## ACKNOWLEDGMENTS

I warmly acknowledge the guidance given me by my co-chairs Dr. Krause and Dr. Thacher. Dr. Krause consistently guided and supported me as I worked as her assistant, and she was also a source of encouragement in my professional and personal writings. Dr. Thacher has an uncanny knack for pushing me to achieve more and to learn more simultaneously. I'm proud of how this paper has grown under her guidance.

I would also like to thank my final chairperson, Dr. Chermak. Without her enthusiasm, constant energy, and encouragement economics would be a heck of a lot more difficult.

I have to thank my husband, Keith, for the roof over my head, my car, my motorcycle, and all of the things that most full-time college students don't have, including love.

**ABSTRACT**

Municipal parks are often assumed to be associated with crime, but if parks do foster crime, the specific relationships are unclear. Park data were collected for a national and a city sample, recognizing four typical amenities in parks: sports, family, ornamental, and undeveloped. These four variables were regressed on eight different categories of crime for both samples. Percent male, percent aged fifteen to twenty-four, and percent white were used as control variables. Given the expected signs on the control variables, the city sample provided more likely results. In that sample, parks with sports, family, and ornamental amenities were associated with an increase in seven of the eight crimes. Undeveloped space showed no significant relationship to crime. The city sample results were used to create a framework for park development decision-makers. Considering samples of the existing literature on parks externalities and on the costs of crime to victims, the potential gains from particular park amenities are compared to the new victim costs associated with those amenities. This analysis shows sports amenities to be unfavorable, while victim costs associated with the family and ornamental amenities may be offset by gains to housing. Undeveloped space is favored in this framework.

# Chapter 1

## Introduction

Park systems across the United States provide physical, social, and spiritual inspiration to surrounding residents and to visitors. National forests and major parks also draw tourism dollars to communities (Young 1995). There is a rich historical connection between Americans and parks. One of the oldest public municipal parks in America is the Boston Common, which was originally founded in 1634 as a common pasture (The Official). In 1853 and 1854, Central Park in New York City, Elm Street in Worcester, Massachusetts, and Bushnell Park in Hartford, Connecticut were established at the forefront of the parks movement (Bushnell; Public).

Though the history is long, the value of municipal parks is often dependent on community involvement and on local politics. Low community involvement in park maintenance can turn a park into an eyesore. Community members are likely to feel insecure near such parks, and the space will more easily be associated with deviant social behavior (Crewe 2001; Mansfield, Pattanayak, McDow, McDonald, and Halpin 2002). In order to justify the opportunity cost of maintaining parks, the association between parks and crime needs to be understood. On the other hand, a well-maintained and monitored park can be a boon for social and family welfare activities. Despite this risk, a history of demand for park services spanning from conservation to recreation is evidence of the public's desire for park systems. Having a clear understanding of the potential costs and benefits of a few of the amenities commonly provided in parks can better inform the allocation of resources to these parks.

The intent of this paper is to take a step toward identifying the relationship between parks and crime. I do this through an ordinary least squares analysis of crime as a function of park amenities. The crimes in question are murder, rape, robbery, aggravated assault, burglary, larceny, auto theft, and arson. The park data are comprised of sums of each of four different park amenities within communities: sports, family, and ornamental amenities, and undeveloped space.

I begin with a review of the park literature, and follow with a brief review of crime literature. Next, I present a model of the criminal decision, which will include predictions on the directional affects of specific park amenities. There are two levels of park data in this study: a small national sample, and a sample taken from the city of Denver, Colorado. The empirical analysis begins with the data collection methods and descriptive statistics for the national sample. This is followed by a presentation of the national regression results, which include very few strong relationships between parks and crime. Only murder, rape, and larceny are found to be affected by either the family or undeveloped amenity. For both amenities the directional relationships are as predicted given previous literature though the control variables are not so well behaved. I next present the collection methods, descriptive statistics, and results for the Denver data. The Denver data provided results for all but the crime of robbery. In this case the undeveloped amenity proved to have no relation to crime, while the sports, family and ornamental amenities were related to various crimes. The control variables are well behaved in this sample, but the directional relationships between the amenities and crime do not fit predictions. The inconsistency between the national and Denver results is likely a result of omitted variable bias or small sample size. Finally, I take a brief look at how these

results could be applied to amenities decisions in community development. A discussion summarizes the paper and provides insight into future research considerations.

## Chapter 2

### Literature Review: Parks

The modern American park systems philosophy began to form in the early nineteenth century from extensions of romanticism and transcendentalism. Briefly, these intellectual movements encouraged the preservation of natural park spaces as a means of maintaining physical and mental wellbeing, and as a means of being “closer to God” (Cox 1981). A common assertion of the time was that the presence of natural parks could help to alleviate crime, among other social transgressions. Parks established under this philosophy were not necessarily left in a natural state, but rather were engineered so they appeared natural and the user could be isolated in the quiet setting (Cox 1981; Young 1995). During the 1880’s, the rationalist movement encouraged segmentation of parks in order to meet more specialized demands. The creation of more parks at the city, state, and national level, reduced the demands on individual parks, further allowing them to specialize to the needs of the nearest residents. Group activities fostered by these new parks were believed to improve individual and group efficiency. Athletic activities could increase health and teach a good mix of social and competitive skills for the workplace. Gathering in playgrounds, groups of children would arguably learn democratic equality and social coherence while at play. The social norms taught and enforced in park activities were supposed to reduce the costs to police and justice systems through the reductions in crime (Young 1995).

Modern attempts to justify facilities and natural parks have included the valuation of externalities, or non-use gains and losses, to adjacent housing. These non-use values include enjoyment of a view of the park, satisfaction from knowing the park is there, and

conversely, irritation over heavy use of certain park amenities. Several studies have derived estimates of these values through hedonic pricing analysis. Housing attributes included several standard housing characteristics, descriptors for various park amenities, and a measure of the distance between the observed homes and the parks (Weicher and Zerbst 1973; Cho, Bowker, and Park 2006; Kopits, McConnell, and Walls 2007; Mansfield et al., 2002). Collected from these studies, Table 1 presents changes to housing prices that can be loosely attributed to one of three different park amenities: athletic spaces such as basketball courts or baseball fields, family facilities such as playgrounds and picnic tables, and natural areas.

Table 1: Present Value of Adjacent Property Gain/Loss from Parks<sup>1</sup>

Study	Athletic	Family	Natural Spaces
Weicher and Zerbst (1973)	-\$3,236		\$3,180
Cho, Bowker, and Park (2006)		\$963 <sup>2</sup>	
Bolitzer and Netusil (2000)		\$1,070-3,382	\$1,580-3,382
Lutzenhiser and Netusil (2001) <sup>3</sup>		\$2,067	\$18,128

<sup>1</sup>Present value determined using 3% annual inflation rate, with PV=hedonic estimate, and n=2008-publication year (accept #11,12).  $FV = PV(1+r)^n$ .

