology, UNC-CH; Harvey Hamrick, Director, Pediatric Resident Training Program, UNC-CH; Peter Morris, Medical Director, Wake Human Services; Rick Mumford, Senior Assistant to the State Health Director for Health Disparities and Workforce Development; Thomas Ricketts, Professor of Health Policy & Administraton and Deputy Director, Cecil G. Sheps Center for Health Services Research, UNC-CH; Marschall Runge, Chairman, Department of Medicine, UNC-CH; Steve Shore, Executive Director, North Carolina Pediatric Society; Evelyn Schmidt, Director, Lincoln Community Health Center, Durham; Pam Silberman, President & CEO, North Carolina Institute of Medicine; Alan Stiles, Chairman, Department of Pediatrics, UNC-CH; Elizabeth Tilson, Medical Director, Community Care of Wake/Johnston County; Brian Toomey, Chief Executive Officer, Piedmont Health Services; and Charles Willson, President, North Carolina Medical Society and Department of Pediatrics, East Carolina University, Greenville.

REFERENCES

1 My sister, a social worker, pointed out that the stroke patient and the obstetric patient might qualify for Medicaid, the first because she is disabled and the second because she was pregnant. Unfortunately the first patient is not a citizen and therefore does not qualify for Medicaid. The second, also not a citizen, probably did qualify for Emergency Medicaid, which covers many costs of prenatal care and delivery for noncitizens. She may have been able to get Medicaid van services during her pregnancy, but if she was, she was unaware of this possibility and did not show for a repeat ultrasound.

North Carolina MEDICAL JOURNAL

One of North Carolina's Largest Philanthropies Supports and Listens to HIV/AIDS Service Providers

Edgar G. Villanueva, MHA

One of the target populations served by the Kate B. Reynolds Charitable Trust (KBR) over the past decade has been low-income North Carolinians with HIV/AIDS. In the past five years, grants totaling over $2.4 million have been made to HIV/AIDS service organizations across the state. While grants have supported prevention efforts, access to primary care, mental health, and end-of-life services, the vast majority of the grants have been for the provision of case management services for HIV/AIDS clients. Case managers play a pivotal role in the health of individuals with HIV/AIDS. For example, case managers conduct comprehensive needs assessments, then develop and manage service plans with clients. They advocate for clients, make appropriate referrals, and link them to public benefits, medical care, mental health services, and substance abuse treatment. They often provide basic counseling and crisis intervention as well.

In January 2006, KBR convened 24 HIV/AIDS service providers, mostly case management agencies, to listen and learn first-hand of the challenges facing the agencies who daily serve this vulnerable population, many in rural, underserved counties. At this gathering, KBR garnered information from those who may be one of the most important links in providing comprehensive, continuous care to HIV/AIDS patients.

When asked what the significant healthcare needs in their communities were regarding HIV/AIDS, the greatest need identified was the lack of access to primary medical care and dental services for HIV/AIDS clients. Other significant needs described were housing and medications. When asked about some of the barriers their agencies faced in delivering HIV/AIDS services, four key issues were noted. The issues were lack of ongoing operating support, education for clients and the community, lack of transportation for clients, and the stigma associated with HIV/AIDS.

Next, KBR inquired about the methodologies (treatment or prevention) that the agencies considered to be most effective in providing HIV/AIDS services. Overall, education and awareness were considered to be the most effective in the prevention and treatment of the disease. Other methods were face-to-face interventions, prevention presentations by HIV+ clients, and outreach and testing. Many agencies commented that they saw the most successful outcomes from one-on-one interventions, especially when HIV+ individuals were involved. These individualized approaches are more effective than social marketing campaigns, particularly in smaller, more rural communities where stigma has prevented the broadcast of HIV/AIDS-related messages. KBR also learned that the agencies most often obtained information about best practices in disease prevention and treatment from the North Carolina HIV/STD Prevention and Care Branch. This is not surprising as the agencies rely on the state for their certification, training, and the majority of their funding. In those communities where Infectious Disease physicians are available, local service providers also relied on these physicians to keep their staff informed.

As KBR learned from the January session, many HIV/AIDS service providers are 'spread thin,' causing them to work in silos, unaware of what their sister agencies are doing. In addition, they often feel disconnected from the medical community. One solution proven to impact this issue is demonstrated through an innovative KBR grant to the Western North Carolina HIV/AIDS Consortium in Asheville for a case manager coordinator. This position served as a point of contact in a 17-county area for 18 case managers. The coordinator ensured that case managers in rural areas had equal access to information and services as those in Asheville.

Despite the efforts of the healthcare and philanthropic community, the number of HIV-infected persons continues to increase. As of July 2005, there were 18,900 individuals living with HIV/AIDS in North Carolina. Many counties with the highest number of cases are among the poorest and most rural. As the number of infected individuals continues to rise, the North Carolina healthcare community and its partners should not overlook the role of community-based case managers in providing and supporting continuous care. Opportunities for collaboration and partnership are ripe to influence health outcomes for this population. **NCMedJ**

Running the Numbers

A Periodic Feature to Inform North Carolina Healthcare Professionals about Current Topics in Health Statistics

From the State Center for Health Statistics, NC Department of Health and Human Services
http://www.schs.state.nc.us/SCHS

Interpretation of Sexually Transmitted Disease Surveillance Data

By law, all cases of chlamydia, gonnorhea, syphilis, and HIV infection in North Carolina must be reported to the appropriate county health department. The information is then forwarded to the HIV/STD Prevention and Care Branch in the North Carolina Division of Public Health in Raleigh for compilation and aggregate reporting to the Centers for Disease Control and Prevention (CDC). The Branch publishes the data in the form of summary counts and rates. Correct interpretation of these published rates requires some knowledge of how the cases are detected and reported.

Chlamydia

The most prevalent reportable sexually transmitted disease (STD) in North Carolina is chlamydia. It is also the disease with the least reliable surveillance data. Cases of laboratory-confirmed chlamydia must be reported to the local health department within seven days. The surveillance problem lies in the fact that chlamydia is most often asymptomatic in both males and females. It is also a major cause of pelvic inflammatory disease (PID) and infertility in females. For this reason, there are a number of programs targeting asymptomatic young women for screening. There are virtually no comparable state programs for screening young men. Most male cases are detected and reported when infected females encourage their male partners to seek care. As a result, chlamydia case reports are highly biased towards screened populations, i.e. young women attending public clinics. In 2005 there were 31,183 cases reported in North Carolina, and more than 80 percent were female.

So how do we interpret the published data? Surveillance data are a very poor indicator of trends in chlamydia incidence. In fact, the growing number of case reports over the last five years is primarily due to the expansion of screening programs, an indication of positive public health activity. However, the surveillance data can provide some useful information. Recognizing that a great many chlamydia cases remain undetected and therefore unreported, the reported cases represent a lower boundary of the estimated prevalence of the disease in North Carolina.

Gonorrhea

Gonorrhea is the second most frequently reported STD in North Carolina, with 15,075 laboratory-confirmed cases reported in 2005. In contrast to chlamydia, nearly all gonorrhea cases among males are symptomatic and females are only slightly less likely to have symptoms. This means that many infected people will present for care and, if gonorrhea testing is ordered, their disease will be detected and reported. Additionally, many asymptomatic young women are screened for gonorrhea during chlamydia screening.

As a result, gonorrhea reporting is quite reliable and has no apparent gender bias (in 2005 50% of North Carolina cases were male and 50% were female). It is possible that public STD clinics may be more inclined than private healthcare providers to order gonorrhea tests (as opposed to presumptive treatment without testing). This tendency, and the female screening programs in public clinics, may lead to some reporting bias towards patients who attend public clinics, but this is difficult to assess. Gonorrhea reports have declined steadily for the last eight years and this is most likely due to a real decline in incidence of the disease.

Syphilis

All reactive syphilis tests must be reported to the local health department within 24 hours. Each individual reported will be investigated thoroughly to determine whether or not the person is infected at all and, if so, whether the infection is a new one or a failed treatment of a previous one. If the infection is new, the appropriate stage must be diagnosed as well. This investigation is conducted by local or regional health department personnel and can take days or weeks. Patients are interviewed to help determine their stage of infection and to identify sexual partners who have been exposed. These partners are then interviewed and tested for syphilis.

RTN—continued on page 396

RTN—continued from page 395

The early stages of syphilis have very distinct symptoms which makes diagnosis errors unlikely. In the later, asymptomatic stages, interviews are needed to establish the time of the infection and therefore the current stage. In general, reporting of early syphilis (primary, secondary, and early latent) in North Carolina is likely to be quite accurate.

Syphilis is much less common than chlamydia or gonorrhea (only 489 cases of early syphilis were reported in 2005). It is also viewed by providers and public health officials as being a much more serious disease. These factors make it much more likely that suspected syphilis cases will be tested and reported. Good initial reporting and thorough contact tracing of related cases make syphilis surveillance data the most reliable and complete STD data available in North Carolina. A small number of cases will always be missed by surveillance, but trends in early syphilis incidence mirror the true incidence in the population more closely than is the case for any other STD. The rate of early syphilis in North Carolina declined by approximately 50% from 2001 to 2005, due in large part to comprehensive public health control efforts.

HIV and AIDS

AIDS, the syndrome resulting from HIV infection, has been reportable in North Carolina since 1984, while HIV infection itself has only been reportable since 1990. Physician diagnoses must be reported to the local health department, which then forwards them to the state. In addition, laboratories must report HIV-positive results directly to the state. As previously described for syphilis, North Carolina has thorough contact tracing and partner notification programs for all cases of HIV infection and AIDS. Many cases are detected when the partners of HIV-infected index cases are interviewed and tested.

Because HIV infection is largely asymptomatic for many years, early detection is very dependent upon whether or not infected people are screened for the disease. This can lead to many of the same problems described previously for chlamydia — the surveillance data reflect the population that receives screening. In the early years of the epidemic, such screening was closely targeted to groups known to be at very high risk of infection. e.g., men who have sex with men and injection drug users. In recent years, HIV testing has been more widespread and public health messages have stressed that "knowing one's HIV status is part of good sexual health." However, the CDC estimates that currently one-fourth to one-third of all people infected with HIV have not been tested and therefore have not been reported with HIV infection.

When an HIV-infected person meets certain criteria (lowered CD4 cell counts, acquisition of certain infectious diseases, etc.) they meet a case definition for AIDS.

Because AIDS is generally symptomatic, it is likely that AIDS reporting is more complete than HIV reporting. However, some providers may be unaware that a patient previously reported with HIV must be reported again when AIDS case status is met. Also, approximately 30% of new HIV infection reports are among people who have already met the case definition for AIDS.

Because the stage of AIDS occurs very late in the course of HIV infection, AIDS surveillance data are not useful in evaluating the current epidemic trends. These data are most useful in assessing the prevalence of AIDS cases and the need for resources for treatment. Surveillance data for HIV disease (the first report of HIV infection, regardless of stage) are a better indicator of which groups are currently at highest risk. In 2005, there were 1,806 new HIV disease cases reported in North Carolina.

Finally, it should be noted that changes in case detection methods will have an impact on how many STD cases are reported. In May of 2004 the State Laboratory of Public Health changed to a more sensitive test for chlamydia. This immediately caused a slight increase in case reports as more tests were found positive. Likewise, the HIV/STD Prevention and Care Branch instituted some new policies surrounding laboratory reporting of HIV in 2003. This caused a number of "old" HIV cases to be first reported in 2003. The surveillance data reflect this with a noticeable increase in reports for 2003, which leveled off in 2004.

To view copies of published reports from the HIV/STD Prevention and Care Branch, please see our webpage: http://www.epi.state.nc.us/epi/hiv/.

Rapid Response Teams in North Carolina Hospitals

> *Mr. Smith, a 52 year old male underwent elective knee surgery. Post operatively on the hospital floor, he complains that he is uncomfortable and his respiratory rate has increased to 34 breaths per minute. His SpO2 dropped to 88 percent despite the 4-liters of nasal cannula O_2. The nurse pages the surgeon and twenty minutes later the surgeon calls back with an order to increase the morphine pump and increase the nasal cannula to 6-liters. A half-hour after the increased morphine and O_2 the nurse notes that Mr. Smith is more comfortable. His respiration had decreased to 26 breaths per minute, but his saturation dropped to 85 percent. The nurse pages the surgeon again and the surgeon verbally orders a CXR, ABG, ECG and a CBC and states that he will see the patient as soon as he finishes with his current patient. Forty-five minutes later the labs, CXR and the ECG were completed. Almost three hours after the symptoms were first noted, the surgeon and the code team enter the 52 year old man's room simultaneously. The man was resuscitated and spent the next 10 days recovering from an AMI in the ICU.*

Mr. Smith needed a rapid response team. The North Carolina Hospital Association, in partnership with the North Carolina Area Health Education Centers Program and The Carolinas Center for Medical Excellence (CCME), was one of nine Robert Wood Johnson Foundation grant recipients selected to establish hospital rapid response teams (RRTs). RRTs, also called medical emergency teams, bring critical care expertise to a non-critical care patient at the first signs of physiological instability. The aim of RRTs is to assist care providers to deliver the *right care* to the *right patient* at the *right time*.

In April 2006, 224 participants representing 58 North Carolina hospitals attended three regional RRT collaborative kick-off sessions. In addition to the kick-off learning sessions, the participants have an opportunity to participate in monthly telephone conference calls and receive individual coaching. Monthly on-line data collection assists the hospitals in trending their progress and evaluating their rapid response team processes. Additionally, the participants have access to a secure Web site that contains tools and resources for all the materials accumulated during the collaborative. The collaborative will be completed in March of 2007.

The data collected by the participating hospitals are: percent of codes outside the ICU; codes per 1,000 discharges; rapid response team utilization; and call data-level information, such as reasons for the calls, duration of the call, intervention, and outcome of the call. It is too early in the data collection phase for the hospitals to see the overall impact of their RRTs, but stories of lives saved are abundant and indicate that success is being realized.

Several different models of rapid response teams exist. Some teams consist of an ICU nurse; others have an ICU nurse and a respiratory therapist, and others consist of an ICU nurse, respiratory therapist and a physician. Most often the process that is set up in hospitals is to notify the patient's attending physician of the call as the rapid response team is being activated. This results in decreased delay to assessment and intervention of a deteriorating patient since the team is in the hospital, yet keeps the attending physician informed. It offers an important safety net to both the patient and the

Quality—continued on page 398

Quality—continued from page 397

attending physician. This immediate assessment and intervention is not to question or take over the attending physician's role or responsibility, but to provide an important safeguard.

The case for RRTs is unmistakable. Buist[1] found that prompt assessment and intervention by personnel who are experienced in the evaluation and care of critically ill patients has been associated with a 50 percent reduction in non-ICU arrests. Early assessment and intervention has also been associated with a reduction in postoperative emergent ICU transfers (44%) and death (37%),[2] and reduction in arrest prior to ICU transfer (4% vs. 30%).[3]

In the vignette above, Mr. Smith's scenario of progression to cardiopulmonary arrest occurs to seven out of 1,000 hospitalized patients. One study found that mortality for these patients is 91 percent. Other studies indicate that these patients showed evidence of physiological instability for six to eight hours prior to a cardiopulmonary arrest.[4,5] RRTs will make failure to rescue scenarios, such as the one Mr. Smith experienced, a thing of the past in more than fifty hospitals in our state thanks to the newly launched statewide initiative to establish RRTs in North Carolina hospitals.

Readers' Forum

To The Editor:

Attitude, Actions and Service at a "Public" Hospital

I am still "manning the clinics" at the University of North Carolina Hospital in Chapel Hill. When I started as a young physician forty-two years ago, there was a sign at the front of the hospital which read: "Built by and for the people of the State of North Carolina."

This service philosophy attracted me a place which has worked hard to educate, to be a leader in medical research, and to provide medical care to all the people of our state. During these years, the costs to accomplish those tasks have greatly increased, and the sources of money have changed. The proportion of the annual budget for education and patient care provided through the UNC Hospitals by the state legislature has dropped to near 10%. All other sources of financing for patient care (e.g., Medicare, Medicaid, private health insurance, etc.) are "managing" their payments for patient services while trying to keep their payments as small as possible, and, in the case of the private insurance companies, to show a profit to their shareholders. The fact that the executives for these companies are getting huge salaries and bonuses is well known and a constant reason to question the yearly announcements of benefit reductions, or increases in co-payments and deductibles associated with these plans and their enrollees.

Those responsible for the "management" of both public and private insurance companies have squeezed the UNC Health System (and all other providers of care), creating make-believe charges (such as $2 for an aspirin tablet) so that as much money as possible can be retrieved from firms that have negotiated a favorable "discount" for the patients they insure. This is fine, except that those without health insurance (which is over 40% at our institution) are billed for the full charges for their care and are asked to make full payment or negotiate a plan for such.

Administrative responsibility for all of this has fallen to our healthcare system "executives." Our chief executive, Dr. William L. Roper, has worked within the current (in my view, broken) system of healthcare payments to make sure that the budget balance for the institution is favorable. Oversight for the enterprise falls to a board of directors largely made up of people from the business world who have done much to support the UNC Hospitals and to keep their services and facilities excellent. The yearly accounting for this "non-profit" institution shows a substantial "profit" (or revenues in excess of expenses).

The dilemma of squeezing money to deliver care out of those who are sick, needy, uninsured, and outside any support network (such as undocumented immigrants, but including many native North Carolinians with low incomes as well) leads to policies which discourage delivery (and the seeking) of service. For instance, there are now telephone calls to remind patients in our hospitals and clinics which include the automatic message "please be prepared to pay any balance of your bill at the time of the visit," or "you will have to bring $250 or $500 to pay before the study/necessary procedure will be performed."

My impression is that such messages (or "attitudes" reflected in these messages) will often lead a patient without adequate healthcare insurance to forego needed medical care or services, and ultimately to a less-than-optimal health outcome. When this type of "caring" occurs at the same time as incentive bonuses are offered to the administrators who organize this "care" (which can be up to $100,000 per year for some), the "service" focus is lost. We need, as a society, to re-examine the whole system, starting with the UNC Health Care System enterprise, but including all elements of the public and private healthcare industry on which we all depend.

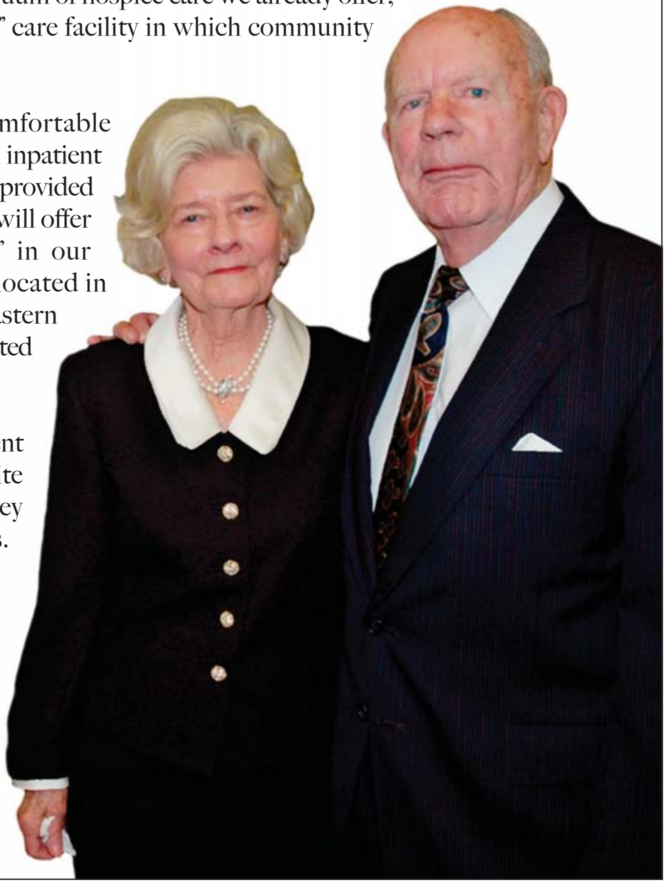
COMMUNITY INVOLVEMENT IS A BIG PART OF WHO WE ARE.

AND IT JUST GOT BIGGER.

SRMC has always believed in the idea of neighbors caring for neighbors. More than a full-service healthcare facility, SRMC is the hub of a comprehensive healthcare system in southeastern North Carolina that offers a wide array of services, such as the newly opened Southeastern Heart Center managed by Duke; five primary care clinics located throughout the county; the Gibson Cancer Center; comprehensive medical imaging services; long-term care; psychiatric care; Southeastern Lifestyle Center for Fitness and Rehabilitation; and home-care services that include Home Health, Home Medical Equipment, and Hospice. Our main focus is giving the members of our community the best healthcare they can receive—throughout their lifetimes.

But this time, we are proud to be on the receiving end of our neighbors' generosity. The generous donation through the SRMC Foundation of local couple Pete and Marguerite Lindsey of Lumberton is enabling SRMC to add, as a part of the continuum of hospice care we already offer, Southeastern Hospice House, an "End of Life" care facility in which community volunteers will play a large part.



While hospice care in the familiar and comfortable surroundings of home is often preferred, at times, inpatient hospice care is more appropriate, and care can be provided more effectively. Southeastern Hospice House will offer inpatient hospice care right here at "home" in our community. Slated to open in early 2007 and located in the former Carolina Manor building, Southeastern Hospice House will include a family lounge dedicated to the memory of the Lindseys' daughter.

SRMC feels honored to be chosen as the recipient of this gift. It's neighbors like Pete and Marguerite Lindsey that make this community special. They truly represent neighbors caring for neighbors.

Surgery and science combine to unlock the secrets of diabetes

A partnership between Pitt County Memorial Hospital and the Brody School of Medicine at East Carolina University is at the forefront of bariatric surgery research. In more than 2,500 documented cases, our surgeons have seen patients overcome dependence on insulin and oral therapy in a matter of days. Some patients have required no further medication for as long as two decades.

The confirmation of these findings by surgeons throughout the world has led to a major grant from the Johnson & Johnson Corporation. The grant will help researchers find an explanation for this medical advance and to see if medication can achieve the same result. Dr. Walter Pories, an ECU professor of surgery and bariatric surgery pioneer, and his colleagues will lead a two-year clinical study of adults with diabetes that evaluates insulin sensitivity and glucose metabolism before and after gastric-bypass surgery. For more information on the study, call 252-744-3290.

Working together, Pitt County Memorial Hospital and Brody School of Medicine surgeons have been performing and studying gastric bypass surgery since 1978. To watch a live web cast of bariatric surgery at Pitt County Memorial Hospital or learn more about bariatric surgeons at the Brody School of Medicine and Southern Surgical Associates, visit www.bariatric.uhseast.com.

Tarheel Footprints in Healthcare

Recognizing unusual and often unsung contributions of individual citizens who have made healthcare for North Carolinians more accessible and of higher quality

Sharon Nicholson Harrell, DDS, MPH
Director, Dental Care Centers, FirstHealth of the Carolinas, Pinehurst, NC

Sharon Nicholson Harrell, DDS, MPH

North Carolina is facing one of the most severe shortages of dentists and primary dental care of any state. Nationally, there are 5.7 dentists per 10,000 population. As of 2004, North Carolina had 4.2 dentists per 10,000. The ratio of dentists-to-population is quite different in metropolitan and rural areas of the state, where there were 4.8 dentists per 10,000 population in urban areas and only 3.1 dentists per 10,000 population in rural areas.

North Carolina's ratio of dentists-to-population is 27% lower than the national average. In fact, North Carolina ranks 47th among the states in terms of the dentist-to-population ratio. Moreover, the maldistribution in this state that has resulted in four eastern North Carolina counties not having a single dentist, three other counties having only a single dentist, and as many as 40 counties in North Carolina where there is no dentist willing to serve a Medicaid patient. This means that small, rural counties in our state are in a considerably more underserved situation than are our urban areas. Even in our metropolitan counties, obtaining services can be difficult if one is covered only by the Medicaid program or otherwise dependent on subsidized (or free) care through local public health departments, migrant or community health centers, or other "safety net" providers.

The good news is that there are dentists in this state, and a few major healthcare organizations, who have stepped up to the plate and taken on the huge task of finding a better way of organizing and providing needed primary dental care services for those most in need. One of those organizations is FirstHealth of the Carolinas, a not-for-profit integrated healthcare system headquartered in Pinehurst in Moore County, but serving a primary service area that includes five North Carolina counties. One of those dentists is Dr. Sharon Nicholson Harrell, who came to FirstHealth in 1998 to launch a dental care program serving those least able to obtain dental care in the counties served by FirstHealth. Through her efforts, three clinics have been opened under the sponsorship of FirstHealth (a full-time clinic in Southern Pines and part-time clinics in Troy and Raeford). These dental centers employ four dentists, 13 full-time staff, and several fill-in dentists and auxiliaries. These dental centers have served more than 13,000 children since they opened the first clinic in Southern Pines in 1998. Approximately 70% of children seen in the first year had either never seen a dentist or had not seen a dentist within the last year.

Dr. Harrell came to her position in Moore County after having served for seven years as Dental Director of the Cumberland County Health Department in Fayetteville, and before that for three years as a public health dentist in York, Pennsylvania. After graduation from the University of North Carolina (UNC) School of Dentistry, she was a fellow in general dentistry at the University of Maryland and then received a master's of public health degree at the UNC School of Public Health. When she was hired by FirstHealth, she was charged with the tasks of planning, designing, and opening three regional centers to provide comprehensive dental care to low-income children up to age 18, administering the centers, serving as an area dental public health consultant, and functioning as the liaison with private dentists in the local area and the state. In each of these arenas, Dr. Harrell has become widely recognized as highly effective, and her opinions and experience in the organization and provision of dental care to the most in-need populations of our state have been sought by many, both in North Carolina and nationally. FirstHealth's new dental care program for low-income children was funded by the Kate B. Reynolds Charitable Trust and The Duke Endowment.

Charles Frock, CEO of FirstHealth, had this to say about Dr. Harrell: "She has distinguished herself professionally in many ways. She has been nationally recognized for the way she mentors young dental health professionals. She is recognized throughout North Carolina for her public health approach to dental care for the underserved, and she is known by her patients and her colleagues as a completely caring, compassionate, and accessible caregiver."

Although meeting the primary dental health needs of underserved children through such special-purpose "safety net" programs as the one begun by FirstHealth of the Carolinas is not likely to meet the majority of unmet need for these services statewide, the 1,000 patient visits these clinics now offer each month, including 8,000 preventive dental sealants they provide yearly, and the 100 new patients they enroll each month are significant and grateful beneficiaries of a model program now being studied and replicated elsewhere. In Dr. Harrell's own words, "It's not only about filling cavities. It's about filling a big need in our community."

For her untiring efforts and considerable accomplishments in meeting the dental healthcare needs of so many children in our state, the Editors of the *North Carolina Medical Journal* are pleased to recognize Dr. Sharon Nicholson Harrell and FirstHealth of the Carolinas for these contributions to the health of the Tar Heel State.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, non-profit organization to serve as a non-political source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and healthcare issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

North Carolina Institute of Medicine

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

The Duke Endowment

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Academy of Physician Assistants, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Association of Health Plans, and the Medical Review of North Carolina. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

The Relationship between Patient's Perceived Waiting Time and Office-Based Practice Satisfaction

Fabian Camacho, MS; Roger Anderson, PhD; Anne Safrit, BS; Alison Snow Jones, PhD; and Peter Hoffmann, MD, MPhil

Abstract

Background: *The amount of waiting time a patient experiences in a primary care or specialty care outpatient setting may have an effect on patient satisfaction and may depend on other visit characteristics. We sought to investigate and quantify the association between waiting time and satisfaction outcomes in clinics belonging to the Wake Forest University Baptist Medical Center and assess how this relationship varies by time spent with the provider.*

Methods: *Cross-sectional survey data was collected at point of care from 18 primary and specialty care clinics at the Center. Overall satisfaction with provider care, the office ratings, and willingness to return were each rated on a 0-to-10-point scale. Multivariate and logistic regressions were performed to examine the relationship between waiting time and outcomes. Covariates included visit time spent with physician, patient care processes, visit convenience, and demographics.*

Results: *2,444 cases were analyzed. Waiting time significantly predicted provider ratings. When time spent with the physician was five minutes or less, provider ratings decreased by 0.3 rating points for each 10-minute increase in waiting time. When time spent with the physician was greater than five minutes, provider ratings decreased by 0.1 rating points for each 10-minute increase in waiting time. The association between waiting time and office satisfaction showed a similar pattern; increased waits also decreased willingness to return (odds decrease by 2% per minute).*

Limitations: *Results may be affected by unreliability of the measures used and from possible selection bias. There is also concern over missing confounders.*

Conclusions: *Our findings confirm that reduced waiting time may lead to increased patient satisfaction and greater willingness to return in primary and specialty care outpatient settings. Furthermore, increased waiting time combined with reduced time spent with the physician coincide with noticeable drops in patient satisfaction.*

Key words: *Patient satisfaction, waiting times, CAHPS*

Introduction

A source of dissatisfaction with healthcare, often noted by patients, is the amount of time they wait during an office or clinic visit. Several studies have documented the relationship between waiting for service and overall satisfaction, with longer waiting times being associated with decreased patient satisfaction. This relationship is not only localized to individual organizations or types of care, but is well documented in general situations involving waiting customers.[1,2]

The strength of the association between waiting time and overall patient satisfaction in healthcare settings varies across the literature. Much of this research has been conducted in emergency departments, where waiting time may be considerable and the level of patient discomfort may be high.[3-7] Results in this area may not apply to traditional primary and specialty care settings, since qualitative differences between situational emergency care and outpatient settings are substantial. Most studies conducted in primary care outpatient settings find a detectable relationship between waiting times and satisfaction,[8-13]

Fabian Camacho, MS, is a Research Associate with the Department of Public Health Sciences, Wake Forest University School of Medicine. Mr. Camacho can be reached at fcamacho@wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157-1063. Telephone: 336-716-5268.

Roger Anderson, PhD, is a Professor with the Department of Public Health Sciences at the Wake Forest University School of Medicine.

Anne Safrit, BS, is a Collaborator with the Department of Public Health Sciences at the Wake Forest University School of Medicine.

Alison Snow Jones, PhD, is an Assistant Professor with the Department of Public Health Sciences at the Wake Forest University School of Medicine.

Peter Hoffmann, MD, MPhil, is Medical Director of the Wake Forest University Physicians Group.

though results seem to be less uniform than in emergency care.

The literature on perceived quality of primary care indicates that key attributes of healthcare valued by patients are patient-centered, including time spent with the physician, willingness of the physician to listen to the patient, and other measures of patient empathy.[14-16] It is uncertain how waiting times combine with these attributes to affect patient satisfaction, even though understanding such combinations may translate to improvements in patient care. For instance, examining how perceived wait times and time spent with the physician combine to influence satisfaction may help preserve satisfaction levels when time and professional staff resources are tightly constrained, as is typically the case.

In this study, we sought to investigate the association between perceived waiting time and satisfaction in outpatient settings of a large North Carolina hospital after accounting for other factors. At the same time, we included an interaction effect of waiting time and time spent with the provider into our models in order to highlight how certain combinations may be associated with particularly low satisfaction levels. Perceived waiting time was conceptualized as a measure of a patient's time investment in accessing a specific set of healthcare services, which we call "willingness to wait." Patients who perceived themselves as having to wait long periods of time to see a healthcare provider on the day of their visit were hypothesized to have a larger investment in the visit.

Methods

Sample

This study was observational and cross-sectional across primary and specialty care clinic settings. Data were collected using a validated survey methodology,[17] in which a handheld computer was used throughout a clinic business day to collect information from a patient immediately after the patient's clinic visit. Convenience samples were collected from two primary and 16 specialty care clinics in the Wake Forest University Baptist Medical Center from May 2004 to September 2004, for an aggregated total of 2,535 patients distributed throughout 18 clinics. Only patients who were 16 years or older in age were selected into the sample.

Measurements

We assessed three distinct dimensions of patient satisfaction: an overall rating of the provider seen by the patient using the Consumer Assessment of Health Plans Study (CAHPS) global item[18] ranging from 0 (worst provider) to 10 (best provider); a global rating for office staff ranging from 0 (worst) to 10 (best); and 'willingness to return for medical care' rating dichotomized into willing to return versus not willing to return. These items were taken from a more comprehensive set of items that assessed satisfaction with quality of care provided by the physician, which were included in our standard survey. The three global measures were selected as dependent variables for this based on parsimony and ease of interpretation, consistent with scientific literature on this topic.[19]

Perceived waiting times at the office were captured by patient self-report after the physician-patient encounter, using an item consisting of six categories: 1-5 minutes waiting time in office, 6-15 minutes, 16-30 minutes, 31-45 minutes, and 46 minutes to 1 hour, and more than 1 hour. The shorter time intervals at the start were chosen in order to capture waiting time with more precision, since previous pilot data suggested approximately 70% of the patients waited less than 15 minutes. Waiting times in the exam room were captured in a similar manner.

Dansky[1] showed, out of several definitions of waiting time, that total time spent waiting in the office and exam room was the strongest predictor of satisfaction. For this analysis, we summed both waiting time variables to create a total waiting time composite. We interpolated the categories of waiting time by their midpoints (assuming an average wait of 1 hour and 15 minutes for the relatively few patients who waited more than 1 hour) and summed the midpoints to produce a continuous measure of time.

Potential predictors of patient satisfaction considered in this study are listed in Table 1. These include visit time spent with the healthcare provider, whether visit was to a primary or specialty care clinic, whether the patient was new to the office, self-reported

Table 1.
Population Characteristics[a] (N = 2,444)

	Descriptive Statistics
Mean waiting time in minutes[b]	20.97 (14.71)
Visit time with provider	
0-4 minutes	14.3%
5-10 minutes	85.7%
Visit was convenient	86.0%
White ethnicity	82.6%
Patient saw preferred provider	34.7%
Age in years[b]	45.9 (16.97)
Highest possible provider empathy score	41.3%
Patient stress reported	45.6%
First visit	22.1%
Visit was for routine check-up	50.5%
Patient had multiple appointments	18.3%
Male gender	34.7%
General practice clinic	7.5%
Office staff rating[b]	8.76 (2.26)
CAHPS provider rating[b]	9.37 (1.23)
Willing to return	83%

a Restricted to patients who had a total waiting time of 75 minutes or less.

b Means are shown with standard deviations in parenthesis.

convenience of visit, reason for visit, whether the patient had multiple appointments during the day, patient stress, gender, age groups, and ethnicity (white versus other minorities combined). Patient perceived stress was measured from a single item asking "Overall, how stressful was your visit today?" Responses were categorized into no patient stress reported versus at least some patient stress reported.

We also used a scale developed and validated for use on a computer platform in order to assess provider empathy.[17] This scale is based on the premise that quality of care can be conceptualized as the patient's perception of provider empathy, concern, friendliness, and compassion.[8] Consistent with previous work, the Cronbach Alpha of this scale in the study sample was 0.93. For analysis purposes, the scale was dichotomized into perfect scores and scores less than perfect.

Statistical Analysis

Multivariate regression and logistic regression models predicting the three satisfaction ratings were estimated using the Generalized Estimating Equations (GEE) method implemented in the SAS System v9 procedure, proc genmod.[20] In order to adjust for clustering, an exchangeable working correlation matrix was specified where the observations were clustered according to clinic. The default robust standard errors in proc genmod were used.

Since 20% of the observations had missing values, we treated missing data by conducting multiple imputations as described in Rubin (1991).[21] The MCMC method in the SAS system's multiple imputation[22] was used to derive imputed values for all the variables listed in Table 1. These same variables were included in the imputation model, as well as the interaction between waiting time and visit time. Three data sets with imputed values were used to conduct the analysis. Wherever possible all estimates and statistics were calculated using combined estimates of three multiply imputed data sets.[23]

Results

Only patients who waited for 75 minutes or less (N = 2,444) were selected for the analysis, as the waiting time variable for patients waiting more than 75 minutes was considered too unreliable, and only 3.6% patients were lost as a result.

From Table 1, mean total waiting time was estimated to be 21 minutes (Standard Deviation = 15), mean age was 46 years (SD = 17), 83% were white and 35% male. Mean office rating was 8.76 (SD = 2.27), mean CAHPS provider rating was 9.37 (SD = 1.23), and 83% of patients were willing to return for care.

Regression results are shown in Table 2. Model predictors explained approximately 23% of the variation for both the CAHPS provider rating and willingness to return, but only 7% of the variation for office rating. No multi-collinearity problems

Table 2.
Regression Results[a]

a Standard Errors are shown in parenthesis. 95% Confidence Intervals are shown next to odds ratios. Sample was restricted to patients who waited less than 75 minutes (97% of original sample). Coefficients and values are derived from multiple imputations with three replications. * implies p-value of significance test is < 0.05, ** is < 0.01, and *** is < 0.001.

b Adjusted R-square as described in Nagelkerke (1991).

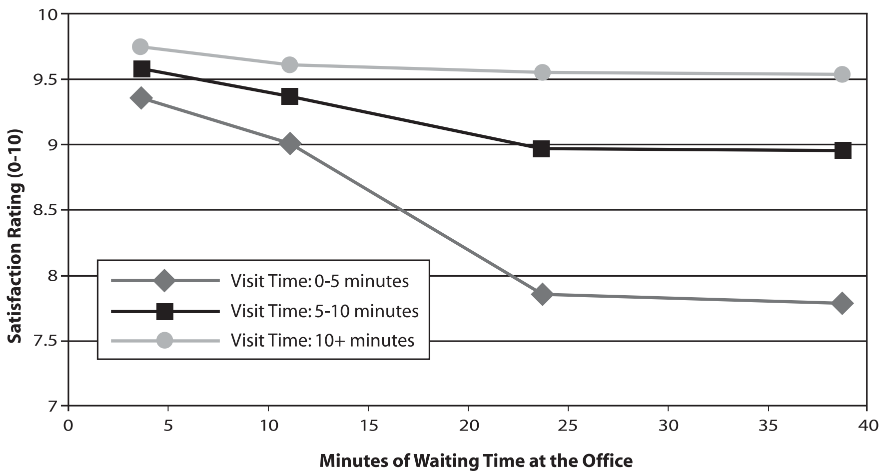
were detected in any of the three regressions, with the lowest tolerance detected at 0.85.

We found that physician satisfaction was lower than expected for patients who waited more than 20 minutes and who had short visit times of 0-5 minutes, as illustrated in Figure 1. The interaction term consisting of waiting time and visit time with physician tested for significance when added to the model (p-value < 0.01).

Satisfaction with the provider decreased by approximately -0.10 rating points per 10 minute increase in waiting when visit times were five minutes or more and -0.30 rating points when visit times were less than five minutes; office satisfaction declined by the same rates; and the odds of willingness to return decreased by 2% per minute.

In addition, satisfaction with the provider was associated with: convenience, quality of care rating, patient age, having a stressful visit, nature of visit, and gender. The findings were consistent by showing that a longer wait, a shorter visit time, a more stressful visit, and lower quality rating were independently associated with lower global satisfaction scores.

Figure 1.
Mean Provider Ratings by Waiting Time and Visit Time



Discussion

This study suggests that increased waiting time is an important source of patient dissatisfaction. For situations in which the time spent with the doctor exceeds five minutes, the regression equations suggest the difference in provider satisfaction may become clinically important after a 50-to-60-minute total wait, at which time the decrease in provider satisfaction exceeds the ½ the standard deviation of the CAHPS provider rating distribution. In addition, the findings suggest longer waits and shorter visits with the physician are, in synergy, associated with increased erosion of overall patient satisfaction (see Figure 1).

We conjecture that a patient's time investment or 'willingness to wait' for healthcare may itself be an indicator of patient satisfaction, analogous to measures of revealed preference for health outcomes, such as the standard-gamble or time trade-off methods.[24] It certainly conforms to methods employed by economists that use consumers' reactions to changes in price and income to learn about their valuation of purchased goods and services.[25] Economic theory predicts that patients will be willing to incur time and money costs that approximately equal their valuation of the benefit that they expect to receive from this expenditure of time and money.[26,27] In this framework, waiting time is an important component of time price, and willingness to wait should rise with patients' perceptions of increased quality of care. Patients' willingness to wait or their "willingness to pay" for care in time units will also depend on their wage rates and on the severity and chronic nature of their illness. Waiting time can also be conceptualized as eroding the value derived from a treatment.[28] In this sense, it can be viewed as the amount an individual would be willing to pay for a reduction in waiting time.

Willingness to wait for medical care could serve as a readily observable indicator for ranking clinics or patient visits by patients' satisfaction levels. However, this does not suggest that perspectives on the timeliness of care are unimportant. It is important to offer brief waiting times so that patients do not feel discomfort or perceive barriers to care, and to communicate respect for the patient. Our results, however, suggest that the threshold for what is satisfying is partially determined by the visit experience and suggest that patients weigh their inconvenience or resource investment against their gain to determine their willingness to return.[29-31] Future work is needed to examine the concept of "willingness to wait" more directly and to explore its value as a measure of patient satisfaction or quality of care.

There are several limitations to this study. The documented reliability of the CAHPS provider rating is fairly low, ranging as low as 0.19 for one subgroup.[32] However, despite this apparent instability, there is a consistent pattern of predictors, which in many cases correspond to the predictors observed for the other two markers of satisfaction, particularly willingness to return. This agrees with other findings in literature that have noticed an association between willingness to return and other measures of patient dissatisfaction.[9,33]

Our survey did not collect additional confounders, which may play a role in changing study results, such as general health status,[30] arriving early,[8] wage rates, travel time to clinic, or additional technical aspects of care, such as provider thoroughness. Of the omitted predictors, general health and wage rate may be strong predictors of the relationship between waiting time and satisfaction. If the reason for visit proxies health status, one might expect people in poor health to be willing to wait longer for care since they would most likely be seeing specialists. It is not clear that they would rate providers lower on quality. Results here suggest that patients who visit for a routine check-up rate their providers higher.

Despite these limitations, our findings confirm that timeliness is an important component of quality of care in this setting, and that clinically significant drops in satisfaction may be observed after a one hour wait. Although measures of patient empathy and, thusly, of interrelated factors, such as personal attention, communication, and interpersonal style may play a more important role in determining satisfaction, these results suggest that timeliness should not be ignored if patient satisfaction rates are to be maintained, especially if the provider cannot devote much time to his or her patients. **NCMedJ**

POLICY FORUM

Worksite Health Promotion and Wellness

> *"...50% of chronic disease in the United States population results from preventable causes related to lifestyle choices, and half of all deaths can be attributed to a limited number of preventable behaviors. Health risks drive present and future costs for employers and employees."*

INTRODUCTION

Policy Forum:
Worksite Health Promotion and Wellness

Ever since the United States Department of Health and Human Services initiated the decennial publication of the *Healthy People* goals for the nation, which began under the Administration of President Carter, ways have been sought to advance the cause of national health improvement through initiatives that would couple a concern for health and health improvement with some of the everyday functional activities of the American people. For the health of children, the schools have been an important venue for a variety of health promotion program initiatives. For working-age adults, the workplace has figured as an important target of opportunity for addressing the fundamental health issues of our population, from disease screening to immunizations to chronic disease self-management to lifestyle modification and health risk factor reduction. With huge proportions of employees spending at least 40 hours per week in one or more occupational settings and consuming a third of their meals during their time at-work, program initiatives that focus on stimulating healthy lifestyle changes can not only improve the prospects of long-term health outcomes, but significantly impact the healthcare cost obligations of the employing organization as well.

In this issue of the *North Carolina Medical Journal*, we have chosen to focus our attention on the potential these types of initiatives may have for businesses and industries, the reasons why some companies have seen benefit in making such investments, why it may not be so easy to establish (or quantify) the "return on investment" (or ROI) that can provide the rationale for these investments, and the kinds of incentives necessary to assure adequate levels of employee participation in such programs when they are offered at the workplace.

We have invited a distinguished group of North Carolinians and national figures in the health promotion field to address these issues, and we are fortunate that so many accepted our invitation. Following an extensive Issue Brief on critical issues in this field by Dr. Joyce M. Young, the person responsible for health promotion and wellness activities in the United States for IBM Corporation, each author offers a particular set of observations on the way this movement in American business has developed. We are also pleased that Dr. Alexandra Farrow, a friend and colleague of many years who studies these issues in the United Kingdom and Western Europe offers her own view of how these same issues have been faced on the other side of the Atlantic.

North Carolina has a number of large, national (or international) corporations with the capacities to provide impressive and effective health promotion programs for their employees at the workplace. But, our state is characterized by having one of the largest proportions of small companies, many of which could never afford to offer such services to their employees. Many cannot even afford to offer healthcare insurance. Hence, a consideration of the value and potential of workplace-based health promotion efforts is a matter of seemingly less importance to North Carolina health policy deliberations than would be the case in other states. This is why our readers need to give serious attention to the commentaries in this issue of the Journal. In these pages, one can discover not only the argument in support of workplace-based health promotion programs, but options for small businesses to consider if they wish to leverage local community resources and programs in support of the health promotion interests and needs of their employees. The health of all North Carolinians is at stake.

A Personal Editorial Note:

With this issue, the 30th under our editorship, we conclude our stewardship of the *North Carolina Medical Journal* in its new format, a venture we began in January 2002. We want to express our deep appreciation to the hundreds of authors, reviewers, Editorial Board members, and our colleagues at the North Carolina Institute of Medicine and The Duke Endowment who have given us this opportunity to engage the leading policy makers, healthcare professionals, and the lay public in lively information exchange and debate on important matters for the health of North Carolinians and our nation as a whole. We welcome Dr. Thomas C. Ricketts III as the Journal's new Editor-in-Chief and wish him and his colleagues the very best as they continue this important work. Having a person of his national reputation and ability accept this responsibility is itself a testimonial to the quality of what this Journal has set out to achieve.

Promoting Health at the Workplace:

Challenges of Prevention, Productivity, and Program Implementation

Joyce M. Young, MD, MPH

Over the period since the 1980s, American business and industry spokespersons have often expressed their frustration and dismay over the rapid escalation of the annual costs of medical care for their employees, dependents, and retirees. As these companies have been forced to re-examine their contributions to healthcare insurance, they have been prone to focus on the impact these expenditures have on their bottom-line and their competitive position domestically and internationally.

In this period, there is rising concern about the ability of businesses to manage healthcare investments, especially since, in comparison with other nations who spend less per capita on healthcare, life expectancy, days of disability, and overall health status put the United States at an unfavorable disadvantage. Business and industry leaders have been forced to look carefully at ways to stem the tide of annual increases in healthcare costs for their employees, dependents, and retirees. In addition to shifting some of the burden and responsibility for healthcare costs to employees through higher co-insurance, deductibles and other out-of-pocket expenses, American business and industry leaders are beginning to give attention to employee health-related lifestyle choices and behaviors. Choices and behaviors related to diet, exercise, tobacco and alcohol use, and stress management affect an individual's health risks and, in turn, their healthcare costs.

> *"Since 63% of the adult population is employed, workplaces provide an excellent opportunity to expose a large number of adults to health promotion programs."*

In an attempt to reduce their employees' health risks (and use of healthcare services), many American companies, particularly larger ones, have chosen to invest in health promotion and wellness programs. These programs may be in addition to conventional health and safety efforts, and some are based at the worksite, while others are offered through arrangements with local commercial health and fitness centers or non-profit organizations, such as local YMCAs. Companies making such investments have used a number of rationales, some having to do with their desire to respond to employee interest in health and fitness; others related to concerns for overall corporate productivity, job performance, and workplace environment, in addition to their concerns about the cost of healthcare and its impact on the corporate bottom line.

These programs sponsored (or arranged) by employers vary a great deal depending on the physical location of the employer's facilities, the characteristics of the employed workforce, and the availability of staff to lead such efforts.

In consideration of the issues related to worksite health promotion and wellness program investments, their cost and their impact on employee and community health, the editors of the *North Carolina Medical Journal* have decided to devote this installment of the Journal's Policy Forum to this topic. While there is considerable evidence of positive benefit accumulating from national examples of worksite health promotion initiatives, the extent of implementation and value of these programs here in North Carolina is not so well documented.

North Carolina has its own mix of large and small companies, but a sizeable proportion (42%) of the state's employed population works for companies with fewer than 100 employees; 30% work for companies with fewer than 25 employees, and 20%

Joyce M. Young, MD, MPH, is the Well-being Director for IBM. Dr. Young can be reached at JMYoung@us.ibm.com or IBM, XE7B/205, 3039 Cornwallis Road, Durham, NC 27709. Telephone: 919-543-5508.

work for companies with fewer than 10 employees. North Carolina, compared to all other states, has the 14th highest proportion of employees working for firms with fewer than 25 employees.[1] For these smaller companies, where nearly half of all North Carolinians work, the capability of offering any kind of workplace-based health promotion options are limited. Yet, there are other options for small companies choosing to support their employees' personal choices to promote their own health and the health of their families.

In his commentary in this issue of the *North Carolina Medical Journal*, David Chenoweth of East Carolina University describes the interest and adoption of these health promotion programs in North Carolina businesses over recent decades.[2] As he points out, the content of these programs has been expanded from simple health risk appraisals and clinical health screenings to include a variety of worksite modifications, which include outdoor walking and jogging trails, lunch 'n learn tutorials on health promotion topics, health-focused newsletters, healthful vending machine options, and Web-based instructional programs.

In this Issue Brief, current patterns of investment in worksite health promotion and wellness programs in the United States are described, along with discussion of the rationale used by businesses for these investments and the return on investment that may be expected. The Issue Brief will also give attention to some of the issues surrounding the development of these programs and their potential for influencing the health of the workforce in those industries where these programs have developed.

The Workplace as a Focus of Health Promotion Programs

Historically, the workplace has been recognized as an excellent location for employee-directed health improvement interventions. Since 63% of the adult population is employed,[3] workplaces provide an excellent opportunity to expose a large number of adults to health promotion programs.[4] Just as schools are seen as an opportune venue for improving the health of our children, worksites offer many advantages as a health promotion venue. One advantage is the social nature of the work environment. Employees interact with each other frequently, have socially important relationships, and provide social support for each other, which suggests that co-workers have the potential to influence each other's health behavior. Existing communication channels between employers and employees also facilitate health messaging,[a] which through repetition has the potential to impact health behavior. Positive health messaging can even extend beyond the workplace to affect employee dependents.

Beyond the logistical advantages, the importance of the workplace as a health promotion venue has grown each year as double-digit increases in healthcare costs have required employers to devote much greater effort to the challenge of allocating and managing health-related resources. Providing health insurance is one of the largest components of employee benefit costs, averaging 10.5% of payroll.[5] Many employers regard health insurance as a benefit, focusing on these costs and ways to contain further increases. As a consequence, opportunities to maximize the value of these investments by ensuring the availability of services that include improving health as a key component have become a higher priority for American business and industry leaders. Including health improvement and risk reduction as a focus in the corporate healthcare strategy provides a means for employers (and employees) to optimize their healthcare spending.

In general, employees view access to and the provision of wellness programs and activities positively. They view it as an indication of their employer's commitment to their well-being and, thus, view the employer more favorably. The United States Department of Health and Human Services has announced the goal of having as many as 75% of *all worksites*, regardless of size, offering *comprehensive* health promotion program opportunities to their employees as part of the *Healthy People 2010* initiative.[4] As Jennifer Childress and Garry Lindsay point out in this issue of the *North Carolina Medical Journal*,[6] recent surveys of business and industry employers find that only 6.9% offer the program elements that experts would consider the five key elements of such "comprehensive" programs: viz., (1) health education, (2) links to related employee services, (3) supportive physical and social environments for health improvement, (4) integration of health promotion into the organization's culture, and (5) employee screenings with adequate treatment and follow-up. In other words, the national goals for worksite-based/sponsored health promotion are ambitious, despite significant progress in this direction among some of the nation's leading business organizations.

In this issue of the *North Carolina Medical Journal*, Michael O'Donnell, President of the *American Journal of Health Promotion*, provides a commentary[7] explaining the rationale for federal governmental incentives to encourage American businesses and industry to invest in workplace health promotion programs and describes proposed legislation introduced in the United States Congress by Senator Tom Harkin of Iowa.

Shifting the focus to regard healthcare (when it includes health promotion and wellness components) as an *investment* rather than merely a *cost*, necessitates identifying outcomes and specifying measurement goals for that investment. Reasonable expected outcomes in health improvement would include: increasing the use of health screenings and immunizations and reducing the health risks associated with tobacco use, physical inactivity, and stress. Adopting benefit strategies with targeted health outcomes are increasingly seen as yielding higher returns than strategies designed only to contain and control healthcare costs. The Towers Perrin 2007 Health Care Cost Survey documented that employers who made aggressive efforts to manage health program performance—including implementing health improvement features—succeeded in slowing the upward spiral

---

[a] Health messaging includes newsletters, web sites, posters, and other communication vehicles devoted to educating and providing information on health related topics.

in their own program costs when compared to similar companies that did not make efforts to manage program performance.[8] Surveyed companies with lower cost trends offered a variety of health management programs, including those directed toward health improvement and disease management.

American Business-Sponsored Health Promotion Programs Offerings and Issues

As early as the 1970s, national interest in the potential of workplace-focused health promotion programs had emerged as a new emphasis in public health. Fielding and colleagues[9] authored the first industry survey reporting on the extent to which large companies had invested in these types of programs. This initial survey was followed by others,[10] and together these sequential surveys revealed a clear trend in the direction of more widespread investment in workplace health promotion programming. Whereas most companies responding to these surveys in the 1970s considered worksite programs that had a specific focus on worker *safety* as "health promotion;" by the 1990s, company respondents to these surveys included a much wider variety of options for employee consideration, and most options were directly related to the enhancement of health status, not merely addressing on-the-job issues of safety.

In this issue of the *North Carolina Medical Journal*, Laura Linnan and Ben Birken,[11] as well as Jennifer Childress and Garry Lindsay[6] offer extensive discussion of not only the trend toward a wider spectrum of employer offerings in the area of health promotion and wellness, but also give a picture of the range of companies, both large and medium-size, now opting for investment in this area.

The goal of workplace health improvement programs is to help employees maintain good health and prevent disease by adopting healthy lifestyles, lowering health threats, and increasing the use of proven clinical preventive medical services. The methods employ change strategies designed to help individuals incorporate beneficial health habits into their regular life routines. These include health education with self-care and consumerism, health risk assessments, and behavior change programs. Delivering these methods through a coordinated delivery infrastructure multiplies the impact of individual initiatives. Comprehensive integrated programs are needed to achieve greater impact. These are comprised of: workplace policies and provisions that advocate and support a healthy work culture; benefit design coverage for screening, clinical prevention, health provider counseling and medications that assist tobacco cessation and weight loss for higher classes of obesity; access to tools for medical information search and use, including medical treatment decision making and consumerism (commonly called "health decision support"); Health Risk Appraisals (see text box page 420); and effective behavior change methods and program evaluation that assesses the effects on employee health status, health cost, and productivity.

Even comprehensive wellness programs need to be integrated within an overall strategy for employee healthcare that addresses the other important aspects for optimal personal and business health management, and successful implementation poses a number of challenges. Many employees know from their own personal experience and failure that improving health behavior is not easy, especially when the time and energy needed to devote is already taken up by work, family, and other commitments. Employees may not fully understand how additional medical expense and reduced work output personally impacts them. These and other factors make it challenging for employers and program managers to achieve sufficient participation in wellness offerings. A pervasive problem is that many organizations' programs are not robust enough to achieve the desired outcomes. Often educational and awareness programs are good at raising awareness, but are ineffective in changing behavior or reducing risk. Workplace behavior change interventions are frequently offered as stand-alone initiatives that only reach a limited proportion of the work community and are too short in duration to affect lasting change. In addition, the lack of data access and integration prevents the feedback and monitoring needed for improvement and performance measurement.

While implementation is hard to do well (given it is not a simple prospect) doing nothing worsens risks, costs, and productivity losses. Employers choose from a mix of approaches using human resource personnel and employee wellness committees, health plan offerings, hiring outside vendors, or a combination of approaches. Education and awareness campaigns (employee- or plan-sponsored) are the most common and frequent interventions. Integrated, comprehensive programs are the most infrequent. Improving health is a process that requires time, and insufficient program duration hampers impact as much as ineffective interventions. Lacking vendor standards or certification, employers have to develop their own vendor selection criteria and methods to select which suppliers are the best fit for their work environments.

Rationale for Company Investment in Health Promotion Programs

It is frequently noted that 50% of chronic disease in the United States population results from preventable causes related to lifestyle choices, and half of all deaths can be attributed to a limited number of preventable behaviors.[12] Health risks drive present and future costs for employers and employees. Many companies do not recognize that the presence of common health risks among employees may account for 15-35% of their annual medical claims cost.[13] This is magnified by the fact that a large portion (approximately 80%) of health claims costs are generated by a small portion of the insured employee workforce (5% to 20%). The smaller segment draws the attention, but the larger segment (employees in "moderate-to-good" health) offers the better option for health promotion-driven cost savings. In this issue of the *North Carolina Medical Journal*, Dee Edington[14] of the University of Michigan argues for the support of workplace health promotion programs that can help this larger group *maintain* a lower level of health risks. Learning that greater healthcare savings could be made through incremental reductions in health risks among the larger group of an organization's more healthy employees can be a surprising finding for many companies. It is Edington's thesis, based on the data he and his colleagues

Health Risk Assessment or Health Hazard Appraisal

What does it mean to complete an "HRA?"

Workplace health promotion or wellness programs in most settings conventionally ask participants to complete a brief questionnaire that summarizes key individual characteristics and health information through which a statistical estimate of one's overall health risk status can be determined at the outset of program participation. These questionnaires (or surveys) are often referred to as "health risk assessments." Years ago, and still in some forms, they were referred to as "health hazard appraisals," but in either case they are most commonly referred to by the initials: HRA.

These instruments take a number of index informational items and from them calculate an assessment of one's life expectancy, based on "risk factors" and the profile they represent. Comparisons are often made to populations of persons of a similar age, with similar patterns of health risk status and behaviors, for whom mortality (and often morbidity) outcomes are known. The results then are summarized in terms of one's "achievable" age IF certain risk factors are modified through systematic behavioral and biomedical change (e.g., weight loss, increased physical activity, better nutrition, alcohol and tobacco use, etc.).

HRA instruments, and the methods by which results are calculated and communicated to those who complete them, vary a great deal. Some go through elaborate calculations based on population-specific epidemiological profiles of mortality risk associated with particular patterns of behavior and biomedical characteristics. Others offer simple summaries of key current risk factors (often displayed in colorful diagrams) followed by specific advice as to which of these are most amenable to modification through intentional efforts toward a more healthy lifestyle and personal health behaviors.

Most would agree that completion of an HRA alone will not likely result in a significant change in one's overall health risk profile. What most experts recommend is that all HRAs should be followed by specific risk-factor counseling and opportunities to participate in health promotion interventions (like nutrition counseling, organized physical activity, or smoking cessation programs) relevant to the significant modifiable risk factors identified through the completion of an HRA.

HRA results, when aggregated in a confidential manner across multiple members of a workplace population, and where HRA results are periodically available from the same respondents, can provide useful and powerful means of tracking the impact of workplace health promotion and wellness programs over time. For this reason, most experts in the field recommend that HRAs be the fundamental starting point in any workplace health promotion effort and that these measures serve as the primary measuring gauge of program impact and effectiveness.

have collected from many companies, that preventing this larger population of "healthy" employees at low-risk from moving to a higher level of health risk holds the key to long-run savings for any company sponsoring health promotion initiatives.

The same common risk factors that affect healthcare expenditures also negatively impact attendance, work output, disability, and job safety. Burton et al[15] found that 10 of 12 health risk factors were significantly associated with self-reported work limitations. Musich et al[16] found increased presenteeism (employees present for work, but unable to contribute at their usual level) associated with high stress, life dissatisfaction, back pain, and absenteeism were associated with overweight, poor perception of health, and chronic disease. In studying 2,200 employees in the northeast, Boles et al[17] found that participants with higher numbers of personal health risk factors reported greater productivity losses.

Recent research has demonstrated that employees are capable of reducing their health risk in the setting of employer-sponsored health improvement programs. Goetzel et al[18] reported that participants in Johnson & Johnson's *Pathways to Change* program achieved significant risk reduction in eight of 13 risk categories over an average of $2\,^{3}/_{4}$ years. Pelletier,[19] who has been reporting on this topic for decades, found that results from randomized clinical trials and quasi-experimental designs suggest that providing individualized risk reduction for high-risk employees within the context of comprehensive programming is the critical element of worksite interventions. Herman et al[20] demonstrated that combining a cash incentive with a physical activity intervention resulted in increased participation and significant levels of health risk reduction. Finally, Pelletier et al[21] reported that individuals who reduced one health risk factor improved their presenteeism by 9% and reduced absenteeism by 2%.

Expected Returns on Investment (ROI) in Worksite Health Promotion Programs

A cynical examination of employer investment trends in health promotion programming would expect that there could be no other motivation for such investments than corporate "bottom-line" returns. But, just how important (or critical) are these ROI considerations to these investments?

Research evidence substantiates the presence of risks among employees and the negative impact on health costs and productivity and the ability of health promotion interventions to reduce both employee risks and associated costs. However, a major reason why businesses have been slow to fully embrace risk reduction programs is the difficulty of quantifying their impact on the overall healthcare cost picture.

Determining the economic impact of wellness has been vexing for many years, primarily due to lack of data and systems to capture and measure information about the relationship between interventions and their impact on cost. It is more common for objective data on productivity to be unavailable than available. Since worksites are not laboratories, randomized trials assessing impact are rare. Likewise, health plans have not translated data into actionable information. Many organizations lack access to claims data and analytic methods for evaluation. In addition, businesses customize their wellness programs, drawing from a wide spectrum of approaches, which limits comparisons and benchmarking. An easy-to-implement, universally applicable approach for calculating potential and actual ROI is not readily available. Employers consistently express concerns about not being able to factor ROI into program evaluations and investment decisions.

However, changing trends and efforts to integrate data from multiple sources to conduct valid systematic analysis are surfacing through numerous publications and the work of organizations like the Integrated Benefits Institute (www.ibi.org) and the Institute for Health and Productivity Management (www.ihpm.org). Reductions in healthcare cost among wellness participants as compared to non-participants and ROI values are reported more frequently. A comprehensive review of current ROI literature determined that results for programs in operation an average of 2.5 years experienced an average annual cost reduction range of 2% to 4% of total healthcare claims for comprehensive health promotion disease prevention. The corresponding ROIs or cost-benefit ratios ranged from 1:1.5 to 1: 3.0.[22] Ozminkowski, Goetzel et al[23] used company data and information from published studies to estimate the amount of risk reduction needed to break even on that company's health promotion programs. They found that a 1.08% to 1.42% per year reduction in lifestyle-related health risk was needed to break even on the costs of the intervention program.

Drs. Goetzel and Ozminkowski have also written, in this issue of the *North Carolina Medical Journal*,[24] a commentary on why employers should (or should not) consider investing in worksite health promotion or wellness programs. In their analysis, Goetzel and Ozminkowski summarize the extant evidence that these programs can have a positive ROI, but acknowledge the difficulty some employers may have in realizing these returns and the factors that may affect these results.

Cost avoidance or reducing the upward trend and velocity of healthcare cost increases is one of the key interests of employers who invest in workplace wellness interventions. In this instance, if the increase in healthcare expenses is less than expected (i.e., reflects a reduced trend) because wellness-driven health improvement and/or risk reduction leads to reductions in health services utilization, then these investments are considered worthwhile. Identifying and quantifying the avoided cost requires a specific analysis that also accounts for the impact of other influences, such as plan design changes or risk pool ratings. Cost avoidance can be determined by comparing the health cost experience of wellness program participants to those of non-participants at the individual level. Achieving a measurable financial impact on the entire employee population can require a robust (i.e., 80% or greater) rate of employee participation in proven interventions shown to be effective—an achievement few organizations are able to realize.

Health promotion's impact on worker productivity is probably larger than it's impact on healthcare cost, amounting to, in some studies, values that are three times higher. Measuring changes in productivity, especially as office workers comprise larger segments of the employment landscape, relies on mechanisms to quantify lost work time or absence and work output, both requiring specific methods for capturing time and assessing productivity. Recording attendance is increasingly less meaningful for knowledge workers. Options to measure productivity include quantitative indicators, such as days worked or units produced; simulation in hypothetical situations (e.g., a typing test); and self-report through surveys or health risk assessment questions. The most frequently used and easiest to administer though, not the most accurate, is self-report. Both attendance and work output can be assessed through self-report. Methods can be as simple as incorporating two to five questions in the HRA or as comprehensive as the 25-item Work Limitations Questionnaire or the Health and Labor Questionnaire that measure as many as four dimensions. A convincing example of health promotion's effect on attendance can be seen in the $600,000 annual savings achieved during a five-year period from reductions in absenteeism in a manufacturing environment.[25] Larry Chapman's meta-evaluation of 56 high quality health promotion economic return studies[26] found an average 26% reduction in the use of sick leave among 44.6% of the studies. Reductions in the use of sick leave ranged from 11% to 68% in this analysis.

In this issue of the *North Carolina Medical Journal*,[27] Larry Chapman of WebMD Health Services, argues that as we raise the expectations of health outcomes of worksite wellness programs (e.g., significant amounts of body weight lost, increasing levels of physical activity, smoking cessation rates, etc.), we should expect to have to raise the incentives and rewards for program participants, including possible monetary rewards. Rewards have the potential to reduce corporate ROIs and require alignment with the Health Insurance Portability and Accountability Act (HIPAA) to avoid ethical and legal complications that could stem from employees' inabilities to engage in these activities at the level of reward eligibility.

The negative impact of employee absence is magnified by the changing nature of work. Work that relies on skills, company-specific knowledge, critical thinking, and innovation cannot easily be performed by substitutes. Given the interdependencies among the work teams present in many companies, the productivity of whole teams of employees may be diminished by the absence of an individual. Therefore the savings from health promotion's ability to reduce absenteeism (as trends indicate) has the potential to be greater than healthcare cost savings.

In this issue of the Journal, Alexandra Farrow of Brunel University in the United Kingdom[28] reviews the history of investment in workplace health and safety programs in that country as well as in Western Europe. Her commentary shows how efforts to stimulate and encourage workplace investment in health promotion in Britain and Europe have been integrated with overall national public health strategies for population health improvement. In this country, where private businesses and local public health agencies have worked in tandem, considerable benefit can be brought to employees who need and seek health promotion opportunities in the larger surrounding community when they are not available through their place of work.

Health Promotion Options for Small Employers

Given the fact that so many of North Carolina's employees work for firms having fewer than 100 employees, and at least a third of all of the state's workers are employed by firms with fewer than 25 employees, the prospects for extensive (and certainly not "comprehensive") worksite health promotion programs seem remote. Many firms with few employees do not offer healthcare insurance to their employees, so the risk to these small firms from employee illness and disability are direct risks to the productivity of the firm and not to the overall bottom-line cost of paying for the healthcare services their employees may need at the time of illness or injury. But, these productivity costs, plus the cost of recruitment and training of new employees, may still present sufficient economic incentive for investment. Moreover, many of these smaller firms have deep and lasting personal commitments to their employees, with whom both the company's productivity and the quality of relationships with business clients have been built over a long period of time. The desire to offer opportunities for employees to realize a more positive health status outlook and to maintain long-term capacity for work and life satisfaction is sufficient motivation for many small business owners to entertain the possibility of offering health promotion opportunities to employees.

In this issue of the *North Carolina Medical Journal*, Ben Birken and Laura Linnan[29] provide an extensive discussion of the prospects for small businesses offering health promotion programming for their employees. While the number of small businesses currently offering such opportunities is still small, there are ways in which these businesses may be encouraged to offer such opportunities to their employees. Both federal and state governments have considered tax incentives for small businesses offering wellness programs, but at present these have not been enacted except in a few states.

One of the most promising avenues for small businesses to consider, if they are interested in encouraging employee participation in health promotion initiatives, is to explore linkages with local YMCAs, hospitals, or other community organizations (such as schools) to make available local recreational resources and programs in which these small business employees may participate. Employers should take full advantage of local advocacy group initiatives that provide training at lower cost on ways to effect health along with creating employer networking opportunities. One such organization is NC Prevention Partners (www.NCPreventionPartners.org), which supplies a wealth of easy-to-use and accessible tools and support to businesses interested in initiating health promotion and wellness programs.

An incentive arrangement might include some time from normal work routines to engage in physical activities or health-related counseling (e.g., weight loss consultation) through these community-based programs. Moreover, screening programs can be arranged in cooperation with local public health agencies or hospitals and conducted on-site at the workplace. As Birken and Linnan point out, many of these initiatives work best if employees serve as the steering committee leading these efforts and have the responsibility for promoting employee participation in these programs once these arrangements have been worked out.[29]

It should be pointed out that many health promotion initiatives in the workplace can be offered at little or no cost. There is little employer cost to implementing policies for smoke-free workplaces, healthy choices in vending machines and cafeterias, and communications (e.g., signage) encouraging physical activity during the day, like stair use and walking opportunities. Government Web sites often contain templates for policies that can easily be implemented in businesses of any size. Benefit plans, including high deductible plans, should include low-cost health risk assessments (HRAs), preventive screening and counseling, and immunizations. Many states have set aside Tobacco Settlement funds for smoking cessation and prevention programs, and employees can be encouraged to take advantage of these where they are available. North Carolina's robust *Quit Now NC* program (www.quitnownc.org) that promotes and sponsors tobacco cessation interventions is highly accessible throughout the state.

Cautions and Prospective Pitfalls in Workplace Health Promotion Programs

Despite the promise and potential of health promotion initiatives based at the worksite, there are some words of caution. First, there are important confidentiality and privacy considerations that should be a part of any workplace-based health promotion initiative. Employees who voluntarily agree to the completion of a standardized health risk assessment (HRA) should have the confidence that his/her responses to such questions will be held in strict confidence and not shared with employers or supervisors unless explicitly agreed to by the responding employee. Questions about health practices and personal risk behaviors should not become a part of the employee's personal employment record. Data derived from the administration of an HRA within a company should be summarized in a general way for management only, and results should not be transmitted in a way that make it possible to identify individual employees with specific health risks. This can be particularly important in small companies with few employees where statistical summaries of data can make confidentiality problematic.

Second, participation in health promotion programs at the workplace should be entirely voluntary, and participation should not be tied in any way to wages or other incentives that effectively discriminate against those who choose not to participate. That said, it is still worthwhile to offer incentives, even monetary incentives, to employees to encourage their participation in programs to both maintain and enhance their overall health status.

One of the ways in which health promotion programs have taken the matter of employee participation into account is through the use of employee-interest surveys at the outset of program planning. As an example, the Running the Numbers section of this issue of the *North Carolina Medical Journal*[30] includes an account of the way in which the North Carolina Department of Health and Human Services conducted such a survey before beginning departmental participation in the State Employees Health Plan Health*Smart* program. Strong support was forthcoming from the chief executive of the Department, Secretary Carmen Hooker Odom. The employee-interest survey (with responses received from more than a third of all employees either on-line and in writing) revealed great interest in ways to increase daily physical activity and the establishment of tobacco-free workplaces. These responses made it possible to target program content to address employee priorities rather than to offer program elements based on the presumed employee interests and needs. Another commentary in this issue of the Journal, by George Stokes, Executive Administrator of the State Health Plan, and his colleagues[31] describes the way in which the six components of the Health*Smart* program (viz., health tracking, including an HRA; centrally designed health promotion interventions; targeted disease management; health coaching services available 24/7; high-risk case management; and worksite wellness) were developed in partnership with state and local health departments, how pilot demonstrations of the program were first implemented, and how employees themselves were involved in planning the initiative itself.

Fourth, health promotion and wellness initiatives undertaken by business organizations of any size will obviously face the inevitable question of staffing such efforts. Although volunteer leaders of these efforts can often be identified from within employee groups, having persons with expertise in relevant fields (e.g., nutrition, exercise and physical activity, stress management, etc.) and having personnel involved in offering such services who are not employee colleagues or members of corporate management can make initiatives more acceptable to a wider spectrum of employees. Just as there are concerns over the privacy and confidentiality of information provided via HRAs, so it is that many employees prefer to receive instruction and other types of health-specific services from persons whose professional roles seem distinct from those of other corporate staff. Moreover, the kind of program elements that are most likely to benefit participating employees and attract the interest of persons who should participate are those that have been carefully designed using the best available knowledge in the technical subfields of health promotion. In some cases, such skills can be acquired from outside the organization and arranged on a contractual or short-term basis. However, some companies may choose to hire their own health promotion staff and not share their time with other organizations. Bonnie Rogers, a nurse and specialist in the field of worksite health promotion, offers a detailed discussion of considerations for the staffing of worksite health promotion programs in this issue of the *North Carolina Medical Journal.*[32]

Summary

In the current complex employment landscape providing employer-sponsored benefits involves much more than offering financial protection when employee illness drives a need for costly medical treatment. The transitions in work from product/service production to knowledge generation, along with the transitions in the predominant health and disease conditions from acute illness to preventable chronic disease, require employers to recognize the need to manage their health investment more strategically. This includes the more recent requirement to maximize their investment by ensuring that provisions for maintaining and improving employee health status are incorporated into their health benefits approach. Meanwhile employee health improvement, a highly active but emerging field, is in the process of incorporating experience, research, and more effective methods that result in favorable and demonstrable employee health (and corporate cost-benefit) outcomes. **NCMedJ**

COMMENTARY

Who Are the Intended Beneficiaries (Targets) of Employee Health Promotion and Wellness Programs?

Dee W. Edington, PhD

The medical journals and medical-related popular press are filling pages with the news about the increasing levels of obesity, diabetes, and other health-related behaviors, risks, and diseases. This development is not new, but has been on the increase for several years. In the early 1970s, some companies began providing health promotion and wellness programs, primarily to their executives and later extended the programs to other employees. The purpose of the programs was to improve the health of the employee, with the company also benefiting from that improved health through lower levels of healthcare costs and increased likelihood of the employee remaining at work. The programs were simplistic and focused on getting to the high-risk individuals, which were typically defined as employees who have the risks for cardiovascular disease. Second generation programs were more inclusive of other risks and behaviors, such as the use of safety belts, but still were primarily focused on metabolic diseases and high-risk individuals.

After 25 years of measuring and evaluating these programs, it has become clear that the current programs are meeting with success only at the margins. Few companies or locations can demonstrate less obesity, more physical activity, and less disease than the benchmarks of 20 years ago. In addition, the overall adoption of these programs was unexpectedly slow until the rapid rise healthcare costs came into focus.

In response to the marginal success of health promotion and wellness programs, it is clear that a different approach is necessary in order for organizations to effectively address the higher levels of obesity and diabetes, for example, and the growing burden of healthcare costs and decreasing productivity. The solution is to expand the economic outcome metrics; to include programming for worksite environmental factors; to include programs for all employees, regardless of risk levels; to expand the programs to families; to seek professional partners in these efforts; and to install measurement metrics that will provide internal feedback for program revisions. With these Next Generation Programs, the benefits derived from health promotion and wellness programs span the total employee population, their respective families, the sponsoring organization, and extend well into the community and eventually to the state.

The economic and personal value of a healthy and productive worksite and workforce is indisputable by most measures of success. Individual employees and their families define health outcomes of employee-targeted health promotion and wellness programs by their level of vitality, quality of life, and freedom from the pain and suffering associated with disease. Employers rely on measures of the energy level, productivity, and creativity of the employees and the moderated medical and pharmacy costs that can be associated with these programs. Communities and states measure health outcomes by the number and sustainability of healthy and productive companies within the community or state.

Although the value of these outcomes is widely shared, obtaining a healthy and productive worksite and workforce has eluded most companies and their employees. The reasons for this are obvious, given the “natural flow” of individual health risks, the “natural flow” of individual medical care costs, and the escalating high-stress worksite cultures that have developed in most modern companies. The natural flow of health risks within a population is toward high-risk, in the absence of programs targeted at maintaining the population at low-risk. The natural flow of medical costs follows the natural flow of risks. Increasing marketplace competition results in a more stressful worksite, unless attention is being paid to the workplace environment.

Companies such as the SAS Institute and IBM, located in the Research Triangle, have been leaders in beginning to design total solution and total population programs for their employees and employees’ families. Dow Chemical and Pitney Bowes are also companies beginning to expand the breath and depth of health promotion and wellness programs into a more comprehensive health management solution for the full population. Most cities and states in this country now have healthcare coalitions, wellness councils, and local examples of companies who began with the early programs, but are now looking for more effective solutions.

Dee W. Edington, PhD, Director of the Health Management Research Center, Professor in the Division of Kinesiology, and Research Scientist in the School of Public Health at the University of Michigan in Ann Arbor. Dr. Edington can be reached at dwe@umich.edu or at the Health Management Research Center, University of Michigan, 1027 East Huron Street, Ann Arbor, MI 48104. Telephone: 734-763-2462.

At the urging of General Motors, we began to model the best of the 22 major companies in our corporate consortium and to learn from other companies to design the Next Generation of Health Management Programs on a total population level, since it was clear that focusing only on the small percent of high-risk individuals has not been successful in changing the clinical and economic outcome measures. In addition, other companies such as Matria, a population health enhancement company, is rolling out its Next Generation Program as are some of the national health plans including Anthem, Aetna, and CIGNA. These Next Generation programs are expected to be available in the spring of 2007.

Next Generation Health Management Programs

It is now clear that *something* was missing from the early (1975-2005) worksite health promotion program strategies and that *something* is really *two* things: (1) paying attention to everyone in the population and (2) paying attention to the worksite culture and environment itself. If employees are the beneficiaries, then all employees need to be given access to programs addressing health promotion objectives and to the incentives that drive participation, and eventually full engagement, in the process. In our thinking about the Next Generation of Health Management Programs, there are seven components that are critical if the employees (and other beneficiaries) are to fully benefit from these initiatives.

1. Corporate leadership must set the vision for health management throughout the company.
2. All environmental policies and procedures must be aligned with the goal of a healthy and productive worksite and enlistment of critical partners in the effort.
3. Health Risk Appraisals should be available to all employees (and spouses/significant others).
4. All individuals should be risk-status stratified and offered access to health promotion interventions and resources appropriate to their needs (risk categories) and interests.
5. Population-based health promotion programs should be available to all employees.
6. Appropriate incentives for program participation should be available to all employees.
7. Measurement, evaluation, and decision support should be conducted to drive program decisions.

The first hallmark of a successful program is the clear and observable vision of the organization's senior leadership. In addition to announcing the vision, leadership must share the vision with everyone in the organization. The next step is to ensure that the organization's policies and procedures are aligned with the goal of a healthy and productive worksite. This includes such things as smoking policies, stairwell access, vending machines, cafeterias, job design, flexible working hours, and benefit design. Critical partners in this effort require the enlistment of the health plan, benefit consultants, primary care physicians, health enhancement companies, and pharmaceutical companies.

Health Risk Appraisals (HRAs) are a core technology for health and wellness programs and need to be completed by everyone in the organization. The critical choice of an HRA depends upon the program's overall objective. Some HRAs are focused on health education, others focus on longevity, but our bias is on a more comprehensive approach, which includes vitality or quality of life, medical and pharmacy utilization, disability absences, and presenteeism. The customized individual profiles obtained from HRA completion focus on vitality and risk and behavioral factors leading to quality of life and possible disease. The organizational reports summarize (in aggregate form) the individual health risk profiles and then the data are combined (or modeled) with outcome data to create a scorecard of the health-status of the population.

Once a person completes an HRA, they then need to contact a coach, advisor, or advocate to discuss their risk/health status profile and to create goals to maintain or improve their current health status. This is a very critical step and one that could continue indefinitely. The fifth step is to provide wellness programs to the total population. "Know-your-numbers," "no weight gain," and a "1,000-step pedometer" are examples of programs or interventions that can serve this function well.

Crown Equipment Corporation

Crown Equipment Corporation, located in New Bremen, Ohio, manufacturers battery powered material handling equipment. Crown is the first company to adopt the components of the Next Generation Health Management Program to move toward a Champion Company.

After successfully rolling out its HRA and wellness screening initiatives with over 90% participation in 2004 to all Crown locations, Crown decided to adopt the full set of health management components while planning for 2007. The president and senior management set the vision to become a Champion Company. The Medical Director, Benefits Manager, and the Program Manager were given the task of implementation to 5,500 employees throughout the company's several locations.

