Preface

Welcome to the proceedings of the Eleventh International Conference on Management Science and Engineering Management (ICMSEM 2017), which will be held from July 28 to 31, 2017, at Kanazawa, Japan. The International Conference on Management Science and Engineering Management (ICMSEM) is an annual conference organized by the International Society of Management Science and Engineering Management (ISMSEM). The conference is to foster international research collaborations in Management Science and Engineering Management as well as to provide a forum for presenting current research work in the forms of technical sessions, roundtable discussions during the conference period in a nice relaxing enjoyable atmosphere. The participants can share their academic achievements in MS and EM, and communicate with others during the conference.

The ICMSEM has been held ten times since 2007 in meeting locations across Asia, Europe, and the Americas and has had a great influence on MS and EM research. In the past ten years, the ICMSEM has been successfully held in Chengdu, Chongqing, Bangkok, Chungli, Macau, Islamabad, Philadelphia, Lisbon, Karlsruhe, and Baku. All accepted papers were put into the proceedings for each International Conference on Management Science and Engineering Management and proceedings for the last five conferences can be retrieved from EI Compendex.

This year, 939 papers from 32 countries were received and 150 papers from 20 countries accepted for presentation or poster display at the conference. These papers were from Algeria, Australia, Azerbaijan, Bangladesh, Canada, China, Indonesia, Iran, Iraq, Japan, Korea, the Republic of Moldova, Pakistan, Portugal, Spain, Thailand, the UK, the USA, Uzbekistan, and Vietnam. Each accepted paper was reviewed by three reviewers, who gave objective and helpful revision advice to the authors where necessary, which has made these conference proceedings of very high quality. The papers in the proceedings have been classified into eight sections: Computing Methodology, Data Analysis, Enterprise Operation Management, Decision Support System, Green Supply Chain, Resource Optimization Management, Risk Control, and Integrated Project Management. The key issues at the eleventh ICMSEM covered many areas of current popularity in Management Science and Engineering Management. To further encourage state-of-the-art research in the field of Management Science and Engineering Management, the ISMSEM Advancement Prize for Management Science and Engineering Management was awarded for the excellent papers at the conference.

We would like to take this opportunity to thank all participants, all of whom worked exceptionally hard to ensure this conference was a success. We want to express our sincere gratitude to the following prestigious academies and institutions for their high-quality papers and great support for the ICMSEM: the Azerbaijan Academy of Sciences, the Moldova Academy of Sciences, Academy of Sciences of the Republic of Uzbekistan, Fuzzy Logic Systems Institute, and Tokyo University of Science, Brock University. We would also like to acknowledge the assistance we received from the International Society of Management Science and Engineering Management, Kanazawa University, and Sichuan University for the conference organization. We also appreciate Springer-Verlag for the publication of the proceedings. We are grateful to Professor Yoshihiko Uesugi as the General Chair, Professor Mistuo Gen and Professor Hidetaka Nambo for their work as the Organizing Committee Chair, and Professor Takashi Oyabu as Local Arrangement Committee Chair. We appreciate the great support received from all members of the Organizing Committee, the Local Arrangement Committee, and the Program Committee as well as all participants. Finally, we would like to thank all researchers for their excellent conference papers. Because of the high quality of the research, the ISMSEM Advancement Prize for MSEM is to be awarded again for papers which have focused on innovative practical applications for Management Science and Engineering Management.

As MSEM research is in continuous development, many new MSEM development trends have emerged. Our work needs to continue to focus on MSEM development so as to encourage greater and more innovative development activity. Next year, we plan to continue the novel and successful ICMSEM and intend to increase our efforts to improve the quality of the proceedings and to recommend more excellent papers for the ISMSEM Advancement Prize. The Twelfth International Conference on Management Science and Engineering Management will be hosted by Monash University, Melbourne, Australia, in July 2018. Professor Lee has been nominated as the Organizing Committee Chair for the 2018 ICMSEM. We sincerely hope you can submit your new MSEM findings and share your ideas in Melbourne, Australia.

Organization

ICMSEM 2017 was organized by International Society of Management Science and Engineering Management, Sichuan University (Chengdu, China), and Kanazawa University (Kanazawa, Japan). It was held in cooperation with Lecture Notes on Multidisciplinary Industrial Engineering (LNMIE) of Springer.

Executive Committee

General Chairs

Jiuping Xu	Sichuan University, China
Yoshihiko Uesugi	Kanazawa University, Japan

Program Committee Chairs

Mitsuo Gen	Fuzzy Logic Systems Institute and Tokyo University of Science
Shavkat Ayupov	Academy of Sciences of Uzbekistan, Uzbekistan
Le Dung Trang	Abdus Salam ICTP, Vietnamese

Abstract. Management is playing an increasingly more important role in modern society. In particular, the development of efficient innovative managerial tools has significantly influenced social progress in management science and engineering management. In this paper, we first give a brief introduction to the eleventh ICMSEM proceedings Volume I. An analysis of the current management science topics reveals that computing methodology, data analysis, enterprise operation management, and decision support system have become key foci in the past few years. We then conduct a literature review to examine the main research in these four areas, after which the central issues in the eleventh ICMSEM Proceedings Volume I are examined using NodeXL. Finally, by analyzing the main keywords using CiteSpace, frontier management science is identified. All in all, the ICMSEM continues to provide a valuable forum for academic exchange and communication and will continue to play an important role in promoting MSEM advancements in the future.

Keywords: Computing methodology · Data analysis · Enterprise operation management · Decision support system

1 Introduction

The Eleventh International Conference on Management Science and Engineering Management (ICMSEM) in Kanazawa, Japan, has given Management Science and Engineering Management (MSEM) academics the opportunity to present their innovative findings in this increasingly popular research field. The papers in this volume demonstrate the substantial growth in interdisciplinary MSEM methodologies and practical applications. The ICMSEM aims to be the primary forum for academic researchers and practitioners to become involved in discussions on state-of-the-art MSEM research and development.

MSEM has shown tremendous growth and expansion since its beginnings. In particular, Management Science (MS) has had a long history associated with universal and impersonal management research disciplines. Scientific management,

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_1

of course, owes its beginnings to the innovative ideas of Taylor and Fayol and their associates, who at the turn of the century attempted to solve industry problems through strict time monitoring, technical production methods, incentive wage payments, and rational factory organization based on efficiently structured work assignments [1,6]. In the period following the Second World War, modern analytical management methods brought the business practice into a new era. Terms such as Decision Theory, Operations Research, System Engineering, and Industrial Dynamics, which were practically unknown in the early fifties, are now as well-known as Accounting or Finance [12]. As time passed, with societal, economic, organizational, and cultural, factors playing increasingly more important roles in management practice, MS used mathematics information science, systems science, cybernetics, statistics and other theories and methods from natural science to develop innovative management and control systems. The integration of these research areas has brought significant improvements to the ICMSEM proceedings Volume I, which is mainly focused on computing methodology, data analysis, enterprise operations management, and decision support system this year.

2 Literature Review

Literature reviews give insights into the focus and new research directions in a particular research field. The widespread research attention given to MS has been mainly focused on four main areas; computing methodology, data analysis, enterprise operation management, and decision support system. Therefore, in this section, we review the pertinent research that had taken place in each of these four areas.

2.1 Computing Methodology

By providing the algorithms for management science and engineering management problems, computing methodology (CM) could be seen to be the theoretical foundation to MSEM. Through a comparative study, an appraisal of wind speed distribution prediction using soft computing methodologies has been examined for energy applications [20]. This soft computing methodologies combination meant that a more complete array from the information database could be used to develop tactical planning forecasts. Obrad Anicic et al. built an effective wind turbine noise level prediction model with the polynomial and radial basis function being applied as the kernel function for support vector regression (SVR) to estimate wind turbine noise levels [4]. Gotmare et al. presented a comprehensive review on the various swarm and evolutionary computing schemes that could be employed for system identification and digital filter design, and envisioned a quick reference for a few popular evolutionary algorithms [11]. A hybrid parallel programming model was designed for which a novel sparse matrix partitioning algorithm, a performance analysis, and an SpMV optimization on a CPU−GPU heterogeneous computing platform was developed to solve the problem [25].

Jardim and Silva presented a simple and computationally efficient methodology for computing robust dynamic equivalents that could be easily embedded in time domain simulation packages [14]. Current scholars are not only focusing on computing methodological theoretical research, but also concentrating on applications to ensure better results.

2.2 Data Analysis

Data analysis (DA) refers to the statistical analysis of large amounts of collected data to extract useful information and form conclusions. West and Post conducted research to quantify potential soil C sequestration rates for different crops with the goal of decreasing tillage intensity and enhancing rotation complexity [24]. For environmental management, carbon sequestration rates have been used in spatial modeling analyses to more accurately predict regional, national, and global C sequestration potential, and data envelopment analysis (DEA) methods have been adapted for eco-efficiency. DEA can provide substitution possibilities for different natural resources and emissions as Kuosmanen illustrated in the development of an application to assess road transportation in the three largest towns in eastern Finland [17]. To demonstrate the accuracy and potential of the methodologies, Muxika et al. used historical data, expert judgement, and multivariate analysis together with a definition of reference conditions to examine changes in the benthic communities in the Basque Country over the last decade [18]. With the development of information technology, big data has become a popular research focus because of its potential to give valued insights for enhanced decision-making. For example, big data and big data analytics methods have been used to assist decision makers better reach their targets [23]. DA is also playing an increasingly dominant role in modern society and as a result, data analysis research has yielded many competing models and contributed both conceptually and empirically to technology and organizational resource management.

2.3 Enterprise Operation Management

Enterprise operation management (EOM) generally refers to enterprise teams with the visibility and automation tools to increase returns on assets, improve management performance, and reduce enterprise costs. In the enterprise network, computing and efficient resource use can provide enterprise-wide information sharing, allowing for convenient communication between employees as well as external information access. Bi et al. investigated the impact of the emerging internet of things on enterprise systems in modern manufacturing by discussing the evolution of manufacturing system paradigms [7]. Camarinha-Matos et al. presented a discussion on the contribution of the collaborative networked organizations paradigm to the challenges faced by manufacturing systems [8]. It is undeniable that big data has attracted significant attention from researchers in the information sciences as well as policy and decision makers in governments and enterprises. Therefore, there is no doubt that business productivity and technological innovation in the future will draw on the advantages offered by big data [9,15]. Because of the promise of more automated information exchanges in networked enterprise scenarios, enterprise information systems (EIS) have become increasingly important for interoperability to increase productivity and efficiency [2]. With improvements in enterprise operations management and the application of advanced management tools, operating efficiency is being continually enhanced, thereby benefiting enterprise operations.

2.4 Decision Support System

Decision support system (DSS) are computer-based information systems that support knowledge management, decision making, and management reporting to assist managers make decisions in highly uncertain and complex environments. As is known, when making decisions, people weigh up individual opinions and combine them using a thought process to come to a final informed decision. Critically analyzing the nature and state of the history of decision support system (DSS), we can see the evolution of research and practice in areas such as personal DSS, group support systems, negotiation support systems, and knowledge management-based DSS [5]. Aiello et al. proposed a methodological approach to the development of a DSS in the specific context of Integrated Pest Management for intensive greenhouse production and provided an experimental validation based on real data [3]. A hybrid decision support system consisting of a three level humanitarian relief chain: a simulator, a rule-based inference engine, and a knowledge-based system: was designed for a humanitarian relief chain in which three main performance measures were considered for an explicit trade-off analysis between cost efficiency and responsiveness [21]. DSS can be applied to most decision making processes through the research, design and development of strategies to ensure adoption and integration.

3 The Central Issues in the Proceedings Volume I

Literature mining identifies the most pertinent scientific research in areas of particular interest [22] and has proven to be a powerful method for revealing major trends in published scientific literature across the years to allow for topic maps to be built [10]. NodeXL was designed to facilitate the learning of the concepts and methods of social network analysis using visualization as a key component [13] and is a powerful, easy-to-use interactive network visualization tool that leverages the widely available Microsoft Excel application as a platform for representing generic graphical data, performing advanced network analyses, and providing a visual exploration of the networks. NodeXL generally supports multiple social network data providers who import graphical data (node and edge lists) into an Excel sheet, and has also been widely used by researchers [16,19]. Therefore, it plays a vital role in the analysis of the keyword trends in our research. Based on the most popular research topics, we called for papers from around the world. This year, 150 papers were accepted which were divided into two proceedings volumes of 75 papers each. The significance of the keywords lies not only in the frequency or ratio but also in the key word connections that demonstrate how these papers revolve around MS concepts and metrics. Information visualization methods have also proven valuable in discovering patterns, trends, clusters, and outliers, even in complex social networks. We have now received the submissions and sorted the keywords using the software Keywords Match to perform keyword matching and to identify similarities. Finally, the processed keywords were put into the NodeXL software, and the results are shown in Fig. 1.