<sup>2</sup>Assuming linear relationship,  $\$172 * 5.28 = \$908$

<sup>3</sup>n=2008-1990

The relation between crime and parks has rarely been tested, and has more consistently been addressed in terms of people's perceptions of fear. Using the Boston South-west Corridor, a five mile strip of parkland, Crewe (2001) examined calls to the police originating from residents adjacent to the park, residents half a block away, and from residents adjacent to more industrially oriented roads nearby. The study also involved a questionnaire regarding the general perception of safety in the park. While the questionnaire tended to affirm concerns of potential criminal activity in parks, the examination of police records did not support this. The homes adjacent to the park were found to have no significant spillover of crime from the park. Troy and Grove (2008)

tested how parks can add additional value to a home in the Baltimore housing market given the crime rate associated with those parks. This was a hedonic study that largely followed the format of several previous studies linking parks to housing value. Standard housing descriptors, such as square footage, number of full bathrooms and bedrooms, and structure age, among others, were used. The parks in the study were defined as parks of greater than two hectares size with at least 50% vegetation cover. The variable of interest was an indexed average of robbery and rape occurrences in census block groups overlaying each of the parks included in their final list. They found that above a threshold value of somewhere between 406-484% of the national crime average, the value of homes begins to decrease with respect to parks. For crime rates below the threshold, housing values were still increasing with respect to parks and despite the crime. Hartman and Depro (2006) looked at the change in crime rates as a result of midnight basketball programs made popular in the early 1990's. Though stressing the preliminary nature of their results, they found that cities with midnight basketball programs saw greater reductions in property crime than cities without.

### **Literature Review: Crime**

Becker's 1968 model of crime, enforcement, and punishment as a cost minimization problem solved by society established the following offense function. The probability of conviction per offense ( $p$ ) and the punishment per offense ( $f$ ) are the decision variables. He establishes the criminal's offense decision as a function of the probability of apprehension, the punishment, and a variable to describe all other decision factors:

$$O = f(p, f, u).$$

He further defines the following utility function where  $Y$  is both monetary and non-monetary income,

$$EU_j = p_j U_j(Y_j - f_j) + (1 - p_j) U_j(Y_j).$$

Becker argues that when other variables are held constant, the probability of apprehension and the punishment are both negatively related with the decision to commit a crime. If public spaces are considered safe and draw visitors regularly than they should increase public awareness. This increase in awareness could increase the probability of conviction and alternatively give the criminal additional incentive to choose legal work as a means of gaining higher utility.

Freeman (1999) generally determines the supply of crimes ( $S$ ) for a given group to be the number of people in that group who commit crimes ( $C$ ) multiplied by the number of offenses per criminal ( $\lambda$ ).

$$S = C\lambda$$

Freeman indicates that his approach is lacking in two ways. First, the crime committing population is determined by observation of crime within a given base population. But even with this observed rate, behavioral issues that better describe criminal tendencies are ignored. The criminal's perception of community awareness, and risk associated with that awareness, could be one of these behavioral considerations. Second, the number of offenses per criminal is defined differently depending on the circumstances of the crime and on the choice of the analyst. For example, selling drugs could easily be counted as a single crime, or as multiple instances of the crime (Freeman 1999).

Similar to Becker's model, Freeman goes on to address crime in market terms. With crime wages ( $W_c$ ), wages from legitimate work ( $W$ ), a probability of apprehension as in Becker's model ( $p$ ), and again, a measure of the punishment ( $f$ ), a person will decide to commit a crime when the benefits of the crime exceed the benefits of legal work:

$$(1 - p)U(W_c) - pU(f) > U(W).$$

This holds that a wage comparison between legal and illegal activities, the probability of apprehension, and the punishment are the major decision factors in the choice to commit crime. In this model the criminal wage must exceed the legal wage, and as  $p$  increases the gap between criminal and legal wages will need to widen. The two types of employment are substitutes herein, though this is not necessarily accurate. Freeman acknowledges that it is possible for people to be participating in legal and illegal work at the same time. The intent herein is to give the potential criminal incentive to choose legal work over illegal work, and this can partly be achieved through increases in the probability of apprehension.

Synthesizing the literature on architecture as a method of crime control, Katyal (2002) found four preventative design measures: natural surveillance, territoriality, building community, and strengthening targets. Natural surveillance stresses that certain architectural structures allow for easy viewing of community spaces. Wide-open pathways and good lighting are examples that are easily, if not naturally, integrated into public parks. Real and artificial barriers such as gateways and doorsteps will create a sense of territoriality, or a sense of ownership. Public parks can include community-serviced areas such as garden entries that will create a sense of ownership to those that

donate their time to the gardens. Community-building mechanisms straddle the first two mechanisms by creating semi-public spaces that will generate openness. These mechanisms can be as simple as community versus individual mailboxes, or benches at the edges of a park that will invite people to view the park as well as create opportunities for passersby to meet and greet. The final mechanism, strengthening targets, can be as simple as putting better locks on a front door, or using graffiti-resistant paint. Structural amenities in parks can be built with the threat of graffiti in mind. Using each of these mechanisms to increase the probability of apprehension in the criminal offense decision will again help to sway the decision toward legal work.

Specific determinants of crime are varied and often suspect. Some of the less reliable determinants include symptoms of poverty, changes in income, household dysfunction, poor education, and weak social controls (South and Messner 2000; Weatherburn 2001). Freeman (1999) states that arrest, incarceration data, and survey data show criminals to most frequently be young, male, undereducated, and victims of troubled families. As described by Gottfredson and Hirschi (1990), the perpetrators of burglary, robbery, homicide, auto theft and rape tend to be young, and 87% or greater are male. Nonwhite people commit a third of burglaries and auto thefts, and more than 51% of robberies, homicides, and rape.

If crime can be attributed to park amenities, it is useful to compare the costs of crime to the previously mentioned externality gains and losses from parks. The cost of crime to victims has been estimated using combinations of both direct and indirect approaches. The direct approaches include valuation of lost or damaged goods, short and long term medical costs, wage and productivity losses, the costs of crime avoidance, the

cost to property value from crime, and through jury awards (Cohen 1988; Miller, Cohen, and Rossman 1993; Rizzo 1979). Indirect approaches attempt to value pain, suffering, and fear using non-market information such as probabilities of injury and willingness-to-pay (WTP) survey data (Cohen 1988; Cohen, Rust, Steen, and Tidd 2004). The final WTP estimates are exceptionally high because, rather than reflecting the costs to an individual, these estimates reflect external social costs across entire communities (Cohen et al., 2004). Table 2 shows a summary of these costs to individual victims in 2008 dollars.

Table 2: Estimated Victim Costs per Incidence of Crime in 2008 Dollars<sup>1</sup>

Study	Rape	Car theft	Burglary	Larceny	Robbery	Assault	Arson	Murder
Miller et al., 1993 <sup>2</sup>	\$83,158				\$34,169	\$25,843	\$43,336	\$4,185,714
Cohen, 1988	\$92,216	\$5,648	\$2,478	\$312-327				
Cohen et al., 2004	\$266,746		\$28,138			\$78,786		\$10,917,435

<sup>1</sup>Present value determined using 3% annual inflation rate, with PV=literature estimate, and n=2008-publication year.  $FV = PV(1+r)^n$ .