Benefit design is the driver of the program. Participation begins with an impressive benefit credit for employees and spouses to engage in the program, including the HRA, wellness screenings, and health coaching. The company engages outside vendors to assist with its programs for 2007. The health advising initiative is particularly innovative and designed to maintain 90% or higher participation to reach total engagement of the employees and spouses in understanding personal health accountability. Participation with the health advisor is driven by a significant cash award for employees and spouses. Resources are made available to any employee or spouse who wants to further engage in any program designed to help them maintain or improve their health risks and lifestyle behaviors.

The company also has an innovative healthier vending program, including offering a healthy drink and healthy snack during break.

For more information, contact Karen O'Flaherty at 419-629-6330 or healthwise@crown.com.

Incentives and measurement are the sixth and seventh steps in the Next Generation Program. We now know that the success of a program requires 80% to 95% participation and engagement of the total population, regardless of risk level. Anything less than that falls short of meeting the objectives of a healthy and productive worksite and a healthy and productive workforce.

One of our major learnings over the 30 years we have been studying the health management of populations is that paying attention to healthy (or low-risk) employees is the secret to creating and maintaining a healthy and productive workforce: that is, *keep the low-risk people low-risk*. The second secret is to *first create winners* in the population. For example, initiatives like "know your numbers" and "no weight gain" programs give employees the opportunity for realizing early accomplishment and serve to motivate further attention to personal health risk issues as interventional opportunities are made available. Most programs go immediately for reductions in blood pressure, cholesterol, and body weight; and most individuals end up right back where they started within one or two years.

Benefits to Employees

Most people immediately think of the employee as the first and foremost beneficiary of these programs, and most programs over the past three decades were focused on the high-risk employees (perceived beneficiaries) in particular, while the low-risk employees were ignored. While a few of the high-risk employees and their families were helped as a result of this strategy, the overwhelming evidence is that high-risk employees (and employed workforce health in general) are no better off by nearly any measure of success than we were 30 years ago.

Three strategies have emerged within the Next Generation Programs. The first strategy is to continue to work with the high-risk individuals, but on a *whole person* and *self-leader* approach, rather than a lifestyle risk or disease management approach. The reason for this is that previous risk reduction strategies focused on single risk factor reduction and tended to ignore other risks that might have influenced the person (e.g., weight loss while ignoring smoking or job satisfaction). In addition, the teaching opportunity is such that each individual could be taught to value their own risk-status and serve as their own leader in maintaining positive risk and behaviors and modifying the rest. The second strategy is to work with all the employees regardless of risk level with the same type of intervention strategy. This strategy is somewhat counter-intuitive, and the goal is to convince the participant to value remaining at a relatively low-risk level. The third strategy flows from the environmental component where the organization creates a working environment and benefits that are aligned with a healthy and productive worksite and healthy and productive individuals.

Benefits to Employers

Employers most often sponsor these programs hoping to improve overall productivity and decrease medical and pharmacy spending. However, there is an even greater benefit to employers: survival and prosperity. It is clear that as the world moves toward a global economy and world-wide competition, any company committed to maintaining a competitive position will need to develop and maintain a healthy and productive worksite and workforce.

Also, given the emerging demographics of the American workforce, the value of older workers will increase exponentially. Companies will find that facilitating good health status offsets the medical costs of older workers and the increased company knowledge and relationship possessed by the older workers can be retained by the company. In this era of the "knowledge worker," older workers are likely to be the reservoirs of much of the important knowledge needed in the future.

The Next Generation Programs were designed in part to engage the maximum number of employees. Previous strategies have suffered from low participation rates (somewhere around 30%) and the obvious avoidance of the programs by the high-risk individuals who felt targeted and stigmatized by the focus on the high-risk interventions. The Next Generation approach attempts to engage all employees—making everyone feel included—and participation rates are now approaching 90% or higher in companies adopting this philosophy and approach.

Employers recognize that they cannot accomplish their goals without help from partners. Health plans, benefit consultants, primary care physicians, health enhancement companies, and pharmaceutical companies all have a major role to play in order for all the benefits to be derived from comprehensive health management programs. Even the most conservative estimates of these programs' economic benefits in relation to medical and pharmacy costs put the benefit at the break-even point, while the most common return is estimated at 3.0. When absentee days, disability days, and worker's compensation costs are added to the calculations, the estimated returns are even greater.

Benefits to Communities and States

Communities and states should encourage employers to sponsor these programs with the intention of improving the overall working environment, an overall decrease in the cost of disease care, and an improvement in productivity, which drives increased revenue for the overall economy and, thus, increased tax revenue. Healthy residents lead to lower medical utilization and higher productivity. When worksites and their workforces are characterized in this way, fewer companies will look for relocation options, and more companies will look to relocate to the state and community where these conditions exist.

Summary

There is nearly no downside to clinically and economically effective health management programs since each stakeholder is a beneficiary: the family, the employee, the employer, the community, and the state. These programs drive both the cost and the revenue sides of the economic equation. **NCMedJ**

What's Holding You Back:

Why Should (or Shouldn't) Employers Invest in Health Promotion Programs for Their Workers?

Ron Z. Goetzel, PhD; and Ronald J. Ozminkowski, PhD

A question we are often asked is: How can I convince my senior management that investing in the health and well-being of workers will save money and produce a positive return on investment (ROI)? If leadership of the organization has already made up its mind that health promotion programs are a waste of time and money, then it is next to impossible to convince them otherwise. If, on the other hand, leaders have not yet made up their minds, and importantly, if they have not been exposed to the body of evidence suggesting that worksite programs have the potential to improve workers' health and lower company expenses, then there is hope.

Below, we offer the main arguments in favor of increased employer investment in health promotion. We emphasize the economic rationale for such investment, rather than arguing that it is the "right thing to do" and a socially responsible way of treating one's workers. We contend that health promotion programs not only improve worker health and well-being, but also produce bottom line effects.

> *"...health promotion programs not only improve worker health and well-being, but also produce bottom line effects."*

Reasons to Invest In Worksite Health Promotion Programs

Some support for our view can be found in the book, *Corporate Responsibility and Financial Performance: The Paradox of Social Cost,*[1] written by two accounting professors, Pava and Krausz. They analyzed the financial performance of 53 companies identified as "socially responsible," and compared them to a control sample of firms matched by industry and size. Among the activities considered reflective of social responsibility were health promotion programs, which the authors described as "viable and legitimate" institutional mechanisms to alleviate an important social problem—poor health habits among workers. The authors concluded that, across almost every one of the financial outcome measures examined, "socially responsible firms … perform no worse and, perhaps, … better than non-socially responsible firms."

But, should employers pay additional money for health promotion programs? We believe the answer is "yes." The rationale for such investment can be summarized as a series of hypotheses, stated as follows. (1) Many of the diseases and disorders from which employees suffer are preventable. (2) Modifiable health risk factors are precursors to a large number of these diseases and disorders. (3) Many modifiable health risks are associated with increased healthcare costs and reduced worker productivity, within a relatively short-time window. (4) Modifiable health risks can be improved through workplace-sponsored health promotion and disease prevention programs. (5) Improvements in the health risk profile of a population can lead to reductions in healthcare costs and absenteeism and improve worker productivity. (6) Well-designed and well-implemented worksite health promotion and disease

prevention programs can save companies money.

Below, we note some of the salient studies addressing the previous hypotheses.

Many Diseases and Disorders Are Preventable, Yet Costly

A large body of medical and epidemiological evidence shows the links between common, modifiable, behavioral risk factors and chronic disease.[2] Preventable illnesses make up approximately 70% of the total burden of disease and their associated costs.[3] Half of all deaths in the United States are caused by behavioral risk factors and behavior patterns that are modifiable.[4,5] In particular, the United States has been witnessing alarming increases in obesity, diabetes, and related disorders for many years.[6] These diseases strain the resources of the healthcare system, as individuals who experience them generate significantly higher healthcare costs.[7] Employers pay over one third of the total national annual medical bill for these and other conditions.[8]

Modifiable Health Risks Increase Employer Costs

Analyses by Anderson et al[9] show that 10 modifiable health risk factors account for approximately 25% of all healthcare expenditures for employers. Moreover, employees with seven risk factors (tobacco use, hypertension, hypercholesterolemia, overweight/obesity, high blood glucose, high stress, and lack of physical activity) cost employers 228% more than those lacking those risk factors.[10] Workers with these risk factors are more likely to be high-cost employees in terms of absenteeism, disability, and reduced productivity.[11] Synthesizing the health promotion literature spanning 15 years, Aldana concluded that there is consistent evidence that a relationship exists between obesity, stress, and multiple risk factors, and subsequent healthcare expenditures and worker absenteeism.[12]

Workplaces Offer an Ideal Setting for Health Promotion

Most people agree that the workplace presents an ideal setting for introducing and maintaining health promotion programs. Individuals generally spend over half of their waking hours at work. The workplace contains a concentrated group of people, usually situated in a small number of geographic sites, who share a common purpose and common culture. Communication and information exchange with workers are relatively straightforward. Individual goals and organizational goals, including those related to increasing profitability, generally are aligned with one another. Social support is available when behavior change efforts are attempted. Organizational norms can help guide certain behaviors and discourage others. Financial or other incentives can be introduced to encourage participation in programs. Measurement of program impact is often practical using available administrative data collection and analysis systems.

Worksite Health Promotion Can Positively Influence Employees' Health Risks

Given the previous information, is there evidence that worksite programs can change habits of worker populations? It appears the answer is "yes." Heaney and Goetzel examined 47 peer-reviewed studies, over a 20-year period, focused on the impact of multi-component worksite health promotion programs on employee health and productivity outcomes.[13] The authors concluded that there was "indicative to acceptable" evidence supporting the effectiveness of multi-component worksite health promotion programs in achieving long-term behavior change and risk reduction among workers. The most effective programs offered individualized risk-reduction counseling, coaching; and self-management training to the highest risk employees within the context of a healthy company culture and supportive work environment.[13] The reviewers concluded that a more comprehensive approach to worksite health promotion across multiple risk factors was preferred to one that is single-risk factor-focused where only a small selected group of employees benefit.

Worksite Health Promotion Can Achieve a Positive Return on Investment

So, if worksite programs can change health habits, can they also save money and even pay for themselves? Several literature reviews that weigh the evidence from experimental and quasi-experimental research studies suggest that programs grounded in behavior change theory and that utilize tailored communications and individualized counseling for high-risk individuals achieve cost savings and produce a positive return on investment.[14-16] The ROI research is grounded in evaluations of employer-sponsored health promotion programs. Studies often cited with the strongest research designs and large numbers of subjects included those performed at Johnson & Johnson,[17,18] Citibank,[19] Dupont,[20] the Bank of America,[21,22] Tenneco,[23] Duke University,[24] the California Public Retirees System,[25] Procter and Gamble,[26] and Chevron Corporation.[27] Even accounting for certain inconsistencies in design and results, most of these worksite programs produced positive cost outcomes.

In the most recent review summarizing results from 42 qualifying financial impact studies conducted over the past two decades, Chapman concluded that worksite programs achieve a 25-30% reduction in medical and absenteeism costs in an average period of about 3.6 years.[28] In a widely cited example of a rigorous ROI analysis, Citibank reported a savings of $8.9 million in medical expenditures from their health promotion program as compared to their $1.9 million investment on the program, thus achieving an ROI of 4.56 to 1.0.[19]

Conclusion

In this commentary, we put forth the main arguments in favor of employer investment in health promotion programs for their workers. There are also legitimate and powerful reasons why some employers have been reticent to spend money on health promotion. Generally, these have to do with philosophical reasons that reflect a desire to avoid the potential for perceived intrusions into the private lives of employees, despite the fact that an economic business case in support of these appears incontrovertible.

As for small businesses that cannot afford to conduct and/or evaluate their own programs, we recommend that they press federal agencies to support collective health promotion purchaser consortia. These consortia would define common health and business objectives, achieve consensus on health promotion program designs, issue a request for proposal to vendors and health plans that can offer desirable programs, and put in place specific guarantees regarding the performance of these programs. Importantly, purchaser consortia should include a requirement for vendors to support rigorous, independent evaluations of the health and economic outcomes from their programs, with reasonable definitions of success and a timetable for reporting results. Making the result of such evaluations public will enhance the credibility of the vendor's programs and contribute to the ability of the human resources manager to make a successful business case. **NCMedJ**

COMMENTARY

Employee Participation in Workplace Health Promotion and Wellness Programs:

How Important Are Incentives, and Which Work Best?

Larry Chapman, MPH

Health promotion and wellness efforts for working populations are receiving significant attention. American employers, faced with unacceptable rates of increase in employee health plan costs are moving to introduce more expansive and better designed wellness programs for their employees.[1] During the past decade, dozens of well-designed studies have documented the health improvements and economic return outcomes from a wide variety of worksite settings.[2]

Also emerging as a *sine quo non* for the field is the equation… participation/engagement = risk reduction = economic return.[3] Generating high levels of participation and engagement is essential to the success of all prevention programs. In the early days of the field, it was thought that by vigorously promoting program activities, offering them during work time, and building cultural awareness and acceptability was all one needed to do to produce high levels of program participation. However, program managers have learned differently. Once the "newness" and curiosity of a wellness/health promotion program has worn off, employee participation will almost always drop significantly. This has led to the almost universal use of incentives for program participation.

> *"The relative effectiveness, or overall participation levels, …is directly related to the dollar value of the rewards."*

Beginning with simple program participation incentives, employers are usually moving through three basic incentive phases. The first phase is usually marked by token incentives, typically limited to inexpensive trinkets (under $10 in cost), such as water bottles, t-shirts, sun visors, or pens. Employees receive these trinkets for participating in programs. For example, they may receive a t-shirt for completing a health risk assessment, attending at an educational workshop, using of an E-Health Web site, or participating in a biometric screening event. The second phase usually capitalizes on moderately priced gift merchandise, such as emergency road kits, flashlights, gift coupons, lamps, and other merchandise in the $20 to $50 cost range. When employees participate in the second phase, they typically accumulate points, which are then redeemed for merchandise. The third phase usually involves significantly larger dollar values and in more easily redeemable forms, such as cash, debit cards, or reductions in health plan payroll deductions. The magnitude of incentives in this third phase is often in the $300 to $1,200 per-employee per-year range, and it usually involves meeting several wellness "criteria," including program participation and wellness achievements, such as maintaining a healthy body weight, healthy cholesterol fractions, and controlled blood pressure. The relative effectiveness, or overall participation levels, of these three phases is directly related to the dollar value of the rewards. The higher the average dollar reward the greater the participation levels. In phases two and three, employers often use lottery or raffle approaches for reward distribution, but this type of approach, where uncertainty is added to reward attainment, rarely equals the participation levels associated with known and surer receipt of rewards.

As we raise the bar of expectations for wellness achievements to include more demanding and difficult achievements, such as losing significant amounts of body weight, increasing physical activity levels, overcoming tobacco use habits, and others, it is clear that the magnitude of the reward has to be raised as well. This also tends to create a concern that, as the reward size gets larger; it is going to be more difficult to maintain a positive level of economic return or return on investment (ROI). Many employers are therefore beginning to realize that they can add

Larry Chapman, MPH, is Senior Vice President of WebMD Health Services. Mr. Chapman can be reached at LChapman@WebMD.net or 17420 44th Ave NE, Lake Forest Park, WA 98155-5509 . Telephone: 206-364-3448.

the projected incentive cost and the wellness program costs to their health plan premium and through premium contributions can have employees share this cost. Employees who don't cooperate then end up paying a larger proportion of the combined premium cost than those who participate or engage in wellness programs and activities. This approach is considered to be a "play or pay" based program strategy and can make all wellness-related costs a zero sum budget expenditure for employers. Some employers have actually generated revenue with this approach.

This third phase of wellness incentives is generally built around a set of voluntary wellness criteria, such as those listed below. Due to the great flexibility inherent in the design of wellness criteria, it is likely that these types of criteria will be tested and refined over time and will help to create a dynamic tension around engaging in wellness behaviors.

For example, in a phase three approach to wellness incentives, if the individual meets any eight out of the following 10 wellness criteria, they may qualify for a $600 reduction in their health plan premium contribution for the year.[4]

- Non-tobacco user or participation in a smoking cessation program.
- Body Mass Index (BMI) less than 30 or participation in a weight management program or wellness coaching.
- Overall Wellness Score from an HRA of 85 or greater.
- Physical activity more than four times per week.
- Completion of 30-minute Webinar on wellness and consumer health.
- Current on preventive screening (form completed by their doctor).
- Agree to wear a seat belt 100% of the time they are in a motor vehicle.
- They have a Primary Care Practitioner (PCP).
- Use of medical self-care in the past three months.
- No more than three sick leave days in last 12 months.

Under the new final regulations for the non-discrimination provisions of the Health Insurance Portability and Accountability Act (HIPAA), this approach is allowable as long as the financial reward does not exceed 20% of the total health plan cost and the approach meets the other four reasonable provisions called for in the final regulations.[5]

In conclusion, incentives are absolutely essential to participation and engagement in wellness and prevention activities for virtually all populations and are likely to become a standard feature of health plans that are serious about managing the health of their members. Additionally, many employers are now demanding increasingly effective approaches to long-term health cost stabilization through health management and health improvement. **NCMedJ**

COMMENTARY

Small Businesses, Worksite Wellness, and Public Health:

A Time for Action

Laura A. Linnan, ScD, CHES; and Benjamin E. Birken, MS

The United States Small Business Administration (SBA) defines a "small" business as an independent business employing 500 or fewer employees. The SBA estimates that there are approximately 25.8 million "small" businesses in the United States, and they employ roughly 50% of the working population.[1] Small businesses tend to offer less health insurance for employees.[2] While 98% of businesses with 200 or more employees offered health benefits, only 59% of firms with less than 200 workers offered health benefits to employees.[3] A lack of health insurance severely limits access to health and medical care for employees and places them in a precarious financial position if an injury or illness befalls the employee or a member of his/her family. National worksite survey results indicate that health insurance or managed care providers are the leading source of health risk appraisals, health screenings, lifestyle behavior change programs, and disease management programs offered by employers of all sizes.[4] As a result, when a small business does not offer health insurance, employees have less access to health promotion programming of all types. However, even among small businesses that offer employee health insurance, the evidence is clear that at nearly every level of employee size, smaller worksites are less likely to offer all types of health promotion programs, offer fewer environmental programs or supports, and report fewer health-oriented policies.[4] Moreover, these patterns have persisted over the past 30 years![4-7] Given growing evidence that worksite-based health promotion programs lead to improvements in employee health, morale, productivity, while helping employers address the rising cost of healthcare. It is a matter of public health concern that small businesses and the 50% of United States workers employed by them do not enjoy these important benefits. This paper will offer some plausible explanations for why small businesses offer fewer health promotion and safety programs, why this problem has persisted over time, suggest a multi-level intervention strategy for increasing the number of small businesses who offer health and safety programs for their employees, and offer a few final research-related next steps.

> *"When business survival is the focus, any other costs, including those linked to employee health, may be seen as prohibitive."*

Why Do Small Businesses Offer Fewer Health Promotion and Safety Programs?

First, we acknowledge that understanding why some small businesses offer health promotion and safety programs (and others do not) is an important question that is worthy of additional research. There may be different reasons for different types of businesses (e.g., service, retail, manufacturing), different "size" businesses (e.g., under 15 employees vs. over 250 employees), businesses in different regions of the country, and/or businesses with different longevity (e.g., start-up, over five years, etc.). While more information would be desirable, here we offer several plausible reasons why small businesses are less likely to offer employee health and safety programs. One likely reason is the additional cost of offering these programs. Small business owners take a serious personal and financial risk to open a new business. More small businesses fail than succeed. Start-up costs for any business are

substantial. Owners must learn how to hire and retain employees and to run a successful business. When business survival is the focus, any other costs, including those linked to employee health, may be seen as prohibitive. In addition to direct costs, a small business may be less likely to offer health and safety programming because indirect costs (e.g., time and resources) for anything other than the business enterprise are typically in short supply. Competing demands to meet production or service goals, to operate efficiently, and/or to grow the business, are constantly being juggled with human capital needs and resources in the small business environment. Thus, employee health promotion may be low on the list of priorities for small business owners.

A third possible reason why small businesses offer fewer health promotion programs is a lack of personnel dedicated to employee health and safety. National survey results indicate that worksites with a dedicated staff person for health and safety are 10 times more likely to offer a comprehensive worksite wellness program than are worksites without dedicated staff.[4] Small businesses have fewer staff members, and these staff tend to have multiple responsibilities. Thus, few small businesses employ individuals who are able to dedicate any time/effort to worksite health and safety. Interestingly, as small businesses grow in employee size, some of the barriers to offering health and safety programs may diminish. Wilson[8] conducted a nationally representative survey of small businesses and learned that employers with 50-99 employees were different than even smaller employers (i.e., those with less than 50 employees) on nearly all categories. While access to safety programming was about the same in these two categories of employers, the slightly larger worksites were more likely to offer employee health insurance, had more formalized health-related policies and practices, and offered more health promotion programming than companies with less than 50 employees. They also found that the slightly larger employers were more likely to have dedicated staff for health promotion, occupational health and safety, and employee assistance programs.[8] Having a dedicated staff person is a necessary, but not sufficient, condition for success. It is important to have dedicated and knowledgeable and/or experienced staff to successfully plan, implement, and evaluate worksite health promotion programs.

One final reason why small businesses are less likely to offer worksite health promotion and safety programs is linked to the small business culture and leadership tendencies of their owners. Here, some fundamental research has been undertaken. Eakin[9] conducted an important study on the social culture of work in small businesses and the role of manager beliefs and attitudes in framing the meaning and experience of work in those environments. She interviewed 53 small business owners and found that the prevailing way of "managing" health and safety issues was to "leave it up to the workers." Owners discounted health hazards overall and emphasized the perspective that if they tried to address employee health behaviors, they were viewed as paternalistic and/or meddling. Linnan and colleagues[10] corroborated these findings with survey results from more than 1,000 managers in 23 small-to-medium size manufacturing worksites where they found that, while managers strongly believed that safety issues are the responsibility of employers to address, they rated far lower the matter of employer responsibility for supporting employee lifestyle health and/or behavioral issues.[10] It follows that, because most United States small businesses have less than 15 employees, issues of privacy and confidentiality, which are essential to ensuring employee program participation in health promotion programs, can be compromised. As a result, some small business owners may choose not to offer any programs at all, so as to avoid the perception that they are prying into the private lives of their employees.

Despite the many reasons why small business owners are less likely to offer health and safety programs, small businesses have assets and strengths that will serve to help facilitate the adoption of these programs. Specifically, small businesses have fewer organizational layers than larger companies to consider in the decision-making process, so that if an owner wants to adopt a new program or create a new policy, it is typically not a cumbersome decision and approval process. In larger companies, these decisions involve multiple people and additional time. In addition, with fewer employees, it is easier to solicit opinions or assess health needs from the entire workforce at a small business. In larger companies with remote locations, these efforts are complicated, and some employees may be left out. Third, the influence of the leader may be more direct and, thus, stronger in small businesses. As a result, if the leader is supportive of health promotion efforts, employees may be more highly motivated to get involved in worksite-sponsored health promotion, given the stronger and more direct interpersonal relationship between managers and employees in small businesses. Small business owners also know that the health of every employee is important; and employees may be family members (or viewed as "part of

"...if the leader is supportive of health promotion efforts, employees may be more highly motivated to get involved in worksite-sponsored health promotion, given the stronger and more direct interpersonal relationship between managers and employees in small businesses."

the family"), which provides additional motivation to treat employee health as a priority issue.

Recognizing both the challenges and potential strengths of working with small businesses to address health promotion is an important first step toward addressing this public health imperative. One of the *Healthy People 2010* national objectives states that "75% of employers (of all sizes) should offer a comprehensive worksite health promotion program," which is defined as including: (1) *Health education programs* (e.g., skill development and lifestyle behavior change along with information dissemination and awareness building); (2) *Supportive social/physical environments*; (e.g., an organization's expectations regarding healthy behaviors and implementation of policies that promote health and reduce risk of disease); (3) *Integration* (e.g., of the worksite program into the organization's structure); (4) *Linkage* (e.g., to related programs like employee assistance programs (EAPs) and programs to help employees balance work and family); and (5) *Worksite screening programs* (e.g., linked to medical care to ensure follow-up and appropriate treatment). While the majority of employers offer one or more of the five key elements of a comprehensive program,[4] it is clear that small businesses offer far fewer of all programs and are unlikely to reach the 2010 national health objective. In the remainder of this commentary, we share some strategies for how to successfully increase the likelihood that small businesses offer worksite health and safety programs for their employees.

Strategies for Success—Increasing Adoption and Implementation of Health and Safety Programs among Small Business Owners

There are multiple reasons why small businesses may not be offering these programs, so a successful strategy for increasing adoption and implementation of health promotion programs among small businesses should involve multiple levels of intervention, consistent with ecological approaches.[11] Here we present a brief review of some promising strategies at three levels of the social ecologic framework (policy, community, organization) and conclude with a call for additional research.

Policy-Level Changes

Public policy at the federal, state, and local levels could be enacted to support small business owners who want to implement employee health promotion efforts. For example, legislation extending tax credits to small businesses that offer selected health promotion programs was sponsored by Senator Tom Harkin (D-IA) in the Healthy Lifestyle and Prevention America Act (S. 1074). This type of legislation was proposed at the state level in Rhode Island as well.[12] In addition to tax credit strategies, public policy changes that would offer some type of universal healthcare coverage at reduced rates to small businesses would be helpful. As noted previously, because managed care or other health plans are the primary source of employer-sponsored health promotion programs, offering health plan coverage that includes a basic health promotion package would be desirable. These public policy changes—whether at the national or state level—have the potential for making an immediate and significant impact on small business adoption and implementation of health promotion programs for employees.

Community-Level Changes

If not a part of a franchise or a larger corporate affiliation, small businesses can be isolated organizational structures without much power or leverage in a given community. Recommended community-level changes to help stimulate small businesses to adopt and implement health promotion programs is all about identifying and creating leverage points for change through partnerships. Promising community-level interventions include encouraging partnerships to address health promotion initiatives with regional Small Business Administration offices, local Chambers of Commerce, local Business Councils, and national or local Business Groups on Health. These organizations typically exist to support businesses, and if health promotion "packages" or training sessions or workshops could be developed with a small business focus, it might stimulate owners to adopt more health promotion programming. In addition, these partnerships create leverage opportunities where members could be called upon to advocate for policy changes at the national, state, or local levels. In Rhode Island, the state health department helped to organize a statewide worksite wellness council that included business leaders of all sizes, health department officials, insurers/health plans, consultants, and researchers.[12] In North Carolina, most local communities have a Healthy Carolinians Task Force that could embrace and sponsor worksite wellness initiatives. University-based partnerships can bring student skills and help; opportunities for student projects or practicum experiences; and expertise in planning, marketing, or evaluating programs. These community-level partnerships and activities could be a powerful force for change.

Organizational-Level Interventions

Here, we refer to interventions that might be initiated within the small business itself to support the adoption and implementation of employee health promotion programs. Barbeau et al[13] reported that there were no significant differences between small manufacturing sites that did/did not agree to participate in a cancer prevention research trial. Happily, there is growing research evidence that small businesses are interested in and can successfully adopt these programs and that employees who participate can improve their health. For example, Sorenson and colleagues[14] found that small businesses randomized to receive a social-contextual intervention, which included employee participation through wellness committees, and a multi-level intervention addressing employee and manager health and work conditions, were significantly more likely than control worksites to improve multivitamin use and physical activity among employee participants.

The types of strategies that an interested small business can use to develop a successful health promotion program include many of the same approaches that other businesses (of all sizes) should consider. Specifically, first it is important to mobilize all available internal and external information and resources that might be related to health promotion (e.g., marketing, facilities, nurses, benefits, etc.). Small businesses should create a small team, task force, or wellness committee including employees who are interested in helping focus attention on employee health. This small group can provide the staffing and leadership needed to get a project underway. Second, if there is a labor union or employer-sponsored healthcare plan already present, resources/expertise available through these sources might offer possible staffing, resources, intervention materials, or expert help. Third, it would be useful to conduct an assessment to determine the top five healthcare claims costs, the top five health needs/interests of managers and employees, the behavioral risk profile of the workforce (e.g., via a Health Risk Appraisal), and the important expectations that managers and employees have for this program. Make sure the most current literature from worksite-based research studies is carefully and critically reviewed. Fourth, develop a working plan that takes into account the assessment results and current evidence about what works, as well as realistic objectives for success. It is essential to obtain approval and encouragement for implementation from top management and the wellness committee or task force established at the worksite. A systematic and tailored communications plan and a festive kick-off event can help to get the program underway. Fifth, it is important to include as program components a menu of evidence-based health promotion program offerings that take into account different learning preferences, convenience, cost, time to participate, and any privacy/confidentiality concerns that might exist among employees.

The program, once implemented, should take steps to stay visible among both employees and managers. The program should include multi-level interventions that address work conditions, as well as the physical and social environment. Ongoing visibility can be aided by E-mail messaging, events, contests, print, video, online sources, classes, support groups, and other relevant methods. In order to identify evidence-based programs for possible program inclusion, one can review the most recent published worksite-based literature, the Community Guide to Preventive Services published by the Centers for Disease Control and Prevention (www.thecommunityguide.org/worksite/), CancerControl Planet (http://cancercontrolplanet.cancer.gov/), the Centers for Disease Control and Prevention-sponsored Healthier Worksite Initiative (www.cdc.gov/nccdphp/dnpa/hwi/index.htm), and other compendia of information about effective programs and policy interventions. Specific resources (handbooks) that include examples of small business success stories can be found at the Wellness Councils of America (WELCOA) (www.welcoa.org) or Partnership for Prevention (2001) (www.prevent.org/) Web sites. Finally, successful worksite health promotion initiatives include specific plans to evaluate the health outcomes at the worksite and employee levels, as well as the process of delivering these programs, so that employees and managers can talk about their experiences and the results of these endeavors. It is important to find ways to periodically share the results with employees, the wellness committee members, and with managers. Similarly, it is important to work toward securing a budget (however small to begin with) and some portion of dedicated staff support for employee health promotion activities. Over time, individual training for health promotion program staff will build internal expertise. Successful programs will pursue all partnership opportunities in the larger community, and within their own company environment, so as to leverage small resources and expertise into successful outcomes.

Research to Benefit Practice

Ongoing research is needed to determine how to create structural, political, and economic incentives, as well as strategies for how best to motivate small business owners to adopt these programs, and then to help owners be successful once they embark on these efforts. Research is needed to decipher what the underlying and persistent barriers are to offering these programs and to determine how best to overcome identified barriers in the highly diverse and complex small business community. Divine[15] recently found that small business owners deciding to offer employee health promotion programs were less motivated by financial arguments (e.g., the programs will address a business need or rising healthcare cost), but were more persuaded by evidence that the wellness programs actually work to improve employee health. Qualitative research is critically important to uncovering the root causes of why this problem has persisted for more than three decades. How to best "tailor" a menu of health promotion offerings to the small business environment continues to be a worthy research question. Because partnerships are central to overcoming some of the barriers to offering these programs in small businesses, future research on which partnerships are most effective, how to best characterize these partnerships, and how these partnerships can grow and be sustained over time seem to be critically important scientific pursuits. The role played by managed care organizations and other healthcare provider organizations needs further investigation. Research on the policy level that uncovers examples of legislation or incentives that work to increase small business adoption is clearly needed as well.

> *"Because nearly 50% of American workers are employed in small businesses, we need to address this problem as a public health imperative."*

For the past 30 years, while worksite health promotion programs have proliferated, and many employees and companies have benefited from these programs, small businesses and their employees have lagged behind and, in fact, have made very few strides toward offering health promotion programs for their employees. Because nearly 50% of American workers are employed in small businesses, we need to address this problem as a public health imperative. We have offered some of the plausible reasons why small businesses have not offered health promotion programs, noted some of the challenges and opportunities, have identified some potential strategies for success, as well as research needs. As we move further into the 21st century, we must take up this challenge so that all workers can benefit equally from successful worksite health promotion efforts, regardless of whether they are employed in a corner convenience store with five employees or a Fortune 500 corporation. This public health challenge is one that we can begin to address with strong partnership models, a multi-level intervention strategy, and the political will to focus attention on this issue now. **NCMedJ**

COMMENTARY

Implementation Challenges in Worksite Health Promotion Programs

Benjamin E. Birken, MS, and Laura A. Linnan, ScD, CHES

Effective worksite health promotion programs address challenges that occur during planning, development, implementation, and evaluation efforts.[1] In this commentary, we focus on implementation challenges faced by employers—issues that must be addressed after an organization has made a commitment to offering a worksite health promotion program. Of course, initial support from top management must be secured. But evidence suggests that management support alone does not guarantee program success.[2,3]

A nationally representative sample of employers responded to the 2004 National Worksite Health Promotion Survey and reported that the most common barriers or challenges to health promotion program success were: lack of interest among employees (63.5%); lack of staff resources (50.1%); lack of funding (48.2%); lack of participation among high-risk employees (48.0%); and lack of management support (37.0%).[4] No significant differences in barriers were reported based on industry type or worksite size except that worksites with 750+ employees were significantly more likely to report lack of participation by high risk employees as a barrier.[4] We review each of these potential implementation challenges and argue that engaging employees and managers in identifying and addressing them early in the planning process allows an organization to develop the necessary strategies to overcome them.

First, some employers clearly believe that employees are not interested in worksite health promotion programs. This tends to occur when employee participation in programs is low. It is important to both understand and clarify some of the potential underlying "causes" of low levels of employee interest and participation.[5] For example, insufficient or ineffective communication about health promotion programs could result in low levels of participation simply because employees were not aware of programs being offered. Another potential "cause" of low perceived employee interest is that employees might not participate at all (or in lower numbers) if they have to pay to join a program, or if the program is offered at inconvenient times or locations, or when child care and other issues may limit participation. Employees exposed to stressful and/or otherwise hazardous work conditions might not participate because they are skeptical of worksite health promotion programs and/or angry if these programs are being prioritized ahead of addressing work conditions.[6] Additionally, if employees believe that employers are intruding on their privacy or trying to "control" their health, they may not participate.[7] Thus, low employee participation may be caused by several of these factors and may lead to a perception among employers that employees are not "interested" in health promotion programs.

> *"...we encourage employers to consider funding worksite health promotion programs as an investment in "human capital" that will lead to bottom line advantages for the organization."*

Benjamin E. Birken, MS, is the Coordinator of the University Steering Committee for Worker Health, Safety and Wellness at the University of North Carolina at Chapel Hill. Mr. Birken can be reached at birken@email.unc.edu or CB# 7426, Chapel Hill, NC 27599-7426. Telephone: 919-966-6085.

Laura A. Linnan, ScD, CHES, is an Associate Professor in the School of Public Health, Department of Health Behavior and Health Education at the University of North Carolina at Chapel Hill and has a joint appointment at the Lineberger Comprehensive Cancer Center. Dr. Linnan can be reached at linnan@email.unc.edu or CB# 7440, Chapel Hill, North Carolina 27599-7440. Telephone: 919-843-8044.

Improving Employee Participation

Strategic program planning efforts can help organizations overcome problems with low participation and low perceived employee interest. First, we encourage employers to mobilize an employee wellness committee—a group of employees that represent key work teams and departments in an organization—who can be involved in planning, promoting, and developing health promotion programs at work.[8] If unions are present, be sure to work with local representatives to understand their priorities and incorporate those into the planning process. Second, develop a comprehensive marketing plan that gets the word out about program offerings through channels that reach all employees. Third, consider offering incentives to increase employee participation. For example, 25.9% of respondents to the 2004 National Worksite Health Promotion Survey reported using incentives for this purpose.[4] Such incentives, if properly designed and communicated clearly to employees, have been shown to enhance participation in worksite health promotion programs.[9] Fourth, be sure to offer high-quality health promotion programs and use a variety of educational methods (self-help, group classes, Internet options, etc.) that appeal to different employee interests and learning styles. These programs should be free, or low-cost, and convenient for employees to participate, including offering options for shift workers and employees who travel or work offsite to participate. If programs are to be held during regular daytime hours, management should be lobbied to either allow employees to participate during work time or to institute a policy of shared employee/work time or flex time. Fifth, finding program "champions" (members of the wellness committee, managers, or members of the general employee population) who both participate and enthusiastically support programs will help increase employee participation as well. Finally, addressing work conditions that are oppressive, stressful, or hazardous to employees will influence participation among employees.[10] Evidence suggests that employees who have a voice in addressing the pace or conditions of work will be more engaged in worksite wellness efforts while maintaining productivity.[11,12] If implemented early in the planning process, all of these strategies can help overcome potential problems with employee interest and/or low participation.

Addressing participation among "high-risk" employees is an implementation challenge recognized by new as well as experienced program staff. Evidence suggests that moving high-risk employees to a lower-risk category will have a positive impact on employers' healthcare costs.[13,14] However, Edington and colleagues have demonstrated that maintaining the health of low-risk employees over time is also important for ensuring long-term control of healthcare costs.[15] While evidence suggests that high-risk employees might face different barriers to participating in health promotion programs than low-risk employees,[16] more research is needed to uncover best practices (e.g., tailored approaches, engaging peer educators, or offering online options that maintain privacy) for increasing program participation among all employees, including those at all levels of risk. For example, Grosch et al[17] surveyed a representative sample of workers from the National Health Interview Survey data and found that, when access to programs was equal for all workers, traditionally "high-risk" employees (e.g., blue-collar workers and blacks) were more likely to report they participated in worksite health promotion programs than were other workers. Emmons et al[18] conducted a qualitative study to ascertain barriers to participation among working women with different health risk factor levels. Research results like these have direct application for improving strategies for success on increasing participation over time.

Overcoming a Lack of Staff Resources

Lack of staff resources was another commonly reported barrier to offering health promotion programs as reported in the 2004 National Worksite Health Promotion Survey.[4] Among large employers, staff resources might be hard to identify or they might be "discovered" through a well-planned needs assessment. Among smaller employers, resources of all types, including staff resources, may be problematic for any programs that are not directly linked to the business operation. Importantly, evidence suggests having a staff person who has dedicated responsibilities for health promotion has been shown to be the single biggest independent predictor of having a comprehensive worksite health promotion program.[4] Existing staff may be both willing and interested in helping to organize health promotion efforts at work. Through continuing education workshops or externally-sponsored training programs, an employer can address this potential implementation challenge. For example, employee wellness committees can assist a designated staff person with program planning and implementation efforts. In fact, the North Carolina State Division of Public Health has worked with the State Health Plan to develop and deliver a training workshop for state employees and teachers who want to start an employee wellness program. (More information is available at http://statehealthplan.state.nc.us/worksite-wellness.html.)

Finding Funds

Lack of funding is the third most commonly cited barrier to offering worksite health promotion programs. This problem often goes hand-in-hand with a lack of staff resources. While all employers face this challenge to some extent, many potential funding and/or sources of support exist and can be tapped for assistance. Specifically, health plans are the leading source of health risk appraisals, health screenings, lifestyle behavior change programs, and disease management programs offered by employers responding to the National Worksite Health Promotion Survey.[4] Local hospitals, voluntary health organizations, health departments, business groups on health, chambers of commerce, and other groups may provide direct assistance to employers who offer worksite wellness programs. The Centers for Disease Control and Prevention sponsored Healthier Worksite Initiative Web site (www.cdc.gov/nccdphp/dnpa/hwi/index.htm) lists resources as well as funding opportunities for worksite health promotion. However, we encourage employers to consider funding worksite health promotion programs as an investment in "human capital" that will lead to bottom line advantages for the organization. Positive changes in employee health behaviors, healthcare claims costs, productivity, turnover, and absenteeism are possible, so program staff should be sure to include related measures in a comprehensive evaluation plan when considering the total return-on-investment perspective.

Cultivate Management Support at All Levels

One final implementation challenge universally acknowledged by employers is a lack of management support. Moreover, evidence suggests that different levels of management (e.g., line supervisors, middle managers, and top managers) report different barriers to program implementation that warrant serious consideration.[3] For example, in one study of over 1,000 managers from 23 manufacturing worksites, senior managers (vs. line supervisors) were significantly less likely to believe space or cost were barriers and were less likely than middle managers or line supervisors to believe production conflicts were a barrier to offering health promotion programs.[3] Management support should be cultivated early in the planning process, and throughout implementation.

Several strategies for ensuring management support are worth consideration. First, management representation should be included on the employee wellness committee as a visible sign that management is committed to its success and to keep management informed of the progress of the program. Second, key managers should be interviewed to ascertain their expectations for worksite health promotion programs. Third, ongoing communications with managers should take place to ensure visibility and to share success stories. Communications should include data that address managerial needs and expectations whenever possible. Finally, national (see Table 1), industry-specific or local data should be used whenever possible as benchmarks for success. Regular reports to management on progress toward achieving those goals are desirable.

Table 1.
Healthy People 2010 Worksite Setting Objectives[19]

Objective	Target
Increase the proportion of worksites that offer a comprehensive employee health promotion program to their employees.	75%
Increase the proportion of employees who participate in employer-sponsored health promotion activities.	75%

Conclusion

An employer who decides to offer a worksite health promotion program faces a number of important implementation challenges, and the underlying causes of these challenges are varied and complex. An effective planning effort can, however, address employer concerns while engaging employees in the process of planning, developing, implementing, and evaluating worksite health promotion programs that are most likely to be successfully adopted, achieve desired employee health outcomes, and sustained over time. **NCMedJ**

Worksite Health Promotion:
Skills and Functions of Professional Staff

Bonnie Rogers, DrPH, COHN-S, LNCC, FAAN

Health promotion and wellness programs are designed to facilitate behavioral change and maintenance, emphasizing optimal health. General agreement exists that interaction among individual, social, and environmental factors influence behavioral choices that may result in detriments to health and/or increased health risk. Alteration or modification of these risk-based lifestyle choices and non-supportive environments are needed so that optimal health outcomes can be achieved. This can best be accomplished through a series of combined strategies that often involve programs, such as risk assessment and management, smoking cessation, weight management, fitness, stress management, and selected screening or targeted disease management programs, such as high blood pressure and cancer control.

Qualified and capable staff are essential to develop, implement, and evaluate worksite health promotion programs. McCauley and McCunney point out that selecting staff may be as easy as turning over programming to existing staff that have skills in health promotion program development, or it could be as difficult as hiring new staff or selecting qualified vendors, or both. However, it is important not to assume prospective staff capability based on credentials and referrals. Assessing prospective staff capability to lead such initiatives should include considerations of substantive knowledge and worksite-based health promotion experience, as well as effective interpersonal, writing, presentation, and management skills.[1] If an itinerant health promotion leader is necessary due to the configuration of business structure and location, then the ability to adapt programs to local worksite circumstances would be essential.

> *"...health promotion staff or specialists need to have not only skills and knowledge in targeted areas, but also the ability to communicate with diverse populations, including being able to deal with issues of language, culture and literacy barriers."*

Adult Learning: Constructing Knowledge

In any worksite health promotion program, staff will need to be intimately familiar with principles of adult learning. The classic work of Malcolm Knowles,[2] former professor at North Carolina State University, differentiates between adult and child patterns of learning and emphasizes the importance of teaching adults based on a framework of andragogy (teaching of adults), rather than pedagogy (teaching children). Knowles discusses that children have often been taught in traditional lecture-learner formats, although educators are finding more success and student interest when the actual principles of what is being taught are applied through hands-on experiences, field trips, and group work. Knowles points out that adults, because of their greater independence and more extensive backgrounds, bring more to the learning experience, and health promotion staff should serve as facilitators and enhancers of the teaching-learning process. Knowles' principles of adult education focus on four areas: independent learning, usefulness of past experience, readiness to learn, and problem-oriented learning.

Bonnie Rogers, DrPH, COHN-S, LNCC, FAAN, is a professor and Director of the North Carolina Occupational Safety and Health Education and Research Center and the Occupational Health Nursing Program at the University of North Carolina at Chapel Hill School of Public Health. Dr. Rogers can be reached at rogersb@email.unc.edu or CB# 7502, Chapel Hill, NC 27599. Telephone: 919-966-1765.

Independent learning emphasizes the importance of respecting the independence of workers and including them as active, self-directed participants, rather than passive recipients. This can be done by finding out what they already know about a topic, what they need to know to do the job better and safer, or what more they would like to learn.

Previous experience utilizes the wealth of life's experiences on which to base new learning. For example, an employee may have a relative who has had a heart attack and may be able to share related information about the rehabilitation process. This also presents an opportunity to assess employee baseline knowledge and to focus on areas of special concern.

Readiness to learn involves recognizing when an employee or employees are ready to engage in new learning events or when a teachable moment presents itself.[3] For example, a woman who becomes pregnant may be more interested in learning about workplace hazards or the effects of related lifestyle hazards, such as smoking, and an employee recently diagnosed with high blood pressure may be more interested in learning about dietary control strategies. Preventive information on topics such as AIDS or diabetes may not have a direct impact unless the employee knows someone affected.

Problem-oriented learning relates to helping employees address a problem area related to changing behavior of personal concern. For example, employees who have had difficulty in quitting smoking will probably consider it a health problem and, thus, be more amenable to a smoking cessation clinic or an educational program. In addition, Loos[4] asserts that adult learners:

- do not regard instruction as a means of reinforcing learning,
- utilize instruction to construct knowledge, and
- learn best what they "discover" for themselves.

Therefore, instructing adults must be an active process wherein the learner constructs knowledge rather than only acquires it, and it involves a process of supporting this construction rather than one of only communicating knowledge.

Communicating, Assessing, Planning, Conducting, and Evaluating

For many years, executives, management, and white- and pink-collar workers were the primary targets for health promotion programs.[1] Today the literature is replete with information about programs designed for special populations. For example, back care and musculoskeletal disorder care and preventive programs have been offered for petroleum workers,[5] healthcare workers,[6] municipal workers,[7] school personnel,[8] and police officers.[9] Hypertension, diabetes management, and stress reduction programs are being increasingly offered to employees from ethnically diverse populations.[10] What this means is that health promotion staff or specialists need to have not only skills and knowledge in targeted areas, but also the ability to communicate with diverse populations, including being able to deal with issues of language, culture, and literacy barriers.[3]

Health promotion programs may do one or more of the following: address an awareness level, focus on lifestyle or behavioral change programs, or encompass environments that encourage healthy lifestyles. Because the concepts of health promotion and wellness are multidimensional in nature, programs can and should encompass social, occupational, spiritual, physical, intellectual, or emotional dimensions.

Health promotion specialists should use a systematic approach to develop, plan, and implement successful health promotion programs.[11] The corporate culture needs to be assessed to determine if health promotion is valued within the organization and what the commitment of management is to health promotion. Assessing employee involvement is also critical for success. What programs would they like to have offered and when? In addition, examining existing healthcare data is critical to justify the need for programs. This information can be used to convince management to establish specific programs like prenatal education, breast self-examination and mammography, and nutrition/exercise programs. Health promotion planners should establish a wellness committee with employee representation that can assist with program planning and contribute to program success. Goals and objectives can be established along with a budget and an evaluation plan. After the program is completed, it must be evaluated. An evaluation of the program serves many important functions, including assessment of the achievement of objectives, identification of the strengths and weaknesses of the program, and analysis of its outcomes.

Specific functions of the health promotion specialist include, but are not limited to, the following activities:

- Assesses and targets health promotion program needs for the workforce.
- Develops and monitors the goals and strategies for the health promotion program.
- Develops and implements primary, secondary, and tertiary prevention programs.
- Provides programs and special events, such as health fairs and health education seminars, which increase awareness of health issues and choices, and help modify health risk behaviors.
- Collaborates with management to provide a healthy work environment.
- Selects and monitors vendor contracts.
- Conducts ongoing evaluation of the specific activities, as well as the overall health promotion program, and integrates cost-containment and cost-effectiveness aspects.
- Plans and directs the evaluation process.

Depending on the type of industry, health promotion planners will need to consider shiftwork, telecommuting, and remote locations. The latter two areas will require skills in distance education. In addition, the health promotion staff will need to be familiar with motivational readiness and concepts related to change.[12,13] For example, Prochaskas's model describes the five stages of change—precontemplation, contemplation, preparation, action, and maintenance. This model attempts to explain five stages through which individuals engage in behavioral change. The health promotion specialist can use this model to identify the stage of change where the employee is and utilize appropriate strategies to help workers move through these change stages, which will include dealing with relapse prevention.[3]

In conclusion, health promotion staff must have knowledge and skills that have breadth and depth. Knowing the worker population and industry needs and being able to communicate with diverse populations using principles of adult learning are essential to have successful and effective outcomes in achieving optimal health. **NCMedJ**

COMMENTARY

Creating a Culture of Wellness in Workplaces

George C. Stokes, MSW; Nancy S. Henley, MPH, MD, FACP; and Casey Herget, MPH, MSW

The North Carolina State Health Plan (SHP), a self-funded plan established by the North Carolina General Assembly, provides healthcare coverage for more than 615,000 active public sector employees, retirees, and dependents. Employee members of the SHP work in 225 organizations in approximately 3,000 worksites throughout the state. Seventy percent of the health plan's medical and pharmacy costs are attributed to preventable chronic diseases related to poor nutrition/obesity, physical inactivity, tobacco use, and stress. In 2003, more than 164,000 SHP members were treated for one or more chronic diseases, an increase of 37% from 2000.[a] In response to these findings, the SHP launched NC Health*Smart*, a healthy living initiative for all eligible members in 2005.[1] The initiative includes six components: health tracking, including a health risk assessment; centrally designed health promotion interventions; targeted disease management; health coaching services available 24/7; high-risk case management; and worksite wellness programs.[b,2]

NC Health*Smart* delivers integrated services directly to the member via the Web, mail, telephone, worksite, and the healthcare community. These wrap-around services are designed to empower the members to play an active role in the management of their health.

Wellness programs in the workplace have great potential to impact employees' long-term lifestyle choices because the average employee spends 50 hours-a-week at work and eats one third of his/her meals at work.[3] Long-term results of wellness programs include improved health outcomes, reduced absenteeism, improved employee morale and retention, and reduced healthcare costs.[4,5,6]

Successful worksite wellness programs are characterized by:[6]

- Individualized behavior change information (self-care information, health risk assessments, behavioral counseling);
- Social supports (wellness challenges, classes, support groups);
- Senior-level management buy-in (financial incentives, department-wide policy changes, communication, long-term commitment); and
- Environmental supports (workplace fitness centers, on-site health services, smoke-free worksites, healthy meal and snack options).

> *"Wellness programs in the workplace have great potential to impact employees' long-term lifestyle choices because the average employee spends 50 hours-a-week at work and eats one third of his/her meals at work."*

---

[a] Members eligible for North Carolina Health*Smart* services are members whose primary health insurance is through the North Carolina State Health Plan and who are not on COBRA.

[b] North Carolina Health*Smart* was developed in collaboration with the State Teacher and Employee Wellness Advisory Committee (STEWAC), North Carolina Institute of Medicine, the University of North Carolina School of Public Health, North Carolina Department of Health and Human Services, and the North Carolina State Health Plan Board of Directors.

George C. Stokes, MSW, is the Executive Administrator of the North Carolina State Health Plan. Mr. Stokes can be reached at George.C.Stokes@shpnc.org or 4901 Glenwood Ave, Suite 150, Raleigh, NC 27612. Telephone: 919-881-2300.

Nancy S. Henley, MPH, MD, FACP, is the Medical Director for the North Carolina State Health Plan. Dr. Henley can be reached at Nancy.Henley@shpnc.org. Telephone: 919-881-2300.

Casey Herget, MPH, MSW, is the Health Promotion and Disease Prevention Consultant for the North Carolina State Health Plan. Ms. Herget can be reached at Casey.Herget@shpnc.org. Telephone: 919-881-2300.

Based on this evidence, the SHP, in partnership with the Division of Public Health (DPH) in the North Carolina Department of Health and Human Services (NC DHHS), has developed the NC Health*Smart* Worksite Wellness Toolkit for use by worksite wellness committees in all North Carolina state government entities. Employers can use the Toolkit to build customized wellness programs. Currently, more than 160 committees from 93 eligible state organizations[c] have been trained to use the Toolkit. The State Health Plan is also funding a worksite wellness team at the DPH to offer new resources and technical assistance to support committee sustainability at these worksites. New services will include a Web site, seminars, a newsletter, and a consultation program. In 2007, the Toolkit and training initiative will be modified for public schools (approximately 175,000 SHP members). This work will integrate with the North Carolina Healthy Schools initiative and occur in partnership with the North Carolina Department of Public Instruction, Local Educational Agencies, and the Division of Public Health.

Pilot Worksite Wellness Program

In 2004, the SHP commissioned and jointly funded a wellness initiative with a single state agency, NC DHHS, as a prototype for leadership development, policy change, and building wellness infrastructure for all North Carolina state government employers. NC DHHS was chosen as the pilot because of leadership support for worksite wellness and its large size (18,700 employees in 22 agencies and 16 hospital and residential school facilities across North Carolina) The initiative aims to:

- Reduce the major chronic disease risk factors among NC DHHS employees, thereby reducing chronic diseases and containing rising healthcare costs.
- Demonstrate the effectiveness of a wellness program model that includes a full-time, department-level director.
- Establish wellness committees to create and sustain work environments that promote and support employee health and wellness.
- Change policies and work environments to help employees become more active, make healthier food choices, avoid tobacco, and manage stress.

Implementation of the Pilot

NC DHHS launched the Wellness Initiative in September 2005. In the first 12 months, the groundwork for a sustainable, department-wide wellness program has been created. It involves leadership at all levels of the organization and formally incorporates feedback from employees and agency wellness committees. NC DHHS developed a three-year strategic implementation and evaluation plan with measurable objectives to guide the initiative. Baseline and follow-up surveys were conducted to assess agency policy and environmental support for wellness, employee interest and participation levels, and management support. An online reporting system was created for committees to submit brief monthly reports of their wellness activities and program outcomes.

Prior to the launch of the Wellness Initiative, each division, office, and facility designated a Wellness Representative. The NC DHHS Wellness Director helped the 38 representatives establish wellness committees and develop tailored agency wellness plans. The Wellness Representatives also serve as members of a new Department-level Wellness Council to advise the Secretary on worksite wellness policy issues. All representatives received training on the Worksite Wellness Toolkit in the fall of 2005. The Wellness Director provides continued technical assistance, which includes on-site visits to help wellness committees implement programs geared to the needs and interests of their employees. Raffle incentives and exercise equipment grants were offered to committees to promote wellness activities and to increase employee participation. Wellness committees are also encouraged to integrate other NC Health*Smart* services, such as health coaching and the health risk assessment, into their program strategies.

NC DHHS determined that approving *department-wide policies* that support employee wellness and creating a *supportive work environment* were the most efficient and cost-effective ways to engage employees in health risk reduction activities. NC DHHS Secretary Carmen Hooker Odom addressed the first policy issue by raising awareness of an existing Department Wellness Policy that allowed employees, with manager approval, to use flex-time schedules to participate in wellness activities. The Secretary continues to consider policy and environmental changes as needs are identified.

> *"I firmly believe that we, the leading public health organization in the state, must fully support our own employees' efforts to live a healthy life," says Secretary Hooker Odom. "I am committed to working with managers and employees to create a 'culture of wellness' within the Department. I encourage other state agency leaders to embrace worksite wellness and to take advantage of what we have learned."*

Policy Recommendations

The NC DHHS Wellness Council made policy recommendations for the Department using employee and agency survey results, evidence-based wellness interventions, and council members' perceptions of department-level barriers. The recommendations are to:

- Increase employee access to on-site exercise opportunities.
- Provide incentives and increase management support for employee participation in wellness activities.

---

[c] State agencies, universities, and community colleges are eligible for trainings in 2006-2007. A modified curriculum will be rolled out to public schools in the next two years.

- Ensure that all employees have access to designated break areas away from their workstations.
- Require training for supervisors on conflict resolution and stress reduction.
- Improve access to healthier meals and snacks in the workplace.
- Support policies that make workplaces tobacco free and provide on-site cessation programs.
- Establish procedures for addressing employees' concerns about air quality and ergonomic work areas.

Secretary Hooker Odom responded to the recommendations by providing key support for the implementation of department-wide formal and informal policy changes. Opportunities to increase physical activity helped drive several changes. State hospitals and resident school facilities with existing fitness areas were asked to allow employees use of the areas. For example, the Dorothea Dix Hospital Campus in Raleigh will reopen a gym facility (infrequently used by hospital patients) to employees, giving them access seven days-a-week. Improved exercise, shower, and locker facilities and scheduled wellness activities are planned for the site. Agencies were also encouraged to designate space for fitness areas. Fourteen sites received a commercial grade treadmill or exercise bike from a grant program offered by NC DHHS. To increase healthy foods at work, the State Services for the Blind vending contracts were modified to require vendors to include 15%, or at least five, healthier vending choices. Work is also underway to provide designated break areas and to offer incentives to support employee participation in health promotion programs.

Year One Outcomes and Participation

During the first 12 months of the Wellness Initiative, NC DHHS wellness committees reported implementing a total of 243 wellness activities and reported 49 changes to policies and environments that increased support for employees to become more physically active, eat healthier foods, avoid tobacco, or manage stress. Worksites with healthier vending options doubled (10 to 20), and the number of worksites providing information on healthy food choices increased from 10 to 41. More worksites have written policies supporting physical activity during the workday, and the number of indoor fitness areas increased from 14 to 22 worksites. More sites disseminated tobacco health risk information (from five to 33) and offered cessation programs (from three to 14). Stress management programs and materials offered in 14 worksites a year ago are now available in 36 worksites. Even without formal incentives, NC DHHS has achieved the highest rate of health risk assessment completion of any state department.

Preliminary data from a November 2006 employee survey (4,788 respondents) found that 62% of employees had participated in at least one workplace wellness activity in the past year. Employees reported exercising more often (51%), citing work-based walking programs (50%) as the most popular activity. They indicated that they were eating more fruits and vegetables (49%), and were closer to a healthy weight (27%). With regard to tobacco use, 106 employees stopped tobacco use completely, and 149 reduced their amount of tobacco use. Employees indicated that they had received health information from their worksite wellness committees (45%), attended health fairs (35%), and received a flu shot at work (46%). The main reason employees reported that they did not participate in wellness activities was a lack of time (36%).

Wellness committees receive survey results to guide their wellness program plans for the coming year. Use of the survey information appears to have played a critical role in achieving high levels of participation. For example, both the baseline survey in 2005 and the second employee survey in 2006 indicate that an indoor place to exercise at work was the primary wellness priority for the greatest number of employees. The Wellness Initiative responded to employee needs by addressing policies that prevent or limit access to existing fitness areas and providing fitness equipment to agencies.

Further evaluation of the NC DHHS Wellness Initiative will include analysis of aggregate employee health risk assessment data. It is anticipated that this information will further confirm changes in a majority of employees' health behaviors. Finally, a comparison of health claims data before and after implementation of the Wellness Initiative will assess the impact of this model of worksite wellness on improving employee health and containing healthcare costs.

The NC DHHS Wellness Initiative will not be completed for at least another year, yet mid-study data suggest that it is already positively impacting individual and environmental behaviors. Modifying lifestyle habits is difficult, and it is critical to use every point of entry to support individuals in taking a more active role in their health. A comprehensive worksite wellness program can increase employee satisfaction and productivity and improve employee health by reinforcing health messages from providers, care management services, and health education campaigns. The State Health Plan will build on the impressive NC DHHS preliminary results by using this experience and other resources to benefit all state government, university, community college, and public school employers and their employee populations. **NCMedJ**

COMMENTARY

National Indications of Increasing Investment in Workplace Health Promotion Programs by Large- and Medium-Size Companies

Jennifer M. Childress, MS, CHES; and Garry M. Lindsay, MPH, CHES

Worksite health promotion programming has received growing interest over the past 20 years. In 1985, the Office of Disease Prevention and Health Promotion (of the United States Department of Health and Human Services) launched its first survey of national worksite health promotion practices. Subsequent to that, there have been three follow-up surveys, the most recent findings published in 1999. The 1999 survey reported that 90% of worksites were offering at least one type of health promotion activity to their employees. The results from the 2004 National Worksite Health Promotion Survey,[1] currently in the publication process, compares health promotion programming among worksites between 1999 and 2004, and more fully assesses the degree to which worksites are meeting the *Healthy People 2010* goal of having 75% of all worksites, regardless of size, offering comprehensive programming to employees. The 2004 National Worksite Health Promotion Survey, sponsored by Partnership for Prevention, Watson Wyatt Worldwide, and the Office of Disease Prevention and Health Promotion surveyed a nationally representative sample of over 1,500 worksites and found that employers offered a wide range of health promotion activities to their workers. However, only 6.9% of the responding worksites offered all five key elements that define a "comprehensive" worksite health promotion program: (1) health education, (2) links to related employee services, (3) supportive physical and social environments for health improvement, (4) integration of health promotion into the organization's culture, and (5) employee screenings with adequate treatment and follow up. Controlling for worksite size, indutstry type, staffing, and experience, worksites from agricultural or financial sectors and those with a dedicated staff person were significantly more likely to offer a comprehensive program.[2]

Along the continuum of worksite health promotion program elements, the level of sophistication usually correlates with the amount of resources invested. Despite the fact that the growth, and in some cases the very sustainability of business, is linked to employee health, many employers do not view worksite health promotion as being a core component of their business strategy. Yet, the issue surrounding the cost of health is at the forefront of business leaders' minds. Over the past four consecutive years, CEOs responding to the Business Roundtable's *CEO Economic Outlook Survey* have cited healthcare costs as their greatest cost pressure.[3]

> *"...research has documented that high-risk employees are also high-cost employees with higher medical and pharmacy expenses."*

Leveraging the workplace to improve health is good for employees and good for business. It's not just the direct costs of healthcare that companies have to take into consideration. The indirect costs of poor health (e.g., absenteeism, disability, presenteeism) can be two to three times higher than direct medical costs (see Figure 1).[4,5,6,7] Productivity losses related to personal and family health problems cost United States employers $1,685 per employee per year, or $225.8 billion annually.[8]

A study conducted at The Dow Chemical Company helped illustrate the total economic impact of employee health, including indirect costs. The analysis illustrated a staggering $750 million economic impact from employee health status by determining

that the indirect cost associated with "presenteeism" far exceeded the costs of absenteeism and medical treatment combined. Spurred into action by these findings, Dow established a comprehensive health strategy with the goals of improving health, reducing health risks, managing costs, and improving health-related productivity (presenteeism).[9]

The Dow Chemical Company's "comprehensive health strategy" includes worksite health promotion integrated with other health-related initiatives. In recent years, many large companies have taken a similar approach by aligning previously separate functions, such as benefit design, occupational and environmental health, occupational and non-occupational disability management, Employee Assistance Programs (EAPs), work-family programs, together with worksite health promotion initiatives and incentives, to address overall employee health and productivity. Large employers are targeting the needs of employees and designing services that will drive the actions of both employees and the health plan/provider. Collectively these combined efforts are often referred to as employee health management, Pioneer Hi-Bred International, Inc. provides another example of an integrated preventive health and wellness program as part of a business strategy supporting the health and well-being of employees, their families, and retirees through maximum engagement and capability. The program aim is to attract and retain a world-class workforce, assure quality, efficient, sustainable, and affordable healthcare, with a safety goal of zero occupational injuries and illnesses. Health plans and programs are designed to encourage prevention, disease management, and the efficient use of the healthcare system and planning for future healthcare needs. Pioneer's program is integrated with the EAP, and life management with search, referral, and counseling services including childcare, eldercare, financial and legal assistance.[10]

Employee health management includes: linking employee health efforts with the company mission, data management, benefit design, supportive environment, programming, and evaluation integrated within a cost-effective business strategy. For more information on these components, and how they apply to organizations, please refer to the Health Management Initiative Assessment in *Leading by Example: Improving the Bottom Line Through a High Performance, Less Costly Worksforce—CEOs on the Business Case for Worksite Health Promotion.*[11] There is strong evidence supporting the cost-effectiveness of investing in employee health management including worksite health promotion. Healthy employees are more productive and consume fewer corporate resources in the form of benefit payments for medical care, short- and long-term disability, and workers' compensation.

- A review of 73 published studies of worksite health promotion programs shows an average $3.50-to-$1 savings-to-cost ratios in reduced absenteeism and healthcare cost.[12]
- A meta-review of 56 published studies of worksite health promotion programs shows:[13]
  - Average 27% reduction in sick leave absenteeism,
  - Average 26% reduction in healthcare costs,
  - Average 32% reduction in workers' compensation and disability management claims costs, and
  - Average $5.81-to-$1 savings-to-cost ratio.

Potential savings from average risk reduction is $153 per person per year, compared to a savings of $350 from risk avoidance (e.g., prevention).[14,15]

Forward-thinking organizations understand the link between the health of their organizations and their employees, and many have been recognized nationally for their efforts by receiving the C. Everett Koop National Health Awards (see Table 1) the Wellness Councils of America Well Workplace Awards (see Table 1), and/or the Innovation in Prevention Award from the Secretary of Health and Human Services (see Table 1). Two elements that are critical to program success, senior leadership support and establishing a supportive environment,[16] are among the criteria upon which candidates are evaluated. In 2004, Partnership for Prevention launched the *Leading by Example* CEO-to-CEO initiative to encourage communication at the senior-most levels regarding investment in employee health management strategies. The first publication released in 2005 featured 19 CEOs, including three state governors. Partnership has recently partnered with the US Chamber of Commerce on a new edition of the publication, which will feature 15 Chamber member companies. In addition to completing a Health Management Initiative Assessment, a tool to assess, in comprehensive terms, areas in which the programs are excelling and areas for improvement, the *Leading by Example* CEOs (see Table 2) have committed to:

- Assuring that senior management is committed to health promotion as an important investment in their human capital.
- Aligning health and productivity strategies with their business' goals.
- Educating all levels of management regarding the link between employee health and productivity, and total economic value.

The aim of the *Leading by Example* initiative is to increase senior executive awareness and involvement in employee health management strategies by transforming the paradigm in which employers view employee health as an investment to be maximized, rather than as a cost to be minimized.

So where does this leave us? Rising healthcare costs are driving changes in how traditional worksite health promotion programs are structured and positioned within large organizations. In past years, worksite health promotion primarily included activity-based programs focused on individuals to improve unhealthy lifestyle choices—lack of exercise, smoking, being overweight, and so forth. More recently, research has documented that high-risk employees are also high-cost employees with higher

medical and pharmacy expenses. Research has also demonstrated that low-risk maintenance (keeping healthy employees low risk) is a necessary strategy for productivity and cost containment. Rather than reducing health benefits or shifting costs to employees, forward thinking organizations are now focusing on improving the health of their overall workforce populations through integrated health management strategies, including worksite health promotion with the support of committed leadership. The amount of evidence suporting the business case for investing in employee health management, along with the identification and recognition of leading practice programs to serve as models, demonstrates growth and investment in the field of worksite health promotion and employee health management. We need to continue to analyze and promote innovative and effective programs in order to further increase the investment in workplace health promotion. **NCMedJ**

COMMENTARY

Workplace Health Promotion:
A North Carolina Assessment of Progress

David H. Chenoweth, PhD, FAWHP

Although a couple of worksite health promotion (WHP) initiatives in the United States can be traced as far back as the late 1890s, many of America's most notable programs were conceived in the 1960s, 1970s, and 1980s. North Carolina's earliest WHP programs were conceived shortly thereafter, with most taking shape in larger cities. The rationale for such programs initially focused on promoting employees' health and boosting their morale and productivity; yet, as employers' medical care costs spurred to double-digit levels in the 1980s and 1990s, a growing percentage of WHP adopters added cost containment to their list of desired outcomes. The original WHP programs consisted primarily of a health risk appraisal questionnaire, clinical health screenings, and educational seminars, with a few sporting on-site fitness and/or recreation centers. Nowadays, it's common to see worksites sporting outdoor walking trails, weekly lunch 'n learns, health newsletters, healthy food vending options, smoke-free workstations, financial incentives, e-mail-delivered daily health tips, and internet-based personal health programs.

> *"...health insurance doesn't really do anything for our company's productivity—healthy employees do."*

It stands to reason that since most adults work for a living and that employers pick up the lion's share of the state's healthcare tab, worksites arguably provide a natural venue to promote the overall health and welfare of employees. Nonetheless, many worksites have been slow to act on this opportunity while others have enthusiastically adopted WHP. Why such a dichotomy? First and foremost, I believe the philosophy of senior management greatly influences the presence or absence of WHP. Although I've seen a handful of WHP programs evolve from a bottom-up [employee-driven] perspective, the vast majority of successful WHP efforts are driven from the top, originating from senior management's belief that employees are an organization's greatest asset. Moreover, I've discovered that successful WHP programs are usually (1) operated by competent professionals, (2) tied, to some extent, to employees' health risk profiles as well as their interests, (3) enhanced with "carrots" (e.g., financial incentives), (4) positioned as a key business strategy, and (5) subjected to regular evaluations.

Fortunately, numerous employers throughout North Carolina have taken advantage of our state's temperate climate by developing outdoor recreational facilities and walking trails for employees to use. Continued growth in our state's evolving high-tech industries, which are typically comprised of more educated and health-conscious employees, also spurs more WHP initiatives for companies to achieve greater health and productivity outcomes. Flexible work hours have also made it easier for employers to offer on-site WHP programs since employees can use this "down time" to pursue on-site wellness opportunities. Also, as more employers are becoming aware of the strong correlation between health status, on-the-job productivity, and healthcare utilization patterns, we're seeing traditional WHP efforts expand into more far-reaching and progressive health and productivity management (HPM) initiatives. I'm also impressed with the growing number and quality of organizations (commercial, educational, healthcare, and governmental) throughout our state that are assisting employers of all sizes in their quest to establish successful WHP initiatives.

Rising Healthcare Costs to Employer Are a Primary Driver

Obviously, rising costs to provide employee healthcare benefits is one of the most pervasive forces behind the growth of WHP, as risk managers grow more frustrated with managed care and other short-term bandages to this long-term problem. Yet, numerous worksites have found out that WHP, like any other

David H. Chenoweth, PhD, FAWHP, is President of Chenoweth & Associates, Inc., and Professor of Worksite Health Promotion at East Carolina University. He can be reached at chenowethd@ecu.edu or 205 Christenbury, Greenville, NC 27858. Telephone: 252-328-6431.

cost-containment strategy, must be positioned within an *integrated health management initiative* to really pay off. Thus, I expect more worksites to engage return-on-investment (ROI) metrics—ranging from break-even analysis to benefit-cost analysis—in their quest to measure the financial impact of these initiatives.

Barriers to Worksite Health Promotion Programs

On the flip side, numerous factors impede the growth of WHP programs in North Carolina. The high cost of doing business in today's costly economy keeps many companies on the sidelines. Business' unrealistic demand for a quick return doesn't bode well for WHP. Sadly, some decision-makers haven't realized that WHP is a human capital investment that yields proportionately greater results over time. Add to this list of barriers, the typical worksite culture that does little, if anything, to respect or support a person's right to practice health promotion.

Certainly, downsizing prevents many business owners from adopting any long-term human resource strategy (such as WHP), especially when they have high turn-over rates and view their workforce as "temporary." Another barrier to WHP is that most worksites spend virtually all of their healthcare budgets on purchasing traditional "defensive-minded" healthcare coverage for their employees; thus, leaving nothing to invest in more progressive health plan options (e.g., "good health rebate" and healthcare expense accounts) that motivate healthy lifestyles in addition to breeding more consumer-driven decisions among employees and covered dependents. No wonder an enlightened business owner recently stated, "health insurance doesn't really do anything for our company's productivity—*healthy employees do.*"

What does the future hold for WHP in North Carolina? Will the growth of WHP in the next 30 years reflect that of the past three decades? In these challenging economic times, how can North Carolina really be competitive in today's global economy without healthy and productive workers? From Murphy to Manteo, much of that challenge can be met head-on if today's business leaders steer their worksites with WHP and other human capital investments that will indelibly foster a healthier and more prosperous 21st Century. **NCMedJ**

Worksite Health Promotion Return on Investment

Many North Carolina employers have realized a positive return on investment (ROI) from their WHP efforts. ROI dividends have been reported by companies from the mountains to the coast. For example, WHP efforts have cut risk factors in 40% of diabetic-prone employees and shaved workers' compensation costs at Replacement, Inc.; enabled GlaxoSmithKline to earn honors as one of Working Mothers Magazine's list of "100 Best Companies to Work For" for 14 consecutive years; earned Capitol Broadcasting Company the state's first Be Active Workplace designation; yielded healthcare cost reductions at Blue Ridge Paper and Asheboro Elastics; reduced emergency room visits and held healthcare costs flat for the past two years at Syngenta Crop Protection; boosted productivity and work-life quality outcomes at SAS Institute; and enhanced employee recruitment and retention at Cisco Systems. Even smaller firms like Charlotte-based Robert Mason Company and Rivers & Associates in Greenville attribute much of their healthcare cost containment and productivity gains to WHP programs.

The Rationale for Federal Policy to Stimulate Workplace Health Promotion Programs

Michael P. O'Donnell, MBA, MPH, PhD

Health and Financial Impact of Lifestyle

Repeated analyses conclude that at least 40% of premature deaths in the United States are caused by lifestyle factors including tobacco use, sedentary lifestyle, poor nutrition, and overweight.[1] Furthermore, these lifestyle factors are responsible for at least 25% of medical costs[2] and possibly as much as 50%. This is occurring at a time when medical care costs are crippling United States employers, with an estimated $7,910 per employee in 2006.[3] These costs make it difficult for many employers to remain profitable. Being competitive in a global marketplace is more difficult for United States companies because per capita medical costs in the United States are double those of all but five other nations and because employee medical costs are highly subsidized by the governments in most other nations.[4]

Evolution of Workplace Health Promotion Programs

Employers started developing workplace health promotion programs in detectable numbers in the 1970s. Most of these programs were clustered in "high-tech" growth areas like the Silicon Valley in California and the greater New York City area and many of them were built around fitness centers. The primary motivation among employers was to attract and retain the most talented workers. Employers realized that spending several hundred dollars per employee per year to building a beautiful fitness center was a more effective recruiting tool than adding four or five dollars to an employee's weekly paycheck. Although it took several decades to produce a robust literature to confirm it, employers soon began to realize that employees with good health habits had lower medical costs and were more productive.[5] A systematic review of the literature on the financial impact of workplace health promotion confirmed this.[6] In fact, Aldana found that 88% of 32 studies showed that programs reduced medical costs, and 100% of 18 studies showed programs reduced absenteeism. He also found a mean return on investment (ROI) of $3.93 for medical cost savings and $5.07 for absenteeism savings.

In the 1980s, public health professionals realized that workplaces might be excellent environments in which to address chronic health conditions, especially heart disease, which had links to smoking, nutrition, sedentary lifestyle, overweight, and stress. Workplaces showed great promise for these programs because employees typically spend more than a third of their waking hours in the workplace, most employees remain in the same company for the year or two it takes to make a successful behavior change, and many are part of cohesive social groups at work that can provide ongoing support. Furthermore, workplace environments can be altered to provide access to healthy food and safe places to be physically active, as well as protection from second-hand smoke. Equally important, employers have financial incentives to support these programs. By the mid-1990s, almost 400 studies had been published on the health impact of workplace health promotion programs. A systematic review of this literature showed that well-designed programs produced short-term health improvements, but that very few programs examined long-term changes.[7]

> *"By 2001, 76% of United States workplaces were smoke free. By any standard, this is a remarkable achievement."*

Michael P. O'Donnell, MBA, MPH, PhD, is Editor in Chief of the *American Journal of Health Promotion*, and Director of Health and Wellness for the Cleveland Clinic. He can be reached at contact@HealthPromotionJournal.com or 1120 Chester Avenue, Suite 470, Cleveland, Ohio 44114. Telephone: 248-682-0707.

The prevalence of workplace health promotion programs has increased significantly during the past few decades.[8]

In summary, workplaces provide an excellent environment to address employee health; hundreds of well-designed programs have shown that programs do improve health, especially in the short term; and dozens of studies have shown that programs reduce medical costs and absenteeism at least enough to pay for covering the cost of the program, possibly producing savings in excess of program costs.

Limitations of Workplace Health Promotion Programs

Despite this positive picture, workplace health promotion is not without problems. The biggest problem is that at least half of working people in the United States do not have access to health promotion programs because they work in small companies or for those employers who have employees deployed in small numbers in multiple sites. Of the 4.9 million firms in the United States, only 936 (0.01%) have 10,000 or more employees, 8,674 (0.18%) have 1,000 or more employees, and 17,246 (0.35%) have 500 or more. Conversely, 99.65% of firms have less than 500 employees, and 97.9% have less than 100 employees. These firms employ 51% and 36% of the working population, respectively.[9] It is difficult for small employers to offer health promotion programs because they typically do not have a central human resources function to develop programs, and they often cannot afford to hire a full-time health promotion staff. Furthermore, their health insurance premiums are typically "community rated," which means their premiums are set by the medical utilization experience of their community. Large employers are "experience rated," which means premiums are based on the company's own medical utilization. The bottom line is that small employers who are successful in reducing medical care costs by improving the health of their employees will still pay the same medical premiums to their insurance company. This eliminates an important financial incentive to develop a health promotion program in these small companies.

Furthermore, most health promotion programs are not comprehensive. Most focus on enhancing awareness of health risks by offering health fairs, conducting health screenings, offering health risk appraisals, and providing information on the importance of a healthy lifestyle. Most employers do not offer programs that convey and enhance the personal skills employees need to make and maintain lasting behavior changes. Few employers make the effort required to create supportive environments, including providing nutritious foods in cafeterias and vending machines, offering access to safe and interesting places to exercise or be physically active, and fostering cultural workplace norms that value healthy lifestyle. The exception is smoking policies. By 2001, 76% of United States workplaces were smoke free.[10] By any standard, this is a remarkable achievement.

Emerging Federal Policy to Support Workplace Health Promotion Programs

In recognition of the success of past workplace health promotion programs, the medical care cost crises facing United States employers, the accelerating obesity epidemic, and the shortcomings of current workplace health promotion programs, Senator Tom Harkin of Iowa has authored legislation called the Healthy Workforce Act. It was introduced on May 18, 2005 as Title II, Subtitle A of the HeLP America (Healthy Lifestyle and Prevention) Act, (S.1074) and will be introduced as a free standing bill in early 2007. The main provisions of the bill are below. Note: This legislation was in revision at press time. Check www.Thomas.gov for final provisions.

- **Employer Tax Credits**
  - Provides employers a 50% tax credit for workplace health promotion programs, up to $200/employee/year, and 50% subsidy for tax exempt employers.
  - To qualify for the tax credit, programs must be offered to all employees who work at least 25 hours per week and be certified by the United States Department of Health and Human Services.
  - Programs for employers with 200 or more employees must have four basic components: programs to enhance awareness, programs to engage employees, programs to facilitate behavior change, and efforts to create supportive workplace environments. Employers with fewer than 200 employees must have three of these four major components.
  - *This tax credit is projected to provide a $734 million annual tax credit to employers, stimulate investments of $3 billion per year in workplace health promotion programs, and increase corporate and individual tax receipts in excess of its cost, making it revenue-neutral to the federal government.*

- **Directs CDC to Do the Following**
  - Contract with experts to provide employers with technical assistance on program evaluation.
  - Conduct a national study on employer health policies and programs.
  - Include questions on workplace health promotion in the Behavioral Risk Factor Surveillance System.
  - Award demonstration grants to test the effect of new workplace interventions and models.

- **Campaign to Educate Employers**
  - Directs CDC to develop a campaign to educate employers on the financial benefits of workplace health promotion programs, in conjunction with workplace health promotion organizations.
  - *This campaign is projected to cost $40,000,000 per year and is critical to stimulating employer investments in health promotion and thus, the increased tax revenues projected to result from the tax credit.*

An unpublished economic analysis of this legislation[11] concluded it is likely to be revenue-neutral or revenue-positive to the federal government. This means it will stimulate more tax receipts to the federal government than it costs in tax credits and subsidies. The bill is projected to stimulate investments of $3 billion in workplace health promotion programs through a combination of promotional campaigns, technical assistance, and employer tax credits or subsidies. The promotional campaigns and technical assistance are projected to have an annual cost of $59 million. The tax credit is projected to have a value of $734 million to employers, but it will be earned only when employers invest in programs, and received the year after the investment is made. Assuming an ROI of 1:1 in medical care cost containment, the economic stimulus from this program is projected to stimulate $985 million in increased federal income taxes, $409 million in FICA taxes, and $183 million in state income tax receipts, and these will be paid in the year prior to the tax credit. The bill will produce net gains to the federal government. With the exception of the $59 million stimulus, receipts to the federal government will be in the same line item as the tax credit and received prior to the tax credit. The savings to the federal government are caused by the increased economic stimulus of investments by employers and not dependent upon significant medical care cost reductions produced by the new health promotion programs. To break even, the health promotion programs must produce an ROI of 0.2 (20 cents on the dollar).