Fig. 1. Research topics in MS for the Eleventh ICMSEM

From this figure, it is not easy to identify the most important and most heavily researched areas. Further, from calculating and screening keyword degrees greater than six, the following graphical results were obtained. It can be seen the central issues of the eleventh ICMSEM proceedings Volume I have been mainly about computing methodology, data analysis, enterprise operations management and decision support system, as shown as Fig. 2. In the following, we focus on some related papers published in the proceedings to highlight the mainstream research this year.

There was a great deal of interest in the computing methodology section. Usman Rafi et al. discusses various scheduling terms and scheduling algorithms and proposes a new approach for scheduling based on a mixture of MQMS, a priority scheduling mechanism, and round robin scheduling. Lin et al. proposes a Bayesian network based particle swarm optimization (BNPSO) for solving a stochastic scheduling problem. Tahyudin and Nambo determine the rules of numerical association rule mining and also calculate the multi-objective function using a combination of PSO and the Cauchy distribution. Shen et al. proposes an AdaBoost algorithmic model based on a back-propagation neural network

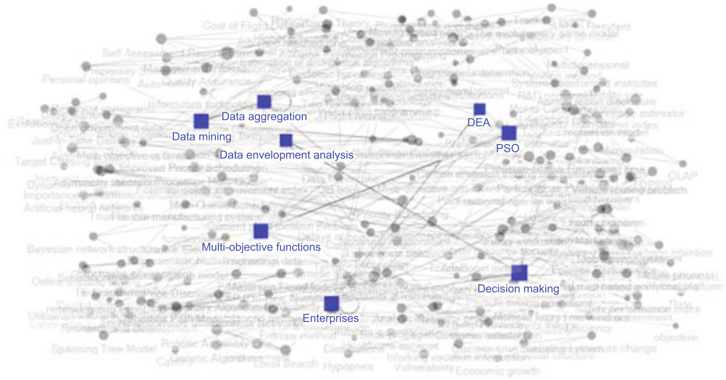

Fig. 2. Research topics in MS for the eleventh ICMSEM

for highly accurate and efficient credit scoring. Both classical and intelligence algorithms are used to develop the model solution.

The data analysis section also presents some innovative work. Yuko et al. provides a method to convert Braille books into machine-readable electronic data. Another interesting study is that in which Yamamoto researches the number of visitors in each period and their characteristics based on mobile phone user location data collected by a mobile phone company. Zeng et al. develops a severity crash count based on a hotspot identification method by extending the traditional empirical Bayes method to a generalized nonlinear model-based mixed multinomial logit approach. In addition, Hu determines the future population trends in Sichuan, China through the establishment of a population development equation. All these papers solve problems by analyzing data and developing useful tools.

For enterprise operations management, Sawada and Yoshida present a novel approach to increase the attractiveness of Facebook pages, Guo et al. uses a Helloing model to analyze the influence of pricing and profit on platform enterprises, Lu uses IPA methods to help identify the strengths and weaknesses of tourist satisfaction towards traditional culture, and Khan et al. provides cognitive support for the development of optimized employee motivation levels through consciousness raising about applied approaches and unrealistic ideas. A method that measures propensity score matching is proposed by Tang to assess how cross listing affects corporate performance. In a word, researchers have studied many aspects of enterprise operations management to improve efficiency and performance.

In the decision support system section, some practical applications to solve decision problems are presented. Pakkak proposes an integrated data envelopment analysis (DEA) and analytic hierarchy process (AHP) approach to obtain attribute weights, Sarwar et al. uses a fuzzy analytical hierarchical process (AHP) and an extent analysis method to choose an appropriate supplier under fuzzy environment, Benmessaoud et al. focuses on the monitoring of a wind farm in real time based on big data collected by the Supervisory Control and Data Acquisition (SCADA) system, and shows how the maintenance decision-making can be assured by the SCADA system, and Zhang et al. provides a corresponding pricing strategy for product crowdfunding, providing inspiration and reference for enterprises and entrepreneurs when making pricing strategy decisions. Integrating modern technology into traditional methods has become a tendency in the study of decision support system.

4 Development Trends for MS and ICMSEM

In this section, we use CiteSpace software to understand the effects of scientific research on future MS research and practice. CiteSpace is citation visualization analysis software based on the analysis of latent knowledge in scientific analysis. CiteSpace, proposed by the Chinese scholar Chen from Drexel University based on Java language, is visual document analysis software that shows the trends and tendencies within a domain of knowledge over a certain period and allows for the identification of the evolution occurring at the research frontier; it has been widely used for knowledge map visualization. The purpose of this work was to visualize and analyze the management science scientific knowledge map. In the "Web of Science" database, "management science" was used as the subject word to search and retrieve articles from 1990 to 2017, from which 62924 articles were identified. To ensure an adequate correlation for the data cleaning, TI = (Management Science) was used as the title word retrieval to exclude other databases and eliminate redundancies, thereby reducing the total to 2231 articles.

4.1 CiteSpace Analysis Results

There are 402 keyword categories and 633 edges in the map for the co-occurring keywords, in which the nodes represent each individual keyword and the lines indicate keyword co-occurrence, with the overall network density being 0.0079. To simplify the display, interactive modification was used on the visualization. By setting up "threshold = 30", we obtained a new keyword co-occurrence network map, as shown in Fig. 3.

However, on the whole, there is a loose structure in the keyword co-occurrence network as the density is not high, indicating that outside collaborations are needed to ensure that sufficient attention is paid to the research subject for international and practical needs. Deeply expanding research around a theme is vital as a lack of breadth and depth is not conducive to the sound development of management science.

In these "Co-occurring keywords", 402 categories appear. To better present the high frequency themes, the top thirty were analyzed and ranked from top to bottom in Table 1.

To investigate the use of different keywords in different time windows, the management keyword frontier research title terms were clustered into 51 categories based on the time statistics and then labelled in sequence. The first ten

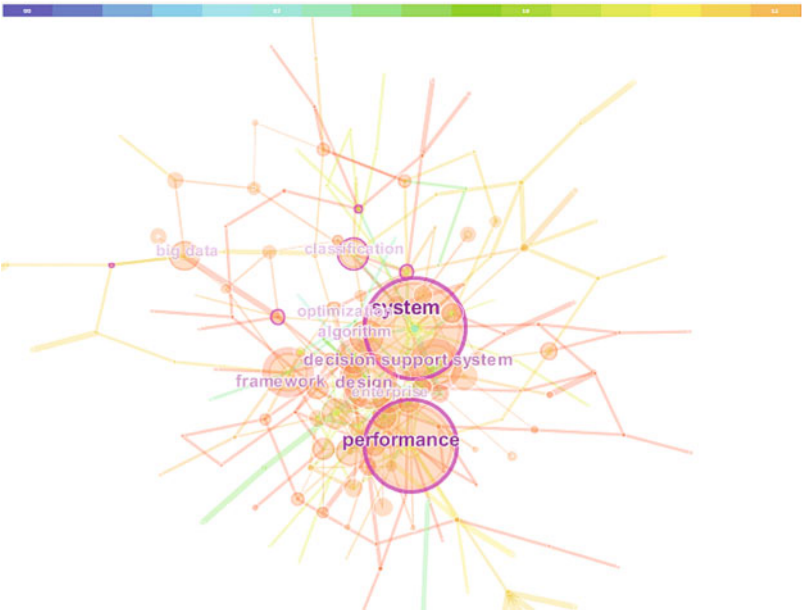

Fig. 3. Results of co-occurring keywords

classes are shown in timezone view in Fig. 4. As can be seen, management science has been in dynamic development at the points where the key word repetition is relatively high; however, there are no stable phases. There were also some indirectly related key words scattered in the small nodes around the center (not shown), which reflected the immaturity in some of the past management science research and the combinations with other research areas.

4.2 Tendency in the ICMSEM Evaluation

To further analyze the popular management science research fields, the research areas were analyzed using "Threshold = 200" in CiteSpace, the results of which are shown in Fig. 5. It can be seen that safety management, uncertainty and weighted objectives, and improved water management were the most popular study areas. From the ICMSEM papers, it can be seen that the research theme directions are similar to the research themes in journal publications. However, there are some small discrepancies between the ICMSEM proceedings volume I themes and the journal publication themes, as the proceedings are focused on innovations and more popular topics.

In addition, Table 2 indicates the highest frequency for the top thirty from the 145 categories. Of these, the most studied areas have been computer science, with the research direction having changed from computer science (2000) to environmental science & ecology (2007) to materials science & multidisciplinary research (2012) over the years. In recent years, research has focused on extending

the range of management science research applications in areas such as resource management, energy management, and education. Though these keywords are not in the top thirty, they are attracting increasing research attention.

When comparing Fig. 2 with the Tables 1 and 2, some of the papers in this volume not only reflect popular research areas but also introduce innovations in other areas. The articles in computing methodology (computer science theory

Fig. 4. Results of clustering keywords

articles included in the ICMSEM proceedings this year appear to be consistent with previous predictions. In the future, the present research vitality will hopefully result in a new round of research so that the ICMSEM continues to highlight the most popular research trends.

5 Conclusion

In this paper, we briefly introduced the four main areas covered in proceedings volume I and summarized previous research in these areas. Using the keyword analysis function in NodeXL, the most prominent topics in these four areas were identified. We also itemized the main research foci in the ICMSEM proceedings Volume I to assist readers better understand the content in this year's papers. Finally, we analyzed the MS and ICMSEM development trends using the literature analysis tool CiteSpace, which found that the research foci in the ICMSEM proceedings volume I are consistent with but slightly different from mainstream MS research. Further work is needed to identify all areas from MSEM journals so as to identify the ICMSEM expectations for the future.

Acknowledgements. The author gratefully acknowledges Jingqi Dai and Lin Zhong's efforts on the paper collection and classification, Zongmin Li and Lurong Fan's efforts on data collation and analysis, and Ning Ma and Yan Wang's efforts on the chart drawing.

Computing Methodology

A Comparison of Pretest, Stein-Type and Penalty Estimators in Logistic Regression Model

Orawan Reangsephet[1(✉)], Supranee Lisawadi[1], and Syed Ejaz Ahmed[2]

Abstract. Various estimators are proposed based on the preliminary test and Stein-type strategies to estimate the parameters in a logistic regression model when it is priori suspected that some parameters may be restricted to a subspace. Two different penalty estimators as LASSO and ridge regression are also considered. A Monte Carlo simulation experiment was conducted for different combinations, and the performance of each estimator was evaluated in terms of simulated relative efficiency. The positive-part Stein-type shrinkage estimator is recommended for use since its performance is robust regardless of the reliability of the subspace information. The proposed estimators are applied to a real dataset to appraise their performance.

Keywords: Monte Carlo simulation · Logistic regression model · Likelihood ratio test · Preliminary test estimator · Shrinkage estimator · Penalty estimator

1 Introduction

For the past few decades, simultaneous variable selection and estimation of submodel parameters has become popular. Many predictors exist to infer an interesting response in the initial model. Some of these predictors may be inactive and not influential; these should be excluded from the final model that represents a sparsity pattern in the predictor space to achieve parsimony, flexibility and reliability. Several researchers, following this information in statistical modeling, have used either the full model or a candidate submodel.

The logistic regression model also called the logit model, is the most widely used for an analysis of the independent binary response data in medical, engineering, and other studies. This model assumes that the logit of the response variable can be modelled by a linear combination of unknown parameters $x_i'\beta$

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_2

where $\mathbf{x_i'} = (x_{i1}, x_{i2}, \cdots, x_{ip})$ is a $p \times 1$ vector of the p predictors for the i^{th} subject and $\beta = (\beta_1, \beta_2, \cdots, \beta_p)'$ is a $p \times 1$ vector of regression parameters. Detailed information on logistic regression can be found in the books by Hilbe [8] and Hosmer and Lameshow [10].

In this article, we consider the problem of estimating the logistic regression model when the response variable may be related to many predictors, some of which may be inactive. Prior information about inactive predictors may be incorporated in the full model to produce the candidate submodel.

The pretest (preliminary test) estimation strategy, is inspired by Bancroft, and the shrinkage estimation strategy, is inspired by Stein, efficiently combine both full model and submodel estimators in an optimal way to achieve an improved estimator. Numerous authors have discussed the pretest, shrinkage, and penalty estimation strategies in many fields including Ahmed and Amezziane [2], Ahmed and Yüzbaşı [4], Al-Momaniet et al. [5], Gao, Ahmed, and Feng [6], Hossain, Ahmed, and Doksum [12], and Yüzbaşı and Ahmed [16,17]. For a logistic regression model, shrinkage estimators and three penalty estimators as LASSO, adaptive LASSO and SCAD were considered by Hossain and Ahmed [11] and Lisawadi, Shah, and Ahmed [13] considered the pretest estimation.

As we know, ridge regression (Hoerl and Kennard [9]) has been widely used when there are many possible predictors to achieve the precision of an estimate. Ahmed et al. [3] found that the ridge regression is highly efficient and stable when there are many predictors with small effect. Hence, we suggest the ridge regression for a logistic regression model. In this article, we propose the pretest and shrinkage estimators in the logistic regression model when it is priori suspected that parameters may be restricted to a subspace and compares the resulting estimators to the classical maximum likelihood estimator as well as the penalty estimators, i.e. LASSO estimator and ridge regression. Monte Carlo simulation study is carried out using the simulated relative efficient to appraise the performance of the proposed estimators.