<sup>2</sup>n=2008-1998

## Chapter 3

### Theory

The criminal's decision to commit a crime, as per Freeman's (1999) model, is based on criminal wages ( $W_c$ ) exceeding the expected cost of punishment ( $f$ ) and the opportunity cost of legal work ( $W$ ). If the potential offender's time can be divided between legal and illegal work in the same way that a budget can be divided between two goods, a change in the probability of apprehension will likely induce him or her to reallocate his or her workload, or change the slope of his or her budget line, to accommodate the new levels of risk associated with crime. A new point of utility maximization, along with a new willingness to trade between legal and illegal work, will result. Recognizing that park amenities may play a role in changing the probability of apprehension, Freeman's expected utility is modified by making probability of apprehension a function of park amenities ( $a$ ):

$$EU = (1 - p(a))U(W_c) - p(a)U(f) - U(W)$$

Assuming parks generally contribute to crime prevention in such ways as community involvement and awareness, the probability of apprehension should increase with an increase in parks. That is,

$$\frac{\partial p}{\partial a} > 0.$$

Further, assuming that the criminal expects benefits to exceed costs, or for criminal wages to exceed costs:

$$U(W_c) - U(f) > 0,$$

then the expected utility should be decreasing with respect to amenities:

$$\frac{\partial EU}{\partial a} = -\frac{\partial p}{\partial a}(U(W_c) - U(f)).$$

The following is a more specific look at some generalized park amenities and their likely effects on crime. Katyal's architectural mechanisms (2002) are easily applied in each case.

Athletic facilities, or sports amenities ( $a_s$ ), generally include open, often lit, visible areas such as ball fields, which facilitate natural surveillance (Katyal 2002). With more eyes on the field criminals are less likely to commit crimes within range of that field. Additionally, the original rationalist theory of parks purports that athletic activities will foster spirited, responsible social behavior (Young 1995). With this increased community awareness, the expected utility from the commission of crime is expected to decrease. Offenders should commit fewer crimes in favor of legitimate work:

$$\frac{\partial EU}{\partial a_s} < 0.$$

It is worth mentioning that a deterioration of the parks overall condition is likely to produce opposite results. If the community generally avoids the park, natural surveillance will fail as a control mechanism (Katyal 2002). This is the case for each of the following amenities as well.

The generally interactive nature of playgrounds and picnicking type amenities will also facilitate natural surveillance, and good social behaviors. In the same interactive respect these kinds of spaces may also act to build community. With two measures of architectural prevention, these interactive types of facilities, or family amenities ( $a_f$ ), should increase the probability of apprehension, thereby decreasing the expected utility of crime commission (Katyal 2002):

$$\frac{\partial EU}{\partial a_f} < 0.$$

Though it may lack the draw of more interactive amenities, the additional investment of ornamental amenities ( $a_o$ ), such as flower gardens or sculptures, in a park might encourage surveillance of the area through general interest in art or other reflective uses. A detailed public debate of the ornamental element before installation, or community involvement in the maintenance of it could also act to increase territoriality (Katyal 2002). Again, the change in the expected utility with respect to ornamental amenities is predicted to be negative:

$$\frac{\partial EU}{\partial a_o} < 0.$$

Finally, the inclusion of natural space, or undeveloped amenities ( $a_u$ ), in a park will likely decrease natural surveillance through the existence of thick natural growth. User-friendly pathways may act to increase natural surveillance somewhat. A sense of territoriality may be established in the space with informational signs placed throughout the space, as well. Both of these mechanisms are hypothetically applied though, and not necessarily guaranteed in a natural park space. Generally, the decrease in visibility may act to decrease the probability of apprehension. Expected utility, and therefore offenses, should decrease (Katyal 2002):

$$\frac{\partial EU}{\partial a_u} > 0.$$

## Empirical Model

Expected utility of crime commission is particularly difficult to define, and to my knowledge no valuation efforts have been made. On the other hand, data on known offenses are easily available. The decision to commit an offense and the derivation of any utility from said offense go hand in hand, and so I will conduct my analysis using the offense decision rather than utility.

Included as control variables in the offense decision are the localized demographics: percentage that is male ( $m$ ), percentage in the age bracket of 15-24 years ( $y$ ), and percentage of the population that is white ( $w$ ). Beyond these will be the data specific to the intent of this paper: park amenities ( $a$ ) present in the city or neighborhood. So park amenities are theorized to play some role in changing community awareness and thus affecting criminal behavior, or the supply of crime, holding all else constant. The offense function is then:

$$O = f(m, y, w, p(a)).$$

The empirical model is:

$$O = \beta_0 + \beta_1 m + \beta_2 y + \beta_3 w + \beta_4 a_i + e,$$

where each park amenity ( $a_i$ ) will be regressed on each crime separately.

Similar to the changes in expected utility from park amenities, Katyal's preventative measures (2002) can be used to ascertain the directional changes in offenses. Sports, family, and ornamental amenities will increase social interactions through increased natural surveillance, territoriality, and community building. This will increase the probability of apprehension, thereby decreasing the number of offenses people are willing to commit:

$$\frac{\partial O}{\partial a_s} < 0$$

$$\frac{\partial O}{\partial a_f} < 0$$

$$\frac{\partial O}{\partial a_o} < 0.$$

Undeveloped space is likely to decrease social interactions because of the lack of the same preventative measures:

$$\frac{\partial O}{\partial a_u} > 0.$$

The choice of an ordinary least squares specification is primarily a matter of ease considering the lack of similar studies available for reference. With a focused approach herein, any existing directional relationships between specific crimes and amenities can be pinpointed for more sophisticated future studies. It is unlikely, however, that any associations between park amenities and crime will be strictly linear. This will limit the predictive capabilities of these analyses.

## Chapter 4

### Empirical Analysis

Following are two separate analyses: a small national sample and a sample based out of the city of Denver, Colorado. One of the primary concerns with the national analysis is the level of aggregation in the data. Even for the smallest cities in the sample, all of their neighborhoods are unlikely to be well represented by a simple average of each variable in the data set. The distances between parks and criminal occurrences may also be problematic. By observing crime and park data at the smaller neighborhood levels found in Denver, these issues should be addressed in part. Additionally, the varying geographic, economic, and demographic structures present across several different cities will lead to omitted-variable bias. In a single city, many general population characteristics can be taken as invariant and therefore will not be needed in the regression analysis.

### National Data

The national sample consists of forty-two non-contiguous municipalities. In order to link park systems and crime, each municipality was first selected based on the availability of data on the Uniform Crime Report. I chose cities of varying population in order to minimize any population density or income affects in municipal development strategies. The populations range from just under 12,000 in Bemidji, Minnesota to over 1.3 million in Phoenix, Arizona. The next selection method was based on the availability of park information on the municipality's respective website. A list of amenities was required for selection. The cities in the national sample are listed in Table 3. In total, these cities have over 3,500 parks, with a lower bound of eleven parks in Huntington,

facilities and undeveloped space had to be verified in large part via Google Maps. The tedious nature of this data gathering process, compounded with the inconsistent presentation of park data across municipal websites, resulted in only forty-two observations being collected for the national sample. The park amenity categories essentially ignore parks that are only manicured fields, parks comprised of geometric cement and greenery elements, and bodies of water. Parks that only feature nature or community centers were not included, except where they did have outdoor elements. Brief descriptions of the park variables can be found in Table 5. Image 2 shows an example of a park as viewed on Google maps, with the four amenities identified.