Conclusion

Workplace health promotion programs show great promise in reducing chronic disease prevalence and containing medical costs. Emerging federal legislation has the potential to improve the effectiveness of existing programs and make new programs available to employees in small companies. **NCMedJ**

COMMENTARY

Workplace-Focused Health Promotion Programs in the United Kingdom and Ireland

Alexandra Farrow, PhD

Workplace health promotion is a fusion of two distinct themes, and in the United Kingdom, one theme has origins in United Kingdom legislation [Health and Safety at Work Act (HSWA), 1974] that promoted safe and healthy working environments. This theme puts the onus on the employer for the organization of the physical and psychosocial work domain. The other theme is related to the behavior, attitude, and lifestyle of the worker and is entrenched in personal responsibility for individual health. In an ideal world, promotion should unify these two concepts. Workplace health promotion is integral to ordinary work practice, the working environment, and the organization[1] and is envisaged as shared between communities, employees, managers, and their environments.[2] The European Union and the Luxembourg Declaration on Workplace Health Promotion[3] further defined workplace health promotion as the combined efforts to improve the health and well being of people at work. Both the healthy workplace environment and individual lifestyle changes are necessary to achieve health promotion goals, and these should go hand-in-hand. In reality, however, individual behavioral change is too often the focus, rather than the organizational aspects of the worker's environment.[4,5]

In the United Kingdom, health promotion activities in the 1980-1990s included smoking, alcohol, and drug education; weight control; exercise; stress management; and screening. New initiatives have been focused on obesity and fitness, exemplified by the recent statement that many young men are not fit enough for recruitment into the British Armed Forces. The former Health Education Authority (HEA)[6] prioritized development and support for health promotion in the workplace. The 1990s saw the emergence of the cost-benefit culture with the development of evaluation and assessment of effectiveness. The HEA report of 1993[7] found the aims of health promotion were not necessarily incorporated within workplace culture. A subsequent publication established that workplace health initiatives were largely motivated by compliance with legislative requirements, rather than the need to promote positive health.[8]

> *"Health promotion initiatives are driven by the belief that economic advantages will be gained from a reduction in absenteeism and accidents and improvement in employee morale. Workers who are motivated and healthy are essential for competitiveness and capacity to innovate."*

Influencing Factors for Health Promotion Initiatives

Health promotion initiatives are driven by the belief that economic advantages will be gained from a reduction in absenteeism[9] and accidents and improvement in employee morale. Workers who are motivated and healthy are essential for competitiveness and capacity to innovate. Another driver is the

increased compensation culture that has had a positive impact on health promotion in that the employer has responded to the risk of litigation by encouraging healthy work environments, specifically seen with respect to passive smoking. However, it is estimated that in the United Kingdom, two million people suffer from ill health caused by work-related conditions, and 35 million days are lost annually.[10,11]

The changing patterns of work include increased part-time work, contracting out, privatization, loss of manufacturing, an increase in the service industry and the number of smaller companies, working from home, and self-employment. All of these have a negative impact on workplace health promotion, making any such initiative difficult to sustain. While there are only a few thousand occupational health doctors and nurses in the United Kingdom, these health professionals seem to overemphasize health problems with reference to worker lifestyle habits and behaviors and to focus on management and personnel requirements, rather than exposures in the workplace, prevention, and rehabilitation.[12]

Even when open to all, engagement in health promotion is limited, with those most likely to participate being healthy, white-collar, salaried staff with relatively high levels of education.[13-15] Barriers to uptake also include the fear that involvement is not confidential. Low participation rates are the limiting factor for any potential public health impact of worksite-based interventions. Therefore evaluation of programs on employee health outcomes, employee families/dependents, and on communities may be difficult.[16]

Provision of workplace fitness programs within health promotion schemes may fail to reduce absenteeism or to improve the health of the workforce. This may be due to the same user characteristics that also fail in public sector leisure activities.[17] United Kingdom employers, unlike those in the United States, rarely contribute to private insurance schemes and, therefore, have less incentive to become involved in health promotion. Nevertheless, large organizations with good workforce retention have much to gain by a holistic approach to health promotion programs. Targets for healthier work environments and lifestyle changes could influence better health over an employees' working life. The infrastructure of large organizations should also facilitate monitoring of take-up and measurement of improvement in health outcomes over time. The National Health Service, the largest employer in Europe, has historically provided long-term employment for a multi-professional workforce, but it has no well-developed strategy for health promotion.

Characteristics

The size of an organization probably has the biggest influence on health promotion activities. Due to economic changes, more people are employed in small- and medium-sized enterprises where there is often no workplace access to occupational health support.[18] Despite campaigns, such as "Good Health is Good Business,"[19] many employers remain unaware of long-term risks for workplace health and the need to take a proactive approach to prevention. The European Network for Workplace Health Promotion (ENWHP) observed that targeting large organizations with suitable infrastructure was more likely to be successful. A 1992 Health Education Authority survey of 1,344 workplaces found that larger workplaces addressed heart health, weight control, exercise, and fitness, with 40% undertaking at least one health promotion-related activity in the previous year. Health promotion increased with workplace size and good infrastructure; the size of an organization is therefore a key determinant.

Trade union representation, occupational health services, and workplace health promotion are concentrated in the larger United Kingdom public sector organizations.[7,14,20] The role of trade unions has mainly influenced the reduction of hazards at work, better working conditions, job conditions, working hours, wages, and job contracts. In 1989 the Labor Research Department study of 500 trade union representatives found common workplace health promotion activities were first aid medical treatment, inspection of hazards, and pre-employment medical screening. Activities that union representatives wanted were stress management, breast screening, and screening for hypertension. Smoking-related health promotion activity was found in 41% where a union was present versus 28% where a union was absent. Workplaces with no health promotion activity were small or medium sized, in the private sector, British owned, and mainly in distribution and catering businesses.

An international feasibility study has demonstrated the importance of partnerships between trade unions, health promoters, and related professionals in efforts to promote employee health. This is of particular importance in view of rapid globalization and the potential for worker health and safety to be overlooked.[21] Trade unions are involved in workplace health promotion partnerships and networks that include a broad range of industry, Chambers of Commerce, National Health Service (NHS), Health and Safety Executive (HSE), local government, education, legal, and independent consultants.

While small organizations may have fewer health promotion activities, a recent survey, commissioned by the Federation of Small Businesses (FSB), reported that the average number of days small businesses lost to absence per employee was 1.8 days (compared to the average of 8.4 days for businesses of all sizes). Employees of small businesses are therefore around six times less likely to take sick days compared to public-sector workers.[22] The national health and safety chairman of the FSB suggests that government should offer incentives to small businesses to provide access to occupational healthcare and health promotion initiatives. Smaller firms should be required to pay less in employers' liability insurance in return for good workplace health and safety initiatives.

Influence of Occupational Health on Health Promotion

The Health and Safety Commission published two reports: *Revitalising Health and Safety Program*[23] and *Securing Health Together*,[24] These presented a long-term occupational health strategy for England, Scotland, and Wales that by 2010, aimed to reduce ill health caused by work activity and accidents, the number of working days lost from work-related injury and ill health by 30% and the incidence rate of fatal and major injury accidents by 10%. The Health and Safety Executive commissioned survey,[25] found that only one-in-seven workers in the United Kingdom had comprehensive occupational health support. The *Securing Health Together* strategy required base-line information on current provision of occupational health, and this was provided by Pilkington et al[26] in a survey of 4,930 organizations. Over half of the companies reported taking steps to improve the general health of employees. The most frequently provided services were health promotion campaigns and information on healthy lifestyles. Least popular services were private healthcare schemes, access to leisure facilities, and well-person health checks. Where occupational health support was defined to include hazard identification, risk management, and provision of information, then approximately 44% of participating companies fulfilled this definition, equivalent to 15% of all United Kingdom companies after adjustment for company size and sector. A more rigorous definition of occupational health included the three parameters above, (i.e., hazard identification, risk management, and provision of information) plus modifying work activities, occupational health training, measuring workplace hazards, and monitoring trends in health. This definition resulted in an additional 3% of companies fulfilling the wider definition of occupational health support. Again more large companies met the criteria than small companies. Occupational health was found to take second place within health and safety, with no distinct identity and often no budget allocation. Formal evaluation of costs and benefits of occupational health support was limited and most likely in larger companies. Commitment to do more to acquire occupational health support was limited by available resources, particularly for smaller companies across all regions and sectors. There was a recognized lack of knowledge about how to deal with health issues, particularly in micro and small companies. Health and Safety representatives and managers were central to increasing awareness of occupational health issues within smaller companies.

Workplace Health Promotion at a European Level

The Health Promotion Unit is represented on the European Network for Workplace Health Promotion (ENWHP) as an informal network of national occupational health and safety institutes, public health, health promotion, and statutory social insurance institutions. It aims through the joint efforts of all its members and partners to contribute to improving workplace health and well-being and reducing the impact of work-related ill health on the European workforce. The Network was formally established in 1996, and since this time, it has been at the leading edge of developments in European workplace health promotion. Over the past three years, the ENWHP has been working on the development of national forums for workplace health promotion, in line with the new health strategy of the European Union, and linking these infrastructures on a European level. Encouraging this, the fourth European Conference on Promoting Workplace Health was held in Dublin in June 2006. The conference was held in the context of the Irish European Union presidency.

National Strategies within the United Kingdom

There are different approaches to health promotion in the four countries of the United Kingdom: England, Wales, Scotland, and Northern Ireland. Within all four home countries, Scotland has been well ahead with a coordinated approach to improving the health of the working population through a developed network, *Scotland Health at Work*.

Health promotion policy in **England** was shared between the Department of Health (DoH) and the Health Education Authority (HEA). The latter's terms of reference were limited, and there was constant disagreement about the extent to which HEA could operate independently. This was illustrated in relation to smoking, where the HEA took a line that was not in agreement with the more voluntary approach favored by Government. The HEA was subsequently split in two, with a research-based arm, the Health Development Agency (HDA), and a more overtly health-promoting arm, Health Promotion England. In 2001, the health-promoting arm was 'absorbed' into the DoH and in 2005, the research arm was incorporated into the National Institute of Health and Clinical Excellence. Legislation on smoking in workplaces and public places is to be introduced in 2007, months and years after other countries within the United Kingdom. The London Workplace Health Network includes members from London Boroughs, the National Health Service (NHS), the Health and Safety Executive, the Office of Deputy Prime Minister and consultancies. The London Regeneration Network focuses on 390 voluntary organizations throughout London, particularly companies with fewer than five employees and encourages them to engage in workplace health promotion.

In **Wales**, a strategy document for *Health at Work*, was published in 1996.[27] New initiatives included the appointment of a National Workplace Health Promotion Coordinator, the examination of the needs of small-to-medium enterprises, and the continued implementation of cardiovascular strategies in the workplace. This strategy built on the significant work developed by Heartbeat Wales in the mid-1980s. Each of these initiatives is expected to promote the development of workplace health promotion. At the same time a formal network of workplaces, stakeholders, and assessors involving an accreditation scheme for organizations that promote health at work has been set up. The Wales Counselling at Work Network has focussed on psychological issues at work while Heartbeat Wales made a major contribution with programs for cardiac health improvement. At the local Board level, workplace coordinators have been appointed with responsibility for the development of workplace health promotion plans and the initiation of pilot projects.

Scotland has been well ahead with a coordinated approach to improving the health of the working population through a developed network, *Scotland Health at Work*. Many organizations in Scotland have addressed health promotion in the workplace by developing and implementing health policies, such as those for smoking, alcohol, and food, forming health circles to identify and to take action on workplace health issues, promoting physical activity through membership of sports facilities, providing bicycle racks, encouraging employees to walk during lunch time, providing access to appropriate screening initiatives, and registering with the *Scotland Health at Work* award scheme. Another aspect is the formation of networks for the different geographical areas. The focus of these groups is to create mechanisms to help small and medium-sized enterprises address worksite and employee health promotion goals.

Northern Ireland, despite having an economy dominated by small businesses, has a well-established workplace health promotion program led by the Health Promotion Agency, known as the *Work Well Program*. Anticipated benefits include reduction in illness-related absenteeism, fewer working days lost, and, therefore, a long-term decline in the sickness rate; increased motivation among staff, and improvements in the working atmosphere in the company, leading to more flexibility, better communications, and readiness to cooperate; a measurable increase in the quality of products and services, more innovation and creativity, and a rise in productivity and improvement of the public image of the company. The *Work Well: Healthy Workplace Guide* is the focal point of the Work Well initiative and the starting point for all businesses interested in adopting a healthy workplace strategy. It is aimed at employers, health and safety workers, human resources staff, occupational health staff, and anyone else working in the field of workplace health.

Workplace health policy in the **Republic of Ireland** is distinctive from that in Northern Ireland, but there are now increasing numbers of cross-border initiatives. The structure emphasizes concepts of self-regulation and monitoring, rather than policing.[28] The *Happy Heart at Work* (HHAW) program, sponsored by the Irish Heart Foundation,[29] and in existence since 1992, is a national program designed to suit the Irish context. It aimed to promote a healthy lifestyle through specific modular materials. Evaluation of this program was commissioned with a survey of 785 registered sites. An initial level of interest in the HHAW program was expressed by 40%. Active organizations were less likely to be Irish owned and more likely to operate in shifts or to have an occupational physician among the staff. The program was purported to improve employees' lifestyle habits and morale and the company's public image. The drawbacks were its relatively low profile, even in actively participating organizations, and the fact that it was not seen to be independently sustainable without intensive and ongoing support.[30] Manufacturing organizations employing more than 200 workers were most likely to take part in HHAW. The Irish Department of Health and Children reported low levels of awareness for health promotion programs among workers with the main obstacle being lack of management commitment.[31]

Recent National Guidance

The English public health strategy was published in 2004.[32] Actions that employers and government can take to promote work and health were addressed, but focused on the NHS as the employer, rather than the English workforce as a whole. Specific sums were allocated to implement the strategy in relation to smoking, exercise, nutrition, sexual health, alcohol, and mental health, but these were largely diverted to cover overspending in other areas. In November 2005, the progress of the program was addressed. The Health and Safety Commission considered whether the Health and Safety at Work Act of 1974 should be amended in response to a changing world of work, and in particular, to ensure the same protection is provided to all workers regardless of their employment status.

In 2006, the Department of Health requested the National Institute for Health and Clinical Excellence to develop public health intervention guidance on workplace health promotion with reference to smoking and what works in motivating and changing employees' health behavior. The guidance will provide recommendations for good practice based on the best available evidence of effectiveness, including cost-effectiveness.

In conclusion, the situation in the United Kingdom is mixed, but the message that appears with respect to workplace health promotion is that it is up and running in large companies, rather than in smaller ones, and in international companies, rather than home companies, and is more likely to flourish where occupational health professionals are present and where there is good management commitment. **NCMedJ**

Hospital Quality and Patient Safety

Notable News from The North Carolina Center for Hospital Quality and Patient Safety

North Carolina Center *for* Hospital Quality and Patient Safety

Hospital Quality Performance Report

The first North Carolina hospital report card has been developed by the North Carolina Center for Hospital Quality and Patient Safety and will be available on a public Web site. This transparent, hospital-specific on-line resource for hospital quality was designed to provide understandable information to patients so they can learn more about inpatient treatment for common causes of hospitalization and can participate in decisions that will impact their health. Furthermore, studies have shown that comparative hospital quality reports intensify hospital quality improvement projects, improve organizational culture toward quality and patient safety, and positively influence hospital operations by placing higher priority on quality performance.[1,2,3] Therefore, in addition to providing standardized and reliable quality information to consumers, the report's objective is to provide performance benchmarks that will assist and stimulate hospitals in continuously improving their quality of care.

The Quality Center initiated the NC Performance Reporting Workgroup to review inpatient clinical measures and to develop recommendations for measurement inclusion and report design. The Workgroup is a multidisciplinary team consisting of physicians, nurses, and executives representing hospitals, health systems, insurance industry, the Carolinas Center for Medical Excellence (CCME), NC Medical Society, and NC Department of Health and Human Services. The principles set by the group were to include measures that were actionable, standardized, well-defined, available, and would not add burden to hospital data collection efforts. In September 2006, the Workgroup's recommendations for the NC Hospital Quality Performance Report were approved by the Quality Center's Board and endorsed by the NC Hospital Association Board of Trustees.

The NC Hospital Quality Performance Report, to be available at www.nchospitalquality.org in January 2007, will display 21 process measure scores currently collected and publicly reported by the Centers for Medicare & Medicaid Services (CMS) (see Table1). The reporting of these measures is voluntary for hospitals; however, they are linked to Medicare payment via the Reporting Hospital Quality Data for the Annual Payment Update initiative. These evidence-based, process-of-care measures are treatment recommendations proven to give the best results to most adults with a diagnosis of heart attack, heart failure, pneumonia, or those admitted for surgery. The scores for each individual measure reflect how often recommended treatment was given for an eligible patient—which only includes patients whose history and condition indicate the treatment is appropriate. The Web site will include descriptions of all the measures, and there will be clear links to other Web sites that offer detailed information about each health condition, the recommended treatments, and the measurement methodology.

The NC Hospital Quality Performance Report will display the scores of the 21 measures and graphically display an overall condition score. The overall condition score is a composite score calculated by dividing the sum of numerators by the sum of denominators from a condition's measures. Benchmarks in the report will include the state mean, state 90th percentile and the national mean per measure. For example, the North Carolina mean was equal to or greater than the national mean on 19 of 21 measures during second quarter 2005 through first quarter 2006. The report will also link consumers to the NC Quality Center Web site and other healthcare improvement organizations to inform patients and providers of the national and statewide quality improvement initiatives currently in place in many North Carolina hospitals.

The NC Quality Center has partnered with CCME to provide enhancements in Summer 2007 to the Web site, such as (1) reporting data more current than available through Hospital Compare, (2) providing hospital- and state-level trend graphs, and (3) including four "optimal care" composite scores per condition. The optimal care measures, also known as "appropriateness of care" measures, use the "all or none" methodology to determine

Hospital—continued on page 467

Table 1.
CMS Process Measures by Condition

Condition	Measure	NC Mean*
Heart Attack	ACE Inhibitor or ARB for Left Ventricular Systolic Dysfunction	78%
	Aspirin at Arrival	93%
	Aspirin at Discharge	89%
	Beta Blocker at Arrival	88%
	Beta Blocker at Discharge	89%
	PCI Within 120 Minutes Of Arrival	66%
	Smoking Cessation Advice/Counseling	85%
	Thrombolytic Medication Within 30 Minutes Of Arrival	31%
Heart Failure	ACE Inhibitor or ARB for Left Ventricular Systolic Dysfunction	81%
	Assessment of Left Ventricular Function (LVF)	86%
	Discharge Instructions	63%
	Smoking Cessation Advice/Counseling	86%
Pneumonia	Assessed and Given Pneumococcal Vaccination	70%
	Initial Antibiotic(s) within 4 Hours After Arrival	79%
	Oxygenation Assessment	100%
	Assessed and Given Influenza Vaccination	72%
	Smoking Cessation Advice/Counseling	82%
	Most Appropriate Initial Antibiotic(s)	81%
	Blood Culture Prior to First Antibiotic	90%
Surgery	Preventative Antibiotic(s) One Hour Before Incision	81%
	Antibiotic(s) are Stopped Within 24 hours After Surgery	75%

if a patient received all of the recommended treatment for which they were eligible.[4] This methodology supports the notion that achieving a desired clinical outcome requires the completion of a full set of tasks and results in more stringent scoring, thus raising the bar for performance and increasing the ability to improve outcomes.[5] Furthermore, the optimal care measures put an emphasis on system-wide improvements in areas such as communication and cooperation and they offer more sensitive scales for assessing improvement.

More measures will be added to the NC Hospital Quality Performance Report. These will include measures that will most likely be aligned with the Hospital Quality Alliance's reporting requirements and have National Quality Forum endorsement. For example, future measures may include patient perceptions (i.e., data from the Hospital Consumer Assessment of Healthcare Providers and Systems survey), 30-day mortality rates for heart attack and heart failure, and expanded information on surgical care that include steps taken to prevent venous thromboembolism and surgical site infections.

Worksite Wellness Interest Survey of NC DHHS Employees

Background: Employers increasingly recognize the benefits of investing in workplace wellness programs to control medical plan costs and reduce absenteeism among their employees. Wellness programs have also been shown to increase productivity and improve employee morale and retention. Wellness programs can bring as much as a four-fold return on each dollar invested in wellness benefits.[1] Long-term evaluation of the impact of a corporate wellness program showed a substantial reduction in medical costs for employees with most benefits occurring after three to four years.[2]

Since 2000, the North Carolina State Health Plan has seen a large decline in the number of healthy state employees and school personnel younger than age 65. Healthy members of the NC State Health Plan are defined as those without medical claims for chronic diseases, acute illness or injury, or catastrophic illness or injury in the current year. Among approximately 408,000 Plan members, healthy members decreased from 64% in 2000 to 58% in 2003. By 2008, if present trends continue, only 51% of state employees will be healthy. Every 1% decline in the number of healthy members results in an additional cost of $68 million in healthcare costs. This decline in healthy employees is largely attributable to an increase in the prevalence of chronic disease conditions. Approximately 70 cents of every healthcare dollar was spent to treat members with one or more chronic diseases. In 2003, the average cost for a member without a chronic disease or major illness or injury was $800. Members with a chronic disease averaged more than nine times that amount ($7,400) per year in healthcare costs.[3]

Two thirds of chronic diseases can be attributed to three major lifestyle risk factors.[4] Low levels of physical activity, poor diet, and exposure to tobacco increase an individual's risk of developing a chronic disease and make the management of existing chronic conditions more difficult. Support in the workplace can greatly influence and sustain employees in changing their health behaviors. The NC Department of Health and Human Services (NC DHHS), with support from the NC State Health Plan, established the DHHS Wellness Initiative in 2004 in an effort to contain rising employee healthcare costs by reducing the major chronic disease risk factors among NC DHHS employees. The initiative focused on establishing wellness committees in each agency and facility within NC DHHS. The goal was to promote and support employee health and wellness primarily through changes to workplace policies and environments that increase opportunities for physical activity, improve access to healthier foods, reduce tobacco use, and help employees manage stress. This initiative is one component of the larger multi-faceted NC Health*Smart* healthy living initiative launched in 2005 by the NC State Health Plan to provide resources and support to keep healthy members healthy and better manage the care of members with chronic diseases.

Survey Description: Baseline information was collected via two surveys to assist NC DHHS agency committees in developing effective wellness plans and to guide a new 38-member NC DHHS Wellness Council in developing wellness policy recommendations for the Department. In September of 2005, wellness contacts in each NC DHHS agency and facility completed a survey of existing support for wellness at NC DHHS worksites. This article reports findings of a second survey launched in October of 2005 to assess the wellness interests of the 18,768 employees in the Department. The employee survey was a 14-item, Web-based questionnaire with primarily multiple choice answer options. Several questions provided employees opportunities for open-ended responses. Respondents were required to identify their agency or facility on the survey.

RTN—continued on page 469

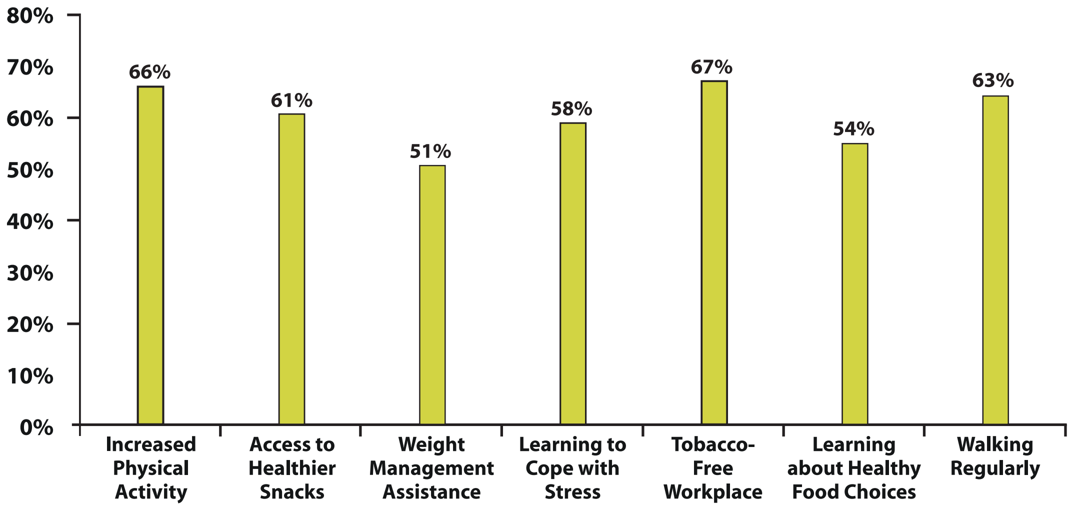
Survey Deployment: The Employee Wellness Interest survey was deployed through an online survey to approximately 10,000 employees with NC DHHS E-mail addresses. Each E-mail address could respond only once to the survey. Hard copies of the survey were provided to wellness contacts at the state facilities to reach their 8,000+ employees without a work E-mail address. The facility wellness contacts distributed the surveys, then collected and mailed them to the Wellness Director in Raleigh. The survey was deployed October 24, 2005 and closed January 9, 2006. E-mail messages were sent to remind employees to complete the on-line survey.

Response: A total of 5,821 employees (31%) responded to the survey. This included 4,256 E-mail responses (43% response rate) and 1,565 hard copy responses (20% response rate) from facility employees.

Analysis: On-line survey responses and scanned hard copy survey data were combined. Responses to open-ended questions were categorized using qualitative data analysis software. No significant differences were observed between the responses to on-line and hard copy surveys.

Results: More than 60% of respondents identified the following as major areas of wellness interest: opportunities in the workplace for increased physical activity and walking, access to healthier snacks, and working in a tobacco-free workplace (see Figure 1). Other workplace wellness interests identified by at least half of survey respondents included weight management, learning to cope with stress, and learning about healthy food choices.

Figure 1.
NC DHHS Employee Wellness Interest Survey Results: Major Areas of Wellness Interest Identified



Results of multiple choice questions shown in Figure 1 were confirmed by open-ended responses to a survey question asking for the single change in the workplace that would have the greatest impact on the employee's health and wellness. The most frequent response was a place to exercise at work. The second and third most frequent responses to that question were reduced work-related stress and improved access to healthier food options at work. Other frequent responses related to issues that were not provided as multiple choice options on the survey. These included employee health concerns regarding air quality, environmental health (mold, dust, lighting, and cleanliness), and ergonomic issues.

RTN—continued on page 470

RTN—continued from page 469

The survey attempted to assess factors affecting employee participation in wellness activities. Time to participate at work was most frequently identified by NC DHHS employees as the single most critical factor affecting their participation in wellness activities at work. Other major factors affecting participation included incentives for participation and authorization to use flex-time to participate. A majority of respondents (53%) identified the lunch break as the preferred time to participate in wellness activities and 30 minutes was the length of time most frequently preferred for wellness activities.

Each agency and facility wellness committee received a summary of their own employee survey responses. The results provided valuable information needed by the committees to develop agency wellness plans geared to the specific interests and needs of employees at their workplace. Information from a summary of all survey responses was used by the NC DHHS Wellness Council to develop broader policy and environmental change recommendations for the Department to improve support for employee wellness programs. A follow up survey to assess employee participation in wellness activities and future wellness interests was disseminated to NC DHHS employees in October of 2006.

Readers' Forum

To The Editor:

It is incredible that we should be addressing the problems of overweight and obesity and be concerned that they are now of epidemic proportion. The July/August issue of the Journal has done a major service in bringing to the attention of all concerned just how pervasive the problem is. As noted by many of the authors, a "cure" for this epidemic will not be easy. Yet, one must be obtained. The impact of each overweight person on the healthcare system, both in terms of their own health and the cost in dollars needed to provide their care, cannot be ignored.

Thank you for providing this most timely issue. And thank you, too for honoring one of North Carolina's most effective and passionate leaders in the fight to provide better health, better resources, and better information for the care of our children. Tom Vitaglione is truly a gift to us all.

The staff of the *North Carolina Medical Journal* would like to express our immense gratitude for the professional design services Angie Dickinson Design has shared with us since 2003.

Besides her artistic ability, technical skills, and professional manner, Ms. Dickinson courteously addresses any print need we have, large or small. She works hard to capture and present our message our way.

We feel fortunate to have her firm working with us, and we attribute much of our success to her dedication, flexibility, and sophisticated understanding of printed material. Thanks to Angie Dickinson Design, we are able to produce high quality Journals and reports that we proudly send to more than 30,000 people every other month.

SOMETIMES LESS IS MORE.

Especially when it comes to surgery. Robotic procedures mean less pain, less scarring, and less recovery time.

Surgery doesn't always have to mean putting your whole life on hold. With the da Vinci® Surgical System, you should have less pain and fewer side effects following your procedure–which means that you can get home, and back to your family and your life, a whole lot faster.

The da Vinci is an advanced surgical tool that allows our skilled physicians to perform complex, delicate procedures with unmatched precision through very small incisions–a monumental difference from standard open surgeries. Cardiac surgeons at Pitt County Memorial Hospital in Greenville, in conjunction with the Brody School of Medicine at East Carolina University, are leaders in da Vinci surgery, responsible for this country's first robot-assisted mitral valve repair in 2000. Since then, the hospital and university have trained more than 1,000 surgeons from around the globe to use the da Vinci robot. Today, we are expanding our advanced robotics program to include general surgery, gynecology and urology, particularly for prostate cancer.

Surgery is always a major step. But with da Vinci, you could find yourself stepping more quickly back into your own life, and all the things that truly matter.

Is the da Vinci right for you? To learn more about this minimally invasive surgical option, visit www.roboticsurgery.uhseast.com.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

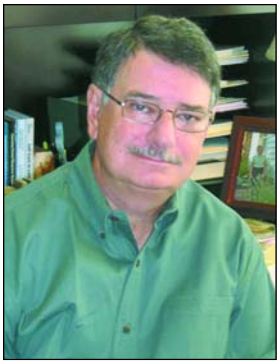
Special Letter from the Publishers of the *North Carolina Medical Journal*

To the readers of the *North Carolina Medical Journal*:



Gordon H. DeFriese, PhD

This issue marks a significant transition in the leadership of the *North Carolina Medical Journal*. Gordon H. DeFriese, PhD, served as the Editor-in-Chief of the *NCMJ* since 2002. Gordon brought the *Journal* under publication of the North Carolina Institute of Medicine (NC IOM) during a time when its future was uncertain. His ambition was to expand and enhance the *Journal* to meet the need for health policy discussions in the state of North Carolina. Through Gordon's passionate dedication, he gathered financial and editorial support for the *Journal*, which became the state's leading avenue for disseminating health information and health policy solutions.

Under Gordon's leadership, the *Journal* highlighted timely and critical health policy issues such as the epidemic of childhood obesity, the need for direct care workers in long-term care, medical malpractice, quality of health care, and access to dental care. Gordon's nurturing of the *Journal* honored its long history, dating back to 1849, by strengthening its value to physicians and giving more exposure to important health policy issues beyond the physician community. Today, the *Journal* is distributed to more than 30,000 readers across the state and the nation including physicians, nurses, dentists, pharmacists, physician assistants, hospital and health care facilities administrators and leaders, other health professionals, health policy makers, and business and community leaders.

The *Journal's* success is a testament to Gordon's vision, energy, and service to improving the health of North Carolina's citizens. Although Gordon's work will continue in various other roles, he has retired from his position as Editor-in-Chief of the *North Carolina Medical Journal*. His tireless work and commitment strengthened the *Journal's* foundation so that its impact on the state will be ongoing.

Beginning with this issue, we are excited that Thomas C. Ricketts III, PhD, MPH, has agreed to serve as the Editor-in-Chief and carry on Gordon's valuable work. Tom, a professor in the School of Public Health and Deputy Director of Policy Analysis at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill, has also dedicated his career to improving the health of North Carolinians, as well as underserved populations throughout the country. He is an expert on health care topics including access, quality of care, rural health, workforce, and technology. His work is well respected by health care leaders throughout the nation and world, enabling him to bring national and international expertise to North Carolina issues. Tom's previous experience as editor of two national health journals provides new skills and perspectives that will allow him to place his own personal touch on the *Journal*.

With our sincerest thanks and gratitude for Gordon's work and a very warm welcome in anticipation of the direction of the *Journal* under Tom's leadership,

Pam Silberman, JD, DrPH

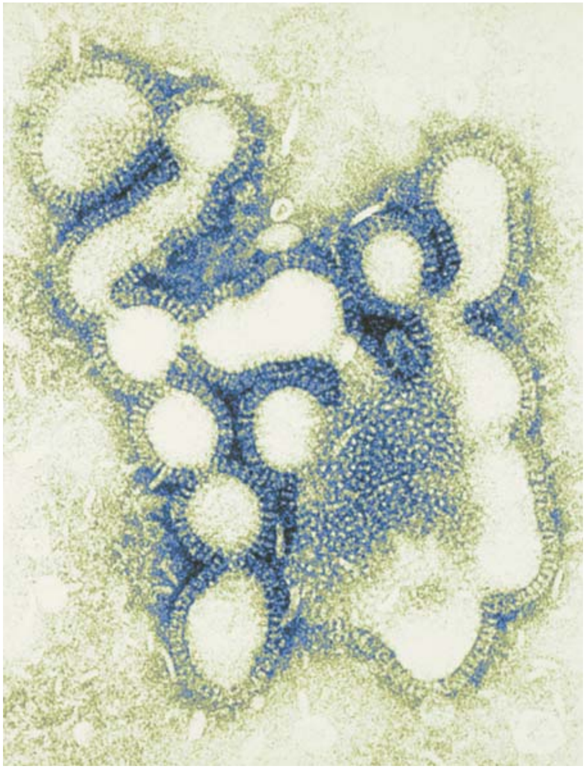
Pandemic Influenza Preparedness in North Carolina

COMMENTARIES

DEPARTMENTS



About the Cover:
Influenza Virus at 295,000 Magnification

Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

Kathleen Colville, MSW, MPH
Public Health Preparedness Coordinator, Alamance County Health Department

Kathleen Colville, MSW, MPH

Public health leaders are specifically charged with promoting and protecting the overall health and well-being of the population during emergencies. When an influenza pandemic arrives, it will be up to the state and local public health agencies and partner organizations to coordinate a public health response to help reduce morbidity, mortality, and social disruption. Local health departments have hired preparedness and response coordinators to prepare for natural or manmade disasters.

As a Public Health Preparedness Coordinator, Kathleen Colville, MSW, MPH, has taken the lead in coordinating the development of Alamance County's pandemic influenza plan. She convenes a community steering committee, provides training to community groups, health care providers, and health department staff, negotiates agreements with other agencies regarding roles and responsibilities during an influenza pandemic, and provides regional leadership through planning drills and exercises. These efforts will better enable Alamance County and North Carolina to respond to an influenza pandemic event when it occurs.

Ms. Colville has distinguished herself by working particularly on preparedness for marginalized populations and has been awarded several grants to reach out to low-income communities to address the unique challenges faced by these communities in the wake of a disaster. She has increased her own skills by volunteering in Florida after the devastating hurricanes in that state and by learning how to use geographic information systems to better survey and assess needs following catastrophic events. She also has learned to apply this technology to typical public health activities, such as community assessment. Dorothy Cilenti, Health Director at the Alamance County Health Department, noted that, "Kathy is a valued asset to the entire community in Alamance County, and as a result of her dedication and professionalism, we are better able to quickly respond to widespread disease or disaster."

Kathleen Colville came to her position in August 2005 after completing Master degrees in Social Work and Public Health at the University of North Carolina at Chapel Hill. She was named a North Carolina Schweitzer Fellow for the 2004-05 academic year for her service project conducting a community needs assessment in response to the elevated number of domestic violence homicides in Alamance County.

Marcy Green, Health Education Supervisor at the Alamance County Health Department, had these comments about Ms.Colville,"I think the number one quality of a Preparedness Coordinator is the ability to work well with different types of people as well as the ability to form strong relationships with community agencies. Kathy's personality and competence have been vital to building a strong relationship with our emergency management partners." Chip Ferguson, Director of Emergency Management at the Burlington Police Department, reiterated this idea. He described Ms. Coleville as a true asset to the police department because of her tireless work to bring public health into the realm of public safety, a collaboration that previously did not exist. Ms. Green concluded, "If Alamance County were to face a small or large disaster, I feel much better knowing that we have Kathy has a leader in this area."

For her efforts and accomplishments in preparing Alamance County for an influenza pandemic, the Editors of the *North Carolina Medical Journal* are pleased to recognize Kathleen Colville, and all preparedness and response coordinators around the state, for their contributions to the health and safety of all North Carolinians.

YOU DIDN'T GO THROUGH DECADES OF TRAINING AND 70-HOUR WEEKS TO TRUST YOUR FUTURE TO JUST ANY BANKER.

The SunTrust Medical Specialty Group has nearly two decades of experience addressing the unique and complex financial needs of physicians and their practices. We have the expertise to see you through anything from personal investments[1], to estate planning, to providing credit solutions as your practice grows. After all, you didn't go to medical school to be a banker. At SunTrust, your specialty is our specialty.

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

Relationship between Nephrologist Care and Progression of Chronic Kidney Disease

Lori A. Orlando, MD, MHS; William F. Owen, MD; and David B. Matchar, MD

Abstract

Background: *Since chronic kidney disease (CKD) affects 11% of the United States population, and its incidence is rising, experts recommend early referral to nephrologists in the hope that it may delay the onset of end-stage disease and improve survival. However, limitations in the capacity of currently practicing nephrologists may prevent widespread early referral.*

Objective: *To examine the relationship between disease progression and timing of nephrology referral.*

Study Design and Data Collection: *We retrospectively identified 1,553 veterans at the Durham, North Carolina VA hospital between January 1998 and December 1999 who had CKD, defined as two outpatient serum creatinines $\geq$ 1.4 mg/dL at least three months apart. Our endpoint was a composite of progression to the next CKD stage or death. We compared the time to the composite endpoint for each CKD stage and for early CKD (stages 1-3) to advanced CKD (stages 4 and 5) using a Cox proportional hazards model for two groups: those with primary care only (PCP-only) and those with primary and nephrology care (nephrology).*

Results: *Ninety-two percent had hypertension, 52% diabetes, 49% coronary artery disease, and 89% proteinuria. Angiotensin-converting enzyme inhibitors and anti-lipid medications were used by 52% and 39%, respectively. The median number of days spent in each CKD stage and the proportion of each groups reaching the composite endpoint are—stage 1: 1,149 days, 68% of the PCP-only group and 73% of the nephrology group; stage 2: 1,206 days, 60% and 65%; stage 3: 1,158 days, 69% and 63%; and stage 4: 794 days, 86% and 72%. Adjusted survival curves for the composite endpoint were similar between the two groups for CKD stages 1 (HR 1.08 for nephrology versus PCP-only) and 2 (HR 1.20); however for CKD stages 3 (HR 0.80, $p < 0.05$) and 4 (HR 0.75, $p < 0.05$), the nephrology group gained 316, 215, and 120 more days of progression-free survival, respectively.*

Limitations: *The major limitation is difficulty accounting for unmeasured bias in specialty referrals. We were unable to analyze stage 5-to-dialysis due to the small number of individuals with the outcome.*

Conclusion: *Our data suggest that an appropriate time for nephrology comanagement of patients with CKD may be stage 3; however, prospective studies are needed to clarify the role and timing of nephrology referral.*

Keywords: *chronic kidney disease, provider, kidney disease*

Background

Chronic kidney disease (CKD) affects 11% of the United States population, about 20 million people.[1] Improving the management of CKD has been shown to increase survival in those with CKD, delay the development of end-stage renal disease (ESRD), and improve morbidity and mortality once ESRD develops.[2] Slowing the rate of progression and delaying ESRD are now more important than ever as the incidence of CKD and ESRD is increasing, in large part due to the increasing prevalence of CKD risk factors such as the aging of the population, hypertension, and diabetes mellitus.[3] This is true at both the national and state level. For example, in 2003 the point prevalence of ESRD in North Carolina was 14,635 with an incidence of 3,207—this makes us one of the top ten states for prevalence and incidence. Even more concerning, the prevalence increased 280% in the ten years between 1993 and 2003, slightly higher than the national average of 250%.[4]

ESRD accounts for $20 billion per year in Medicare expenditures. With the increase in its incidence, expenditures are

---

Lori A. Orlando, MD, MHS, is Assistant Professor at the Center for Clinical Health Policy at Duke University and the Durham VA Medical Center. Dr. Orlando can be reached at lori.orlando@duke.edu or 2200 W. Main Street, Tower Suite 220, Durham, NC 27705.

William F. Owen, MD, is Chancellor of the Health Sciences Center at the University of Tennessee in Memphis, TN.

David B. Matchar, MD, is a Professor at the Center for Clinical Health Policy at Duke University and the Durham VA, Durham, NC.

projected to reach $42 billion per year by 2010.[5] Given concerns over the rising impact of CKD on the health of the general population and increasing expenditures for dialysis care, researchers have begun to investigate the impact of care in the pre-ESRD period on ESRD outcomes. Several of these studies have suggested that nephrology referral early in the pre-ESRD course may improve the morbidity and mortality on dialysis.[6] These studies, while methodologically limited by dichotomizing and varying the definition of early referral (from one month to one year predialysis), and the use of dialysis populations (not generalizable to predialysis populations), provided preliminary evidence in favor of early referral to sub-specialists.

Based upon these preliminary studies, experts have recommended early referral to nephrologists for all CKD patients. However, widespread implementation has been limited by the disparity between the capacity of currently practicing nephrologists and the number of CKD patients.[7] Since this disparity exists and the preliminary studies were methodologically limited, researchers have begun to investigate in more detail the impact and timing of nephrology care on renal-related outcomes.

In view of the conundrum between an inadequate number of subspecialists to deliver care and uncertainty about when their intervention may be of the greatest benefit, we examined the relationship between the severity of CKD, the presence of subspecialty care, and progression of CKD in a pre-ESRD population.

Methods

We performed a retrospective observational database study of 1,553 veterans with CKD at the Durham, North Carolina Veterans Administration Hospital (VA). Our primary objective was to identify whether care provided by a nephrologist increases the time spent in any chronic kidney disease stage (ie, slows progression). The Durham VA Internal Review Board (IRB) approved this study.

We identified subjects by searching the local VA laboratory database for patients with serum creatinine concentrations measured between January 1, 1998 and December 31, 1999. Patients with two values ≥ 1.4 mg/dL, the upper limit of normal for our laboratory, during outpatient lab visits at least three months apart were included in the study. Patients were excluded if they were not followed in our primary care or nephrology clinics or if renal replacement therapy was initiated within 90 days of the first identified serum creatinine measurement.

Measures

For every subject in the cohort, we obtained all serum creatinine, calcium, phosphorus, albumin, hemoglobin, low density lipoprotein (LDL), hemoglobin A1C (HgA1c), and urine protein quantification values in the laboratory database between the inclusion date and December 31, 2004. Creatinine measurements were converted into an estimated glomerular filtration rate (GFR) using the modified Modification by Diet of Renal Disease Study formula (GFR= exp[5.228 - 1.154 x ln(Scr) - 0.203 x ln(age) - 0.299 (if female) - 0.192 (if black)])[8] and assigned a CKD stage using the Kidney Disease Outcomes Quality Initiative (KDOQI) CKD staging guidelines.[9] Specifically, stage 1 = GFR ≥ 90 mL/min with proteinuria, stage 2 = GFR < 90 mL/min and ≥ 60 mL/min with proteinura, stage 3 = GFR < 60 mL/min and ≥ 30 mL/min, stage 4 = GFR < 30 mL/min and ≥ 15 mL/min, and stage 5 = GFR < 15 mL/min or renal replacement therapy. The values for calcium, phosphorous, albumin, hemoglobin, HgA1c, and LDL were each averaged over three-month periods during follow-up. CKD-related complications included hypocalcemia (serum calcium < 8.5 mg/dL), hyperphosphatemia (serum phosphorus > 4.5 mg/dL), hypoalbuminemia (serum albumin < 4 g/dL), and anemia (serum hemoglobin < 12 mg/dL), and were defined here according to the Renal Physicians Association's and KDOQI evidence-based guidelines.[10] Complications were considered present if ≥ 50% of the averages exceeded the recommended goal. HgA1c (goal ≤ 7.0%), LDL (goal ≤ 100mg/dL), and blood pressure values (goal ≤ 135/85mmHg), also defined according to the above guidelines, were handled in the same manner. We used this method in order to evaluate the relationship between chronic exposure to CKD-related complications and/or poorly controlled comorbidities and long-term outcomes, such as disease progression and death.

We obtained data from the local pharmacy database on angiotensin converting enzyme inhibitors (ACEIs), angiotensin 2 receptor blockers (ARBs), erythropoietin, and lipid lowering agents prescribed during the study period. Prescriptions from the VA pharmacy are generally considered to be excellent indicators of medication usage since most veterans do not obtain drugs outside of the VA pharmacy and, due to the copay, do not request refills for medications not being taken. Medications were only included in the analysis if they were prescribed for at least six months.

We also collected data for the study period from the national inpatient and outpatient VA databases maintained in Austin, Texas. Data collected included demographics, comorbid conditions, blood pressure, and resource use (number of clinic visits and hospitalizations). These databases are a cumulative index of admissions and discharges from all United States VA medical centers and have been validated for reliability.[11] Comorbid conditions, including the presence of diabetes mellitus, hypertension, left ventricular hypertrophy (LVH), coronary artery disease (CAD), and current tobacco use, were identified using ICD-9 codes, while patient encounters with primary care physicians or nephrologists, clinic visits, and hospitalizations were identified using clinic and provider encounter codes. Race was categorized as white versus nonwhite. The CKD stage at first visit to nephrology was defined as the stage at initiation of nephrology care. Initiation of renal replacement therapy was identified by using ICD-9 and clinic codes from all three (local, national inpatient, and national outpatient) sources, as well as chart reviews of all patients with at least one GFR < 31 mL/min. Death was identified using the national VA benefits database maintained in Austin.

Analysis

The date of the first GFR within the cohort identification period (January 1, 1998 and December 31, 1999) for each patient was identified as the index date (time 0). The date of each subsequent GFR was used to calculate the number of days from the index date in order to construct a time course of GFR and CKD stage for each patient. In an effort to reduce the effect of regression to the mean and laboratory imprecision, we identified the index GFR as the average GFR for the three months prior to index date and we assumed that an individual remained in their current CKD stage until two measurements at least three weeks apart were either both higher or both lower than the previous stage. When this occurred, a new stage was assigned based upon the GFR at the time of the first of the two measurements.

In order to assess the effect of nephrology care on CKD course, we created two groups: PCP-only and PCP with nephrology (nephrology). Individuals who had nephrology clinic visits were assigned to the nephrology group, whereas those followed by a primary care physician only were assigned to the PCP-only group. Baseline characteristics were compared between these two groups using the Student's T-test for continuous variables and the Mantel-Haenszel chi-square for categorical variables.

Survival curves were constructed using all patients in a given stage to determine the time spent in each stage (ie, from stage 1 to 2, stage 2 to 3, stage 3 to 4, etc.), and the time from pre-advanced CKD, stages 1-3, to advanced CKD (ACKD), stages 4 and 5. The time spent in a given stage was defined as the time period between the very first assignment to that stage and a composite endpoint of either first assignment to a higher stage or death. If neither endpoint was reached then patients were censored at the time of their last follow-up. If an individual advanced more than one stage between measurements, then the time to the endpoint was defined as one half of the interval observed. Since many patients progressed through several CKD stages, a single individual may be represented in more than one survival curve.

We used a Kaplan-Meier survival curve to calculate the unadjusted progression-free survival time for each stage and a Cox Proportional Hazards model to compare the adjusted and unadjusted progression-free survival times between the nephrology and PCP-only groups for each stage. The adjusted model included age in years, race (white versus nonwhite), ACEI (use versus non-use), ACEI started during the analyzed stage, Anti-lipid agents (use versus non-use), uncontrolled diabetes (versus controlled diabetes—as defined in the measures section for HgbA1c > 7%), current tobacco use (versus noncurrent or no use), and diabetes (versus no diabetes), hypertension (versus no hypertension), cardiovascular disease (versus no cardiovascular disease), or proteinuria (versus no proteinuria). We excluded measures of control (other than diabetes) from the model because we were limited in the number of covariates we could analyze by the frequency of the outcome. We also excluded CKD-related complications and resource use because we could not distinguish between cause and effect with our study design. Only individuals followed by a nephrologist during the stage being analyzed were assigned to the nephrology group, and only those taking a medication during the specified stage were assigned the medication. Since ACEIs may acutely decrease and then stabilize GFR, we created an indicator variable for those who initiated an ACEI during the analyzed stage (ACEI started during stage) in order to distinguish between its short-term and long-term effects.

We incorporated the propensity to be seen by a nephrologist into our model in order to account for potential bias in patients referred to subspecialists. These continuous scores, which represent the probability that an individual received nephrology care based upon modeled characteristics, are incorporated into the Cox Proportional Hazards model as a covariate to balance observed characteristics between the two groups. We calculated a propensity score[12] for the probability of receiving nephrology care using a logistic regression model adjusted for age (in years), race (nonwhite versus white), diabetes (versus no diabetes), hypertension (versus no hypertension), cardiovascular disease (versus no cardiovascular disease), ACEI use (versus non-use), anti-lipid medication use (versus non-use), hypocalcemia (present versus not present), hyperphosphatemia (present versus not present), anemia (present versus not present), number of hospitalizations, and rate of progression prior to nephrology care (average change in GFR prior to first visit).

Table 1.
Characteristics of the Study Cohort and the Two Subgroups at Baseline

	Total	Nephrology	PCP-only	p-value
Number	1,553	456	1,097	
Age (range)	70 (26-98)	68.7	70.3	0.01
Nonwhite race (%)	32%	33%	32%	0.77
Diabetes (%)	52%	58%	49%	0.002
Hypertension (%)	92%	98%	90%	< 0.001
Proteinuria (%)	89%	75%	58%	< 0.001
Current Tobacco use (%)	21%	21%	21%	1.0
Coronary Artery Disease (%)	49%	56%	57%	0.49
Left ventricular hypertrophy (%)	3%	3%	3%	1.0
Hyperlipidemia (%)	24%	25%	24%	0.60
Average stage at cohort entry	1.3	1.6	1.1	< 0.001

Results

The baseline characteristics for our cohort and the two subgroups, PCP-only and nephrology, are reported in Table 1. Follow-up characteristics, including disease management and the development of CKD-related complications, are reported in

Table 2. Our cohort was composed of mostly elderly individuals. All were male and 33% were nonwhite. More than 90% had hypertension, 50% had diabetes and coronary artery disease, 50% used ACEIs, and 39% used anti-lipid medications. Only 3% used erythropoietin and less than 1% used ARBs, which reflects limitations on access to these two classes of drugs at our VA. The average stage at entry into the cohort was very early (1.3), and the average stage for referral was also early (1.6). When comparing those followed by nephrologists to those followed only by a PCP, individuals in the PCP-only group were older and were less likely to have diabetes, hypertension, hypoalbuminemia, or hyperphosphatemia. Management of diabetes, hypertension, and hyperlipidemia were similar between the PCP-only and nephrology groups and both groups had a similar number of days of follow-up, 1,310 for the nephrology group and 1,285 for the PCP-only group. Of the cohort of 1,553 individuals, only 133 (8%) were lost to follow-up.

Table 2.
Characteristics of Management and CKD-related Complications during Follow-up of the Study Cohort and the Two Subgroups

	Total	Nephrology	PCP-only	p-value
Number	1,553	456	1,097	
Days of follow-up (mean)	1,296	1,310	1,285	0.30
Hospitalizations, mean (range)*	2.6 (0-28)	2.8	2.5	0.03
Clinic visits, mean (range)*	141 (7-1,412)	170	129	< 0.001

ACEI=angiotensin converting enzyme inhibitor; HgA1c=hemoglobin A1c; LDL=low density lipoprotein

*This is the average and range of the total number of visits during the follow-up period per patient.

Individual values for each patient were averaged over three-month periods during follow-up. If ≥ 50% of the averages exceeded the recommended goal then the patient was considered uncontrolled. Table reports % of patients who are uncontrolled.

Legend: Medication use is presented as the proportion of the group using the medication for at least six months during the study period. The management of diabetes, hypertension, and hyperlipidemia as well as the complications of CKD are presented as the proportion with 50% or more of their three-month averages outside of the recommended values.

The outcomes of the survival and Cox proportional hazard analyses are presented in Tables 3 and 4 and the curves derived from Cox proportional hazard analysis for each stage are depicted in Figure 1. These show that individuals spent a median of 3.2 years per stage in stages 1, 2, and 3, but only 2.1 years in stages 4-5. There was no difference between the PCP-only and nephrology groups for the unadjusted time spent in stage 1 or stage 2; but for stages 3 through 5 and early to advanced CKD, those in the nephrology group spent 316, 251, 120, and 55 more days, respectively, in each stage than those in the PCP-only group. Of those who reached the composite endpoint, more individuals in stage 1 progressed to the next stage than died, an equal number progressed as died in stage 2, and more progressed than died during stages 3 through 5. At each stage, proportionally fewer individuals in the PCP-only group progressed to the next CKD stage, but more died, than in the nephrology group.

The hazard ratio, an estimate of the relative risk for each covariate, is shown in Table 4. For the stage 4 to 5 model we only incorporated age, race, ACEI use, and anti-lipid medication use because the small number of outcomes limited the number of covariates that could be included in the model. All other models were analyzed with all the prespecified covariates. Nephrology care at stages 3 and 4 and during early CKD improved survival (adjusted HR 0.80, 0.75, and 0.91, respectively). ACEIs transiently reduce GFR as signified by a hazard ratio of greater than 1 for the ACEI started during stage variable; however, long-term they are protective and reduce the rate of progression by almost 40% for stages 1-3 and for pre-ACKD to ACKD. Lipid-lowering agents appear to be protective, whereas diabetes appears to be harmful. Both effects were present across all the stages analyzed. In addition, proteinuria appears to predict a more rapid disease course for pre-ACKD to ACKD. We did not perform the Cox Proportional Hazards analysis for the stage 5 to ESRD group because of its small size, and we excluded comorbid conditions from the stage 4 to 5 analysis because the small number of individuals who reached the endpoint limited the number of covariates that could be analyzed.

Discussion

Our findings suggest that nephrologists' involvement in the care of individuals with CKD is associated with a prolonged course of early CKD and delayed onset of ESRD. Individuals who were followed by a nephrologist in addition to their PCP spent significantly more time in CKD stages 3-5 than those followed only by their primary care providers. This finding lends support to current recommendations for initiation of care by a subspecialist and suggests that referrals may be most beneficial around stage 3.

While our study suggests that the addition of nephrology care around stage 3 may play an important role in prolonging disease course, it does not provide an explanation for why this occurs. In order to gain some insight, we evaluated the management of comorbidities and the presence of chronic CKD-related

complications between the two groups during follow-up. Both the PCP-only and nephrology groups provided similar levels of control for diabetes, hypertension, hyperlipidemia, hypercalcemia, and anemia; however chronic hyperphosphatemia and hypoalbuminemia were more common in the PCP-only group. In addition, there was greater use of ACEIs in the nephrology group; however, the 1% absolute difference is not clinically significant. It is not possible to distinguish between cause and effect

Adjusted Survival Curve: Stage 3 to 4

Adjusted Survival Curve: Stage 4 to 5

Adjusted Survival Curve: Stage 5 to Dialysis

Adjusted Survival Curve: Early to Advanced CKD

Legend: Graphs the survival curve (ie, time to the composite endpoint of death or CKD progression) for the nephrology (solid line) and PCP-only (dashed line) groups during each stage. The x-axis represents the time in days, and the y-axis reflects the proportion of the group that has not reached the endpoint. The curves display the proportion of the initial group that has not reached the endpoint over time. The median time for the group to reach the endpoint is reflected by the time point on the x-axis that corresponds with 0.5 on the y-axis.

with our study design; however, these findings are suggestive, and because nephrologists in practice will not be able to expand their capacity to accommodate all stage 3, 4, and 5 patients (almost nine million individuals), it is imperative that we perform well-designed prospective studies to further investigate the answer to these questions.

Similar to the results of a recently published study,[13] we found that mortality was profound, particularly at higher CKD stages. Only at stages 1 and 2 did fewer individuals die than progress, despite the fact that the percentage of individuals reaching the composite endpoint remained relatively similar across all stages (values for stage 4 and 5 are imprecise due to the few individuals in these two groups). When comparing the nephrology group to the PCP-only group across all stages, fewer individuals in the PCP-only group progressed to a higher stage; however more individuals died. This relationship may be related to a lower referral rate for individuals with comorbidities conferring an increased risk of death, such as cancer. The limitations of our data prevent us from examining this association in more detail.

Previous studies evaluating the impact of nephrology care on renal-related outcomes have focused upon the association between the morbidity and mortality of dialysis and the patterns of pre-ESRD care.[14,15] These retrospective studies consistently found that individuals referred to a nephrologist early had less morbidity and mortality than those referred late, however early referral was dichotomized (ie, before or after a prespecified cut-off time), the definition varied (one month to one year predialysis), and the findings were not generalizable to pre-ESRD populations. This is the first study to evaluate a CKD population in various stages of disease over an extended follow-up time. By performing a study to investigate the impact of nephrology care at each CKD stage, we were able to more closely assess the impact of a nephrologist on mortality and progression in those with pre-ESRD who receive medical care by primary care physicians. This is an important distinction since the impact of recommending early referral will be limited to those already receiving medical care. It will not affect those who receive no pre-ESRD medical care.

The retrospective design of our study raises the possibility that the difference in outcomes between the two groups may have been related to unmeasured variables or bias in patients referred to nephrologists. We attempted to account for this possibility by using a propensity score to adjust the analysis. Propensity scores are able to improve upon statistical analysis in potentially biased populations, but they are still subject to the problems of unmeasured bias. The average stage at referral, 1.6, is quite low, indicating that most patients seen by subspecialists were referred during their earliest stages and that crossover between the nephrology and PCP-only groups at later stages was limited. The study design also prevented us from controlling loss to follow-up; however, only 133 of the original 1,553 individuals transferred out of the system, and there was excellent long-term follow up, averaging 3.5 years.

The population we studied limits the generalizability of our results to other veterans since VA populations may be different than non-VA populations and the patterns of care may also be different. In particular, patients tend to have more comorbidities with more severe disease. Referrals may take longer and follow-up by subspecialists may not be as close as in other systems. In addition, we were unable to determine if an individual received care from a non-VA nephrologist or if they received medications outside of the VA, although both are uncommon in our experience. To address this concern, we performed an informal survey of primary care providers at the Durham VA and a limited chart review for 50 patients in each group. The informal survey found that providers believed only 1-2% of their patients may obtain additional care outside of the VA and that less than 1% obtained medications outside the VA. The chart review did not identify any patients with either care or medications from outside the VA.

Our study suggests that the addition of subspecialty care to standard care by a PCP around CKD stage 3 may improve outcomes. However, well-designed prospective studies should be performed to further clarify the role and timing of nephrologist care in the management of patients with CKD. If the relationship is supported by additional studies, the reason for the phenomenon could have important clinical and health policy implications. If it is attributable to care that requires nephrology training or is otherwise only feasible in the context of a nephrology practice, then we will need to train more nephrologists. However, if some or all of the effect can be attributed to activities that can be incorporated into PCP practice, then PCPs will need to become more adept at these activities. **NCMJ**

Attitudes about Tobacco Policies among North Carolina Parents

Kelly L. Kandra, MA; Adam O. Goldstein, MD, MPH; Ziya Gizlice, PhD; Robert L. Woldman, MA; and Scott K. Proescholdbell, MPH

Abstract

Background: *While tobacco use reduction remains a major public health goal, little evidence exists on how citizens in North Carolina view policy issues related to tobacco control. This research examines attitudes toward tobacco policies among North Carolina parents.*

Methods: *Randomly selected North Carolina adults with a child living in his or her household were invited to participate in the Child Health Assessment and Monitoring Program (CHAMP) telephone survey. A sample of 3,973 parents or guardians was interviewed in 2005. Support for tobacco prevention and policies was analyzed by demographic characteristics.*

Results: *Of the 86% of initial respondents who were eligible to participate, 83% completed the 2005 CHAMP survey. Most parents in North Carolina (90.1%) support stronger policies for tobacco prevention. Parents also strongly support restrictions on tobacco in schools (85.6%) and recreational areas and fast food restaurants (83.9%). While many parents report being well prepared to talk to their children about smoking (97.6%) and report talking about the dangers of smoking monthly (84.7%), few report that their child currently smokes (3.9% of high school students and 0.6% of middle school students).*

Limitations: *Because the CHAMP survey is telephone-based, the results are limited to North Carolina parents who have a land-line telephone.*

Conclusions: *Despite the state's historical ties to tobacco, the overwhelming majority of North Carolina parents are in favor of stronger efforts at tobacco use prevention, including increased policy measures. These results suggest that prevention efforts should be expanded and that policy makers who take a stronger stance against tobacco will most likely receive broad support by North Carolina parents.*

Keywords: *parents, tobacco control, smoking restrictions, media campaigns*

Introduction

Smoking is the leading cause of preventable death in the United States and is attributable to over 400,000 deaths each year.[1] In North Carolina, it accounts for more than 11,500 deaths a year at a cost of $1.9 billion in direct medical expenditures.[2] In 2002, North Carolina's Medicaid costs associated with smoking were estimated to be more than $940 million.[3] According to recent survey research conducted by the North Carolina State Center for Health Statistics, 22.6% of North Carolina residents over the age of 18 are current smokers, giving the state a higher adult smoking rate than two thirds of states nationwide.[4]

In an effort to combat death and disease attributable to cigarette

smoking, the Centers for Disease Control and Prevention (CDC) recommends that each state establish a comprehensive tobacco control program.[5] Comprehensive programs should not only encourage youth and adults to quit, but they should also focus on youth prevention of tobacco use and eliminating exposure to secondhand smoke. Policy research shows that for every 10% increase in the price of cigarettes, a 3 to 5% decrease in cigarette consumption occurs among adults and even higher reductions in consumption are seen among youth;[5] mass media anti-smoking campaigns can reduce the number of teens smoking across the country;[6] and enacting 100% tobacco free school policies can significantly reduce environmental exposure to secondhand smoke in the school setting.[7] Despite the evidence supporting these (and similar) efforts across the United States, significant barriers exist to tobacco prevention, including preemption (state laws encouraged by the tobacco industry that prevent strong local regulations) and lack of funds to sustain tobacco-prevention programs.[5]

Stakeholders in tobacco farming and production also inhibit policy measures, particularly in tobacco-producing states.[8] Despite significant declines, North Carolina remains the largest tobacco-producing state in the country, employing approximately 13,000 people in tobacco-related jobs, including 4,100 tobacco farmers.[9] While the economic impact of tobacco farming in North Carolina has declined significantly, the impact from tobacco manufacturing remains substantial, representing over one half of all United States tobacco manufacturing activity.[9] It is no surprise then, that North Carolina policy makers have traditionally not supported strong regulations on tobacco use.[8] For example, in 1993 the North Carolina legislature passed a "preemption" law that required state-controlled buildings to have 20% of the indoor space allocated for smoking and eliminated the ability of local governments to ban smoking in most public places.[3] Until recently, North Carolina ranked 50th in the country in its tobacco excise tax rate.[10]

Within the last few years, support for the tobacco industry among policy makers in North Carolina has begun to decline, resulting in stronger support for state tobacco control policies. Legislation to raise the state tobacco excise tax from 5¢ to 30¢ passed the North Carolina legislature in 2005, with an additional increase of 5¢ taking effect in July 2006.[10] Within the last two years public health advocates successfully expanded the number of venues with the ability to eliminate tobacco use (ie, schools, health departments, hospitals, social service agencies, and the General Assembly).[11] Perhaps the most significant example of the state's changing atmosphere is the decision to invest state tobacco settlement money into the prevention of tobacco use by adolescents.[2] From 2003 to 2004, the state, through its Health and Wellness Trust Fund, invested $6.2 million in its teen tobacco use prevention and cessation programs, with an increased investment to $15 million in 2005-2006. While this investment is far less than the CDC recommends for comprehensive state programs, the investment did move North Carolina from near the bottom nationally in state spending on tobacco control to near the middle within a short period of time.

Little data exists about the attitudes that North Carolina citizens have toward tobacco policies and regulation. A recent North Carolina public opinion poll found that almost two thirds of those interviewed supported a statewide ban on smoking in public places, suggesting that the attitudes of many citizens may have shifted even more strongly than that of policy makers.[12] This study provides insight into how a random sample of approximately 4,000 North Carolina parents who have children under the age of 18 feel about various tobacco-related policy issues.

Methods

This study uses data from the 2005 Child Health Assessment and Monitoring Program (CHAMP) survey conducted by the North Carolina State Center for Health Statistics (SCHS). The CHAMP survey is a follow-up to the North Carolina Behavioral Risk Factor Surveillance System (BRFSS), a random, telephone survey of noninstitutionalized adults 18 years of age and older. Telephone numbers are generated from a computer in groups of 100 consecutive phone numbers that contain at least one published household telephone number. The telephone number groups are then assigned to two strata: (1) high density or listed numbers and (2) low density or unlisted numbers. The listed numbers are sampled at a higher rate than unlisted numbers in an effort to lower cost and improve interviewer efficiency. Data collection for the BRFSS is ongoing throughout the year, with interviews conducted 7 days per week at varying times of the day.

While the BRFSS is a national surveillance system, the CHAMP survey is unique to North Carolina. The CHAMP survey allows all adult respondents in North Carolina who completed the BRFSS survey and have children living in their household to participate in a supplemental survey. One child in each household was randomly selected through a computerized randomization procedure and the adult identified during the BRFSS interview as most knowledgeable about the health of the selected child was interviewed in the follow-up CHAMP survey. Approximately one week after completion of the BRFSS interview, an SCHS interviewer would begin to attempt to contact the household for the CHAMP survey. During the 2005 data collection period, 86% of BRFSS households agreed to participate in the CHAMP survey, with 83% of those households completing the survey. The final CHAMP sample size was 3,973 North Carolina parents or guardians.

The purpose of the CHAMP survey is to measure the health characteristics of North Carolina children, ages 0 to 17. The survey measures a wide variety of health-related topics affecting children and parents, including breast feeding, early childhood development, access to health care, oral health, mental health, physical health, nutrition, physical activity, family involvement, and parent opinion on topics such as tobacco and childhood obesity. The majority of questions on the CHAMP survey originate from pre-existing telephone surveys from the National Center for Health Statistics.

The data presented in this report are population-weighted responses to the tobacco-related questions, with corresponding 95% confidence intervals. The use of weighted data adjusts the results of the sample to better represent the entire population of North Carolina. Adjustments are made to account for the unequal probabilities of selection due to the disproportionate sampling method and due to people living in households with different numbers of residential telephone numbers and different numbers of children in the home, as well as unequal nonresponse rates among different demographic groups. The tobacco-related questions on the CHAMP survey reflect opinions about policy measures and initiatives that are currently being debated on a local and state level, as well as questions assessing parental knowledge of their child's cigarette use.

Results

The demographics of the parents who answered the tobacco-related questions showed that approximately 11% were male, 71% were white, and 32% of households had at least one college graduate living in the home.[a]

Parents were asked about their children's smoking behavior and their own efforts to educate their children about the ill effects of smoking. When asked about whether or not their child had ever smoked cigarettes, 16.9% (95%, CI 14.2 to 20.0) of parents of high school aged students responded that their child had ever smoked, and only 3.9% (95%, CI 2.37 to 5.44) reported that their children currently smoked cigarettes. Parents of middle school students responded that 5.1% (95%, CI 3.4 to 7.5) of their children had ever smoked cigarettes, and only 0.6% (95%, CI 0.0 to 1.5) reported that their children currently smoked. Parents reported that they were well prepared to talk to their children about the dangers of tobacco use, with 97.6% (95%, CI 96.9 to 98.1) responding that they felt well prepared to talk to their children about ways to reduce their children's chances of smoking. A similarly high percentage, 84.7%, (95%, CI 82.7 to 86.6) reported talking to their children at least once a month about the dangers of tobacco use.

Parents in this survey were also asked to give their opinions on various tobacco policies and initiatives in North Carolina (see Table 1). Parents reported that they were strongly in favor of making tobacco use prevention more of a priority in the state, with 90.1% (95%, CI 88.8 to 91.2) of North Carolina parents surveyed responding that it was very important for the state to take additional actions to prevent and reduce tobacco use among North Carolina youth. One such action, making their child's school 100% tobacco free, was strongly supported by 85.6% (95%, CI 84.3 to 86.9) of parents. Similarly, 83.9% (95%, CI 82.5 to 85.3) of the parents strongly supported making all indoor recreational areas and fast food restaurants tobacco free. An increase in the state excise tax on cigarettes, as a way to reduce youth tobacco use, was strongly supported by 67.2% (95%, CI 65.4 to 69.0) of the parents surveyed, with only 12.7% (95%, CI 11.4 to 14.0) of the parents reporting that they did not support any increase in the state excise tax on cigarettes. While there was some variability across demographic categories, the majority of parents, regardless of the highest level of education in the household or age or race of their child, supported these policy measures (see Table 1).

Results from the CHAMP survey revealed that 58.4% (95%, CI 38.9 to 44.2) of the parents said they had seen or heard about the state-funded Tobacco.Reality.Unfiltered. (TRU) tobacco prevention media campaign at least once. Approximately one third, 36.0% (95%, CI 33.4 to 38.6), of the parents surveyed reported hearing about or seeing the campaign at least three times in the past year (see Figure 1).

Discussion

In North Carolina and neighboring states, for most of the latter half of the 20th century, economic ties to tobacco farming and the tobacco industry have limited the extent of many public health initiatives against tobacco.[8,13-15] In the last few years, coincident with the declining influence of the tobacco industry, policy makers have begun to take stronger stances on tobacco regulation with legislative gains occurring in many areas of the country, even in historically strong tobacco-producing regions.[11,13,14] One study in a tobacco-producing state found that citizens in the state were more likely to support restrictions on smoking in public places than legislators.[15] Support for stronger tobacco regulation occurs at the same time as support grows for helping tobacco farmers diversify away from tobacco farming. In one national sample, 57% of respondents supported government involvement in helping tobacco farmers try new farming ventures.[16]

While North Carolina is still the nation's largest producer of tobacco, the results of this survey indicate that parents in the state have strong opinions about tobacco and its health effects. Although it is reassuring to know that over 8 out of 10 parents state that they talk about the dangers of tobacco use with their children on a monthly basis, North Carolina parents appear to dramatically underestimate or are unaware of the likelihood of their own children's use of cigarettes. Published surveys of North Carolina youth document that 5.8% of middle school students and 20.3% of high school students currently smoke cigarettes, rates much higher than that reported by parents in the CHAMP survey.[17,18] Previous research has indicated that parents do underestimate their children's cigarette use.[19,20] It is likely that if parents were more aware of their children's smoking behavior, support for tobacco prevention policy measures would be even higher than that reported in the CHAMP survey. Further research would also be useful to assess parental estimates about their child's use of other types of tobacco products, including spit tobacco (chewing tobacco or snuff). Currently, the CHAMP survey only assesses cigarette use. Since the children of the parents surveyed were not interviewed, additional studies are needed to explore the relationship between reports of

---

[a] Demographics vary slightly across questions due to skip patterns in the survey or respondent's refusal to answer.

Table 1.
Support Among North Carolina Parents for Strengthening Tobacco-Related Policies Affecting Youth

	How important do you think it is for North Carolina to take additional actions to prevent and reduce tobacco use among our youth? **% very important (95% CI)**	*To what degree do you support a 100% tobacco free policy in your child's school?* **% strongly support (95% CI)**	*To what degree do you support a tobacco free policy in indoor recreational areas and fast food restaurants?* **% strongly support (95% CI)**	*To what degree would you support increasing the tax on cigarettes in North Carolina to reduce youth access* **% strongly support (95% CI)**
Total	90.1% (88.8 – 91.2%)	85.6% (84.3 – 86.9%)	83.9% (82.5 – 85.3%)	67.2% (65.4 – 69.0%)
Gender of child				
Male	90.2% (88.4 – 91.7%)	85.5% (83.5 – 87.3%)	83.7% (81.6– 85.6%)	67.1% (64.5 – 69.6%)
Female	90.0% (88.1 – 91.5%)	85.8% (83.8 - 87.6%)	84.2% (82.1 – 86.1%)	67.4% (64.7 – 69.9%)
Age groups				
Under 5	89.7% (87.2 – 91.8%)	88.5% (86.0 – 90.6%)	86.6% (83.9 – 88.9%)	66.9% (63.3 – 70.4%)
5 – 10	89.9% (87.7 – 91.8%)	84.9% (82.3 – 87.2%)	84.3% (81.7 – 86.6%)	70.2% (67.0 – 73.2%)
11 – 13	90.9% (87.7 – 93.4%)	85.9% (82.3 – 88.8%)	83.5% (79.9 – 86.6%)	66.9% (62.4 – 71.1%)
14 – 17	90.0% (87.4 – 92.1%)	83.1% (80.0 – 85.8%)	80.5% (77.3 – 83.4%)	63.4% (59.5 – 67.0%)
Race of child				
White	88.7% (87.2 – 90.2%)	84.7% (83.0 – 86.3%)	83.9% (82.2 – 85.5%)	64.9% (62.7 – 67.1%)
Black	92.3% (89.8 – 94.3%)	86.7% (83.6 – 89.2%)	84.0% (80.7 – 86.8%)	70.0% (66.0 – 73.7%)
Other	93.6% (89.8 – 96.0%)	89.8% (85.4 – 93.0%)	83.7% (78.7 – 87.7%)	77.7% (72.3 – 82.4%)
Highest education achieved in household				
Less than high school	93.2% (88.7 – 96.0%)	85.8% (79.7 – 90.3%)	82.3% (76.0 – 87.3%)	73.0% (66.0 – 79.0%)
High school	89.2% (86.3 – 91.5%)	82.7% (79.5 – 85.5%)	78.8% (75.3 – 81.9%)	58.9% (54.9 – 62.8%)
Some college	91.5% (89.2 – 93.4%)	81.2% (78.1 – 84.0%)	78.8% (75.6 – 81.7%)	61.2% (57.4 – 64.8%)
College graduate	89.1% (87.1 – 90.8%)	89.5% (87.6 – 91.1%)	89.6% (87.7 – 91.2%)	73.8% (71.2 – 76.3%)

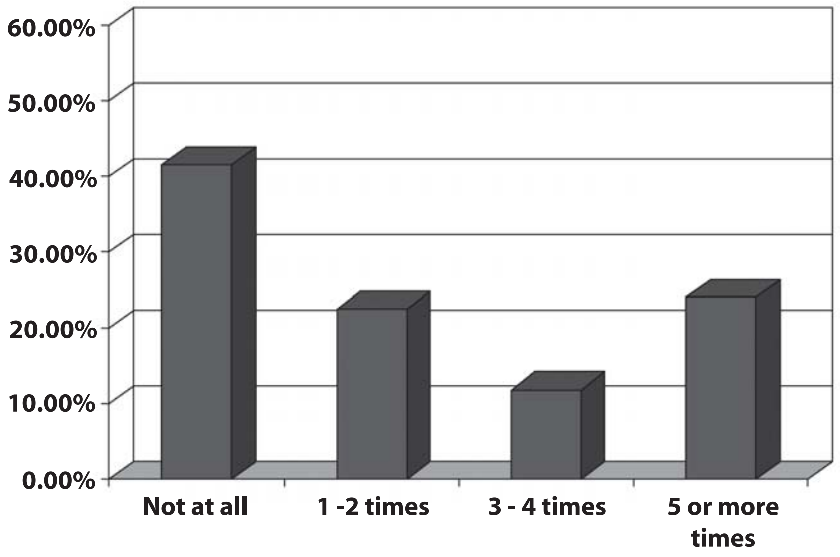
parental awareness of their children's smoking behavior and children's actual smoking behaviors.

The CHAMP data indicate that parental opinions extend from its effects on their own children to statewide public policy. Parents indicate strong support for policy makers to take increased steps to regulate tobacco products, decrease exposure to secondhand smoke, and spend more funds to accomplish both. These policy actions include increasing the state's tobacco excise tax, adopting regulatory measures for 100% tobacco-free schools, and adopting regulatory measures for 100% smoke-free environments in restaurants and recreational facilities. Strong support for policy actions was shown across the board and did not depend on the highest level of education in the household, race, or age of child.

This data, combined with results from a recent statewide poll, support the conclusion that citizens in the state are increasingly likely to demand more attention be paid to decreasing involuntary exposure to secondhand smoke.[12] One recent study of seventh and eighth graders in North Carolina public schools found that 15% of the asthma cases reported were caused by exposure to secondhand smoke.[21] A positive development is that in the last two years an increasing amount of North Carolina public school districts have adopted 100% tobacco-free school policies.[7] With the United States Surgeon General recently reporting that there is no safe level of exposure to secondhand smoke, the complete elimination of exposure to secondhand smoke in schools and public venues is a justified concern of all parents.[22] While statewide legislation can achieve significant reductions in secondhand smoke exposure, in North Carolina, the state's preemptive smoking law needs to be repealed in addition to policy makers adopting a comprehensive measure.[22,23]

North Carolina policy makers have already decided to invest significant resources into youth tobacco use prevention and cessation through the North Carolina Health and Wellness Trust Fund and its teen tobacco programs.[24] A major component of that program is a statewide media campaign, *Tobacco.Reality.Unfiltered.* or TRU. The CHAMP data indicate that parents have tuned in to this statewide television campaign to prevent youth tobacco use. The TRU campaign began television advertisements targeting youth across the state in 2004 and features real stories from North Carolina youth about

Figure 1.
How frequently in the last year have you heard about or seen the North Carolina *Tobacco.Reality.Unfiltered.* (TRU) media campaign?



tobacco experiences, illnesses, and diseases of their loved ones. While the campaign is directed at youth, the stories featured in the ads are also the stories known by North Carolina parents. The CHAMP survey suggests that the ads do reach parents, and thus, the ads may have a positive effect on parental attitudes against tobacco use by their children. Future research could assess the degree to which the TRU campaign may affect adult as well as youth tobacco attitudes.

A couple of limitations to the data and analysis exist. Despite parents reporting that they were strongly in favor of increased policy measures for tobacco prevention, these questions were asked in isolation. It is possible that if parents were asked to compare the priority for tobacco prevention to other policy issues in the state, the results may be different. It is also possible that parents' smoking status may be related to support for policy measures. Unfortunately, the data collection methods of the BRFSS and CHAMP surveys prohibit this relationship from being explored. While smoking status is assessed on the BRFSS, there is no guarantee that the person who responded to the BRFSS survey is the same person who participated in the CHAMP survey as the person most knowledgeable about their child's health. A final limitation is one common to all telephone surveys—the pool of respondents is limited to only those who have a land-line telephone. Even though the telephone numbers are randomly selected and the data is weighted to represent all North Carolina parents, there are some limits to its generalizability as a result.