To further illustrate the proposed estimators in the logistic regression model, we apply the proposed estimator to the South African heart disease data set and provide a bootstrap approach to compute simulated relative efficiency (SRE) and simulated relative prediction error (SPE) of the estimators. The detail of this data set will be described in the Sect. 4. Hossain, Ahmed, and Doksum [12] also considered this data in the generalized linear model via the pretest estimator, positive-part Stein-type shrinkage estimator, and three penalty estimators as LASSO, adaptive LASSO, and SCAD The performance of these estimators are evaluated in terms of simulated relative efficient (SRE).

Under the prior information about inactive predictors, the full parameter vector β can be partitioned as $\beta = (\beta_1', \beta_2')'$ where β_1 and β_2 represent a $p_1 \times 1$ active parameter and a $p_2 \times 1$ inactive parameter subvector, respectively, such that $p = p_1 + p_2$. Therefore, our interest lies in the estimation of the active parameter subvector β_1 when the information on β_2 is readily available. In other words, this information about the inactive parameters may be used to estimate the active parameter subvector β_1 when their values are near to some specified value β_2^0. Without the loss of generality, it is plausible that β_2 may be set to a zero vector, $\beta_2 = 0$. Keep in mind that the candidate submodel estimator is more efficient than the full model estimator when the candidate submodel is correct. On the other hand, the submodel estimator may not be reliable and become considerably inefficient when the candidate submodel incorrectly represents the data at hand.

The remainder of this article is organized as follows; the model and the efficient estimation strategies are proposed in Sect. 2, the results of a Monte Carlo simulation study are reported in Sect. 3, real data applications are described in Sect. 4, and finally, discussions and conclusions are presented in Sect. 5.

2 Model and Estimation Strategies

Let $y_1, y_2, \cdots, y_n$ be independent binary response variables which contain only two possible outcomes, and $\mathbf{x_i} = (x_{i1}, x_{i2}, \cdots, x_{ip})'$ is a $p \times 1$ predictors vector for the i^{th} subject and $i = 1, 2, \cdots, n$. The simplest idea would be to let z_i be a linear function of the predictors, suppose

$$z_i = \mathbf{x_i'}\beta, \tag{1}$$

where β is a $p \times 1$ vector of regression coefficients. Thus, the logistic regression model assume that

$$P\left(y_i = 1|\mathbf{x}_i\right) = \pi\left(z_i\right) = \frac{\exp\left(z_i\right)}{1 + \exp\left(z_i\right)} = \frac{\exp\left(\mathbf{x}_i'\beta\right)}{1 + \exp\left(\mathbf{x}_i'\beta\right)}. \tag{2}$$

The log-likelihood function of the logistic regression model is given by

$$l\left(\beta\right) = \sum_{i=1}^{n} y_i \ln\left\{\pi(\mathbf{x}_i'\beta)\right\} + \sum_{i=1}^{n}(1 - y_i)\ln\left\{1 - \pi\left(\mathbf{x}_i'\beta\right)\right\}. \tag{3}$$

The derivative of the log-likelihood function with respect to β is obtained by solving the score equation:

$$\frac{\partial l\left(\beta\right)}{\partial\beta} = \sum_{i=1}^{n}\left[y_i - \pi(\mathbf{x}_i'\beta)\right]\mathbf{x}_i = 0. \tag{4}$$

2.1 The Unrestricted and Restricted Maximum Likelihood Estimator

The unrestricted maximum likelihood estimator (UE) of the parameter vector β denoted by $\hat{\beta}^{UE}$ is obtained by solving the non-linear score Eq. 4, and this can be solved by using an iterative method like Newton-Raphson.

Under the certain regularity conditions of maximum likelihood estimator (MLE), Gourieroux and Monfort [7] showed that $\hat{\beta}^{UE}$ is a consistent estimator of β and asymptotically normally distributed with a variance-covariance matrix $(I(\beta))^{-1}$, where $I(\beta)$ is the information matrix which is defined as

$$I(\beta) = \sum_{i=1}^{n} \pi(\mathbf{x}_i^{'}\beta)\left\{1 - \pi(\mathbf{x}_i^{'}\beta)\right\}\mathbf{x}_i\mathbf{x}_i^{'}. \tag{5}$$

The restricted maximum likelihood estimator (RE) of β denoted by $\hat{\beta}^{RE}$ can be obtained by maximizing the log-likelihood function (3) under the subspace restriction $\beta_2 - \beta_2^0 = 0$.

2.2 The Linear Shrinkage Estimator

The linear shrinkage estimator (LS) of β denoted by $\hat{\beta}^{LS}$ is a linear combination of the unrestricted and restricted estimator, that is

$$\hat{\beta}^{LS} = \lambda\hat{\beta}^{RE} + (1-\lambda)\,\hat{\beta}^{UE}, \lambda \in [0,1], \tag{6}$$

where λ defines the degree of confidence in the given prior information and is a fixed constant. The linear shrinkage estimator shrinks $\hat{\beta}^{UE}$ toward $\hat{\beta}^{RE}$. If $\lambda = 0$, then LS simplifies to an unrestricted estimator, while it simplifies to a restricted estimator when $\lambda = 1$. The performance of the linear shrinkage estimator is better than the unrestricted and restricted MLE in some part of the parameter space.

2.3 The Preliminary Test Estimator

The preliminary test estimator or pretest estimator (PT) of β denoted by $\hat{\beta}^{PT}$ is defined as

$$\hat{\beta}^{PT} = \hat{\beta}^{UE} - \left(\hat{\beta}^{UE} - \hat{\beta}^{RE}\right) I\left(\mathscr{L}_n \leq \mathscr{L}_{n,\alpha}\right), \tag{7}$$

where $I(.)$ is an indicator function, and $\mathscr{L}_{n,\alpha}$ is the α-level critical value of the exact distribution of a suitable test statistic $\mathscr{L}_n$ under $H_0 : \beta_2 = \beta_2^0$. For testing $H_0 : \beta_2 = \beta_2^0$, the likelihood ratio statistic $\mathscr{L}_n$ is suggested:

$$\mathscr{L}_n = -2\log\left(\frac{L\left(\hat{\beta}^{RE}\right)}{L\left(\hat{\beta}^{UE}\right)}\right) = 2\left(l\left(\hat{\beta}^{UE}\right) - l\left(\hat{\beta}^{RE}\right)\right), \tag{8}$$

where $l(\hat{\beta}^{UE})$ and $l(\hat{\beta}^{RE})$ are values of the log-likelihood at the unrestricted and restricted estimates, respectively. Under H_0, the distribution of $\mathscr{L}_n$ converges to Chi-square distribution with p_2 degree of freedom as $n \to \infty$.

Clearly, the pretest estimator takes the value of the unrestricted estimator when the test statistic lies in a rejection region, otherwise, it takes the value of the restricted estimator. This estimator has limits due to the large size of the pretest.

2.4 The Shrinkage Pretest Estimator

The shrinkage pretest estimator (SP) of β denoted by $\hat{\beta}^{SP}$ is defined by replacing the restricted estimator with the linear shrinkage estimator in Eq. (7), that is

$$\hat{\beta}^{SP} = \hat{\beta}^{UE} - \left(\hat{\beta}^{UE} - \hat{\beta}^{LS}\right) I\left(\mathscr{L}_n \leq \mathscr{L}_{n,\alpha}\right). \tag{9}$$

An alternative form of the estimator is

$$\hat{\beta}^{SP} = \hat{\beta}^{UE} - \lambda\left(\hat{\beta}^{UE} - \hat{\beta}^{RE}\right) I\left(\mathscr{L}_n \leq \mathscr{L}_{n,\alpha}\right). \tag{10}$$

Ahmed [1] found that the shrinkage pretest estimator significantly improves upon the pretest estimator in terms of size α, and it dominates the unrestricted estimator in a large portion of the parameter space. For $\lambda = 1$, the pretest estimators are used to estimate the parameter, while we use a UE as $\lambda = 0$. Generally, the estimators based on the pretest strategy are biased and inefficient when the null hypothesis does not hold.

2.5 The Stein-Type Shrinkage Estimator

The Stein-type shrinkage estimator which combines the unrestricted and the restricted estimator in an optimal way to dominate the unrestricted estimator. The Stein-type shrinkage estimator (S) of β denoted by $\hat{\beta}^{S}$ is given as follows

$$\hat{\beta}^{S} = \hat{\beta}^{RE} + \left(1 - (p_2 - 2)\,{\mathscr{L}_n}^{-1}\right)\left(\hat{\beta}^{UE} - \hat{\beta}^{RE}\right), p_2 \geq 3, \tag{11}$$

alternatively,

$$\hat{\beta}^{S} = \hat{\beta}^{UE} - (p_2 - 2)\,{\mathscr{L}_n}^{-1}\left(\hat{\beta}^{UE} - \hat{\beta}^{RE}\right), p_2 \geq 3. \tag{12}$$

For some insight to this estimator, we refer to Hossain, Ahmed, and Doksum [12], Yüzbaşı and Ahmed [17] among others. The Stein-Type shrinkage estimator will provide uniform improvement over the unrestricted estimator. However, the Stein-type shrinkage estimator tends to over-shrink the unrestricted estimator towards the restricted estimator when the test statistic $\mathscr{L}_n$ is very small in comparison with $p_2 - 2$. To avoid the over-shrink behavior of this estimator, the truncated version is suggested which is called the positive-part Stein-type shrinkage estimator.

2.6 The Positive-Part Stein-Type Shrinkage Estimator

The positive-part Stein-type shrinkage estimator (S^{+}) of β denoted by $\hat{\beta}^{S^{+}}$ is a convex combination of the unrestricted and restricted estimator, that is

$$\hat{\beta}^{S^{+}} = \hat{\beta}^{RE} + \left(1 - (p_2 - 2)\,\mathscr{L}_n^{-1}\right)^{+}\left(\hat{\beta}^{UE} - \hat{\beta}^{RE}\right), p_2 \geq 3, \tag{13}$$

where $a^+ = \max\{0, a\}$. Alternatively, it can be written in the following conical form as

$$\hat{\beta}^{S^+} = \hat{\beta}^{RE} + \left(1 - (p_2 - 2)\,\mathscr{L}_n{}^{-1}\right)\left(\hat{\beta}^{UE} - \hat{\beta}^{RE}\right) I\left(\mathscr{L}_n < (p_2 - 2)\right), p_2 \geq 3. \quad (14)$$

The positive-part Stein-type shrinkage estimator is particularly important to control the over-shrinking inherent in $\hat{\beta}^S$.

2.7 The LASSO Estimator

Tibshirani [15] introduced the LASSO estimator of β which minimizes the negative log-likelihood in Eq. (3) under the L_1 constraint. It can be defined as

$$\hat{\beta}^{\text{LASSO}} = \operatorname{argmin}_{\beta}\left\{-l(\beta) + \gamma \sum_{i=1}^{p} |\beta_i|\right\}, \gamma \geq 0, \quad (15)$$

where λ is the tuning parameter which controls the amount of a shrinkage. The LASSO shrinks some coefficients to exactly zero. Therefore, LASSO procedure performs variable selection and parameter estimation simultaneously.

2.8 The Ridge Regression Estimator

Hoerl and Kennard [9] proposed the ridge regression estimator of β which minimizes the negative log-likelihood in Eq. (3) under the L_2 constraint. It can be defined as

$$\hat{\beta}^{RIDGE} = \arg\min_{\beta}\left\{-l(\beta) + \gamma \sum_{i=1}^{p} {\beta_i}^2\right\}, \gamma \geq 0, \quad (16)$$

where λ is a tuning parameter which controls the amount of shrinkage. The ridge regression estimator always keeps all the predictors in the model; thus, this estimator cannot produce a parsimonious model.

3 Monte-Carlo Simulation Studies

In this section, we carry out a Monte Carlo simulation to compare the performance of the pretest, Stein-type and penalty estimators in terms of the quadratic risk, namely mean squared error (MSE). Our simulations are based on a logistic regression model with the sample size $n = 250$. A binary response data is generated from the following model

$$\ln\left(\frac{p_i}{1 - p_i}\right) = \mathbf{x_i}'\beta = \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots + \beta_p x_{ip}, \quad i = 1, 2, \cdots, n, \quad (17)$$

where $p_i = P(y_i = 1|\mathbf{x_i})$ and the predictor values $\mathbf{x_i}$ have been drawn from a standardized multivariate normal distribution.

We consider the hypothesis $H_0 : \beta_2 = 0$. We partition the parameter vector β as $\beta = (\beta_1', \beta_2')'$ and where β_1 and $\boldsymbol{\beta_2}$ represent a $p_1 \times 1$ and a $p_2 \times 1$ vector, respectively, such that $p = p_1 + p_2$. We set the true value of $\beta = (\beta_1', \beta_2')' = (\beta_1', 0)'$ with $\beta_1' = (1.90, -1.05, 0.25, -0.78)$.