Image 2: Park amenities example at Reichmuth Park, Sacramento Ca. Left: close up of the top half of park.

An example of the park data for the Fredericksburg, VA municipality is presented in Table 4, and all data can be found in appendix A. Again, amenity information was

culled from information provided on the municipal website in addition to the overhead views provided by Google Maps. In this case, the Dorothy Hart Community Center and the Motts Run Nature Center did not have any outdoor amenities and so were not counted. The Canal Path did not include substantial undeveloped space, nor did it have family amenities that would have given it credit here. The remainder included easily identifiable amenities. The totals of the four categories, on a per one thousand person basis, were taken as the observations for the municipality. In order to match with census and crime data, all parks acquired after the year 2000 were excluded.

Table 4: Example of Park Amenities List for Fredericksburg, VA

Park Name	Sports	Family	Ornamental	Undeveloped
Dorothy Hart comm. center				
Alum Spring Park		1		1
Canal Path				
City Dock				
Dixon Park	1	1		1
Fredericksburg Dog Park		1

Old Walker-grant School	1	1		
Riverside Drive Park				
Snowden Park Playground		1		
Snowden Baseball fields	1			
W.I. Harris Playground		1		
Sum:	4	10	2	3

For the national sample, the Federal Bureau of Investigation's Uniform Crime Report (UCR) provides data on annual occurrences of several categories of crime, including murder and non-negligent homicide, forcible rape, robbery, aggravated assault, burglary, larceny-theft, motor vehicle theft, and arson. I took the known offense counts

for year 2000 from the Index of Crime by Metropolitan Statistical area, on a per one thousand capita basis, as my dependent variables.

The descriptive statistics for all variables are presented in Table 5. Larceny averaged more than forty-one occurrences per one thousand people for the year, and was the most frequently occurring crime. The next most frequently occurring crime was burglary, averaging at nearly eleven occurrences per one thousand people for the year. The remainder of the crimes fell below an average of six occurrences, and in the cases of arson, rape, and murder, less than one per one thousand people each happened in that year. Park amenities all average below one per one thousand people, with family amenities occurring most frequently, followed by sports, undeveloped, and ornamental amenities. For the control variables, percent Male is predictably nearly 50% with a small standard deviation. The percent Aged 15-24 and percent White variables have much wider ranges, with averages of 17 and 72%, respectively.

Table 5: National Sample Descriptive Statistics per 1000 Residents, n=42

Variable	Mean	Std. Dev.	Min	Max
<u>Crime</u>				
Murder	0.07	0.06	0.00	0.27
Rape	0.49	0.23	0.00	1.06
Robbery	2.12	1.50	0.20	6.29
Aggravated Assault	3.43	2.49	0.37	14.32
Burglary	10.89	5.91	1.43	30.16
Larceny	41.53	14.02	6.78	81.23
Auto Theft	5.92	3.78	1.18	14.89
Arson	0.42	0.34	0.00	1.28
<u>Park Amenities</u>				
Sports: Marked athletic fields, blacktops and pools	0.23	0.11	0.05	0.53
Family: Playgrounds, picnic tables, pavilions, barbecue grills and off-leash dog parks	0.32	0.16	0.07	0.76
Ornamental: Sculptures, water fountains, monuments, historic sights, and large-scale flower gardens	0.08	0.09	0.00	0.39
Undeveloped: Any natural space that a person could be submerged in relative to developed properties around the park	0.10	0.10	0.01	0.50
<u>Control Variables: U.S. Census Data</u>				
% Male	48.9	2.38	45	61
% Aged 15-24	17.33	5.05	12.6	39.2
% White	71.72	14.76	34.4	94.2

### *National Analysis: Murder*

For the crime of murder, models presented in Table 6, only the family amenity was associated with a decrease in crime. The association was relatively weak though, with a p-value of only 0.84. This negative association supports Katyal's architectural mechanisms (2002) theory that amenities intended to foster socialization should decrease crime.

Table 6: OLS Results, y=Murder Rate per 1000 Residents

Variable	Murder	Murder
% Male	-0.005 (0.003)	-0.007* (0.004)
% 15-24	-0.001 (0.002)	-0.000 (0.002)
% White	-0.003*** (0.000)	-0.002*** (0.000)
Family		-0.075 (0.052)
Constant	0.491*** (0.149)	0.599*** (0.165)
Adj R-sq'd	0.4749	0.4900

n=42

\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

Again looking at Table 6, the marginal effect of  $-0.075 \pm 0.052$  from an additional family amenity seems close to the average occurrence of the crime: 0.07. It seems unlikely that the presence of a park with family amenities would have this large an impact. Evaluated on the mean, about 1/3<sup>rd</sup> of a family amenity for every one thousand people, results in 0.024 fewer murders per one thousand people, which is a more reasonable result.

### *National Analysis: Rape*

The incidence of rape, as shown in Table 7, was affected negatively by family and positively by undeveloped space. The associations are as predicted. These results indicate that a loss of natural surveillance from undeveloped space, as the architectural mechanisms theory suggests, will increase this crime (Katyal 2002).

Table 7: OLS Results, y=Rape Rate per 1000 Residents

Variable	Rape	Rape	Rape
% Male	-0.026 (0.018)	-0.044** (0.020)	-0.015 (0.018)
% 15-24	0.006 (0.008)	0.014 (0.009)	0.001 (0.009)
% White	0.001 (0.003)	0.004 (0.003)	0.000 (0.003)
Family		-0.549* (0.279)	
Undeveloped			0.797* (0.398)
Constant	1.551* (0.822)	2.338** (0.888)	1.113 (0.821)
Adj R-sq'd	-0.0159	0.0558	0.0587
n=42			

\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

Again, there is only a little more than a 1/3<sup>rd</sup> of a family amenity and 1/10<sup>th</sup> of an undeveloped space per one thousand people. Evaluating at these means, there would be a 0.18 decrease in the incidence of rape attributable to the family amenity or a 0.08 increase attributable to undeveloped space. The average occurrence of this crime is 0.49 per one thousand people.

### *National Analysis: Larceny*

As it was for rape, undeveloped space was also positively associated with the crime of larceny, which is shown in Table 8. This association is consistent with architectural mechanisms for crime prevention theory (Katyal 2002).

Table 8: OLS Results, y=Larceny Rate per 1000 Residents

Variable	Larceny	Larceny
% Male	-2.706** (1.010)	-2.125** (1.028)
% 15-24	0.767 (0.479)	0.480 (0.490)
% White	-0.125 (0.142)	-0.192 (0.142)
Undeveloped		41.80* (22.60)
Constant	169.7*** (46.40)	146.7*** (46.67)
Adj R-sq'd	0.1115	0.1647

n=42  
\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

In this case, the coefficient for undeveloped space seems large at nearly 42. Evaluated at the mean occurrence of undeveloped space, the incidence of larceny is increased by 4.18.