While this is the first CHAMP survey of parental attitudes of tobacco policies in North Carolina, its findings clearly indicate that most North Carolina parents have moved beyond traditional pro-tobacco attitudes and are in favor of tobacco use prevention for their children and increased policy measures for the state. Current parental attitudes about tobacco suggest that policy makers who take a stronger stance against tobacco use will likely receive broad parental support in the state. **NCMJ**

Appendix A. Questions Used in Analysis

Parent Opinon

1. How important do you think it is for North Carolina to take additional actions to prevent and reduce tobacco use among our youth? Very important / Somewhat important / Not at all important
2. To what degree do you support a tobacco free policy in your child's school so that no one, not students, nor teachers, staff or visitors, could smoke or use other tobacco products on the school grounds at any time? Strongly support / Moderately support / Do not support
3. To what degree do you support a tobacco free policy in indoor recreational areas (skating rinks, bowling alleys) and fast food restaurants where your child plays, works or eats? Strongly support / Moderately support / Do not support
4. To what degree do you support increasing the tax on cigarettes in North Carolina to reduce youth access to tobacco in our state? Strongly support / Moderately support / Little support / Don't support
5. Do you feel well prepared to talk with (CHILD) about reducing the chances of smoking? Yes / No / Don't know or Not Sure

Tobacco Indicators

1. How often have you discussed the dangers of tobacco use with (CHILD) in the last 12 months? Once a day / Once a week / Once a month / Once a year / Don't know or not sure / Never
2. To your knowledge, has (CHILD) ever smoked cigarettes? Yes / No / Don't know or not sure
3. To your knowledge, does (CHILD) currently smoke cigarettes? Yes / No / Don't know or not sure
4. How frequently in the last year have you heard about or seen (on TV, from your children, or in other media) the North Carolina *Tobacco.Reality.Unfiltered.* (TRU) media campaign directed to preventing tobacco use among youth? Not at all / Once or twice in the last year / Three or four times / Five times or more / Don't know or not sure

ARTICLE

Patient Attitudes toward Screening

Denise E. Bonds, MD, MPH; Shellie D. Ellis, MA; Erin Weeks; Peter Lichstein, MD; Kim Burke; and Chris Posey

Abstract

Background: *Physician organizations recommend screening for health care behaviors. Despite these recommendations, health care providers worry that questions on sensitive topics may not be accepted by their patients. To determine if there is a relationship between health care screening by providers and acceptance of that screening by patients, a survey of female patients was analyzed.*

Method: *Two telephone surveys were conducted two years apart. Each was a cross-sectional sample of female patients over the age of 18 years who had been seen by their primary care provider (PCP) in the previous 12 months. Patients were asked if they had been screened for eight different health behaviors (exercise, smoking, use of alcohol or drugs, excessive stress, sexual functioning concerns, safety or violence in the home, guns in the home) in the past year. They were also asked about their attitudes toward screening for those behaviors by health care providers. Odds ratios were calculated for patients who both agreed that screening should occur and reported having been screened in the last year.*

Results: *3,175 women were surveyed. There was high acceptance of routine screening for exercise (75%), smoking (72%), alcohol/drugs (68%), and stress (62%), but less for sexual functioning (40%), safety/violence (40%), or guns (23%). There was a higher likelihood of agreeing with routine screening if the patient reported having been screened in the past year: exercise (OR 2.3, 95% CI 1.8-2.9), smoking (OR 1.6, 95% CI 1.3-1.9), alcohol/drugs (OR 2.3, 95% CI 1.9-2.7), stress (OR 1.7, 95% CI 1.4-1.9), sexual functioning (OR 2.7, 95% CI 2.2-3.4), safety/violence (OR 3.4, 95% CI 2.8-4.2), and guns (OR 4.4, 95% CI 3.4-5.8).*

Limitations: *Only women in established relationships with primary care providers were surveyed. The cross-sectional nature of the survey prevents determination of the causality of the relationship.*

Conclusion: *Women who had been screened for a health behavior had greater acceptance of routine screening for that behavior. Although further research is needed to determine the casual relationship, providers should not worry about offending their patients when screening for sensitive health behaviors.*

Introduction

Physician organizations recommend screening patients for risky health behaviors to reduce morbidity and mortality and to increase quality of life. Behaviors such as smoking, alcohol and drug use, and sedentary lifestyle have been strongly associated with increased morbidity and mortality.[1,2] Evidence suggests that routine screening with appropriate follow-up counseling can improve health outcomes.[3,4] Although there is less evidence for routine screening for other health behaviors or risks, such as guns in the home[5] and domestic violence,[6] many professional societies advocate for their incorporation into routine clinical practice on other grounds.[7]

Despite the evidence and encouragement to conduct screening, rates vary by physician specialty, physician gender, health behavior, and patient race.[8-15] Multiple factors have been shown to contribute to this variability. Studies have shown that physicians' perception of the ease of the intervention, the intervention's potential to

Chris Posey, is a Student with Wake Forest University in Winston-Salem, North Carolina.

improve health outcomes, the health care providers' personal beliefs or practices, and their acceptance and comfort in asking about sensitive topics all influence screening rates.[8,12,13,15-24] Moreover, patients may have varying attitudes toward screening.[25,26]

Researchers have not fully elucidated the relationship between patient attitudes and provider practice. Health care providers may be less likely to screen if they sense disapproval or discomfort from their patients on particular health subjects. This reluctance to screen for fear of offending has been best documented in the literature with regard to screening for domestic violence.[27] With the increasing shift in the delivery of health care toward a consumer-oriented model and an emphasis on patient satisfaction as a measure of health care quality, providers may avoid asking questions on topics they view as sensitive to avoid lowering patient satisfaction. This fear may result in decreased health care quality if providers miss an opportunity to provide appropriate referral and assistance to patients, thus reducing the effectiveness of the patient-provider relationship. Conversely, patients' attitudes toward questions on sensitive topics may change with routine screening due to normalization of the behavior as a health risk. Patient satisfaction with and trust in their health care provider may increase as providers explore topics that patients did not link with their medical condition but may ultimately impact their health or quality of life. To determine if routine screening was associated with increased patient acceptance, we analyzed patient survey data from Providers Asking About ViolencE (Project PAAVE), a practice-based intervention to increase screening for domestic violence.

Methods

Project PAAVE was designed to increase the rate of screening for domestic violence by primary care providers. For this study, primary care providers were defined as academic or community-based internal medicine, family medicine, or obstetrics and gynecology practices with at least two providers. PAAVE was a multi-modality intervention conducted in western North Carolina that included both standardized educational sessions at the beginning and throughout the 18-month intervention period and components customized to the needs of participating practices. The intervention was evaluated through a pre/post telephone survey of female patients seen within the last 12 months at the practice. To protect women who were in violent situations, the question on screening for violence in the home was embedded in a larger questionnaire. This report utilizes the data collected in the additional questions asked of patients. The study was reviewed and approved by the Institutional Review Board at Wake Forest University School of Medicine.

Survey

A previously validated survey was used.[28-30] This survey was developed for use in the federally supported Women's Health Centers of Excellence and has been tested in over 1,000 female patients with an alpha of 0.95 for the measure of comprehensiveness of care that include the screening questions used in this analysis.[30] Patients were asked about their experiences being screened for particular health behaviors/risk factors, their medical utilization patterns, and other demographic information. Smoking, the use of alcohol or drugs, exercise, a gun in the home, concerns about safety or violence at home, family or relationship concerns, sexual functioning, and stress management were the health behaviors/risk factors included in the survey. Response options were "Yes," "No," and "Don't know." Patient demographic factors included age, marital status (married or marriage-like relationship versus not married), race (white, nonwhite), income (less than $25,000, $25,001 to $50,000, $50,001 to $75,000, greater than $75,001), and medical insurance (any, none). Medical utilization questions included the number of visits for any type of health care in the previous year, type of provider seen (family or general practitioner, internist, gynecologist, physician assistant, or nurse practitioner), and the gender of the health care provider.

To ascertain patient attitudes about the types of screening questions asked by health care providers, eight additional questions were added to the survey. The attitude questions mirrored the health behaviors/risk factors already included in the survey. Patients were asked if they thought providers *should* ask patients about smoking, use of alcohol and drugs, exercise, guns in the home, concerns about safety or violence in the home, sexual functioning concerns, and if they are under excessive stress. Four options were provided: "Yes, at every visit;" "Yes, once a year;" "Yes, if there is a reason;" and "No." We defined routine screening as screening that occurred regardless of a whether the condition is clinically apparent. For the purpose of these analyses, we defined acceptance of routine screening as either the response "Yes, at every visit" or "Yes, once a year."

Patients

Each clinic was asked to supply a list of at least 400 female patients who had been seen in the last year. One clinic was unable to compile a list of 400 patients, so all patients on its list were called. To be eligible for the survey, the patient had to be over the age of 18 years, speak English (due to lack of bilingual staff), be able to understand and respond to questions, and have been seen in the clinic in the previous 12 months. The training of the health care providers occurred during September 2002 to November 2002. Women interviewed at baseline were randomly sampled from women with a visit to any one of the participating health care providers between September 2001 and August 2002. Those women interviewed for the follow-up were drawn from a new pool of women who visited a health care provider between July 2003 and June 2004. Although it was possible for a patient to appear on both lists and participate in both surveys, no attempt was made to track patients between the two surveys. Patients were selected for inclusion using a random number table, then contacted by telephone and asked to participate. At least three attempts at different times of the day were made to contact the participant. If a selected patient was not reached or refused, the next consecutive patient was attempted. This sequence was continued until 100 completed surveys were obtained from each clinic at each point in time (baseline and follow-up; total from each clinic n = 200).

Statistical Analysis

Analyses were performed using STATA version 8.0 (Stata Corp, College Station, TX). Each survey (baseline and follow-up) was analyzed separately and then the data sets were combined. Generalized estimating equations were used to account for the effect of clustering by clinic site. The unadjusted effect of recent screening for the health behavior on acceptance of each specific health behavior was examined (eg, recent screening for exercise on odds ratio of agreeing with routine screening for exercise). We then adjusted for patient and practice characteristics. Specifically, we modeled the odds ratio of agreeing with routine screening as a function of having been screened in the past year after adjusting for age, marital status, race, income, insurance, PCP gender, PCP type, number of visits, and clustering by clinic. Possible variation by survey year was accounted for by inclusion of a variable for survey time in all models.

Results

Practices

Seventy-nine practices were contacted by mail or phone during the three-month recruitment period. Seventeen academic (n = 5) and community-based (n = 12) primary care practices were recruited, among them four internal medicine, 11 family, and two obstetric and gynecology practices. Two practices are excluded from our analysis. One practice dropped out after the initial training session and one closed shortly after the study began (both community-based family practices).

Patients

Approximately 6,000 patient names at each time point were randomly selected for inclusion in the study (pre: 6,319; post: 5,967). Only three attempts (one each in the morning, afternoon, and evening) were made to reach each participant; thus a large number of potential participants were contacted but not reached. (pre: 3,962 - 62%; post: 3,718 - 62%). Six hundred and fifteen patients (pre: 310; post: 305) were reached but did not meet inclusion criteria due to reasons including inability to understand questions, male gender, age less than 18 years, no clinic visit in the previous year, and inability to speak English. Eight hundred and thirteen (pre: 403; post: 410) were reached but refused to participate. The resulting number of women included in the analyses described in this paper is 3,175 (pre: 1,534; post 1,641, overall response rate 26%). No information is available on the non-responders. The median age was 48 years, about one third stated they were of non-white race, and half said they were married or living with a partner (see Table 1). Nearly half reported their income was less than $25,000 per year and nearly all had some type of insurance. Most participants stated they were seeing a family medicine physician, and more than half of the health care providers were female. The mean number of visits to any health care provider was 7.7.

Survey Results

When participants were asked whether physicians should screen for particular health behaviors or concerns, most agreed that physicians should routinely ask about exercise, smoking, use of drugs or alcohol, and if they are under excessive stress (see Table 2). Fewer participants felt that health care providers should routinely screen for sexual functioning concerns, safety or violence in the home, and guns in the home. Respondents did feel that sexual functioning and safety and violence in the home were questions that should be asked if the provider had a reason. Most respondents felt that physicians should not ask about guns in the home.

When asked about previous health behavior screening by their primary care provider in the past year, most recalled having been asked about exercise, smoking, use of drugs or alcohol, and the level of stress in their lives (see Table 2). Fewer stated their physicians had discussed sexual functioning concerns or safety and violence in the home. Only 7% of participants recalled having a discussion about guns in the home. Previous health behavior screening was highly associated with participants' attitudes toward screening in all seven areas (see Table 3).

Table 1.
Description of Sample Population

	N = 3,175[a] % (N)
Age (mean)	48 years (SD 17 years)
Nonwhite race	35%

[d] Answered “Yes” to the question “In the past 12 months has a doctor or other health professional discussed with you…?”

Those participants that recalled having been screened for a particular health behavior in the previous year were more likely to agree that health care providers should screen for that health behavior at either every visit or at least once a year. For example, those participants who had been screened for exercise in the last year were more likely to answer “Yes, at every visit” or “Yes, once a year” to the question “Should health care providers ask their patients if they exercise?” This association was stronger for those issues that had relatively low level of acceptance for routine screening: sexual functioning concerns, safety or violence in the home, and guns in the home. The association remained after adjustment for patient demographics (age, marital status, race, income, insurance), provider characteristics (gender, specialty), number of visits, clustering by clinic, and survey year (see Table 3). When the response “Yes, if there is a reason” was excluded and the analyses rerun, the association of previous screening with acceptance of screening was even stronger, particularly for the three most controversial questions: sexual functioning concerns (adjusted OR 5.8, 95% CI 3.5-9.4), concerns about safety or violence in the home (adjusted OR 5.6, 95% CI 3.9-8.1), and guns in the home (adjusted OR 6.5, 95% CI 4.7-9.1).

When the characteristics of participants who answered “No” to the questions about whether physicians should screen were examined, these individuals were generally older, less likely to be married, more likely to state their income was less than $25,000 a year, less likely to be working, and reported having more visits to a health care provider. However, in statistical analysis, most of these differences were not significant (data not shown). Only three participants responded “No” to all “should health care providers screen” questions, and 187 responded “No” to the three most controversial questions of screening for sexual functioning concerns, safety or violence in the home, and guns in the home. When the demographic and socio-economic characteristics of these 187 were compared to the remaining participants, no significant differences were seen (data not shown).

Discussion

We found a positive relationship between self report of previous screening and patient attitudes toward screening in this large sample of female patients receiving care in western North Carolina primary care clinics. This relationship was especially strong between those health behaviors that could be considered sensitive, such as sexual functioning and violence in the home. We also found that more patients felt they should be screened than were actually screened for all health behaviors included. This finding is especially significant in light of the importance of routine health screening.[31]

There may be several reasons for the relationship we found. It is possible that the act of asking screening questions increases acceptance through provision of information. Providers may normalize the question (“Violence affects many of my patients, so now I routinely ask all patients”) such that patients view screening as a routine part of their health care. A reverse relationship is also possible. Patients may seek out health care providers who support their beliefs on health care. However, there is limited evidence that patients change providers[32,33] and, for those who do, it is unclear that screening behaviors would be a motivator for doing so[32,34-35] or that patients would have access to sufficient information to be able to do so.[32,36,37] Similarly, health care providers may screen for particular behaviors because they perceive that such screening would be accepted and expected by particular patients. Finally, it is possible that our results reflect a recall bias. Patients with greater acceptance of screening may preferentially remember being asked those questions by their health care providers.

Although we found good acceptance among the participants for screening for certain health behaviors including screening for tobacco and alcohol use, other screening questions such as guns in the home, safety and violence in the home, and sexual functioning had less support. The evidence supporting improved health care outcomes with screening for these items is mixed. While the United States Preventive Services Task Force (USPSTF) did give screening for firearms in the home a "B" recommendation in its 1996 review, meaning there is fair evidence supporting its use and it is recommended that clinicians provide the service to eligible patients, it has since stated that this recommendation needs updating.[5] Health care provider screening for domestic violence received only an "I" recommendation,[6] meaning there was insufficient evidence to determine the net benefit of the service or to recommend for or against routinely providing it. The USPSTF has not reviewed the effectiveness of screening for sexual functioning. Given our findings of lower patient acceptance for these behaviors and the lack of evidence supporting improved patient outcomes, screening for these behaviors may not represent optimal use of patient or provider time. However, our finding of higher rates of acceptance among patients who had been screened should reassure providers that if they do choose to screen, their patient will accept that screening.

This study is unique in the breadth of health behaviors patients were asked about and the size of the sample. Previous studies have focused on one type of health behavior, such as screening for guns[18,38] or safety or violence in the home.[39-43] Results of these limited surveys have been mixed, with some studies demonstrating patients' strong support for routine screening for safety and violence in the home[39,40] and other studies showing less support.[38-44] To date, there have been no other studies that have examined the relationship of previous screening to attitudes toward screening. Our ability to include survey data from two time points also supports the strength of the relationship. Even when the survey time point was included in the model, the odds ratio showed little change.

While this study includes a variety of health behaviors and large sample size, it is limited by the geographic location of the sample. All survey participants were obtained from western North Carolina. The responses given may not be representative of the general population in the United States. Additionally, we only surveyed women and only those in established relationships with primary care providers. Men and individuals who do not have ongoing health care relationships may have differing views. We are unable to tell if the same patient was interviewed at both time points, thus some patients may have been included in both. Additionally, our response rate was low. Nevertheless, the sample size is large (more than 3,000 individuals) and represents a broad range of ages and socioeconomic status. Due to survey length, only one question about each health behavior was included, and we did not ask if the patient personally engaged in the health behavior. Additionally, we relied on participant self-report about previous screening. Previous studies have demonstrated that patient recall has high specificity when compared to direct observation, but variable sensitivity with better recall for counseling on smoking cessation and lower recall for increasing physical activity.[45,46] Further questions exploring the reasons for their answers would assist in the interpretation of the results.

Table 3.
Odds Ratios of Agreeing with Routine Screening for a Particular Health Behavior if the Participant Had Been Screened for the Behavior in the Past Year

Screening Question	Unadjusted OR[e] 95% CI			Adjusted OR[f] 95% CI		
	Pre	Post	Both	Pre	Post	Both
Exercise	2.2 (1.6-2.9)	2.3 (1.8-2.9)	2.2 (1.9-2.5)	2.7 (1.8-4.0)	2.5 (1.8-3.4)	2.3 (1.8-2.9)
Smoke	1.5 (1.2-2.0)	2.0 (1.6-2.6)	1.7 (1.5-2.0)	1.4 (1.0-1.8)	1.9 (1.4-2.5)	1.6 (1.3-1.9)
Use alcohol or drugs	1.8 (1.3-2.4)	2.7 (2.0-3.6)	2.0 (1.7-2.4)	2.2 (1.7-2.8)	2.4 (1.7-3.4)	2.3 (1.9-2.7)
Are under excessive stress	1.6 (1.3-2.0)	1.9 (1.5-2.4)	1.7 (1.5-1.9)	1.8 (1.3-2.5)	1.5 (1.2-2.1)	1.7 (1.4-1.9)
Have sexual functioning concerns	2.8 (2.2-3.6)	3.1 (2.6-3.7)	2.7 (2.3-3.2)	2.6 (1.9-3.8)	2.9 (2.2-3.7)	2.7 (2.2-3.4)
Have concerns about safety or violence in the home	4.4 (3.1-6.1)	3.8 (2.7-5.3)	3.4 (2.8-4.2)	3.9 (3.1-5.0)	3.8 (2.6-5.6)	3.4 (2.8-4.2)
Have a gun in the home	6.0 (4.1-8.8)	4.9 (3.9-6.3)	4.9 (4.0-6.0)	5.3 (3.4-8.3)	4.2 (3.0-5.9)	4.4 (3.4-5.8)

[e] Respondents with missing data are not included in the analysis for which the variable is missing.

[f] Adjusted for patient demographics (age, marital status, race, income, insurance), provider characteristics (PCP gender, PCP type), number of visits, clustering by clinic, and time of survey.

This study provides a valuable contribution to the understanding of health behavior screening. We found a significant association of previous screening with a positive attitude toward routine screening. This relationship was especially strong for those health behaviors that had lower rates of acceptance among patients. Further research is needed in different populations and to determine the causality of the association. We know that health care providers can have a powerful influence on health behaviors. If our finding is substantiated, it provides evidence that health care providers can also affect patients' attitudes regarding what healthy behaviors are. **NCMJ**

Acknowledgments: This study was funded by a three-year grant from The Duke Endowment as part of a portfolio of programs to improve health care for women.

POLICY FORUM

Pandemic Influenza Preparedness in North Carolina

COMMENTARIES

> *"Deciding who should have priority to receive limited resources during an influenza pandemic will be among the most difficult ethical dilemmas facing government officials, policy makers, and health care providers."*

INTRODUCTION

Policy Forum:
Pandemic Influenza Preparedness in North Carolina

Concern about the potential for an influenza pandemic has been at the top of the nation's agenda since 2004. In November 2005, President Bush introduced the *National Strategy for Pandemic Influenza*, which outlines how the federal government plans to prepare, detect, and respond to a pandemic. It describes the various roles of the federal, state, and local governments, private and international partners, and individual citizens during a pandemic. Congress has supported preparations for an influenza pandemic through appropriations since fiscal year (FY) 2004. Congress has approved over $6.1 billion in emergency supplemental appropriations to support flu pandemic preparedness and research. The bulk of that funding was provided to the United States Department of Health and Human Services (HHS), which will manage the federal public health and medical response during a pandemic.

The *Pandemic Influenza Plan* will guide the HHS response to an influenza pandemic at the national level. It focuses on developing infrastructure for vaccine production capacity, stockpiling antiviral drugs and other medical supplies, ensuring the capacity of public health to detect and respond to a potential pandemic, monitoring disease spread, coordinating federal, state, and local preparation, and enhancing outreach and communications planning. The North Carolina Division of Public Health will lead the influenza pandemic response at the state level. It has developed the *NC Pandemic Influenza Plan*, which it will use to coordinate activities during an influenza pandemic. The article by Jeffrey Engel, MD, in this issue of the Journal describes the potential consequences of an influenza pandemic and the state's planned response to the crisis.

A moderate influenza pandemic in North Carolina is expected to impact over three million people, with 1.6 million doctor visits, 35,000 hospitalizations, and 8,000 deaths. It is projected that more than 40% of the state's workforce would be out of work due to illness or caring for an ill family member. Such a widespread epidemic would have a huge impact on the state's economy, local businesses, and individuals' lives. In this issue of the *North Carolina Medical Journal*, we are focusing our attention on the impact an influenza pandemic will have on a number of different communities in North Carolina, including industry, faith, health care, and the underserved, and how those communities can prepare for such an emergency. Commentaries present the issues faith communities will face and the important role they can play in guiding the responses of their congregations, the models critical industries have used to develop pandemic influenza business plans, and the perspectives of private and public health providers who will be called to serve during a pandemic. Other commentaries highlight the need to understand the differences between quarantine, isolation, and social distancing and examine public health's authority to implement such measures, the importance of including representatives from underserved communities in the planning processes to avoid discrimination and bias during the pandemic, and the preparations that are being made outside of public health to prepare for the emergency.

Finally, this issue features the work of the NC Division of Public Health and NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning. The Task Force was convened to assist the Division of Public Health in developing an ethical framework for evaluating ethical dilemmas that are likely to arise during an influenza pandemic, such as requirements that workers in critical industry perform despite increased risks of contracting the virus and the reciprocal benefits they are owed for such hazards; restrictions on individual rights due to isolation, quarantine, or social distancing measures instituted to limit the spread of disease; and prioritization of limited health care resources such as vaccines and antivirals.

We hope this issue of the *Journal* will help inform North Carolina communities and providers of the potential for an influenza pandemic, the steps being taken at the state and local levels to prepare for such an emergency, and what individuals and organizations can do to prepare themselves.

Pandemic Influenza:
The Critical Issues and North Carolina's Preparedness Plan

Jeffrey P. Engel, MD

A Brief Primer

Influenza pandemics have been recorded throughout human history, on average occurring three times in a century, with ten in the last 300 years. Influenza pandemics are simultaneous worldwide epidemics and occur when a new influenza virus evolves that infects humans, is spread efficiently from person-to-person, and because of no prior immunity causes severe disease and death. Between pandemics, called the inter-pandemic period, the milder seasonal influenza (also known as the "flu") exists in the wintertime months in populations living outside of the tropical zones, whereas in the tropics, influenza is a year-around disease. Seasonal viruses are adapted pandemic strains that have weakened mainly due to developed immunity in the human population.

Influenza is characterized by the abrupt onset of fever, chills, muscle pain, and joint pain, followed within hours by respiratory symptoms including cough and congestion. It is a disease primarily of the upper respiratory tract, which in uncomplicated cases resolves in about a week. Complications include bronchitis, pneumonia (both primary viral and secondary bacterial), heart inflammation (myocarditis), and brain inflammation (encephalitis); death can result from any of these complications. In a typical season in the United States, 36,000 people die of influenza, deaths occurring chiefly among infants and the elderly.

The type A influenza virus is unique among viruses because it allows for genetic recombination to occur by the exchange of any or all of its eight gene segments of two different influenza virus strains. Additionally, the influenza virus can mutate and gradually adapt to new environments. Such recombination and adaptation in type A influenza viruses are the cause of pandemics.

Type A virus subtypes are named by the viral surface proteins, hemagglutinin (HA) and neuraminidase (NA), which elicit an immune response, and thus, comprise major components of the influenza vaccine. In nature, 16 HA and 9 NA proteins exist; however, the human pandemic and seasonal viruses have contained only the subtypes, H1, 2, or 3 and N1, 2, or 3.

The Animal-Human Interface: Zoonotic Influenza

Only type A influenza virus is capable of infecting a broad host range, primarily water fowl and shore birds. Wild water fowl usually harbor type A influenza in their digestive tract and have no symptoms. Spread to other susceptible hosts, usually related species like domestic poultry, happens directly with species intermingling or indirectly via contact with contaminated surface water because type A influenza virus can survive in fresh water for days to weeks.

Type A influenza virus is a type of infectious disease that is transmittable under natural conditions from vertebrate animals to

> *"The impact of a pandemic or any disaster is proportional to how prepared individuals and society are. Preparedness is a shared responsibility that requires local, state, and federal public health systems to form a robust response network."*

Jeffrey P. Engel, MD, is the State Epidemiologist and Chief of the Epidemiology Section of the Division of Public Health, NC Department of Health and Human Services. He can be reached at jeffrey.engel@ncmail.net or 1902 Mail Service Center, Raleigh, NC 27699-1902.

humans, also called "zoonosis." Zoonoses are usually sporadic; however, they are also the origins of epidemics and pandemics. If a human is exposed to an infectious agent from another animal, an infection results if the person is susceptible. Disease may range from asymptomatic to severe, resulting in immunity and recovery or death. An epidemic or pandemic erupts when the disease microorganism adapts via genetic mutation to the new human host and becomes capable of human-to-human transmission. Notorious examples of recent zoonotic-origin pandemics include the human immunodeficiency virus (HIV), the cause of AIDS (from chimpanzees in West Africa),[1] and the severe acute respiratory syndrome (SARS)-coronovirus (from bats in Southeast Asia).[2]

Type A influenza viruses are often the source of sporadic zoonotic infections, most often from avian, or bird, viruses. Humans are exposed to avian influenza viruses in developing countries across Eurasia and Africa due to animal husbandry practices that involve close contact with diseased or dead domestic fowl, especially ducks and chickens. In developed countries, zoonotic influenza infections have occurred in commercial poultry workers managing infected flocks.

Not all zoonotic influenza cases are of avian origin. In 1976, several soldiers at Fort Dix, New Jersey developed infections, some fatal, from a type A swine influenza virus. It is unknown how these individuals were exposed to a swine virus; however, this cluster led some scientists and policy makers to the false conclusion that this was the harbinger of the next pandemic. It was from this event that the infamous "Swine Flu" vaccination program emanated.

Contemporary methods in the study of human viruses provide information about influenza viruses dating back to 1889. The four pandemics between 1889 and 1968 were of avian origin, and they differed only in the number of avian influenza genes present in the pandemic strain (Table 1).

Table 1.
Hypothesized Evolution of Pandemic Influenza A Viruses[3]

Pandemic	Subtype	Avian Genes
1889	H2N2	?
1918 "Spanish"	H1N1	8
1957 "Asian"	H2N2	3 (PB1,* HA, NA)
1968 "Hong Kong"	H3N2	2 (PB1, HA)

* PB1 is a viral gene encoding a replication enzyme

H5N1: The Next Pandemic?

In the last 50 years, the science of influenza has made many great strides. In addition to the molecular study of the virus, worldwide human and animal surveillance and the study of population health have greatly expanded. The World Health Organization (WHO) has devoted huge resources to influenza monitoring and study. WHO coordinates the global influenza laboratory surveillance network that characterizes circulating human seasonal virus strains. This information is used to determine the annual human vaccine.

Through this global network, human disease due to avian influenza strain H5N1 was first reported in Hong Kong in 1997. Because this was an avian strain capable of causing severe infections in humans (six of 18 cases reported were fatal), WHO increased the pandemic alert level to Phase 3 (Table 2). Virtually all Hong Kong chickens were slaughtered in an attempt to eradicate the virus. This appeared to have been successful because no further clusters of H5N1 in people or domestic poultry were reported for several years. However, beginning in December of 2003, outbreaks in poultry and humans were reported in Vietnam and Thailand, and through 2006 human reports have increased across Eurasia and Africa with an alarming 60% case-fatality rate (Figure 1).

Table 2.
WHO Pandemic Phases

Period	Phase	Event
Interpandemic	1	No new subtype in humans
	2	No new subtype in humans, animal subtype poses risk
Pandemic alert	3	Human infections with new subtype, no human-to-human spread
	4	Small clusters of limited human-to-human spread
	5	Larger human clusters, but spread still localized
Pandemic	6	Increased and sustained transmission in the general population

H5N1 is currently widespread in wild and domestic birds in Eurasia and Africa with sporadic and often fatal cases in humans. It has notched up the WHO pandemic alert system to Phase 3 since 1997 and satisfies all but one important property of a pandemic-causing influenza virus (Figure 2). Will H5N1 mutate and become capable of efficient human-to-human transmission?

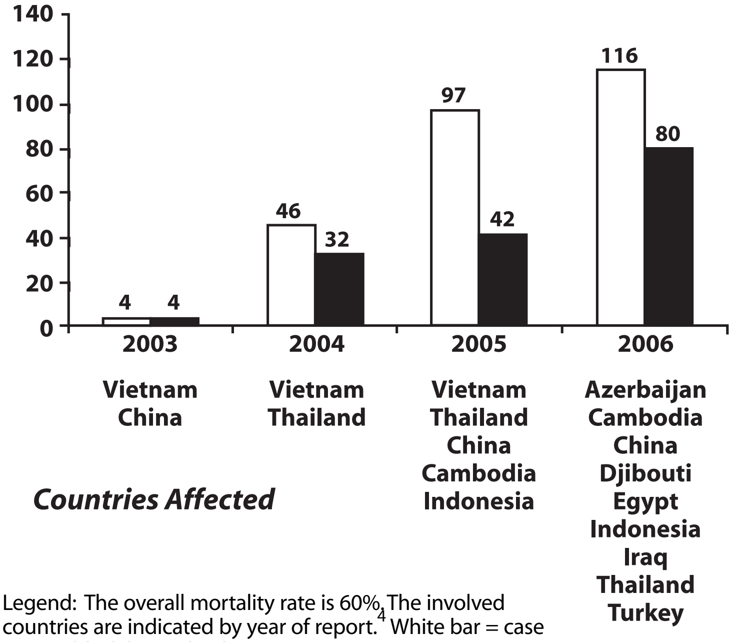
The Present Threat: When, Not If

If we know that pandemics are of avian origin and that they occur cyclically, on average three times in a century, then the question is when will the next avian influenza virus emerge that will cause the next pandemic? Certainly, H5N1 is the leading candidate. In regards to preparation, several subquestions can be generated that assist planning for the next pandemic:

- When will the virus arrive and spread?
- How much time from its source to arrival in the United States or North Carolina?
- What will the principal age and other risk groups be?
- How many will be affected?
- What will be the morbidity?
- What will be the mortality?

In terms of transmission dynamics or spread, nothing is more concerning to an epidemiologist than a community respiratory

Figure 1.
Epidemiological Curve of Reported H5N1 Human Cases by Reporting Country, 2003-2006."



Legend: The overall mortality rate is 60%. The involved countries are indicated by year of report.[4] White bar = case counts, black bar = deaths.

virus. Transmitted through respiratory droplets from a cough or a sneeze, or direct contact from a person's hands, these viruses can literally spread like wildfire through a susceptible population. The basic reproductive number, R_0, pronounced "R-zero" or "R-naught," is the expected number of people a contagious person could infect during the infectious period.[6] An R_0 greater than 1 ($R_0 > 1$) results in a self-sustaining outbreak until there are no more exposed susceptible people. In prevaccination days, a community respiratory virus like mumps with a short incubation period and an $R_0 = 6$ would literally burn through a school-age population.

Influenza virus with an incubation period of 1-5 days and $R_0 = 3$ moves quickly through a community as well. With seasonal influenza, however, R_0 is proportionately reduced by population immunity. For example, if half of the population is immune (from natural infection or vaccination) in a given season, $R_0 = 1.5$.[6] In a pandemic, however, potentially everyone is susceptible and, at least in the beginning, there will be no vaccine, thus the wildfire analogy.

Worse Case Scenario: A Syndemic

It behooves planners to assume the worst, and for pandemic influenza, that would be a 1918 "Spanish flu"-like pandemic. Worldwide, the second epidemic wave (there were three waves) of the Spanish flu, caused by an H1N1 subtype, swept across the globe with amazing speed and destruction. In its wake, 50 million people died; in the United States the death toll was 500,000 during the later summer and fall of 1918. Equally disturbing were the high attack and mortality rates that occurred in previously well people in the second and third decade of life, quite unusual for influenza that usually kills the very young and very old.

Historical accounts of young adult victims of the Spanish flu revealed a rapid death due to respiratory failure. People were well one day and dead the next, with facial cyanosis (blue discoloration from lack of oxygen) and a rapid breathing pattern occurring in the hours before death (a condition we now call the acute respiratory distress syndrome or ARDS). Examination of diseased lung tissue showed air sac damage from viral pneumonia. The body's response to the pneumonia caused leaks in the air sacs, drowning the victims (non-cardiogenic pulmonary edema).

In preparing for the next pandemic, it would be helpful to understand why the Spanish flu was so catastrophic. Certainly one reason was the virus itself. The second wave virus has been reconstructed from 1918 victims' lung tissue (both from exhumed remains frozen in the Alaskan tundra and lung tissue preserved from an autopsy sample).[7] The reconstructed 1918 virus was found to be highly lethal in the mouse model following intranasal infection. Genetic sequencing revealed it to be a zoonotic type A influenza virus strain whose entire genetic makeup was from a mutated bird strain. This truly novel virus adapted to the new human host acquiring the capability, through evolution, to spread efficiently from person-to-person.

However, in understanding the calamity of 1918, a separate analysis of the social milieu is required, specifically exploring the agents of human activity existing at the time. Historian and author John M. Barry carefully chronicles the global situation in 1918, particularly as the United States prepared for World War I.[8] Barry's meticulous research of influenza death records and outbreaks associated with massive troop deployments, staging, and overcrowding is compelling. Epidemics in Boston and Philadelphia were traced to ill troops arriving from overseas and

Figure 2.
Checklist of Pandemic Properties of Avian Influenza Type A/H5N1[5]

☑ Widespread prevalence in migratory birds; broad host range
☑ Continued outbreaks among domestic poultry
☑ Mammalian infection (cats, pigs, etc.) lethal
☑ Virus is evolving
☑ Sporadic human cases
  – Most in young and healthy
  – Case-fatality 60%
  – Rare person-to-person transmission
☐ Sustained and rapid person-to-person transmission

an overcrowded patriotic street parade, respectively. Many more examples are cited and all are consistent with massive human crowding and/or movement in the presence of a virulent respiratory virus. In epidemiologic terms, in some settings (barracks, troop ships, etc.), a virus reproductive number (R_0) of 5 or higher was common. Thus, the sociologic and biologic conditions in 1918 formed the perfect storm, a syndemic.

A syndemic is defined as "two or more afflictions, interacting synergistically, contributing to excess burden of disease in a population."[9] The term was first used by anthropologist Merrill Singer describing the HIV epidemic among the urban poor in the United States: the SAVA syndemic, for substance abuse, violence and AIDS.[10] He described a new virulent infectious virus, HIV also of zoonotic origins,[1] which spread efficiently by needle sharing intravenous drug abuse and unprotected sexual behavior that wrecked havoc among the poor, particularly in urban minority communities in the United States.

For 21st century pandemic influenza planning, then, I argue that to prevent a 1918-like scenario, we must do syndemic planning. Taking examples from recent natural disasters, such as the 1995 Chicago heat wave that killed 700 elderly people in a week,[11] the 2005 tsunami in Indonesia, Hurricane Katrina in New Orleans, or the SAVA syndemic, the common lesson learned is that the natural disaster impact, whether in a developing nation or the United States, is greatly multiplied by crowding and poverty. In 1918, the global population was 1.8 billion; today it is 6.5 billion, 2.7 billion (42%) living in moderate to extreme poverty as measured by income less than $2/day.[12]

The syndemic model predicts that the next influenza pandemic will be catastrophic in countries such as India and China where 36% of the world population lives, many in poverty and in crowded urban areas. Although these sociologic conditions exist in some areas in the United States and North Carolina, more worrisome in developed countries are the equally vulnerable including those without health insurance or who are underinsured; those who lack the capacity to access information due to illiteracy, low English-speaking skills, and other forms of social isolation; and finally, select special populations such as the homeless, institutionalized, and the underserved mentally ill.

If a 1918-like influenza virus causes the next pandemic, how our nation and state mitigate the impact will depend on pandemic and syndemic prevention. To accomplish this, at the national, state, and local level, public health is leading the planning efforts for the health care sector, government, and society.

Summary of North Carolina's Pandemic Influenza Preparedness Efforts

The fundamental objective of pandemic influenza planning is to save lives. To be successful, all corners of society must plan, including individuals and families, business and industry, schools and universities, and state and local government. These overarching plans, referred to as pandemic implementation strategies, are underway or complete in many sectors, but beyond the scope of this review. Here, I will highlight the critical components of *North Carolina's Public Health Pandemic Influenza Plan.*[13]

Quenching

In public health, prevention is the key, thus a critical strategy is the early detection of initial outbreaks and rapid containment of the disease where it emerges, a process known as quenching.[14] Through global and national collaboration with the WHO and the Centers for Disease Control and Prevention (CDC), once an influenza pandemic is declared somewhere in the world, the North Carolina Division of Public Health (DPH) will enhance frontline detection and response and rapid laboratory diagnosis. The early cases in North Carolina will likely be among travelers to regions where person-to-person transmission is ongoing.

In WHO pandemic phases 4, 5, and early 6, international travel advisories will be issued by federal authorities. DPH will notify health care providers of the situation and explain how to suspect and manage patients who may be manifesting pandemic influenza symptoms. Suspect patients shall be reported immediately to local or state public health agencies (North Carolina General Statute 130A-135), isolated (NCGS 130A-145),[15] and treated with antiviral medication pending laboratory confirmation. The North Carolina State Laboratory for Public Health will activate three regional labs in Charlotte, Asheville, and Greenville, as well as the core facility in Raleigh, to rapidly (within hours) process clinical specimens (nasopharyngeal swabs) for detection of the pandemic strain. These labs will not attempt to cultivate pandemic viruses because of the biosafety hazard; cultural confirmation will be done solely by the CDC in Atlanta, Georgia.

The goal of quenching is for public health and other response agencies to aggressively keep the $R_0 < 1$. Once a suspected patient has been reported to public health agencies, active surveillance will begin to identify close contacts (eg, airplane passengers, household and workplace contacts). If an index case is presumptively confirmed by the labs, symptomatic contacts will be isolated and referred for medical evaluation and asymptomatic contacts will be quarantined for 10 days (or the maximum incubation period) from the time of last contact to a case. Based on what is known about the contagiousness and virulence of the pandemic virus, quarantined people may be offered antiviral prophylaxis at no cost from a federal or state stockpile. Antiviral prophylaxis of exposed contacts in quarantine may be the single most effective strategy in preventing a full-blown pandemic, an $R_0 > 1$.

Isolation and quarantine are restrictions of movement and/or action of the sick (isolation) and the well but exposed (quarantine). An effective quenching plan requires rapid active surveillance and diagnosis, treatment or post-exposure prophylaxis with antivirals, and enforcement of isolation and quarantine. During the 2003 SARS response in North Carolina confirmation of a single case led to the isolation of three persons and the quarantine of 30 others. All affected people complied with local public health authorities, law enforcement was not necessary, and the spread was contained.

WHO Phase 6: Widespread Pandemic in North Carolina

Planning assumptions identify a point in time when quenching fails or is no longer feasible. This may happen if there are multiple simultaneous outbreaks across the state, a local jurisdiction's capacity to quench is overwhelmed and there are no state or federal assets available to assist, or supplies of antiviral medications are depleted leaving enough only to treat the sickest. To decrease illness and death, the strategy at such a point will be to slow the spread and buy time until an influenza pandemic vaccine is available. To accomplish this, countermeasures known as nonpharmaceutical and pharmaceutical interventions will be used.

Nonpharmaceutical Interventions

The nonpharmaceutical intervention for preventing or slowing a pandemic is the physical separation of people. This is accomplished in fundamentally two ways: personal protective equipment for those who must be close to the sick (health care workers, first responders) and social distancing and hygiene. The worst-case scenario is that 50% or more of those who become ill will seek medical care. The number of hospitalizations and deaths will depend on the virulence of the pandemic virus and Table 3 projects these numbers based upon the experiences of the moderate and severe pandemics of 1957 and 1918. Depending on severity, health care medical surge plans must scale accordingly, the largest challenge being the maintenance of adequate staffing. To provide for the safety of those on the frontline, occupational health protection through infection control is a critical planning component. In hospitals, respiratory droplet and airborne precautions that are part of everyday activity will be essential during a pandemic. For routine patient care, properly donned and doffed eye protection and a plain surgical mask are adequate along with hand washing with soap and water before and after patient contact. For higher risk contact where infectious aerosols are more likely to be generated (eg, airway suctioning, resuscitation, bronchoscopy), a fit-tested N-95 respirator is required. In the community, there is no evidence that personal protective equipment, such as the donning of masks by well people, will prevent transmission of influenza. Hence, stockpiling masks or respirators outside of the health care setting is not recommended and is not part of the *NC Pandemic Influenza Plan.*

Table 3.
Impact of an Influenza Pandemic in North Carolina*

Characteristic	Moderate (1957-like)	Severe (1918-like)
Illness	3,000,000	3,000,000
Outpatients	1,600,000	1,600,000
Hospitalized	35,000	300,000
Deaths	8,000	65,000

* Numbers based on NC population = 9,000,000; 35% attack rate (CDC FluAid 2.0)

The broader community containment strategy will rely on social distancing interventions. In WHO Phase 6 for a moderate to severe pandemic, at some threshold a state of emergency will be declared where so-called mass quarantine will be utilized. Mass gatherings including entertainment venues like sporting events and theaters will be canceled or closed, religious services will be discouraged or prohibited, nonessential workers will be told to remain at home, and schools and universities will be closed. In 1918, the city of St. Louis implemented these measures and succeeded in reducing influenza-related mortality. Indeed, government may not need to impose these measures because individuals are likely to self-quarantine if the pandemic is bad enough.

The societal disruptions will be immense, but can be lessened by cross-sector preparation. Continuity of operations planning is the core of the national implementation strategy and is essential for critical industries such as utilities, businesses, educational institutions, and government.

Pharmaceutical Interventions

Pharmaceutical interventions refer to the specific countermeasures for prevention and treatment of influenza A infections: antiviral medications and vaccines. The planning assumption for antivirals is that they will be effective in the treatment and prevention of pandemic influenza. Although clinical trials will be difficult to conduct against the current H5N1 threat, there is accumulating evidence that these drugs will have broad-spectrum activity against pandemic influenza.[16] The current federal government guideline calls for the stockpiling of enough antiviral medications to treat 25% of the population, roughly two million five-day courses for North Carolina. The stockpiling challenges lie in accumulating an adequate supply to meet the need, establishing rationing criteria until the supply is adequate, and extending the shelf-life beyond five years.

Assuming the antiviral medications are found to be life-saving and the supply is inadequate at the time of the pandemic, then difficult rationing decisions will have to be made. To ensure fairness and equity and to assist frontline providers, the *NC Pandemic Influenza Plan* aligns with the federal tier groups to receive antiviral treatment in the event of suspected influenza illness only.[17] The top five tier priority groups to receive treatment are hospitalized patients, health care workers and emergency medical technicians, high-risk outpatients including the immunocompromised and pregnant women, public health responders (eg, vaccinators, vaccine and antiviral manufacturers, government decision makers) including public safety (police, fire, and corrections), and increased risk outpatients (children 12-23 months, adults aged 65 years and above, and people with chronic medical conditions). To reiterate, this rationing scheme is for treatment only, it is assumed during a widespread WHO phase 6 event, there will not be enough medication for prevention.

The second pharmaceutical intervention is a pandemic vaccine, which can abort the pandemic once available for the entire population. The planning assumption, however, is that it will probably take a year or more to scale up production to immunize everyone. Further, because the population will be naïve to the pandemic virus, a booster shot will be required one month after the priming dose. Thus, once again, rationing of the first supplies of the pandemic vaccine is a planning component aligning with federal tier groups.[17] In Tier 1, there are four subtiers who will get the vaccine first:

1) Vaccine and antiviral manufacturers, essential medical and public health workers;
2) High-risk persons (> 65 years old, medical co-morbidities)
3) Pregnant women, household contacts of severely immuno-compromised, household contacts of children < 6 months old;
4) Public health emergency response workers, key government leaders.

Syndemic Prevention: Preparedness and Communication

Ultimately, how North Carolina responds to a severe influenza pandemic will depend upon countermeasures applied equitably to all who reside in the state. Since human beings are the vector and reservoir of the disease, neglecting or limiting resources to any sector of society (outside of established rationing protocols) does not make any epidemiologic sense. In addition, it is unrealistic to believe that society can mitigate the syndemic conditions of crowding, poverty, and the needs of special populations in advance of a rapidly moving pandemic wave. How do we approach this daunting challenge?

The impact of a pandemic or any disaster is proportional to how prepared individuals and society are. Preparedness is a shared responsibility that requires local, state, and federal public health systems to form a robust response network. Implementation strategies must build international and domestic, animal and human health, and public and private sector partnerships. Health, security, and economic protection are at stake, and all these risks should be managed cooperatively.

Syndemic prevention will rely on our ability to reach those outside of traditional networks, and to accomplish this, clear communication channels must be established to the public using trusted messengers. Health disparities during a disaster are preventable if people are prepared with accurate and timely information. How well public health is able to coordinate consistent messages, encourage people to take action steps to prepare now, and provide updates when new information becomes available will determine how we weather the perfect storm. **NCMJ**

COMMENTARY

Ethical Guidelines for an Influenza Pandemic

E. Kiernan McGorty, JD, MA; Leah Devlin, DDS, MPH; Rosemarie Tong, PhD; Natasha Harrison; Mark Holmes, PhD; and Pam Silberman, JD, DrPH

The major challenge facing public health officials is that they do not know when the next pandemic influenza will occur or how severe it will be. History indicates there are approximately three pandemics each century. Since the last outbreak of pandemic influenza occurred in Hong Kong in 1968-1969, many experts suggest that we are overdue for another influenza pandemic. They warn that it is not a question of *if* but *when* the next influenza pandemic will arrive.

The North Carolina Department of Health and Human Services, Division of Public Health (DPH) will have the responsibility of coordinating the public health response to an influenza pandemic. The goal of the public health response will be to reduce morbidity, mortality, and social disruption. In order to carry out its *North Carolina Pandemic Influenza Response Plan*,[1] DPH will need the assistance of health care workers and workers in other critical industries, such as public safety, food, and transportation. Certain individuals will need to work, despite risks of infection, to ensure that society can continue to function during the pandemic. To prevent the spread of disease, DPH may need to pursue social distancing strategies, such as quarantine, isolation, or closing of schools, which may at times conflict with individuals' civil liberties. In addition, DPH will be responsible for allocating scarce resources, such as vaccinations and/or antiviral medications. An outbreak of pandemic influenza will pose many ethical dilemmas (Table 1).

Table 1.
Ethical Dilemmas that May Arise During Pandemic Influenza

Scenario 1: Nancy has been a nurse in an orthopedist's office for 10 years. She heard the local hospital needs nurses to take care of pandemic influenza patients. Nancy wants to help, but she is concerned that she is unfamiliar with the type of care flu patients will require. She also is worried she might catch the flu and bring it home to her family. Does Nancy have a responsibility to work? What responsibility does society or the hospital owe to Nancy and her family to minimize the threat of infection?

Scenario 2: Bill is a cook at a diner and gets paid by the hour. During the height of the pandemic, the government has asked that people stay home from work for two weeks in order to prevent the spread of disease. Bill wants to stay home, but he needs his wages to pay his rent and he is afraid his boss will find someone else to do his job. If Bill responds to a governmental request that nonessential workers remain at home, what responsibility does government have to assure that his basic subsistence needs are met?

Scenario 3: The state has defined priority populations for pandemic influenza vaccinations, but the local health department does not have enough vaccines to cover everybody who falls into the priority populations. How should the health department allocate the limited vaccines among different priority populations?

During an influenza pandemic, it is likely there will not be enough time to discuss publicly the ethical tradeoffs inherent in critical decisions. It is impossible to anticipate all the critical decisions that may need to be made during an outbreak. Therefore, it is important to identify the ethical principles that should be considered when faced with difficult choices. Developing an ethical blueprint that incorporates public input in advance of a pandemic and later applying these recommendations during the crisis will help assure the public that decision makers are making reasoned responses to the crisis. Public acceptance of the ethical framework will increase the likelihood that society maintains order during the emergency.

DPH determined the need to develop an ethical framework from which to base implementation of its Pandemic Influenza Response Plan and asked the North Carolina Institute of Medicine (NC IOM) to help in this effort. The NC IOM convened a task force to explore some of the ethical issues the state may face during an influenza pandemic and to consider the rights and responsibilities of private organizations and individuals. The Task Force was comprised of different stakeholder groups including representatives of (1) public health and safety, (2) other governmental agencies, (3) health care providers,

---

E. Kiernan McGorty, JD, MA, is a Project Director at the North Carolina Institute of Medicine. Ms. McGorty can be reached at kmcgorty@schsr.unc.edu or 5501 Fortunes Ridge Dr, Suite E, Durham, NC 27713.

(4) business and industry, (5) the faith community, (6) advocacy groups, and (7) ethicists. In addition, NC IOM partnered with DPH and the Old North State Medical Society to host four regional forums in order to obtain public input into these difficult ethical decisions.

The Task Force weighed different ethical considerations in developing its framework, including (1) the need to ensure accountability, (2) equitable treatment among similarly situated individuals, (3) proportionality of actions, and (4) inclusiveness and timeliness in decision making. Government must act as the public steward, operate in a transparent fashion, and make decisions that are reasonable and responsive in order to garner the public's trust. It is important to foster cooperation and collaboration among different governmental agencies, the public and private sectors, and private citizens. The Task Force developed an ethical framework for guiding decision making in the following areas: responsibilities of and to health care workers and other critical workers, the balance between the rights of individuals and protection of the public, and prioritization and utilization of limited resources. The Task Force's report will be available shortly at www.nciom.org.

> *"...experts suggest that we are overdue for another influenza pandemic. They warn that it is not a question of if but when the next influenza pandemic will arrive."*

Responsibilities of and to Health Care Workers and Other Critical Workers

An influenza pandemic would have widespread, significant effects on North Carolina's workforce. During an influenza pandemic, 40% of workers may be out ill, creating challenges for businesses and organizations to maintain normal operations. However, critical industries, such as food, utilities, and transportation, will need to continue functioning to provide society's essential goods and services during a pandemic.[2]

North Carolina's critical industries have experience maintaining essential functions during natural disasters, such as hurricanes and ice storms. However, an influenza pandemic would place unprecedented stresses on the ability of industries to function due to its duration, likely limited outside support, lack of workers, and risk of secondary infection. An influenza pandemic may consist of multiple waves lasting eight weeks or longer; in contrast, the immediate impact of many natural disasters is shorter in duration. Also, natural disasters often impact only a limited area, allowing other communities to provide support to the impacted area. In contrast, a pandemic likely will impact most, if not all, of the state and country, limiting the availability of outside support. Further, it may be difficult to find sufficient workers in general. During a pandemic, many workers may become infected with the virus and, as a consequence, will be unable to work. A pandemic also will lead to high absenteeism because workers may fear contracting the flu and may need to take care of sick family members. Thus, North Carolina's critical industries are likely to face unprecedented challenges in the event of a particularly virulent pandemic.

An influenza pandemic in North Carolina would be especially hard on the health care system. The health care system would face tremendous challenges in providing appropriate care for thousands of patients with acute, life-threatening infections, as well as continuing to provide care to others who are ill or injured. North Carolina might experience as many as 1.6 million doctors visits and 29,000 hospitalizations during one wave (ie, 8-12 weeks) of a moderate pandemic, although the numbers could be eight times higher in the event of a particularly virulent pandemic (Table 2).

Table 2.
Impact of Regular Flu versus Projected Impact of Pandemic Flu in North Carolina

	Regular Flu	Moderate Pandemic Flu
Doctor visits	750,000	1.6 million
Hospitalizations	6,000	35,000
Deaths	1,100	7,900

To get industries thinking about operational issues that could arise during an influenza pandemic, the Task Force recommended that **employers and contractors design business continuity plans to prepare for events such as a pandemic.** Plans should identify those positions that are critical to the continued operation of the industry and determine whether jobs need to be performed on-site or can be adequately performed off-site. Workers who would be required to work should be made aware of the expectation to work during events such as an influenza pandemic upon hiring or upon the adoption of the plan. Employers and contractors should specify the supports that will be available to the critical workers to enable them to work, as well as the sanctions that will be enforced if critical workers fail to show up for work during a time of crisis.

Despite the difficulties that will arise during an influenza pandemic, critical industries will need to continue providing their essential goods and services during an influenza pandemic. Workers in critical industries should acknowledge a responsibility to continue to work in times of crisis so that essential goods and services are provided to maintain the functioning of society. In general, the enhanced obligation to work during a crisis stems from three main responsibilities: professional, employment, and general human responsibilities to care for others (Table 3). Health care professionals have an added obligation to provide

Table 3.
Responsibilities of Critical Workers to Work

Professional Responsibilities: Licensed professionals in critical industries have a professional obligation that results from their choice of profession. This obligation is based largely upon the special expertise of licensed professionals, the unique roles granted by reason of licensure, and the authority to self-regulate the profession.

Employment Responsibilities: In return for their salary, employees are expected to meet their job responsibilities and to support the work of the organization. Society has an expectation that critical industries will continue to function in the event of a public health emergency. Businesses can only operate with sufficient staffing. Thus, workers who have chosen to work in a critical industry are assuming a heightened responsibility to continue to work even during times of crisis. In addition, employees may have a formal contractual obligation that specifies their duty to work during emergencies.

Human Responsibilities: The welfare of everyone in the community is enhanced when all its members recognize their moral responsibility to assist each other in times of great need.

care because of their professional license and because their ability to provide care is greater than that of the public. By freely choosing that profession, health care personnel have assumed an ethical obligation to act in the best interests of the ill and to assume a proportional share of the risks to which their professions and/or employment setting expose them. As a result of these obligations, the Task Force recommended that **workers in critical industries have an ethical responsibility to perform their regular employment duties during an influenza pandemic *and* to assume new responsibilities for which they are trained, as long as their actions will not lead to greater harm than the failure to act.** Although workers in critical industries may have enhanced obligations to work during a crisis, the Task Force also agreed that their responsibility to work must be balanced against other considerations, including their own safety and their responsibility to care for family members who are ill.

Critical industry employers and contractors, as well as government, have a reciprocal responsibility to protect and support workers to enable them to continue working during an influenza pandemic. Depending on the nature of the influenza virus, certain workers in critical industries may face disproportionate health risks. Workers may be asked to work longer hours or under more stressful work conditions than generally allowed. If critical organizations are short-staffed because of increased demand, worker illnesses, or absenteeism, other workers may be called upon to provide services outside their normal scope of work. The Task Force determined that **government and employers have a reciprocal responsibility to ensure that workers are protected from pandemic influenza-related harm and liability to the extent possible.** For example, workers in critical industries at increased risk of infection should receive priority for available personal protective equipment, vaccinations, antiviral drugs, and other nonmedical control measures. All critical workers should receive behavioral health services and other goods or services needed to enable them to work. In addition, employers have a responsibility to ensure that workers are appropriately trained to fulfill the tasks assigned to them during a crisis. Government should also provide health care personnel and organizations with qualified immunity from liability, in order to encourage health care professionals to work under less than ideal conditions (eg, limited resources, lack of health care professionals, the need to assume new responsibilities).

Balancing the Rights of the Individual and the Need to Protect the Public

Public health leaders are specifically charged with promoting, protecting, and improving the overall health and well-being of the population during emergencies. In a pandemic, public health officials may need to implement measures to limit illness and death or to slow the progress of the epidemic that could conflict with personal liberties and individual privacy. These measures include isolation, quarantine, or other forms of social distancing. Public health officials may require individuals with the influenza virus or who have been exposed to the influenza virus to remain at home, in temporary housing, or in a health care facility to prevent the spread of the disease to others. Isolation and quarantine are most effective in the early stages of an influenza pandemic when few people have been infected. Government should ensure that people who are subject to isolation or quarantine have their basic necessities met. To accomplish this, the Task Force recommended that **all levels of government ensure that individuals who are affected by isolation or quarantine orders receive needed assistance in accessing resources to meet their basic needs while they are subject to restrictions.**

Other types of social distancing measures may be necessary once the influenza virus is more widespread. The goal of social distancing measures is to reduce contact with potentially infected individuals. Such measures may include, but are not limited to, closing schools or day care centers and asking churches to suspend their normal services. Social distancing measures may also include voluntary requests that employees stay home or work off-site and that people take care of sick family members at home, rather than bring them to overcrowded health care facilities. For the individuals and families involved, restrictions on personal liberties can pose significant difficulties, such as loss of income and social support. Business and industry may be affected by the loss of workers or other sources of income.

Safeguards are needed to ensure that infringements on personal liberties are proportional to the need and are applied equitably to all similarly situated individuals. Thus, the Task Force recommended that **government leaders implement restrictions on personal liberties deemed likely to be effective to limit illness and mortality in the context of a pandemic, but limit these measures to the least restrictive alternative reasonably necessary to protect the public.**

Every attempt should be made to ensure the public is aware of the need for pandemic-related restrictions of individual liberties. Informing the public about the reasoning behind these social distancing measures likely will improve compliance. The Task Force recommended that **the North Carolina Department of Health and Human Services partner with local health departments to develop a public outreach campaign, ensuring that the public is well-informed of the potential need to use community mitigation efforts or to prioritize the use of limited resources.** During a pandemic, it will be critically important that accurate health information be conveyed to the public in a timely manner to minimize the spread of misinformation or panic. Thus, the Task Force recommended that **the Governor's Office, in conjunction with the North Carolina Department of Health and Human Services and Crime Control and Public Safety, develop a coordinated communications plan to ensure that the public obtains timely, accurate, and continuous information about the influenza pandemic.**

Prioritization and Utilization of Limited Resources

In crisis situations, citizens often look to the government to manage the allocation of essential limited resources. Many essential resources are likely to be limited in the event of an influenza pandemic. In particular, there will be a sudden increase in demand for medical supplies, such as personal protective equipment, vaccines, antivirals, and hospital beds. These demands, as well as the large numbers of ill persons, will stretch the health care system's limits. Furthermore, large numbers of the population may be ill at any given time during the pandemic, making it difficult to maintain the normal functioning of many critical industries. As a result, there may be insufficient supplies of food, fewer essential services provided, and restrictions on certain utilities. Deciding who should have priority to receive limited resources during an influenza pandemic will be among the most difficult ethical dilemmas facing government officials, policy makers, and health care providers. These allocation decisions should be based on widely accepted, reasonable criteria. The Task Force also recognized the importance of individual responsibility for pandemic influenza planning, recommending that **individuals reserve supplies and have plans to care for family members during a pandemic.**

The priority given to the allocation of certain preventive resources (ie, primary prevention), such as vaccines, may not be the same as the priority that should be given to the allocation of limited health care resources needed for a patient who is already sick (ie, secondary treatment), such as ventilators or hospital beds. One way to conceptualize the allocation decisions is to classify medical resources as either *pharmaceutical* or *nonpharmaceutical.* Given this framework, the Task Force recommended a prioritization system recognizing different goals for different resources (Table 4). To the extent possible, individuals who do not make the priority list for life-sustaining care should be provided palliative care.

Nonpharmaceutical primary prevention resources will be critical in the early stages of a pandemic when vaccines are not yet available. Personal protective equipment and other nonpharmaceutical prevention resources may be the only way to minimize the likelihood of contracting the virus. As a result, the Task Force recommended that these limited resources be first allocated to health care workers or other critical workers who are at increased risk of contracting the disease and to private individuals who are at increased risk of spreading the disease. Once vaccines are available, the Task Force agreed that priority should be given to health care workers or other critical workers who are increased risk of contracting the disease. The Task Force recommended that priority for antivirals be given to those at highest risk of dying if they get sick and to critical workers so they can recover and return to work. Priority for curative resources should be given to those most likely to benefit.

To avoid the appearance of nepotism or favoritism, the Task Force recommended that **disease control and medical decisions be based on clinical factors, the epidemiology of the spread of disease, and assuring the functioning of society.** Decisions about which people to treat and what services to provide during an influenza pandemic *should not be made* based on socio-economic or other factors unrelated to these criteria.

Table 4.
Goals to Guide the Allocation of Limited Health Care Resources

	Primary Prevention	**Secondary Treatment**
Nonpharmaceutical Intervention	Examples: personal protective equipment Goals: assuring functioning of society and minimizing the spread of disease	Examples: ventilators, hospital beds Primary goal: minimizing illness, hospitalizations, and deaths
Pharmaceutical Intervention	Examples: vaccines Primary goal: assuring the functioning of society Secondary goal: minimizing the spread of the disease	Examples: antivirals, antibiotics Priority goal: minimizing illness, hospitalizations, and deaths Secondary goal: assuring the functioning of society

Conclusion

In major emergencies, decisions have to be made in a timely manner under high stress conditions and often in the face of incomplete information. This is the situation the state will most likely confront in the event of an influenza pandemic. Decisions by the federal government, state agencies, health care professionals, emergency management responders, and other critical institutions will need to be coordinated and will directly affect large numbers of residents. Under such conditions it will be important to have a set of ethical principles that serve as the blueprint to the coordinated response.

The work of the NC IOM/DPH Task Force on Ethics and Pandemic Influenza Planning encouraged stakeholders from a variety of groups to consider and discuss the ethical dilemmas that are likely to arise in the event of an influenza pandemic. Advance notice of these dilemmas may help people adjust to and prepare for the difficult decisions that may affect them later. However, the unpredictable nature of influenza pandemics requires that individuals, industries, and governmental entities continue to examine and adapt their roles in influenza pandemic preparation. **NCMJ**

Pandemic Flu:
Why Faith Groups Must Care

J. George Reed

It's not time to panic, but it is time to plan. In 1918-1919, Spanish flu spread around the world. In the United States, more than 500,000 people died. Most health professionals agree that the world will face another flu pandemic at some point in the future. It could be H5N1, the strain of avian flu currently spreading around the world in birds, or it might be some later flu. But it will come.

Put aside for now the question of whether it's this bird flu and it hits relatively soon or another strain of flu many years hence. I want you to think about the potential impact of a pandemic.

One of the things that distinguishes flu pandemic from regular flu is that people will have little or no immunity to it. Health care systems could be overloaded and medical supplies will be in short supply. A flu disaster would be unlike a natural disaster. First, the area impacted would be much wider. North Carolina wouldn't be sending volunteers to Louisiana, nor would we be receiving help from other states. Second, the duration of the disaster itself, not just the response, would be much longer. A pandemic could come in waves over 12 to 18 months. There could be bans on travel, closings of schools, cancellation of events, and disruption of businesses.

Estimates are that as much as 20% of the population could get the flu and as many as 40% of workers might stay home at its peak because they are sick, a family member is sick, or they don't want to risk exposure. Think of the impact these absences would have on a community's infrastructure: utilities, water purification systems, food supplies and preparation (including transportation of food to groceries and restaurants), trash pickup, public transportation, medical care, and availability of prescription drugs.

An influenza pandemic, whenever it comes, will also disrupt church life and raise serious questions for churches and their leaders. Consider the potential impact on regular worship services; communion/Eucharist; hospital visits by clergy and laity; funerals, grief counseling, and other pastoral care; committee meetings and other church gatherings; child-care centers, soup kitchens, food pantries, and free clinics; national and international meetings; and missions trips.

> *"So, what should the faith community be doing? Our first step is still to get flu pandemic on our radar screens."*

And, some of the hard questions for churches:

- What is the duty of clergy regarding parishioners sick or hospitalized with the flu: to visit them as a sign of God's presence or to not visit so as not to spread the flu?
- In deciding whether to cancel activities, should the church act more quickly in order to set the example in preventing the spread of disease or less quickly because of the importance of gathering to worship during a crisis? Should parishioners help others, but risk spreading flu?
- Who makes decisions about canceling services or altering communion? Would a congregation follow a public health recommendation to limit services or wait until it was mandatory?
- Are there essential services within the church that must be continued during a pandemic?

---

George Reed is Executive Director of the North Carolina Council of Churches and was a member of the NC Division of Public Health and NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning. He can be reached at greed@nccouncilofchurches.org or 1307 Glenwood Avenue, Suite 156, Raleigh, NC 27605-3256.

Also, think about some of the justice issues involved:

- Would lower-paid workers (support staff at hospitals, for example) be required to show up for work while higher-paid workers could stay home and telecommute? What happens to hourly-wage workers if businesses must close?
- In a time of greater rationing of health care, would poor people get to see a doctor, be admitted to a hospital, have use of a ventilator? How would limited supplies of vaccines and antivirals be allocated?
- What would happen to poor people who didn't have the resources to stockpile food and water, if those delivery systems were affected?

So, what should the faith community be doing? Our first step is still to get flu pandemic on our radar screens. Early last year, one state's council of churches asked bishops and other leaders about meeting with health officials to discuss a flu pandemic. Only two out of more than twenty expressed any interest. We all have a lot on our plates, but as one public health person pointed out, "If we try to make plans during the crisis, we're not planning, we're improvising."

Second, we must be at the table in the development of contingency plans. The state's public health and emergency planning agencies are hard at work and looking for community allies across the state.

Third, we must have firm plans for our congregations and judicatories. What supplies should be stocked now, or with the first news of the spread of flu among humans?

What can be done to help families make plans? The federal government has established checklists for a variety of groups, including faith communities. See them at www.pandemicflu.gov.

Fourth, we must be well enough involved and informed to be a voice for moral and ethical decision making, helping to balance the community's needs with our calling to treat all of God's children equally. In the event of a pandemic, we should also use our credibility in the community to be a source of good and true information.

Let me be clear: As of this writing the H5N1 avian flu has not been found in North or South America, even in birds. It has shown up in only about 274 humans worldwide (though more than half of them have died).[1] Almost all of the human cases were caught from birds, not other humans. The risk is if H5N1 mutates in a way that enables it to be transferred easily among humans. Then, because we have virtually no immunity, the world would have a pandemic, one that could spread rapidly around our interconnected globe.

The difficulty in raising these questions is that no one wants to spread panic. I feel a bit like Chicken Little ("The sky is falling") in writing this. But we are better prepared to deal with a crisis if we are informed and have made careful plans. Otherwise we could find ourselves improvising in the midst of a worldwide health disaster. **NCMJ**

Shall We Gather By the River? Yes… No… Maybe So…

Paul L. Anderson

Many years ago, I would look into a black and white television and watch Andy Griffith sing while he sat on the front porch with Aunt Bee, Barney, and other characters from this timeless television show. Since then, many things have drastically changed in our world. We all have digital high definition means of viewing the historic television. Most of us are streaming television shows and or other visuals through our handheld, state-of-the-art multimedia devices.

Numerous facets of our lives have changed, while other things almost remain the same. The classic example is the manner in which faith groups worship their concept of God. The three basic faith groups that consider themselves monotheistic, Judaism, Christianity, and Islam, are still "gathering by the river" when they come together to worship. It is that sense of gathering that is essential to their "life giving stream," or the faith that carries them through the good times and bad. It is through the practice of fellowship, or sharing our faith with one other, we believe that we are "fellowshipping with the Devine—God."

My faith tradition is based upon the concept of gathering together. I am a Christian. It is the basic Christian belief that whenever two or three people are gathered in the name of Jesus, God's presence is manifest through the Holy Spirit. It is through fellowship with other believers that true worship of God occurs. This fundamental practice would drastically be altered if a flu pandemic invades our society.

An influenza pandemic would alter the entire context of the Christian faith and most other faith groups. The concept of a gathered assembly is predominant through all of Christianity. It starts when a child is born and continues through life cycles culminating with end of life rituals.

When a child is born, the Christian community awaits the day the child is blessed or baptized, or attains the blessings of God and the community in a service of worship. The parents, grandparents, aunts, uncles, and family friends all gather at the place of worship to witness this rite of entrance into the culture and receive blessings of both God and "the church," the gathered assembly. It is during this service that the child is either blessed or baptized by the priest or the pastor. This practice is essential in the belief structure of Christians. If this practice is omitted or deleted, the faith of parents and children is somewhat uncertain. This is similar for many other life cycle faith events. Would a flu pandemic eliminate the visitation of priest and laity to the hospitalized? Should the many acts of mercy such as soup kitchens, homeless shelters, and safe havens for the abused and fragile be dismissed? The religious community needs to ask itself the question of how will we justify not risking our lives for the benefit of others, which is the true essence of self sacrifice.

An influenza pandemic would interrupt the entire ritual of the gathered assembly, from birth to last rites in burial. Whenever the Christian community is not gathering, is it in willful disobedience to one of its commands by God? Most religious leaders have yet to engage in this meaning dialogue because it will completely shake the foundations of organized religious systems as we know them today.

The question is: How will the religious community manage a flu pandemic and maintain true faithfulness to the Holy Book? I am not sure how this flu pandemic will modify the view of God's requirements in acts of mercy and justice. Shall we gather at the river since our ultimate quest is to be with God? If our ultimate quest is to be God, do we continue as we have in the past and accept death as fate? This is the true essence of the real question.

Reverend Paul L. Anderson is Pastor at Baptist Grove Church. He was also a member of the NC Division of Public Health and NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning. COMMENTARY

Eliminating Injustice Toward Disadvantaged Populations During an Influenza Pandemic

By George L. Saunders III, MD; Thea Monet, MAEd

In the spirit of its founders, A.M. Moore, M.T. Pope, L.A. Scruggs, and J. Williams, Old North State Medical Society (ONSMS) has dedicated itself to equity in health care, equal opportunity for black medical professionals, and equal care for minorities, including blacks, and very poor patients. The organization, which represents the interests of more that 1,200 minority physicians in North Carolina and thousands of patients from all walks of life, has been a voice for those without means for 120 years. In many instances, its members have provided health care when few or no other options were available. For members of Old North State Medical Society, finding ways to improve access to appropriate health care has required bringing truth to the phrase "with justice for all." Finding ways to infuse *justice* into protecting the health and wellbeing of those most easily overlooked, deliberately untouched and ignored, minimally regarded, and likewise treated has been one of our greatest challenges. ONSMS has not wavered in its commitment of "assuring equity in the delivery of health care to all people."

> *"Can there be justice for all in the midst of a flu pandemic outbreak?"*

Today, we are asked very necessary and important questions including:

- What might be done to eliminate injustice toward disadvantaged populations during an influenza pandemic?
- What policies and plans need to be in effect to ensure that those with limited incomes have what they need to stay healthy during a flu pandemic?
- What will happen to people and families who cannot stockpile food and water in preparation for a pandemic and the thousands of North Carolina children receiving their best or perhaps only meals through free breakfast and lunch provided at schools? When a flu pandemic emerges and schools close, what will they do?

We do not have all the answers, however, there are cornerstones for preparedness that can strengthen us despite racial, ethnic, educational, health, and financial disparities. First, a pre-emptive action leading to promoting justice for the disadvantaged during an influenza pandemic involves gathering together the grassroots leaders of diverse racial, ethnic, economically stratified, disenfranchised, vulnerable, underserved, and underrepresented groups. Community physicians, pastors, community action program workers, local business leaders, particularly those providing personal care to residents like barbers, beauticians, and elder leaders, are key to any meaningful efforts to raise awareness about a pandemic crisis. They are also potentially the most valued teachers. Assessing their perceptions and expectations of community needs during an influenza pandemic represents a first step in the process of winning their long-term commitment to support local community preparation for flu pandemic preparedness. Engaging leaders who will be respected, followed, trusted, and favored by local community members will be integral to the best possible decision making or planning for and with communities across the state. Self-determination and determination in the interest of one's community engenders internal strengths. That strength will increase potential for compliance with rules of the day. Nothing can be more defeating than feeling helpless to provide assistance and guidance in a situation during a period of panic and absence of confidence in favorable outcomes.

Building bridges that forge partnerships and alliances between grassroots leaders, government, and public and private resource providers is a second key for enabling preparedness and eliminating injustice. Communities have to understand the inherent challenges posed during a pandemic long before it arrives. How vaccine is distributed, how ventilators are assigned, where priority is placed and where it is not are issues

---

George L. Saunders III, MD, is President of the Old North State Medical Society. He can be reached through the ONSMS website: www.onsms.org. or 114 W Parrish Street, Durham, NC 27701.

Thea Monet, MAEd, is Executive Director of the Old North State Medical Society.

that should be shared with the community. Understanding the implications of these shortages enables fuller response and commitment to behavior that protects against and minimizes further spread of disease. When community leaders understand the challenges that await us during an influenza pandemic, they can actively promote preparedness and cautious behavior through their organizations' activities and venues. This action can save lives during an outbreak. Community leaders can also couple preparedness messages with other health improvement messages that remind us of the importance of vaccinations and getting medical care early for oneself and loved ones.

A pivotal key in eliminating injustice toward members of underserved communities is having community leaders and health organization leaders collaborate with one another and increase community representation on committees, panels, task forces, and planning groups tasked with setting guidelines that will prepare us for the challenge that lies ahead. Involvement in policy development can increase community access to the array of resources that will be needed during the influenza. The goal is to keep people fed, protected, and informed about where to turn and what to do next to minimize the threat of further contamination. By getting individual and families, especially those who are historically undeserved and discriminated against through this event safely, we reduce health disparities that can occur during a pandemic.

Reducing injustice involves developing protocols for resource distribution that reflect knowledge of the needs of special populations. Acknowledging intent to be fair and equitable in providing resources to communities will reduce the incidence of real and perceived instances of injustice. Public discussion about potential for injustice toward disadvantaged populations, whether on radio, television, or in the newspapers, will greatly deter injustice. Public buy-in on limiting and reporting any evidence of injustice in the treatment of people can also have a positive effect. Statements from public officials announcing how important it is to exercise just and equitable distribution of resources and services during an influenza pandemic can also curtail injustice. All off this becomes a cornerstone to getting us through the emergency because many people of color feel a heighten sense of distrust in public response systems, government, and the established rules of the day. The justified memories of unequal treatment in all areas of life may dominate.

All communities need information about the potential for an influenza pandemic and the need to prepare in advance for such an emergency. Early outreach is important because avenues of communication with public health and government may be limited. It is suggested that caution be used to avoid inciting panic in the general public. However, people must be informed and aware. Therefore, selecting community leaders to provide such messages will likely minimize premature panic.

Community leaders need the benefit of early training and support. They will be integral to squashing rumors, preventing stereotyping, and restoring a sense of order if communication breaks down.

Can there be justice for all in the midst of a flu pandemic outbreak? Neither children, the disabled, those who cannot stockpile food, those who do not speak English, nor the elderly should be hungry; nor should they have unequal access to treatment during a flu pandemic. Treatment, prophylaxis, and basic needs (ie, food, shelter) should be provided in a nondiscriminatory fashion. The following guidelines will help prevent disparities during a flu pandemic.

- Make all resources available on the basis of a distribution plan that permits fair distribution to all. The disenfranchised and people of color should have an opportunity to contribute to the distribution plan. It is imperative that their voices be heard from the beginning of the planning process and that they understand the resource limitations that will exist during this crisis.
- Develop a process to immediately correct misallocation of any resource(s). Ensure that the public can witness and validate the correction(s). This includes eliminating any known obstacles and developing distribution formulas that adjust for social disparities, financial and economic disparities, mental health disparities, and primary health disparities.
- Prepare culturally relevant materials to educate the broader public about this situation and techniques for reducing its impact. All materials should be current and easy to read and understand. They should also emphasize issues important to disadvantaged individuals and those with preexisting health conditions.
- Encourage public health departments to invite community leaders to the planning tables to share in local discussions on protocol development and to provide feedback from their community's perspective.
- Invite every community organization, public and private, to assist in planning for and meeting the actual and anticipated needs of disadvantaged populations in their communities. Make every possible effort to identify available resources for use during a crisis and see that community leaders have ways to access resource providers.
- Engage community members to assist others in identifying instances of prejudicial thinking, biased behavior, and acts of unfair distribution. Provide them with information about reporting such instances through the appropriate channels in time for effective interventions.

Combining our strengths, pulling together, and preparing based on these guidelines will help prevent disproportionate challenges to disadvantaged populations. However, we must recognize that such injustices will still occur and we must identify and rectify such problems.

An example of such uniting and recognition is the collaborative work of the North Carolina Division of Public Health (DPH), Old North State Medical Society, and a number of community organizations. Those organizations include the National Association for the Advancement of Colored People (NAACP), North Carolina Commission of Indian Affairs, El Pueblo, the Mexican Consulate, Alliance of Black Elected Officials, North Carolina Institute for Economic Development, North Carolina General Baptist State Convention, Webb Patterson Inc, JMG

Marketing, Brad Thompson and Associates, NC Mutual Life Insurance Company, and numerous other community-based public, nonprofit, and private organizations. These organizations have a steadfast interest in uplifting the community and protecting its members in every possible kind of way. Our collective interest brought us together to plan for these issues.

The Old North State Medical Society and DPH are partnering through a contractual relationship to guide the development of statewide strategies to reach vulnerable populations, as mandated in the funding guidance. They will implement a health disparities prevention project focusing on flu pandemic planning, preparedness, and response in African American, American Indian and Hispanic/Latino communities. Furthermore, ONSMS will bring to bear the leadership, vision, perspectives, knowledge, skills, abilities, and commitment of the state's African American medical community to assist the Division of Public Health in assuring that African American, American Indian, and Hispanic/Latino communities in North Carolina are reached in the event of a flu pandemic and that the communities are not disproportionately or adversely affected by the outbreak.

This action gives promise for achieving justice for all through the aforementioned guidelines. It also directly responds to the need for the development of culturally relevant documents and culturally appropriate involvement of minority communities in disaster planning, preparedness, and recovery, as recommended by the August 2005 report prepared by the National Center for Disaster Preparedness.

The partnership between DPH and the ONSMS is establishing a Disparities Prevention Advisory Committee and developing an action plan to promote, facilitate, and implement at least four pilot projects that address flu pandemic planning, preparedness, and response in African American, American Indian, and Hispanic/Latino communities. The partnership will also identify barriers to and facilitators for communicating flu pandemic-related risks to African American, American Indian, and Hispanic/Latino communities and link and facilitate communication and interaction between key leaders in those communities and public health leaders who are engaged in flu pandemic planning.

This work will also involve conducting three events in the African American, American Indian, and Hispanic/Latino communities. Feedback from these events will enhance public health's understanding of how to meet community needs in the event of a flu pandemic. The final report from this collaboration will include recommendations for next steps in preparing for and responding to the needs of racial and ethnic minority communities during a flu pandemic.

Ensuring fair and equitable distribution of resources or "justice for all' is possible when people are educated about the facts, included in developing protocols and response plans, while respecting and valuing those affected as problems arise. The answers to the primary questions reside in the continuing commitment of leaders across the spectrum to collaborate in the interest of full and equitable distribution of goods and services during an influenza pandemic. **NCMJ**

COMMENTARY

Manufacturing a Flu Vaccine

Marguerite Donoghue Baxter, RN, MSN

Vaccines are considered the most cost-effective public health intervention, saving millions of lives every year by preventing major human diseases. The new Novartis Vaccine and Diagnostics Division is on the vanguard of vaccine development to prevent seasonal flu and, potentially, also pandemic influenza. New research techniques and manufacturing technologies have sparked a revival and strong double-digit growth in this sector of the pharmaceuticals industry, as well as provide life-saving intervention for people most at risk for preventable viruses.