The value of λ is set to 0.25, 0.50, and 0.75. The value of significance level α is set to 0.01, 0.05, 0.10 and a higher value 0.35.

We now define the parameter Δ^* representing the distance between the simulated model and the candidate submodel estimator by

$$\Delta^* = \left(\beta - \beta^{(0)}\right)' \left(\beta - \beta^{(0)}\right) = \sum_{i=1}^{p} \left(\beta_i - \beta_i^{(0)}\right)^2, \tag{18}$$

where $\beta^{(0)} = \left(\beta_1^{'}, 0\right)^{'}$ and β is the true parameter in the simulated model. Samples were generated using Δ^* between 0 and 4.

The number of replications in the simulation was initially varied and it was determined that $N = 1,000$ iterations were adequate to obtain a stable result for each combination of parameters.

Based on the simulated data, we estimated the MSE of all the proposed estimators. The performance of the estimators was evaluated using the notion of simulated relative efficient (SRE), which is the MSE relative to the MSE of $\hat{\beta}^{UE}$. For any estimator $\hat{\beta}^*$, the SRE of $\hat{\beta}^*$ with respect to $\hat{\beta}^{UE}$ is defined as

$$SRE\left(\hat{\beta}^{UE}, \hat{\beta}^*\right) = \frac{\text{SimulatedMSE}(\hat{\beta}^{UE})}{\text{SimulatedMSE}(\hat{\beta}^*)} = \frac{\text{Simulated } \sum_{i=1}^{p} \left(\beta_i - \beta_i^{UE}\right)^2}{\text{Simulated } \sum_{i=1}^{p} \left(\beta_i - \beta_i^{*}\right)^2}. \tag{19}$$

Keep in mind that an SRE is larger than the one that indicates the degree of superior of the estimator $\hat{\beta}^*$ over $\hat{\beta}^{UE}$.

3.1 Model with Correct Candidate Submodel ($\boldsymbol{\Delta^* = 0}$)

First, the case when the candidate submodel is assumed to be correct, is $\Delta^* = 0$. Various choices of active and inactive predictors are provided for $(p_1, p_2) = (4, 3), (4, 5), (4, 7), (4, 10)$, and $(4, 15)$, and the SRE results are reported in Tables 1, 2 and 3. The tuning parameter γ of the two penalty estimators is estimated using 10 fold-cross validation. The findings from Tables 1, 2 and 3 are summarized as follows:

We note that SREs of all the estimators increase as the number of inactive predictors $_2$ is increased for fixed λ and α. Interestingly, the restricted estimator is the best, and all estimators are superior to the unrestricted estimator for all configurations except the ridge regression estimator. The linear shrinkage estimator depends on the choice of λ. Its SRE decreases sharply to 1 as $\lambda \to 0$ and approaches to SRE of the restricted estimator for higher value of λ. The SREs of the pretest estimators depend on the size of the test α. For small α,

Table 1. The SREs of the estimators with respect to the UE for $\lambda = 0.25$ at $\Delta^* = 0$.

the pretest estimator is comparable to that of the restricted estimator. On the contrary, its SRE decreases as the size increases.

Moreover, the performance of the shrinkage pretest estimator depends on the choice of λ and α. Its performance becomes poorer with an increase in and a decrease in λ. Unsurprisingly, the pretest estimator outperforms the linear shrinkage estimator at $\Delta^* = 0$. As we would expect, the positive-part Stein-type shrinkage estimator outperforms the Stein-type shrinkage estimator in any situation.

Similar results are observed for the LASSO estimator which performs better than the estimator based on the Stein-type strategy for small p_2. On the other hand, the estimator based on the Stein-type strategy is preferable when there are many inactive predictors. However, the ridge regression estimator does not perform well, but its performance slowly improves as the number of inactive predictors increases.

3.2 Model with Correct and Incorrect Candidate Submodel ($\boldsymbol{\Delta^* \geq 0}$)

The penalty estimators are not included in the $\Delta^* > 0$ case because these estimators do not take advantage of the fact that the regression parameter lies in the subspace $\beta_2 = 0$. In this case, the simulation model has an active coefficient vector $\beta_1 = (0.5, -1.5, 0.2)$ and inactive coefficient vector $\beta_2 = (\beta_4, a)$ where β_4 is a scalar and assumes various values; thus, $\Delta^* = (\beta_4)^2$ when the candidate submodel is used. We choose $\beta_4 = 0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.8, 1.0, 1.5,$ and 2.0

and a is $k \times 1$ zero vector with different dimensions, $k = p_2 - 1$ to be the number of inactive predictors in the model and we use $p_2 = 5, 7, 10$, and 15 in the simulations.

The choice of α was fixed to be 0.01, 0.05, 0.10, $\lambda = 0.75$ and $n = 250$. SREs of the proposed estimators are are reported in Table 4 are graphically represented in Figs. 1, 2 and 3. The findings are summarized as follows:

The restricted estimator $\hat{\beta}^{RE}$ outperforms all the estimators at and near $\Delta^* = 0$. In contrast, as Δ^* becomes larger than zero, the relative efficiency of $\hat{\beta}^{RE}$ as well as the linear shrinkage estimator decrease and become unbounded. However, the relative efficiency of all the other estimators remains bounded and approaches to 1. These show that an incorrect candidate submodel is fatal to the restricted and linear shrinkage estimators.

The pretest estimator is much better than the shrinkage pretest estimator when the candidate submodel is correct, i.e. $\Delta^* = 0$. On the contrary, the shrinkage pretest estimator does well relative to the pretest estimator in a small part of the parameter space. However, the SRE of both pretest and shrinkage pretest estimators approaches to one as Δ^* moves away from zero, but after becoming inferior to $\hat{\beta}^{UE}$, and later at some point, they join the SRE of one from below. In addition, they outshine the estimator based on Stein-type strategy where Δ^* is near zero and for small and moderate p_2. The estimators based on Stein-type strategy are superior to the unrestricted estimator in the entire range of Δ^* especially their gain in risk reduction is impressive as p_2 increases. Lastly, we found that the estimators based on Stein-type strategy perform better than all other estimators in the wider range of Δ^* and these estimators are little impacted by severe departure from the restriction.

4 Real Data Example: South African Heart Disease Data

In this section, we apply the proposed estimators to the South African heart disease data set. Rousseauw et al. [14] described a retrospective sample of males in a heart-disease high-risk region of the Western Cape, South Africa. This study comprised over 462 samples and the set of variables is described in Table 5.

We notice that the condition index (CI) value is calculated as 392.718 which implies the existence of multicollinearity in this data set. After applying the variable selection procedure based on AIC criterion, BIC criterion, and LASSO, the results are given in Table 6.

Table 6 shows that the candidate submodel based on AIC and BIC criteria contains 5 active predictors, while LASSO selection procedure contains 7 active predictors. Hence, we will consider the candidate submodel with 5 active predictors that is tobacco, famhist, ldl, typea, and age. The restricted subspace is $\beta_2' = (\beta_{\text{adiposity}}, \beta_{\text{obesity}}, \beta_{\text{alcohol}}, \beta_{\text{sbp}}) = (0, 0, 0, 0), p = 9, p_1 = 5$, and $p_2 = 4$.

To examine the performance of the proposed estimators for the candidate submodel, we draw $m = 250$ bootstrap rows with replacement $N = 1,000$ times from the data. The performance of the proposed estimators with respect to the

AIC,BIC	Chd	tobacco, famhist, ldl, typea, age

unrestricted estimator is evaluated by simulated relative efficiency (SRE) and simulated relative prediction error (SPE) of the estimators which is defined as:

$$\text{SRE}\left(\hat{\beta}^{UE}, \hat{\beta}^{*}\right) = \frac{\text{Simulated } \sum_{i=i}^{p}\left(\beta_i^{\text{true}} - \hat{\beta}_i^{UE}\right)}{\text{Simulated } \sum_{i=1}^{p}\left(\beta_i^{\text{true}} - \hat{\beta}_i^{*}\right)}$$

$$\text{and SPE}\left(\hat{\beta}^{UE}, \hat{\beta}^{*}\right) = \frac{\text{Simulated } \sum_{i=1}^{m}\left(Y_i - \pi(\mathbf{x}'_i\hat{\beta}^{UE})\right)}{\text{Simulated } \sum_{i=1}^{m}\left(Y_i - \pi(\mathbf{x}'_i\hat{\beta}^{*})\right)}, i = 1, 2, \cdots, m.$$

Note that SPE is less than one; this means the unrestricted estimator is doing better. This study assumed the empirical distribution $\hat{F}$ based on 462 actual observations to be the true distribution and the resulting logistic regression coefficient $\hat{\beta}$'s to be the true parameter values. We assumed $\alpha = 0.01$ and $\lambda = 0.50$. The results of the point estimates, standard errors, SREs, and SPEs of the estimators are shown in Table 7.

Table 7 reveals that the restricted estimator is the best, and all the estimators outperform the unrestricted estimator. The performance of linear shrink-

age, pretest, and shrinkage pretest estimators is dominated by the restricted estimator as our data in the resampling scheme are generated from an empirical distribution where the candidate submodel is correct, that is $\Delta^* = 0$.

Furthermore, the positive-part Stein-type shrinkage estimator outshines the LASSO estimator when there are moderate or relatively large numbers of the inactive predictor in the model. In fact, the true parameter values are not exactly zero, and there is the multicollinearity problem. Unsurprisingly, the ridge regression estimator performs well. Lastly, the LASSO estimator shows good performance in terms of SRE but not in terms of SPE because of the instability estimation.

5 Discussion and Conclusions

In this article, we compared various estimators based on pretest and Stein-type strategy and two penalty estimators to the unrestricted and restricted maximum likelihood estimators in the context of the logistic regression model under the restriction of parameter. We established the properties of the proposed estimators via Monte Carlo simulation study.

By using Monte Carlo simulation study, we found that the performance of a restricted maximum likelihood estimator depends heavily on the quality of the candidate submodel. The restricted maximum likelihood estimator is the best estimator when the candidate submodel is correct or nearly correct. For any scenario, the estimators based on Stein-type strategy outperform the unrestricted maximum likelihood in the entire parameter space, especially the truncated version of the Stein-type shrinkage estimator. On the contrary, the performance of the estimators based on the preliminary test procedure lacks this property. The LASSO estimator is preferable to the Stein-type estimators when the number of inactive predictors is small. In contrast, the Stein-type estimators dominate the LASSO estimator only when the number of inactive predictors is relatively large. The ridge regression cannot produce a parsimonious model, thus the ridge regression estimator does not perform well when the model is sparse. However, the positive-part Stein-type shrinkage estimator is robust. It would be interesting, therefore, to investigate the relative performances of adaptive LASSO and smoothly clipped absolute deviation (SCAD) estimators. We will leave this for further consideration.

Abstract. To solve the moJSRP model, with the framework of proposed MoEDA, the probability model of the operation sequence is estimated firstly. For sampling the processing time of each operation with the Monte Carlo methods, allocation method is used to decide the operation sequence, and then the expected makespan and total tardiness of each sampling are evaluated. Subsequently, updating mechanism of the probability models is proposed according to the best solutions to obtain. Finally, for comparing with some existing algorithms by numerical experiments on the benchmark problems, we demonstrate the proposed effective estimation of distribution algorithm can obtain an acceptable solution in the aspects of schedule quality and computational efficiency.

Keywords: Job shop rescheduling · Multi-objective optimization · Estimation of distribution algorithms

1 Introduction

In current manufacturing systems, production processes and management are involved in many unexpected events and new requirements are emerging constantly. For modern flexible decision making in manufacturing systems it is necessary to adapt the unexpected changes with rescheduling processes. As a result, production managers in the volatile environment have to generate high quality schedules [3,8]. Rescheduling is defined as periodically or event-driven operation to better arranging activities for the next time period based on both the state of the system and the vested schedule. Many literatures have reported researches on the rescheduling topic. Typically, Vieira et al. presented a comprehensive survey for most applications of rescheduling in manufacturing systems [8]. This methodology is summarized in Table 1.

In this paper, job shop rescheduling problem (JSRP) in dynamic environment will be studied, more specifically, the study takes into account the effect of random job arrivals and machine breakdowns. Since JSRP is ubiquitous in manufacturing systems, it has attracted great attention to design optimization methods

for finding the desired effective solutions. It is well-known that Job shop scheduling problem is NP-hard, and various methods have been introduced to obtain optimum solutions. From the practical point of view, many dispatching rules and composite dispatching rule have been developed for the JSRP [8]. Sabuncuoglu and Kizilisik proposed several reactive scheduling policies and tested their performances with various experimental conditions, processing time variations, and random machine breakdown Table 1. Sha and Liu presented extended data mining tools for extracting knowledge of job scheduling with respect to due date assignment in a dynamic job shop environment [7]. Vinod and Sridharan presented the salient aspects of a simulation-based experimental study on scheduling rules in a dynamic job shop where the setup times are sequence dependent [9]. However, a key challenge is to balance available capacities among jobs at different processing stages, especially in the shops with re-entrant flow, like those in semiconductor wafer fabrication plants [5]. Furthermore, in job shop rescheduling, job arrival of specific product is often unexpected, critical job information is not available in advance which would eliminate schedulers to anticipate future workloads effectively. However, all these researches transform the multi-objective problem to a single objective problem using a weighting method. They do not discuss the implications of non-dominated solutions for the multi-objective dynamic job shop scheduling problems.