### *National Analysis: Additional Comments*

For the crimes robbery, aggravated assault, burglary, auto theft and arson, no park variable was found to have statistical association. Tables of these results can be found in appendix B.

Across all models in the national sample, the negative relationship between percent male and crime stands out as a surprising result. This is also supported by the correlations, shown in Table 9. Existing literature suggests that this relationship should be

positive rather than negative. The percent aged fifteen to twenty-four control variable did not behave so consistently but was more often negatively related to crime which, again, is contrary to existing literature. Literature indicates a negative relationship between percentage white and crime. For seven of the eight crimes modeled, this was the case (Freeman, 1999; Gottfredson and Hirschi, 1990; South and Messner, 2000).

Table 9: Correlations Between Crimes and Control Variables

	Percent Male	Percent Aged 15-24	Percent White
Murder	-0.3099	-0.3073	-0.6707
Rape	-0.1875	0.0108	0.0824
Robbery	-0.3194	-0.3734	-0.7155
Aggravated Assault	-0.2401	-0.204	-0.4452
Burglary	-0.2197	-0.3399	-0.395
Larceny	-0.333	0.02	-0.1378
Auto Theft	-0.2028	-0.293	-0.5431
Arson	-0.3859	-0.2799	-0.4774

Overall the national analysis only provided evidence of amenities' relationships to crime for three of eight crimes. Additionally, the control variables did not all behave as expected across the national models. The over-aggregation of data or the use of single averages to describe large and variable cities, the potential for omitted-variable bias across several cities of differing demographic structures, and the small sample size may explain some of these troubles. These arguments motivate the following analysis of several communities in the city of Denver, Colorado.

### National Versus Denver Analysis

In Table 10 there are two columns of information about Denver. The first column, the National Occurrence, is simply the points of data for the Denver observation in the national sample. The second column, City Average, is comprised of the averages across

all observations collected for the Denver analysis. There are three things that will create differences between these two columns. First, accuracy can be lost in taking one average relative to taking several averages and combining them. A neighborhood with a higher population will put less weight on the same number of crimes than a neighborhood with a lower population. The second difference will come from the different reporting units. The Denver Police Department and the Federal Bureau of Investigation are not necessarily using the same standards to count each crime, and any judgment used at the Denver Police Department is likely to reflect local concerns that will differ from the national concerns of the FBI. The third difference is in the base on which two of the crimes in particular are reported. For the Denver data, sexual assault and burglary were reported on a per female and per household basis, respectively. In converting these number to per capita bases, averages of census tract data were used. Again, a degree of accuracy is likely lost in averaging.

Table 10: Comparison of National and City level Denver Data

Variable	National Occurrence	City Average
Murder	0.06	0.07
Rape/Sexual Assault	0.53	0.58
Robbery	1.87	2.30
Aggravated Assault	2.74	2.63
Burglary	8.98	11.40
Larceny	23.15	26.35
Auto Theft	10.08	12.50
Arson	0.64	0.71
Sports	0.19	0.24
Family	0.16	0.29
Ornamental	0.06	0.10
Undeveloped	0.02	0.02
% Male	50.50	50.16
% Aged 15-24	14.00	13.45
% White	65.30	66.91

## Denver Data

The data for the city of Denver is collected by neighborhood, each of which tend to fall over groupings of one to five census tracts. There are seventy-eight of these neighborhoods in the city of Denver, sixty-five for which I was able to verify the park, crime, and census data. A map of these neighborhoods and the respective list of data appear in the C appendices. See Table 5 for park variable descriptions. The park data was normalized per one thousand residents. The control data (population percent male, population percent aged 15-24 years, and population percent white) are composed of averages of the representative census tracts. Household size was collected in order to convert the burglary data, which was originally presented per household. An example of the park amenities count is provided for the West Highland neighborhood in Table 11. Between the two parks inside the West Highland neighborhood, there are two sports, two family, and one ornamental amenity.

Table 11: Example of Park Amenities list for the West Highland Neighborhood

Parks	Sports	Family	Ornamental	Undeveloped
Highland Park	1	1	1	
Pferdsteller Park	1	1		
Sum:	2	2	1	0

The city of Denver Police Department website has available crime statistics data for the years 2001-2006 by neighborhoods. The data from 2001 was used herein. Similar to the national data, the crime categories are homicide, sexual assault, aggravated assault, robbery, burglary, larceny, auto theft, and arson.

Descriptive statistics for all Denver variables are shown in Table 12. For the city of Denver, larceny has the highest average number of occurrences: 26.4. Auto theft and

burglary are also fairly high, with 12.5 and 11.4 occurrences, respectively, during the year 2001. The remainder of the crimes fell below three occurrences per one thousand people, which is similar to the national dataset. The national larceny average is over 41 per one thousand people, where it is only 26 for Denver. The national auto theft average was lower though, at nearly six occurrences, compared to the Denver average of 12.5. The park amenities can be ranked from most frequently occurring to least as family, sports, ornamental and undeveloped. This differs from the national sample only in that ornamental and undeveloped switched places in the ranking.

Table 12: Denver City Sample Descriptive Statistics per 1000 Residents, n=65

Variable	Mean	Std. Dev.	Min	Max
<u>Crime</u>

% White	66.91	21.43	15.65	96.2

### *Denver Analysis: Murder*

Given the Denver data, the sports amenity is the only amenity associated with the crime of murder, and contrary to predictions, it is a positive relationship. Table 13 presents these results. Katyal's notion of natural surveillance, and the Rationalist theory of productive socialization in sports activities were the rationale behind the prediction that sports would be negatively associated with crime (Katyal 2002; Young 1995). For natural surveillance, it is possible that the surveillance created in and around parks is not substantial enough to deter criminals. A similar argument can be made against the Rationalist theory. Sports activities may engender good socialization and responsibility in participants, but they may not be a large enough group of people relative to the non-participants to induce such good behavior over entire communities. Instead, it seems likely that some other mechanism related to the sports amenity has a stronger positive relationship to crime. As an example, it is possible that participation in sports may create a more aggressive disposition rather than an acceptably competitive one.

Table 13: OLS Results,  $y$ =Murder Rate per 1000 Residents

Variable	Murder	Murder
% Male	0.004 (0.006)	0.006 (0.006)
% 15-24	-0.001 (0.005)	-0.002 (0.004)
% White	-0.001 (0.001)	-0.001 (0.001)
Sports		0.147** (0.063)
Constant	-0.021 (0.280)	-0.157 (0.277)
Adj R-sq'd	-0.0075	0.0621

n=65  
\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

### *Denver Analysis: Sexual Assault*

Of the park amenities, only the ornamental amenity appeared marginally significantly related to the incidence of sexual assault, with a positive association and a modest p-value of 0.80. This is presented in Table 14.