Despite availability of safe and effective vaccines, seasonal influenza causes millions of infections and kills an estimated 250,000 people worldwide every year. Health authorities in many countries are preparing to increase coverage rates for seasonal flu vaccine to comply with a recommendation from the World Health Organization (WHO) to reach 75% coverage of at-risk groups—the elderly and people with chronic diseases—by 2010. The United States is leading the way, recommending seasonal flu vaccinations for all Americans over the age of 50, children from the age of two months to five years, and other at-risk groups, including health care workers.

> *"Despite availability of safe and effective vaccines, seasonal influenza causes millions of infections and kills an estimated 250,000 people worldwide every year."*

During the 20th century, there were three pandemics, or simultaneous worldwide epidemics of influenza. The 1918 "Spanish flu" killed more than 20 million people. Subsequent pandemics in 1957 and 1968 were less severe but also killed millions around the globe. It is the concern about future pandemic influenza that has mobilized health regulators to encourage manufacturers to improve the development and production of vaccines in advance of an outbreak. As such, production capacity is expected to rise sharply by 2009—yet the WHO acknowledges that the projected rise in capacity for seasonal flu vaccine will not reach levels sufficient to serve the worldwide population in case of a pandemic. Newer technologies, however, can help boost production and availability of the necessary vaccines.

Cell Culture-Based Influenza Vaccines

Cell culture-derived influenza vaccines (commonly referred to as "flu cell culture" vaccines) use modern biotechnology cell cultures rather than chicken eggs for primary production. Current egg-derived vaccine production requires several months of logistics for ordering and receiving eggs. This lead-time can hinder the response to unanticipated demands such as the discovery of pandemic strains, production failures, and seasonal influenza virus strain changes. In contrast, flu cell culture production enables flexible, faster start-up of vaccine manufacturing, and is independent of the availability of eggs, providing a particularly important advantage in the event of an influenza pandemic.

Also, cell culture vaccines are noninferior to the traditional alternatives. In one large-scale Phase III study conducted in Poland during the 2004-2005 influenza season, cell culture-derived influenza vaccine was shown to be as effective as egg-based vaccines in provoking an immune response (immunogenicity) against influenza.

Dispensing with eggs in production also promises benefits to people who are allergic to eggs. Currently, strains of seed virus used in seasonal influenza vaccine are selected partly because of their ability to grow well in eggs. This egg adaptation will not be needed with cell culture-based influenza vaccines, which could translate into better efficacy of seasonal vaccines by more closely

Marguerite Donoghue Baxter, RN, MSN, is Vice President for Government Affairs at Chiron Corporation, Novartis Vaccines & Diagnostics, Inc. She can be reached at 4560 Horton Street, Emeryville, CA 94608-2916 or Marguerite_Baxter@chiron.com.

matching the vaccine with the influenza strain in circulation.

In July, 2006, Novartis announced plans to build the first cell culture-derived influenza vaccine manufacturing plant in the United States at a new site in Holly Springs, North Carolina. In parallel, Novartis is making additional investments to expand capacity for flu cell culture vaccine production in Marburg, Germany. Novartis Vaccines submitted the first application for a flu cell culture vaccine to European regulators in June of last year, following successful completion of Phase III clinical studies. In the United States, clinical trials of the cell culture influenza vaccine began in 2005 and are ongoing.

The United States government offered key support for the new technology when the Department of Health and Human Services (HHS) awarded Novartis a contract of up to $220 million to support development and manufacture of cell culture-derived influenza vaccine in the United States. The contract is part of a larger HHS initiative to expand domestic infrastructure for influenza vaccines, as well as ensure domestic capacity to produce 600 million doses of pandemic influenza vaccine within six months of a pandemic declaration. Part of the HHS contract will support planning and equipment for the new cell culture-based influenza vaccine manufacturing plant in North Carolina.

Pandemic Preparedness

Cell culture technology represents a potentially critical tool to boost production capacity, and thereby help to reduce the current gap between potential vaccine demand and supply anticipated during an influenza pandemic. The WHO's latest action plan for a global influenza pandemic warns that potential vaccine supply today is "several billion doses short of the amount needed to provide protection to the global population."

A new influenza strain, known as H5N1, is spreading through bird populations in Asia, Africa, and Europe. Only 244 human cases have been recorded so far, but, chillingly, the fatality rate has been more than 50%. Though avian flu remains primarily an animal disease, if the virus develops the capacity for sustained, efficient human-to-human transmission, it could spread quickly around the globe.

In 1999, Novartis Vaccines was the first manufacturer to successfully test an experimental vaccine against a variant of the H5N1 influenza virus following the initial outbreak of avian flu in Hong Kong. Ironically, because the H5N1 strain that caused the outbreak was lethal to the egg cells that are needed in egg-based production, Novartis Vaccines was forced to use a closely related H5N3 strain to produce its vaccine.

That initial H5 vaccine also included a proprietary adjuvant called MF59. An adjuvant is a substance added to a vaccine to boost the body's immune response against the vaccine's active constituent, called the antigen. In 2003, a follow-up study showed that the adjuvanted H5 vaccine also offered cross-protection against H5N1 strains that have circulated across Asia since the initial Hong Kong outbreak.

Importantly, the use of an adjuvant could provide effective protection at lower doses than nonadjuvanted vaccines, potentially enhancing production capacity and supply in the event of a pandemic. The WHO has proposed clinical studies of H5N1 vaccines, including MF59 and other adjuvants with a proven safety record in humans, as part of its global pandemic action plan.

The Novartis cell culture-based pandemic vaccine is still in preclinical development but clinical trials are expected to begin this year. In Europe, Novartis was one of several vaccine producers in 2006 to file "mock-up," or stand-by, registrations for a pandemic vaccine that would enable companies to begin production immediately if the WHO declares a pandemic. Novartis has also submitted a dossier to the European Medicines Agency for a H5N1 prepandemic vaccine that could be sold freely to private individuals and companies, in addition to governments and other payors.

Meanwhile, Novartis Vaccines has received orders from the United States and United Kingdom to supply prepandemic H5N1 avian influenza vaccine—in some cases containing MF59 adjuvant—for national stockpiles.

Conclusion

Cell culture-based influenza vaccines provide greater reliability, faster production, and more accurate viral strain matching. As health agencies prepare for potential pandemics of influenza, new strains of seasonal influenza and avian influenza, this cutting edge technology will be of critical importance to the health of at-risk populations. **NCMJ**

COMMENTARY

Likely Ethical, Legal, and Professional Challenges Physicians will Face During an Influenza Pandemic

Janelle A. Rhyne, MD

Health care workers are some of the most integral front-line responders during natural and biological disasters. As such, they often face serious risks to their health and well-being. Many physicians volunteer to assist during crises because they recognize the value of their skills to the needs at hand. However, other physicians are reluctant to expose themselves, and by extension, their families, to such risks. In preparing for a public health crisis like an influenza pandemic, it is important to take steps to eliminate or minimize the risks physicians will incur if they choose to assist with serving the needs of the population.

Events of recent years provide examples of inadequate measures to properly minimize risks to physicians. The outcomes of these situations illustrate the importance of preparedness for public health emergencies and natural disasters. In 2005, Hurricane Katrina hit the Gulf Coast Region and in its aftermath, 6,000 physicians left the area. This led to a need for additional medical personnel to travel to the region to assist with the injured and deceased. Furthermore, many of those who left have yet to return and some have no plans to do so.[1] Now, much of the region has a shortage of providers, which may adversely affect reconstruction efforts.

> *"If, for the public good, society expects physicians to voluntarily expose themselves to potentially lethal risks, what ought society provide physicians in return?"*

The 2003 Severe Acute Respiratory Syndrome (SARS) outbreak in Canada offers another example of risks to health care professionals and the challenges faced in minimizing their risks. Forty-three percent of those falling prey to SARS were health care workers with a case fatality rate of about 15%.[2] As a result, staffing at Canadian facilities treating SARS patients became a problem because many providers did not want to expose themselves to danger. In addition to the health risks, 49% of SARS health care workers reported social stigmatization and 31% reported ostracism by family members.[3] Regardless of these physical, social, and emotional challenges, failure to report to work resulted in permanent dismissal of hospital staff. As a result, many health care workers voluntarily left the profession for new careers rather than expose themselves and their families to risks associated with caring for patients with potentially lethal infectious diseases.

Ensuring a positive work environment for physicians is important because a recent analysis published in *Health Affairs* projected a shortage of physicians that will grow even worse within the next fifteen years.[4] Therefore, developing a plan to minimize the stresses that could affect physicians during a public health crisis is more critical than ever. Furthermore, it is important to remember that practicing physicians and other health care workers are not the only ones providing services during an emergency. Medical students, interns, residents, and other training health care professionals provide emergency assistance and are the future caregivers. In addition, the health care workers themselves are not the only ones at risk when they expose themselves to potential infections. Many health care workers are concerned about the safety of their families in the event that they were to become infected. Therefore, society needs to safeguard families as well as physicians and medical trainees.

In preparing for a public health crisis, it is important to understand the ethical and professional standards that guide physicians in their practices. Current North Carolina Medical Board policies and regulations only address the obligations of a physician to an established patient. The Board does not assert

---

Janelle A. Rhyne, MD, FACP, is President-Elect of the NC Medical Board and practices at New Hanover County Health Department. Dr. Rhyne can be reached at jrhyne@phrst2.org or 2029 S. 17th Street, Wilmington, NC 28401.

an ethical requirement for a physician to accept a new patient or treat or care for anyone. In its policy statement entitled "Termination of the Physician-Patient Relationship," the Board "recognizes the physician's right to choose patients and to terminate the professional relationship when he or she believes it is best to do so."

Several national professional societies addressed ethical imperatives to provide care after the September 11, 2001 terrorists attacks by adopting policy statements that focus on the medical professional's duty to care in a public health emergency. The American Medical Association (AMA) Policy E-9.067 Physician Obligation in Disaster Preparedness and Response says:

> National, regional and local responses to epidemics, terrorist attacks, and other disasters require extensive involvement of physicians. Because of their commitment to care for the sick and injured, individual physicians have an obligation to provide urgent medical care during disasters. This ethical obligation holds even in the face of greater than usual risks to their own safety, health, or life. The physician workforce, however, is not an unlimited resource; therefore, when participating in disaster responses, physicians should balance immediate benefits to individual patients with ability to care for patients in the future.

The AMA Ethics Manual statement H-140.873 says: "Front-line physicians have an increased ethical obligation to avail themselves of safe and effective protective and preventive measures (for example, influenza vaccine)."

The American College of Physicians (ACP) Ethics Manual addresses medical risk to physician and patient and the responsibility to work with the following statements:

> Traditionally, the ethical imperative for physicians to provide care has overridden the risk to the treating physician, even during epidemics. In recent decades, with better control of such risks, physicians have practiced medicine in the absence of risk as a prominent concern. However, potential occupational exposures such as HIV, multidrug-resistant tuberculosis, severe acute respiratory syndrome, and viral hepatitis necessitate reaffirmation of the ethical imperative. Physicians should evaluate their risk for becoming infected with pathogens, both in their personal lives and in the workplace, and implement appropriate precautions. Because the diseases mentioned above may be transmitted from patient to physician and because they pose significant risks to the physician's health, some physicians may be tempted to avoid care of infected patients. Physicians and health care organizations are obligated to provide competent and humane care to all patients, regardless of their illness. Physicians can and should expect their workplace to provide appropriate means to limit occupational exposure through rigorous application of infection control methods. The denial of appropriate care to a class of patients for any reason, including disease state is unethical.

According to these statements, medical professional associations and societies support the safety of physicians, but also assert an ethical obligation and responsibility to work during a public health crisis despite personal risks. The preeminence of the AMA and the ACP notwithstanding, the ethical imperatives to work they elucidate do not bind physicians who may, in good conscience, believe otherwise.

Nonetheless, whatever obligations physicians may have, surely the public has reciprocal obligations. If, for the public good, society expects physicians to voluntarily expose themselves to potentially lethal risks, what ought society provide physicians in return?

The following suggested remedies address some of the concerns that may contribute to a physician's reluctance to provide care in a health crisis situation such as an influenza pandemic.

1 Establish liability immunity for good faith medical treatment and triage[a] judgments.
2 Provide antiviral medications and vaccinations for physicians and their families.
3 Provide personal protective equipment such as masks, gloves, gowns, etc.
4 Provide community support services (ie, health services, food, and supplies) for physicians' families in the event of extended absence from home.
5 Suspend Health Insurance Portability and Accountability Act (HIPAA) regulations enforcement in cases of necessary and/or inadvertent violations in a crisis situation.
6 Provide a compensatory program modeled on workman's compensation for physicians who die or become disabled as a consequence of providing care in a pandemic.

The development of policies by our legislature to ensure the safety of our practicing physicians and physicians in training will benefit the present and future care of patients in North Carolina. If, however, reciprocal obligations to physicians are not acknowledged, failure to do so may adversely affect physicians' decisions to continue practicing medicine and it may dissuade others from becoming physicians in the first place. **NCMJ**

---

[a] The American College of Emergency Physicians Policy on triage states that "when the number of patients and severity of their injuries overpower existing resources, triage decisions must classify patients according to both their need and their likelihood of survival. The overriding principle should be to focus health care resources on those patients most likely to benefit who have a reasonable probability of survival."

Roles of Hospitals During an Influenza Pandemic

Barb Bisset, PhD, MS, MPH, RN, EMT

With most area hospitals operating at about 95% to over 100% capacity on any given day, it's evident that a flu pandemic will quickly overwhelm our ability to treat the thousands of patients who will surely stream toward the nearest emergency room.

Plans are being made now to cope with this potentially explosive threat. If worst-case projections were to materialize, Wake County could have as many as 225,000 residents in varying degrees of illness during a pandemic. In addition to readying our facilities and professional staff, the highest priorities are to prepare people to care for themselves and others at home, and to work with community partners to pool resources.

"We know that, logically, the first place people will turn to is their nearest hospital, but realistically, it will be impossible for any health care facility to expect to manage the huge influx of patients," says WakeMed Health & Hospitals CEO William K. Atkinson, PhD. "We see our leadership role as putting into place now a wide range of plans, including in-house preparation and training, and a vital network of community partnerships and public education. The absolute key to our success will be collaboration with other community partners."

Like most hospitals, WakeMed is approaching its organizational planning on five levels:

- ***Individual and personal preparedness*** – Informing the public that individuals will need to assume a great deal of responsibility for their own care or for that of their loved ones.
- ***Employee preparedness*** – Helping staff work through their own logistics to ensure they can be at work. This includes thinking through childcare options if daycares and schools are closed and taking other steps to put their personal lives in order.
- ***Organizational preparedness*** – Organizing the hospital system, at the executive level, to clearly understand necessary actions to be taken at both the community level (in coordination with other area hospitals) and within its own organization (eg, implementing the Hospital Incident Command System).
- Departmental preparedness – Educating each department within the hospital about how it specifically fits into the institution's bigger plan, such as considering every employee as essential and knowing that job duties may change rapidly as needed. For instance, we should expect that one person might take on tasks that are handled by many people on a normal day (eg, drawing blood, delivering food, emptying trash) in order to reduce the risk of exposure to affected patients.
- ***Planning with key community partners*** – Coordinating with other hospitals, home health agencies, the county's public health department, and emergency responders such as fire and police departments and emergency medical services. In addition to local partners, we need to understand what the state is doing and how the state fits into federal plans.

> *"If worst-case projections were to materialize, Wake County could have as many as 225,000 residents in varying degrees of illness during a pandemic."*

Finally, the most difficult part of planning involves grappling with the inevitable ethical quagmires that await us in deciding who gets treated and how. How do we determine the sufficient level of care without lowering quality of care? Who will get respirators and limited medicine? Currently, many of society's health care efforts are directed at the elderly. This will, in all likelihood, not be the case when resources and treatment options are severely restricted.

Barb Bisset, PhD, MS, MPH, RN, EMT, is Executive Director of the Emergency Services Institute at WakeMed Health & Hospitals. Dr. Bisett can be reached at bbisset@wakemed.org or 3000 New Bern Avenue, Raleigh, NC 27610.

Special Challenges Faced by Hospitals

As Dr. Atkinson noted, people are likely to turn first to the nearest emergency room. Hospitals need to be prepared to deal with large numbers of people at once because many people will likely fall ill within a relatively short time span. Hospitals should also be prepared for the fact that ill people are likely to be in panic mode or close to it. This will require having traffic control and security measures in place to ensure safety of both personnel and patients.

Once patients are inside our doors, we need guidelines for triage decision making, with an emphasis on saving the most lives. Subsequent decisions will revolve around who gets treated, and then *how* they get treated. For those who are turned away, will we be prepared to arm them with information and possibly supplies that will help them cope?

When patients are admitted, another range of issues needs to be addressed, such as authority to use sufficient standards of care that may be different from the normal levels, maintaining a healthy, hygienic environment, and doing our best to minimize the risk of exposure to the caregivers. In addition to ensuring proper quarantine procedures and protective equipment for staff, we need to allow for staff rotation to prevent burnout, and provide stress management programs to help staff cope with the emotional aspects of such an overwhelming event.

Additionally, hospitals need to make sure other contingency plans are in place, including figuring out how to sustain core business activities over several weeks, mapping how financial issues related to reimbursement will be handled, and determining how to respond to interruptions in service, such as sanitation, water, or power. We must anticipate shortages, including in personnel (assuming various degrees of absenteeism) and supplies (because of the very real probability of disruption in deliveries due to suppliers' own absenteeism issues).

One of the most critical aspects of dealing with a pandemic—and one of the biggest challenges—will be both internal and external communications. From an internal standpoint, we need to anticipate employee fear and anxiety and be prepared to respond to rumors and misinformation quickly, calmly, and factually. WakeMed already has in place an "E-Notify System" for key response teams, allowing us to quickly alert needed personnel.

Externally, we will need to disseminate timely and accurate information to the community, including the status of our response and consistent messages about when and where to seek care. It will be critically important that all responding agencies coordinate their information efforts with community partners by using a Joint Information Center (JIC), with a single spokesperson for the JIC or from each agency. This will reduce confusion and present a more cohesive approach to the public.

Another challenge will be helping families, particularly those from out of town, obtain information about friends and family members they are unable to reach. As part of the planning process, decisions should be made about how to handle these calls and all communications, including designating a public spokesperson for the hospital who will represent us at a JIC if one is established.

Public Policy Options Needed

In the spirit of collaboration and preparedness, a flu pandemic drill was held in February 2006, bringing together 250 individuals from 36 agencies across the region. Wake County's hospitals participated (WakeMed Raleigh Campus, WakeMed Cary Hospital, Rex Healthcare, and Duke Health Raleigh Hospital), as did state health officials, Wake County Human Services, Wake County Emergency Medical Services, and a number of representatives from law enforcement, municipal governments, and nonprofit agencies.

Separately, the North Carolina Hospital Association created a Disaster Roundtable in response to the September 11th attacks that resulted in mutual aid agreements signed by all eligible North Carolina hospitals in 2004. These agreements address the sharing of resources, including staff, and provide a good foundation for any mass casualty disaster.

While these efforts are beginning to address the public policy issues raised by a flu pandemic, many remain. Wake County's Community Health Director Gibbie Harris sees the thorniest issues as the ethical dilemma of who gets treated, and how? "Everybody is really struggling to even have a conversation about this, because it's so difficult and it's so huge," she said. "We know there will not be enough respirators, enough hospital beds, enough medicine. Whether we are going to be able to get to a place in this country where we make some public policy decisions on this remains to be seen. If we can't, then the decisions are left to organizations or, when you get right down to it, to individual doctors."

Some decisions over who receives care will be performed initially by the 9-1-1 emergency response centers. In Wake County, callers are evaluated and placed in one of five categories. This same approach can be used in a pandemic to make preliminary decisions about who is even transported to a hospital or another care facility says Wake County Emergency Medical Services (EMS) Medical Director Brent Myers, MD, MPH.

Another public policy issue under consideration is the role of community health providers in a pandemic. For instance, public health departments could serve as a bridge for hospitals by establishing alternate care facilities that can serve those who are not the most critically ill but are unable to care for themselves at home. Harris believes all communities should explore possible alternative care venues as part of the planning process and then work out agreements that establish roles and sharing of supplies and other resources. "The key is to look in your county or your region, and collaborate and consolidate resources as part of your planning process, knowing that you will need more capacity than hospitals can provide and knowing there will be people who need different levels of care," she said.

An innovative example of planning ahead and using resources wisely is the approach taken by Wake County EMS. Currently, all EMS personnel are trained to give shots. Even though a specific vaccine would likely not be available, having this skill available adds value to the health care sector. "We know we need to protect our workforce and keep them well enough to come to work," says Dr. Myers. "So today, we are all able to administer vaccinations, and we practice annually with flu shots. If a vaccine is available before or during a pandemic, we will be able to step up and help."

Dr. Myers says his agency learned lessons shared by the Toronto EMS during the February 2003 SARS outbreak, and recommended that others use those lessons as a basis for planning. "Putting certain protocols into place early, such as what type of protective gear should be worn, provides EMS personnel with the confidence that their own risk of exposure will be minimized," he says. "Our own responders need to know that we will modify some procedures as needed or outline the steps they should take to reduce their own chance of infection, and that will increase our chances that they will come to work when and where we need them."

He echoes advice about forming partnerships now and modifying existing plans rather than starting from scratch. "The number one key is to make sure that you sit across the table and talked with your public health representatives," he says. "Often, we operate in different spheres, but you have a lot of catching up to do if you are sitting down for the first time in a crisis situation."

Conclusion

As is the case with any emergency planning, the key to preparing for a flu pandemic is to think through all of the "what if" scenarios and get plans in place now for future use. The day the first wave of flu patients presents to your emergency room is *not* the day to begin planning how best to handle it. The large number of resources available through the federal and state governments are a good place to start. They provide guiding principles and checklists, such as a United States Health and Human Services' booklet on bioterrorism and other public health emergencies, called *Altered Standards of Care in Mass Casualty Events*.[1]

In addition, exploring potential collaborations with partners takes time, so reaching out to other area hospitals, public health departments, and nonprofits is a good way to form working partnerships. Deciding which resources can be pooled, including personnel, and drawing up legal or other formal agreements ahead of time can make for much more efficient operations later.

Also, it's important to draft a plan in advance that can be shared with your organization and the general public, so that everyone has a clear understanding of what to expect, where to go, and who to call for information. If you do not have plans in draft stages, please make this a priority for your organization. If you have plans well underway or in place, congratulations! Let's hope that you will never need to use them. **NCMJ**

COMMENTARY

All Politics, Pandemics, and Plans are Local

John Morrow, MD, MPH

As the threat of a flu pandemic becomes more of a possibility with each passing month, local health departments are busy preparing local flu pandemic plans. Local health departments tasked with the mission of protecting the public health have taken the lead in local preparedness for such an event. This is a daunting task.

North Carolina's local health departments were originally established in the early 1900s to help deal with significant communicable disease threats like typhoid, yellow fever, and tuberculosis. As these diseases were controlled with interventions such as improved sanitation, vaccines, and antibiotics, the infrastructure and funding support for these communicable disease programs drastically deteriorated. Most current local health department staff members have never dealt with a large, serious local epidemic of a communicable disease, and none have dealt with a true pandemic. This situation is analogous to a fire station that has not fought a fire in a very long time. With only limited state and federal government support, local public health departments have struggled to maintain or rebuild their epidemiology functions.

Federal bioterrorism funding provided to state public health departments since September 11, 2001 has somewhat improved this situation because the processes and interventions for bioterrorism are similar to those for other emerging infectious diseases of natural origin like a flu pandemic. Furthermore, North Carolina laws have been strengthened to help state and local departments deal with serious communicable disease threats. Also, local health department staff members have been trained in incident command system (ICS). The ICS emergency structure, initially developed by the United States Forest Service to fight fires, is now used by all types of emergency responders during various incidents or disasters. For example, both hurricane Ernesto and the *Tall Ships* event in Morehead City used ICS in 2006. This system allows all emergency responders to speak the same language and to read from the same page when a crisis occurs.

The newest challenge for local health departments is to slow the onset and progression of an influenza pandemic within their communities until a vaccine is available. Although many in our society may expect a solution for pandemic problems to come from space-age science labs far away or from the Centers for Disease Control and Prevention, the truth is that the most powerful interventions will likely be basic sanitation methods that have proven themselves for thousands of years. During a pandemic, simple things like cough etiquette, hand washing, and social distancing can make the difference between life and death. Educating people with this critical information expeditiously and in an easily understandable format is one of our greatest challenges today. These interventions will be most effective if the behaviors are well ingrained among the population *before* the pandemic arrives.

> *"During a pandemic, simple things like cough etiquette, hand washing, and social distancing can make the difference between life and death."*

North Carolina prides itself as being one of the best prepared states for disasters. Much of this confidence is attributable to the state's extensive experience responding to hurricanes and other weather-related events. However, unlike a weather event, a pandemic will likely impact the entire state simultaneously and be much longer in duration (eg, 12–18 months). Unlike a hurricane or similar local disaster, the cavalry is not coming to save the day during a pandemic. It will be left up to the local communities to sustain themselves and care for their families and neighbors for an extended period of time.

The most valuable lesson that I learned as a local health

John Morrow, MD, MPH, is Health Director at the Pitt County Department of Public Health. He was also a member of the NC Department of Public Health and NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning. He can be reached at jhmorrow@co.pitt.nc.us or 201 Government Circle, Greenville, NC 27834.

director from Hurricane Floyd is that, in a time of crisis, most people will do what you ask them to and even more. Although laws may exist for enforcing social distancing measures, it is unlikely that they will actually be enforced on the local level during such a crisis. However, I believe the public will self-enforce most of these public health interventions. People will respond to the public messages they receive. Therefore, it is critical that public information come from a trusted source and be accurate.

A bigger public health problem during a pandemic will be controlling limited assets that will be in high demand when many people fall ill. Included in this list will be hospital beds, ventilators, and antiviral medications. We will need to distribute these fairly and in an open manner. This is where local boards of health can be helpful. Local boards of health exist in every county and serve as the policy-making body for the health departments. In the setting of a pandemic (or any other public health crisis), the local Board of Health (BOH) can be a critical component to maintaining social order and in the continuation of local government operations. The eleven member BOH is appointed by the County Commission and is composed of seven professional members representing medicine, nursing, pharmacy, dentistry, optometry, veterinary medicine, and engineering. Three additional at-large members and one representative from the County Board of Commissioners fill the remaining seats. During a pandemic, this board can help reassure a skeptical public that limited services and supplies like vaccines and antiviral medications are distributed in a fair and equitable fashion. The Board of Health can help ensure an objective and nonpartisan review of these very acute and complicated public health problems and can also help to insulate elected officials from these potentially volatile issues. The other advantage the Board of Health has is that, unlike ordinances passed by the County Board of Commissioners, the rules approved by the Board of Health have jurisdiction for the whole county, including all of its municipalities. Infectious diseases like influenza have no respect for political boundaries, thus our public health interventions must also not be restricted by these.

The types of interventions that will be necessary will depend upon which pandemic phase we are in. For instance, if the initial cases of a flu pandemic present themselves in a North Carolina county, as in World Health Organization (WHO) phase 4,[1] then isolation, quarantine, and antiviral treatment and prophylaxis may all need to be quickly instituted. On the other hand, if our counties are not affected until late in the pandemic (WHO phase 6[2]), then isolation and quarantine may be of little use and the supply of antiviral medications will likely not be sufficient for all those in need. Guidance from the World Health Organization, Centers for Disease Control and Prevention, and North Carolina Division of Public Health will likely be adjusted throughout the pandemic as we learn more about the virus and its transmission and treatment.

Local pandemic plans must be flexible enough to quickly adjust to these different scenarios. These plans should be designed by a multidisciplinary team including representatives from local governments, businesses, hospitals, schools, religious groups, and volunteer and other community organizations. These plans must be cross-checked with other agency and entity plans to make sure that resources are not planned to be in two or more places at the same time, and to make sure that roles and procedures are clear to everyone involved. The plans need to be agreed to and signed by the major partners and should be updated annually. They should also be exercised on a regular basis to identify what works well and what doesn't. As we witnessed with hurricane Katrina, it doesn't matter how well the federal and state plans are written if they cannot be effectively implemented on the local level.

In facing this challenge of preparing for the next pandemic influenza, we must prepare ourselves, our families, our workplaces, and our communities. Effective preparation efforts are already under way, but certainly much more can be done to help every community feel ready. Our goal in the east is to be as well prepared for a pandemic as we are for a hurricane. I just hope and pray that the pandemic and hurricane don't happen at the same time." **NCMJ**

COMMENTARY

Pandemic Influenza and the Law:
Isolation, Quarantine, and Other Legal Tools for Containing Outbreaks

Jill Moore, JD, MPH

Today, governments, health care providers, businesses, and others are developing plans to respond to an influenza pandemic. These plans may discuss isolation or quarantine, or use related terms such as social distancing. But what do they mean by those terms?

The words isolation and quarantine, in particular, are used different ways by different people. For a physician, the word isolation may suggest precautions that are taken against the spread of infection, or a particular place in a health care facility where people with infectious diseases are treated. For the general public, the words may conjure up images of what I call the "TV movie of the week" form of isolation or quarantine: a home with a red-lettered sign on the door, a subdivision surrounded by a chain-link fence, or roadblocks manned by armed law enforcement officers. But for the public health system, isolation and quarantine are simply two of the legal tools available to control the spread of communicable disease. In North Carolina, these tools are part of a comprehensive legal framework for communicable disease that includes:

- laws that allow the public health system to detect communicable disease within the population,
- laws requiring public health agencies to investigate cases and outbreaks of communicable disease, and
- laws that specify—and require individuals to comply with—communicable disease control measures, which may include isolation or quarantine.

The varying common-sense and professional understandings of terms such as isolation and quarantine are good for the purposes they serve, but they may conflict with how the terms are defined in law—and it is the legal definitions that both authorize and constrain how these strategies may actually be used in an outbreak. It is therefore important for anyone involved in pandemic preparedness to understand the legal meaning of isolation and quarantine, and also the broader legal framework in which they are used.

The Framework: Legal Authority to Control Communicable Disease

The individuals and agencies that make up North Carolina's public health system—including the state health director and division of public health, local health directors and the health departments they administer, and the seven Public Health Regional Surveillance Teams (PHRSTs)—would likely be the first to identify and respond to a disease outbreak. North Carolina laws give the public health system specific duties during an outbreak, as well as specific powers to help it perform those duties.

> *"North Carolina laws give the public health system specific duties during an outbreak, as well as specific powers to help it perform those duties."*

The starting point for communicable disease control is to be aware that a disease exists in a population—thus, one of the duties of a public health system is to detect disease. One of the ways public health meets that duty is by requiring certain diseases to be reported. North Carolina law presently requires physicians and specified others to report known or suspected cases of communicable diseases or conditions that have been declared "reportable" by the state's Commission for Health Services.[1] The list of reportable communicable diseases and

Jill Moore, JD, MPH, is an Associate Professor of Public Law and Government at the University of North Carolina at Chapel Hill School of Government. She can be reached at moore@sog.unc.edu or School of Government, CB# 3330 Knapp-Sanders Building, UNC Chapel Hill, Chapel Hill, NC 27599-3330.

conditions is dynamic and has grown rapidly in recent years, so that it now includes over 70 diseases and conditions. Novel influenza viruses are a recent addition to the list—known or suspected cases must be reported to the local health department immediately.[2]

In addition to this routine reporting, another state law authorizes the state health director to temporarily require health care providers to make reports of conditions that are not on the list.[3] The idea behind this law was to allow the public health system to act rapidly to detect an emerging illness or syndrome. State law also supports disease detection by authorizing public health to obtain access to medical information so that it can carry out public health surveillance.[4]

When a communicable disease or condition is detected, whether through the receipt of a disease report or a surveillance system, the public health system's duty to investigate is triggered.[5] Again, state law gives public health specific legal powers to help it meet this duty. Both state and local public health officials are authorized to obtain access to medical and other confidential records that may be relevant to a case or an outbreak. Health care providers are required by state law to make medical and other records available to public health officials in these circumstances.[6,a] Investigations may also include interviewing ill or exposed people, collecting specimens for laboratory analysis, and identifying others who may be ill or exposed.

By carrying out its duties of detection and investigation, the public health system lays the foundation for its ultimate duty: controlling the spread of the communicable disease. Supporting this duty is a state law that requires all persons in North Carolina to comply with communicable disease control measures—that is, the steps individuals, their health care providers, or the public health system must take to control the spread of disease.[7]

Communicable disease control measures are disease-specific and cover a wide range of strategies. In the event of an influenza pandemic, how will public health officials decide which control measures are appropriate? They should look first to guidelines and recommended actions issued by the Centers for Disease Control and Prevention (CDC). North Carolina law specifies that CDC guidelines will be the source of control measures when they are available,[8] and it is expected that CDC will issue guidelines during a pandemic. If for some reason it does not, the law also permits public health officials to devise their own control measures that are reasonable and meet certain guidelines depending on the disease's route of transmission (airborne, bloodborne, etc).

Because CDC guidelines are the primary source for control measures, and because those are likely to evolve in an emerging illness event, public health officials cannot know for certain what the control measures for an outbreak of a novel influenza virus will be. However, it is expected that the control measures would include at least:

- Immunization, if an effective vaccine is available
- Use of antiviral medications, if effective and available
- Isolation of infected individuals
- Quarantine of exposed individuals

In addition, public health officials will likely urge individuals and communities to embrace social distancing strategies, such as avoiding unnecessary outings.[b]

The Definitions: Isolation and Quarantine in the Law

The main distinction between isolation and quarantine is that isolation is a control measure applied to sick people, whereas quarantine is applied to people who might get sick—usually because they have been exposed to an infected person. North Carolina's legal definitions begin with this fundamental notion, but then they take it a bit further. State law defines "isolation authority" as the authority to limit the freedom of movement or the freedom of action of a person who is infected with, or is reasonably suspected of being infected with, a communicable disease or condition.[9] "Quarantine authority" includes the authority to limit the freedom of movement or the freedom of action of a person who has been, or is reasonably suspected of having been, exposed to a communicable disease or condition.[10] Either a local health director or the state health director may exercise isolation or quarantine authority.[11]

The definitions of isolation and quarantine authority refer to limiting either a person's "freedom of movement" or "freedom of action," and several North Carolina laws make important distinctions between orders based on which freedom they limit. For example, the law that authorizes health directors to order isolation or quarantine provides that orders limiting freedom of movement expire after 30 days unless they are extended by a court—even if the subject of the order is still a threat to the public health.[12] The same limit does not apply to orders limiting freedom of action. It is therefore critical for public health professionals to understand when they are limiting freedom of movement and when they are limiting freedom of action—but no law defines these terms. However, the definitions can be inferred from longstanding public health practice.

An order limiting freedom of movement essentially prohibits

---

[a] Health care providers sometimes worry that providing access to records with individually identifiable health information violates the federal HIPAA privacy rule, but the privacy rule explicitly states that providers may comply with state laws that require the disclosure of such information. (45 CFR. 164.512(a).)

[b] As this commentary was going to press, the Centers for Disease Control and Prevention released *Interim Pre-pandemic Planning Guidance: Community Strategy for Pandemic Influenza Mitigation in the United States* (Feb. 2007), available on the Internet at http://www.pandemicflu.gov/plan/community/community_mitigation.pdf. The document states that it is "highly unlikely" an effective vaccine will be available in a pandemic and recommends control strategies that include isolation of the ill, quarantine of the exposed, and use of social distancing strategies such as school closures and cancellations of large public gatherings.

an individual from going somewhere. It may confine the person to a particular place, such as his home or a health care facility, or it may prohibit the person from entering a particular place. For example, a person with active infectious tuberculosis may be required to remain at home until laboratory tests reveal he or she is no longer infected, or an unimmunized child may be required to stay home from school for the duration of a measles outbreak. In contrast, an order limiting freedom of action restrains a person's behavior, but not her ability to move about freely in society. For example, a person taking medication for tuberculosis that is no longer in the active infectious stage may be ordered to participate in directly observed therapy. This is a limit on freedom of action.

Thus, in North Carolina, an order requiring a person to be physically separated from the public would be called an "isolation order" (for an infected person) or a "quarantine order" (for an exposed person). But an order simply directing a person to comply with control measures that do not include physical separation would also be called an isolation or quarantine order. This counterintuitive use of the terms isolation and quarantine can be tricky even for public health professionals, but it is important to understand. Health care providers and patients who receive isolation or quarantine orders need to know what is actually being required of them.

During the Pandemic: Isolation, Quarantine, and Other Forms of Social Distancing

During an outbreak of influenza, an isolation or quarantine order might limit either freedom of movement or freedom of action—but it seems most likely that the isolation and quarantine authority would be used primarily to separate ill or exposed people from the general public. It also seems likely that isolation and quarantine would be used early in an outbreak in an effort to contain it as quickly as possible, but these strategies may well be abandoned if widespread illness affects a community. There is some question about whether public health officials would have the legal authority to order a television movie-style isolation or quarantine—but of greater importance, such measures are widely considered to be both impracticable and likely ineffective.

In contrast, isolation or quarantine orders that are directed to individuals, or groups of individuals with a common exposure (such as the passengers and crew of an airplane carrying an ill person), are clearly within public health's legal authority and may play an important role in preventing widespread community illness, depending on how the outbreak unfolds. Indeed, North Carolina used isolation and quarantine in this fashion during the severe acute respiratory syndrome (SARS) outbreak of 2003. Although only one person's infection was ultimately confirmed to be SARS, several people were isolated because they were suspected of being infected, and several dozen were quarantined because they were exposed to one of the isolated people.

There is, of course, no guarantee that an outbreak of novel influenza would be as limited as SARS was in North Carolina, and there are good reasons to believe that it would not. If an outbreak becomes widespread in the community, it is likely that isolation and quarantine would become less important than other forms of social distancing. Social distancing could happen spontaneously, if members of the worried well population elect to stay home. It could also occur voluntarily in response to the urging of public health officials to avoid unnecessary outings. There are also various governmental actors who have the legal authority to compel different types of social distancing. North Carolina local governments can adopt ordinances that permit them to take a number of actions in emergencies, including restricting the movement of people.[13] The Governor has the authority to declare a state of disaster and may, with the consent of the Council of State, prevent people from congregating in public places.[14] School boards can close schools and, to answer one of the questions I am most frequently asked: if the universities do not do it on their own, state or local officials could probably cancel the Carolina-Duke game, or at least prevent the public from attending. Although everyone hopes it does not come to that, the legal authority is there to be exercised if necessary. **NCMJ**

Business Preparation for an Influenza Pandemic

Jon Kerin

In fall 2005, the Department of Homeland Security identified the electric industry as a key component of the national infrastructure and requested that utilities, including Progress Energy, prepare an emergency response plan for a pandemic.

While our company has experience with and continually refines its plans to respond to hurricanes, ice storms, and other natural disasters, putting together our flu pandemic plan proved to be a long process and forced us to address issues that had not arisen in storm situations.

For example, natural disasters destroy infrastructure. Our employees pull together to ensure our customers get service restored as soon as possible. Many employees stop doing their regular daily jobs and take on specific storm jobs to ensure we can meet our customers' needs quickly.

In planning for a flu pandemic, though, the scenario is much different. Rather than destroying infrastructure, a pandemic has much more human impact and little if any effect on infrastructure. A flu pandemic incident is outside of our experience. Instead of bringing our employees together, as we are used to in storm events, a flu pandemic could push our employees apart, with many being unable to come to work.

Whatever the effects of such an occurrence, it is critical that electric utilities and other industries, such as banking and transportation, be prepared to continue providing society's essential needs during a pandemic.

Progress Energy took a hard look at its emergency and business continuity plans and determined that we needed to start fresh in looking at our pandemic plan. We learned some very important lessons during this process, and we believe we have developed a robust, comprehensive plan that will ensure we take care of our customers and our employees.

Involve Everyone

We formed a Pandemic Working Group, made up of departments throughout the company, including:

- Health & safety
- Power plant operations (nuclear and fossil)
- Transmission
- Distribution
- Supply chain
- Information technology & telecommunications
- Corporate communications
- Human resources
- System planning
- Customer service
- Accounting
- Security

This group met frequently for many months to develop our corporate-wide flu pandemic plan along with plans for their individual departments. Having this many groups involved helped us identify enterprise-wide gaps and develop solutions for our company as a whole.

> *"And we decided we shouldn't wait until a threat was imminent—we wanted to educate our employees now about a pandemic and what they could do to prepare themselves and their families."*

Jon Kerin is Director of Health & Safety Services at Progress Energy Service Company, LLC and was responsible for developing the company's comprehensive flu pandemic plan. Mr. Kerin can be reached at jon.kerin@pgnmail.com or 401 S. Wilmington Street, PEB 4A, Raleigh, NC 27601.

Break Down Plan by Phases

Progress Energy chose to use the North American Electric Reliability Council's pandemic phases to guide our planning; this structure is different from the World Health Organization's six levels of pandemic alert phases. We then identified key steps for the company to take in each phase. These steps are outlined in Table 1. These steps are by no means an exhaustive list, but rather a look at the action items that the entire company needs to undertake in each phase.

Table 1.
Key Company Steps, by Pandemic Phase

Pandemic Phase	Status of Pandemic	Key Company steps
Phase 1: Pandemic Alert	Governments, owners, and operators are notified a pandemic is possible and preparedness plans should be reviewed and updated.	• Provide information to employees • Develop a list of health-related inventory items • Identify essential staffing needs and identify personnel to meet those needs (assuming a 35% to 40% absentee rate), including backups for key personnel • Develop and update the company's meeting policy • Develop and update the company staff travel policy • Identify augmented workforce requirements • Modify Human Resources policies associated with working from home, remaining sequestered at a job site, and absenteeism • Identify critical operation supplies • Implement an enterprise-wide hand-washing campaign • Develop a training plan for backups • Ensure business continuity plans have been revised to incorporate pandemic plans • Perform a self-assessment
Phase 2: Pre-Pandemic	Localized outbreaks of the disease are occurring with human-to-human transmission. Governments and electricity sector entities begin to assign resources, prepare staffing, and implement contingency plans. Begin an information distribution program to promote appropriate responses by employees.	• Periodically test and verify preparedness plans and procedures via a simulation exercise, tabletop exercise, or process walk through • Develop and update workforce deployment policies regarding teams and crews working together and the potential need to keep employees separated • Set up telecommuting capabilities for identified personnel • Stock up on water, beverages, and food • Consider the need and conditions for more extreme measures, such as sequestering on-site critical staff
Phase 3: Pandemic Outbreak	General outbreaks of the disease across borders and continents. Implement response plans.	• Activate Crisis Management Center • Notify employees • Implement the protocol for telecommuting • Notify all staff on site to leave their full name, employee ID, and after-hours contact numbers • Provide each workstation with disinfection supplies • Close noncritical common areas • Assess the need to vacate all noncritical staff from facilities • Sequester on-site critical staff, as needed
Phase 4: Maximum Disruption	High absentee rates would occur (35%) and fatalities would begin to impact workforce. This phase could last for several months.	• Analyze/reevaluate staffing levels • Analyze/reevaluate supplier effectiveness
Phase 5: Prolonged Recovery	Recovery will be slow. Altered business conditions will be prevalent. This phase will last at least three months and possibly up to six months.	• Deactivate Crisis Management Center • Implement business continuity plan and business resumption plans • Communicate with personnel and departments not addressed in resumption plans • Return to normal business operations

Employees are Customers, Too

Time and time again in our discussions, the planning group found itself not only talking about how to maintain reliable electric service, but also how our company should take care of its employees in a pandemic.

We looked for nontraditional communications channels, so we could make sure our employees had the information they would need during a pandemic. We had detailed conversations about Human Resources policies and how those might change, going as far as to write new policies to have ready in the event of a pandemic.

And we decided we shouldn't wait until a threat was imminent—we wanted to educate our employees *now* about a pandemic and what they could do to prepare themselves and their families. Using our company's daily electronic newsletter, we began sharing information about a pandemic and providing preparation checklists. We also published questions and answers and linked our employees to the Federal government's pandemic Web site (www.pandemicflu.gov) and the United States Centers for Disease Control and Prevention.

Be Realistic

We often found ourselves in many "what if" conversations during our planning, all of which helped us to address some key issues. However, it is important to recognize that a company plan cannot include every step to handle every possible contingency. Instead, we are realistic about the limitations of a written plan and use it as a higher-level guide that can be used in many different situations.

Challenge One Another

While we did not have any formal "challenge sessions" during our planning, Progress Energy's pandemic planning team frequently engaged in tough debates about the number of critical employees, whether sequestering employees would be necessary, and if and when supplies should be purchased. As is often the case in hypothetical situations, there were no right or wrong answers, but each department was able to further refine their plans based on these tough questions.

Test and Refine Your Plan

Finally, plans are only as good as the last time they were tested and updated. We have already held one company-wide drill to test our pandemic plan, and we plan to continue these drills in the future.

Providing critical services like electricity will be a challenge in a pandemic situation, but we believe our experience with other disasters and our comprehensive planning process will help us meet the needs of our employees and our customers if a pandemic ever occurs. **NCMJ**

COMMENTARY

Pandemic Influenza:
The Consequences beyond Public Health

Major General Gerald A. Rudisill, Jr. (ARNG Ret.)

Nearly everyone who has lived in North Carolina during the past ten years has some experience responding to a natural disaster. The many hurricanes, floods, tornadoes, and snow and ice storms that hit the state in the past decade have tested our ability to respond to emergencies in virtually every corner of the state. Those experiences may prove invaluable if there is an influenza pandemic. No one knows exactly how a flu pandemic would impact our lives or how long it would last. However, such an epidemic would greatly challenge the emergency response capacity of our state—and country—and stretch our resources in ways never experienced before.

> *"It is conceivable that the services we take for granted such as electricity, potable water, sanitation, and natural gas could cease."*

Most weather-related disasters that impact North Carolina have a warning period. The disaster is usually of short to moderate duration, and the aftermath's impact on facilities, infrastructure, crops, animals, and people is somewhat predictable. Technological disasters such as transportation accidents, hazardous materials events, and fixed nuclear facility accidents would likely impact people suddenly with little warning, but would only directly affect people and property relatively near the incident. An influenza pandemic would be an entirely different type of disaster. It would impact large percentages of the population over long periods of time and require innovative, immediate, and continual responses.

Aside from the staggering impacts to public health, the potential impacts of an influenza pandemic on manpower levels and critical systems could be tremendous. As people are affected, the workforce supply would be reduced, whereas demand for goods and services would rise. The impact would be not only local, but global in nature. Consider this: as the flu spreads, providers of essential services such as food, transportation, fuel, medicine, utilities, and banking could be devastated by manpower shortages reaching 40%. Attempts to prevent the spread of flu through the implementation of social distancing measures could further reduce the workforce, thus reducing production and supply. It is conceivable that the services we take for granted such as electricity, potable water, sanitation, and natural gas could cease. Social interaction would also be curtailed because social distancing measures would limit participation in faith communities, civic groups, sports, and public entertainment activities.

The workforce challenges facing health care agencies would be no different. Furthermore, while some businesses can expect to see a decline in activity during a pandemic emergency, health care institutions will experience an overwhelming increase in demand for services.

The North Carolina Department of Crime Control and Public Safety is the state agency charged with coordinating disaster response among local, state, and federal governments. The State Emergency Response Team (SERT) is an arm of state government that is comprised of more than 40 state agencies, nonprofits, and volunteer organizations that work as a team to mobilize the state's assets to support local governments and affected citizens. It is this group that assesses and responds to local community or regional health, safety, utility, transportation, food, and housing needs following any man-made or natural disaster.

Maj. Gen. Gerald A. (Rudy) Rudisill, Jr. (ARNG Ret.), is Deputy Secretary of the North Carolina Department of Crime Control and Public Safety. The Department's mission is to improve the quality of life for North Carolinians by reducing crime and enhancing public safety. It coordinates the state response to emergencies and directs relief efforts to disaster victims. Deputy Secretary Rudisill was a member of the NC Division of Public Health and NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning. He can be reached at grudisill@nccrimecontrol.org or 4701 Mail Service Center, Raleigh, NC 27699-4701.

Bad News of the Past may Mean Good News for the Future

Fortunately, years of experience responding to numerous hurricanes, floods, ice storms, and other severe weather events have provided North Carolina with a solid foundation for any ongoing response necessitated by an influenza pandemic. For natural disasters, the SERT frequently activates 24 to 48 hours before a disaster and remains operational long enough to respond to the immediate needs of the disaster victims. Depending on the nature of the event, the group can be working around the clock for several days to several weeks. Following Hurricane Floyd in 1999, the SERT was activated for more than five months while the state recovered from devastating floods. During that same time, the SERT also responded to the January 2000 blizzard that dumped nearly two feet of snow in central North Carolina. In the past decade, the SERT has been activated more than 50 times in response to hurricanes, ice storms, blizzards, tornadoes, and chemical explosions.

Those incidents provided the SERT numerous opportunities to work with dozens of agencies and hundreds of communities. That experience and those relationships will be vital during an influenza pandemic. In such an event, the SERT would likely be activated for weeks and possibly months. Representatives from the North Carolina Division of Public Health (DPH) would serve as technical advisors to the SERT leadership and the governor. DPH would help develop strategies to protect the public, predict future impacts, and make recommendations for protective action. The governor, SERT, and DPH leaders, in coordination with local governments, would then implement any recommended actions.

Coordination and collaboration at the local level will be imperative. A flu pandemic would cross state boundaries, thus greatly reducing the ability of the Federal Emergency Management Agency (FEMA) to support North Carolina. Assistance from many of the other traditional government and private support organizations, such as the National Guard, Red Cross, Salvation Army, and faith groups, could also be very limited due to the widespread nature of a flu crisis.

Rising concerns about safety and fears of the unknown could spark chaos. It is imperative that all levels of government – local, state, and federal—as well as private institutions, such as health care facilities, be prepared to provide essential law enforcement and public safety services to maintain public order. Public safety systems must be planned, organized, and exercised well before an event occurs. DPH and the Division of Emergency Management each have already sponsored flu pandemic exercises and training to educate our response and recovery personnel on the potential issues that may arise and appropriate responses. Leaders throughout the state's communities should actively discuss ways to partner during an influenza pandemic to keep people connected, calm fears, and offer hope for the future.

Preparing for Pandemic

The most significant need during a flu pandemic will be for solid, steady leadership that relays critical, honest, and concise information and direction to the public throughout the developing crisis. Some of that vital information is available already. To help individuals and families prepare for all types of disasters, the Department of Crime Control and Public Safety launched an emergency preparedness website—readync.org/. The site provides basic information about what to do during floods, hurricanes, tornadoes, earthquakes, fires, winter storms, a terrorism act, or a disease outbreak. It instructs users how to prepare for evacuation, as well as what to do if they must seek shelter in their homes for an extended period of time. Information and links are included to help citizens understand what preparations the government is taking and what individuals must do to ensure their safety. For instance, to prepare for a flu pandemic outbreak, families are encouraged to stockpile enough food, bottled water, medicine, cash, and fuel for several weeks.

Community cooperation where neighbors help neighbors will be the key to weathering a pandemic outbreak. A shortage of goods will spark tendencies to control limited supplies and competition for resources could become violent, even deadly, if not properly managed from the beginning. Safety and survival will depend upon the willingness of neighborhoods and communities to come together for the common good. Government will have to establish supply lines and deliver critical resources to local receiving and distribution centers just as they would after any large disaster.

To ensure other essential government services are not disrupted, last summer Governor Easley required every state agency to prepare a Continuity of Operations Plan to guarantee ongoing operations in the event that substantial numbers of employees become incapacitated due to illness. Contingency plans must evaluate and prepare for reassignment of personnel responsibilities and for conducting business long term from remote locations. Personnel are encouraged to develop alternate family care plans for periods during which they are away performing critical functions. Those plans have been developed and will be tested through mock disaster drills in the coming months.

Hospitals, public health departments, physicians' offices, and emergency medical service providers also have been preparing for an influenza pandemic emergency for the past two years. Each hospital has a plan for providing health care during an emergency, including an alternate care facility for when the hospital is overwhelmed or otherwise unavailable. Although readiness levels can never be achieved to address every possible health care contingency, tremendous progress has been realized over the past year.

When many people consider the possibility of a disaster, they think, "It isn't going to happen here. If it does happen here, it won't be that bad. If it does happen here, and it is that bad, then the government will be here to take care of me." Unlike the response to a natural disaster, the communicable nature of the flu pandemic may mean that the government response will not be as quick and seamless as expected.

The truth is our nation is totally dependent upon the systems we have built. Grocery stores, restaurants, gas stations, water systems, electricity, flushing toilets, television, radios, cell phones, internet, pharmacies, law enforcement, emergency management services, hospitals, fire departments, banking, and credit systems are all part of our way of life. If a flu pandemic develops as a major statewide event, and likely national and worldwide event, none of these systems could be relied upon to operate continually and consistently. Everyone will experience shortages and those who are dependent upon the luxuries in our modern life may have a more difficult time surviving.

I honestly believe the key to success lies in communities pooling existing local resources and sharing what is available. This is a foreign concept to many Americans, except in a disaster environment. Government can and must lead the population during a pandemic event. A three-tiered response involving cities and counties, the state, and federal government will be necessary despite the new and unanticipated demands placed on these systems.

No one knows what the future holds. However, as we plan for emergencies, our responsibility is to consider the possibilities, define the assets and liabilities, and plan for the deficits. Government cannot be expected to do it alone. Individuals and families must prepare themselves and communities must band together. We must all accept some responsibility and do what is necessary to ensure our safety, health, and welfare. **NCMJ**

COMMENTARY

Ethics and Avian Flu

Rosemarie Tong, PhD

Health care professionals and public health officials are gearing up for the next influenza pandemic to strike the United States. For them, it's not a question of if a pandemic will strike the United States, but when. For this reason, they are paying very close attention to the avian influenza A (H5N1) virus which has killed around 150 people so far, but has not yet mutated into a virus capable of triggering a pandemic. Should such a mutation occur, chances are that the virus would spread quickly worldwide, rapidly finding its way to United States shores where it could sicken 90 million of us and kill at least 1.9 million. The United States government is preparing for the possibility of an avian flu outbreak, but so far its preparedness plan has focused largely on the development and distribution of a vaccine and the stockpiling of antivirals. But Arthur Caplan, Director of the Center for Bioethics at the University of Pennsylvania School of Medicine, stresses that no preparedness plan is complete without addressing the ethical issues likely to confront our society during a flu pandemic. These are excruciatingly difficult moral questions that the North Carolina Division of Public Health and the North Carolina Institute of Medicine are asking *now* while there is still time to think critically, carefully, and calmly about what ethical values should guide decision makers, health care workers, workers in other critical industries, and the general public when an influenza pandemic strikes.

Consider that during the first year of a pandemic fewer than 10% of us will have access to an effective vaccine. Federal stockpiles of experimental vaccines that may or may not work may be available for more of us, but it will take months for a truly effective vaccine to be developed, manufactured, and distributed. Early in the vaccine's attack on United States shores, we will also probably lack an adequate supply of antiviral medications such as Tamiflu, which some individuals, private practices, and hospitals may already be stockpiling. To add to our concern, during the height of a pandemic, we probably won't have enough ventilators for the hundreds or thousands of patients who will desperately need them for up to 18 days if the avian flu hits their lungs with the same intensity that it hit the lungs of SARS victims a couple of years ago. We will be confronted with some difficult questions: What about the patients who are already on ventilators when the pandemic strikes? Should a ventilator be removed from a baby who hasn't been doing all that well on it and given instead to a baby with the avian flu whose survival odds look really good if he or she can get on a ventilator immediately?

> *"Should a ventilator be removed from a baby who hasn't been doing all that well on it and given instead to a baby with the avian flu whose survival odds look really good if he or she can get on a ventilator immediately?"*

The specter of a pandemic and the reality of truly scarce resources force all of us to confront the very hard question: "Who shall live when not all can live?" This is a question that most Americans hate to ask themselves. It sounds downright unpatriotic to them. "Hey this is America! What do you mean we can't all live? Each of our lives is unique, special, valuable, important!!! We deserve whatever we need to keep on living, and don't you dare try to use any one of us as a means to serve

---

Rosemarie Tong, PhD, is Director of the Center for Professional and Applied Ethics and a Distinguished Professor for Health Care Ethics in the Department of Philosophy at The University of North Carolina at Charlotte. She also served as co-chair of the NC Department of Public Health and NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning. Dr. Tong can be reached at rotong@email.uncc.edu or 9201 University City Boulevard, Charlotte, NC 28223-0001.

the common good. The end doesn't justify the means." To which the reply must be, the rules of ethics shift during a pandemic. Under dire circumstances, the value of the common good must be weighed more heavily than the value of respecting individual rights and personal autonomy. The dread "R" word—rationing—must be uttered. There is no escaping its harsh sound. But, if we take a step back and think through the situation, rationing can be our friend. During a pandemic, it can help us maintain the value of justice, provided it is done ethically—that is, by directing scarce resources to where they will do the most good for us all, and letting everyone know why it is we have chosen a particular distribution method.

But how can we get rationing to work for us rather than against us? Lawrence O. Gostin recently articulated eight ethical options for rationing scarce health resources in a pandemic.[1] As he sees it, the relative importance of the ethical options shifts during the different stages of pandemic. The ethical options Gostin articulated include: (1) prevent new infection; (2) protect both essential medical personnel so they can care for the sick and essential scientific and pharmaceutical personnel so they can develop, make, and distribute the vaccines and antivirals we will desperately need; (3) protect other essential workers without whom our society might devolve into chaos, such as police, sanitation workers, utilities workers, food makers and distributors, bankers, communication personnel, etc.; (4) protect those with the greatest medical need; (5) save younger persons, protecting their opportunity to live a long, full life; (6) make it a priority to be sure that the typically underserved—the people who live in poor, rural, isolated and all-to-often forgotten communities—get their fair share of available resources; (7) think globally as well as nationally and regionally about flu pandemic because Asian and African lives are not less valuable than American lives and because people in many developed nations have already been devastated by HIV/AIDS, malaria, and tuberculosis; (8) make it a priority to be transparent and to secure public cooperation—for unless everyone understands the reasons behind a resource allocation plan, and is convinced that it is fair, the plan will fail miserably.

Of course, rationing scarce medical resources is not the only ethical challenge our society will confront during an influenza pandemic. When Americans are faced with the implications of isolation, quarantine, and social distancing measures, how will they react? In Canada during the SARS epidemic, people complied with restrictions on their freedom largely because their fellow citizens made it a point to meet their basic human needs. The situation was otherwise in some Asian cities where many individuals either did not understand why their movement had to be restricted and/or feared that unless they took care of themselves and their loved ones no one else would. Before long, the police entered the picture and were instructed to use deadly force if necessary.

Finally, there are all the ethical challenges that will greet medical workers and first responders during a pandemic. Can they be expected as a matter of duty to help flu victims even if doing so means risking their own lives or those of their families? Can they even be forced to do so? And if medical workers and first responders courageously accept the risks society wishes to impose upon them, what will society give them in return? How will society show its appreciation for people willing to put their lives on the line to serve the common good?

As a member of the NC Division of Public Health/NC Institute of Medicine Task Force on Ethics and Pandemic Influenza Planning, and in my role as one of its ethicists, I have come to the conclusion that as important as an ethics of justice will be during a flu pandemic, even more important will be an ethics of care. In the end, we human beings are a very vulnerable lot. We are radically dependent on each other for survival and we need to view ourselves as folks in a lifeboat in the middle of the ocean with no visible sign of rescue. If there aren't enough supplies to go around until help arrives, we can do several things: we can ask for volunteers to jump off the boat; we can start drawing straws for who gets pushed off the boat; we can have a majority vote about which lives are most dispensable; or we can look in each others' eyes and see ourselves—fearful, hopeful, and in need of compassion—and then we can start paddling together to get to shore, knowing that although we might not all make it, we didn't turn on each other in our panic. What we most need to weather a pandemic is an ethics of trust, reciprocity, and solidarity. If we have that, we will have the most precious health care resource of all. **NCMJ**

Are Your Patients Having Trouble Tolerating CPAP?

We offer alternatives to CPAP or soft palate surgery to treat snoring and obstructive sleep apnea (OSA). Jaw advancement (utilizing either oral appliances or jaw advancement surgery) may be the answer for your noncompliant patients, or simply for those who don't want or can't tolerate CPAP or soft palate surgery.

Newly published Practice Parameters produced by the American Academy of Sleep Medicine recommend oral appliances as an important first line treatment option for patients with mild to moderate Obstructive Sleep Apnea, and as a viable second-tier treatment for some patients with severe OSA.*

How do you know if your patient is a candidate for an oral appliance? All it takes is a sleep study and an upper airway evaluation. Don't allow your patients to suffer from the symptoms and sequelae of obstructive sleep apnea any longer. *Journal SLEEP, February 2006

Kent E. Moore, M.D., D.D.S. is the founding chairman of the American Association of Oral & Maxillofacial Surgeon's Clinical Interest Group on Sleep-Related Breathing Disorders and Obstructive Sleep Apnea and has served as faculty for the National Sleep Medicine Board Review Course 2002-2005 (sponsored by the American Academy of Sleep Medicine). He is immediate past president of the American Academy of Dental Sleep Medicine and founding board member of the International Society of Sleep Surgeons.

Influenza Surveillance

For health care providers, the start of flu season is often heralded by an increased number of patients complaining of fever, cough, and aches asking the question, "Do I have the flu?" For public health departments, the onset of flu season is often heralded by calls from health care providers asking the question, "Is flu reportable?" The answer to this question is a qualified "yes."

In North Carolina, any fatal case of influenza in a child (< 18 years of age) is reportable by health care providers to the health department. In addition, any infection with a novel influenza virus, such as the current avian influenza H5N1 strain that has caused human cases in multiple countries since 2003, is also reportable. Influenza outbreaks in closed settings such as schools or long-term care facilities are also reportable. The total number of influenza cases is not reportable and neither are fatal cases of influenza in persons 18 years of age or older (other than on a death certificate).

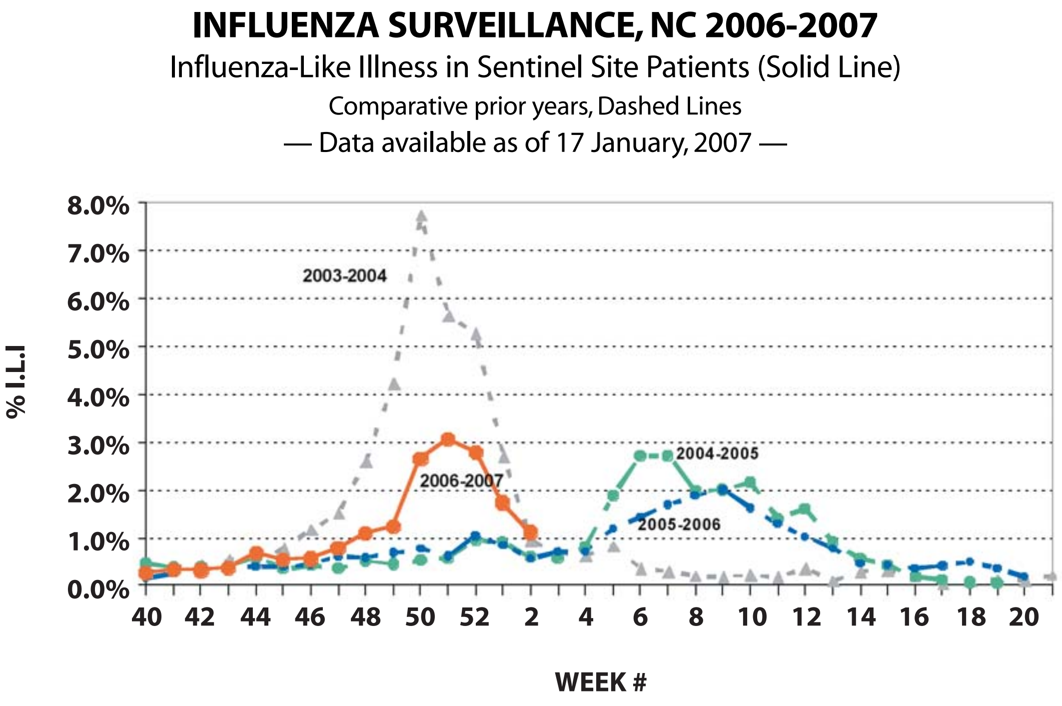
In North Carolina, routine influenza surveillance is conducted from October through May of each year. Although it does not provide a count of all influenza cases, it can be used to determine when and where influenza is circulating, the types of influenza viruses that are causing illness, and the level of influenza activity present in the state.

Disease-based surveillance is comprised of a network of voluntary providers who serve as sentinel sites for influenza activity in a variety of outpatient settings. For the 2006-2007 season, 74 providers representing 45 counties volunteered to serve as sentinel providers. Of these sentinel sites, 34 sites are private health care providers, 19 sites are county health departments, 15 sites are college and university student health centers, and 6 sites are hospital-based clinics. Sentinel providers record the number of patients they see each week with an influenza-like illness (ILI), which is defined as a fever of 100^{o} F or greater and one respiratory symptom such as cough or sore throat. Sentinel providers also submit a count of the total number of patients seen each week. This gives a proportion of visits that are attributed to ILI on a weekly basis throughout the flu season, and enables public health officials to monitor influenza activity across the state.

Figure 1 shows data on influenza activity from the sentinel provider network over several influenza seasons. The weeks of the influenza season are assigned a number, with the start of the flu season in October represented by week #40 and the end of the flu season in early May represented by week #20. The current influenza season is shown in red. For the week ending with January 12 (week #2), approximately 1.1% of all visits to the sentinel provider sites was for an ILI. This is down from a peak of 3% in week #51. Figure 1 also illustrates that every influenza season is different, both in severity as well as timing. For example, flu activity began peaking earlier (December) in the current flu season compared with the two previous seasons in which flu activity peaked in February or March (2005-2006 shown in blue and 2004-2005 shown in green).

RTN—continued on page 75

Figure 1.
Influenza Surveillance in the Sentinel Provider Network, 2003-2004 to 2006-2007



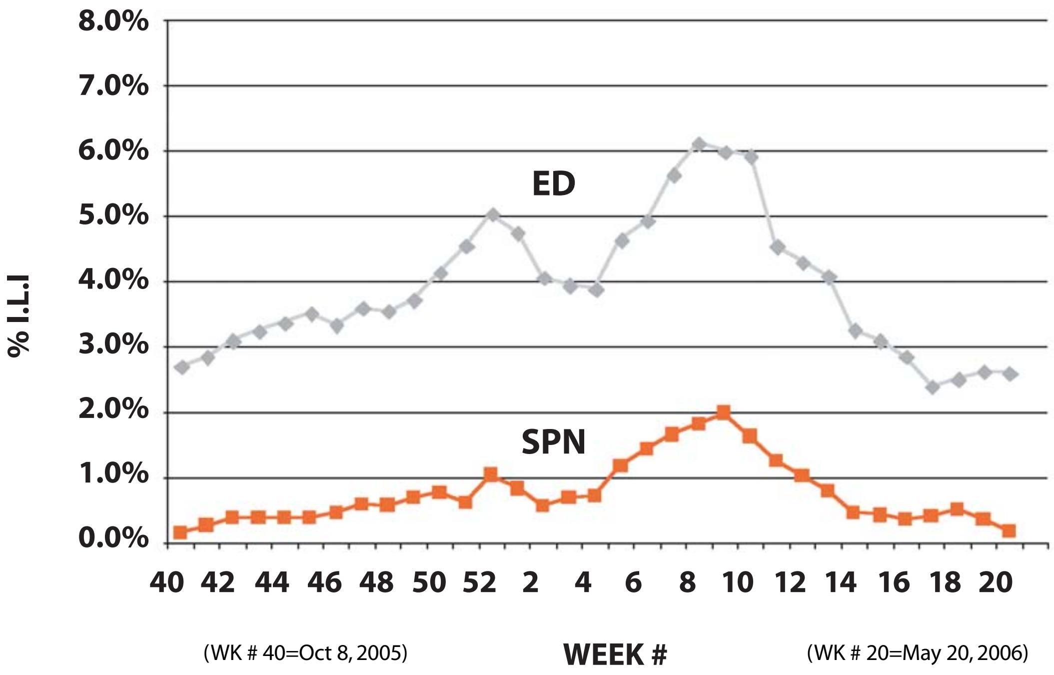
Beginning in the 2005-2006 influenza season, disease-based influenza surveillance was also conducted in hospital emergency departments (EDs) by monitoring ILI using the North Carolina Disease Event Tracking and Epidemiologic Collection Tool (NC DETECT) system. NC DETECT currently monitors real-time data from 90 hospital-based emergency departments throughout the state. The system categorizes visits into syndromes in real time in order to detect unexpected cases and outbreaks earlier in their course than traditional disease-based surveillance would allow.

The case definition for ILI in hospital EDs is broader than the ILI case definition used in the sentinel provider network. Emergency department visits are grouped into syndromes by analyzing the chief complaint and, when available, the triage notes and initial ED temperature. ILI cases must include any case with the term "flu" or "influenza" or have at least one fever term and one influenza-related symptom. The hospital ED data were compared with the sentinel provider network data for the 2005-2006 flu season (Figure 2).

RTN—continued on page 76

RTN—continued from page 75

Figure 2.
Influenza-Like Illness Surveillance in North Carolina, 2005-2006 Influenza Season. Comparative Trend between Two Surveillance Systems: Sentinel Provider Network (SPN) and Hospital Emergency Department (ED)



Although the patient populations, severity of illness, and case definitions for ILI are different in these two surveillance systems, it is important to note that the trends in ILI activity are well correlated. The use of NC DETECT as one method of monitoring ILI activity is validated by the existing sentinel provider network data. The trends for the first half of the 2006-2007 flu season are also well correlated.

In the event of an influenza pandemic, there will be significant challenges to influenza surveillance. Current systems of influenza surveillance will likely become overwhelmed, and flexibility will be essential in adapting current systems to meet the demands of tracking the pandemic across North Carolina. It is expected that the voluntary sentinel provider network will not be able to report weekly data regarding the percentage of visits for ILI because this data collection is still done the old-fashioned way: by hand. Syndromic surveillance for ILI in emergency departments, on the other hand, may be a viable option since these data are collected electronically as patients are being triaged through the emergency department. Another advantage of NC DETECT over the sentinel provider network is that it provides the opportunity for immediate surveillance of a new condition. This could apply to an outbreak of a novel strain of influenza in which the current case definition for ILI may need to be modified to capture cases. Expansion of NC DETECT to all hospitals in North Carolina with licensed acute care 24/7 emergency departments is underway.

Worksites Need to Know How to Get Started.

To The Editors:

We congratulate the *NC Medical Journal* for addressing the important public health issue of worksite health promotion in the November/December 2006 issue. Many employers and policymakers are seeking solutions to the rising cost of healthcare and in so doing, turn to worksite wellness. Oftentimes, they wade into these waters without an understanding of what works, what resources exist, what to measure, what is considered a success, or how to even begin.

NC Prevention Partners has made the strategic decision to address worksite health promotion because it is an important way to significantly improve the health of North Carolinians. While the Healthy People 2010 goal is for 75% of businesses to establish a comprehensive worksite health promotion program, only 6.9% nationwide have done so. The majority of NC employers are not actively engaging in health promotion efforts because they simply do not know where to start.

Many of the tools and training opportunities developed by NC Prevention Partners focus on implementing policies and creating environments that can significantly influence the behavior of all employees, regardless of their health status. Establishing a solid foundation of supportive policies and environments can help keep healthy people healthy and can help reduce health risks in persons with existing disease conditions.

For the business community, the problem—rising healthcare costs—is clear, but the solutions are not. We recommend the following quick-start, low-cost, high-return health promotion strategies as the place to start.

- **Start with a prevention audit.**
  NC Prevention Partners has created a web-based Prevention Audit as part of the *Prevention 1st Challenge* (www.preventionfirstchallenge.com). The audit helps employers take a critical look at their policies and environments, and take steps to create healthy worksites.
- **Make it convenient to choose healthful options at work.**
  In Orange County, businesses participating in the Prevention 1st Challenge are making healthy snacks available in vending machines and starting walking groups. NC Prevention Partners established a worksite policy making healthy options like fresh fruit and spring water available onsite and more convenient than the soda and snack machines down the hall. For other strategies, visit www.eatsmartmovemorenc.com.
- **Go 100% tobacco-free campus wide.**
  Hospitals in North Carolina are making significant changes to eliminate exposure to secondhand smoke through the *Healthy Hospital Initiative*, a partnership between NC Prevention Partners, the NC Hospital Association and The Duke Endowment. With tools and support, North Carolina hospitals are leading the nation in establishing 100% tobacco-free campus wide policies. For more information on reducing secondhand smoke in the workplace, visit www.healthyhospital.org and www.fammed.unc.edu/enter/.
- **Purchase benefits that give employees access to proven preventive care.**
  A new publication, *A Purchaser's Guide to Clinical Preventive Services: Moving Science into Coverage*, from the National Business Group on Health (www.businessgrouphealth.org) and the Centers for Disease Control and Prevention is an excellent tool to help businesses purchase proven preventive benefits. In addition, NC Prevention Partners' Preventive Benefits Watch (www.ncpreventionpartners.org/preventivebenefits) is a web-based resource that provides policymakers and businesses the opportunity to learn about preventive benefits offered by North Carolina insurers. Using this tool can assure businesses that they are purchasing the best prevention coverage, which should be actively promoted to their employees.
- **Businesses can learn more at the April or November 2007 NC Prevention Institutes (www.ncpreventionpartners.org).**
  - Complete a Prevention Audit and begin to create healthy policies and environments.
  - Gain insight about what works from the National Business Group on Health and the Centers for Disease Control & Prevention.

Spotlight on the Safety Net

A Community Collaboration

James D. Bernstein Community Health Center

In early March, local and statewide leaders gathered in Greenville, North Carolina to dedicate the James D. Bernstein Community Health Center. The center was founded on the premise that a person's health depends on much more than just access to health care. This multipurpose facility is designed to integrate professional and community educational programs, job training, and social support systems, as well as health services. These services are tailored to the unique needs of rural, low-income families.

The concept was born out of a sense of community need expressed by Pitt Partners for Health, a Healthy Carolinians partnership. Local safety net providers, agencies, and volunteer groups came together four years ago to form the Eastern Carolina Community Health Care Consortium. That group envisioned a new kind of health center to be named after Jim Bernstein, the founder of the state's and the nation's first Office of Rural Health. The land and site work was donated by E. R. Lewis Construction and the building is owned by Access East, an independent 501(c)3 organization formed by Pitt County Memorial Hospital and East Carolina University to house indigent care programs. The lease for the building is only $1 a year plus maintenance. Greene County Health Care, Inc, a federally qualified health center which has won national recognition for its innovative programs, is charged with the operation of the health component of the center including full medical and dental services. Pitt Community College is responsible for the coordination of educational programs including current courses in health information management, dental hygiene, and radiation technology. East Carolina University Brody School of Medicine operates the pharmacy, which offers 340b (lowest available costs) pricing and access to all pharmaceutical company assistance programs. The East Carolina University School of Nursing and Department of Child Development and Family Relations also provide medical and behavioral health services at the center.

Jim Bernstein, the center's namesake, was a tireless, unselfish and brilliant advocate for North Carolina's rural poor and medically underserved. His office founded the first rural health center in the state, located only twenty miles from the site of the newly dedicated Bernstein Community Health Center. That center, the Walstonburg Community Health Program, has become a part of Greene County Health Care, Inc, a network of seven clinics.

In that same spirit, those who have worked hard to bring the center into existence follow the motto by Thomas G. Irons, MD, "We will do what's right, do it well, and do it together."

Funding for capital and operational costs were generously provided by the following local, state, and national organizations: Blue Cross Blue Shield of North Carolina Foundation, Bureau of Primary Health Care Health Resources and Services Administration, The Duke Endowment, Dunn & Dalton Architects, E.R. Lewis Construction Company, Inc., Golden LEAF, Inc., Kate B. Reynolds Charitable Trust, North Carolina Office of Rural Health and Community Care, North Carolina Rural Economic Development Center, Inc., Pitt Memorial Hospital Foundation, and R.R. Miller Construction, Inc.

SOMETIMES LESS IS MORE.

Especially when it comes to surgery. Robotic procedures mean less pain, less scarring, and less recovery time.

Surgery doesn't always have to mean putting your whole life on hold. With the da Vinci® Surgical System, you should have less pain and fewer side effects following your procedure– which means that you can get home, and back to your family and your life, a whole lot faster.

The da Vinci is an advanced surgical tool that allows our skilled physicians to perform complex, delicate procedures with unmatched precision through very small incisions–a monumental difference from standard open surgeries. Cardiac surgeons at Pitt County Memorial Hospital in Greenville, in conjunction with the Brody School of Medicine at East Carolina University, are leaders in da Vinci surgery, responsible for this country's first robot-assisted mitral valve repair in 2000. Since then, the hospital and university have trained more than 1,000 surgeons from around the globe to use the da Vinci robot. Today, we are expanding our advanced robotics program to include general surgery, gynecology and urology, particularly for prostate cancer.

Surgery is always a major step. But with da Vinci, you could find yourself stepping more quickly back into your own life, and all the things that truly matter.

Is the da Vinci right for you? To learn more about this minimally invasive surgical option, visit www.roboticsurgery.uhseast.com.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

How strong is your insurance carrier?

You carry the weight of the world on your shoulders. At Medical Protective, we know just what that's like because more than 70,000 healthcare providers count on us every day. That's why we take such pride in the fact that:

- We are a Berkshire Hathaway company
- We hold an "A++" (Superior) A.M. Best rating and S&P rating of "AAA"
- We have the means and wherewithal to fight

Strength. Defense. Solutions. Since 1899, these are the virtues Medical Protective has stood for. They are what make Medical Protective the nation's premier medical malpractice insurer.

For more information on how Medical Protective can help protect you, call us at 800-4MEDPRO or visit us on the web at www.medpro.com.

MEDICAL PROTECTIVE
Strength. Defense. Solutions. Since 1899.

Medical Protective is a member of the Berkshire Hathaway group of businesses.
All insurance products are underwritten by The Medical Protective Company® unless otherwise indicated. The Medical Protective Company® is licensed in all states and the District of Columbia. Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

H. Neil Kirkman, MD
Kenan Professor Emeritus of Pediatrics
The University of North Carolina at Chapel Hill

H. Neil Kirkman, MD

The Newborn Screening Program of the North Carolina Division of Public Health is considered to be one of the most important public health programs today. The program screens newborns for genetic disorders and provides early diagnosis and timely treatment to those affected. As such, it mitigates the terrible outcomes of undiagnosed and untreated disorders, which may include mental retardation or even death. This screening program has both ethical and financial benefits for the state. Screening and the subsequent treatment of affected newborns is a better use of resources than the long-term care of undiagnosed and untreated children. Moreover, it reduces the emotional burden for families with affected children. Most of the states in the US started to offer this program in the 1960s and North Carolina was no exception. North Carolina started its program in 1965 with screening for a single disorder (phenylketonuria, or PKU) and has, since that time, expanded to screen for more than 30 disorders.

Dr. Kirkman came to North Carolina in 1965, only 6 months before the newborn screening for PKU began. Infants with PKU were initially treated at 2 or 3 university medical centers, but it became apparent that the management for such an uncommon disorder was most economically and effectively done at a single medical center, which became the PKU Center at the University of North Carolina at Chapel Hill (UNC Chapel Hill). Dr. Kirkman served as the Chief of the Division of Genetics and Metabolism at UNC Chapel Hill from 1965 until his retirement in 1991. During his tenure, he cared for nearly all the PKU babies in North Carolina. Along with his medical team, he talked with the parents by telephone the same day he received the word that the baby likely had PKU and made an appointment for the parents to bring the infant to the hospital immediately. He needed to confirm that all the infants who tested positive actually had PKU and that the special PKU diet would not be deadly to the child or be overly restrictive for quality of life reasons. At the hospital, he and his medical team also gave the parents a positive message about early diagnosis of PKU and provided them with an opportunity to ask questions. He continued to care for his PKU patients on a part-time basis even after his retirement. Dr. Kirkman fully retired from seeing patients in 2000. According to Dr. Dianne Frazier, Professor of Pediatrics and a longtime colleague of Dr. Kirkman, "He is loved by all his patients and their families. They still ask about him whenever they come to the clinic."