In this paper, to solve the moJSRP model, with the framework of proposed MoEDA, the probability model of the operation sequence is estimated firstly. For sampling the processing time of each operation with the Monte Carlo methods, allocation method is used to decide the operation sequence, and then the expected makespan and total tardiness of each sampling are evaluated. Subsequently, updating mechanism of the probability models is proposed according to the best solutions to obtain.

The rest of the paper is organized as follows: in Sect. 2, the mathematical model of moJSRP is formulated; Sect. 3 describes the proposed EDA-based approach for solving the moJSRP; in Sect. 4, the computational experiments and analysis of results are presented; finally, Sect. 5 gives the summary and the conclusions of this research.

2 Mathematical Formulation

(1) Assumption

The job shop scheduling problem (JSP) concerns with the determination of the operation sequences on the machines so that the makespan is minimized. It may consist of several assumptions as follows:

A1. Each machine processes only one job at a time.
A2. Each job is processed on one machine at a time.
A3. Jobs never visit the same machine twice.
A4. For each operation, the processing time and machine assignment are known in advance.
A5. There are no precedence constraints among operations of different jobs.
A6. Operations cannot be interrupted.
A7. Neither release times nor due dates are specified.

For a new job arrival, the following assumptions are given:

A8. The 1rst operation of the new job has to be started after the processing operation is finished on one machine.
A9. For new job, the processing time and machine assignment of each operation are determinate.
A10. There are no precedence constraints between operations of original jobs and new job.
A11. For new job, neither release times nor due dates are specified.

The JSP has already been confirmed as one of the NP-hard combinatorial problems. There are N jobs and M machines to be scheduled; furthermore, each job is composed of a set of operations and the operation order on machines is pre-specified. Each operation is characterized by the required machine and the fixed processing time [3].

(2) Notation

Indices:

i, i', k: job index; where i is original job index, i' is any job index, k is the index of new arrival job;
j, j', l: operation index; where j is operation index of original job, j' is any operation index of any job, and l is the operation index of new arrival job.

Parameters:

J: number of original jobs;
N: number of new jobs;
M: number of machines;
N_i: number of operations of original job i;
N_k: number of operations of new job k;
o_{ij}: operation j of original job i;
o_{kl}: operation l of new job k;
$o_{i'j'}$: operation j' of any job i';
m_{ij}: machine on which operation is to be assigned;
p_{ij}: processing time of operation o_{ij};
p_{kl}: processing time of operation o_{kl};
t_ij: begin time of original operation o_{ij};
t_b: predefined time at which schedule is renewed, i.e., rescheduling point'.

Decision Variables:

t'_{ij}: begin time of operation o_{ij} in the original schedule;
t'_{kl}: begin time of operation o_{kl} in the new schedule.

The first objective Eq. (1) of the moJSRP is to minimize the makespan of new job. The second objective Eq. (2) is to minimize the costs caused by disruption on original schedule, where the term Δt_{ij} and $\Delta\bar{t}$ denote the deviation and its mean of begin time respectively in the original schedule.

$$\min \ t_{MS} = \max_k (t'_{kN_k} p_{kN_k}) \tag{1}$$

$$\min \ \sigma = \frac{1}{\sum_i N_i} \sum\nolimits_i \sum\nolimits_j (\Delta t_{ij} - \Delta\bar{t})^2 \tag{2}$$

$$\text{where } \Delta t_{ij} = \left| t_{ij} - t'_{ij} \right| \tag{3}$$

$$\Delta\bar{t} = \frac{1}{\sum_i N_i} \sum\nolimits_i \sum\nolimits_j |\Delta t_{ij}| \tag{4}$$

$$\text{s. t.} \ \left(t'_{t,l-1} + p_{k,i-1}\right) \leq t'_{kl}, \forall k, l > 1 \tag{5}$$

$$(t_{i'j'} - (t_{ij} + p_{ij})) \wedge (t_{ij} - (t_{i'j'} + p_{i'j'})) + \psi \left| m_{ij} - m_{i'j'} \right| \geq 0, \forall o_{ij}, o_{i'j'} \tag{6}$$

$$t'_{ij} = t_{ij}, t_{ij} \leq t_b \tag{7}$$

$$t'_{ij} > 0, \forall i, j \tag{8}$$

$$t'_{kl} > 0, \forall k, l, \tag{9}$$

where, inequity (5) ensures that the $(l-1)^{th}$ operation of job k should be processed before the $l-th$ operation in the same job. Equation (6) expresses the operation precedence constraints. Equation (7) ensures that the original operations that are fixed for execution at the rescheduling point cannot be changed. Inequities (8) and (9) represent the nonnegative restrictions.

3 Effective Multiobjectives Estimation of Distribution Algorithm

3.1 A Descriptive Analysis of Air Pollution and Death Data

The multiple objective optimization problems have been receiving growing interest from researchers with various backgrounds since early 1960. There are a number of scholars who have made significant contributions to the problem. In the paper, we present a scheme of hybrid multiobjective estimation of distribution algorithm (h-MoEDA). In h-MoEDA, MoEDA takes care of exploration that tries to identify the most promising search space regions, and modeling the distribution of the stochastic variables. For NP-hard combinatorial optimization problems, it became necessary that the global search dynamics of EDAs ought to be complemented with local search refinement [6]. Variable neighborhood search (VNS) is proposed to improve the solution quality, and the simple principle for driving this improvement is based on the systematic change of neighborhood within a possibly randomized local search.

In Fig. 1, h-MoEDA starts by generating the solutions kept in the population randomly. The set of solutions of high fitness, which refers to promising solutions, is selected from the population using a selection method, and the promising solutions are used to learn the probability model. Thereafter, probabilities defined by the probability model are estimated, and the new candidate solutions

Hybrid moEDA routine

Input:
X: $X = (X_1, X_2, \ldots, X_n)$, vector of the decision variables.
$popSize$: number of the population solutions kept by moEDA.
gen : number of the generations (iterations).
$prRate$: rate of the promising solutions kept by moEDA.
$elimRate$: elimination rate of the keeping promising solutions.
Output:
S_{best}: the best Pareto solution.

begin
Initialization:
Step 1: $t \leftarrow 0$.
Step 2: Initialize the population $Pop(0)$ with the size $popSize$ solutions randomly.
Step 3:Calculate objectives $f_k(Pop), k = 1, \ldots, q$ by decoding routine.
Step 4 Create Pareto optimal solutions $E(Pop)$ by nondominated routine.
Step 5 Calculate fitness $eval(Pop)$ by HSS-EA routine and keep best Pareto solution S_{best}.
Optimization:
while *terminating criteria are not met* **do**
Step 6: Select the promising data set D from $Pop(t)$ consisting of $popSize \times prRate$ solutions.
Step 7: Estimate the probabilities $p(x_i)$ for each variable X_i over the set D, and sample $candidates$ based on the $p(x_i)$.
Step 8: Perform a problem-specific local search $DoLocalSearch(candinates)$.
Step 9:Calculate objectives $f_k(Pop), k = 1, \ldots, q$ by decoding routine.
Step 10:update Pareto optimal solutions $E(Pop)$ by nondominated routine.
Step 11 Calculate fitness $eval(Pop)$ by HSS-EA routine and keep best Pareto solution S_{best}.
Step 12: Replace $popSize \times elimRate$ worse items of the keeping population solutions with the best solutions $candidates$.
Step 13: $t \leftarrow t + 1$.
end
end

Fig. 1. Pseudo-code for h-MoEDA

are sampled according to the given sampling method. For a candidate solution, problem specific local search algorithm is used to improve each candidate solution to reach a local optimum. Finally, the new solutions are evaluated, and these with high fitness are incorporated into a solution pool, which keeps these individuals contributing to the makeup of promising solutions. The iteration will continue until the predefined termination criteria are met.

The following subparagraph presents the vital components of the proposed h-MoEDA in detail. Firstly, the representation of a chromosome for an individual is described. Then, transition probability model is presented. Finally, fitness assignment mechanisms are discussed.

3.2 Solution Representation

The representation of the operation sequence uses job-based encoding [1], and the length of the chromosome equals the total number of operations. The job number denotes the operation of each job, and the l^{th} occurrence of a job number refers to the l^{th} operation in the sequence of this job. Figure 1 presents an example considering a rescheduling with a 4 jobs and 3 machines.

ID	1	2	3	4	5	6	7	8	9	10	11	12
Operation	o_{11}	o_{12}	o_{13}	o_{21}	o_{22}	o_{23}	o_{31}	o_{32}	O_{33}	o_{41}	o_{42}	O_{43}
Chromosome v	-	4	7	-	-	3	-	-	6	1	2	5

Fig. 2. Illustration of the representation of a solution for moJSRP

Giffler-Thompson based heuristic algorithm [4] based decoding procedure is applied to generate a feasible schedule. This produces a timetable with the start and end of the processing period, and the makespan time. The Gantt chart of this solution is illustrated in Fig. 3.

ID	1	2	3	4	5	6	7	8	9	10	11	12
Operation	o_{11}	o_{12}	o_{13}	o_{21}	o_{22}	o_{23}	o_{31}	o_{32}	O_{33}	o_{41}	o_{42}	O_{43}

Fig. 3. Gantt chart of the schedule encoded by the operation sequence shown in Fig. 2

An example of reschedule repaired priority-based chromosome are shown in Fig. 4.

3.3 Transition Probability

For traditional EAs, the representation of a chromosome for an individual is generated by mapping the decision space into the search space or directly encoding the decision variables. Each position in a probability vector indicates the

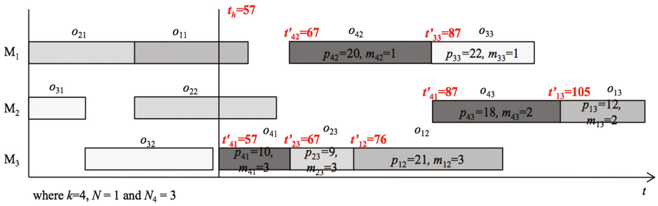

Fig. 4. An illustration of reschedule generated by repaired priority-based representation

distribution of probability regarding each variable. When prior knowledge of distribution is not assumed, the domain of discrete variable X is a set of pre-defined values (x). The distribution of random variable X has the same equal probability; the initialization is as following:

$$p_{t=0}(X) = 1/|X|, \tag{10}$$

where $|X|$ denotes the number of values in the set of domain X.

After the initialization of EDA, probability sample for new alternative solutions and the new solutions are evaluated according to a specific system objective. EDA collects all new alternative solutions and replaces the inferior solutions in the promising data. The probability distribution of X can be estimated as follows:

$$B\_t(X = x) = (N(X = x) + 1/|X|)/\text{prSize} + 1/|X|, \tag{11}$$

where $N(X = x)$ denotes the number of instances in promising solutions with variable $X = x$, and represents the low bound to the probability of X.

The distribution probability of X in the probability vector is learned toward the estimated distribution of promising data, as follows:

$$P_{t+1}(X = x) = (1 - \alpha) P_t(X = x) + \alpha B_t(X = x), \tag{12}$$

where α denotes the learning rate from the current promising solutions; in particular, for $\alpha = 1$, the probability distribution is completely reconstructed by the current promising solutions.

To maintain the diversity of sampling, the distribution probability of X is updated toward the estimation distribution. The distribution can be tuned with probability pm of the mutation, and the mutation is performed using the following definition:

$$P_{t+1}(X = x) = \frac{P_t(X = x) + \lambda_m}{\sum_{x' \in X \setminus \{x\}} \max\left(P_t(x) - \frac{\lambda_m}{|X|-1}, \varepsilon\right) + (P_t(X = x) + \lambda_m)}, \tag{13}$$

where λ_m is the mutation shift that controls the amount for mutation operation, and ε is a small probability value to avoid the negative probability value.