Table 14: OLS Results, y=Sexual Assault Rate per 1000 Residents

Variable	Sexual Assault	Sexual Assault
% Male	0.037 (0.024)	0.031 (0.024)
% 15-24	0.008 (0.018)	0.013 (0.018)
% White	-0.009*** (0.003)	-0.010*** (0.003)
Ornamental		0.535 (0.408)
Constant	-0.756 (1.086)	-0.556 (1.091)
Adj R-sq'd	0.1887	0.1982

n=65  
\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

The positive association of this amenity and sexual assault is contrary to the predictions of this paper. Territoriality and natural surveillance were the applicable architectural mechanisms in predicting a negative relationship between ornamental amenities and crime (Katyal 2002). As stated in the original prediction, ornamental amenities may not draw as large, or as consistent, a crowd as sports or family amenities, and so the increase in community awareness may be too small to affect crime. The territoriality assumption comes from the community involvement in establishing the amenity, such as choosing a sculpture or planting a garden, but that involvement may be short lived or may only occur on given time intervals. Thus the sense of ownership may be intermittent or decreasing with time. Again, it is possible that these effects are too insubstantial to decrease criminal behavior.

### *Denver Analysis: Aggravated Assault*

The crime of aggravated assault, presented in Table 15, is positively associated with the sports and ornamental amenities.

Table 15: OLS Results,  $y = \text{Aggravated Assault Rate per 1000 Residents}$

Variable	Aggravated Assault	Aggravated Assault	Aggravated Assault
% Male	0.136 (0.085)	0.166** (0.082)	0.110 (0.085)
% 15-24	0.013 (0.063)	-0.004 (0.061)	0.036 (0.064)
% White	-0.065*** (0.012)	-0.061*** (0.012)	-0.067*** (0.012)
Sports		2.236** (0.865)	
Ornamental			2.438* (1.451)
Constant	-0.002 (3.899)	-2.072 (3.814)	0.908 (3.880)
Adj R-sq'd	0.4028	0.4537	0.4202

n=65

\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively. Standard error in parenthesis.

Again, the signs on both of these amenity coefficients are positive, which is contrary to predictions. For aggravated assault, natural surveillance, territoriality, and the rationalist expectations of spirited social behavior were applied in predicting negative relationships, and it seems these are not substantial enough effects, or it appears the amenities have unexpected effects (Katyal 2002).

### *Denver Analysis: Burglary*

The sports and family amenities are both positively associated to the crime of burglary. This is shown in Table 16.

Table 16: OLS Results, y=Burglary Rate per 1000 Residents

Variable	Burglary	Burglary	Burglary
% Male	0.606** (0.245)	0.664*** (0.244)	0.450* (0.243)
% 15-24	-0.318* (0.182)	-0.351* (0.181)	-0.259 (0.176)
% White	-0.089** (0.035)	-0.081** (0.035)	-0.077** (0.034)
Sports		4.297* (2.572)	
Family			6.228** (2.426)
Constant	-8.796 (11.25)	-12.77 (11.34)	-4.336 (10.91)
Adj R-sq'd	0.1115	0.1368	0.1861

n=65  
\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

These burglary models are the first for which the family amenity has been significant in the Denver sample. The family amenity was predicted to have a negative relationship to crime because of natural surveillance and community building architectural mechanisms (Katyal 2002). Both mechanisms are either ineffectual at the scale of an entire neighborhood, or again the family amenities are more strongly tied to unaddressed factors that increase crime.

### *Denver Analysis: Larceny*

In Table 17, sports, family and ornamental amenities all prove to be positively associated to larceny, with the ornamental amenity having a p-value of just 0.84. As has been consistent across the Denver models, these positive relationships are contrary to the predictions of this paper.

Table 17: OLS Results,  $y=Larceny$  Rate per 1000 Residents

Variable	Larceny	Larceny	Larceny	Larceny
% Male	2.053** (0.929)	2.295** (0.920)	1.601* (0.940)	1.803* (0.937)
% 15-24	-0.599 (0.691)	-0.737 (0.681)	-0.429 (0.682)	-0.380 (0.701)
% White	-0.030 (0.133)	0.001 (0.131)	0.004 (0.131)	-0.048 (0.132)
Sports		18.12* (9.690)		
Family			18.00* (9.401)	
Ornamental				23.05 (15.95)
Constant	-66.55 (42.62)	-83.32* (42.73)	-53.66 (42.26)	-57.94 (42.67)
Adj R-sq'd	0.0308	0.0689	0.0713	0.0478

n=65

\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

In this case, natural surveillance, community building, territoriality, and the rationalist expectations about sports and good behavior all fail to explain the positive associations between the park amenities and crime.

### *Denver Analysis: Auto Theft*

As with the crime of larceny, for auto theft the sports, family and ornamental amenities are the only statistically significant park amenities, with ornamental having the lowest p-value of 0.84. These models are presented in Table 18. By now, the positive relationship these amenities have to crime, given this dataset, is not a surprise.

Table 18: OLS Results,  $y = \text{Auto Theft Rate per 1000 Residents}$

Variable	Auto Theft	Auto Theft	Auto Theft	Auto Theft
% Male	0.426 (0.346)	0.540 (0.336)	0.278 (0.3520)	0.334 (0.349)
% 15-24	0.147 (0.257)	0.082 (0.249)	0.202 (0.255)	0.227 (0.261)
% White	-0.183*** (0.049)	-0.168*** (0.048)	-0.171*** (0.049)	-0.189*** (0.049)
Sports		8.536** (3.539)		
Family			5.878* (3.520)	
Ornamental				8.445 (5.934)
Constant	1.367 (15.85)	-6.536 (15.61)	5.577 (15.82)	4.520 (15.87)
Adj R-sq'd	0.2672	0.3206	0.2881	0.2794

n=65  
\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

### ***Denver Analysis: Arson***

The sports and family amenities are again positively associated to arson, and are highly significant. These models are shown in Table 19.

Table 19: OLS Results,  $y = \text{Arson Rate per 1000 Residents}$

Variable	Arson	Arson	Arson
% Male	0.041 (0.026)	0.049* (0.025)	0.020 (0.025)
% 15-24	-0.010 (0.019)	-0.015 (0.019)	-0.003 (0.018)
% White	-0.013*** (0.004)	-0.012*** (0.004)	-0.011*** (0.003)
Sports		0.612** (0.266)	
Family			0.822*** (0.248)
Constant	-0.360 (1.185)	-0.926 (1.172)	0.229 (1.113)
Adj R-sq'd	0.1795	0.2336	0.2954

n=65

\*, \*\*, and \*\*\* indicate 90%, 95%, and 99% significance, respectively.  
Standard error in parenthesis.

### ***Denver Analysis: Additional Comments***

The Denver sample showed amenity relationships for seven of the eight crimes. The only crime remaining was robbery, which was also shown to have no amenity relationship in the national sample. The undeveloped space amenity was not significant for any crime in the Denver models.

The Denver sample provided more expected results with regards to the control variables when compared to the national results. The percent Male, or gender, variable was positively related to crime in all cases, and was statistically significant in many of them. The percent White, or race variable, was negatively related to crime in all but a few

of the larceny models, as predicted, and was also significant in many of the models. The age variable was negatively related five of the eight crimes and was only significant at 90% or better for burglary. This inconsistency with the age variable is similar to the national results.