Dr. Kirkman is not only a clinician but also a laboratorian. He wrote the computer program for confirmatory test for galactosemia, which is still being used in the newborn screening laboratory. After his full retirement in 2000, he made several attempts to develop an automated galatose-1-phosphate uridyl transferase assay, traveling from Chapel Hill to Raleigh. He continues to write and publish scientific papers with his longtime research colleague Dr. Gian Gaetani. His latest project is to write the history of the North Carolina Newborn Screening Program.

Even after his retirement, Dr. Kirkman continues to serve as an active member of the NC Newborn Screening Advisory Committee and campaigns vigorously for the North Carolina Newborn Screening Program. Several years ago, he wrote to the state legislature against privatization when a for-profit commercial company tried to dismantle the state-managed Newborn Screening Program.

His tender care to his patients and his dedication to the North Carolina Newborn Screening Program have won the respect of his patients, their parents, and his colleagues. As Dr. Dianne Frazier summarizes, "He is a scholar and a gentleman, who always went about his work with deep regard for both patients and colleagues."

The Editors of the *NC Medical Journal* are pleased to recognize Dr. H. Neil Kirkman for his lifetime of work dedicated to quality patient care, development of a successful newborn screening program, and contributions to the field of laboratory science and clinical pathology.

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

ARTICLE

Correlates of Intimate Partner Violence Among Female Patients at a North Carolina Emergency Department

Melissa Roche, MA; Kathryn E. Moracco, PhD, MPH; Kimberly S. Dixon, MSW; Elizabeth A. Stern, MPH; J. Michael Bowling, PhD

Abstract

Objective: *This paper identifies comorbid factors among female emergency department (ED) patients who have experienced intimate partner violence (IPV).*

Methods: *321 adult female patients completed self-administered questionnaires while in an urban North Carolina emergency department. IPV was assessed by questioning whether the patient had ever been afraid of a partner, physically hurt or threatened by a partner, or forced to have sex by a partner.*

Results: *One third of all female patients reported at least one form of IPV in their lifetimes. IPV was associated with a low self-rating of physical and mental health, frequent visits to the ED, and problems with alcohol, drugs, and mental health. In multivariate analysis, only a history of alcohol and mental health problems and a low self-rating of mental health remained significant.*

Conclusions: *The findings illustrate the need for IPV screening protocols that address mental health and substance abuse and also emphasize the importance of screening all women for IPV.*

Background

It is well established that physical, sexual, and psychological intimate partner violence (IPV) against women is both widespread and a serious threat to women's health. The National Violence Against Women Survey estimates that 25% of women are physically or sexually assaulted by intimate partners in their lifetimes.[1] Physical health consequences of IPV include fatal and nonfatal injuries, trauma-specific and generalized pain, unwanted pregnancies, sexually transmitted infections, and gynecological problems.[2,3,4,5] IPV is also associated with substance abuse and a variety of mental health problems including depression, anxiety, suicide, and post-traumatic stress disorder (PTSD).[6,7,8,9,10] Victimized women view themselves as being less healthy and report lower levels of physical and mental well-being than women who have not been victimized.[1,11,12]

The prevalence of IPV among emergency department (ED) patient populations varies widely depending on the definition of IPV, identification method, sample, and setting. Research indicates that 5% to 19% of all female ED patients have been physically or sexually abused in the previous year and 33% to 54% report a lifetime history of abuse.[13,14,15,16] Moreover, studies suggest that 2% to 7% of *all* female ED patients present with acute trauma due to abuse,[17,18,19] and 30% to 41% of the

J. Michael Bowling, PhD, is a research associate professor at the Department of Health Behavior and Health Education at the University of North Carolina at Chapel Hill.

violence-related injuries to female ED patients are inflicted by intimate partners.[20,21] However, most battered women present in emergency departments with health problems other than injuries.[16,20]

The ED is an optimal setting for identifying and referring victims of IPV because clinicians come into contact with past, current, and future victims daily, yielding multiple opportunities to reduce morbidity and mortality caused by IPV. Accordingly, during the past two decades there has been a call for emergency departments to develop and implement IPV screening protocols for female patients. Since 1992, the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) has required that accredited emergency departments have IPV policies, procedures, and educational opportunities in place. Despite widespread efforts to train providers and institutionalize IPV protocols, research indicates that IPV screening rates in emergency departments remain low.[22,23] This is in part because health care providers feel they lack effective interventions to respond to the needs of women who disclose violence.[24]

The purpose of this paper is to identify comorbid factors among adult female ED patients who have experienced intimate partner violence. Given the high prevalence of IPV in this population, distinguishing characteristics and conditions that are associated with IPV may enable providers to respond more effectively to these patients by identifying their specific physical and mental health needs.

Methods

Data for this study come from an evaluation of a hospital-based intervention designed to increase IPV detection and provide appropriate services to IPV survivors in the emergency department of a mid-sized community hospital located in an urban, ethnically diverse county in north central North Carolina. We consecutively approached all female patients age 18 and older who visited the ED to receive care for themselves during randomly selected six-hour shifts within two three-week periods pre and postintervention. Women were excluded from the study if they showed signs of cognitive impairment (including intoxication), were in police custody, did not speak English or Spanish, or were admitted to the hospital.

Participants completed a two-page self-administered questionnaire (available in English and Spanish) that included questions about their demographic characteristics, self-assessed physical and mental health status, history of IPV, and whether they were asked about IPV during their ED visit. Respondents indicated whether they were willing to be called for a 15 to 20 minute phone interview, and if so, they were asked to provide a safe date, time, and number for project staff to call.

In order to protect patients' safety and privacy, participants were offered one of two versions of the questionnaire. Women who were unaccompanied or could complete the form alone received a full version of the questionnaire, which contained questions about adult lifetime IPV experience and IPV screening in the ED. Women who could not complete the form in privacy received an abbreviated version that did not contain questions about IPV. Those women who completed the abbreviated questionnaire and indicated willingness to participate in a phone interview were called and asked the questions about IPV. All participants received $5 in cash for completing the survey.

The Institutional Review Boards of Durham Regional Hospital, Duke University Health System, and the Pacific Institute for Research and Evaluation (PIRE) all reviewed and approved this study.

Variable Definitions

Lifetime experience with IPV was assessed via 3 items on the questionnaire that asked whether the respondent had ever been (1) afraid of a partner, (2) physically hurt or threatened by a partner, and (3) forced to have sex by a partner. For this study, we categorized women as having experienced IPV during their lifetime if they responded "yes" to any of the 3 questions.

Demographic variables included age, race, educational level, and marital status. Health-related variables included single questions about participants' self-assessment of their current physical and mental health ("Compared to women your age, would you say your physical / mental health is: excellent / very good / good / fair / poor?"), disability status ("Do you have a physical disability or health condition that limits your physical functioning?" yes / no), history of problems with mental health ("Have you ever had any mental health problems, like depression, bipolar disorder, or post-traumatic stress disorder?" yes / no), alcohol ("Have you ever had a problem with alcohol?" yes / no), and drugs ("Have you ever had a problem abusing prescription or nonprescription (recreational/illegal) drugs?" yes / no). We also asked participants a number of health care related items, including how many times they had been to the ED in the past 12 months, how most of their medical costs were covered (self pay, Medicare, Medicaid, private insurance, other), the reasons for their current visit (injury, illness, or other), and satisfaction with their current ED visit (very satisfied, somewhat satisfied, somewhat dissatisfied, very dissatisfied).

Data Analysis

We used SPSS version 11.3 (SPSS Inc, Chicago, IL) for all analyses. After examining univariate frequencies, we used Fisher's exact tests for analysis of bivariate associations with whether or not women reported IPV. We then included factors that were significantly associated with experiencing IPV in a logistic regression model and calculated adjusted odds ratios (AOR) and 95% confidence intervals (CI). A p-value of .05 was considered significant for all analyses. We assessed for multi-collinearity among the independent variables in our model and did not find any cause for concern using the criteria of variance inflation factor (VIF) = 2.5.[25]

Results

A total of 346 female patients completed the survey during a visit to the emergency department, representing 75% of eligible patients. Of those, 321 completed the full form that included questions about their personal experience with IPV and 25 completed the abbreviated form. Of the women who completed the full form, seven failed to provide information about their history of IPV. Of the 25 women who completed the abbreviated form, seven were successfully contacted by telephone and provided information about IPV. In total, 321 women (93%) provided information on their history of IPV and are thus included in the analysis. Of the sample included in this analysis, 124 women were interviewed preintervention and 197 were interviewed postintervention. Given that the intervention was designed to increase identification of IPV among female ED patients and that respondents were, in fact, more likely to have been asked about IPV by ED staff postintervention, there is a possibility that the women surveyed postintervention would be more likely to note a history of IPV on their self-administered survey. However, we found that the pre and postintervention groups did not differ significantly on any of the independent variables nor in their reporting of IPV.

Table 1 describes the characteristics of the study sample. The ages of women ranged from 18 to 74, with a mean age of 37. Two thirds of the patients were African American and more than half (56%) were not married. In addition to the current visit, most (81.2%) of the patients had made at least one other visit to an ED in the previous 12 months, with 63.9% of the sample reporting 2 or more other ED visits in the last year.

One third of women (33.3%) reported that they had experienced some form of IPV in their lifetimes. Table 2 presents the combinations of IPV reported by women who disclosed some form of IPV. As indicated in the table, most types of IPV did not occur in isolation.

Table 3 presents the results of the bivariate analyses of factors associated with reporting IPV. Factors consistently associated with all 3 forms of IPV are describing current mental health as fair or poor, a self-reported history of alcohol problems, a self-reported history of drug problems, and a self-reported history of mental health problems. Factors associated with reporting IPV, but not consistently associated with the individual forms of IPV, are Medicaid status, describing physical health as fair or poor, and two or more visits to the ED in the past year. None of the other factors analyzed were significantly associated with reporting IPV, including whether the woman was at the ED due to an injury or came accompanied by a partner.

We included the variables that were bivariately associated with IPV in a logistic regression analysis, with reporting any IPV as the outcome variable (Table 4). After controlling for age, education, race, and marital status, only a self-described history of mental health problems, history of alcohol problems, and reporting mental health as fair or poor remained significantly associated with experience of IPV. Marital status also independently predicted experience of IPV. Women who were separated or divorced were more than eight times more likely (AOR 8.47; 95% CI: 3.44-20.88) to report a history of IPV compared with single women.

Discussion

Our finding that a third of female ED patients have experienced IPV in their lifetimes is consistent with the high prevalence of IPV among female patients found in other ED-based studies.[13,14,15,16] Also consistent with previous research are the findings that most women who have experienced IPV visit the ED for noninjury complaints, and that there are few discernable differences between victims and nonvictims.[13,14,15,16] The differences that remained significant, self-reported histories of alcohol and mental health problems and fair or poor self-assessed

All three forms of IPV	33	30.8

mental health status, indicate that ED patients who are IPV survivors may have unaddressed mental health and substance abuse needs.

The results of this study indicate that the ED is a good place to identify and assist IPV survivors, and that all women should be screened for IPV, regardless of their presentation. We recognize that there is an ongoing debate over the effectiveness of IPV screening in health care settings, including how to measure the long-term effectiveness of IPV screening.[26,27] While there certainly is an urgent need for rigorous research regarding the effectiveness of screening, universal IPV screening for female ED patients seems warranted given the high prevalence of IPV among female ED patients, support for screening by professional organizations as well as patients,[16,28,29,30] and the lack of evidence that screening is more harmful than not screening.

The fact that IPV survivors were more likely than women who had not experienced IPV to report having ever had alcohol and mental health problems, and that they were more likely to rate their current mental health status as fair or poor, suggests that women who have experienced IPV have potentially unaddressed mental health and substance abuse needs. Previous research has documented the strong association between IPV and mental health problems, particularly depression and post-traumatic stress disorder (PTSD).[6,7,8,9,10] Similarly, alcohol use or abuse has been associated with an increased risk of past or current IPV.[6,10,16,31] The etiology of mental illness and substance abuse among battered women is unclear, as the bulk of previous research cannot establish temporal sequence. Regarding the link between IPV and mental health problems, Frank and Rodowski (1999) note that mental health problems may be more common among female IPV victims "both because mentally ill women are more vulnerable to abuse and because verbal or physical abuse may precipitate or perpetuate psychiatric disorders."[32] Regardless of the exact nature of the relationship, previous research, along with this study's findings, suggest that a high proportion of IPV survivors presenting in the emergency department will have concurrent mental health needs. Referrals to services to address these needs should be part of IPV screening protocols in health care settings.

C statistic = .788 (95% CI .733 - .843, p < .001)

The results of our study should be viewed within the context of its limitations. First, because the study was conducted in a single urban emergency department, it is not generalizable to all women in the state nor to all female ED patients. The study also only included women who were discharged from the ED. These women may be significantly different from women who were subsequently admitted to the hospital in terms of the severity of their illness or injury. In addition, given that the ED intervention was designed to increase identification of IPV among female ED patients and that respondents were, in fact, more likely to have been asked about IPV by ED staff postintervention, there is a possibility that postintervention respondents would be more likely to note a history of IPV on their self-administered survey. However, we found that the pre and postintervention groups did not differ significantly in the proportions reporting of IPV.

We also asked women about their lifetime experience with IPV without collecting any information about the characteristics (eg, recency, severity, frequency, duration) of those experiences. It is possible that some participants experienced only isolated incidents of IPV in the distant past. However, previous research has demonstrated that IPV has profound and long-lasting effects on women's physical and mental health,[2,3,4] and past victimization is a risk factor for current and future IPV.[33] An additional limitation to the study is potential misclassification bias that could have occurred because respondents provided self assessments for several of the key independent variables, notably their histories of substances abuse and mental health problems. All respondents may not have understood and interpreted these questions in the same way.

Finally, the cross-sectional nature of this research makes it impossible to establish temporality, and the study is subject to both recall and reporting bias.

Despite these limitations, our study provides further evidence that the emergency department is an important setting in which to identify and assist women who have experienced IPV. It also reinforces the need to screen all adult female ED patients regardless of their presenting complaint. Providers should also be cognizant of the potential concurrent mental health needs of women who have experienced or are experiencing IPV and ensure that they are equipped to provide appropriate referrals to mental health providers, substance abuse services, and intimate partner violence agencies. **NCMJ**

Call for Papers

John W. Williams, Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

ARTICLE

Providing Medical Care in State Psychiatric Hospitals

Susan Saik, MD; Brian B. Sheitman, MD; Scott Mann, MD; Walter W. Stelle, PhD;
James W. Osberg III, PhD

Abstract

Background: *Dorothea Dix State Psychiatric Hospital (DDH) was cited by regulatory agencies in 1999-2001 for serious deficiencies in providing medical care to psychiatric patients. This resulted in a change in the discipline responsible for providing medical care. We report here how clinical staff and regulatory agencies evaluated the change. In addition, we sought to determine how medical care is currently provided at other state hospitals across the nation.*

Methods: *A transition occurred whereby the responsibility for medical care (direct care and supervision of physician extenders) was changed from psychiatrists to internists. We surveyed psychiatrists and nurses about their impressions of the change and calculated the number of citations from regulators pre-and post-changeover. In addition, a survey was sent to all 212 state psychiatric hospitals.*

Results: *Response rates were: 100% for DDH psychiatrists, 42% for DDH nurses, and 67% for state hospitals. At DDH, clinicians favorably viewed the changeover with 23 (96%) of the 24 psychiatrists reporting a preference for internists having overall responsibility for medical care. There was also a marked reduction in deficiencies cited by regulatory agencies, with 10 prior to the change and only one after the change. Responses to the State Psychiatric Hospital survey revealed that psychiatrists currently provide or are responsible for at least some portion of the medical care at 69% of all facilities.*

Limitations: *DDH staff evaluated a change from a system that had not been in place for 3 years. Quality of care measures were not available. How these data generalize to other state hospitals is unknown.*

Conclusions: *Having internists responsible for medical care was well received by staff and regulatory agencies. Currently, state psychiatric facilities use different approaches to provide medical care. Further research is needed on how quality of care, and ultimately patient safety, may be impacted by these different service delivery models.*

Key words: *Inpatient psychiatry, state hospitals, medical comorbidity*

Introduction

Patients with psychiatric and/or substance abuse disorders have an increased prevalence of comorbid medical disorders compared to the general population.[1-4] A recent report on the physical health of the 1500 schizophrenia patients enrolled in the Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) study showed that over 40% had signs and symptoms consistent with the metabolic syndrome.[5] This syndrome is characterized by insulin resistance and associated with an increased risk of diabetes and cardiovascular disease. In addition, among patients hospitalized for either a medical or surgical condition, those patients with schizophrenia, when compared to those without the condition, had significantly more complications, with their average length of stay 10 days longer.[6] The reason for the increased prevalence of medical problems is less clear and likely multifactorial.[7-10] A reduced commitment/ability to maintain overall good health, side effects of prescribed psychotropic medications, an increased neuro-developmental vulnerability, increased use of tobacco products, and some combination of all

Susan Saik, MD, is chief of medical services and assistant clinical director at Dorothea Dix State Psychiatric Hospital in Raleigh, NC and clinical associate professor in the Department of Medicine at the University of North Carolina at Chapel Hill. Dr. Saik can be reached at Susan.Saik@ncmail.net or Dorothea Dix Hospital, 820 South Boylan Avenue, Raleigh, NC 27603.

Brian B. Sheitman, MD, is chief of adult psychiatry and associate director of clinical research at Dorothea Dix State Psychiatric Hospital and clinical professor in the Department of Psychiatry at the University of North Carolina at Chapel Hill.

Scott Mann, MD, is an attending internist at Dorothea Dix State Psychiatric Hospital and clinical assistant professor in the Department of Medicine at the University of North Carolina at Chapel Hill.

Walter W. Stelle, PhD, is currently retired and was the prior hospital director at Dorothea Dix State Psychiatric Hospital.

James W. Osberg III, PhD, is hospital director at Dorothea Dix State Psychiatric Hospital.

the above have been suggested. Recent recommendations acknowledging the increased medical comorbidity among schizophrenia patients now call for mental health providers to offer physical health monitoring in primary care settings for those patients who do not routinely receive ongoing physical health monitoring.[11]

How to best provide medical care for psychiatric inpatients in state facilities or freestanding psychiatric hospitals (not affiliated with a general medical hospital) has received limited systematic investigation. Given Dorothea Dix Hospital's (DDH) history of regulatory problems directly related to the proper medical care of patients on the psychiatric units, a decision was made in 2001 to change the professional medical discipline responsible for providing and supervising all medical care from psychiatrists to internists. The purpose of this report is to describe the impressions of clinical staff (psychiatrists and nurses) and outside regulatory agencies on how they evaluated the changeover to the current system. In addition, we conducted a survey of all state psychiatric hospitals in the United States, whereby we requested information on which medical disciplines are responsible for providing medical (nonpsychiatric) care to the patients on the psychiatric units.

Methods

Part I. This study was conducted at DDH in Raleigh, North Carolina. The hospital maintains both Joint Commission on Accreditation of Hospital Organizations (JCAHO) and Centers for Medicare and Medicaid Services (CMS) certification. The hospital is the primary off-site training location for the University of North Carolina at Chapel Hill (UNC-Chapel Hill) Department of Psychiatry. Psychiatric residents and medical students rotate through the adult and adolescent admission wards. In addition, all psychiatric residents spend two months of their medicine rotation on the DDH medical unit. All of the teaching attending physicians have faculty appointments at either the UNC-Chapel Hill Departments of Psychiatry or Medicine.

DDH serves adolescent, adult, and geriatric patients. The hospital also has both a Pre-trial Evaluation Unit and a 90-bed Forensic Treatment Program. There is a separate medical unit that provides a scope of service capable of handling most acute medical problems (ie, with capabilities similar to a general hospital non-Intensive Care Unit bed). There are approximately 4500 admissions per year to the hospital and an average daily census of about 320. The hospital serves both acute patients and those requiring extended stays. The primary diagnoses among the acute admissions patients are substance abuse disorders (60%) and the major mental illnesses (40%), consisting of schizophrenia, schizoaffective disorder, and bipolar disorder. The longer stay patients are primarily diagnosed with a major mental illness.

A transition in the provision of direct medical care began toward the end of 2001. Internists were made responsible for these functions rather than psychiatrists who had previously been providing direct medical care and were also supervising the physician extenders. The change was fully implemented by the end of the year 2002.

Management believed the changeover was remarkably successful and that almost everyone was pleased with the new system. However, data was not systematically collected to verify this opinion. Therefore, in the winter of 2005, a survey was conducted of all psychiatric and nursing staff. The survey was conducted anonymously for nursing staff, but not for the psychiatrists. Conducting the survey anonymously for psychiatrists, as well, was considered but decided against due to the difficulty of achieving true anonymity given the relatively small number of psychiatrists employed (n=24).

The investigators developed the survey and designed it to be brief. The psychiatrist survey consisted of 6 questions, with 5 of the 6 questions requesting a selection of the best response out of 3 or 4 choices (ie, yes, no, not sure). The other question, "What do you like or not like about the way medical care is provided to psychiatric patients at DDH," instructs the psychiatrist to select as many of the listed responses that are applicable. There is also a space left to write in responses. The authors did not formally assess the validity of the instrument before using it. The surveys were sent directly to all psychiatrists, and their supervisor was responsible for following up to see that it was completed. Completed surveys were sent to the clinical director's office. The nursing survey consisted of 3 questions. Similar to the psychiatrists' survey, the nurses' survey included a question asking what they liked or disliked about how medical care is provided at DDH. The nursing surveys were distributed from the director of nursing to nursing supervisors, who then distributed the surveys to the individual nurses. Nursing staff were instructed to send the surveys back to the director of nursing's office. Surveys were sent one time only, though supervisors were asked to remind nurses to respond. No incentives were offered to those who responded. At the time of the survey, there were 24 staff psychiatrists at the hospital, of which 21 were diplomates of the American Board of Psychiatry and Neurology Board (ie, board certified) with the remaining 3 board eligible. Sixteen psychiatrists had worked at either DDH or another state hospital where psychiatrists were directly responsible for providing medical care. There were 155 nurses employed at the time of the survey.

Part II. The Centers for Medicare & Medicaid Services (CMS, formerly known as the Health Care Financing Administration or HCFA) facility and compliance survey records were reviewed for two 3-year periods: 1999-2001 and 2003-2005. All regulator-cited deficiencies specifically related to the medical care of patients for each period were recorded. To be counted as a deficiency, there needed to be a specific reference in the CMS record to care that did not meet either the element, standard, or condition of care as required by CMS. If the same deficiency was cited in more than one place (ie, cited as deficient on multiple elements, standards, or conditions) it was only counted one time.

Part III. Due to the impression of how successful the changeover had been at DDH and to the anecdotal stories of the many different ways medical care was provided in other state hospitals, we sought to systematically collect data on this issue. Therefore, a list of all state psychiatric hospitals (n=212), including chief executive officers (CEOs) and addresses, was obtained from the National Association of State Hospital Program Directors (NASHPD) website in 2006. A brief survey was developed by the investigators consisting of 5 questions with instructions to choose the best answer from a list provided or to write in a response if the response choices did not fit their institution. The survey was then sent to each hospital's CEO with instructions to please forward the survey to the person at the institution who could best answer questions about which disciplines were providing medical care on the psychiatric units. Questions addressed both normal business hours and off–hours coverage since many institutions use "moonlighting" providers (ie, licensed physicians either within or outside of their specialty who typically work nights or weekends, in addition to their regular jobs, to earn additional compensation). The survey was sent one time only and no incentives were provided.

Given the types of data collected, only descriptive statistics were used for all data analyses.

Results

Survey of psychiatrists and nurses at Dorothea Dix Hospital

Psychiatrists

All 24 psychiatrists responded to the survey. All except one (96%) preferred having internists provide and be responsible for the medical care of patients. One (4%) psychiatrist wasn't sure. The most common reasons sighted for this preference were:

a. Reduces my concern about missing a serious medical problem 100%
b. Gives me more time to focus on psychiatric issues 96%
c Reduces my potential medical legal risk 83%

Psychiatrists described their working relationship with the internists and the physician extenders as follows: excellent 92% (n=22), good 8% (n=2), fair and poor 0%.

Nurses

Of the 155 nurses who were sent surveys, 65 (42%) responded. All except four (94%) stated that they preferred the current approach. Forty-seven nurses had worked at DDH for more than 4 years and had experience with both service delivery systems. The most common reasons sighted for their preference were:

a. I feel more comfortable having a medical provider address medical issues.....................................88%
b. I prefer to contact the person who will specifically address the problem, rather than often being asked to make more than one call................................71%

Deficiencies Cited by CMS

During the period 1999-2001, there were 10 citations identified by regulators that were directly related to the medical care of patients. Thus, the hospital was found to be out of compliance with the "Conditions of Participation" and needed immediate plans for correction to avoid losing federal funding. During the period 2003-2005, there was one citation related to medical care. This was corrected by the time regulators visited, so there were no requirements for additional follow-up.

Survey of State Hospitals

Responses were received from 145 (67%) of the state hospitals and included the following:

1. Medical (nonpsychiatric) care during business hours was provided as follows:
   Psychiatrists 65/143 (45%), physician extenders 58/143 (41%), physicians other than psychiatrists 137/143 (96%). Note: Many hospitals reported that multiple disciplines provided coverage; therefore, the numerator does not add up to 143.
2. If physician extenders were used, who was responsible for their supervision?
   Physician extenders were used in 70/143 facilities (12 facilities reported using physician extenders as moonlighters). They were supervised by psychiatrists in 35/70 (50%) of facilities and internists in 66/70 (94%) of facilities.
3. Off-hours coverage was provided by moonlighting physicians in 68/143 (48%) of the facilities. Psychiatrists provided this coverage in 42/68 (62%) facilities, nonpsychiatric physicians in 52/68 (76%), and physician extenders in 13/68 (19%).
4. Nonpsychiatric physicians solely provided medical care in 44/143 (31%) facilities, while psychiatrists were responsible for medical care by either directly caring for patients during regular business hours, supervising physician extenders, or providing moonlighting coverage in 99/143 (69%) of the facilities.

Discussion

These data suggest that the transition from psychiatrists to internists went very well at DDH. Both psychiatrists and nurses overwhelmingly endorsed the current system with most having experience working in the previous model. Psychiatrists unanimously endorsed that the change reduced their concern about missing a serious medical problem. In addition, despite some concerns that there would be an emergence of "turf" battles between psychiatrists and nonpsychiatric physicians, relationships between the two disciplines were described as excellent by 22/24 psychiatrists and good by the other two psychiatrists. Nurses also overwhelmingly reported that they preferred having a medical provider address medical issues and preferred directly contacting the person who would address the problem. Moreover, there was a marked reduction in the number of regulator-cited deficiencies in the medical care provided to patients.

The data received from the survey of all the facilities would suggest that there is currently no consensus on which disciplines should be providing medical care to patients in state facilities. Though psychiatrists do not provide medical care at our facility, this remains the case at 69% of the facilities. Psychiatrists provide direct medical care during business hours in 45% of hospitals, are responsible for supervision of physician extenders in 50% of facilities that use them, and are responsible for medical care while moonlighting at 62% of hospitals where moonlighting occurs.

We were in favor of the change from psychiatrists to internists because we felt that staying current with the latest psychiatric advances is a full-time job, and it is unrealistic to expect psychiatrists, no matter how competent, to keep up with the internal medicine literature as well. Interestingly, the Psychiatry Board recertification exam contains no questions directly related to internal medicine. Anecdotal accounts suggest that having "split" treatment (ie, mental health care treatment by a psychiatrist and nonmental health care by a nonpsychiatrist) seems to be the way most outpatient psychiatrists operate their practice. Furthermore, the larger issue of how to best provide medical care to a patient hospitalized for a different indication is not only relevant to psychiatric inpatients. A recent publication described a project whereby a hospitalist-orthopedic team worked together in a collaborative model with orthopedic surgery patients, as opposed to the traditional consultant model used in academic medical centers.[12] They reported a reduction in minor postoperative complication rates, with no statistically significant differences in length of stay or cost. Both the nurses and surgeons strongly preferred the comanagement hospitalist model.

This report has its limitations. The survey data are comparing two different time periods and are limited to "satisfaction" with the change, not differences in specific quality of care measures. In addition, psychiatrists were not surveyed anonymously, which could have biased their opinions, and only 42% of the nurses responded. DDH also has a medical unit with a scope of service beyond what some other state hospitals may have, and it also has a strong affiliation with an academic medical center located relatively close to it. Nevertheless, we believe this is a very important topic for the medical field. Currently, state psychiatric facilities use different approaches to provide medical care for patients. These data suggest that further research is needed on how quality of care and, ultimately, patient safety may be impacted by these different service delivery models in order to eventually make best practice recommendations. **NCMJ**

POLICY FORUM

Laboratory Medicine and Clinical Pathology: Changing Paradigms of Practice

COMMENTARIES

> *"The volume and precision of information we can gather has brought us to the threshold of a new paradigm in health care where we are changing from a system in which diagnosis and treatment prevail to one in which prognosis is joined with treatment to anticipate the effects of interventions, even to anticipate the incidence and existence of disease."*

INTRODUCTION

Policy Forum:
Current Topics in Laboratory Medicine and Clincal Pathology

Modern day medicine has become a very complex process that depends more and more on specific information about individuals. We are familiar with "tests" that assess the nature and content of our fluids, tissues, and physiological functions and recognize that these tests provide necessary information to ensure the best possible care. What we may not understand is how precise, sensitive, and complex those tests have become and how much the practice of health care has come to depend on these assays and evaluations. In fact, the volume and precision of information we can gather has brought us to the threshold of a new paradigm in health care where we are changing from a system in which diagnosis and treatment prevail to one in which prognosis is joined with treatment to anticipate the effects of interventions, even to anticipate the incidence and existence of disease.

One area of testing that has received perhaps more attention than others is genetic testing for susceptibility to disease. This line of work has evolved such that we are able to assess the overall disease susceptibility of the human genome for groups of people and for individuals in some cases. That work is controversial and raises ethical concerns for the bedside clinician, the laboratorian, and the policy makers who shape payment and information sharing rules. This issue of the *North Carolina Medical Journal* includes discussions of these consequences as well as the promise of the new technologies.

The location of testing has broadened from the hospital, clinic, or laboratory to the home or workplace. Diabetes monitoring and pregnancy testing are the most familiar in-home tests, but there are emerging tests for drug monitoring and other disease self-management. We are seeing intensive testing and screening efforts making use of health fairs, there are a range of tests available in "minute clinics" in pharmacies, health clubs and fitness centers are offering a range of tests, and shopping malls have become the location for testing centers or volunteer efforts that include taking samples. These new opportunities for testing may be seen as a "disruptive technology" that threatens the organization of medical care or as a chance to intervene more effectively in population health.

This issue of the *Journal* ventures into some quite technical areas such as nucleic acid amplification, karytotyping, mass spectromtetry in proteomics, polymerase chain reaction, and flow cytometry. These may seem to be very complex and specialized parts of the world of pathology and laboratory medicine, but they are becoming more and more the workhorse components of day-to-day health care. These techniques and approaches will likely be so ubiquitous that the material covered in this issue of the *Journal* may become part of the standard vocabulary and knowledge base for all caregivers as well as patients in the not-to-distant future

The goal of this issue of the *Journal* is to help the lay person as well as the broadest array of caregivers begin to understand how rapidly this field is developing and how it has the potential to bring even more change to clinical care and prevention of disease as we seek to give people healthier and happier lives.

ISSUE BRIEF

Polishing the Crystal Ball:
Emerging Trends in Contemporary Clinical Laboratory Medicine

Dana D. Copeland, MD, PhD

For clinical laboratory medicine in the 21st century nothing is so important as strong prediction. Strong in the sense of robust and specific detail of the predicted events and strong in the sense of high likelihood of predicted outcomes. For a discipline that has focused primarily on diagnosis for more than a century, this new ascendancy of prognosis in the application of clinical laboratory data represents a paradigm shift. The value of a laboratory test in the modern era is often measured by the utility of the test result in predicting a future clinical event in the patient's course. In some cases the test result will be useful in predicting relevant events that will occur in the next few minutes or hours and, in other cases, events years and even decades in the future.

> *"In the new 21st century paradigm, the role of the laboratory will increasingly be one of helping the physician answer the question: What will happen to this patient and will any of several interventions likely change what will happen in a favorable way?"*

The prevailing diagnostic applications of medical laboratory testing in the 20th century are giving way in the 21st century to prognostic implications for risk stratification, prevention, therapeutic design and timing, and ultimately even for disease definition. In the 20th century the laboratory helped the physician answer the question: Is anything wrong with the patient and if so what? This paradigm led to a generalized notion that a laboratory result was either normal or abnormal. In the new 21st century paradigm, the role of the laboratory will increasingly be one of helping the physician answer the question: What will happen to this patient and will any of several interventions likely change what will happen in a favorable way? In the new paradigm, significance for laboratory results will increasingly be measured in incremental impact on likelihood of clinically significant events and methods of prevention or mitigation.

This issue of the *North Carolina Medical Journal* examines some of the factors driving this paradigm shift and the implications of increasing prognostic utility for laboratory testing. We explore some innovations that illustrate the trend and the implications for health care providers and patients alike in commentaries that illustrate emerging technologies, evolving platforms for testing, and new ways of applying the data to shape the interaction of patient and health care provider. For contemporary clinical laboratory medicine, change occurs along 3 principal axes: what we can detect, where the analysis occurs, and how the result is applied in patient management.

What we detect in the modern clinical laboratory changes, as it has for over 150 years, through the power of advances in analytic technology. Today clinical laboratories in most modern hospitals routinely detect analytes down to a level of one part per 10 billion. Not only has the detection level of our assays been improved by several orders of magnitude, but the inventory of analytes with clinical significance has exploded as our more sensitive assays allow researchers to explore in detail the relationships between disease and body chemistry. Dozens of new markers with potential

clinical significance are introduced every year. Advances in proteomics, nucleic acid amplification, and molecular genetic pathology promise to accelerate the introduction of new tests with clinical significance.

Where we test is undergoing a dramatic shift. The first useful clinical laboratory test was the visual, olfactory, and gustatory analysis of urine. Analysis was often performed at the patient's bedside. In the 20th century, the emergence of more sophisticated testing that required either laboratory expertise or expensive equipment led to centralized laboratories in hospitals or at reference sites. Specimens were obtained from the patient and then transported to the testing laboratory, sometimes in the same building and sometimes thousands of miles away. Most testing moved away from the patient and into the remote laboratory. Then with the introduction of semi-quantitative glucose testing with dipsticks in the early 1960s and true quantitative glucose testing with portable glucometers in the 1970s, analytical chemistry testing began to return to the near patient environment. The trend has only accelerated with the introduction over the past two decades of a variety of point-of-care testing devices that put powerful analytic capabilities into the hands of health care professionals at the bedside, require only minimal expertise for operation, and provide real-time data for clinical management and decision making.

In contemporary clinical laboratory medicine, the site of testing is determined in part by the time frame in which prognostic significance applies. If the results of the test predict clinical events or therapeutic impact that will occur within minutes, the testing is likely to occur in a setting near the patient. For tests with prognostic significance in the hour to 24-hour range, a centralized laboratory remains the most likely venue. Intense clinical management of the patient in either the inpatient or ambulatory setting favors rapid turnaround for even routine tests, and economic pressures for efficient and cost-effective care are driving dramatic changes in the centralized hospital laboratory of the early 21st century.

Already for diabetes, and in the near future for other conditions, the ease of operation and reliability of point-of-care devices will facilitate the migration of traditional laboratory testing not only away from the central laboratory but also out of the hands of health professionals and into the hands of patients. Patients so empowered will be able to participate more effectively in the management of their own disease and in triage decisions that determine if and when intervention by medical professionals will be necessary.

A third area of accelerating change, and perhaps the most intriguing, is how the data generated by clinical laboratory medicine is employed in the management of the patient. Modern medicine and the experimental laboratory were born conjoined twins in the 19th century with the discovery of causal agents for disease, especially micro-organisms. A classification of diseases based on etiology and pathogenesis is still used today and continues to evolve in large measure on the basis of discoveries in the experimental laboratory. Once a causal understanding of the disease is established in the experimental laboratory, the clinical laboratory is positioned to test for the presence of etiological agents or their biochemical or immunological footprints. For the 20th century and the latter 19th century, the role of the clinical laboratory was to support or refute a physician's diagnosis.

While advances in the clinical laboratory continue to support this diagnostic paradigm, increasingly the clinical laboratory produces data with direct prognostic implications. Molecular studies can identify patients with genetic risk for the future development of disease; proteomics offers the promise of detecting patients that are evolving toward a disease state long before the disease is clinically manifest; and immunopathological assays may identify which patients among a group with the same type of tumor will do well on one treatment regimen and which will do better on another. Polymerase chain reaction (PCR) detection of microbials offers the promise of detecting and identifying pathogens in real clinical time instead of the days or weeks required by conventional microbiological assays, and identification of human papillomavirus strains in infected patients now rivals and supplements the value of the tried and proven morphologic pap smear in predicting which patients require intervention to prevent progression to cervical cancer.

Milestones in the History of the Laboratory Medicine

A cursory outline of milestones in the development of clinical laboratory medicine is helpful in understanding the implications of the rapidly evolving discipline. Examination of urine for prognosis was advocated by Hippocrates as early as 400 BC. Kouba et al recently described the 1100 year evolution of the prognostic application of uroscopy to a diagnostic approach advocated by Theophilus.[1] The objective and systematic use of urine examination by Theophilus became a paradigm for the use of an analytic test to establish diagnosis.[1] By 900 AD, guidelines for the use of urine examination as a diagnostic aide were available, and by 1500 AD, color charts for the interpretation of urine in diagnosis were widespread.[2]

The invention of the microscope in the 17th century greatly extended the power of observation as a tool for diagnostic formulation. The microscopic analysis of urine sediment emerged as an important additional quantitative analysis in the latter half of the 18th century with J. W. Tichy's work.[2] The microscopic recognition of the cellular components of blood by Marcello Malpigihi in 1661-1665, and subsequent studies by Antony von Leewenhoek, promoted a second body fluid to importance in laboratory medicine.[3] However, throughout the 17th and 18th century, urine continued to be the sample of choice for medical analysis. The 17th century chemical analysis of blood was significantly advanced by the important work of William Hewson, who first demonstrated the presence of a coagulable substance that could be separated from the cellular component of blood. Hewson's discovery of "coagulable lymph," or fibrinogen, provided the foundation for the laboratory investigation and evaluation of coagulation and disorders of coagulation.[2]

The second century Greek physician Galen is often considered the most influential medical author of all time. Galen taught that illness was a result of imbalance in the 4 fundamental humors (phlegm, blood, yellow bile, and black bile). This view was unassailed until the mid 18th century when the work of Giovanni Battista Morgagni in the post-mortem laboratory established a systematic correlation between clinical symptoms and anatomical changes in organ structure. Morgagni's seminal work *De Sedibus et Causis Morborum (On the Sites and Causes of Diseases)* became a foundation for the development of the science of pathologic anatomy. Nevertheless, the notion that the anatomical changes were themselves reflective of some imbalance in body humors continued for another hundred years.

The emergence of the germ theory of disease in the late 19th century not only laid to rest the humoral theory of Galen but also forged a relationship between modern medicine and the laboratory that came to dominate western medicine in the 20th century.[5] Physicians and patients had long recognized that outbreaks of epidemic disease implied an element of contagion, but assumed that some ambient and nonliving substance causing an imbalance in humors led to disease. Thus in the great London cholera outbreak of 1854, "miasma," a conjectured, noxious, and airborne substance arising from the decay of organic matter, was proposed by most medical authorities of the time as the cause of the epidemic. Physician John Snow, after a careful study of the patterns of case occurrence, came to the conclusion that the disease was spread by an agent in contaminated water from a particular pump in the city.[6] Snow's work advanced public hygiene and epidemiology and stimulated the search for specific agents for epidemic disease. The work of Snow as well as Semmelweis and Lister, established that at least some diseases were the results of contagious agents and the spread of these agents could be restricted by antiseptic procedures. A search for these contagious agents culminated in the revolutionary laboratory work of Louis Pasteur and Robert Koch that demonstrated the agents to be microbes.[4] The demonstration that living organisms caused disease advanced an approach to classifying disease based on external cause, an approach that persists and dominates our modern view.

A cornerstone in the development of a causal taxonomy of disease was the introduction of Koch's postulates in 1884. The postulates provided criteria for establishing an etiological link between a microbe and a disease. The four postulates in modern form are: (1) the putative causative organism must be found in every patient with the disease, (2) the organism must be isolated from a diseased individual and grown in culture, (3) the organism must produce disease when introduced into a healthy individual (usually an experimental animal), and (4) the organism must be reisolated from the experimentally infected animal.[7] Postulates 3 and 4 fall entirely into the domain of the experimental laboratory. However, the requirements of the first 2 postulates provided great impetus to the emergence of the clinical microbiology laboratory. If Koch's postulates are satisfied and a causal link established between a microbe and a disease, then it should be necessary in a patient with symptoms of that disease to require that the causative agent be recovered from the patient and grown in culture in order to establish a definitive diagnosis. This logic provided a strong tradition for clinical laboratory measures in confirming a medical diagnosis.

By the end of the 19th century, the clinical laboratory provided the culture of microbial pathogens, hemoglobin estimation, counting of red and white blood cells, microscopic identification of some parasites, clotting time in coagulation disorders, examination of sputum in tuberculosis, simple immunological tests such as agglutination tests for typhoid fever, and the demonstration of amino aciduria in liver disease.[2]

The first half of the 20th century saw an explosion of advances in analytical techniques in clinical chemistry, immunology, and blood banking as well as microbiology. With the exception of the important therapeutic applications of blood banking, the emphasis was almost entirely on the application of the methods of the clinical laboratory in diagnosis. The first textbook of laboratory medicine was edited by James C. Todd and published in 1908 as *A Manual of Clinical Diagnosis*. Ninety-eight years and seven editors latter, the 21st edition remains the authoritative reference for clinical pathology under the title, *Henry's Clinical Diagnosis and Management by Laboratory Methods*.[8] The addition of the word management reflects the emerging importance of the laboratory in not only helping make a diagnosis but also in providing data to monitor progression of disease and therapy.

Many diagnostically useful tests in clinical chemistry were developed in the first 50 years of the 20th century: serum phosphorus (1920), serum magnesium (1921), protein electrophoresis (1926), erythrocyte sedimentation rate (1929), alkaline phosphatase (1930), lipase (1932), amylase and acid phosphatase (1938), ammonia (1939), creatinine phosphokinase (1954), lactate dehydrogenase (1955), and alanine aminotransferase (1956).[9] The tests were useful but labor intensive and required manual methods by skilled technologists using sophisticated instrumentation. They were primarily applied in patients only after a physician's thorough evaluation and examination had narrowed the differential diagnosis to a short list of possibilities.

The introduction of the first automated clinical chemistry analyzer by Technicon Corporation in 1959 was a watershed in the application of these clinical analyses.[10] The Technicon Auto-Analyzer and the subsequent development of ever more powerful automated analyzers ushered in an era in which large batteries of laboratory tests could be performed quickly and economically. The ease and economy of performing multiple clinical chemistry tests presented for the first time in laboratory medicine the potential of screening healthy populations with batteries of tests to detect disease early, before pathological damage could occur. In the case of screening neonates for inborn errors of metabolism this strategy has worked exceedingly well. In 2006, the North Carolina Laboratory of Public Health screened 127 175 newborns for 41 genetic disorders. In the well adult population the results have been less satisfactory. For a period of time in the 1970s and 1980s, annual physicals might include batteries of 40 or more laboratory tests; but this approach led to little measurable improvement in outcomes. For most of the analytes in these batteries, there is overlap between values encountered in healthy and diseased populations. The more tests performed, the greater the likelihood that one or

Prediction and Accuracy

Galen and Gambino and subsequent researchers[a,b] have applied mathematical tools to medical decision making to quantify the justifiable level of confidence a particular test result can offer physicians and patients in predicting the presence or absence of disease. A full understanding of the subject is challenging for many health professionals and formidable for the lay public, however, some generalizations are possible. The overlap in the distribution of values for analytes in diseased and healthy populations means no one test can perfectly discriminate between diseased and healthy individuals.

The *sensitivity* of a test is the probability of getting a positive test result in a diseased patient. The *specificity* of a test is the probability of getting a negative result in a person without the disease. For any given test we can adjust the limit of the reference range to improve sensitivity and capture a greater portion of the diseased population, but in doing so we also increase the number of healthy patients in the test positive group *(false positive)*. If we make an adjustment in the reference limit in the other direction, we can exclude more healthy individuals from the test positive population, but we also exclude some diseased individuals *(false negatives)*. Tests that have both higher sensitivity and specificity for a certain disease are preferred. We can compare tests by plotting the true positive rate against the false positive rate at all cutoff points for reference range. This curve, called the *receiver operating characteristic curve* (ROC curve), provides a measure of the accuracy of the test for that disease. The test with the bend in the curve that is closest to the upper left hand corner of the graph is the more accurate test.[b]

The clinical laboratory strives to develop tests with optimal sensitivity and specificity. Clinician and patients are most interested in the interpretation of a particular test result for a given patient: the *predictive value*. The *positive predictive value* of a test gives the probability of a disease given a positive test result, whereas the *negative predictive value* gives the probability of no disease given a negative test result. A counter-intuitive concept it that the predictive value of a test depends not only on the accuracy of the test, but also on the prevalence of disease in the population tested.[a] Therefore, the same test can have different predictive values when applied to different populations with different prevalence of the same disease.

Consider this example. We have a test that returns a positive result 99% of the time in diseased individuals and only 1% of the time in healthy individuals (false positive rate). We apply the test to a group of 200 000 individuals with a disease prevalence of 50%. The test will return a true positive finding in 99 000 of the 100 000 individuals with disease and a false positive finding in 1000 of the 100 000 individuals without the disease. Accordingly, any one individual with a positive test will have a 99% chance of having the disease.

Now we apply the same test to a population in which the prevalence of the disease is only 0.1%. Only 200 patients out of 200 000 have the disease and 198 (99%) will test positive. Of the 199 800 individuals without disease, 1% or 1998 will test positive. We now have 2196 individuals with a positive test result and only 198 with the disease: a predictive value of 9%. Therefore, in different populations the same test has an entirely different significance for a positive result. This is the reason that some tests may be excellent at confirming a suspicion on the part of the physician that a disease is present, but not very good for screening healthy populations with low disease prevalence. By evaluating relevant medical history, symptoms, and risk factors and then choosing tests for diseases that might fit these findings, the physician effectively creates a test population with a much higher prevalence of disease than the general population. Confirmation by laboratory testing will have much greater positive predictive value in such prescreened populations. It is also the reason that screening healthy individuals with large batteries of laboratory tests in the 1970s and 1980s generated so many false positive results.

more test results will fall outside the reference range, not because the patient has a disease, but simply because of variation in the distribution of values for that analyte in the healthy population. The problem of getting abnormal laboratory results in normal patients led to important advances in the mathematical quantification of predictive value for test results in Galen and Gambino's publication of the landmark 1975 monograph, *Beyond Normality: the Predictive Value and Efficiency of Medical Diagnosis*.[11] Advances in analytical technology have only accelerated at the end of the 20th century with the development of radioimmunoassay (1950), immunoelectrophoresis (1952), high-performance liquid chromatography (1969), enzymatic immunoassay (1972), and the laser cell sorter (1975).[12]

At the start of the modern medical era, Louis Pasteur advocated for the advancement and expansion of the medical laboratory.[13] By the end of the 20th century western medicine was dominated by this diagnostic laboratory paradigm: in the experimental laboratory, understanding the etiology and pathogenesis of the disease and, in the clinical laboratory, identifying the etiologic agent or the footprints of the pathogenic process to confirm the diagnosis. Then, from the diagnosis, formulate a prognosis and, if necessary, propose a treatment. The dominance of this paradigm was summarized by Andrew Cunningham and Perry Williams in the opening paragraph of their 1992 monograph, *The Laboratory Revolution in Medicine*.

> If you feel unwell and go to see a doctor or are admitted to hospital, the chances are that the physicians will take a sample of your body – generally blood, tissue or urine – and send it away to another place for testing; in such cases the decision as to whether you are ill or not, and if you are, what disease you have, will be primarily taken not by you and not by your doctor but by a laboratory test. If you require treatment, this will probably involve the administration of medicinal substances prepared not by you or your doctor but in a highly specialised factory-like laboratory. If you decide to become a doctor yourself, your formal professional training will begin not with general practice, nor with hospital work, but with study of the medical sciences, in lecture rooms, libraries and laboratories.[5]

Now, at the start of a new century, this diagnostic laboratory paradigm may be undergoing a new revolution.

The Case of Cardiac Troponin

Cardiovascular disease is the leading cause of death in the United States and has been every year since 1900 except for the pandemic flu year of 1918.[14] More Americans die of cardiovascular disease than of the next 4 leading causes of death combined.[14] Coronary artery disease leading to myocardial ischemia accounts for more than half of deaths due to cardiovascular disease.[14] Despite the importance of this disease, laboratory tests for the diagnosis of myocardial injury due to ischemia lagged the development of tests to detect disease in other organs until the discovery of transaminase elevations following myocardial infarction (MI) in the 1950s.[15] Because glutamate-oxaloacetate transaminase (now aspartate transaminase) and alanine transaminase are also released by damage to other organs such as liver and skeletal muscle, elevations of the transaminases were poor discriminators for injury to cardiac muscle versus other tissue.

A significant advance in the laboratory detection of myocardial injury was the introduction of creatine kinase isoenzyme assay.[16] Creatine kinase (CK) exists in 3 isoforms. One of the isoenzymes, CK-MB, is present in greater concentration in heart muscle than in skeletal muscle. While massive increases of CK can be seen in injury to skeletal muscle, a CK increase with a greater ratio of CK-MB to the other isoforms suggests injury of cardiac muscle. The clinical utility of the assay was initially limited by the need to perform electrophoretic separation of the isoenzymes, so assays could only be performed about once a day. At a time when patients were being admitted to hospitals for several days just to exclude MI, that limitation was acceptable.

With the advent of efficacious therapies for treatment and prevention of MI, the need for rapid laboratory confirmation of MI increased. Direct immunometric assay for CK-MB[17] (CK-MB mass) significantly reduced the time required to perform the test, making stat assays in an hour or less possible. CK-MB mass assay greatly facilitated the laboratory confirmation of a diagnosis of MI. However, since CK-MB is not specific for myocardium, the assay still suffered from low sensitivity for small infarcts and low specificity in the setting of skeletal muscle injury. The initial detection of CK increase in the setting of MI had been possible because of the enzymatic properties of CK.[18] The technology of immunometric assay made possible the detection at low levels of protein markers without enzymatic activity. A search for a protein specific to cardiac muscle culminated in the identification of cardiac troponin subunits I and T (cTnI and cTnT), which are specific to cardiac muscle. Cardiac troponins are released into the circulation following necrosis of myocardial fibers. In the absence of irreversible myocardial damage, the level of cardiac troponin is so low that it is undetectable by most assays. Following myocardial injury, cardiac troponin is released from damaged myocardial fibers and becomes detectable 2 to 4 hours after ischemic onset. Troponin levels rise and peak 24 to 48 hours after the infarct. Elevations of cTnI persist for 5 to 10 days after the infarct.[19]

Because cardiac troponin is only present in heart muscle, its presence in blood is a very sensitive and specific marker for cardiac injury. CK-MB was a significant advance over previous enzyme methods and reached sensitivity levels of 80%. With the most current cTn, assays sensitivity for myocardial injury is 96% to 98%.[19] Because of the greater sensitivity cTn is the preferred marker for detecting and ruling out MI.[19,20,21] The rise in cardiac troponin and CK-MB occurs only 2 to 4 hours after ischemic injury, so samples taken within the first 2 to 3 hours after symptoms may not demonstrate an elevation.[19] Cardiac troponin assay in serial samples taken 1 to 2 hours apart provides the most sensitive means for both detecting and excluding MI. Acute MI can be excluded in those patients with chest pain who, 4 to 6 hours after onset of symptoms, still have nonrising serial cTn levels below the 99% reference cutoff for the assay utilized.[22]

The diagnostic power of current cardiac markers is so strong that in 2000 the American College of Cardiology and the European Society of Cardiology issued a consensus statement redefining MI based on changes in sensitive and specific biomarkers such as cTn and CK-MB. The new clinical definition provides that MI is diagnosed when there is a typical rise and fall of biochemical markers of myocardial necrosis and one of the following: ischemic symptoms, development of pathologic Q waves on the ECG, ECG changes indicative of ischemia (ST segment elevation or depression), or coronary artery intervention (eg, coronary angioplasty).[23] The one finding that has to be present is the temporal change in a sensitive and specific marker for cardiac necrosis such as cTn or CK-MB.

The troponin story to this point is just another illustration of how a clinical laboratory test can be a powerful aid to diagnosis. The prognostic power of cTn emerged when patients with low or borderline elevations of cTn were studied. The pathologic definition of MI is the irreversible damage of cardiac muscle due to ischemia. While diagnosing and treating MI is important, it's better to prevent it. When cTn assays were first introduced, many physicians complained that the tests were too sensitive because some patients had elevated levels of troponin but did not have clinical evidence of MI. However, when followed, these patients had a much higher incidence of significant cardiac events and sudden death after discharge than did patients with no cTn elevation.[24] Multiple studies have demonstrated that patients with stable or unstable angina or acute coronary syndrome all have significantly worse prognosis if cTn is elevated.[25,26,27] Moreover, the increase in mortality risk in patients with acute coronary syndrome with increased cTn levels is proportional to the increase in cTn.[26] The prognostic significance of small elevations of cTn, less than the cut-off level for diagnosis, has proven to be so prognostically significant that troponin elevation is a key criterion in the risk stratification and clinical management of patients with unstable angina and acute coronary syndrome.[23,28]

Cardiac troponin has proven to be an exquisitely sensitive marker for myocardiac injury arising from any source. Elevations can be seen in cardiotoxicity from drugs, hypothyroidism, sepsis, inflammatory myocarditis, heart failure, and cardiac trauma among others. In these cases the cTn elevation reflects real damage to cardiac fibers. In chronic conditions the cTn tends to be stable and clinical interpretation is necessary to distinguish cTn elevation due to ischemia from elevations due to myocardial injury from other causes. Even in those patients without symptoms or other evidence of cardiac disease, cTn retains prognostic significance. Patients with sepsis, noncardiac patients on critical care units, and emergency department patients without cardiac illness all have increased risk of short-term mortality if cTn is elevated compared to similar patients with normal cTn.[29]

The Emerging Paradigm

Cardiac troponin is just one of many laboratory assays with strong prognostic significance. Cardiac troponin elevation predicts increased risk for patients with infarction, angina, and acute coronary syndrome, but some patients without elevated cTn still experience significant cardiac events including infarction and sudden cardiac death in the the 60 days following a cTn assay.[19] A search is underway for biomarkers that can predict ischemic events in asymptomatic patients without cTn elevation. No marker with prognostic significance comparable to cTn for this group of patients has yet been identified but several candidates, including C-reactive protein (CRP), sCD40 ligand, matrix metalloproteinases, myeloperoxidase, and ischemia-modified albumin, are being intensely studied.[19] For all of these analytes, prognostic significance is the desired characteristic.

In the case of heart failure, brain-type natriuretic peptide (BNP) is released by myocardium in response to stretch. BNP and its pro peptide NT-proBNP are increased in heart failure and have proved useful in diagnostic triage of patients with dyspnea.[30] High levels of BNP and NT-proBNP indicate poor prognosis in both heart failure patients and patients with acute coronary syndrome.[31,32]

Biomarkers with prognostic significance for disorders other than cardiovascular disease are also proliferating. Molecular genetics already has wide implications in the diagnosis, prognosis, and therapeutic management of neoplasia.[33] There are currently 17 588 disorders, variations, or protein structural alterations demonstrated to have a genetic basis in humans. While the majority of these are rare or cause minor changes of no clinical significance, some have increased risk of subsequent development of disease ranging from amyotrophic lateral sclerosis to hereditary breast cancer.[33] For many common diseases, genetic predisposition may depend on complex interactions of multiple alleles. The possibility of widespread screening using DNA microarray technology for genetic combinations that predispose to disease has attracted wide commentary.[34] Identifying those at increased risk has the potential to benefit the individual by interventions or lifestyle modifications that prevent or delay the onset of the disease. Identifying those at risk also entails significant ethical and social issues and has the potential to stigmatize and harm individuals.

Not everyone who has a demonstrated genetic predisposition for a certain disease will develop the disease. The relative risk factor may vary substantially and most diseases for which a genetic basis has been demonstrated entail complex interactions between several genes and often environmental agents as well. For diabetes mellitus[35] and some other autoimmune diseases[36] there is promise that autoantibodies that appear years before the onset of the symptoms may help predict which patients will go on to develop the disease. In the case of type 1 diabetes, autoantibodies to insulin, glutamic acid decarboxylase, and islet antigen-2 may appear as early as 10 years before onset of the disease. When one antibody is present a person has a 10% chance of developing type 1 diabetes within 5 years. When 2 antibodies are present the risk increases to 50%, and when all 3 antibodies are present the risk exceeds 60%.[35] Similarly in rheumatoid arthritis an autoantibody to citrulline may appear as early as 10 years before onset of the disease and the appearance of the autoantibody increases the risk of onset of rheumatoid arthritis 15 fold.[36] Finally, mathematical techniques will be increasingly used to predict future clinical events based on combinations of biomarkers independent of a patient's specific diagnosis. In a recent report, Gruenewald used recursive partitioning techniques to identify combinations of 13 biomarkers that conveyed higher risk of mortality in a 12-year study of older adults.[37]

In the 21st century, emphasis in clinical laboratory medicine has shifted from diagnosis to prognosis, risk stratification, treatment selection, and monitoring. If the medical paradigm of the 20th century was: first diagnosis then prognosis and treatment; then the paradigm for this century may be: first assess risk, then suggest risk modification or intervention; next monitor for early predictors of progression and, if detected, intervene; if symptoms appear, stratify for selected treatment based on prognostic tests.

Rocket Science or Stamp Collecting?

This is an exciting time for clinical laboratory medicine. Rapid advances in science and technology are expanding the role and utility of clinical testing in the central laboratory, at the patient bedside, and in patients' homes. New and more sensitive assays provide valuable information for clinical decision making in real time. It's also an intriguing time as research in scientific laboratories identifies a host of markers that provide, for many patients and healthy individuals alike, powerful predictions of clinical events in the near and distant future. These technologies herald a paradigm shift in the relationship between medicine and the clinical laboratory from diagnosis to greater emphasis on prognosis, prevention and management, and from binary decisions about the patient as "diseased or well" to incremental prediction of risk and potential therapeutic benefit.

There is a significant difference in the predictive power of those sciences in which progress in knowledge is manifest by ever more powerful and elegant mathematical formulas and those descriptive sciences in which progress in knowledge is expressed by ever more complex and arcane taxonomies. The distinction was famously articulated by the early 20th century physicist and Nobel prize winner Ernest Rutherford who quipped, "all science is either physics or stamp collecting."[38] Collectors are students and illustrators of the taxonomies created to describe the objects they collect. In the early 20th century when Rutherford made his remark, many sciences including botany, zoology, geology, and medicine were primarily concerned with classification. From Rutherford's perspective, physicists calculated the formulas that orchestrated the universe, whereas other scientists simply classified. The relationship between the laboratory and medicine throughout the 20th century has been based on a taxonomic approach to disease. We have, from Rutherford's perspective, primarily been stamp collectors.

Despite the disdain in Rutherford's remark, we should not underestimate the important advances made through diagnostic taxonomy. Since the mid-19th century a classification of disease has evolved based on scientific understanding of the dysfunctions in anatomy, physiology, and chemistry that cause illness. This understanding is often founded upon, and evolves through, investigations in the experimental laboratory. The critical first step in the approach to an ill patient is to diagnose or classify the patient's disorder. Once the classification or diagnosis is established, the physician can answer the patient's question, "Is something wrong with me, and if so, what will happen to me?" Armed with a diagnosis, the physician can make predictions about the patient's likely clinical course. If the course is unfavorable, intervention can be considered and selected.

Making a diagnosis has prognostic and therapeutic significance because we have studied the natural course and response to therapy of other patients that have been assigned to the same diagnostic category. Of course, we know that the patients assigned to these disease categories are never exactly alike, and natural course and response to therapy will vary among patients with the same diagnosis. So our predictions for outcome, response to therapy, and side effects based upon the classification of the patient's disease are too often couched in terms of probabilities that leave the patient and family confused and dissatisfied. For all the progress scientific medicine and the laboratory have made together, we are humbled when we consider the rocket scientist who, armed with the calculus of physics, can hurl an object into space and predict with stunning accuracy when and where the probe will rendezvous with a speeding comet, millions of miles away and months or even years in the future. Beside the predictive power of scientists who calculate, the prognostic skill of the scientist who classifies seems feeble indeed.

The clinical laboratory has been and will continue to be a powerful source of data for classification and diagnosis. The promise of the clinical laboratory in the 21st century will be to increasingly provide data with which the physician can calculate as well as classify. In some cases the calculation will have clinical significance for the patient well before pathologic changes that permit a diagnosis have occurred. In other cases the data may support calculation of a prognosis that is much more specific than could be rendered on the basis of diagnosis alone. There is much speculation that the future of medicine will entail a highly personalized approach to prevention, treatment, and disease management in each patient. With the help of the clinical laboratory, the physician may well be moving toward a fuller implementation of the dictum "treat the patient and not the disease" and in doing so becoming a little more of a rocket scientist and a little less of a stamp collector. **NCMJ**

Public Policy Recommendations for Oversight of Molecular Laboratory Tests

Margaret L. Gulley, MD

Laboratory tests have long been used to help diagnose and classify disease. Increasingly, these assays are used to predict disease in healthy individuals or to predict outcomes in response to a specific therapy (See Table 1). The subspecialty of molecular genetic pathology (MGP) has recently emerged to promote and recognize physician expertise in DNA- and RNA-based testing. In fact, the University of North Carolina at Chapel Hill has the nation's first accredited MGP fellowship training program to graduate a physician who subsequently became board-certified.

Table 1.
Clinical Utility of Molecular Assays

Clinical Application	Diagnosis	Screening	Monitoring	Prediction
Heritable trait or disease	Detect germline mutation causing inherited disease	Determine carrier status		Predict disease presymptomatically, predict drug toxicity or optimal dose
Oncology	Help diagnose tumor based on acquired genetic defects	Screen high-risk individuals for cancer	Measure tumor burden, detect early recurrence	Predict drug efficacy, resistance, or toxicity
HLA typing & identity testing	Help diagnose HLA-linked disease	Match potential organ donors to recipients	Measure engraftment of transplanted hematopoietic stem cells	Predict organ rejection or graft versus host disease
Infectious disease	Detect pathogen based on unique DNA or RNA sequence	Screen blood donor for transfusable pathogen	Measure viral load during therapy	Predict drug resistance

The public should be reassured that molecular genetic tests are analytically valid. All clinical laboratories in the United States (with the exception of certain government laboratories) are subject to regulatory oversight by the Centers for Medicare and Medicaid Services (CMS) involving, among other things, demonstration of accuracy and precision, periodic revalidation of assay performance, laboratory inspections, and biennial recertification.[1] Proficiency surveys offered by the College of American Pathologists are voluntarily used by many testing laboratories to further check the quality of various DNA- or RNA-based assays. Indeed, laboratorians are widely recognized as leaders among health care practitioners in terms of measuring the quality of our clinical services.

Although demonstration of "clinical utility" for tests is not mandated by law, the vast majority of laboratory tests are known to be clinically useful even if they have not been reviewed by the Food and Drug Administration (FDA). The physician consultant in every testing laboratory has an ethical duty to look out for the best interests of the patients whose samples are being tested, and the laboratory physician assumes the risk of legal action if harm ensues. There are abuses: A recent report from the Government Accountability Office warned that certain genetic tests being marketed directly to the public (via the internet) seem to have no clinical value.[2] These tests may not directly harm the health of a consumer, but they are likely to harm their pocketbook.

Margaret L. Gulley, MD, is professor and director of molecular pathology at the Department of Pathology and Laboratory Medicine at the University of North Carolina at Chapel Hill. She can be reached at margaret_gulley@med.unc.edu or 101 Manning Dr, 913 Brinkhous-Bullitt Building, Chapel Hill, NC 27599-7525.

Most people are surprised to learn that many genetic tests are not FDA approved. Achieving FDA approval is costly to those who prepare and submit a completed application (estimated at hundreds of thousands of dollars),[3,4] and that money may be better spent on higher priority efforts such as improving access to health care. Furthermore, the FDA lacks the manpower required to review validation data for all genetic tests. Overcoming this shortage would be burdensome to the FDA and would likely have the unintended consequence of delaying and impeding the availability of testing for patients. Finally, there is no demonstrated evidence that the quality of laboratory testing would substantially improve if FDA clearance were achieved. In this regard, it appears that existing governmental oversight of laboratory testing is adequate.

The Pathologist as a Resource for Clinicians

It is estimated that at least 60% of medical decision making is based on laboratory test results, implying that the pathologist is among the most important members of the health care team.[5] Clinicians are encouraged to consult pathologist colleagues for advice on which laboratory test(s) to order, optimal specimen collection and handling, interpretation of test results, and implications for patient management. Pathologists, in turn, may formally document each consultation in the patient's medical record (using, for example, procedure codes 80500 or 80502) so that their expert advice and any links to additional resources are recorded in a way that may be accessed immediately by the requesting clinician and later by other members of the health care team.

Clinicians face tough challenges as they are bombarded with massive amounts of medical information, including both patient-specific data and never-ending piles of published literature.[6,7] The amount of medical information is estimated to double every five years, and the pace of progress seems even faster in the realm of molecular pathology where new technologies are now available to inform translational research and clinical practice. These new tools for analyzing DNA or downstream RNA transcripts and proteins encoded by the human genome (or by human pathogen genomes) have resulted in many new opportunities to diagnose and classify disease and to predict outcome in response to various alternative therapies. Every medical journal now seems to deal with novel genotype-phenotype associations or proposed targeted therapy based on analysis of the biochemical pathways that are altered in disease.

> *"At least 60% of medical decision making is based on laboratory test results, making the pathologist among the most important members of the health care team."*

Pathologists are well positioned to keep up with the medical literature on the tests that their laboratory offers, as well as guiding use of esoteric tests available from outside laboratories. An increasingly important role is understanding and conveying useful genetic information to clinicians. This consultative role extends to surgical pathologists since molecular assays are increasingly applicable to a wide variety of sample types including formalin-fixed, paraffin-embedded tissues, thus helping to reunite the two major subdisciplines of pathology—anatomic pathology (dealing mainly with biopsy tissues) and clinical pathology (dealing with blood and other body fluids). Furthermore, quantitative DNA amplification assays are being used to monitor disease levels (eg, tumor burden or viral load) so as to inform how a given therapy is working. The exquisite sensitivity of molecular assays can allow us to predict early on (before complete drug resistance develops) that the therapeutic regimen should be altered.[8,9]

Predicting Drug Efficacy, Optimal Dose, or Toxicity

Pathologists have traditionally been involved in diagnosis of disease, whereas clinicians select therapy. But novel laboratory assays are increasingly informative with regard to optimizing therapy, making it all the more important that each laboratory physician is well versed in validating, interpreting, and assuring quality of test results. An excellent example of the drive for quality improvement is a recent guideline jointly issued by the American Society of Clinical Oncology and College of American Pathologists on the performance of ERRB1 (Her2) assays for predicting trastuzumab (Herceptin) efficacy in breast cancer patients.[10] Some of the early work developing molecular assays for Her2 was done at the University of North Carolina at Chapel Hill.[11] Another pharmacogenetic test with local ties targets the VKORC1 gene and predicts (at least in part) optimal dose and toxicity of warfarin (eg, Coumadin) therapy. The VKORC1 gene was first characterized in 2004 at the University of North Carolina in Chapel Hill by Darryl Stafford and colleagues.[12] The clinical importance of this discovery was quickly recognized so that, within two years, molecular tests for alterations in VKORC1 were being correlated with clinical outcome in response to warfarin therapy.[13]

Progress through Clinical Research

New molecular tests further expand our ability to predict as well as detect disease. This creates new challenges for policy makers who will be asked to support the costs of these tests as well as fund the new knowledge necessary to optimally apply them. More backing for translational research is needed to support clinical trials that will ultimately define algorithms for managing patients based on molecular test results. The utility of our powerful new molecular tools is only just beginning to be understood, but already their promise is quite evident. **NCMJ**

COMMENTARY

The Ethics of Genetic Testing:
Is More Always Better?

Nancy M. P. King, JD

The recent explosion of interest in prognostic genetic testing raises a host of ethical issues for patients, research subjects, physicians, investigators, policymakers, and the public. None of these issues is really new, but all of them have gained new significance as the science of gene finding accelerates and new genetic tests become more widely available.

Public expectations are high regarding the potential value of genetic information. This confidence extends to the information obtained from new genetic tests, especially those identifying genes associated with common complex disorders. After all, nearly everyone knows someone with diabetes, heart disease, depression, asthma, attention deficit hyperactivity disorder, osteoarthritis, cancer, or any of the other common multifactorial disorders that mark the human condition, and the promise of the Human Genome Project[a] has always been both to explain the human condition and to ameliorate it.

> *"Is it meaningful to base clinical recommendations, health behavior change, or public policy on predictive genetic testing?"*

Today, science is increasingly able to assign precise percentages to at least some of the genetic contribution to an individual's chance of developing a common complex condition. This quantification of risk is a seductive enterprise. Simply knowing that many people develop emphysema later in life does not seem to mean as much as knowing that individuals with a particular genetic test result are a specified percentage more likely to develop emphysema than those whose test is negative. But are we right to think this? Does more precision mean more accuracy, or more truth? Is it meaningful to base clinical recommendations, health behavior change, or public policy on predictive genetic testing?

Ethical questions arise in the process of research, development, and marketing of predictive genetic tests; in their use and interpretation by physicians and patients; and in the utilization of predictive genetic test results in public health and other policy contexts. The issues to consider include understanding probabilistic and uncertain information, informed decision making, the medicalization of nondisease states, stigmatization of individuals and groups, genetic essentialism and fatalism, and the potential for genetic discrimination.

Logically, first among issues are those surrounding gene finding. To identify genetic associations of interest requires large-sample gene discovery research and biospecimen collection, "biobanking," and specimen sharing. Long-standing questions exist about the scope of consent to biospecimen research and sharing, how biobanks should be established and overseen, and how research results should be reported and interpreted.[1,2] It is far from clear, for example, that everyone who provides a biospecimen for genetic research into one disorder (eg, Tourette syndrome) would agree to share that specimen with investigators seeking genes associated with a different disorder (eg, colon cancer or

---

[a] The US Human Genome Project was begun in 1990 by the US Department of Energy and the National Institutes of Health to identify all the genes in human DNA, determine the sequences of the base pairs that make up human DNA, store this information in databases, improve tools for data analysis, transfer related technologies to the private sector, and address the ethical, legal, and social issues that may arise from the project. (US Department of Energy Office of Science. Human Genome Project Information. Available at: http://www.ornl.gov/sci/techresources/Human_Genome/home.shtml. Accessed March 21, 2007.)

Nancy M. P. King, JD, is a professor in the Department of Social Sciences and Health Policy and director of the Program in Bioethics, Health, and Society at Wake Forest University School of Medicine. She can be reached at nmpking@wfubmc.edu or Medical Center Boulevard, Winston-Salem, NC 27157.

cystic acne). Should they be asked? Or should consent forms simply inform specimen providers that their DNA could be shared and studied for any scientific purpose? And is such a broad consent really consent at all?

Once research is underway, questions arise about its results. There is considerable uncertainty about the significance of genetic associations in common complex disorders and gene-environment interactions. Even though knowledge is expanding rapidly in genetics, it is simply not yet known how the interplay of multiple genetic and environmental factors affects the likelihood of developing a disorder or its probable severity.[3] Thus, associating a gene with a disorder is only a small piece of a rather large puzzle. How, then, should researchers and clinicians describe that single piece? Moreover, as is already well recognized, population-based research results are difficult to translate into individual application. Although the espoused goal of genetic research is "personalized medicine" (ie, prediction at the individual level), at present, genetic associations are usually reported in broad general categories of questionable meaning. Most notably, genetic research results are grouped by race and ethnicity (eg, "X gene, associated with Y disease, is three times as common in African-Americans as in whites."). Although genetic research has definitively shown that racial categories have no biological meaning, such racialized characterizations remain all too common.[4,5] Ironically, these categories help to wrongly reify race as genetically significant. Not incidentally, reporting about research in this way is often highly stigmatizing to members of the racial and ethnic groups thus identified (eg, "Another 'Jewish gene' has been identified by researchers.").[6]

The process of translating such imperfect data into a genetic test used predictively in individuals is similarly fraught with ethical challenges. Standards for the development and marketing of genetic tests are at present nearly nonexistent. Whether and how to regulate these tests is the subject of major policy debate.[7,8] What counts as a valid and reliable test? How are commercial genetic tests advertised to practitioners and consumers? Even when these questions have been answered satisfactorily, others loom regarding the best uses of such tests. Should children be tested for genetic predispositions to adult-onset disorders?[9,10] Does it matter whether the test results are used to monitor the child's health, to initiate a prophylactic regimen, or to help the child's parents make decisions about future reproduction?

How should doctors decide whether to base recommendations to their patients on genetic test results? It has long been known that health care providers may themselves have difficulty understanding and explaining probabilities to patients. Making use of probabilistic information in the context of risk reduction, which is how predictive genetic test results will be used, is even more complex than applying probabilities to treatment choices. This difficulty is compounded in genetic testing by the temptation to view genes as deterministic and, thus, to overestimate their importance—especially in common complex disorders.[11] Since the beginning of the Human Genome Project, much attention has been given to providing genetic education to primary care providers and the general public. However, the available information changes so quickly that it's necessary to run very fast to keep up—and it's all too easy to fall behind. As a result, much decision making about genetic testing is likely to be based on poor information and poor understanding. Not surprisingly, poor information and poor understanding make for imperfect decisions about whether to test, how to interpret the results, and what to do with them.

What should be done with the information that predictive genetic testing provides? It is essential to acknowledge that even with perfect information, there is a substantial gap between gene identification and effective prophylaxis (let alone treatment).[12] Just consider the decision making challenges faced by women who learn they have a breast cancer (BRCA) gene: intensive monitoring? prophylactic drug regimens? radical surgery? or only standard exams and mammography, since having a BRCA gene is far from a guarantee of developing breast or ovarian cancer?[13] Now multiply that range of options by every new genetic association identified by prognostic testing, such as other cancers, type II diabetes, cardiac disease, obesity, psychiatric and behavioral disorders, asthma and allergies, and lots more we probably haven't even thought of as disorders—yet.[14]

One issue of principal concern has not materialized as a significant reality, but profoundly affects public perceptions about genetic testing information. The risk of genetic discrimination can deter testing, even when test results are well characterized and prophylaxis can make a difference. There is little evidence to date of discrimination in the cost or availability of health insurance, or in employment, on the basis of genetic predisposition information, although discrimination on the basis of existing disease is common, and troubling.[15,16] However, many states—North Carolina included[17]—have legislation in place prohibiting genetic discrimination, and federal legislation (the Genetic Information Nondiscrimination Act, "GINA"[18]) stands an increasingly good chance in Congress.

Another kind of discrimination by health insurers, in the name of health promotion, is actually somewhat more likely. Many health insurers are beginning to offer incentives to their insured members to change their behavior in an effort to reduce health care costs. Could an insurer require members to undergo predictive genetic testing and use the results to adjust premium rates? Could an insurer base those adjustments not solely on the test results, but on whether members with certain test results make use of certain preventive or health maintenance services (eg, stop smoking, successfully lower cholesterol or blood pressure levels, or maintain a certain weight) because their genetic profiles make them more likely to develop associated disorders? This may make good fiscal sense, or even good public health sense, but it can be quite intrusive on personal privacy. In most cases it makes little sense to distinguish between those with and without incriminating genetic profiles for disorders that are common in the general population.

Will the future bring us to more precise information and the truly personalized genome? Perhaps, in awhile; but what we do until we get there matters a great deal. If we can encourage both health care providers and patients to learn more about the meaning of genetic information, ask lots of questions about genetic information, and examine each use of genetic information carefully and comprehensively, then it may be possible to make both scientific and moral progress.[19]

There are, unfortunately, no easy answers. The best way to address these ethical issues is the hard way: taking great care in how we think about, talk about, understand, and use genetic information. We are not just our genes. For every genetic test that informs us of a susceptibility to a common complex disorder, there are many ways to alter the environmental influences that we know are also implicated, both at the individual level and as matters of public health and social policy. We already have ample reason to change habits of diet and exercise, improve the availability of healthy food choices in shops and schools, reduce environmental pollutants and hazards in the workplace, and make safe physical activity possible in all communities. The discovery of genetic associations adds scant momentum, if any, to these efforts and could be detrimental if poorly understood.[20]

More information isn't always better; only good information is better. It may be time to say no to the genetic testing explosion —at least until we know what is hype and what is not. **NCMJ**

COMMENTARY

Molecular Diagnosis of Infectious Diseases

Melissa B. Miller, PhD

During the past 10 to 15 years, we have seen expansive growth of the use of molecular technology in the clinical laboratory for diagnosing infectious diseases. As a result, many laboratories are able to offer more sensitive testing, faster turnaround times, and ultimately improved patient care. The gold standard in bacteriology largely remains culture, primarily due to cost accounting and the potential complex nature of associated infections (ie, urine, wound, and respiratory cultures). However, in circumstances in which there may be minute quantities of a specific pathogen present, the patient may have received antibiotics prior to specimen collection, or the etiologic agent may require unusual culture conditions, molecular detection offers a great advantage to culture techniques. In many virology laboratories, molecular detection has supplanted cell culture techniques for the identification of several viral pathogens and in many cases has become the new gold standard. Though molecular techniques can offer an abundance of added benefits when used to augment current gold standards such as culture and/or serology, the optimal use of molecular methodologies in microbiology resides with specimens in which a limited number of pathogenic organisms are sought and in cases where the enhanced sensitivity and faster turnaround time of molecular methods far outweighs the increased cost.

> *"The optimal use of molecular methodologies in microbiology resides with specimens in which a limited number of pathogenic organisms are sought and in cases where the enhanced sensitivity and faster turnaround time of molecular methods far outweighs the increased cost."*

Applications in Bacteriology

A classic example of successful nucleic acid amplification (NAA) testing in microbiology is the detection of *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (NG) from vaginal, cervical, urethral, and first-void urine specimens. Sexually transmitted infections such as those caused by CT and NG can be rapidly and accurately identified using NAA, thus improving treatment and transmission prevention. Implementation of routine screening for CT has lowered the prevalence rates of CT and associated pelvic inflammatory disease.[1] The increased sensitivity offered by NAA detection of CT and NG is important not only for the diagnosis of symptomatic patients, but also for the asymptomatic individuals that account for more than 70% of positive cases. Until implementation of NAA testing for CT and NG, culture was the gold standard, although it has subsequently been shown to have only 60% to 75% sensitivity compared to NAA.[2] A further disadvantage of culture is that organism viability must be preserved during transport. The implementation of routine confirmatory testing should be considered when using NAA for a low prevalence population that results in a positive predictive value below 90%.[2]

Another prime example of NAA results positively impacting patient care is the laboratory diagnosis of tuberculosis. Using

Miller, PhD, is an assistant professor of pathology & laboratory medicine, director of the molecular microbiology laboratory, and associate director of the microbiology-immunology laboratory at the School of Medicine at the University of North Carolina at Chapel Hill. She can be reached at MBMiller@unch.unc.edu or Campus Box 7525, Chapel Hill, NC 27599.

direct detection of *Mycobacterium tuberculosis* (MTB) from respiratory samples, tuberculosis can be confirmed in less than 24 hours as opposed to 6 to 8 weeks. The sensitivity of NAA detection of MTB in smear-positive respiratory specimens is 96.9%, and the specificity is 100%, whereas the sensitivity and specificity in smear-negative specimens is 72.0% and 99.3%, respectively.[3] It should be noted that NAA of MTB does not replace the need for routine mycobacterial culture and susceptibility testing. In addition to the direct detection of MTB, techniques such as probe-based technology and sequence analysis can be applied to cultured isolates to decrease the time to identification over routine biochemical analysis. Rapid identification of MTB impacts not only patient care, but also infection control. Due to the increasing frequency of isolation of mycobacterial species associated with immunocompromised hosts and the increased incidence of multi-drug resistant MTB, it has become imperative to offer accurate yet rapid diagnostic tools for the detection and identification of mycobacteria.