3.4 Fitness Assignment Mechanisms

The multiple objective optimization problems have been receiving growing interest from researchers with various backgrounds since early 1960. There are a number of scholars who have made significant contributions to the problem. Among them, Pareto is perhaps one of the most recognized pioneers in this field and recently. Many multi-objective genetic algorithms differ mainly in the fitness assignment strategy which is known as an important issue in solving multiple objectives optimization problem [1]. Zhang et al. proposed a hybrid sampling strategy-based evolutionary algorithm (HSS-EA) in which a Pareto dominating and dominated relationship-based fitness function (PDDR-FF) is used to evaluate the individuals. PDDR-FF of an individual S_i is calculated by the following fitness assignment function (14):

$$\text{eval}\,(S_i) = q\,(S_i) + 1/\,(p\,(S_i) + 1)\; i = 1, 2, \cdots, \text{popSize}, \tag{14}$$

where $q(\cdot)$is the number of individuals which can dominate the individual $S \cdot p(\cdot)$ is the number of individuals which can be dominated by the individual S_i. The PDDR-FF can set the obvious difference values between the nondominated and dominated individuals as shown in Fig. 5.

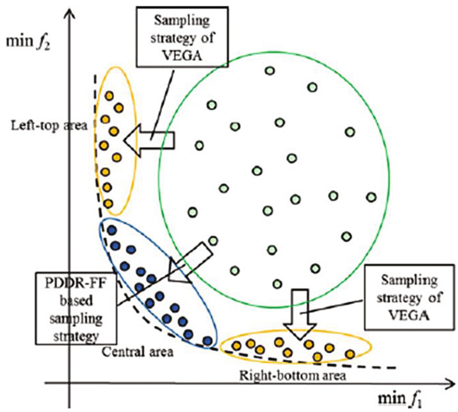

Fig. 5. The description of HSS-EA

4 Experiments and Discussion

To examine the practical viability and efficiency of the pro- posed MoEDA, we designed a numerical study to com- pare MoEDA with efficient algorithms from previous studies. The proposed MoEDA was compared with adaptive weight genetic algorithm (awGA) [1], Non-dominated Sorting Genetic Algorithm II (NSGA-II) [2] and Strength Pareto Evolutionary Algorithm 2 (SPEA2) [10] for a set of simulation data of testing standard benchmark problems. All of the above algorithms were implemented using JAVA under the Eclipse environment, and the simulation experiments were conducted on Intel Core $i5$ (2.3 GHz clock) with 4G memory. Data were collated from 30 test runs for each algorithm. In order to compare the performance of these algorithms fairly and under the same environment, the strategies of related algorithms and their respective parameters are presented in Table 2.

Table 2. The parameters of NSGA-II, SPEA2, AWGA and h-MoEDA

	NSGA-II, SPEA2 and awGA	MoEDA
Interaction	1000	1000
Population	200	200
Selection	Roulette	Tournament (k)
Operators	Crossover (P_c)	Sampling
	Mutation (P_m)	Improvement (P_i)
Parameters	$P_m = 0.20$	PromisingRate $= 0.7$
	$P_c = 0.80, w_2 = 0.6$	$\alpha = 0.02, \beta = 0.02$
	$w_1 = 0.4, w = 0.6$	$P_m = 0.4, k = 2$

In order to evaluate the performance of a given algorithm for MoJSRP, the following two performance measures are considered in this paper. Let S_j be a solution set for each solution method ($j = 1, 2, 3, 4$). $S*$ is a known set of the Pareto-optimal set.

Coverage $C(S_1, S_2)$ is the percent of the individuals in S_2 who are weakly dominated by S_1. The value $C(S_1, S_2) = 1$ means that all individuals in S_2 are weakly dominated by S_1.

On the contrary, $C(S_1, S_2) = 0$ denotes that none of the individuals in S_2 is weakly dominated by S_1 [10]. The larger $C(S_1, S_2)$ is; the better S_1 outperforms S_2 in C.

4.1 Convergence

Table 4 shows a comparison of coverage by MoEDA, awGA, NSGA-II and SPEA2. Figure 6 presents the distribution range of coverage conducted on LA35. From Table 3 and Fig. 6, it is easy to see that the h-MoEDA is better than MSGA-II, SPEA2 and awWA on C measure. Such better convergence should mainly attribute to the hybrid sampling strategy of VEGA's preference for the edge region of the Pareto front and PDDR-FF's tendency converging toward the centre area of the Pareto front.

They preserve better performances both in efficacy and efficiency. Especially, h-MoEDA can also keep diversity evenly without special distribution mechanisms like NSGA-II and SPEA2. h-MoEDA is better than MSGA-II, SPEA2

Table 3. Comparison of coverage measure by h-MoEDA, AWGA, NSGA-II, SPEA2 and AWGA

Problem	Algorithm	Mean		Improved	SD	
		C(h-MoEDA,A)	C(A, h-MoEDA)	(C(h-MoEDA,A)-C(A,h-MoEDA))(%)	C(h-MoEDA,A)	C(A, h-MoEDA)
LA29	NSGA-II	0.4669	0.3524	11.45	0.0842	0.0709
	SPEA2	0.4965	0.3224	17.41	0.0696	0.0603
	awGA	0.5731	0.2541	31.90	0.0451	0.0553
LA35	NSGA-II	0.6846	0.2824	36.63	0.0777	0.0794
	SPEA2	0.6606	0.2618	39.89	0.0860	0.0631
	awGA	0.6844	0.2127	46.73	0.0672	0.0460
LA38	NSGA-II	0.4543	0.3425	11.19	0.0779	0.0754
	SPEA2	0.5063	0.3412	16.52	0.0696	0.0603
	awGA	0.5625	0.2767	28.58	0.0572	0.0619

and awWA on C measure. Such better convergence should mainly attribute to the hybrid sampling strategy of VEGA's preference for the edge region of the Pareto front and PDDR-FF's tendency converging toward the center area of the Pareto front. They preserve better performances both in efficacy and efficiency. Especially, h-MoEDA can also keep diversity evenly without special distribution mechanisms like NSGA-II and SPEA2.

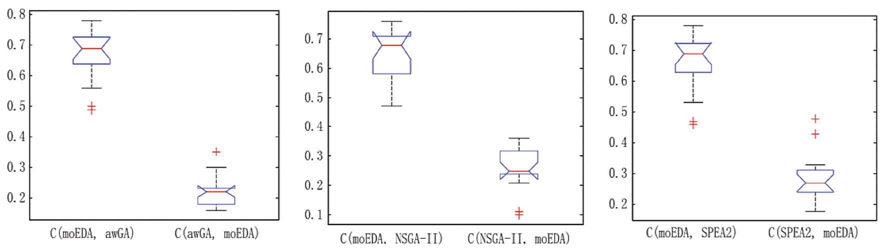

Fig. 6. Box plot of coverage measure conducted on LA35

4.2 Distribution Performance

The experiment results of dispersion performances, SP are shown in Table 4 and Fig. 7 presents the distribution range of space conducted on LA35. It indicates that MoEDA is obviously better than awGA, while better than NSGA-II and SPEA2. Without special mechanism to preserve the diversity evenly, h-MoEDA can also achieve satisfactory dispersion performance.

4.3 Computation Costs

The computation costs of evolutionary-based algorithms mainly depend on the number of fitness evaluations. We need to compare h-MoEDA with other methods, and the termination criterion is to reach the maximum number of iterations

Table 4. Comparison of the spacing measure by h-MoEDA, NSGA-II, and SPEA2 and AWGA

Problem	Algorithm	Mean		Improved	Sd	
		SP (h-MoEDA)	SP(A)	(SP(h-MoEDA) SP(A))/SP(A)(%)	SP(h-MoEDA)	SP(A)
LA29	NSGA-II	16.3568	20.1712	−18.91	4.4081	6.4981
	SPEA2	16.3568	22.2868	−26.62	4.4081	6.7942
	awGA	16.3568	25.8421	−36.70	4.4081	7.2521
LA35	NSGA-II	19.0001	24.8423	−20.31	4.9569	6.2297
	SPEA2	19.0001	24.9510	−23.85	4.9569	7.0526
	awGA	19.0001	33.2410	−42.84	4.9569	7.1686
LA38	NSGA-II	17.1736	21.4569	−19.96	5.2566	6.9774
	SPEA2	17.1736	24.0161	−28.49	5.2566	7.1136
	awGA	17.1736	27.0155	−36.43	5.2566	7.9576

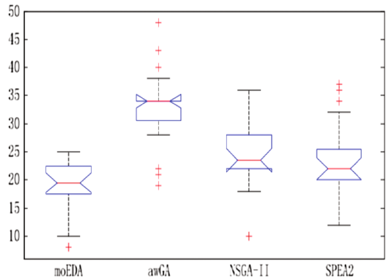

Fig. 7. Box plot of space measure conducted on LA35

(generations). The mean computation cost of h-MoEDA is 217.78 s, NSGA-II and SPEA2 are 245.54, 390.24 s respectively. Compared with SPEA2, SPEA2 needs to calculate all the distances of each individual to all the other individuals first. Then SPEA2 gets the *k-th* nearest distance for each individual after sorting its distances and the time complexity of SPEA2 is $O(mN2 \log N)$ where m is the number of objectives. It is clear that the NSGA-II achieved better computation costs. Without special dispersion preservation mechanism, the time complexity of fitness calculation (PDDR-FF) in h-MoEDA is $O(0)$. It is slightly better than NSGA-II while h-MoEDA needs to estimate the parameters of probability model using the promising solutions.

5 Conclusion

This paper presents an effective h-MoEDA, which solves the MoJSRP. It minimized the expected average makespan and expected total tardiness within a reasonable amount of calculation time. With the framework of the proposed EDA, the explicit probability model of the operation sequence is estimated on the distribution of good solutions found so far and use the constructed model to guide further search behavior. The sampling operator based on the probability model achieves better convergence and stability than the conventional operator such crossover and mutation. In our future work, further experiments will be conducted to determine accuracy of the proposed EDA in response to variations among the parameters.

Abstract. Operating Systems acts as a base software and acts as a driver for both application programs and system programs. All the programs residing in an operating system has to become process for execution. A modern computer system supports multitasking by single user or multiple users. Different processes have different priorities. The major goal of an operating system is to reduce waiting time and enhance throughput by scheduling processes in some way. This paper discusses various scheduling terms and scheduling algorithms. We have proposed a new approach for scheduling. This proposed algorithm is based on the mixture of MQMS, Priority Scheduling mechanism and Round Robin scheduling. The proposed algorithm facilitates operating system by managing separate queue for separate priority of process and manages queue scheduling in round robin fashion with dynamic time slicing. Processes are added to appropriate queue and this decision is based on any user defined or system defined criteria. We have also discussed various case studies regarding this algorithm and compared its results with priority scheduling algorithm. These case studies are limited to two queuing system up till now. We have also proposed multiple queue management (more than 2), dynamic time slicing instead of half execution scheme and varying execution times of queues as future work of this algorithm scheme.

Keywords: Priority scheduling · Multi-queue scheduling · Dynamic time slice execution · Fair priority scheduling · Single processor multi-queue scheduling · Improved priority scheduling

1 Introduction

A computer system comprises of software and hardware. Software includes programs for system and user needs. Hardware is a set of resources including CPU,

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_4

GPU, RAM and many more of them. The most important software is Operating System that acts as an interfacing layer which serves the users in using hardware effectively. User needs are fulfilled by set of Application Software that requires a base software to run i.e. operating system. Software may be in running state or it may not be running. The former is called a Process while the latter is called Program. A process requires certain resources for execution. CPU and RAM are major resources that each process requires for execution. CPU is the most costly and important resource. It must be utilized properly. CPU should never be left underutilized. Operating System must ensure proper utilization of the CPU.

A computer system may be Single Processor System or it may be Multi-Processor System. Single processor system allows only one process to acquire the CPU and gets execute on it. On the other hand multi-processor system allows more than one processes to be executed with one on each processor at a time.

A process changes its activity from time to time as it executes. Process activity is defined in terms of two-state model or five-state model. Two-state model defines that a process can have two states: running and not running. It gives an abstract idea. Two state model is shown in Fig. 1. Stallings [21] described a more elaborative version of two state model called five-state model. Five state model took into account the reason of process for not being in the running state. So, five-state model described five process activities: new, ready, running, waiting and terminated. Figure 2 shows five state model for process execution states.

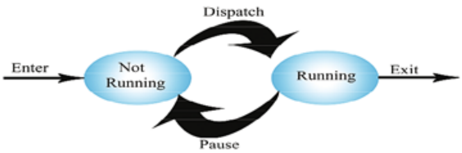

Fig. 1. Two state model for process states

Fig. 2. Five state model for process states

Section 2 of the paper describes CPU Scheduling, its need, various queue management systems, queues involved in scheduling and scheduling criteria. Section 3 is organized to give a brief idea of various scheduling algorithms. Section 4 describes some of related work. Sections 5 and 6 describes our proposed algorithm, its working logic and pseudo code. Section 7 comprises of various case studies and results of our proposed algorithm. The results of our proposed algorithm are compared with the priority scheduling algorithm in Sect. 8.

2 CPU Scheduling

Operating system may be designed to be Single Programmed Systems or Multi Programmed Systems.

A single programmed system can only accommodate single process in memory for execution. CPU has to remain idle in the case of process waiting for some I/O operation. This results in underutilization and causes increase in waiting time and turnaround time.