### **Analysis Summary: Denver and National**

In looking at the control variables, there was one obvious difference between the two datasets. The coefficients on the male variable were negative in the national sample and positive in the Denver sample. Considering previous crime literature, this is the most telling observation when choosing whether one dataset or the other might be more valid (Freeman 1999; Gottfredson and Hirschi 1990; South and Messner 2000). The national and Denver results agree for the most part on the directional relationships of the aged fifteen to twenty-four and white variables.

Beyond considerations of the specific variables are considerations of sample size, aggregation levels, and omitted variable biases mentioned previously. Both samples are relatively small, but the Denver set is a larger sample and it represents more than 80% of the neighborhoods in Denver. Thus, the Denver sample is more likely to capture the true effects of park amenities on crime for this city, whereas the national sample may confuse differing park relationships between cities.

Looking at the park variables and their coefficients, as presented in Table 20, across crimes there are no similarities between the national and Denver results. Not only are the directional relationships different, but the few crimes that are in part related to

park amenities in the national sample are not related to the same amenities in the Denver sample.

Table 20: Summary of Denver and National Marginal Effects on Crime per 1000 Residents

	Murder	Sexual Assault	Robbery	Aggravated Assault	Burglary	Larceny	Auto Theft	Arson
<u>Denver</u>								
Sports	0.147			2.236	4.297	18.12	8.536	0.612
Family					6.228	18.00	5.878	0.822
Ornamental		0.535		2.438		23.05	8.445	
Undeveloped								
<u>National</u>								
Sports								
Family	-0.075	-0.549						
Ornamental								
Undeveloped		0.797				41.80		

With the exception of the undeveloped amenity, the Denver results showed strong and consistent relationships for sports, family and ornamental amenities. In all cases, these relationships are positive, which was contrary to the predictions based on Katyal's architectural mechanisms (2002). As a reminder, this theory suggests that natural surveillance, territoriality, community building, and strengthening of targets will combine to deter crime. With increased awareness of community members and behavior, criminals will face a higher risk in the choice to commit a crime because people are more likely to be watching and more willing to address suspicious behavior. That these results show a positive relationship between social amenities and crime suggests that either architectural mechanisms fail to deter crime or that park amenities are not contributors to community awareness. The latter is plausible given the spatial dimensions of parks and criminal activity. Park locations are fixed and are likely to be somewhat distant from the locations of many crimes. Parks' positive effects may be strictly localized.

Looking back to related literature, Crewe (2002) found that reports of crime originating from communities around a park tended to center more on those streets adjacent to commercial streets than those adjacent to the park. It is possible that the park variables are catching other community characteristics, such as commercial zones, that may have a more effective spatial relationship to crime. Troy and Grove (2008) found that implementation of midnight basketball programs coincided with decreased crime rates. Since the dataset herein only addresses the parks and their intended uses, not necessarily their actual uses, it is possible, again, that the variables are catching other unintended behaviors, or unintended uses for the park.

If the positive relationship between crime and the sports, family, and ornamental park amenities cannot be so easily attributed to some other unobserved variables, than the relationship is definitely one worth scrutinizing. Some of these coefficients predict a particularly large increase in crime from the addition of one park with the given amenity. Table 21 presents both the average occurrence of each park amenity for the Denver sample, and the coefficients evaluated from those means. Though these numbers may seem more realistic, at their extreme, the murder coefficient still suggests a fifty percent increase by the doubling of the available sports amenities per one thousand people. At the lowest, these coefficients suggest a 6.7% increase in auto thefts from doubling ornamental amenities. These are still large enough effects to merit further investigation.

Table 21: Coefficients Scaled to an Increase of Two Times the Amenity Average

	Average Amenity Occurrence	Murder	Sexual Assault	Aggravated Assault	Burglary	Larceny	Auto Theft	Arson
<u>Denver</u>								
Sports	0.24	0.035		0.537	1.031	4.349	2.049	0.147
Family	0.29				1.806	5.220	1.705	0.238
Ornamental	0.1		0.054	0.244		2.305	0.845	
Undeveloped	0.02							

Overall, these results suggest that more in depth research is required to sort out the true relation between parks and crime. Further research could be approached with three major considerations in mind. First, with sophisticated data collection tools, such as GIS, parks could be accounted for not only in terms of their amenities but their size. It is possible that a small playground surrounded by several acres of sports fields may have a different impact on crime than a playground beside a small patch of grass. Similarly, a park that is less than an acre in size will likely affect a community differently than a park that is over one thousand acres. Additionally, it seems that a concurrent analysis of several municipal park systems, at a similar or smaller aggregation level than the Denver sample here, may reveal more concisely which of the national or the Denver results was more reliable. The results for Denver, Colorado may present differently than similarly acquired results for a city such as Rochester, New York. With enough cities, one might find even find consistencies across regions. A second consideration for further research is that the crime data may also be a source of bias in the results. For both the Denver and national datasets the crime data is a reporting of all convictions, and not all criminal activity. The annual National Victimization Survey, which attempts to determine the likelihood of victimization through surveys to 135,300 residents, may be a more accurate reflection of both reported and unreported criminal behavior. This latter survey suggests

that three times more crime is occurring than will be reported by convictions because the victims choose, for various reasons, not to report the crime (Freeman 1999). It is possible that where parks appear to positively affect crime in my results, the residents are simply more likely to report crime. The final consideration is the functional form of the analysis. Non-linear specifications are likely to provide more precise measures of any specific relationships between parks and crime.

## Chapter 5

### Application

If crime is indeed related to park features, the costs of crime and the benefits of these park spaces should be compared in order to advise future decision-making. If the benefits of parks to surrounding homeowners outweigh the costs to victims of additional crimes, decisions could be more easily made in the favor of expanding parks systems, regardless of the additional crime. If the costs of crime exceed the benefits of park spaces, then it may be advisable to reevaluate park system amenities or to decide to allocate the land to other uses. This section will take the Denver regression results from Table 20, combined with estimates of the costs of crime (see Table 2), and the externality gains from parks to surrounding housing (see Table 1), to create a cost-benefit framework for community decisions on new park amenities.

For some of the externality gains estimates and crime cost estimates in the literature review there were more than one applicable value. The lowest of these estimates will be used in order to create a lower bound for the cost-benefit analysis. Existing literature does not have a close approximate for parks that specifically contain ornamental amenities. It is my general feeling, after having collected the dataset, that ornamental amenities are more frequently placed in passive parks, or parks of a more mild or decorative intent. This is most similar to the family amenity, and so I will apply the same value to ornamental amenities as for a family amenity.

To start, this framework assumes the decision to establish a park has already been made, eliminating the need to consider the opportunity cost of the acreage devoted to the park space.

For each of the homes surrounding a particular park, the externality gain from the park can be seen as the partial derivative of the home's price function ( $P_i$ ) with respect to a variable describing the park amenity ( $a$ ). The value of the park can be seen as a sum of all the individual externality gains or losses to adjacent homes ( $e_a$ ).

$$e_a = \sum_{i=1}^n \frac{\partial P}{\partial a_i}$$

The decision for park developers can be informed when it is seen that the externality gains ( $e_a$ ) will exceed the costs to victims ( $v_i$ ), or vice versa. The cost to victims is the amenity coefficient ( $\beta_i$ ) times the previously estimated costs of crime, in table 2.

$$v_i \leq e_a \text{ OR } v_i \geq e_a$$

In concert with the Denver results in Table 20, Table 22 presents the marginal costs ( $v_i$ ) for each crime. The total costs by crime category are across the bottom and totals by amenity type are on the far right.