A debate exists regarding the gold standard for the laboratory diagnosis of *Bordetella pertussis*. Historically, culture plates collected at the patient's bedside (ie, cough plates) have been considered the reference method. Although culture is very specific, its sensitivity suffers partially due to the organism's fastidious nature, but primarily because the highest sensitivity for culture occurs before patients are symptomatic. NAA remains positive for longer after therapy than culture, and NAA is also positive for a longer period after onset of symptoms.[4] Therefore, NAA is useful for patients presenting later in their illness. NAA testing allows for same-day results and since erythromycin-resistant *B. pertussis* is still rare, a cultured isolate is rarely needed for antimicrobial susceptibility testing. Multiple studies have demonstrated significant increased detection of *B. pertussis* when comparing NAA to culture: reported PCR-positive, culture-negative samples range from 13% to 88%.[5] However, due to potential false positive and false negative results with *B. pertussis* NAA procedures, it is strongly recommended that results be considered in the context of patient clinical presentation, and clinically inconsistent results should be confirmed by a second method.

NAA is also being used in bacteriology to detect antimicrobial resistance. Since antimicrobial resistance can be multi-factorial, this practice is limited to organisms in which the results can be interpreted with confidence in regard to the genotypic relationship to clinical treatment and/or infection control precautions. Such examples are direct detection of vancomycin-resistant *Enterococcus* (VRE) and methicillin-resistant *Staphylococcus aureus* (MRSA) from rectal and nares surveillance cultures, respectively. Screening patients for VRE and MRSA carriage is a key strategy for preventing the spread of these organisms in health care settings. NAA technology reportedly increases VRE detection by up to 120%.[6] In addition, enterococci that confer low-level intrinsic resistance, and thus not considered "true" VRE, are accurately ruled out preventing unnecessary contact precautions and contributing to hospital savings.[6] NAA detection of MRSA has been shown to be equal in sensitivity to culture-based methods, but has the advantage of offering a faster turnaround time, thus impacting hospital cost savings.[6] However, it should be noted that direct specimen testing for MRSA comes with limitations, often including a lower positive predictive value than conventional methods.[7,8] More recently, new strains of MRSA have appeared that are associated with skin and soft tissue infections in outpatients and are called community-associated MRSA (CA-MRSA).[9] The increasing incidence of CA-MRSA is causing overall rates of MRSA to rise. Therefore, it has become even more important to quickly and accurately identify resistant isolates.

Applications in Virology

Monitoring the viral load (quantified determinations of virus using NAA) in patients infected with human immunodeficiency virus (HIV), hepatitis C virus (HCV), or hepatitis B virus (HBV) is useful for tracking therapeutic response to antivirals and potential antiviral resistance. In addition, viral load monitoring for cytomegalovirus (CMV) in transplant recipients has allowed clinicians the benefits of identifying patients most at risk for developing clinical CMV disease, monitoring antiviral therapy response, and optimizing pre-emptive treatment.[10] Analogously, Epstein-Barr virus (EBV) viral loads can be monitored in the posttransplant setting to identify patients at risk for developing posttransplant lymphoproliferative disorder.

Molecular detection of viruses has extended beyond the standard therapeutic monitoring of viral loads in specific patient populations. For example, NAA testing for the laboratory diagnosis of herpes simplex virus (HSV) encephalitis and enterovirus (EV) meningitis has become the standard of care. Cell culture techniques are insensitive due to the low viral burden typically found associated with encephalitis and perhaps also the presence of host neutralizing antibodies.

HSV is the most common cause of nonepidemic encephalitis in the US, accounting for up to 20% of cases. CSF culture for HSV detects less than 2% of clinically determined adult HSV encephalitis cases and 40% of neonatal central nervous system (CNS) disease.[11] In contrast, HSV NAA is positive in most adult cases resulting in sensitivity and specificity > 95%[11] and is 75% sensitive and 100% specific for neonatal meningitis.[12] The rapid diagnosis of HSV encephalitis can prevent a brain biopsy and rapidly determine the need for acyclovir therapy.

Enterovirus is the most common cause of aseptic meningitis in the summer and fall months in temperate climates and accounts for 10% to 20% of encephalitis cases. A wide array of cell lines must be utilized to recover the majority of EV types by culture, and culture sensitivity still remains approximately 70%.[13] The sensitivity and specificity of CSF NAA for EV are estimated to both be > 95%.[12]

Nucleic acid amplification has also been successfully applied to other etiologies of viral CNS disease, such as CMV and varicella-zoster virus (VZV), but these assays have not been implemented as broadly as those for HSV and EV, so are still transitioning to becoming the method of choice. It should be noted that not all encephalitis viruses are readily detected by NAA. For example, due to the short period of viremia in many

"With the use of molecular technology to detect potential etiologic agents of disease, we need to remember Koch's postulates."

arboviral infections (ie, West Nile Virus), CSF NAA has low sensitivity, and the gold standard remains serology.[14] CSF NAA false negative results can occur due to collection of CSF very early or very late in illness, rapid viral clearance in immunocompetent hosts, and NAA inhibitors.[12] False positive CSF NAA results also occur primarily due to lack of data to suggest the detection of certain viral nucleic acids correlates with clinical CNS disease, but can also be caused by the presence of peripheral blood in the CSF.[12] While CSF NAA is considered by many the diagnostic standard of care as discussed above, the lack of standardized FDA-approved assays has made implementation of CSF NAA difficult in nonacademic settings. While most laboratories offering CSF NAA use qualitative methods, data indicate a role for quantitative CSF NAA in differentiating nonspecific presence of virus and virus-associated disease, to aid in prognosis for improved patient management, and in monitoring antiviral therapy.[14]

Challenges and Opportunities

The field of molecular infectious disease testing has grown so rapidly that the diagnostic industry has not kept up. To fill this void, independent investigators have turned to the development of user-defined, or "homebrew," molecular detection methods in the clinical laboratory. The implementation of user-defined NAA testing has revolutionized clinical molecular infectious disease testing. In addition, commercially-available non-FDA-approved NAA assays are increasingly becoming available as analyte specific reagents (ASRs). Though all reagents necessary for the amplification reaction can be purchased commercially, assay development and verification studies must be performed by individual laboratories. In many cases, there are no comparative studies between user-defined NAA procedures, including ASRs, limiting the comparative value of assays between institutions (particularly in viral load monitoring) and restricting the application of such procedures to more experienced laboratories.

It is not without considerable cost that a molecular infectious disease diagnostic lab is developed. It represents an institutional commitment because the costs may only be offset when analysis of hospital-wide cost savings is employed (ie, shorter hospital stays, decreased use of unncecessary antibiotics). The costs incurred not only stem from instrumentation purchases, but also from the dedicated, expert staff required for such testing. Since many academic medical centers have resorted to implementing user-defined assays, verification and validation studies are substantial and require extensive resources, including time, staff, and expertise. These studies are crucial to defining the performance of the assay and determining appropriate clinical utilization. Most laboratory directors view the implementation of user-defined assays and ASRs as a temporary fix until FDA-approved assays are available. However, many diagnostic companies are opting not to seek FDA-clearance to replace current ASRs or "research use only" tests. The FDA, diagnostic companies, and major molecular infectious disease laboratories need to work together to resolve the poor standardization that exists between laboratories using user-defined assays or ASRs. Further, in the absence of FDA-approved tests, many nonacademic medical centers will not have the opportunity to enter the field of molecular infectious disease diagnostics.

Conclusion

The applications of molecular technology in clinical microbiology are endless, but challenges also abound. We are still learning what many NAA results mean in terms of infectious etiology. With the use of molecular technology to detect potential etiologic agents of disease, we need to remember Koch's postulates.[15] Is the mere presence of an organism's nucleic acid convincing evidence of disease causation? Undoubtedly, additional clinical scientific evidence is needed to make such a claim, and such evidence or lack thereof should be considered when interpreting molecular infectious disease results. Though there is still much to be learned regarding the appropriate application and interpretation of molecular infectious disease testing, there are numerous exciting opportunities on the horizon. User-defined assays and ASRs have allowed experienced laboratories to offer critical diagnostic services that have yet to become available with FDA clearance. As investigators refine molecular applications for infectious disease testing, diagnostic companies market such applications, quality control and government organizations standardize results, and as costs associated with implementation decrease and reimbursement increases, molecular infectious disease testing will not only be available in academic medical centers and reference laboratories, but will also transition to community hospitals, thus more globally impacting patient care. **NCMJ**

COMMENTARY

New Developments in Proteomics

Mark W. Massing MD, PhD; Judyta Misiurek; Srinivas R. Chadaram, PhD; Christine E. Marx, MD, MA; Roger Madison, PhD

Genes are relatively static instruction sets for protein manufacturing processes in the cell. Fundamental genetic components (encoding regions) are linked, modified, and combined to create a wide variety of unique protein products. The total number of human protein-encoding genes has been estimated by the Human Genome Sequencing Consortium to be 20 000 to 25 000 genes.[1] The size of the proteome, the complete set of proteins expressed from the genome, is far larger and may exceed 100 000 proteins in humans.[2] Proteomics, the study of the proteome, is the next great challenge in biology and medicine and may rival genomics in complexity, costs, and benefits.

Legacy protein chemistry techniques such as chromatography, electrophoresis, and affinity columns have been used for decades and are an effective means to identify and characterize individual proteins. Proteomics is distinguished from protein chemistry in that proteomics tends to focus on patterns and systems of protein expression rather than on single components.[3] Proteomic techniques are capable of simultaneously examining the expression of thousands of proteins to identify unique patterns associated with phenotypes, tissues, disease states, and responses to environmental or therapeutic exposures.[4] Clinical proteomics encompasses an understanding of protein systems in pathologic processes leading to new diagnostic and prognostic tests, the discovery of protein targets for new pharmacologic therapies, and the identification of patients most likely to benefit from these therapies.[5]

"New and emerging technologies in the application of mass spectrometry to the field of proteomics offer clinicians a means to rapidly identify markers of disease leading to new diagnostic tests and treatments."

The central problem in clinical proteomics is to distinguish and identify multiple proteins related to a disease or condition, even when these proteins are initially unknown. The underlying assumption is that a given disease or condition is manifested by a pattern of protein expression that is unique and identifiable. Proteomic methods compare protein expression in patients with and without a given condition to identify unique patterns or profiles of protein expression related specifically to that condition. Once a condition-specific protein expression pattern is discovered, its constituent proteins are identified

as potential biomakers for diagnosis and prognosis and as targets for treatment.

Mass spectrometry (MS) has become a promising technique in proteomics following advances supporting the processing of large molecules.[4] Mass spectrometry enables the separation and characterization of proteins in a complex tissue sample based on their different physical and chemical properties. The 2002 Nobel Prize in chemistry was awarded to John Fenn and Koichi Tanaka for their pioneering work in this area. Tanaka's approach utilized laser induced protein ionization and led to the development of matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) in the 1980s and to surface-enhanced laser desorption/ionization mass spectrometry (SELDI-MS) during the 1990s.[6-8]

In practice, these MS techniques are carried out in a series of steps. First, proteins are extracted from tissues by disruption of cellular structures and removal of nonprotein components. Next, protein solutions are cocrystallized with a matrix substance on specially developed chemically inert (in the case of MALDI-MS) or chemically active (in the case of SELDI-MS) surfaces. The matrix facilitates ionization of proteins when excited by laser energy.

Mass spectrometry devices identify patterns of protein expression by measuring the abundance of proteins at different molecular weights with a technique known as time-of-flight (TOF) detection. Figure 1 illustrates the basic concept of TOF detection. Proteins are ionized when struck by laser light and "fly" (ie, leave the surface). Ionized proteins are then captured by a high voltage electrical field and are accelerated in a vacuum chamber. During this acceleration period, or "flight," proteins become separated based on their charge and mass, arriving at a detector at different times. The more massive the protein, the less it is accelerated and the later it arrives at the detector.

Proteins striking a detector after TOF separation create a signal with an intensity related to the number of molecules arriving at the detector. The greater the abundance of molecules, the greater is the amplitude of the signal. Proteins with similar masses and charges arrive at the detector at approximately the same time creating a high amplitude spectral "peak" (Figure 1). The pattern of peaks in a complex sample creates a spectrum—a unique fingerprint characterizing protein expression in a given tissue (Figure 2).

The MS spectrum graphically relates a protein's mass and charge (X-axis) to its abundance as measured by its signal intensity (Y-axis). Spectra from different tissue samples can be compared and common patterns of expression identified. Expression pattern differences can be mapped and analyzed. Peaks at similar mass-to-charge ratios (clusters) are identified across spectra (Figure 2) and relative signal amplitude differences are compared using sophisticated pattern recognition software to identify expression patterns that uniquely characterize specific diseases or conditions.

Recent developments in MS proteomics incorporate the use of chemically active surfaces on commercially available arrays known as protein chips.[9,10] Chemically active surfaces allow for on-chip selective extraction of proteins based on chemical properties to simplify processing of complex clinical samples.

Despite the promise of this new technology, a number of

technical obstacles impede its rapid adoption. Often the most difficult issue is defining and obtaining clinical samples suitable for proteomic analyses. Variations in patients, sample handling, and collection protocols constitute substantial challenges. The first step in any proteomics experiment is to obtain and prepare the tissue sample for processing. Tissue preparation is frequently the most resource intensive activity.

Investigators are currently developing and refining SELDI-MS protocols to process a variety of tissue types including serum/plasma, brain, cerebrospinal fluid, urine, tears, saliva, cells from washes and biopsies, and muscle. The earliest efforts at biomarker discovery with SELDI-MS focused on markers associated with various cancers, especially those remaining asymptomatic until late stages such as ovarian[11] and pancreatic[12] cancers. Diagnostic and prognostic tests for these diseases were desirable and tissue preparation protocols for blood were developed early and have been refined considerably over the years.[13]

An issue of critical importance for proteomics analysis of complex biological and clinical samples for discovery of biomarkers is the need for reduction of tissue sample complexity prior to MS analysis. Most tissue samples contain far too many proteins to be evaluated on a single protein chip. These complex samples are broken down into a series of less complex fractions based on the chemical properties of constituent proteins. Conventional methods such as fractionation of complex clinical samples by ionic exchange chromatography and new methods such as enriching low abundant proteins by affinity capture with a combinatorial library of ligands[14] provide much needed tools for processing complex biological and clinical samples for proteomics research.

Another major concern is ensuring that tissue preparation and subsequent processing is standardized and does not vary between samples within experiments. Tissue samples from different individuals are never uniform. Even if gross tissue mass is identical, differences in connective tissue, vascularization, and fat content may result in differences in tissue protein expression patterns.

In examining the entire proteome, it is frequently the case that multiple protein expression differences are found when comparing tissues from different sources or time frames. A challenging problem in proteomics is the identification of patterns of expression associated with a given condition of interest using voluminous experimental data.[15] Mass spectrometry analysis of the proteome can generate an intimidating amount of data. A single clinical tissue sample could generate many thousands of data points describing protein expression patterns. Even small experiments generate too much data to be processed manually. A variety of different approaches, frequently borrowed from genomics, have been used including decision tree analyses, genetic algorithms, and neural networks.[16-18] Development of standardized and universally accepted approaches to analyze protein expression patterns is a goal that has yet to be realized.

It is hard to overstate the potential clinical relevance of the application of MS to the field of proteomics. New and emerging technologies offer clinicians a means to rapidly identify markers of disease leading to new diagnostic tests and treatments. Objective screening tests for conditions such as psychiatric illness based on proteomic techniques could revolutionize the care of patients and lead to better treatments. However, it is important to temper our enthusiasm with an understanding of the challenges that await us as nascent proteomics technologies mature. Sound experimental protocols and analytic methods must keep pace with the rapid development of proteomics tools and hardware. A rush to process experiments without considering common standards and potential pitfalls could generate misleading results and wasted effort. With this caveat in mind, the upcoming era of proteomics should complement genomics and provide a direct clinical relevance not possible by genomics alone. **NCMJ**

Specialized Testing in Hematopoietic Disorders Aids Diagnosis and Prognosis

Matthew J. Snyder, MD

Introduction

The classification of hematopoietic, or bone marrow and lymph node, disorders (eg, leukemia, lymphoma, myelodysplastic syndrome, myeloproliferative syndrome) has changed significantly over the last 10 to 15 years. Historically, leukemias and lymphomas had been categorized largely by morphology (microscopic appearance). The resulting broad categories gave some prognostic and therapeutic guidance, but the heterogeneous nature of disease entities within each group limited the accuracy of the information.

The tide started turning in the early 1970s with the discovery of the so-called Philadelphia chromosome in patients with chronic myelogenous leukemia,[1] a blood disorder in which the bone marrow typically produces too many white blood cells, which have impaired function. The Philadelphia chromosome is a result of a chromosomal translocation that juxtaposes the gene *ABL* on chromosome 9 to the gene *BCR* on chromosome 22. This results in the production of an abnormal protein that causes the unregulated growth of bone marrow cells. This monumental discovery added focus to the genetic basis of many disorders, especially hematopoietic ones.

There are many methods in the clinical pathology laboratory to examine chromosomes and their respective genes. Karyotyping involves microscopic examination of the chromosome structure itself. It offers an overview of all the chromosomes and can detect some abnormalities. This method remains very useful, despite being time-consuming and requiring cells to divide in culture, a potential technical challenge. If a known, specific genetic abnormality is being sought, fluorescence *in-situ* hybridization (FISH) can be used to detect translocations, gene deletions, monosomies (loss of an entire chromosome), trisomies (gain of an entire chromosome), and other abnormalities. The most sensitive method for detecting targeted chromosomal abnormalities is the polymerase chain reaction (PCR). However, this is used on a somewhat more limited basis due to the technically demanding nature of the test and the general requirement of an unfixed specimen in some circumstances, although recent advances in PCR automation are making its use more widespread.

While the science of cytogenetics has been evolving, another technology called flow cytometry has found a vital niche in the categorization of leukemias and lymphomas. The power of this technology lies in its ability to help classify these disorders based on the pattern of expression of certain cell surface molecules and to detect a very tiny population of abnormal cells among predominantly normal ones.

> *"Karyotype, FISH, PCR, and flow cytometry are being used currently in everyday practice to aid diagnosis and prognostication of hematopoietic disorders and to guide therapy. While each test can add an important level of understanding to a patient's disease, none of them should be used in isolation or without regard to other clinical information."*

Matthew J. Snyder, MD, is medical director of anatomic pathology at WakeMed Health & Hospitals. He can be reached at matsnyder@wakemed.org or 3000 New Bern Ave, Raleigh, NC 27610.

All of these technological advances are used in the clinical pathology laboratory, and data from these tests, in conjunction with morphologic features, form the foundation of the most recent classification scheme for disorders of the hematopoietic system from the World Health Organization (WHO).[2] This scheme is widely accepted by health care professionals around the world because it is based largely on genetic characteristics that have direct impact on treatment and prognosis. Elucidation of mechanisms by which these genetic abnormalities produce disease has led to the discovery of targeted therapies with dramatic clinical success. One example is imatinib mesylate (Gleevec® from Novartis Pharmaceuticals), which has proved a great therapeutic success for patients with chronic myelogenous leukemia.

Although targeted therapies are not available for many hematopoietic disorders, the genetic and flow cytometric characteristics of a hematopoietic disease can play an enormous role in evaluating an individual's prognosis and choosing the most appropriate therapy. These methodologies will be explained in greater detail as they relate to the new classification scheme of hematopoietic disorders, and examples of how the technologies are used for diagnostic, therapeutic, and prognostic purposes will be given.

Karyotype

Karyotyping, the standardized arrangement and morphologic analysis of cell chromosomes, has long been used to diagnose congenital genetic abnormalities, and its significance in evaluating hematopoietic diseases is now well entrenched. Since karyotyping requires cells to divide, this technique is useful in the evaluation of primary bone marrow diseases such as myelodysplastic syndrome, myeloproliferative disease, and acute leukemia. Diseases producing more mature cells, such as many types of lymphoma, are difficult to study using this method because they do not divide readily in culture. Multiple, well-documented cytogenetic abnormalities have been described in patients with myelodysplastic syndrome (MDS). These include abnormalities involving chromosomes 5 and 7 and trisomy 8.[2] In conjunction with morphology, detection of these abnormalities is used to help make the diagnosis of MDS and to track the progression of disease. For example, as some patients with MDS progress toward acute leukemia, additional cytogenetic abnormalities are acquired and serial karyotype analyses can detect this evolution. These changes help predict which patients will persist with a relatively indolent disease versus those who are at a greater risk of developing acute leukemia. Also, there is a particular type of MDS, known has 5q minus syndrome, in which a unique set of clinical and morphologic findings exist. The loss of the genetic material on the long arm of chromosome 5 confers a good prognosis with a very low risk of progression to acute leukemia.[3]

There are several acute leukemias that are now classified primarily based on cytogenetic findings that directly affect treatment and prognosis (Table 1). One example is acute promyelocytic leukemia (APML), which is characterized typically by a translocation of the *PML* gene on chromosome 15 next to the *RARα* gene on chromosome 17. The translocation results in the overproduction of the retinoic acid receptor, making retinoic acid an essential component of the therapy by inducing maturation of the abnormal promyelocytes.[4] The cytogenetic

Table 1.
Examples of Genetic Findings Used for Prognosis

Disease based on WHO classification	Prognosis	Characteristic flow cytometric or morphologic findings
Myelodysplastic syndrome		
Multiple chromosomal abnormalities or complex karyotypes	Poor	
5q minus	Good	X
Acute myeloid leukemia		
Translocation (8;21)	Good	X
Inversion 16	Good	X
Translocation (15;17)	Good	X
Abnormalities of 11q23	Intermediate	
Acute lymphoid leukemia		
Hyperdiploid (>50 chromosomes)	Good	
Translocation (12;21)	Good	X
Translocation (9;22)	Poor	
Abnormalities of 11q23	Poor	X
Translocation (1;19)	Poor	
Hypodiploid	Poor	
Chronic lymphocytic leukemia/Small lymphocytic lymphoma		
Trisomy 12	Poor	
Deletion 13q14	Good	
Deletion 17p13	Poor	
Deletion 11q22-23	Poor	
Multiple myeloma		
Deletion 13q14	Poor	
Translocation (11;14)	Good	
Deletion 17p13	Poor	

finding is important to recognize due to this unique therapy. It also predicts a good prognosis, and bone marrow transplantation is often not considered as a treatment option. This is in contradistinction to many other types of acute leukemia for which it occasionally offers the only chance for extended remission.

Fluorescence *In-situ* Hybridization (FISH)

This technology offers similar information to a karyotype but generally detects abnormalities on a much more targeted part of the genome. However, FISH has the advantage of not requiring dividing cells and, hence, can be performed much more quickly and on a wider variety of specimens than a karyotype. Cells are incubated with fluorescently-labeled primers (manufactured segments of DNA) that bind, or hybridize, to a specific DNA sequence within the cell. The cells are then viewed under fluorescent microscopy and the fluorescent signals analyzed. The relatively rapid turnaround time is important in certain situations, such as in APML. If certain features present in an acute leukemia raise the suspicion of APML, FISH for the translocation can confirm the diagnosis and appropriate therapy can begin promptly. This is vital in this setting because conventional chemotherapy can actually be harmful for patients with APML. Another instance where FISH plays a role in rapid confirmation of a diagnosis is Burkitt lymphoma. This lymphoma grows very rapidly due to overreplication of the *c-MYC* gene on chromosome 8 that causes the cells to remain in a near constant state of division. The confirmation of Burkitt lymphoma is important because treatment typically begins very soon after diagnosis, and it is treated more aggressively than other types of lymphoma.[5]

FISH plays a crucial role in prognostication of diseases that have historically been difficult to characterize by karyotype because they do not divide readily in culture. Chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) and multiple myeloma are two notable examples. (See Table 1.) A panel of FISH studies is typically performed on these to arrive at a genetic profile of an individual's disease. This information is then integrated with clinical parameters to arrive at an overall prognosis that guides treatment options. Consequently, some patients are treated with a "watch and wait" approach because of a very low risk of significant progression, whereas others are treated very aggressively at initial diagnosis because of a significant risk of rapid progression. Prior to these genetic advances, the outcome of patients with CLL/SLL and multiple myeloma was quite variable, and there were only limited ways to predict how an individual's disease would behave.

Polymerase Chain Reaction (PCR)

Polymerase chain reaction is an exquisitely sensitive method of genetic investigation and has many applications. Relevant to this discussion, PCR is used to detect genetic abnormalities and, in some instances, to measure the quantity of the abnormality. Although advances in automation are currently available, PCR remains time consuming and requires relatively high technical expertise due to the sensitivity of the method to contamination. The test can use an unfixed sample or, for some PCR primers, a fixed sample. A series of tightly controlled steps amplify, by making many copies, and then detect a genetic target. A practical application of PCR in evaluating lymphomas is the detection of clonality in B and T cell lymphomas. Detecting monoclonality can confirm malignancy, but it is generally not used as the sole determining factor. Furthermore, the PCR characteristics of an individual's lymphoma are often unique and can be used to determine if a subsequent tumor is a recurrence of the former lymphoma or a new primary. This distinction is often of prognostic and therapeutic importance.

Quantitative analysis precisely measures the amount of PCR product, and this can be of value in some settings. Quantitation of the gene fusion product resulting from translocation between chromosomes 9 and 22 that characterizes chronic myelogenous leukemia (CML) can be followed over time to assess the response to imatinib mesylate, the targeted therapy for CML. A negative or decreasing quantitative PCR test is reassurance that the current treatment regimen is controlling the disease, whereas an increasing amount of PCR product could trigger an increase in the dose of imatinib mesylate or consideration of other treatment, such as bone marrow transplant.

Flow Cytometry

Flow cytometry is a technology that detects the presence and quantity of certain molecules that exist on cell surfaces or in the cytoplasm. By examining the pattern of expression (presence) of these molecules, cells from peripheral blood, bone marrow, or a lymph node are grouped into populations of similar cells. Flow cytometry is used primarily as a diagnostic aide in the classification of lymphoma and leukemia, and, as mentioned, the diagnostic categories in the WHO classification[2] carry therapeutic and prognostic significance. One practical application of flow cytometry allows classification of acute leukemia into two major categories, myeloid and lymphoid. Lymphoid tumors can be further subcategorized into B and T lymphoblastic types. These categories of acute leukemias are treated differently and carry different prognoses, especially when correlated with genetic findings. (See Table 1.) Some acute leukemias express molecules that are not characteristic of a particular cell line, known as aberrant expression. These aberrant markers can be unique to an individual's disease and offer a useful way to detect minimal residual disease by easily separating the abnormal cell population from primarily normal cells.

The molecules that are detected by flow cytometry can serve as a surrogate marker for some of the genetic findings described earlier. (See Table 1.) For example, APML has a distinctive profile by flow cytometry in that it lacks expression of HLA-DR and CD34, two molecules that are very frequently present on other types of acute leukemia.[6] Along with morphology, these findings prompt the pathologist to investigate for the characteristic translocation.

The Future

The methods of molecular and genetic evaluation discussed so far originated as research tools, and their utility in the clinical pathology laboratory has evolved quickly. Another type of test that might make this transition is gene microarray technology, sometimes called "gene chip." The results of this test, on a research basis, have been shown to be a very powerful tool to further evaluate how hematopoietic diseases relate to each other and, in some instances, offer an even clearer understanding of the mechanism of disease, prognosis, and optimal therapy.[7] Researchers hope that the identification of specific gene expression in these diseases will lead to effective gene-targeted therapies. This assay entails extracting DNA from tissue and simultaneously analyzing for the overexpression or underexpression of thousands of genes to create a gene expression profile. At present, the gene microarray chips are generally too expensive for routine clinical testing, and the amount of data generated can take many hours to analyze using today's fastest computers. Moreover, storage of these massive amounts of data presents another challenge. Great advances in automation of this test have been made recently, and the cost has also decreased substantially in just a few years. As all of these technological and economic aspects improve, this test will very likely play some role in the evaluation of hematopoietic disorders and may subsequently alter the classification of these diseases.

Table 2.
Examples of Genetic Findings Used for Diagnosis

Genetic Abnormality	WHO Classification Diagnosis
Translocation involving 8q24	Burkitt lymphoma
Translocation (14;18)	Follicular lymphoma
Translocation (11;14)*	Mantle cell lymphoma
Translocation (11;18)	Extranodal marginal zone lymphoma
Translocation (2;5)	Anaplastic large cell lymphoma

* This translocation defines mantle cell lymphoma but has also been reported in some cases of multiple myeloma.[2] These diseases can be differentiated by morphology and flow cytometry.

Conclusion

Karyotype, FISH, PCR, and flow cytometry are being used currently in everyday practice to aid diagnosis (Table 2) and prognostication of hematopoietic disorders and to guide therapy. While each test can add an important level of understanding to a patient's disease, none of them should be used in isolation or without regard to other clinical information. The pathologist plays a critical role in this process by correlating the microscopic morphology with these data from specialized tests and making an overall assessment. Pathologists oversee the performance of these tests, interpret the results in light of the clinical context, and communicate this information to oncologists, radiation oncologists, surgeons, and other treating physicians. This invaluable information about an individual patient's disease has a direct, and often dramatic, impact on the type and duration of therapy and offers an indication of the individual patient's prognosis. **NCMJ**

COMMENTARY

Human Papillomavirus Testing for Precancerous Lesions of the Cervix

Fidel A. Valea, MD

Introduction

Human papillomavirus (HPV) infection is the most common sexually transmitted viral infection. An estimated 20 million Americans are currently infected with HPV and approximately 6 million new cases develop each year with the majority occurring in the adolescent age group.[1] The annual burden of cervical HPV-related diseases in the United States is estimated to cost between $2.25 billion and $4.6 billion, and the annual burden of cervical cancer is approximately $181.5 million to $393 million.[2] Persistent HPV infection is the most important risk factor for the development of cervical cancer and constitutes the basis for screening. The incidence of cervical cancer has decreased in every country that instituted mass screening for the disease.

> *"The annual burden of cervical HPV-related diseases in the United States is estimated to cost between $2.25 billion and $4.6 billion."*

Until recently, screening for cervical cancer was predominantly cytology based, relying on the detection of dysplasia, or cellular abnormalities, which are a precursor to cervical cancer. Screening with conventional smears has a sensitivity ranging from 50% to 60%. Despite this poor sensitivity, it was responsible for a 75% reduction in the incidence of cervical cancer in the United States since its introduction as a screening test in 1949.[3] With the advent of liquid-based cytology, where the sample is suspended in a fixative solution instead of smeared on a slide, cytologic screening is not only more sensitive, but also more versatile. Liquid-based cytology enables cytotechnologists to perform further tests on the specimen in solution, such as HPV DNA testing, which cannot be performed on the slide. Recent well-controlled clinical trials with verification of positive and some negative results have found sensitivities of 70% to 80% for conventional cervical cytology and 85% to 95% for liquid-based cytology.[4,5] Despite this, even the liquid-based methods can miss between 15% and 35% of high-grade dysplasia or cancer.[6] Unfortunately, given the current health care dollars spent on HPV infections, even small imperfections in the screening process can have significant financial implications.

Computer-Assisted Screening Technology

Liquid-based screening was first introduced over a decade ago. It is now the preferred method of screening, and its versatility has paved the way for other advancements in cervical cancer screening. The specimen in suspension can be filtered and sprayed evenly on a slide, allowing for less artifact and a more consistent specimen to evaluate, which results in fewer false negatives. The uniformity and clarity also enable the use of computer-assisted screening using an automated microscope to further decrease false negative results and increase the ability to identify the truly abnormal Pap test. There are currently 2 Food and Drug Administration (FDA) approved automated systems: the Focal PointTM Slide Profiler (FPSP) and the ThinPrep® Imaging System (TPIS).[7,8] They both use the principle of morphometry, the appearance and size of the cells, and both use slides created with the liquid-based technology. However, the FPSP is also approved for screening conventional Pap test slides.

The FPSP system is only approved for screening specimens from a defined low-risk population of patients. The slides are evaluated using FPSP image analysis software and assigned to

one of following groups: (1) *negative for intraepithelial lesion or malignancy*, needing no further review; (2) *review*, requiring manual review by a cytotechnologist; (3) *quality control*, requiring manual review of slides with the highest probability of having an abnormality; and (4) *process review*, requiring manual review of slides that cannot be successfully processed by the FPSP system. This system limits the amount of manual review by a cytotechnologist and focuses him/her on the slides of concern. It can use any of the currently available liquid-based systems.

The TPIS system can only evaluate slides that use the liquid-based thin layer technology, but it can be used in both low- and defined high-risk patient populations. It scans every slide and identifies cells of interest and the 22 fields that contain them. The cytotechnologist reviews these fields using an automated microscope and assigns them as no intraepithelial lesions if all fields are judged to be normal or, if any cell is suspicious, the entire slide is reviewed and abnormal cells are evaluated by a pathologist. With this technology, all slides are reviewed, but the computer directs the cytotechnologist to the areas of concern.

HPV Testing

The ability to detect HPV DNA in the liquid-based Pap vial has led to a paradigm shift in cervical cancer screening. Instead of just looking for cellular abnormalities, the current technology allows for the assessment of the causative agent, HPV. However, there are over 100 different types of HPV and each has a different oncogenic risk. For clinical simplicity, they are usually stratified into two groups: low and high risk for the development of cervical cancer. In 2001, the results of the landmark *Atypical Squamous Cells of Undetermined Significance/Low-Grade Squamous Intraepithelial Lesions Triage Study (ALTS)* were published.[6] They compared three different methods of triaging patients with equivocal Pap testing results, atypical cells of uncertain significance (ASCUS). The results indicated that women with an ASCUS Pap test can undergo high-risk HPV DNA testing from the same liquid-based Pap test vial to evaluate for the presence of high-risk DNA. If high-risk DNA is present they should undergo further diagnostic evaluation. But, if a woman was high-risk HPV DNA negative, she had less than a 1% chance of developing a high-grade lesion within the year and could undergo routine screening the following year. The reported sensitivity of this combination of tests was 96%. As a result, fewer women were referred for costly diagnostic tests and reflex high-risk HPV DNA testing became the recommended management for women with ASCUS Pap test results.

As a result of numerous studies confirming the low prevalence of HPV in women over the age of 30, high-risk HPV DNA testing can be offered to women in addition to the liquid-based Pap test.[9] This is different than reflex testing because it is done in conjunction with, rather than as a result of, the liquid-based Pap test. If both Pap test and HPV test are negative, the woman can be rescreened in three years because she is at very low risk of developing a high-grade lesion during this time. Unfortunately, this is only cost effective in the 30 and older age group because the prevalence of HPV in the younger age group is so high.

HPV Vaccine

In June of 2006, the FDA approved the first HPV vaccine, Gardasil®, a quadrivalent vaccine against HPV 6 and 11, the low-risk types associated with 90% of anogentital warts and low-grade lesions, as well as HPV 16 and 18, the high-risk types responsible for 70% of high-grade lesions and cervical cancer.[3] Cervarix®, a vaccine against HPV 16 and 18, was also developed, but is not yet approved by the FDA. Both vaccines approach 100% efficacy in the prevention of HPV 16 and 18 associated high-grade lesions in the patients that received vaccination before contact with either virus. Gardasil® is also effective at preventing the low-grade lesions and anogentital warts associated with HPV types 6 and 11.[10] Based on available data, the Centers for Disease Control and Prevention (CDC) Advisory Committee on Immunization Practices suggested routine vaccination for girls as young as 9 years of age.[11] Several other groups such as the American College of Obstetricians and Gynecologists have also supported these recommendations.[12] Patients that are HPV naïve (ie, women who have never been exposed to the virus) will be best served by this vaccine because they have the most to gain. Although its utility in males is still not proven, if efficacy is shown, vaccination for males may be recommended as well. The true impact of the HPV won't be realized for several years, but its impact on the low-grade lesions may be apparent sooner.

Summary

As new technologies are introduced that increase the sensitivity of detecting patients at risk and the incidence of cervical cancer continues to decrease in the US, annual screening for this disease may actually be overscreening. It has been shown that the screening interval can safely be increased to every 2 years if liquid-based testing is performed with reflex HPV testing in patients under 30 and can be increased to every three years in patients over the age of 30 if they are done together and both are negative.[13,14] As we move into the age of risk stratification as a screening tool with HPV testing and liquid-based screening, it is imperative that the aforementioned recommendations are followed in order to keep the costs of screening at a minimum. Unfortunately, despite data confirming its safety and efficacy, many patients are unconvinced.[15] The overwhelming respondents in one series would still seek to obtain annual screening. In order to complete the paradigm shift in the screening for cervical cancer using the current technologies, more education will be required of the public and health care community to understand and accept the differences, most notably the increased screening interval. The true effects of the HPV vaccine will not be known for some time. Therefore, appropriate screening is still imperative even for those vaccinated because it does not offer complete protection from other strains of the HPV virus. **NCMJ**

COMMENTARY

Automation in the Clinical Pathology Laboratory

Michael Weinstein, MD, PhD; Grover Smith, PhD

A large proportion of hospital pathology laboratories in the US were built or renovated in the 1960s or 1970s, and prevailing medical practice and the medical economics of the time led to common design themes. The forces felt by laboratory directors and managers today are considerably different from those that shaped the labs of the earlier era. A widening gap between what is desired from many laboratories and what they are physically capable of delivering is becoming increasingly apparent. The requirement for timely, accurate, well-communicated laboratory results is crucial. Approximately 70% to 80% of major clinical decisions are based, at least in part, upon information coming from the pathology laboratory.[1,2] Thus, the impact of a successful laboratory on the efficiency and quality of care is far-reaching. Current pressures for design and process change include cost, turnaround time, the tightening technologist market, and reduction in clerical and preanalytical errors.

Cost

The advent of diagnosis-related group-based reimbursement for inpatients shifted hospital laboratories from revenue generators to cost centers. Since then, the requirement to reduce the cost of testing has been relentless.

Turnaround Time

The desire to reduce turnaround times stems from both the impact of rapid delivery of data-based therapy on outcomes in some circumstances (eg, chest pain and stroke protocols) and the drive to reduce hospital lengths of stay.

Tightening Technologist Labor Market

The average age of medical technologists is continuing to increase and, in some markets, as many as 84% of laboratories report that finding and hiring medical technologists is either difficult or extremely difficult.[3]

Reduction in Clerical and Preanalytical Errors

Recent years have seen increasing national awareness that a significant number of poor outcomes for hospitalized patients are avoidable. Clerical and identification errors are responsible for a large fraction of such outcomes, and as many as 40% of errors occur during the preanalytical phase of testing. Reduction of human involvement in this process can result in improved patient safety, with fewer errors due to sample misidentification. Automation can also reduce sample processing time.

While our primary intention is to discuss automation in the clinical pathology laboratory, it must be emphasized that, ideally, implementation of automation should be coupled with process review. Automation often allows optimization of processes in ways that are not possible in a manual laboratory, and implementation of automation without thorough assessment of current laboratory processes is likely to result in missed

> *“Thus, the impact of a successful laboratory on the efficiency and quality of care is far-reaching. Current pressures for design and process change include cost, turnaround time, the tightening technologist market, and clerical and preanalytical errors.”*

Michael H. Weinstein, MD, PhD, is director of pathology laboratories at WakeMed Health and Hospitals.

Grover Smith, PhD, is deputy director of pathology laboratories at WakeMed Health and Hospitals. He can be reached at gsmith@wakemed.org or PO Box 14045, Raleigh, NC 27620-4045.

opportunities. The flow of specimens and information and the activities of laboratory personnel should be examined with fresh eyes. Although this reevaluation may be difficult, it represents a crucial responsibility of the laboratory leadership, and everything should be put on the table. In particular, all preanalytical processing steps should be optimized to gain the full benefit afforded by automation. Container selection, specimen collection, specimen labeling, identification, receiving, and accessioning, and, ultimately, specimen tracking through the laboratory should be reevaluated. Autoverification of results, reporting methods, specimen retrieval for add-on testing, and ease of result interpretation are also vital considerations as processes are examined. Merely recapitulating the manual laboratory with machinery is not likely to reap the greatest possible benefits in efficiency and service improvement from the expenditure of resources.

Laboratory automation reduces the number of steps in testing requiring human intervention. When suitably implemented, automation reduces turnaround times for many tests. Automated systems do not reduce turnaround times by virtue of an ability to perform any individual step faster than a skilled technician does. Instead, these systems operate at or near maximum throughput up to capacity and do not suffer from potential lapses of attention. They allow a smaller number of skilled medical technologists to operate the instruments in a large laboratory. A specific example is the automated location and retrieval of specimens stored in a refrigerated stockyard for add-on testing. This does not require any human intervention, saves time, and avoids human error. With automation, the technologists expend a greater fraction of their time and energy on judgment tasks, making assessments and decisions that require their training and intelligence. Thus, the affect of the tightening labor market can be blunted.

The combination of automation and computerized interfaces has the potential to reduce the risk of clerical and identification errors. Primary sources of such errors are the preanalytical phase, the postanalytical phase, and, less commonly, any point in the analytical phase in which there is a hand-off from one person to another. Positive patient identification entails unique bar coding of the patient armband. Corresponding unique bar codes are printed at the bedside on specimen labels, which allow each specimen to be tracked during its travel through the automated system. Results are unerringly associated with the proper patient. In combination with a robust laboratory information system, this has the potential to drastically reduce errors, especially in the preanalytical phase of testing.

It is not clear a priori that the capital expenditure required to purchase the equipment to automate any individual laboratory will eventuate in an overall cost reduction. Moreover, the physical layout of some laboratories may not be amenable to large-scale automation. Thus, careful financial analysis must take into account current and projected specimen volumes, personnel costs based upon efficient management of laboratory staff, and the cost of the automation equipment and any required renovations of the laboratory space. Another factor that should be considered is that consistently short turnaround times may obviate a clinically relevant need for some types of point-of-care testing, which is usually manifoldly more expensive than testing within the laboratory.

In summary, the circumstances in which pathology laboratories now find themselves are very different from those that drove the design of a great fraction of laboratories decades ago. Laboratory automation can be a powerful tool to help many laboratories meet the challenges of the current environment and pressures. **NCMJ**

COMMENTARY

Point-of-Care Testing:
Guidelines and Challenges

Robert L. Sautter, PhD, HCLD (ABB), Edward H. Lipford, MD

Laboratory diagnostics play an important role in managing patients. With the pressures to reduce hospital length of stay and with newer therapy options, the laboratory has been asked to decrease the turnaround time from sample to result. Therefore, point-of-care testing (POCT), testing near the patient or bedside, was developed to generate quicker results. The goal of POCT is to provide the clinician with rapid results, which can improve patient outcomes and quickly supply therapeutic interventions as compared to those results obtained from the core laboratory.[1] Laboratory point-of-care testing is not new; however, it experienced a veritable explosion in manufacturing, clinical oversight, and regulations following the "waived provision" of the Clinical Laboratory Improvement Amendments (CLIA) of 1988.[1,2,3] The number of laboratories holding a Certificate of Waiver increased from 67 294 in 1993 to 105 138 in 2004.[3] In addition, the number of Medicare Part B waived tests performed increased from 14 million to over 23 million between the years 2000 and 2004.[3] (See Table 1.) Inherent with POCT growth come challenges in performing high quality accurate testing. Decreasing laboratory errors and improving patient safety must also be considered as POCT increases.

The Centers for Medicare and Medicaid Services (CMS) regulates laboratory testing on humans through CLIA to ensure quality testing. CLIA classifies tests as "waived complexity," "moderate complexity,"[a] and "high complexity" based upon criteria developed by the federal Department of Health and Human Services. Waived complexity tests are simple laboratory examinations that are approved for home use and which employ methodologies that are simple and accurate. They render the likelihood of erroneous results negligible or pose no risk of harm to the patient if the test is performed incorrectly. Quality standards for moderately and highly complex tests are designated for proficiency testing, patient test management, quality control, personnel qualifications, quality assurance, and quality control.[2] The more complex the test, the more stringent the testing requirements. A complete listing of the tests by classification can be found on the website of the Center for Devices and Radiological Health of the US Food and Drug Administration.[4]

> *"When considering that millions of laboratory tests are performed at the point-of-care each year, it is imperative that we, as health care providers, do everything we can to dispense quality laboratory care for all patients."*

---

[a] An additional subcategory classification under moderate complexity is "provider-performed microscopy." It was developed as a special consideration to allow laboratories that are otherwise classified as "waived" to perform moderately complex tests utilizing microscopic analysis.[3]

Several regulatory bodies are primarily involved in inspections for the POCT laboratory. Point-of-care testing occurs on floors of hospitals, nursing homes, clinics, physician offices, radiology suites, and any other location where testing is classified as a regulated laboratory test. Laboratories may apply for a Certificate of Waiver, Certificate of Compliance, or a Certificate of Accreditation.[b,3] Those that are accredited are usually accredited by private peer organizations such as the College of American Pathologists (CAP) and the Joint Commission on Accreditation of Healthcare Organizations (JCAHO). These two organizations have been inspecting hospital laboratories inside health systems for quite some time. Recently, both the CAP and JCAHO have been granted "deemed status" to inspect laboratories for CMS.[5] Laboratories are inspected in regard to directorship, quality assurance, quality control, testing personnel (training and competency), reporting, and verification of testing procedures. Accredited laboratories are inspected on a two-year cycle. All inspections are now performed on an unannounced basis. However, those laboratories that obtained a certificate of compliance or certificate of waiver have not been inspected on a regular basis in the past due to a lack of resources available to inspect the thousands of laboratories doing this testing.

Two state pilot inspection programs of physician office laboratories (POL) with certificates of waiver showed that a significant number of laboratories had serious deficiencies with regard to their compliance with regulations.[3] Testing without employee training, failure to document procedures, or failure to follow manufacturer's packaged instructions were among the most concerning deficiencies identified. Subsequent inspections of more than 1000 laboratories confirmed these problems nationwide. CMS plans to inspect only 2% of the waived laboratories yearly. Inspection results in several states have shown improvement; however, without oversight overall improvement may be difficult to achieve. The executive summary of the waived laboratory project from CMS included this review of compliance with manufacturer's instructions for performance of tests:

> *Expanded pilot studies by the Centers for Medicare and Medicaid Services (CMS), formerly the Health Care Financing Administration (HCFA), of laboratories issued a certificate of waiver (COW) and provider performed microscopy procedures (PPMP) laboratories demonstrate that 50% of laboratories performing waived tests do not follow the manufacturer's instructions or do not have manufacturer's instructions. The only CLIA requirement for COW laboratories is to follow the manufacturer's test instructions. These findings mirror those of previous pilots conducted by Colorado, Ohio, New York and most recently, the Office of the Inspector General (OIG). If these percentages are nationally representative, as many as 60,000 laboratories may not be following manufacturer's instructions and may be performing tests incorrectly to potentially harm patients.*[6]

---

[b] A Certificate of Waiver is issued to a laboratory that only performs waived tests. A Certificate of Compliance is issued to a laboratory following inspection by the state department of health that determines the laboratory is compliant with CLIA requirements. A Certificate of Accreditation is issued to a laboratory based on accreditation.

Tests designed to be performed in the point-of-care setting are manufactured to be relatively fast and easy to operate. The results should be made available while the patient is present or so that the provider can respond to him during the visit. Many point-of-care tests offer these advantages and ideally result in better outcomes for the patient.[7] Pressures to see more patients in the office or to free space in an emergency department have stimulated a real need for faster results. However, faster is not always better if the result's timeliness has little or no impact on the outcome of care.[8] Unfortunately, there are few studies available showing that patient outcomes improve with tests performed at point-of-care location over those performed in the clinical laboratory. Therefore, more research is needed in this area.[7]

When considering that millions of laboratory tests are performed at the point of care each year, it is imperative that we, as health care providers, do everything we can to dispense quality laboratory care for all patients. Some problems in achieving this goal include the lack of adequate accessibility of laboratory data by those in charge of oversight, poor training and low competency of testing personnel, and lack of evidence-based studies linked to patient outcomes.

Evidence-based guidelines for point-of-care testing have been developed by the National Academy of Clinical Biochemistry (NACB) in cooperation with the College of American Pathologists and the American Society for Microbiology.[8] The guidelines cover subjects in POCT ranging from management to technical areas such as critical care, coagulation, cardiac markers for diagnosing acute coronary syndromes, infectious diseases, and renal function tests.[9] The monograph answers critical clinical and managerial questions using literature searches and grading outcome-generated studies into various categories of recommendations based upon the available literature. A key component in performing POCT at any site is managing the program. The monograph divides the management of POCT into quality control, technical oversight, data management, training and education of operators, and continuous quality improvement with quality indicators.[10]

Multidisciplinary approaches to POCT are necessary to implement a successful program.[10] Administration can supply the appropriate resources to achieve this goal along with technical expertise from physicians, nursing, and the laboratory. Each health care professional must realize his/her responsibility to achieve this goal. Decisions made by the group need to be based upon factual data or observations. These data must include a balance between sensitivity, specificity, positive and negative predictive values of the tests evaluated, and the clinical need for the results. Cost for disseminating the results is also an important consideration.

Handling laboratory data electronically clearly offers an advantage over manual systems in tracking quality care issues, following patient test results, and assuring compliance with regulations.[10,11] Remote monitoring allows technically skilled individuals to monitor performance and evaluate problems with instrumentation and suggest corrective action. A universal connectivity information system is imperative to be able to manage the many manufacturer options in POCT. Until recently, manufacturers were reluctant to connect test systems from companies not in business relationships with each other. There are now systems that allow such a connectivity to be instituted for a fee.[10,11,12] The performance of quality assurance and quality control is an expensive and time-consuming portion of laboratory medicine. In order to improve the quality of POCT, the NACB recommends developing a formal process of risk management and reducing medical errors by using an interdisciplinary committee to manage POCT, instituting POCT training programs, implementing data management systems, and instituting continuous quality improvement with quality indicators.[9]

It has been shown that 25% to 40% of laboratory tests are unnecessary.[13] Furthermore, there is potential for over utilization of point-of-care testing and the potential to do harm with results.[9,13] This makes it extremely important to make sure that all laboratory testing is warranted and that the results affect the outcome of patient management. In the critical care arena, few well-controlled outcome studies have been performed to show the benefit for POCT.[14] One positive study in sepsis patients demonstrated a decrease in mortality from 47% to 31% when early directed therapy to point-of-care arterial blood gases (including direct response to pH, oxygen saturation, and lactate) was instituted rapidly. Therefore, the Laboratory Medicine Practice Guidelines (LMPG) state there is fair evidence that arterial blood gases in the point of care should be performed for intensive care unit patients.[14] The evidence for other POCT is absent or less convincing.

For example, the detection of *Trichomonas vaginalis* in the physician office laboratory is usually made by performing microscopic examination of a wet preparation (WP). Unfortunately, the sensitivity of this testing is between 49% and 89%.[15] Although the use of POCT is recommended by the LMPG, outcomes based upon a wet mount for *T. vaginalis* do not link this agent with premature rupture of membranes.[15] The lack of sensitivity of WP necessitates a need for more sensitive tests. When tests with increased sensitivity are used in the point-of-care or core laboratory, *T. vaginalis* may in fact be associated with premature rupture of membranes.[15]

Point-of-care testing has the ability to improve outcomes and result in decreased mortality when performed correctly and following laboratory guidelines.[1,14] Using good laboratory practices, POCT will be beneficial at any patient site.[3] Some example benefits of POCT include faster decision making for cardiac patients, quicker optimization of treatment for anticoagulation, and increased patient satisfaction. Point-of-care testing will only increase in numbers and diversity of methods in coming years. The advent of complete electronic medical records including home health testing with regional databases will undoubtedly make more data available to the clinician. **NCMJ**

COMMENTARY

The Feasibility of Home or Patient Self-Testing

Thomas E. Wall, MBA

In contemporary society, the most prevalent and the most demanding forms of illness are chronic diseases. These can involve daily regimens of care and self-management, usually for a lifetime, and often require significant modifications in the lifestyles and activity patterns of those affected. Recent year estimates suggest that as much as 75% of total health care costs can be attributed to the treatment of persons with chronic illnesses and their associated comorbidities and acute care episodes.[1] In decades past, the predominant concerns of health and medical care were largely related to the burden of illness associated with communicable and infectious diseases. However, today, our focus has shifted to the prevention and long-term management of chronic diseases.

Over many years, the emphasis in chronic illness care has been on the protocols for disease management and attempts to increase patient adherence to specific regimens of care. Health care technology applications have sought better methods for the detection and monitoring of disease indicators and the collection and analysis of trends in these indicators as part of overall strategies for patient care management. Despite the efforts of many, there continue to be widespread feelings of frustration and disappointment in the health care professions over the inability to achieve high levels of control of hypertension, diabetes, asthma, and other chronic conditions where patterns of personal health-related decisions and behaviors can affect these critical indicators of chronic disease self-management.

If satisfactorily controlling these vital health indicators among chronic disease patients were easy, it would not have required the efforts of so many over such a long period of time, with so few examples of successful and sustained outcomes. The good news is that there are now promising new forms of computer-assisted technology that offer the possibility of bringing the best knowledge in fields like health behavior and health education, clinical medicine, and information technology together to achieve a much more effective interventional mode of long-term management of chronic diseases. Effective disease management care can significantly improve quality of life for those with these diseases, lead to a more effective outcome of medical therapies, and decrease overall costs of care.

New Technologies Available for Chronic Disease Self-Management

There are a number of exciting and promising developments in the field of chronic disease self-management that take advantage of existing technologies and integrate them in new ways to achieve greater efficiency and more effective self-management. For a number of years physicians and other health care professionals have used telephones to give patients the opportunity to dial in to report or upload recent readings of key clinical indicators and to contact them for reinforcement of medical advice and counseling. To date, many of these telehealth solutions have been tethered to the patient's home telephone line. They provided solutions for the critically ill, but were not ideal for the large population living a mobile lifestyle while trying to manage a chronic disease. The emergence of the cellular phone and its

> *"The emergence of technology for data signal transmission to and from cellular telephones has opened up an entirely new dimension of communicating basic clinical information to and from a central site."*

Thomas E. Wall, MBA, is vice president of Confidant International LLC. He can be reached at thomas.wall@confidantinc.com or 2530 Meridian Parkway, Suite 300, Durham, NC 27713.

growing ubiquity and enhanced capabilities have provided a mobile platform to support chronic disease management in this on-the-go community.

The emergence of technology for data signal transmission to and from cellular telephones has opened up an entirely new dimension of communicating basic clinical information to and from a central site. Now it is possible, with the development of home medical devices recording biomedical indicators, to digitally transmit this information using Bluetooth® communications protocol to a cellular telephone and then to a file server. The file server can then interpret this information, comparing it to other measures taken over time, and send encouraging or instructional messages back to the patient to motivate positive health actions related to the chronic health condition. Simultaneously, a summary of this same information can be sent to the physician or other health care professional involved in the care of the patient. All of the data are accessible through a secure internet portal to the health care professional and the patient. These measurements can be taken, transmitted, interpreted, and commented upon within a few seconds, thus making it possible for both patient and health care provider to communicate about the ongoing management of one's chronic condition in near real-time.

Figure 1 depicts the way in which this new communication linkage can work with a telehealth software application installed on an off-the-shelf cell phone. Recent feasibility (acceptance) trials for Type 1 and 2 diabetes and congestive heart failure have shown that patients and their health care providers find this system an easily usable tool.

What are the Implications of These Technologies for Chronic Disease Care?

To be successful in managing chronic diseases the individual must take ownership of his/her disease. By using new mobile technology to provide a link to the doctor and to reinforce positive behaviors, the individual becomes empowered. The linkage enhances the physician-patient relationship and, through automatic notifications, keeps patients and providers updated on key aspects of the patient's treatment plan.

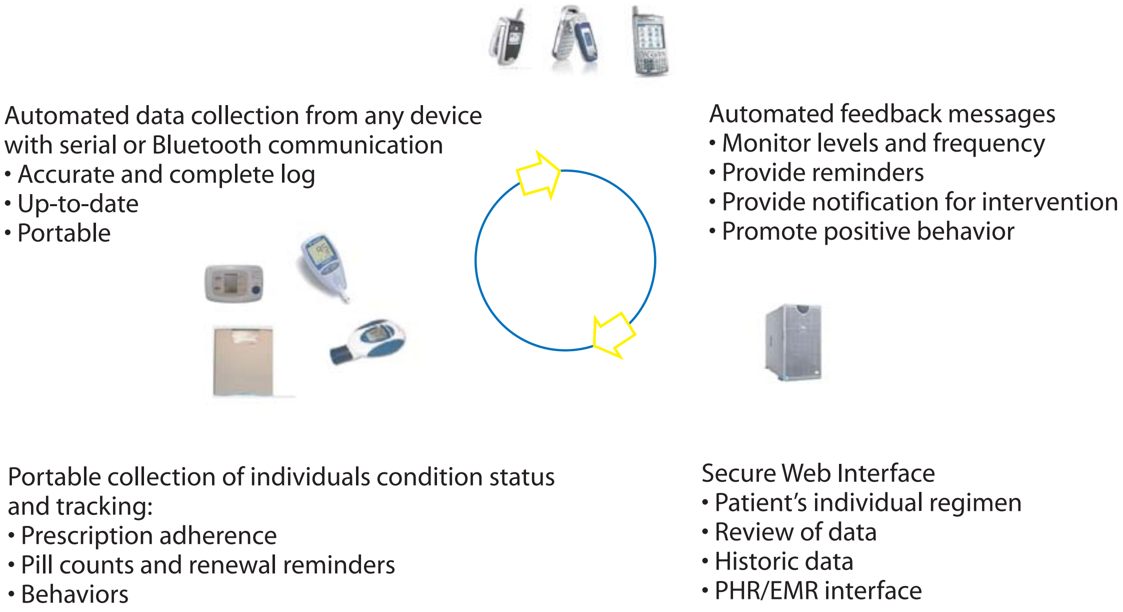
From a payer's perspective, good chronic disease management is good business. This new mobile telehealth tool has proven effective in early product trials with diabetes patients. It produced improved outcomes including more frequent testing, better glucose control, and lower HbA1cs. In addition to better short-term outcomes that translate to fewer emergency room visits, improving self-management and education is proven to reduce long-term complications and costs of care.

Other chronic diseases that require home medical device testing bear many of the same self-management issues and can benefit from this technology tool. For instance, by using an electronic weight scale, a cell phone-based weight management application can be used to promote positive behaviors in the individual's home. A protocol of self-reported symptoms and peak flow/spirometer readings can support improved asthma management. Patient reporting of prescription adherence, coupled with reminders and real-time biometric data, can be valuable to the patient as well as the provider.

In order for this or any tool to be successful in improving

Figure 1.

Cell Phone Telehealth Applications for Diabetes, Obesity, Asthma and Other Chronic Diseases Can Be Run on Many Mobile Devices



chronic disease self-management, it must be easy to use, nonintrusive, and be perceived to add value to the user. Using the cell phone, which is becoming an integral part of daily life, greatly reduces the complexity barrier and allows for the strengthened connection to the provider to become part of the user's daily routine. **NCMJ**

North Carolina
MEDICAL JOURNAL

Readers' Forum

To the Editor:

The November/December 2006 issue of The *North Carolina Medical Journal* offered a comprehensive discussion on the issue of worksite wellness and health promotion, providing both the most current research and field-based insights into what can work and how to implement those successful components. Employers have been faced with increasing employee health care costs for several years and many have considered worksite wellness as an option to address cost containment. At issue has been the true definition and scope of successful worksite wellness.

At Blue Cross Blue Shield of North Carolina we have been developing our employee health promotion program over the past several years. Among others, we sought the insight of several of the contributors to the recent issue. In part, as a result of that consultation and subsequent implementation of several initiatives, we have realized a significant increase in the proportion of members participating actively in our health and wellness programs.

In addition, we recently held our annual Health Care Symposium, which was attended by approximately 150 human resources and benefits managers from our business customers. This year's program focused on the topic of worksite and employee wellness. As a takeaway from the conference, we presented each attendee with a copy of your November/December issue as a resource to them as they further develop their own worksite wellness solutions.

Our ultimate goal is not only to successfully offer the type of worksite wellness programming highlighted in the last issue but also to continue to demonstrate objective improvements in employee health, productivity, and retention. As we accumulate more experience and develop or revise programs, we will share our experiences and success with our partnering employer groups and interested audiences across the state and nation.

Thank you for defining the issues, presenting achievable strategies, and setting the bar for the direction of worksite wellness in North Carolina.

Sincerely,
Don Bradley, MD
Chief Medical Officer
Blue Cross and Blue Shield of North Carolina

To the Editor:

Primum non nocere, first do no harm. While many consider this maxim dated and irrelevant in our techno modern world of medicine, no concept applies better in the debate of physician participation in capital punishment. The American Medical Association and North Carolina Medical Society have firmly stated that even physician presence at an execution is unethical and unacceptable. While the North Carolina Medical Board has officially stated that physician presence will not be sanctioned (in deference to North Carolina state law that requires physician presence), active participation is strictly forbidden, which includes monitoring of vital signs, levels of consciousness, etc.

Primum non nocere. As physicians, our duty is to always advocate for our patients. To always acts in their best interests. To eschew all other interests but those that best serve our patients. So how is it that a physician is brought into the realm of a state-sponsored execution to ensure proper sedation and level of consciousness so that a lethal combination of drugs will lead to an individual's demise? This was the requirement that was imposed upon the state to allow executions to continue, so that the United States constitutional requirement that prohibits cruel and unusual punishment is satisfied. But that policy conflicts with our basic tenants and ethics. How can we sedate and anesthetize, only to allow lethal drugs to be administered?

Primum non nocere. State sponsorship, state sanctioning, legislative approval, popular vote do nothing to remove physicians from their sacred duty to always act in the best interests of their patients. And our patients are anyone who we touch, treat, review, or opine. To act otherwise undermines our profession and our raison d'etre (ie, reason for existence).

Primum non nocere. We physicians must resist any action, by anybody, for any reason, that attempts to move us to violate our ethics, our tenants, and our sacred profession.

Primum non nocere.
Douglas K. Holmes, MD

Spotlight on the Safety Net

A Community Collaboration
Kimberly M. Alexander-Bratcher, MPH

Community Health Network of Henderson County

In the southwestern corner of North Carolina, local health and social service providers have joined into the Community Health Network of Henderson County (CHN). Community Health Network is a network of providers who access a shared client information system (Case Management Information System – CMIS). That system was adapted by Partnership for Health, Inc (PFH), 5 Rivers Systems, the NC Foundation for Advanced Health Programs, and the Office of Rural Health and Community Care to meet the network's needs. The CMIS electronically links health care providers and human services agencies in a 3-county area in western North Carolina to share client protected information to better serve clients, reduce duplication of efforts and services among various social service agencies and health care providers, and decrease gaps in access to services for low-income people in the Hendersonville-Brevard-Saluda area. The CMIS shared electronic database provides access to resource information used to quickly assist low-income people in finding health care, medications, and other basic human needs.

The collaboration began in 1997 when a post graduate resident physician in the Mountain Area Health Education Center (MAHEC)-sponsored Hendersonville Family Medicine Residency Program started a free clinic for homeless clients at the Henderson Rescue Mission. In 1998, MAHEC provided a licensed physician as the medical director for the Henderson County Health Department. This forged a unique relationship between the two organizations. As they encountered difficulties with mental health reform and expanded coordination with a local community health center, more stakeholders began working collaboratively. A Healthy Communities Access Program (HCAP) grant from the Health Resources and Service Administration (HRSA) was applied for and received to fund the CHN program under the umbrella of Partnership for Health (PFH), a Healthy Carolinians Partnership.

From its simple beginnings, CHN now includes more than thirty partners and is a model of community collaboration. Of 2157 applicants to the network program, 1929 have been enrolled in the network at the 15 enrollment sites. Although CHN does not provide direct services, the member organizations offer a variety of services in 9 primary care sites and 5 integrated behavioral health care sites. More that 4000 prescriptions valued at $400,741 have been filled for 742 patients. The target conditions of the program are diabetes, depression, and asthma, and more than 40% of the over 1900 CHN enrollees are affected by one of the 3 conditions. The full list of CHN members are listed in the table to the right.

When asked to describe the Community Health Network of Henderson County, medical advisor Steve Crane, MD, shared these thoughts, "Over the years there has been an extraordinary degree and breadth of cooperation between agencies and individuals in our community who care about access and quality of our health system. Each success has fostered a new project or collaboration resulting in today's multi-faceted approach. I trace the kernel of these efforts back to Jim Bernstein, who encouraged and mentored many of us to move in this direction."

POSITION ANNOUNCEMENT

Department of Family Medicine Behavioral Medicine
Brody School of Medicine at East Carolina University
Greenville, NC 27834

Vacancy Number:
Working Title: Head, Behavioral Medicine

The Department of Family Medicine announces an opening for Head of Behavioral Medicine. This position is responsible for the administration and coordination of the behavioral medicine curriculum for residents; teaching of residents and medical students; and collaborative clinical and educational work with graduate students in Psychology and Marriage and Family Therapy; provision of clinical services including individual, couple and family therapy; collaboration with other medical providers; and supervision of other behavioral clinicians. Scholarly and other creative activity expected. Innovation and leadership are encouraged.

Minimum requirements:

1. Ph.D./Psy.D. in Psychology, Marital and Family Therapy or related field.
2. Two years post-doctoral clinical training or experience in ambulatory medical setting.
3. Licensed in North Carolina or immediately license eligible.
4. Experience in teaching behavioral medicine in a family medicine residency program or other medical setting strongly preferred.

The Brody School of Medicine is known nationally for its commitment to family medicine. ECU with approximately 22,000 students is the third largest university in the 16-member UNC system. Greenville, NC home of ECU, has consistently won awards for its quality of living.

To apply, send a letter of interest, a current CV, and names with addresses of three references to Valerie Gilchrist, MD, Chair, Department of Family Medicine, Brody School of Medicine, East Carolina University, 600 Moye Boulevard, Brody 4N-84, Greenville, NC 27834.

East Carolina University is an EEO/AA employer, which accommodates individuals with disabilities. All applicants must comply with the immigration Reform and Control Act.

STATE-OF-THE-ART TECHNOLOGY WITH A HOMETOWN TOUCH.

At Southeastern Regional, you'll find some of today's most modern advancements in medicine, such as state-of-the-art CT and MRI scanners that precisely and safely guide neurosurgery in the brain and spine by feeding information directly to computers in the operating room.

From new noninvasive surgery techniques to our recently opened Heart Center, you might be surprised that a medical center in southeastern North Carolina would offer the same services and expertise usually found only in larger regions. But having these new technologies here in Lumberton bring patients the best in care without their having to drive hours from home. And that, we believe, is one of the most important parts of the healing process—being close to home, with the support of family and friends.

Fast Turnaround

SOMETIMES LESS IS MORE.

Especially when it comes to surgery. Robotic procedures mean less pain, less scarring, and less recovery time.

Surgery doesn’t always have to mean putting your whole life on hold. With the da Vinci® Surgical System, you should have less pain and fewer side effects following your procedure–which means that you can get home, and back to your family and your life, a whole lot faster.

The da Vinci is an advanced surgical tool that allows our skilled physicians to perform complex, delicate procedures with unmatched precision through very small incisions–a monumental difference from standard open surgeries. Cardiac surgeons at Pitt County Memorial Hospital in Greenville, in conjunction with the Brody School of Medicine at East Carolina University, are leaders in da Vinci surgery, responsible for this country’s first robot-assisted mitral valve repair in 2000. Since then, the hospital and university have trained more than 1,000 surgeons from around the globe to use the da Vinci robot. Today, we are expanding our advanced robotics program to include general surgery, gynecology and urology, particularly for prostate cancer.

Surgery is always a major step. But with da Vinci, you could find yourself stepping more quickly back into your own life, and all the things that truly matter.

Is the da Vinci right for you? To learn more about this minimally invasive surgical option, visit www.roboticsurgery.uhseast.com.

The North Carolina Institute of Medicine

In 1983 the North Carolina General Assembly chartered the North Carolina Institute of Medicine as an independent, nonprofit organization to serve as a nonpolitical source of analysis and advice on issues of relevance to the health of North Carolina's population. The Institute is a convenor of persons and organizations with health-relevant expertise, a provider of carefully conducted studies of complex and often controversial health and health care issues, and a source of advice regarding available options for problem solution. The principal mode of addressing such issues is through the convening of task forces consisting of some of the state's leading professionals, policy makers, and interest group representatives to undertake detailed analyses of the various dimensions of such issues and to identify a range of possible options for addressing them.

The Duke Endowment

The Duke Endowment, headquartered in Charlotte, NC, is one of the nation's largest private foundations. Established in 1924 by industrialist James B. Duke, its mission is to serve the people of North Carolina and South Carolina by supporting programs of higher education, health care, children's welfare and spiritual life. The Endowment's health care grants provide assistance to not-for-profit hospitals and other related health care organizations in the Carolinas. Major focus areas include improving access to health care for all individuals, improving the quality and safety of the delivery of health care, and expanding preventative and early intervention programs. Since its inception, the Endowment has awarded $2.2 billion to organizations in North Carolina and South Carolina, including more than $750 million in the area of health care.

North Carolina's Primary Care and Specialty Workforce

COMMENTARIES

DEPARTMENTS

About the Cover:
Pressures on supply mean that North Carolina's practitioners will have to step outside their current roles and disciplinary structures to meet the needs of the state, especially in rural and underserved areas.

Tarheel Footprints in Health Care

Recognizing unusual and often unsung contributions of individual citizens who have made health care for North Carolinians more accessible and of higher quality

Recognizing Daniel Stroup, MD Hayesville, NC

Daniel Stroup, MD

When the National Health Service Corps was established in 1968, its goal was to recruit enthusiastic physicians to practice in remote and underserved areas. The expectation was that they would find their missions in these rural places and remain there as community doctors. That ideal outcome was not often achieved but there is at least one example of an ideal outcome in western North Carolina in the hills above Lake Chatuge.

In 1982 Dan Stroup came to North Carolina as a National Health Service Corps scholar. He had just finished his family medicine residency in Waukesha, Wisconsin and was recruited by the North Carolina Office of Rural Health to a practice in Hayesville in Clay County. Twenty-five years later Dr. Stroup is still there but he's much more than the "town doc." He is the leader of a progressive and modern medical practice of 3 physicians, a nurse practitioner, and a physician assistant serving the local hospital, a nursing home, and the citizens of Clay and Cherokee counties.

The Chatuge Family Practice, which has offices in Hayesville in Clay County and Murphy in Cherokee County, is known for its progressive outlook and early adoption of quality-enhancing technology. The practice has an electronic medical record system that links into the PPRNET quality management system, a regional system of disease management and care coordination. This dedication to keep up with the latest in medical care is one of the characteristics of Dr. Stroup who combines old-fashioned community care with the best and latest medical information and the mechanisms to apply that information to care.

Dr. Stroup supports the local schools and their sports teams in both Clay and Cherokee counties as well as taking care of patients in the local nursing home, acting as medical director of the office, and taking call for the hospital in Murphy. He also has served an 11-year stint as county medical examiner and currently is on the Murphy Hospital Authority Board. These supporting roles are done to enhance the scope and quality of the primary care practice and are done on a voluntary basis. Even with all this, Dr. Stroup still finds time for kayaking the Ocoee River in nearby Tennessee.

The people who work with Dr. Stroup see him as a "firm but fair" leader who treats everyone equally—patients and staff alike. He acts as the supervising physician for a nurse practitioner, Judith Wikstrom, who has been with the practice for 12 years and a physician assistant, John Tucker, who joined the practice in 2004. Dr. Stroup was instrumental in recruiting his physician colleagues to the community. Dr. Theresa Heavner came in 1990 and Dr. Matthew Molison, another National Health Service Corps scholar, arrived in 1997. Both have found a permanent home in Cherokee County.

Dan Stroup is a model for how the National Health Services Corps can work. But it requires special people with dedication and the drive to build up as well as just "fill-in" a place. It also requires the support and assistance of organizations like the NC Office of Rural Health and Community Care which brought Dr. Stroup together with the people of Hayesville as well as the support of colleagues and patients to make rural primary care in the North Carolina mountains a leader in quality.

The editors of the *North Carolina Medical Journal* are pleased to recognize Dr. Daniel Stroup for his service and dedication to provide access to quality health care in rural North Carolina.

ARTICLE

Physician Reported Communication About Depression and Psychosocial Issues During Postpartum Visits

Betsy Lynn Sleath, PhD; Naveen Thomas, MD, MHP; Elizabeth Jackson, PhD; Suzanne L. West, PhD; Bradley N. Gaynes, MD, MPH

Abstract

Objective: *Postpartum depression occurs in 13% of women after delivery, making it one of the most common puerperial complications. The purpose of the study was to examine: (1) the extent to which obstetricians/gynecologists and family physicians report discussing depression and other psychosocial issues during postpartum visits and (2) how physician specialty and gender are related to whether physicians report discussing depression and other psychosocial issues with patients during postpartum visits.*

Methods: *A survey was sent to a random sample of 600 obstetricians/gynecologists and 600 family practitioners in North Carolina.*

Principal Findings: *The overall response rate was 42%. Forty-six percent of the responding physicians (N=228) reported that they had seen women for postpartum visits during the past 3 months. Of physicians conducting postpartum visits within this time period, 43% of physicians were almost certain to ask whether the woman felt down, depressed, or hopeless and 27% were almost certain to ask about the woman's interest in her usual activities. Seventy-nine percent of physicians stated that they were unlikely to use a formal screen for depression. Obstetricians/gynecologists were less likely to ask about a woman's social support network (OR=0.33, 95% CI=0.14, 0.75), to ask about her relationship with her partner (OR=0.40, 95% CI=0.18, 0.87), and to use a formal depression screen (OR=0.16, 95% CI=0.04, 0.57) than family practitioners.*

Limitations: *The study only examined physician self-report of the extent to which they communicated about different issues with women during postpartum visits.*

Conclusions: *Communication about depression and related psychosocial issues during postpartum visits is substantially limited, likely contributing to the underdiagnosis of this common disorder.*

Background

The most recent estimates suggest that 13% of women have postpartum depression after delivery.[1] Yet it is only during the routine postpartum visit that occurs approximately 4 to 6 weeks after delivery when postpartum depression can be detected. Women may not readily discuss depression with their providers. Therefore, detection depends on whether the health care provider asks about the woman's emotional and psychological well-being to elicit indicators of postpartum depression. Very little is known about the interaction of providers and patients during postpartum visits, especially with regard to emotional or social support content. In a recent study of obstetrician-patient interactions during the prenatal period, Roter and colleagues[2] noted that most of the communication was predominantly biomedical with little psychosocial or social discussion.

Betsy Lynn Sleath, PhD, is an associate professor in the School of Pharmacy and a research associate at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill. She can be reached at Betsy_Sleath@unc.edu or CB 7590, Chapel Hill, NC 27599-7590.

Naveen Thomas, MD, MHP, is a medical officer, specialist scale, at Hutt Hospital in Lower Hutt, New Zealand.

Elizabeth Jackson, PhD, was a research associate at the time this research was conducted at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill.

Suzanne L. West, PhD, is a research associate professor and director of research for the Center for Women's Health Research at the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill.

Bradley N. Gaynes, MD, MPH, is an associate professor in the Department of Psychiatry at the School of Medicine at the University of North Carolina at Chapel Hill.

One of the only studies that assessed general practitioners' beliefs about what should be discussed during postpartum visits was conducted in Australia.[3] Seven hundred and fifteen general practitioners responded (70% response rate) to a survey that asked about physical symptoms such as urination and back problems rather than psychosocial ones. Despite the focus on physical problems, 88% of practitioners believed that the mother's feelings should be discussed during postpartum visits and 49% believed that the woman's relationship with her partner should be discussed. The researchers did not specifically ask whether the providers felt the woman's social support network should be discussed, whether they discussed depression or anhedonia (loss of interest in usual activities), or whether they used a depression screener during postpartum visits.

Previous studies have found that the following psychosocial factors are related to whether women develop postpartum depression: (a) lack of adequate social support,[4-6] (b) being a single parent,[7-9] (c) marital instability,[6,10,11] and (d) stressful life events.[6,8,12,13] If physicians took the time to ask women about these areas and about the women's emotions and feelings during postpartum visits, they could potentially identify and help those women who already have or are at risk of developing postpartum depression.

To our knowledge, no prior study conducted in the United States has examined the extent to which either family practitioners or obstetricians/gynecologists report discussing psychosocial issues with women during postpartum visits. Examining whether there are differences in communication about psychosocial issues during postpartum visits by physician specialty could help target efforts to where they are most needed. Furthermore, examining whether there are differences in communication about psychosocial issues during postpartum visits by physician gender could also help tailor efforts. Gunn et al[3,14] surveyed 1104 Australian general practitioners and found that female general practitioners were 3.7 times more likely to provide postpartum care than male general practitioners. Roter et al[2] examined communication between obstetricians and their patients, and they did not find gender differences in physician discussion of social and emotional adjustment during prenatal visits. However, the researchers did not specifically examine whether depression or other specific psychosocial issues (eg, relationship with partner, social support network) were discussed. The researchers found that only 8.6% of male physicians and 7.3% of female physicians discussed social adjustment, and 3.4% of male and 1.7% of female physicians talked about emotional adjustment.

Therefore, the purpose of the current study was to examine: (1) the extent to which obstetricians/gynecologists and family physicians report discussing depression and other psychosocial issues during postpartum visits and (2) how physician specialty and gender are related to whether physicians report discussing depression and other psychosocial issues with patients during postpartum visits.

Methods

We developed a data collection instrument using information derived from a literature search focusing on surveying physicians about depression or postpartum depression and communication about depression or postpartum depression.[2,3,15,16] The survey was targeted toward determining physician attitudes and experiences in providing postpartum care.[3,15,16] Some questions were modified from other studies and new questions were added. After obtaining IRB approval, the survey was pretested on 7 physicians (3 family practitioners and 4 obstetricians/gynecologists), and their suggestions were used to develop a final version of the survey.

The survey was sent to a random sample of obstetricians/gynecologists and family practitioners licensed in the state of North Carolina. They were identified from the 2002 North Carolina Physicians Database (NCPD) which is maintained by the North Carolina Medical Board. Information for a random sample of 600 obstetricians/gynecologists and 600 family practitioners was obtained from the NCPD, including physician name, address, specialty, practice setting, birth date, date of medical school graduation, and demographic information. A second mailing of the survey was sent to nonresponders approximately 3 weeks after the first mailing was sent. All identifiers were destroyed after the second mailing.

The first question of the survey asked whether the physicians had seen women for postpartum visits during the last 3 months. If physicians answered no, they were asked to stop and return the survey at that point.

Measurement

There were two sources of variables used in this study, the NCPD and the survey. Physician specialty (family practice or obstetrics/gynecology), gender, age, years of experience, and race were obtained from the NCPD. Physician gender and specialty were measured as dichotomous variables. Physician age and years of experience were measured as continuous variables. Physician race was originally measured as a categorical variable (white, Hispanic, African American, American Indian/Alaskan native, Asian/Pacific Islander, other) but was recoded into a dichotomous variable (white, nonwhite) because the majority of physicians were white. As physician age and years in practice were highly related (Pearson correlation coefficient = 0.96, $p<.001$), only physician age was included in the analyses.

The variables that examined physician likelihood of discussing psychosocial and other issues with women during postpartum visits were obtained from the survey. We asked about psychosocial and nonpsychosocial issues so that the physicians would not know that our main focus was communication about psychosocial issues. The physicians were asked on a 4-point Likert scale how likely (unlikely, somewhat likely, very likely, almost certain) they were to discuss 11 different areas with women during postpartum visits. The 11 areas were: (a) breastfeeding, (b) interest in her usual activities (anhedonia), (c) exercise patterns, (d) diet, (e) feeling down, depressed, or hopeless, (f) relationship with her partner, (g) social support network, (h) sleeping patterns, (i) job/work,

(j) using a formal tool to screen for depression, and (k) sexual functioning. Of note, either anhedonia (b) or depressed mood (e) is a required core element of a postpartum depression diagnosis. For analysis purposes, the 11 variables were recoded into dichotomous variables (unlikely or somewhat likely versus very likely or almost certain).