Silberchatz et al. [18] narrated that a multi-programmed system facilitated the efficient utilization of processor by allowing multiple processes or jobs ready/waiting (residing in memory) for execution and switching the CPU among these processes. If an executing process had to wait for some I/O operation, the CPU no longer remained idle. It switched to the next job waiting for CPU allocation to get executed. In this manner proper utilization of CPU was achieved. To achieve this utilization, scheduling was required. Scheduling scheme comprised of criteria and algorithm to implement this criteria. CPU scheduling was of immense importance in multi-programmed systems because CPU was expansive and scarce resource.

2.1 Ready Queue Management

The ready queue is a bulk of processes ready to get executed. Ready queue may be partitioned as it is done in Multilevel Queue Scheduling and Multilevel Feedback Scheduling. There are following two ways to manage ready queue:

(1) SQMS
SQMS (Single Queue Management System) involves no partitioning of ready queue. SQMS consists of single partition ready queue in which all the incoming processes are stored. It is a straight forward queue management scheme. It is due to the fact that processes are to be picked for execution from a single queue. So operating system requires only process scheduling algorithm. Only a single queue has to be managed and scheduled. No overhead is involved in terms of scheduling ready queue partitions or multiple ready queues. In addition to this, operating system doesn't require any overhead for deciding the addition of processes to un-partitioned ready queue.

(2) MQMS
MQMS (Multi-Queue Management System) scheme maintains multiple ready queues of jobs or partitions of ready queue. Processes are added to appropriate ready queue portion depending upon certain criteria. MQMS scheme is complex scheme in terms of implementation, management and scheduling. The selection of process for execution requires two important decisions: (i) appropriate queue selection and (ii) appropriate process selection from the selected queue. Hence MQMS involves both queue scheduling algorithm and process scheduling algorithm. MQMS scheme involves overhead in terms of queue selection.

A process is first added to job queue. After this, it is moved to ready queue. Process can now move itself among ready queue, running state and waiting queue as and when required. All these state changes depend upon a criteria on the basis of which the Operating System decides that which process move to ready queue, which started execution next, which process will be needed to move to waiting queue and which process pre-empted and moved to ready queue. These decisions are taken by intelligent algorithms, executed by CPU Scheduler.

3 Scheduling Algorithms

Tanenbaum [22] described that First Come First Served (FCFS), Shortest Job First (SJF), Shortest Remaining Time First (SRTF), Round Robin (RR) and Priority Scheduling (PS) algorithms were commonly used Scheduling Algorithms. These algorithms were implemented in the form of SQMS. However, priority scheduling may had MQMS version. Mishra and Khan [11] narrated that SJF only permitted process with lowest burst time to acquire CPU for execution and lowered average waiting time. RR scheduling defined a time quantum for assigning CPU fairly to each process present in the ready queue for specific amount of time. We discuss Shortest Job First (SJF), Shortest Remaining Time First (SRTF), Round Robin (RR) and Priority Scheduling algorithms below.

3.1 Shortest Job First (SJF)

Shortest Job First is based on the Burst Time of processes. SJF is based on a simple idea derived from FCFS, that is, executing smaller processes before larger ones lowers the Average Waiting Time (AWT) of process set. If a sub set of processes have same burst time, then they are executed in FCFS fashion. The processes are arranged in a queue on the base of their Burst Times in a way that process with smallest burst time is placed at the Head/Front of queue while the process with largest burst time is placed at Rear of queue. In this way, CPU Scheduler always picks the process with smallest burst time from ready queue. It's a non-preemptive scheduling algorithm. The main advantage of SJF is to decrease the Average Waiting Time of process set. However, this algorithm does not take into account process priorities. SJF may result in starvation of larger processes.

3.2 Shortest Remaining Time First (SRTF)

Shortest Remaining Time First scheduling algorithm is simply preemptive version of SJF. In SRTF, the main idea is simply the same, that is, execute small process before large one. But in this algorithm, if a process is under execution and during course of its execution a new process enters the system. Then the burst time of newly entered process is compared with remaining burst time of currently executing process. If the comparison results in the fact that entering process has smaller burst time, then CPU is preempted and allocated to the newly entering process. However, if the new entering process has same burst time as that of already executing process, then FCFS manner is used for their scheduling. The major advantage is the exploitation of phenomenon to lower Average Waiting Time of process set. The demerit of SRTF is that, the processes in real environment have priorities and SRTF does not support priorities. Moreover, it is not necessary that smaller processes are important while larger ones are less important. This algorithm also includes high overheads for queue managements, queue rearrangements, burst time comparisons and context switches. It may also give rise to starvation for large processes.

3.3 Round Robin (RR)

Round Robin scheduling algorithm is same as that of FCFS with certain innovation. This innovation includes preemption and Time Quantum. Time Quantum is a small amount of time. Processes are arranged in a circular queue. CPU is allocated a process from the queue; CPU executes the allocated process for a time period equal to that of time quantum. When the time quantum expires, the CPU is preempted and next process from the queue is selected. Next process is also executed for a time length equal to time quantum. This algorithm continues to schedule processes in this fashion until queue is empty. The major advantage of this scheme is that each of the process gets fair share and equal opportunity of execution. The major drawback is that, if time quantum is very small, then too many context switches are involved. On the other hand, if time quantum is large, then RR may perform same as FCFS. Moreover, RR also does not consider priorities of processes. Siregar [23] narrated that starvation could be avoided if CPU was allocated fairly to processes. Time quantum was an important factor in RR scheduling scheme for lowering waiting time of process set. Time quantum could take any value. But best time quantum should be discovered for minimizing average waiting time.

3.4 Priority Scheduling (PS)

Priority Scheduling s involves assigning a Priority to each process. A Priority is either indicated by an integer number (0, 1, 2, 3, etc.) or a string (low, medium, high etc.). In the case of numeric priority, two choices exist: higher number may indicate a higher priority (our proposed algorithm consideration) or lower priority (other algorithm consideration). This scheduling algorithm is implemented using a Priority Queue. Processes are arranged in decreasing order of priority (Front to Rear) with process having highest priority placed at front while process having second highest priority placed at a place next to front and so on. The CPU Scheduler picks process with highest priority and allocates CPU for execution. If a number of processes have same priority then they are scheduled in FCFS fashion as of in SJF and RR case. PS may be preemptive or non-preemptive. If non-preemptive version is being used, then no matter how much higher priority process enters the queue, if CPU is executing a process then it will not be preempted unless the process is completed. On the other hand, the preemptive version preempted the CPU if such a situation occurs. The main attraction in PS is realistic approach about priorities. However, PS can lead to starvation situation preventing lower priority processes from execution. Its implementation involves high overheads of queue rearrangements and priority comparisons in case of preemptive version. PS can be implemented in the form of either SQMS (Traditional Priority Scheduling) or MQMS (Multi-Level Queue Scheduling). Rajput and Gupta [14] narrated that in priority scheduling, processes were arranged in queue according to their fixed priority values. A high priority incoming process interrupted low priority process. Waiting time of low priority processes were thus increased and hence starvation occurred.

Adekunle et al. [2] analysed the performance of FCFS, SJF, RR, SRTF and Lottery scheduling algorithms. SJF showed higher while RR showed medium CPU utilization. SJF also showed lower average waiting time and good response time as compared to RR. However, RR algorithm was found to be fair and starvation free.

Almakdi et al. [4] simulated FCFS, SJF, RR and SRT algorithms for analysing scheduling algorithm performance. The results showed that the lowest average waiting time and the lowest average turnaround time were showed by SJF. However, high average core utilization and high average throughput were resulted by RR.

4 Related Work

Rao et al. [15] elaborated that Multilevel Feedback Queue Scheduling involved use of multiple queues. Process could be migrated (promoted/demoted) from one queue to another. Each queue had its own scheduling algorithm. Similarly, criteria were also defined for promotion and demotion of processes. PMLFQ resulted in starvation because of execution of high priority process queues before low priority process queues.

Goel and Garg [5] explained fairness was an important scheduling criteria. Fairness ensured that each process got fair share of CPU for execution. Further, higher priority processes exhibited smaller waiting time and starvation could take place for lower priority process.

Shrivastav et al. [16] proposed Fair Priority Round Robin with Dynamic Time Quantum (FPRRDQ). FPRRDQ calculated time quantum on the basis of priority and burst time for each individual process. Experimental results when compared with Priority Based Round Robin (PBRR) and Shortest Execution First Dynamic Round Robin (SEFDRR) scheduling algorithms, showed that FPRRDQ had improved performance considerably.

Patel and Patel [13] proposed a Shortest Job Round Robin (SJRR) scheduling algorithm. SJRR suggested to arrange processes in SJF fashion. The shortest process's burst time was designated as time quantum. Case study showed reduction in average waiting time of process set.

Abdulrahim et al. [1] proposed New Improved Round Robin (NIRR) algorithm for process scheduling. The algorithm involved two queues ARRIVE and REQUEST. In this algorithm, the time quantum was calculated by finding the ceiling of average burst time of process set. First process in the REQUEST queue was allocated to CPU for one time quantum. In any case, the executing process had burst time less than or equal to half time quantum then CPU reallocated for remaining CPU burst time. Otherwise, process was removed from REQUEST and added to ARRIVE. NIRR algorithm improved scheduling performance and also lowered number of context switches as the case of RR algorithm.

Mishra and Rashid [12] introduced Improved Round Robin with Varying Time Quantum (IRRVQ) scheduling algorithm. IRRVQ proposed arrangement of processes (in ready queue) in SJF fashion and setting time quantum equal to burst time of first process. After a complete execution of first process, next processes were selected and assigned one time quantum. If finished, processes were removed from ready queue otherwise, processes were preempted and added to tail of ready queue.

Sirohi et al. [20] described an improvised round robin scheduling algorithm for CPU scheduling. This algorithm calculated the time quantum by finding the average of the burst times of processes. The processes were allocated to ready queue in SJF order. CPU was allocated to first process for one time quantum. The reallocation of CPU was based on remaining burst time of process under execution.

Akhtar et al. [3] proposed a preemptive hybrid scheduling algorithm based on SJF. Initially, it showed similar steps as that of SJF. The algorithm reduced number of context switches considerably but only showed minor change in average waiting time. The algorithm could exhibit starvation.

Joshi and Tyagi [7] explained Smart Optimized Round Robin (SORR) scheduling algorithm for enhancing performance. At first step, the SORR algorithm arranged processes in increasing order of burst times. In the second step, the mean burst time was calculated. Third step involved calculation of Smart Time Quantum (STQ) after which the CPU was allocated to first process in the ready queue for a time quantum equal to calculated STQ. If the allocated process was remained with burst time less or equal to 1 time quantum, CPU was reallocated for the burst time. Otherwise process was preempted, next process was selected from ready queue and CPU was allocated to the newly selected process for STQ.

Lulla et al. [10] devised a new algorithm for CPU scheduling. The algorithm introduced mathematical model for calculating initial time quantum and dynamic time quantum. Dynamic time quantum assisted in lowering number of context switches. The algorithm proposed execution of top two high priority processes by assigning calculated initial time quantum followed by the calculation and assignment of dynamic time quantum for execution of top two high priority processes.

Goel and Garg [6] proposed Optimized Multilevel Dynamic Round Robin Scheduling (OMDRRS) algorithm. This algorithm suggested the allocation of dynamic time slices. Factor analysis based on arrival time, burst time and priority was calculated for sorting processes in ready queue. Burst values of first and last process were used for time slice calculation. Simulated results, statistically analysed using ANOVA and t-test, showed considerable performance improvement.

Kathuria et al. [8] devised Revamped Mean Round Robin (RMRR) scheduling algorithm. RMRR involved two queues ReadyQueue (RQ) and Pre-ReadyQueue (PRQ). Time quantum was calculated by taking mean of the burst time of processes. The proposed algorithm lowered average waiting time, average turnaround time and number of context switches as compared to RR scheduling. RMRR showed the best response time when compared with FCFS, SJF and RR scheduling algorithms.

Singh and Singh [19] proposed a hybrid scheduling algorithm based on Multi Level Feedback Queue (MLFQ) and Improved Round Robin (IRR) scheduling principles. The proposed algorithm suggested the sub-division of memory in three queues as in MLFQ. Fonseca and Fleming's Genetic Algorithm (FFGA) was implemented for optimization. Results showed optimized performance in comparison to various algorithms (Fig. 3).

5 Proposed Algorithm

In this paper, we proposed a new scheduling algorithm as an extension of priority scheduling. Here, we proposed it only for single processor system (neither multiple processors nor multi-core processors). It is based on hybrid concepts of multiple queue management, priority scheduling and round robin scheme. In our algorithm, multiple queue management scheme facilitates subdivision of ready queue in multiple portions. Shukla et al. [17] described the use of multi-level queuing approach. Multi-level queuing involved partitioning of ready queue into various sub queues. In such scheduling, processes were assigned permanently to specific queue. Memory size, process type and priority were some of parameters used for such assignments.