Table 22: Marginal Costs For Crime With Respect to Amenities<sup>1</sup>, summed

	Murder	Sexual Assault	Robbery	Aggravated Assault	Burglary	Larceny	Auto Theft	Arson	Sum:
Sports	\$615,300			\$57,785	\$10,648	\$5,653	\$48,211	\$26,522	\$764,119
Family					\$15,433	\$5,616	\$33,199	\$35,622	\$89,870
Ornamental		\$44,490		\$63,005		\$7,192	\$47,697		\$162,384
Undeveloped									\$0
Sum:	\$615,300	\$44,490	\$0	\$120,790	\$26,081	\$18,461	\$129,108	\$62,144	

Using lowest estimated victim cost for murder from Table 2, nearly 4.2 million dollars, it is not surprising that Table 22 shows murder to be the most costly of crimes affected by any amenity. That auto theft and aggravated assault are nearly equal to each

<sup>1</sup> New Crime Cost = Marginal effect (from Table 20) \* Victim costs (from Table 2)

other in additional costs is surprising. The marginal cost of an auto theft is estimated to be about a fifth that of assault, which indicates that auto theft is increased dramatically in relative terms. At a minimum estimated cost of only \$312 for an additional larceny, it is again not surprising that larceny is the cheapest crime in total.

The extreme cost of murder acts to exaggerate the overall effect of the sports amenity as compared to other amenities totaled at the far right of Table 22. Without murder, a sports amenity would only increase victim costs by about \$150,000. Still, the sports amenity does seem to be the most costly amenity in terms of crime. Ornamental amenities would rank next, at nearly a fifth of the cost of sports amenities. Family amenities are the cheapest in these terms. Of course undeveloped space was insignificant in this modeling and therefore costless in these terms.

In a rework of Table 22, Table 23 shows the marginal costs with respect to amenities,  $\frac{\partial P}{\partial a}$ , but adds a new row for each amenity to address the sum of externality gains ( $e_a$ ) from the amenity. The marginal externality gains from each amenity (from Table 1) are at the left of each of these new rows. Below each marginal cost is the number of homes required to make the externality gains equal that cost:

$$e_a = v_i.$$

Table 23: The Break-even Quantity on Homes Receiving Externalities to Crime Costs

	Murder	Sexual Assault	Robbery	Aggravated Assault	Burglary	Larceny	Auto Theft	Arson
Sports	\$615,300			\$57,785	\$10,648	\$5,653	\$48,211	\$26,522
$\frac{\partial P}{\partial a_s} = -\$3,236$	-			-	-	-	-	-
Family					\$15,433	\$5,616	\$33,199	\$35,622
$\frac{\partial P}{\partial a_f} = \$963$					16	6	34	37
Ornamental		\$44,490		\$63,005		\$7,192	\$47,697	
$\frac{\partial P}{\partial a_o} = \$963$		46		65		7	50	
Undeveloped								
$\frac{\partial P}{\partial a_u} = \$1,580$								

Looking across the sports rows on Table 23, notice that the externality from a sports amenity is negative. This means that not only are homes losing value from this type of park amenity, but crime is being increased by it as well. In this framework sports amenities are a lose/lose decision. For family and ornamental amenities, many of the new costs to victims would likely be offset by gains in value to adjacent property owners. For larceny, only six homes are required to offset the new costs given a family amenity. In the case of aggravated assault with respect to ornamental amenities, sixty-five homes would be necessary to cover the new victim costs. With this large a quantity, two issues must be addressed in considering the plausibility of benefits equaling costs. First, parks are not as likely to be large enough to have over sixty homes adjacent to them, and so there are simply not enough homes to distribute these new costs over. Second, these crimes will occur on an annual basis, whereas the gains to property are likely to only be realized when the property is sold and not annually. With a smaller number of homes required for  $e_a = v_i$ , equality may still be reached given enough property sales, but with a

larger number of homes, this is far less likely. Again, undeveloped space appears to be a win/win situation considering it does not affect crime and it does add value to adjacent homes.

More generally considering the results on Table 23, it seems there are only obvious policy implication for the sports and undeveloped amenities. The addition of new sports amenities in park systems should be carefully considered, especially when a different amenity might be used instead. An understanding of benefits outside of this framework, such as an attempt to measure public health with respect to sports amenities, may help to advise this decision further. The addition of undeveloped space is obviously supported by these results. A likely constraint is the scarcity of undeveloped land in cities, but this can also be addressed with further research. As for family and ornamental amenities, the costs and benefits are likely to be equalized for at least the incidence of larceny, and possibly that of burglary. It is less likely equalized for sexual assault, aggravated assault, auto theft, and arson. For these two amenities, this framework is a less concise indicator, and other community concerns will likely present a more clear case in establishment of new park amenities.

## Chapter 6

### Summary

This paper considers the historical and social perspectives on park systems. In both perspectives, a relatively unexplored relationship between parks and crime is apparent (Cox 1981; Crewe 2001; Troy and Grove 2008; Young 1995). I presented a regression analysis of crime in an attempt to substantiate this relationship specifically for four common park amenities. The amenities considered were sports, family, ornamental (such as flower gardens and sculptures), and undeveloped space. The crimes were murder, sexual assault, robbery, aggravated assault, burglary, larceny, auto theft, and arson. The data included a widely dispersed national data set of forty-two cities, and a localized data set for sixty-five neighborhoods in Denver, Colorado. Taking the most statistically significant regression results, I created a basic framework for community development decision-makers regarding the question of park amenities.

A comparison of results between the national and city level regressions revealed largely contradictory findings. At the national level, the family amenity was negatively related to the crimes murder and rape, and undeveloped space was positively related to rape and larceny. These were the only significant results, but the directional relationships are as expected. A major problem in the national results is in the control variables. In every national model the percent male variable was negatively related to crime, which strongly contradicts existing literature (Freeman 1999; Gottfredson and Hirschi 1990; South and Messner 2000). Interestingly, the Denver sample suggested that crime is positively affected by sports, family, and ornamental amenities, and not affected at all by undeveloped space. These directional relationships contradict the national results. Again,

the key indicator is in the control variables. In every Denver model the percent male variable was positively related to crime. This consistency with existing literature adds credence to the Denver models.

The Denver results were applied in the amenities decision framework. The coefficients for each crime, with respect to each amenity, were multiplied by victim costs from existing literature to determine the cost of new crime given a new park. Additionally, externality gains/losses to homes from parks were pulled from existing literature. The crime costs were compared to the externality gains to see if certain gains in crime could be offset by welfare gains to surrounding housing. It appeared possible that the additional crime associated with family and ornamental amenities could be absorbed by externality gains to housing given certain circumstance. It was impossible that the costs generated by sports amenities could be absorbed. Sports negatively affected adjacent homes and increased crime costs. For undeveloped space, there were no significant effects on crime and the homes surrounding such space gain value.