Analysis

Descriptive statistics were calculated for physician characteristics. We compared responding and nonresponding physicians by gender, age, race, and specialty using chi-square or t-tests. We then compared physicians who did see women for postpartum visits during the last 3 months to those who did not by gender, age, race, and specialty using chi-square or t-tests. Our remaining analyses included only those physicians who reported seeing women for postpartum visits during the last 3 months. Descriptive statistics were calculated for physician reports of how likely they were to communicate about certain issues during postpartum visits. Next, the bivariate relationships between the variables were examined using t-tests, chi-square statistics, and Fisher's exact tests. Multivariable logistic regression techniques were run to predict how physician gender, age, race, and specialty influenced whether physicians reported being almost certain or very likely to ask about depression, anhedonia, a woman's social support network, the woman's relationship with her partner, job/work, and sleeping patterns and whether physicians used a formal screening instrument to assess for depression. All analyses were conducted by the first author (Betsy Lynn Sleath).

Results

A total of 1200 physicians were sent surveys with postage-paid return envelopes. Sixteen were returned as undeliverable (2 obstetricians/gynecologists and 14 family practitioners). The response rate for obstetricians/gynecologists was 43% compared to 40% for family practitioners. The overall response rate for both specialties was 42% (N = 491). Responding and nonresponding physicians did not differ significantly by gender, age, or race.

A total of 228 of the 491 (46%) responding physicians reported that they had seen women for postpartum visits during the past 3 months. Female physicians were significantly more likely to report seeing women for postpartum visits during the past 3 months than male physicians (56% versus 42%; Pearson chi-square = 8.55, p = 0.003). Obstetricians/gynecologists were significantly more likely to report seeing women for postpartum visits during the past 3 months than family practitioners (74% versus 16%; Pearson chi-square = 168.56, p < 0.000). Female physicians who responded to our survey were not significantly more likely to be obstetricians/gynecologists than male physicians. Younger physicians were significantly more likely to report seeing women for postpartum visits during the last 3 months than older physicians (t-test = 6.08, p <0.000). Table 1 presents the characteristics of the physicians who reported seeing women for postpartum visits during the past 3 months.

Table 1.
Characteristics of Responding Physicians Who Treated Women for Postpartum Visits During the Past Three Months

	Percentage (N)
Age	
26 - 41	53.9 (123)
42 - 56	40.0 (91)
57 - 71	6.1 (14)
Sex	
Female	37.3 (85)
Male	62.7 (143)
Race	
White	82.9 (189)
Nonwhite	17.1 (39)
Practice type	
Obstetrics	84.2 (192)
Family practice	15.8 (36)
Sample Demographics (N = 228)	

Table 2 illustrates how likely these physicians were to communicate about depression and psychosocial and other issues during postpartum visits. Forty-three percent of physicians were almost certain to ask about the woman feeling down, depressed, or hopeless and 27% were almost certain to ask about the woman's interest in her usual activities. Twenty percent of physicians were almost certain to ask the woman about her relationship with her partner and 16% of physicians were almost certain to ask the woman about her social support network. Seventy-nine percent of physicians stated they were unlikely to use a formal screen for depression.

We found no differences by physician race, gender, age, or specialty in whether physicians were very likely or almost certain to ask versus somewhat likely or unlikely to ask the woman about feeling down, depressed, or hopeless or whether they were to ask about her interest in her usual activities (results not shown).

Table 3 presents the multivariable logistic regression results. Obstetricians/gynecologists (46%) were significantly less likely to be almost certain or very likely to ask about a woman's social support network than family practitioners (75%; OR=0.33, 95% CI=0.14, 0.75). Obstetricians/gynecologists (49%) were significantly less likely to be almost certain or very likely to ask about the woman's relationship with her partner than family practitioners (68%; OR=0.40, 95% CI=0.18, 0.87). Obstetricians/gynecologists (4%) were significantly less likely to be almost certain or very likely to use a formal tool to screen for depression than family practitioners (14%; OR=0.16, 95% CI=0.04, 0.57).

Table 2.
Physician Reports of How Likely They Were to Communicate About Depression and Psychosocial and Other Issues During Postpartum Visits (N=228)[a]

Physician race-nonwhite	0.86 (0.41, 1.81)	0.74 (0.36, 1.51)	0.28 (0.12, 0.62)**	0.38 (0.18, 0.79)**	1.07 (0.20, 5.74)

* p<0.05, ** P<0.01

When examining nonpsychosocial issues, we found that male physicians (68%) were significantly less likely to be almost certain or very likely to ask about a woman's job/work than female physicians (86%; OR=0.38, 95% CI=0.17, 0.85). Nonwhite physicians (59%) were significantly less likely to be almost certain or very likely to ask about a woman's job/work than white physicians (78%; OR=0.28, 95% CI=0.12, 0.62). Nonwhite physicians (49%) were significantly less likely to be almost certain or very likely to ask about a woman's sleep patterns than white physicians (68 %) (OR=0.38; 95% CI=0.18, 0.79).

Discussion

Postpartum depression occurs in more than 1 out of every 10 women who have a baby. It is an important problem that can have effects on both the baby and the mother. One of the key places where postpartum depression can be recognized and diagnosed by a health care professional is during a woman's routine postpartum visit. We found that 43% of physicians stated that they were almost certain to ask about the woman feeling down, depressed, or hopeless and just 27% were almost certain to ask about the woman's interest in her usual activities. These are two of the core symptoms of depression, at least one of which is required for the diagnosis of major depressive disorder. Assessing women for depression is an essential part of postpartum care.

Less than 6% of physicians stated that they were very likely or almost certain to use a formal depression screening instrument during postpartum visits. Physicians might consider using a brief depression screen among women during postpartum visits so that problems are identified early and treatment initiated if appropriate. For example, the 9-item Patient Health Questionnaire is an easy to use depression screening instrument that has been successfully used in primary care and obstetrical settings; the Edinburgh postnatal depression scale[17,18] is another option.

In addition to screening for depression, it is also important that women who screen positive for depression have access to appropriate systems to receive treatment. This may include practices referring women to mental health professionals in their area if they do not have a mental health specialist as part of their practice. Future research should examine the extent to which practices have systems in place to treat women with postpartum depression.

Physician demographics were not significantly related to whether physicians reported being very likely to almost certain to ask about depression or anhedonia. However, there were some interesting differences by specialty. Family practitioners were more likely than obstetricians/ gynecologists to report asking women about social support and their relationships with their partners and they were more likely to report using a depression screener. Perhaps this is due to differences in educational training or differences in the amount of time spent with patients. Future work should explore why there might be differences between family practitioners and obstetricians/gynecologists in discussing psychosocial issues.

The study was limited in that we only examined physician self-report of the extent to which they communicated about different issues with women during postpartum visits. Future research should compare physician self-reported communication to actual care, as documented through audio tapes or other research methods. The study was also limited in that only 42% of physicians responded and responding physicians might have been more interested in these issues. Another limitation is that social desirability bias may have led to overestimates of physician self-report practices.

Despite the limitations, the study provided new information on the extent to which physicians report discussing different psychosocial issues with women during postpartum visits. Postpartum visits are one of the key places where postpartum depression can be recognized and treated. Providers should consider asking all patients at their postpartum visits about depression, anhedonia (loss of interest in usual activities), and risk factors for postpartum depression (social support, relationship with partner). Providers should also consider using a brief depression screen during postpartum visits so that problems are identified early and treatment is initiated if appropriate. **NCMJ**

Call for Papers

John W. Williams Jr., MD, MHS
Scientific Editor, *North Carolina Medical Journal*

North Carolina is blessed with some of the finest medical research institutions in the world. The work of the medical scientists that labor in our research facilities becomes complete (in many ways) and public when it is published in peer-reviewed journals.

While medical researchers in North Carolina have many journals to which they can submit their manuscripts, we want them to consider keeping their work here at home. To be more specific, we invite the authors of our state to submit their papers to the *North Carolina Medical Journal*.

The Journal seeks papers that convey the results of original research. We are especially interested in publishing research papers that have relevance to the health of the people of our state.

An editor reviews all papers received and those of sufficient quality are peer-reviewed. As with any journal of merit, only papers of high quality will be published. Papers printed in the Journal are indexed in the National Library of Medicine's MEDLINE public database.

We generally accept two types of manuscripts for review: (1) original clinical or health services research contributions and (2) systematic reviews (both regardless of specific topic).

The *North Carolina Medical Journal* is published six times a year. It is distributed free of charge to the members of the North Carolina Medical Society, the North Carolina Hospital Association, the North Carolina College of Internal Medicine, the North Carolina Board of Pharmacy, the North Carolina Association of Pharmacists, the North Carolina Division of Public Health, the North Carolina Dental Society, the North Carolina Health Care Facilities Association, and The Carolinas Center for Medical Excellence. The Journal is available by subscription to others.

For guidance on manuscript preparation, authors should consult the "Author Guidelines," which can be found at www.ncmedicaljournal.com.

North Carolina
MEDICAL JOURNAL

Instructions for Authors

Unsolicited manuscripts containing original material are accepted for consideration if neither the article nor any part of its essential substance, tables, or figures has been or will be published or submitted elsewhere before appearing in the Journal.

All unsolicited manuscripts submitted for peer-review must contain a brief structured abstract including the following (when relevant): Objective; Study Design; Data Source(s)/Study Setting; Data Collection Methods; Intervention; Principal Findings; Limitations; Conclusions; Relevance. Papers submitted without a structured abstract may be considered incomplete and returned to the author.

Submit a cover letter and the article (via e-mail attachment) containing the double-spaced text, preferably in Microsoft Word. The letter should indicate that the article is not under consideration for publication elsewhere and has not previously been published in any form.

POLICY FORUM

North Carolina's Primary Care and Specialty Workforce

> *"By 2030, under almost any realistic scenario, North Carolina is likely to experience significant practitioner shortages absent any changes in supply or productivity."*

INTRODUCTION

Policy Forum:
Primary Care and Specialty Supply in North Carolina

Many of us have had the experience of wanting to see a doctor or a primary care practitioner as soon as possible but are told we have to wait for an appointment. Sometimes that wait is many days, even weeks. The ability to see a health care practitioner "on demand" is as much a function of their local availability as it is a problem with the overall supply of practitioners in the state. For individuals seeking care of a certain type or in a certain geographic region of the state, getting to see the doctor or any health care professional for a nonurgent problem can be even more difficult. These delays can have consequences for an individual's health.

North Carolina, along with the rest of the nation, is beginning to experience a situation where the availability of practitioners is becoming tighter. Some parts of the state have had a chronic undersupply of physicians and other primary care professionals, and there is evidence that we will soon experience regional shortages for some specialists. The good news is that North Carolina, as a whole, currently has what most would consider a sufficient number of practitioners on a population basis. However, there are a few exceptions, specifically in the areas of child psychiatry and in some rural and low-income communities. These conditions exist in places not too distant from cities with some of the highest concentrations of physicians in the entire nation.

What has become apparent, given the lack of any appreciable growth in the number of doctors trained in the United States, is the fact that we will not be bringing in as many physicians as we have in the past. This pattern is especially problematic because our population continues to grow, age, and face a higher incidence of chronic disease. North Carolina is one of the fastest growing states in the nation. However, the supply of practitioners is not expected to increase at the same rate. We also expect that demand for services will grow very quickly as the baby-boom generation reaches the age when need for care rises rapidly. The physician population also is aging, and many practitioners will be preparing to retire in the next two decades.

In response to these trends that have emerged over the past 3 years, a group of North Carolina health policy experts, government officials, health care providers, and businesses formed a task force to evaluate strategies for ensuring the state's ability to meet our health care needs under these conditions. The nature of the problem itself presents a challenge. Practitioners are working more efficiently and they can be even more efficient with the advent of new technology and the expansion and sharing of roles and skills within and across disciplines and professions. Thus, the issue may not be one of simply supply and demand or need for practitioners, but of organization and policy. This issue of the *North Carolina Medical Journal* highlights the perspectives of a number of individuals who participated in the North Carolina Institute of Medicine's Task Force on Primary Care and Specialty Supply.

The commentaries in this issue highlight a range of opportunities for improving future access to care. Some of the strategies include increasing the supply of underrepresented minority practitioners, expanding clinical rotation and residency opportunities for medical and health professional students, developing new models of care, and targeting funding to programs that support putting practitioners in underserved areas of the state or in shortage specialties.

We hope these commentaries illuminate the primary care and specialty supply challenges facing North Carolina and present tangible strategies for improvement. Clearly, no single strategy will sufficiently address our future concerns. However, if we implement a number of different strategies and take action now, we have the opportunity to make a difference in reducing future shortages. We should encourage our policy makers to heed the warning signals and support policy changes that could greatly benefit the future health of North Carolinians.

ISSUE BRIEF

Weathering the Practitioner Workforce Shortage

Pam Silberman, JD, DrPH; E. Harvey Estes Jr., MD; Kristen L. Dubay, MPP; Mark Holmes, PhD

Publisher's note: The print version of this article inadvertently omitted reference to the central role the Kate B. Reynolds Charitable Trust played in the formation and deliberation of the North Carolina Institute of Medicine Task Force on Primary Care and Specialty Supply. This oversight is corrected within the text.

Growth in the overall population, and particularly growth among older adult populations, will have significant implications for North Carolina's health care system. The state's population is expected to grow by 39% over the next 25 years (July 2005-2029). The population of older adults age 65 or older is expected to grow more quickly, by 107% during the same time period, and the cohort of adults age 75 or older will grow by 100%.[1] On average, people make approximately 3 visits per year to a physician's office or clinic. However, visit rates vary by age: in 2003, 25-34 year olds made 2.3 annual visits to a physician's office or clinic, whereas 65-74 year olds made 6.2 visits and 75-84 year olds made 7.3 visits.[2] In addition to rapid growth among older adult populations, North Carolina is experiencing growth in the number of people with chronic illnesses.[a,3] These 3 factors—growth of the overall population, aging of the population, and increased prevalence of chronic illnesses—will create increased demand on the health care system. Within 25 years, the confluence of these factors will create a perfect storm of health care need. Absent any meaningful change in production or retention, the supply of health care practitioners will not grow sufficiently to meet this need.

Physicians, physician assistants (PAs), nurse practitioners (NPs), and certified nurse midwives (CNMs) comprise the health care workforce needed to diagnose and treat individual patients. Having access to these practitioners contributes to the overall well-being of our population. While the exact relationship of overall practitioner supply to population health measures is disputed,[4] specific contributions of physicians, PAs, NPs, and CNMs to individual health is not in doubt. The consequences of not being able to see health care practitioners when needed are clear.

> *"These 3 factors—growth of the overall population, aging of the population, and increased prevalence of chronic illnesses—will create increased demand on the health care system."*

---

[a] Between 1987 and 2002, there was a significant increase in the treated disease prevalence of certain chronic diseases such as cerebrovascular diseases (161% increase); kidney problems (99% increase); pulmonary conditions (90% increase); diabetes (64% increase); the presence of abnormal or elevated lipids (fatty molecules) in the blood (437% increase) with cholesterol being most common; and certain back problems (78%).

Pam Silberman, JD, DrPH, is president and CEO of the North Carolina Institute of Medicine. She can be reached at silber@schsr.unc.edu or 5501 Fortunes Ridge Drive, Durham, NC 27713.

E. Harvey Estes Jr., MD, is chairman emeritus of the North Carolina Institute of Medicine Board of Directors, professor emeritus of the Department of Community and Family Medicine at Duke University, and chair of the North Carolina Institute of Medicine Task Force on Primary Care and Specialty Supply.

Kristen L. Dubay, MPP, is a project director with the North Carolina Institute of Medicine and managing editor of the *North Carolina Medical Journal*.

Mark Holmes, PhD, is vice president of the North Carolina Institute of Medicine and senior research fellow at the Cecil G. Sheps Center for Health Services Research.

Studies have shown people with less access to medical care live shorter lives, with more disability and lower productivity.[5]

No one currently knows the optimal number of or type of practitioners needed to optimize population health. Yet, by most measures, North Carolina has neither too many nor too few physicians. North Carolina had 20.7 physicians to every 10 000 people in 2005, which is slightly less than the national average. If nothing is done to change the supply of practitioners in North Carolina, the ratio of physicians-to-population is expected to decline by 8% by 2020 and by 21% by 2030. The ratio of all practitioners-to-population, including PAs, NPs, and CNMs, is expected to drop between 2% and 13% by 2030.

The practitioner workforce shortage is not only a problem North Carolina will face in the future; practitioner shortages currently exist in many areas of the state. Many counties have experienced a decline over the last 5 years in primary care practitioners, psychiatrists, general surgeons, and practitioners delivering babies. In addition, the state has far fewer minorities in these health professions than their representation in the population.

The Kate B. Reynolds Charitable Trust recognized these issues and asked The North Carolina Institute of Medicine (NC IOM) to convene the Task Force on Primary Care and Specialty Supply to analyze current and projected trends in practitioner supply and to examine whether the existing production of physicians, PAs, NPs, and CNMs would address the state's growing health care needs. In addition to providing the impetus for the task force, the Kate B. Reynolds Charitable Trust graciously funded the work and offered its years of experience increasing practitioner supply in underserved areas of the state to guide and inform the task force. The task force was a collaborative effort with the North Carolina Area Health Education Centers Program (AHEC), the Southeast Regional Workforce Center, and the North Carolina Health Professions Data System in the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill (UNC-CH). The task force met for more than a year, and its work culminated in a one-day summit to obtain feedback from a larger group of practitioners, leaders of academic health centers and health professional schools, and community leaders. This issue brief summarizes the findings of the task force along with its priority recommendations. The paper is organized into 4 sections: overview of future supply, areas of the state experiencing persistent shortages, trends in practitioner supply by practitioner specialty (including primary care), and underrepresentation of minorities in health professions.

Overall Supply

For most of the last 20 years, North Carolina experienced a steady increase in the ratio of practitioners-to-population because the number of licensed practitioners grew faster than the population. However, the rate of growth has slowed over the last 5 years. The physician-to-population ratio increased by approximately 2.1% annually between 1985 and 2000 but has slowed to a 0.9% growth rate since 2000.

The physician workforce is aging. A sizable portion of physicians are likely to retire in the next 25 years, and older physicians who do not retire tend to work fewer hours in direct patient care. A significant proportion of nurse practitioners and, to a lesser extent, physician assistants also will reach retirement age within the next 25 years. Absent significant increases in production, in-migration, or retention of practitioners in North Carolina, the supply of practitioners is unlikely to keep up with growing demand. Assuming current growth trends, the number of primary care and specialty practitioners is expected to grow between 23% and 39% between 2005 and 2030 while the population is expected to grow 42% during this same time period. The aging of the population and increased number of people with chronic illnesses will lead to the growing demand for health services beyond that due to population growth.

It is impossible to fully predict the demand for and supply of practitioner services 25 years into the future. There are a number of different factors that must be considered in projecting practitioner supply and increased demand for health services. Some of these factors include the anticipated growth in supply of new physicians, PAs, NPs, and CNMs; anticipated exodus of practitioners from the profession (due to death, retirement, moving out of state, or other factors); growth in the overall state population; aging of the population (which affects demand for services); and overall prevalence of chronic illness. The combined effect of 3 of the primary drivers of demand—growth of the overall population, aging of the population, and increased prevalence of chronic illnesses—is expected to increase demand for services in North Carolina (measured in annual visits) considerably. The first two factors alone will lead to a 52% increase in annual visits between 2005 and 2030. The increasing prevalence of chronic disease may add an additional increase of 5%.

The NC IOM Task Force on Primary Care and Specialty Supply developed different workforce projections based on different assumptions, including a "best case" and "worst case" scenario. (See Table 1.) The "best case" scenarios are based on

Table 1.
Projected Change in Practitioner-to-Population Ratios, North Carolina, 2020 and 2030

	Projected Change in Practitioner-to-Population Ratios		Projected Change in Practitioner-to-Adjusted Population Ratios	
	2020	2030	2020	2030
Physicians only	-8%	-21%	-12%	-26%
All practitioners				
Best case	4%	-2%	-1%	-8%
Worst case	-4%	-13%	-8%	-19%

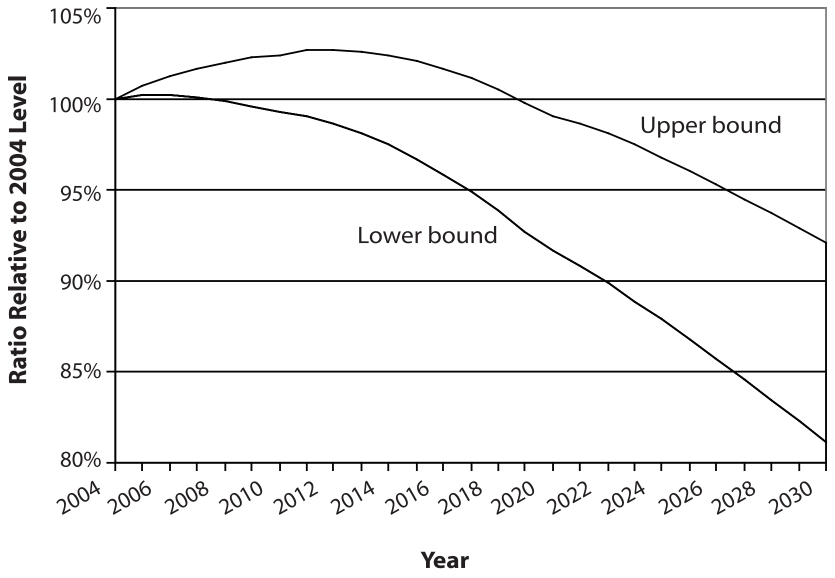
Source: NC Institute of Medicine and the North Carolina Health Professions Data System.

current growth of physicians and the higher than average rate of growth of PAs, NPs, and CNMs experienced in the last 5 years. These projections weigh PAs, NPs, and CNMs at 0.75 full-time equivalent (FTE) of a physician.[6] The "worst case" scenarios are based on current growth of physicians and average rate of growth of PAs, NPs, and CNMs averaged over the last 25 years. These projections weigh PAs, NPs, and CNMs at 0.50 FTE of a physician (as used by federal workforce projections). In addition, there are separate estimates for practitioner-to-population only and practitioner-to-adjusted population (based on increased demand due to aging of the population). These projections do not factor in growth in the number of people with chronic illnesses because current projections for disease prevalence and its effect on ambulatory services are too tenuous. By 2030, under almost any realistic scenario, North Carolina is likely to experience significant practitioner shortages absent any changes in supply or productivity.

Chart 1 presents the best and worst case projections for the age-adjusted populations between 2005 and 2030. The supply of practitioners-to-population is expected to increase until 2015, at which time North Carolina will see a precipitous drop in the overall supply of practitioners.

There are two fundamentally different approaches the state can take to address future practitioner shortages: (1) restructure the health care delivery and finance system to create new and more efficient systems of care (particularly for people with chronic illnesses) or (2) increase practitioner supply.

Chart 1.
Range of Projected Practitioner-to-Population Ratios, North Carolina, 2005-2030



Note: Lines represent upper and lower bounds of reasonable estimates of practitioner supply per North Carolinian, relative to 2004 levels.

Source: NC Institute of Medicine and the North Carolina Health Professions Data System.

The state should explore ways to restructure the health care delivery and financing systems to increase quality and efficiency so that practitioners, practices, and health care systems can appropriately manage a higher caseload. Theoretically, this goal could be accomplished through expanded use of PAs, NPs, and CNMs or interdisciplinary teams of practitioners. Lloyd Michener discusses these new models of care in his commentary of this journal issue. Another trend which may increase the number of patients that practitioners can see in an ambulatory setting is use of hospitalists. Hospitalists free up community practitioners' time by assuming care of patients once they are admitted to hospitals. While these options are conceptually attractive, few large-scale system redesigns have led to major increases in productivity. Yet these models are worth further study. **Thus, one of the task force's priority recommendations was that North Carolina foundations fund and evaluate new models of care to improve quality and efficiency of existing practices. If effective, insurers and other payors should reimburse practitioners to support these models.**

Absent new models of care or improvements in the underlying health status of the state's population, North Carolina is likely to need a significant increase in the number of practitioners practicing in the state. The state must either increase the number of practitioners entering practice, decrease attrition, or both. (See Figure 1.) There are short-term and long-term strategies to address the practitioner shortage. Over the short term, the state can try to recruit more practitioners from other states to practice in North Carolina. However, as Tom Ricketts describes in his commentary, most other states also will be experiencing a physician shortage.[b,7] As a result, there will be increased competition in recruiting the limited number of physicians.

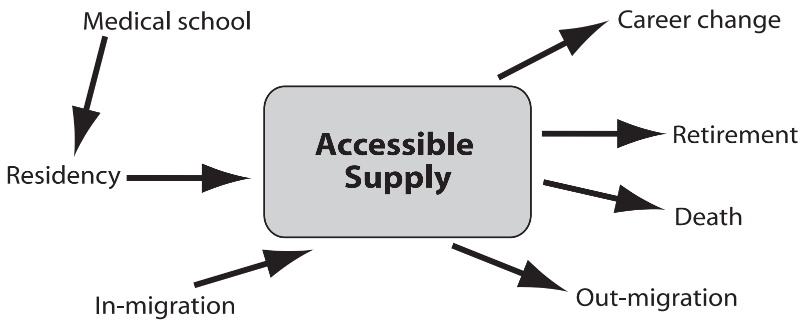
Over the long term, there is a need to educate and train more physicians by increasing undergraduate medical education and residency positions.[c,8] **The task force recommended that North Carolina increase the number of physicians trained in North**

---

[b] The following states have issued reports highlighting physician workforce shortages: Texas (2002), California (2004), Mississippi (2004), Wisconsin (2004), Arizona (2005), Georgia (2005), Kentucky (2005), Massachusetts (2005), Michigan (2005), and Oregon (2005).

[c] The Association of American Medical Colleges recently recommended US medical schools increase the number of undergraduate medical students they enroll by 30% in order to meet the need for physicians in the future.

Figure 1.
Factors in Physician Supply



Carolina medical schools either by increasing enrollment on existing campuses, by creating a satellite campus, or by creating a new medical school. James McDeavitt and Kara King discuss the potential to expand the medical school class of UNC-CH through a satellite campus at Carolinas Health Care System in Charlotte, while Gary Bowers, Teck Penland, and Joseph Damore discuss the potential for creating a medical school expansion in Western North Carolina. Nevertheless, it is not sufficient to train new physicians if these physicians ultimately choose to practice in another state. Over the last 40 years, only 40% of students trained in North Carolina medical schools ended up practicing in-state.[9] Those who complete their training in a publicly-funded medical school with a mission to serve the state are more likely to practice in-state. (See Table 2.)

The task force also recommended that North Carolina medical schools expand enrollment and the priority recommendation suggested that state funding be targeted to medical schools that produce North Carolina physicians that fill the unmet health needs of the state's population. The task force also recommended the state expand the number of residency positions. Almost half (49%) of physicians who completed their residency in North Carolina over the last 40 years set up practice in-state. This percentage is even higher among residents who completed their residency at AHEC family practice programs: more than two thirds (67%) of these physicians remained in-state. Unfortunately, the federal government has frozen funding for new residency positions so any expansion would need to be supported with state funds. **The task force recommended that the General Assembly appropriate money to support 100 new residency positions across the state targeted toward the high priority specialty areas of primary care, general surgery, psychiatry, and other types of specialties experiencing shortages as well as to support programs designed to graduate physicians likely to settle in rural or other underserved areas of the state.**

North Carolina also needs to train more PAs, NPs, and CNMs to meet the state's health care needs. Justine Strand, Nancy Short, and Elizabeth Korb discuss the important role of PAs, NPs, and CNMs in meeting the health care needs of the state's population. Expanding the number of PAs, NPs, and CNMs is a less expensive option and yields more immediate results than increasing the number of physicians. Unlike medical schools, which typically require 4 years of training and 3-year, postgraduate residency programs, NPs, PAs, and CNMs can complete their education and training within 2 to 3 years after completing their undergraduate degrees. In North Carolina, the PA, NP, and CNM schools collectively graduate approximately the same number of practitioners as do the medical schools. **Along with increasing medical school enrollment, the task force recommended that North Carolina health professional schools increase enrollment of PAs, NPs, and CNMs, but that state funding be tied to those schools that produce practitioners who meet the health care needs of the state.**

Table 2
North Carolina Medical School Enrollment and Graduates Practicing in the State

	2004-2005 Academic Year			
School	Total Enrollment	New Entering Students	% New Students In-State	% Graduates Practicing in NC*
Brody School of Medicine, East Carolina University	290	72	100%	59%
Duke University School of Medicine	467	101	20%	24%
University of North Carolina School of Medicine	649	160	85%	49%
Wake Forest University School of Medicine	427	108	40%	39%

Source: American Medical Association. Medical schools in the United States. *JAMA*. Medical Education Issue. September 7, 2005;294(9):1119-1127; NC Health Professions Data System. September 2006.

There are many challenges to creating new schools or expanding existing schools including the costs of expansion, limited classroom space or lab space in existing schools, and limited faculty (depending on the type of program). Lack of clinical training sites is a challenge for existing programs and would be exacerbated if new programs were created or existing programs expanded. As Tom Bacon discusses in his commentary, there are challenges to creating new clinical training sites.

Further, clinical training sites often impact where health professional students choose to practice. Thus, there have been attempts to move clinical rotations out of academic health centers and hospitals and into communities, particularly underserved communities, in an effort to enhance clinical training and to encourage practitioners to set up practice in those locations. **The task force recommended that the General Assembly provide additional funding to the North Carolina Area Health Education Centers Program to support the development of additional clinical training sites necessary for the training of additional health professional students.**

The task force also recommended other options to increase overall practitioner supply including expanded marketing efforts to recruit out-of-state practitioners to North Carolina, maintaining and/or improving the practice environment for health care practitioners, and expanding the supply of trained practice managers to help physicians and other health professionals maintain financially viable practices. To continue examinations of impending practitioner shortages and develop workable strategies to expand the health professional workforce, **the task force recommended that the General Assembly appropriate funding to support and expand the current Health Professions Data System, housed within the Cecil G. Sheps Center for Health Services Research at the University of North Carolina at Chapel Hill, and create an ongoing Health Workforce Policy Board.**

Maldistribution

North Carolina's practitioner-to-population ratio is similar to the rest of the country; the ratio of physicians per 10 000 population in North Carolina reached 20.7 in 2005. This ratio is lower than the US average of 22.77 per 10 000 but is consistent with ratios for states that border North Carolina.[10] However, this statewide average masks some stark differences in practitioner supply. Some areas of North Carolina have an abundance of health professionals while others lack sufficient practitioners, forcing individuals to travel long distances for health care. Shortages typically exist in rural areas, but there also are pockets of low practitioner supply in low-income areas of larger cities.

The Bureau of Health Professions in the US Department of Health and Human Services has designated certain communities, population groups, or medical facilities as health professional shortage areas (HPSAs).[11] Certain counties, or parts thereof, are considered primary care HPSAs if they have more than 3500 people per primary care practitioner.[d] In 2005, 11 whole counties and parts of 40 additional counties in North Carolina were designated as HPSAs.

Some counties change their HPSA designation from one year to the next depending on growth in the population and whether the county gained or lost a physician. However, other counties are persistently considered HPSAs. The task force focused on areas of the state designated as HPSAs in 6 of the last 7 years or as "persistent health professional shortage areas" (PHPSAs). Eleven counties in North Carolina are considered whole-county PHPSAs and 27 counties are part-county or special population PHPSAs. (See Map 1.) In the last 5 years, more than half (55%) of the 38 PHPSAs experienced a decline in their primary care practitioner-to-population ratios. Whole-county PHPSAs are more likely to be rural and to be located in eastern North Carolina than non-PHPSAs and have a higher percent of the population living below the poverty line (15.2% for whole, 10.4% for non-PHPSAs).[12]

Populations with lower physician supply may be less able to address their health care needs in a timely manner. Not only does lack of practitioners have an impact on access to health services, it also can have an adverse impact on the economic health of a community. In his commentary, Aaron McKethan discusses the importance of having a stable health professional workforce when recruiting industries into rural areas. The current and future health professional shortage has implications that go beyond the specific health care needs of individuals.

Historically, North Carolina's Office of Rural Health was considered a national leader in recruiting physicians and other practitioners into rural areas.[13] Torlen Wade, director of the North Carolina Office of Rural Health and Community Care (ORHCC), Maggie Sauer, director of the North Carolina Community Practitioner Program, and Christine Kushner discuss the state's past experience recruiting practitioners into rural and medically underserved areas of the state. North Carolina made significant headway in addressing practitioner maldistribution problems in the 1980s and 1990s; however, improvements have stagnated, and now maldistribution problems appear to be getting worse.

Practitioners choose their location of practice based on a number of factors including economic potential, lifestyle, family preference, and training location. Provider practices must be financially sustainable, which is a challenge in rural areas that lack population density and in low-income communities where a higher proportion of people lack health insurance. Financial incentives and practice support (eg, information technologies) will increase the financial viability of practices treating historically underserved areas and populations. **To address these maldistribution problems, the task force recommended that the General Assembly appropriate additional funding to ORHCC to recruit practitioners and provide them with loan repayment or other financial**

---

[d] Areas that are designated as HPSAs must define and justify a rational service area for the delivery of health services (often a county), have a sufficiently low practitioner-to-population ratio, and show evidence that nearby resources are overutilized, too distant, or otherwise inaccessible. For primary care professionals, areas with more than 3500 people per primary care provider can qualify as HPSAs, although the standard is lower for certain "high need" areas. An area is designated as "high need" if the area has more than 100 births per year per 1000 women aged 15-44, has more than 20 infant deaths per 1000 live births, or has more than 20% of the population (or of all households) with incomes below the poverty level.

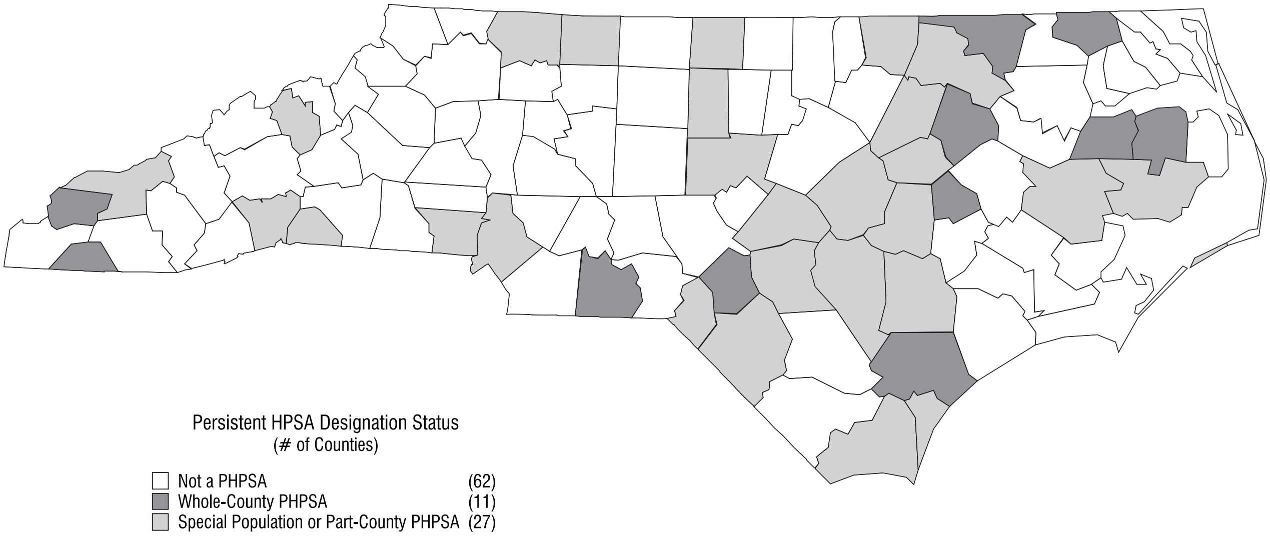
Persistent Health Professional Shortage Areas* (PHPSAs) in North Carolina, 2005



Source: Area Resource File, HRSA, DHHS, 2005; Bureau of Health Professions, Shortage Designation Branch, 2005.

Persistent HPSAs are those designated as HPSA by the Health Resources and Services Administration (HRSA) from 1999 to 2005 or in 6 of the last 7 releases of HPSA definition.

incentives to encourage them to establish practice in underserved areas of the state. In addition, the task force recommended that North Carolina foundations fund regional, multi-county demonstrations to test new models of care to serve patients in rural and urban underserved areas.

Primary Care and Specialty Shortages

Examining overall supply of physicians, PAs, NPs, and CNMs can mask shortages in particular specialty areas and overlook the importance of having an appropriate mix of practitioners. The task force was unable to examine every medical specialty. Instead, the task force focused on the supply of primary care practitioners, practitioners who deliver babies, general surgeons, and psychiatrists. As Erin Fraher, director of the North Carolina Health Professions Data System, discusses in her commentary, North Carolina currently has an adequate supply of most practitioner types when compared to national or regional averages. However, practitioner types are not well distributed throughout the state, and North Carolina is likely to experience severe shortages among many of these practitioner types in the future.

Primary care: Primary care practitioners (PCPs) serve as the entry point into the health care system for most patients.[e] They provide preventive, primary, and acute medical services that can address most of a person's health care needs.[14] Recent evidence suggests fewer practitioners, including allopathic trained physicians, PAs, and NPs, are going into primary care than in the past. For example, between 1997 and 2005, the number of medical student graduates choosing primary care residencies dropped 50%.[15] Instead, students are moving into specialty areas. PAs and NPs also are less likely to practice primary care today than 4 years ago.[16] As noted in the maldistribution section, primary care practitioners are not well distributed throughout the state.

One reason for declining interest in primary care is that primary care practitioners experience increased demands with lower overall reimbursement. The number of and need for recommended preventive and chronic care treatment services has increased to the point that it is impossible for physicians to provide all recommended care to their patient mix in a regular workday.[15] Although the scope of care has increased, primary care practitioner reimbursement has decreased in inflation-adjusted dollars. Between 1995 and 2003, inflation-adjusted salaries decreased 7.1% for all physicians but 10.2% for primary care physicians.[17] Primary care practitioners are paid less for their services than are specialists. Insurers generally pay more for procedures and less for cognitive and diagnostic skills, which make up a greater proportion of the clinical work of primary care practitioners. (See Chart 2.)

Primary care is very important for preventing disease, increasing quality of care, and reducing costs. Barbara Starfield and Leiyu Shi discuss the influence of primary care practitioner supply on community health. Evidence indicates that unnecessary hospitalization rates are higher in communities with limited

access to primary care practitioners. Studies also show quality of care is higher and expenditures are lower in states with higher generalist-to-population ratios compared to those with higher specialist-to-population ratios.[15] **To encourage more practitioners to become primary care practitioners, the task force recommended that public and private insurers enhance payments to primary care practitioners to recognize the value of their diagnostic and cognitive skills. Specifically, primary care practitioners should be provided financial incentives to create a primary care home where patients can obtain preventive health services, chronic disease management, and case management.**

Practitioners who deliver babies: Ensuring women have continuous and early prenatal care is critical to the well-being of the infant and mother. Women need access to physicians and other clinicians who are trained to deliver babies and who can address any complications that might arise during delivery. North Carolina appears to have an adequate number of practitioners who offer prenatal care and delivery statewide, but the statewide average masks significant practitioner shortages in certain parts of the state. Currently 13 counties in the state have no physicians reporting a practice location that provides prenatal care services. Eight of these counties have no practitioners (physician, PA, NP, or CNM) who report providing prenatal care on their licensure files. Community members in these counties have access to some prenatal care through their local health departments, but delivery services are not available in these counties. Even in counties with prenatal practitioners, there is wide variation in the ratio of practitioners to women of childbearing age.

There is even more of a maldistribution problem of physicians who deliver babies. In 2004, there were 19 counties without physicians who reported delivering babies; 12 of these counties had not had a physician deliver a baby in the prior 5 years. More than one half of all North Carolina counties had either a decline in the ratio of physicians delivering babies to women of childbearing years between 2000 and 2004 (40 counties) or no physicians providing deliveries in either 2000 and 2004 (12 counties). **To address the shortage of practitioners delivering babies in underserved areas, the task force recommended that the General Assembly appropriate funding to help subsidize the malpractice premiums for physicians and CNMs who provide delivery services in medically underserved areas of the state.**

General surgeons: North Carolina currently has more general surgeons per 10 000 population (0.75) than the nation as a whole (0.60) or the south (0.64). However, trends indicate fewer medical graduates are choosing to practice in general surgery. For most entering surgeons, progressive specialization is narrowing their scope of practice. In addition, supply of general surgeons varies drastically across the state. In 2005, North Carolina had 22 counties with no surgeons while another 35 counties had below the state average of 0.62 general surgeons to 10 000 population. The majority of the counties with no surgeons or fewer than 0.62 surgeons per 10 000 population are found in the eastern and western parts of the state. As Larry Chewning and Jeff Spade discuss in their commentary, general surgeons are critical to the viability of small rural hospitals. **The task force recommended that medical schools be incentivized to produce the type of physicians (eg, physicians who deliver babies, general surgeons) needed to meet the state's health care needs. In addition, special consideration should be given to funding a track in an existing residency program that focuses on training general surgeons for rural practice. The task force also recommended that some of the funding to the ORHCC be used to provide incentives to general surgeons who practice in underserved areas.**

Psychiatrists: Nationally, almost one third of nonelderly adults and a sizeable number of children experience a mental disorder in any given year.[18] Many types of health professionals treat mental health disorders including, but not limited to, psychiatrists, psychologists, primary care practitioners, social workers, and clinical nurse specialists. While these practitioners are all trained to provide psychotherapy, some people need further consultations and treatment by psychiatrists or other physicians who can prescribe medication therapy. Aside from primary care practitioners, psychiatrists are among the lowest paid of physician specialties (Chart 2) which may discourage some physicians from choosing to specialize in this field.

As with other types of health care professionals, the statewide ratio of psychiatrists-to-population masks severe maldistribution problems. In 2004, there were 17 counties with no psychiatrists and another 27 counties with ratios low enough (0.33 or below) to be designated as mental health HPSAs.[19] Psychiatrists are most densely located close to the state's 4 mental health hospitals, in counties with major medical centers, and in large metropolitan areas. In general, psychiatrists are less likely than all other physicians to locate in rural areas or in HPSAs.

North Carolina's mental health reform has also impacted the provision of care to mental health patients in the public sector. Mental health services in North Carolina are coordinated by local management entities (LMEs). Between 2003 and 2005, the number of LME psychiatrists per capita fell 16%. Per capita losses were higher in rural areas (20%) compared to urban areas (14%). Small-population LMEs experienced an even larger decrease (44%) in the number of psychiatrists per capita.[20] In the absence of psychiatrists, primary care practitioners often are faced with the responsibility of diagnosing and managing the care of people with mental illness. However, 7 of the 17 counties with no psychiatrists are also whole-county primary care HPSAs.

To address the shortage of psychiatrists, the task force recommended that the General Assembly and North Carolina Division of Mental Health, Developmental Disabilities and Substance Abuse Services provide funding to establish new models of care to serve public patients in rural and underserved areas. In addition, public and private insurers should reimburse psychiatrists to consult with primary care practitioners and other clinicians through face-to-face consultations or telemedicine. John Frank, Director of the Kate B. Reynolds Charitable Trust, discusses one such model, ICare, in the Philanthropy Profile of this journal issue.

Underrepresentation of Minorities in Health Professions

Minority populations comprise 30% of North Carolina's population, but they account for only 15% of physicians, 12% of PAs, and 10% of NPs in the state.[21] African Americans, American Indians, and Hispanics are particularly underrepresented in health professions. (See Chart 3.)

When given the option, people are more likely to choose a practitioner that has a similar racial and ethnic background.[22] Concordance of practitioner and patient race or ethnicity might be particularly important for members of minority populations who, because of real and perceived past discriminatory treatment, have lower levels of trust in practitioners of other racial groups.[23]

Underrepresented minority practitioners also are more likely to practice in underserved areas than are white practitioners.[f] Similarly, health care practitioners from underrepresented minority ethnic and racial groups are more likely to serve patients of their own ethnicity or race and patients with poor health.[24,25,26] This practice is very important because African Americans, American Indians, and Hispanics are more likely to lack health insurance, suffer from certain chronic health conditions, and report access barriers to health care.[27]

In order to increase the supply of underrepresented minorities in the professions, the task force recommended that North Carolina medical and health professional schools develop new strategies to increase the number of racial and ethnic minorities admitted and trained in North Carolina. For example, the state could expand minority scholarship programs or develop new or satellite health professional schools in historically minority public or private colleges or universities. Schools could modify their admission policies to facilitate the enrollment of minority applicants or hire faculty and chairs who are members of underrepresented minorities in order to reduce the professional isolation of minority health professional students. **The task force also recommended that the state evaluate existing minority health professional pipeline programs and tie future state funding to the programs that are most effective in increasing underrepresented minorities in the health professions.**

More bilingual and bicultural practitioners are needed to reduce language and cultural barriers to health care services. In North Carolina, there are approximately 150 000 Spanish-speaking residents who do not speak English well or do not speak English at all.[28] Studies show people with limited English proficiency are more likely to report being in fair or poor health and are more likely to defer needed medical care, miss follow-up appointments, and experience drug complications.[29,30] Bilingual and bicultural practitioners can help address language and cultural barriers for the growing Latino and immigrant populations. **The task force recommended that medical and health professional schools recruit and admit more bilingual and bicultural students into their programs and encourage others to take Spanish medical language courses as part of their training.**

Conclusion

Access to health care practitioners including physicians, PAs, NPs, and CNMs is very important to the health of individuals and populations. However, North Carolina is likely to face challenges meeting the population's demands for care over the next 25 years. Although the potential shortfall is considerable, the state has a number of policies that could be used to reduce

---

[f] Underrepresented minority practitioners are 3 times more likely than white practitioners to serve in whole-county PHPSAs (12% for minority practitioners compared to 4% for white practitioners) and are more likely to serve in part-county PHSPAs (42% for minorities and 34% for whites).

this deficit. The state should identify options to improve the quality and productivity of existing practices so that health professionals can provide high-quality health services to more North Carolinians. The state should concurrently examine options to develop new models of care that would reduce the need for health care practitioners and/or expand the supply of physicians, PAs, NPs, and CNMs. North Carolina needs to engage in multiple strategies, simultaneously, to increase the balance of supply with needs. If new medical school slots are created without new residency slots, then in-state retention of the expanded number of medical school graduates will not be realized because many will need to leave the state for residency and are not likely to return. Similarly, initiatives to increase awareness of health careers among rural and minority middle and high school students will have little impact without also expanding available enrichment programs to help students overcome the hurdles to being accepted into medical school. North Carolina also should explore ways to recruit physicians and other practitioners into North Carolina and to encourage existing practitioners to remain in practice in North Carolina. In short, many of the policy options are interdependent. Success requires adoption of many complementary strategies.

North Carolina need not implement all the practitioner supply strategies in order to maintain the current practitioner-to-population ratio. For example, the state does not need to increase the number of physicians, PAs, NPs, and CNMs each by 30% in order to maintain current ratios. To some extent, these recommendations are alternate strategies that depend, in part, on when the strategies are implemented. If implemented *today*, the state could maintain its current ratio over the next 25 years by:

1. Increasing yearly educational production of physicians by 20%, *or*
2. Increasing production of PAs, NPs, and CNMs by over 30%, *or*
3. Increasing in-migration to produce a net increase of physicians by 15%, *or*
4. Increasing capacity of the health system to manage effectively the health of more North Carolinians or improve the health of North Carolinians to reduce the need for health services by 15%.

The time to act is now. The longer the state waits to implement the recommended strategies, the greater the number of practitioners it will need to produce on a yearly basis to address anticipated practitioner shortages. The state must take the necessary steps to ensure we have the right mix of practitioners in the right locations to meet current as well as future health care needs. **NCMJ**

COMMENTARY

Reinventing the Wheel, Yet Again!

E. Harvey Estes Jr., MD

In 1966, I became the chair of a new department at Duke University created to address the growing shortage of primary care physicians in North Carolina and the nation. Computers, physician assistants, and new models of care were among the "solutions" that emerged from this effort. In 1978, I chaired a major task force of the Institute of Medicine of the National Academies to "formulate a cohesive health manpower policy for assuring the accessibility and appropriateness of primary health delivery." Reduction in payment disparities between primary care physicians and other physicians and payment to physicians for health education and preventive services were among the recommendations. Preferential selection of medical students likely to go into primary care, clinical experience in primary care settings, and training of all medical students in a team approach were some of the other recommendations.

Forty years later, we are facing the same problems of insufficient numbers of primary care physicians and maldistribution of practitioners, plus an added shortage of other essential medical specialists and a projected shortage of all medical practitioners. As can be seen in the North Carolina Institute of Medicine Primary Care and Specialty Supply Task Force report, we are proposing many of the same solutions. Why have we not solved these problems? Why were many of these recommendations not implemented?

The health care system is a ponderous, complex, and expensive system with many parts and no single controlling authority. Each of the component parts has decades of experience and investment in the *status quo* and resists change. The system clearly responds to new infusions of money, but there has been little investment in ordinary medical care and the infrastructure for its delivery. At the same time, there has been a huge investment in science and technology. Each advance brings forth a call for even more investment and the promise of even more spectacular new advances, but at an ever increasing cost. New specialized treatment centers and new "dreaded disease" research centers have more appeal to citizens at large and to legislatures than new investments in primary care or other shortage specialties.

> *"New specialized treatment centers and new "dreaded disease" research centers have more appeal to citizens at large and to legislatures than new investments in primary care or other shortage specialties."*

The disparity in available health care between larger cities and small communities and rural areas seems greater now than 40 years ago, in spite of a modest increase in per capita supply of physicians. At that time, generalist physicians and doctors delivering babies were available in most small communities, and small hospitals were still viable. In the interval, general internists and pediatricians have joined general practitioners and family doctors on the endangered list, and small hospitals are disappearing at an increasing rate. Large hospitals and technical specialties appear to thrive, but the expense of possessing and maintaining the latest technology and keeping up with similar enterprises is taxing their financial capacity.

No logical person would argue that every North Carolina town should have the same medical facilities and personnel as the major medical centers. But the fact is that even in our most privileged communities, well-insured citizens now have difficulty obtaining the personal medical advice and care that was generally available 40 years ago. This disparity is compounded when the community is hours away from a medical center, is economically

E. Harvey Estes Jr., MD, is chairman emeritus of the North Carolina Institute of Medicine Board of Directors, professor emeritus of the Department of Community and Family Medicine at Duke University, and chair of the North Carolina Institute of Medicine Task Force on Primary Care and Specialty Supply. He can be reached at eestes@nc.rr.com or 3542 Hamstead Court, Durham, NC 27707.

distressed as a result of recent plant closings, and has no major shopping centers or desirable social amenities.

The recommendations in the NC IOM report are aimed at increasing the overall number of medical practitioners, but they are principally directed at those areas and communities that are at the bottom of the pile in practitioner supply. They call for both increased production and measures to move practitioners into shortage areas and to increase the number of minority practitioners. Many of the recommendations are remarkably similar to those made decades ago. Why should we think that these recommendations will work now, when they have not solved the problem in the past?

Perhaps the fact that the problems are worse will convince decision makers in the health care system to work harder at solutions and to make the needed changes. More and more ordinary citizens and recipients of health care are unhappy with our system. Business and industry leaders are increasingly alarmed with the cost of health care and the fact that we are not achieving the level of benefit seen in other countries with less expensive systems. The lack of care available in some areas of our state, combined with the financial distress of poor counties that must pay their share of Medicaid costs, leads to calls for adjustments in the distribution of state tax dollars.

The unpleasant predictions of this new task force may not seem very alarming to most people or to most health professionals. A shortage of medical practitioners in 2030 may seem to be a distant and even unlikely possibility, in spite of the sound analyses upon which this prediction is based. To some, asking the legislature, philanthropic organizations, and the public to support this set of recommendations will seem foolish, especially to those who fear bigger government roles, higher taxes, and intrusions into personal and professional lives. Why should legislators risk their political future by directing new money to increase the supply of medical practitioners several decades in the future? Why should leaders of academic medical centers retool to recruit a new type of student, change curricula, increase enrollment, and take other measures when this course can be predicted to divert resources and attention from the current highly rewarding path of research and the development of technical superiority in highly specific diagnostic and treatment methods?

The first task is to convince citizens of the state that the predictions contained in the report are valid and that change is needed. Most will turn to physicians, other health care leaders, and government experts for confirmation. This report is the first step in this process. It must receive wide attention, and the serious consequences of inaction must be recognized. Community leaders must have access to the details and understand that our state must compete with our neighbor states and other parts of the country, which face the same problems and have not previously worked as hard as North Carolina to recruit new practitioners. We must accept that change is necessary and be willing to work unselfishly to achieve it.

Even with widespread acceptance of the impending shortage of practitioners, can we be assured that the needed changes will occur? The leaders of our current academic health centers must play a huge role in achieving the objectives outlined in the report. They face a daunting task. How can they recruit more students from minorities and from small North Carolina communities (those most likely to settle in small towns) without curtailing those activities in their current mix that produce a large part of the financial rewards supporting their work? How can they convince their current faculty, largely engaged in research and cutting edge practice, that these new students have equally important life goals which must be nurtured and respected? How can they be convinced that training family doctors for rural towns is equal in importance to training potential Nobel prize winners and achieving a higher score in the *US News and World Report* annual ranking? Financial incentives and added attention to their role in achieving these new goals must be among their rewards.

One of the most important ways to improve the supply of needed specialists is to reduce the current payment disparities between specialties. It is no coincidence that the specialty groups in short supply are those in the bottom tier of professional incomes. An anesthesiologist earns 2 or 3 times as much as a family physician, yet has a more predictable schedule and personal life. It is not hard to see why career choices are made as they are today. This could be corrected by increasing reimbursement for low paying specialties, by reducing the pay of higher paying specialties, or by a mixture of both. Payment of physician services is largely determined at a federal level through the Medicare payment scale but North Carolina legislators and administrators have an important role through their influence in the NC Medicaid Program and the State Employees Health Plan.

These and other key objectives can only be achieved with the approval and support of the North Carolina General Assembly. It has an absolutely critical role in assuring that we have the practitioners we need in 2020 and 2030. This group must work in a bipartisan fashion and show great political courage because adopting these recommendations will face opposition from powerful groups including some that will receive less as a result of reallocations of funds. The NC General Assembly must recognize that good medical care is a necessary component in the restoration of prosperity in areas of the state that have been hardest hit by the decline of tobacco as a crop and the relocation of manufacturing to other countries. Legislators must see that the greatest potential for economic recovery lies in achieving productive employment for the young people in these communities. They must see that there is no better solution to this problem than the creation of higher level health careers and investing these careers in health care in their own home towns.

Other groups critical to implementing the recommendations of the current report are the professional groups representing health care providers such as physicians, nurses, and hospitals. They too must recognize that investments to enhance the prosperity of low-wealth counties eventually enhance the prosperity of the state as a whole. Some who have prospered from previous investments may see this as a setback for their own prosperity, but, in the longer time frame, these groups will also benefit from the more equitable distribution of both health and prosperity in the entire state.

It is also important to recognize that the recommendations in the NC IOM report involve more than the health care sector. Our educators and educational institutions are heavily involved. Identification of young people who have the intellectual and personal skills to become caregivers, guiding them into careers without limitations as to level, and equipping them to assume professional roles in needed areas of our state, is a major objective of this report. This investment has profound implications for our state which state leaders must recognize and support.

It is my sincere hope that the North Carolina Institute of Medicine Primary Care and Specialty Supply Task Force report will produce a more profound and long-lasting effect than those activities cited at the beginning of this article. I see it as blazing a trail for a more prosperous and optimistic North Carolina, with more equitable opportunities for young people, with more equitable health care, and an even better state in which to live. I also hope that those who must clear the trail and make it a well established roadway to progress will share this vision. **NCMJ**

New Models of Care:

Building Medical Homes in Empowered Communities

J. Lloyd Michener, MD

Quality health care has long been viewed as a relationship between a competent and compassionate physician and a patient who seeks advice and guidance.[1] Unfortunately, for a growing number of North Carolinians such relationships are increasingly hard to find, and the health outcomes, even in the best of circumstances, are often less than ideal.[2]

There is no question that having an adequate number of physicians is essential to ensuring health, but it is also increasingly clear that doctors alone are not sufficient. This is not because individual physicians have become less important, but rather because there is not enough time for individual physicians to provide everything a patient needs; the challenges our patients face today require new models of care that build on the work of physicians and extend out to involve entire communities.

The growing rates of chronic disease, rising numbers of uninsured, unrelenting racial disparities, and soaring obesity rates are problems for which physicians have essential roles but which require multidisciplinary teams across multiple locations to provide the continuum of needed services. From the public health department dietitian or agricultural extension agent encouraging healthy eating and exercise habits to the church members who are providing health ministries about chronic illness, every part of the community has a role to play.

> *"...the challenges our patients face today require new models of care that build on the work of physicians and extend out to involve entire communities."*

The traditional focus on individual patients in the office and hospital, which is necessary to deal with acute care needs, has often obscured the need for physicians to collaborate and partner with community groups who can help institute the larger changes needed to confront the growth of chronic disease. This new model seeks such collaboration and resolves the growing time demands on practicing physicians by sharing tasks—in particular, those dealing with prevention and education—with members of the office team and other groups within the local community. In doing so, this model extends the efforts of each physician.

The Time Trap

Primary care physicians today face a scarcity of time due to our exceptional fortune in finding effective therapies to prevent or treat illness in primary care settings. As the number of prevention and treatment guidelines has increased, so has the burden of following those guidelines. In our own research at Duke University, we found that it takes an average of 7.4 hours a day for a physician to deliver recommended prevention messages and services to an average panel of patients. To deliver all recommended care for patients with chronic conditions takes an additional 10.6 hours a day.[3]

A vicious cycle ensues. There is not enough time for individual doctors to properly encourage prevention and, too often, this lack of prevention leads to the onset of chronic conditions. A lack of good chronic disease management leads to increased acute care visits that are more painful for the patient, difficult for the physician, and costly to the system. The increased level of acute care cases (and the higher reimbursement rates for

J. Lloyd Michener, MD, is professor and chair of the Department of Community and Family Medicine and director of the Duke Center of Community Research, at Duke University Medical Center. He can be reached at miche001@mc.duke.edu or Box 2914 Medical Center, Durham, NC 27710.

procedures associated with them) encourages physicians to choose specialties other than primary care.

The number of medical students attracted to primary care has been steadily declining in recent years in part because of the inflexible demands on their time. Students, as well as currently practicing doctors, care about having time for their personal lives. Among physicians under the age of 50, time for family is cited as very important by 69%—more than any other factor. Of physicians under 50, 80% would reduce their hours if they could.[4]

This cycle seemingly indicates that primary care is a Sisyphean effort—only doomed to failure. The time needed is impossible for one physician who holds her or himself accountable for delivering all needed care. However, it is quite possible for an interdisciplinary team of physicians, nurse practitioners, physician assistants, nurses, health educators, social workers, and other professionals assisted by technology who work with each other and in tandem with their community.

Interdisciplinary Teamwork

Primary care has been traditionally centered on the role of the physician with subordinate roles for all other members of the health care team—including the patient. But as the demands and expectations on practices grow, the role of the physician needs to shift. With medical practice increasingly faced with the challenges of managing chronic disease, the role of the nurse practitioner, physician assistant, nurse, health educator, social worker, psychologist, and dietitian become more important. And with so many of the underlying cases of chronic disease rooted in personal behaviors, the role of community health and nonhealth agencies in supporting long-term behavior change becomes as important as the work done in the office.

The idea of interdisciplinary teams is not new. Literature abounds with examples of successful interdisciplinary teamwork in all fields of medicine. In primary care practices across the nation, private and group practice physicians have invested in training their office staff, physician assistants, nurse practitioners, and nurses in office systems that rely on technology to seamlessly capture patient information, ease scheduling and billing, consistently provide patient education, and ensure follow-up.[5,6,7,8] Physicians based solely in the hospital managing inpatient care are also helping to streamline care and free up doctors in outpatient settings. What is different in all of these new models is the shift from the physician being the center of the team, coordinating all of the care, to the patient being at the center of the team with the physician playing a key leadership role.

Here at Duke, we are working to change our primary care offices systemwide. By shifting staffing, we are able to better support our many patients with chronic illness. We are adding dietitians, social workers, physician assistants, and nurse practitioners to enhance the services of our clinics and make appointments and care more available. Developing new electronic medical records helps our clinics coordinate information across offices and hospitals.

The transition from physicians operating as independent practitioners to their participation in and sharing of tasks and responsibilities within interdisciplinary teams is a significant challenge by itself. But teamwork alone is not the answer to improving primary care if it means that care begins only after patients choose to come to us for help. Teamwork must be accompanied by delivery systems that are accessible to those we seek to serve. Although the science of prevention and chronic disease management has grown stronger, racial and ethnic minorities and the poor have not benefited from these advancements as much as other groups. For example, minorities and those with lower incomes are more likely to be at risk for cancers and chronic diseases and less likely to be screened or treated effectively. Waiting for people to be seen in the medical office is not sufficient. For too many, the office is too far, too threatening, or too expensive.

Empowered Communities

We also need to be effective not only in forming teams downstream with specialists, hospitalists, and others involved in the care of our patients but also upstream with organizations and leaders in our communities that have the capabilities to support the difficult lifestyle changes that our patients increasingly need.

Careful coordination of resources at all levels on the continuum —upstream and downstream—is the keystone to the overall health of a community. Data from the United Health Foundation, which ranks health status in each state, find that offering and rendering more services does not always equate to better overall health care and, in fact, in some states greater use of services goes hand-in-hand with poorer quality and lower satisfaction.[8]

Instead, we need to think creatively about how and where to deliver health care services and information in a way that centers on the patient. For example, care does not always need to be provided in the doctor's office. Community-based teams of health educators and social workers can ably assist patients in caring for their illnesses, as has been demonstrated in communities across the state by Community Care of North Carolina.[9,10] Senior center-based physician assistants using laptops with electronic medical records and backed up by physicians, can dramatically improve outcomes for senior citizens—and decrease inpatient admissions as well—even when these patients already have primary care physicians.[11]

The effectiveness of the office encounter is greatly enhanced when it works in tandem with communities. At Duke, we are working with neighborhoods across the state to find ways to reduce the risk of chronic disease from obesity and inactivity, building on the strengths and resources of not only doctors but also schools, health departments, and community agencies. Through the Just for Us program, in-home chronic disease management visits are provided to over 350 Durham seniors living in 10 low-income apartment complexes.[12] The LATCH program connects thousands of Latino immigrants in Durham to health care services and culturally and linguistically appropriate health education classes. We operate 4 school-based clinics and 2 neighborhood clinics offering easier access to services for hard-to-reach populations. Community health isn't just a concept. It's a reality that improves the health of thousands of North Carolina residents every day.

These innovations are not ideas that can be instantaneously dropped into place. A rural county with rampant poverty and a dearth of providers or a wealthier suburban area with higher rates of insurance but care that isn't integrated will require different solutions.[13] Diverse communities require diverse solutions, but the common thread to each is teamwork and new roles for all the members of the primary care team including the physician.

Preparing physicians for both teamwork and a focus on community-centered care requires new approaches at every level of education. In undergraduate and graduate medical education, students must be afforded opportunities to practice teamwork so they can appreciate the overlapping and complementary skills of different disciplines. And those who teach them must model that teamwork and interdisciplinary collaboration.

Communicating across disciplines is also a challenge and educators in programs for nurses, physicians, social workers, dietitians, physical therapists, nurse practitioners and physician assistants need to standardize how teamwork is conceptualized and taught. In real-world situations, this highly coordinated communication and collaboration among teams is facilitated by technology. Educational programs need to address teamwork and define explicit goals, methods, and outcomes so that graduates are competent to practice in this new environment.

As has been widely reported, Duke is restructuring our Family Medicine Residency program to better prepare family physicians for teamwork both upstream with the community, downstream with hospitalists and specialists, and horizontally within the office. Part of our effort to restructure the program is a shift in emphasis from the inpatient setting to the community. Hospitalization rates for primary care have dropped by almost 72% over the past decades[14] so it no longer makes sense to focus family medicine residencies in hospital settings. Instead, we should be training residents in the settings where needs are greatest and there is more opportunity to practice prevention and early intervention. In addition to moving where we train residents, we are changing how we train residents. We want to find ways to better instill teamwork with physician assistants, nurse practitioners, physical therapists, and other health professionals.

Put all of these pieces together and the result is a very different form of medical practice. It begins by asking the community what services it needs, provides an analysis of the areas for potential improvement in health status (and in North Carolina there are plenty of opportunities) and then seeks to provide those services in ways acceptable to those being served. The practice does not wait for a patient to come to the office with a problem; the practice is engaged with community groups, employers, schools, and health departments to identify ways in which it can help support needed services without duplicating them. It uses health educators to supplement the individual instruction in the office and to empower and educate patients to take control of their health and take on primary leadership roles in their care. It uses physician assistants and nurse practitioners in the community and in the office to provide care in settings and frequencies beyond what the most dedicated physician can provide.

To many old timers and small town physicians, this may not seem radical or even new. Those who trained in community-oriented primary care, and/or public health, or who have already evolved this community-integrated form of practice, are familiar with these concepts. But to mitigate, and eventually reverse, the decline of primary care, what once was an interest of a few now needs to become a core skill of all.

An obvious critique of all these ideas is, "How do you pay for it?" The financial challenges to primary care are well documented.[15,16] The reimbursement system is currently not equipped to encourage or sustain these types of innovations and to build the case for change requires evidence of success. So should we wait or should we try? Funding for innovation is difficult but not impossible. At Duke, we have used a mixture of grants, contracts, public and private insurance funding, and our own funds to create sustainable, community-oriented programs.[17] It has not been easy, but it is possible. It is the obligation of physicians, and especially academic physicians, to help find ways to improve the health of our citizens.

What if we succeed in redesigning care? Imagine that interest in primary care is rekindled by medical students who know they do not have to do it all, who are equipped with the knowledge, skills, and attitudes to not only be excellent clinicians but also excellent leaders, and who can effectively harness the power and spirit of teamwork to improve the health of their communities. Imagine empowered, informed populations that become leaders in managing their own health, instigating a culture of accountability, and improving access to and quality of care in their communities. Imagine that the racial and economic gaps in health care delivery narrow and evaporate, that the incidence of chronic disease is lowered, and that those who do live with chronic disease find their challenges eased. If we succeed in this effort to build and test new models that allow adequate time for prevention and disease management, we just might find a North Carolina with healthier people and happier and more productive doctors. **NCMJ**

COMMENTARY

Medical Practitioner Supply from a National Perspective

Thomas C. Ricketts III, PhD, MPH

Medical practitioners are the central asset of our health care system. As a society we have committed substantial resources to preparing skilled and effective professionals. We use public tax revenues and funds collected under the Medicare program to support their training. Our state and federal laws give them special privileges and freedoms to treat injuries and cure disease. For these reasons, the question of whether there are enough practitioners to meet the health care needs of our population is a public issue.

Medical care in the United States through much of the twentieth century had been the exclusive preserve of physicians. In 1950, the professional medical care supply for the nation could be described almost exclusively by the total number of allopathic physicians in active practice. There were alternative groups of practitioners but their numbers were small and they were not fully recognized as "doctors" in many states. At that time, most physicians were generalists practicing in small communities and larger cities and many rural parts of the country had no doctor. By 1960, the nation began to recognize there was a doctor shortage and that it was primarily affecting the generalists. By the late 1960s and into the 1970s, Congress took note and began to support the medical education of primary care practitioners and to encourage them to practice in less well served communities. Some of the programs developed included the National Health Service Corps (NHSC), which placed doctors in health professional shortage areas; Area Health Education Centers (AHEC), which trained doctors in rural settings; and a series of programs that came to be known under the generic term Title VII, which encouraged minorities to consider medical careers and promoted the development of family medicine and primary care training programs. In the 1980s, federal programs were introduced to support rural practice and training.

> *"...we are faced with the question of whether we have the right number and the right kinds of health care practitioners in the right places to meet our current health care requirements."*

Over the same time, states also recognized their role in expanding the supply of physicians and began the process of expanding the medical franchise to other professions. In the 1960s and 1970s, new medical schools were opened to train predominantly primary care physicians with an emphasis on rural practice. East Carolina University, East Tennessee State University, The University of South Carolina, and Eastern Virginia Medical School were all of this generation of new, primary care-oriented medical schools. The profession of physician assistants (PAs) was developed at Duke University and the University of Washington, and programs to train nurse practitioners (NPs) were opened. North Carolina graduated the first NPs who were soon working in the state's new rural health clinics (RHC), which were developed by the nation's first Office of Rural Health.[a]

These national and state efforts should have alleviated the problems of physician supply and distribution, but they have not. In 2007, we are still talking about an impending shortage of doctors, as well as nurses, and a need to reorganize the structure and financing of medical care to achieve an effective health care delivery system focused on the patient with primary care, or as

we now term it, the medical home, at the center of the system. One primary reason for this situation is the countervailing influence of the largest input into physician training—graduate medical education payments. Graduate medical education payments go to teaching hospitals through the Medicare and, to a lesser extent, Medicaid programs. They are combined with the physician component of the reimbursement structure of Medicare itself and tend to favor specialty medicine practiced in large cities.

The past 30 years have seen a diffusion of authority and privilege to other practitioners. Thus, we need to look beyond physicians to understand how many and what kinds of human resources are available to meet our health care demands and needs. Nurse practitioners, physician assistants, and certified nurse midwives have become important contributors to the equation that balances supply of practitioners to needs and demands for health care.

In this first decade of the 21st century, we are faced with the question of whether we have the right number and the right kinds of health care practitioners in the right places to meet our current health care requirements. This is due to a growing recognition that we have not invested in expanding the ways and means to prepare physicians in the United States while the population has grown and become proportionately older. We have expanded the number of new primary care clinicians we train—nurse practitioner and physician assistant programs have increased rapidly in recent years. For example, in 1990 there were 1000 students enrolled in PA programs; by 2005 that number grew to 4460. There were an estimated 140 000 nurse practitioners at work in the US in 2005, up from 104 000 in 2000. Despite that growth, these new clinicians will not allow us to meet growing requirements brought on by population growth, especially among older people, and to utilize the opportunities to cure and prevent disease fostered by technology changes.

A tightening in physician supply appeared during the period around 2000. Studies of consumer and practitioner behavior found patients waiting longer for appointments and physicians reporting inadequate time with their patients.[1] One promising development in the supply situation during this period was that physicians did work more often with nurse practitioners and physician assistants. In 1980, the ratio of first year medical students per 100 000 people in the US began a steady decline from 7.3 that year to 5.6 in 2005.[2] This trend in medical education reflects the

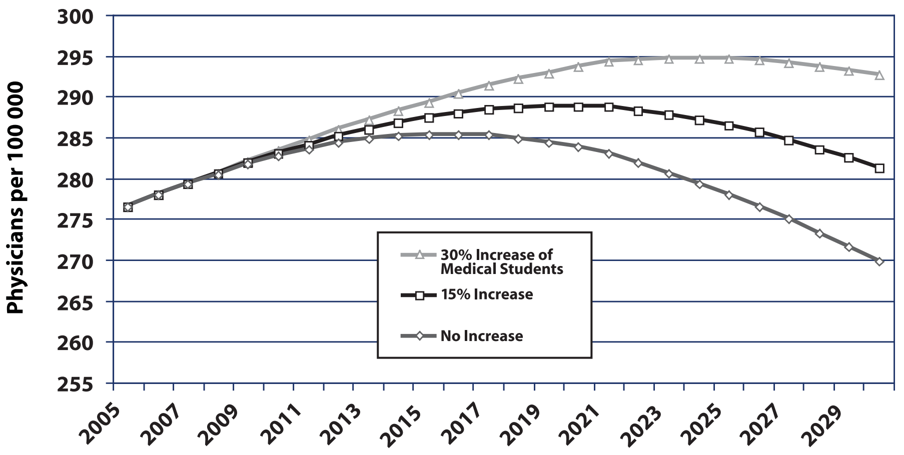
Figure 3.
Anticipated Trends in US Physician Supply



Source: AAMC Center for Workforce studies. Unpublished data, 2005.

policy decisions of earlier decades based upon incorrect predictions of a persisting physician surplus by 2000 and beyond.

In response to those predictions, there were practically no new allopathic medical schools established in the US between 1980 and 2000, and total medical school enrollment stayed steady at around 68 000 students. In 1985 there were 126 allopathic medical schools graduating 16 117 students. In 2006 there were 17 370 entering first year medical students in 125 allopathic medical schools, a very meager growth rate of 7% given the US population grew 25% in the same period. In 1985 there were 1560 osteopathic medical students graduating from 15 schools. In 2005 there were 2740 from 20 schools. The growth in the number of osteopathic medical schools has been rapid and will continue; six new schools opened since 2000 and 6 more are set to open. In comparison, there are only 2 new allopathic schools, both in Florida, that are on schedule to accept students. Osteopathic medical doctors are licensed equivalently in all of the states with osteopaths practicing more often in primary care and rural areas than allopathic physicians.

This slowdown in production has been filled in the recent past by international medical graduates (IMGs) coming into the US for their post graduate training or as immigrants. Slightly more than a quarter (25.3%) of all US physicians are IMGs. Half of these are US citizens or permanent residents.[3] Similarly, a quarter of all physicians in post-graduate training (residencies) are IMGs. Again, 45.6% of these are US citizens or permanent residents.[4] This trend may not persist because many other nations have also turned to our traditional sources of IMGs to bolster their medical practitioner supply. Furthermore, there are efforts to stem the importation of physicians into the developed countries to stop what has been termed "brain drain," which is seen as thwarting health status improvement in the developing world.[5]

The term "shortage" has evoked a good deal of controversy because many see the human resource problem of our health system as being a problem more of organization and financing than of numbers. However, there is more predictability in the demography of the workforce than there is in the policies that structure those professionals. The demographic trends point clearly toward a period of stress between what we expect from medical practitioners in terms of numbers and access to care and what can be delivered. **NCMJ**

COMMENTARY

Carolinas Medical Center Academic Infrastructure:
Implications for Physician Workforce Expansion

James T. McDeavitt, MD; Kara C. King, PhD

The city of Charlotte is known for being the second largest banking center in the country after New York. Its growth rate in recent years—in terms of new businesses, jobs, and population—has been nothing short of explosive. While such distinctions are positive, Charlotte has one other distinction that renders the city something of an anomaly in the world of medical education: it is one of the largest cities in the United States without a medical school.

> *"...Charlotte has one other distinction that renders the city something of an anomaly in the world of medical education: it is one of the largest cities in the United States without a medical school."*

However, this may change. Late in 2006, leaders of the University of North Carolina School of Medicine (UNC-SOM) approached Carolinas HealthCare System (CHS) with a proposal to develop a second UNC medical school campus in Charlotte. The plan as initially proposed by UNC would expand the existing class size by 50 students, from 160 to 210. The students would complete their first two years of training in Chapel Hill. To accommodate the expanded class during the last two years of training, a new campus would be developed in Charlotte in association with the Carolinas Medical Center (CMC).

One major advantage of the UNC proposal is that it builds on the existing academic infrastructure at CMC. Carolinas Medical Center, the 861-bed flagship facility of CHS, has a long history of involvement with education and research and serves as one of 5 state designated academic medical center teaching hospitals. The academic nature of the other 4 hospitals is probably more apparent because all are affiliated with highly visible universities (Duke University, Wake Forest University, The University of North Carolina at Chapel Hill, and East Carolina University). Nonetheless, CMC hosts residency and fellowship programs that serve over 200 medical school graduates at a given time. These students come from 32 states and represent 84 different US medical schools. In fact, CMC has hosted approximately 1000 medical students from UNC-SOM in the past 4 year years alone as part of the school's normal clinical rotations. As a result, the addition of a more formal program, should it occur, would be a fairly logical extension of current capabilities.

There is growing consensus that North Carolina, and the nation, face a significant physician shortage. The Association of American Medical Colleges, for example, recently called for a 30% increase in the number of trainees being produced by American medical schools over the next decade.[1] The North Carolina Institute of Medicine recommends similar sharp increases in training of physicians and other health care practitioners.[2] To better understand the benefits of a proposed collaboration between UNC-SOM and CHS, it is helpful to know something about the origins of CHS and its long history of involvement in both medical education and research.

Carolinas Medical Center traces its history, which is extensively documented,[3] to the years following the Civil War. In 1876, Charlotte Home and Hospital of St. Peter's Episcopal Church was established as the state's first civilian general hospital. The hospital grew and relocated several times during the next 50

James T. McDeavitt, MD, is senior vice president of Education and Research at Carolinas HealthCare System. He can be reached at James.McDeavitt@carolinashealthcare.org or PO Box 32861, Charlotte, NC 28232.

Kara C. King, PhD, is research project manager of Education and Research at Carolinas HealthCare System.

years, and the name eventually changed to St. Peter's Hospital.

By the 1930s, local physicians were pioneering a movement to construct a new public hospital that would be spacious enough to eventually accommodate more than 800 patients. Their goals at the time were to practice medicine to the best of their abilities, serve the community, including the indigent population, and reflect the superior training of Charlotte's physicians through high-quality care. Other key objectives were to take advantage of that same physician training to educate and train medical residents and encourage research.[3] After start-up proposals were thoroughly investigated and justified, a decision was made to construct a new facility known as Charlotte Memorial Hospital. Charlotte Memorial, which formally opened in 1940, was constructed utilizing land donated by St. Peter's Hospital.

The hospital grew steadily over the years and in 1990 was renamed Carolinas Medical Center to more accurately reflect the growth and regional presence of the institution. Today, CMC is the highest-volume provider of tertiary/quaternary medical services in the state. During this same period CMC's parent corporation, Carolinas HealthCare System, was beginning a period of steady regional expansion that involved acquiring, leasing, or managing hospitals and physician practices primarily in North Carolina but extending into South Carolina as well. Today CHS is the third largest public health care system in the United States behind only the University of California system and the nationwide system of Veterans Affairs hospitals.

Carolinas HealthCare System owns, leases, or manages 19 hospitals and has two more under development. Including 11 nursing homes, the system has nearly 4500 licensed beds. CHS has more than 150 delivery sites in all, including 75 Carolinas Physician Network medical practices, and employs approximately 29 000 part- and full-time employees. Carolinas Medical Center's commitment to graduate medical education took root at the time of its founding, in 1940 with the establishment of a variety of graduate training programs. Residency programs grew steadily during the 1960s, prompting CMC to begin recruiting full-time teaching faculty to supplement the strong support already being provided by private practitioners.

Physician residency programs are currently offered in 10 fields including emergency medicine, pediatric emergency medicine, family medicine, rural family medicine, internal medicine, obstetrics and gynecology, orthopedic surgery, pediatrics, physical medicine and rehabilitation, and general surgery. Fellowships are offered in medical toxicology, sports medicine, orthopedic trauma, vascular surgery, and thoracic surgery. In addition, CMC is actively considering the addition of fellowships in gastroenterology and pulmonary/critical care medicine. All programs are fully accredited by the Accreditation Council for Graduate Medical Education (ACGME) and are competitive in attracting the best qualified of the nation's medical students. After completion of residency, approximately 80% of CMC-trained physicians enter practice directly while 20% pursue fellowship training. Current plans for CHS to merge with NorthEast Medical Center in Cabarrus County will also complement the overall educational portfolio. When the merger is complete, it will result in the addition of an innovative family medicine training experience that incorporates a strong rural focus as a part of CHS's expanding commitment to general and graduate medial education.

Currently, CMC's residency program includes 212 physicians. Additionally, there are 193 faculty members (up from three dozen less than 25 years ago) teaching in the following primary care and subspecialty departments: pediatrics, family medicine, internal medicine, obstetrics and gynecology, emergency medicine, general surgery, physical medicine and rehabilitation, orthopedics, oral medicine, vascular surgery, thoracic surgery, and neurology. All faculty physicians at CMC are expected to make contributions in the 3 areas of clinical care, education, and research.