In our proposed algorithm, each job is allocated to specific queue according to criteria predefined criteria. The criteria consists of two factors: (1) Priority of individual process and (2) Burst Time of process. Firstly, a priority criteria is defined in a set of processes. The processes are allocated after comparing process priorities to priority criteria. Our proposed algorithm assumes that the largest number represented highest priority and smallest number represented lowest priority. Shortest job first scheme is applied while arranging processes when they are transferred from the job pool to the ready queue partitions. Jobs inside a specific queue are scheduled as defined by priority scheduling scheme. Khan and Kakhani [9] suggested SJF based PS was proposed for performance improvement. Processes were placed in ready queue in higher to lower order of priority. SJF was employed for arranging process in case of more than one processes having similar priority. Results of SJF based PS were compared to FCFS based PS and results showed considerable decrease in average waiting and average turnaround times. Moreover, the queues are scheduled in a round robin fashion from the highest priority queue to the lowest priority queue. Round robin scheme is based on dynamic time slicing. Whenever a queue is given time slice it is according to the process burst time and some variations of it. Our algorithm has following main steps:

Step 1. Create Multiple Queues (one for high priority processes and other for low priority processes) based on Priority Scheme. These queues are designated as High Priority and Low Priority Queues.

Step 2. Create Processes in Job Pool.

Step 3. Define Priority Criteria.

Step 4. Allocate processes to queues based on priority criteria and burst time. Processes are arranged in decreasing order of priority from front to rear. Additionally following are considered:

- **Step 4.1.1** If process priority is less than or equal to priority criteria then add it to the Low Priority Queue. Otherwise add it to High Priority Queue.
- **Step 4.1.2** If multiple processes have same priority then arranges them in a way that the process with shortest burst time comes first in the queue.

Step 5. Select first process from High Priority Queue and execute it fully (for entire burst time by assigning time slice equal to the burst time) and remove it from queue head.

Step 6. Select first process from Low Priority Queue and execute for a time equal to half that of burst time (assign time slice equal to half the burst time). Important thing to consider is that, in this case, each low priority process completed in two halves.

Step 7. Repeat Steps 5–6 until both queues are empty.

One of the interesting things to note is that, CPU is alternated between high priority and low priority processes in order to increase the fairness. Our approach lowers the starvation faced by low priority processes in the presence of high priority processes. Another point may arise that why low priority processes are executed in two halves? The answer of this question is that, it is done so that if a low priority process is executed fully, then the purpose of two queues is unclear. Similarly, if high priority process is executed for half time, then the use of priorities becomes meaningless.

6 Pseudo Code

Proposed Algorithm (P[1, $\cdots$, n], Priority Criteria) (Fig. 4)

```
begin
Create Queue Portions QH[1....nh], QL[1....nl]
For each P[i] in P[1.......n]
        If (P[i].Priority <= PriorityCriteria) Then
                Add P[i] to QL in such a way that processes are arranged in
                decreasing order of priority and increasing order of burst time
        Else
                Add P[i] to QH in such a way that processes are arranged in
                decreasing order of priority and increasing order of burst time
              End If
Repeat following steps while QH and QL are not empty
        Select a process from QH head, allocate CPU, execute completely and
        remove it from QH
        Select a process from QL head, allocate CPU, execute for the time half to
        its original burst time
                If (P[i].RBT) = 0 Then
                    Removes it from QL
                Else
                    place it back to QL head
            End If
                Goto step 4
            End while
Completion of process set
End Algorithm
*RBT = Remaining Burst Time
```

7 Case Studies

7.1 Case Study 1

Gantt Chart of above process data when executed by Priority Scheduling is as Fig. 5 (Table 1).

Table 1. Process set with five processes

Process	Burst time	Priority
P1	10	3
P2	1	1
P3	2	3
P4	1	4
P5	5	2

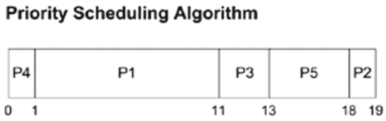

Fig. 5. Gantt chart for priority scheduling algorithm

Average Waiting Time = 8.6 ms.
Average Turnaround Time = 12.4 ms.
Now we define certain parameters related to proposed algorithm.
(1) Priority Criteria: Process with Priority > 2 is placed in High Priority Queue while process with Priority <= 2 is placed in Low Priority Queue.
(2) Ready Queue Partitions: As Fig. 6.
The proposed algorithm on given data results in Fig. 7.

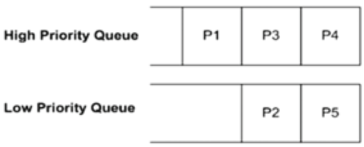

Fig. 6. Scheduling queues

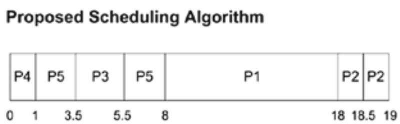

Fig. 7. Gantt chart for proposed algorithm

Average Waiting Time = 6.5 ms
Average Turnaround Time = 10.3 ms

7.2 Case Study 2

Gantt Chart of above process data when executed by Priority Scheduling is as Fig. 8 (Table 2).

Average Waiting Time = 7.0 ms.
Average Turnaround Time = 10.8 ms.
Now we define certain parameters related to proposed algorithm.

Table 2. Process set with five processes

Process	Burst time	Priority
P1	10	3
P2	1	1
P3	2	4

7.4 Case Study 4–Special Case

This case deals with a situation involving same priority processes (high priority). Similarly, inverse case of this can also be assumed. In such cases all the processes added to a single queue either high or low priority (Table 4).

Gantt Chart of above process data when executed by Priority Scheduling is as Fig. 14.

Average Waiting Time = 3.67 ms
Average Turnaround Time = 9.33 ms
Now we define certain parameters related to proposed algorithm.
(1) Priority Criteria: Process with Priority > 2 is placed in High Priority Queue while process with Priority ≤ 2 is placed in Low Priority Queue.
(2) Ready Queue Partitions: As Fig. 15
The proposed algorithm on given data results in Fig. 16.

Average Waiting Time = 3.67 ms
Average Turnaround Time = 9.33 ms

In the case with all the processes getting place in a single queue, the proposed algorithm gives an average waiting time and average turnaround time exactly equal to priority scheduling algorithm.

8 Results and Discussion

8.1 Comparison of Average Waiting Time

In this section we compare average waiting time of our proposed algorithm and traditional priority scheduling algorithm. This comparison is based on case studies discussed in the previous sections.

The average waiting time is minimized by our proposed algorithm as compared to the baseline scheduling algorithm as shown in Fig. 17. However, the last case showed same average waiting time. This was because, the last case comprised of special dataset involving all the processes with same priority (high). In this case, only one priority queue was formed rather two queues. So, in this case it exhibited same behaviour as that of traditional priority scheduling algorithm.

8.2 Comparison of Average Turnaround Time

In this section we presented comparison of average turnaround time of our proposed algorithm with traditional priority scheduling algorithm. This comparison based on case studies discussed in the previous sections.

Figure 18 clearly showed that in first three case studies the average turnaround time of our proposed scheduling algorithm was less than traditional priority scheduling algorithm. However, the last case showed same average turnaround time. This was because, the last case comprised of special dataset having

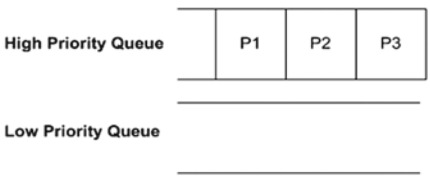

Fig. 15. Scheduling queues

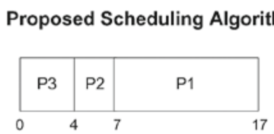

Fig. 16. Gantt chart for proposed algorithm

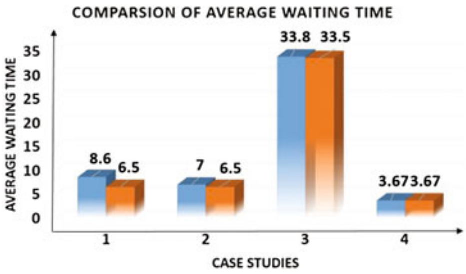

Fig. 17. Comparison of average waiting time

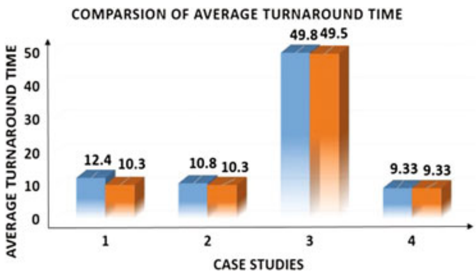

Fig. 18. Comparison of average turnaround time

all the processes having high priority. In this case only one priority queue was formed rather two queues.

9 Conclusion and Future Work

It is concluded that our proposed algorithm used minimum waiting and turnaround time as compared to baseline Priority Scheduling algorithms. Our proposed algorithm also supported multiple queue supporting operating systems using different priorities. Each type of priority can be managed with a separate queue. The proposed algorithm provided fairness to both high priority and low priority jobs and thus saved low priority jobs from starvation. The importance is given to high priority process within both high priority and low priority list by our proposed algorithm. Our algorithm also enhanced throughput by lowering average waiting and average turnaround time. As compared to Round Robin scheduling with small time slice, proposed algorithm used a scheme requiring only two context switches per process. In this way, our proposed algorithm limited the number of context switches required for a job. This algorithm is a good mixture of priority scheduling, shortest job first and round robin scheduling.

As a future work, we will try out different execution lengths or time slices for high priority processes and low priority processes to find optimized solution providing optimized results of scheduling criteria. We will also extend this algorithm in a way that for each priority type a single queue may be used.

Abstract. In the real world, there are a lot of scenes from which the product is made by using the robot, which needs different assembly times to perform a given task, because of its capabilities and specialization. For a robotic assembly line balancing (rALB) problem, a set of tasks have to be assigned to stations, and each station needs to select one robot to process the assigned tasks. In this paper, we propose a hybrid genetic algorithm (hGA) based on an order encoding method for solving rALB problem. In the hGA, we use new representation method. Advanced genetic operators adapted to the specific chromosome structure and the characteristics of the rALB problem are used. In order to strengthen the search ability, a local search procedure is integrated under the framework the genetic algorithm. Some practical test instances demonstrate the effectiveness and efficiency of the proposed algorithm.

1 Introduction

An assembly line system is a manufacturing process in which interchangeable parts are added to a product in a sequential manner to produce a finished product. It is important that an assembly line is designed and balanced so that it works as efficiently as possible. Most of the work related to the assembly lines concentrate on the assembly line balancing (ALB). The ALB model deals with the allocation of the tasks among stations so that the precedence relations are not violated and a given objective function is optimized.

Since the ALB model was first formulated by Helgeson et al. [13], many versions of ALB arise by varying the objective function [26]: Type-F is an objective independent problem which is to establish whether or not a feasible line balance exists. Type-1 and Type-2 have a dual relationship; the first one tries to minimize the number of stations for a given cycle time, and the second one tries

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_5

to minimize the cycle time for a given number of stations. Type-E is the most general problem version, which tries to maximize the line efficiency by simultaneously minimizing the cycle time and a number of stations. Finally, Type-3, 4 and 5 correspond to maximization of workload smoothness, maximization of work relatedness and multiple objectives with Type-3 and Type-4, respectively [15]. Furthermore, most versions of above models are NP-hard [12].

Recently, genetic algorithm (GA) and other evolutionary algorithms (EAs) have been successfully applied in a wide variety of ALB problems. Falkenauer and Delchambre [6] were the first to solve ALB with GAs. Following application of GAs for solving ALB model was studied by many researchers, e.g., Anderson and Ferris [2], Rubinovitz and Levitin [22], Gen et al. [10], Bautista et al. [3], Sabuncuoglu et al. [24], Goncalves and Almeida [11], Brown and Sumichrast [4], and Nearchou [21]. However, most of the researchers focused on the simplest version of the problem, with single objective and ignored the recent trends, i.e., mixed-model production, u-shaped lines, robotic lines and etc.

Sigeru focused on implementing particle swarm optimization (PSO) to optimize the robotic assembly line balancing (RALB) problems with an objective of maximizing line efficiency. By maximizing the line efficiency, industries tend to utilize their resources in an efficient manner [14]. Slim studied a robotic assembly line balancing problem which goal is to maximize the efficiency of the line and proposed some resolution methods which define the suitable component and point positions in order to define the strategy of pick and place for each robot [5]. In Nilakantan's research, bio-inspired search algorithms, viz. particle swarm optimization (PSO) algorithm and a hybrid cuckoo search and particle swarm optimization (CS-PSO) were proposed to balance the robotic assembly line with the objective of minimizing the cycle time [20]. Armin et al. extended the existing algorithms to solve the robotic assembly line problem [27]. Yoosefelahi et al. [29] considered a different type II robotic assembly line balancing problem (RALB-II). One of the two main differences with the existing literature is objective function which is a multi-objective one. The aim is to minimize the cycle time, robot setup costs and robot costs. The second difference is on the procedure proposed to solve the problem. In addition, a new mixed-integer linear programming model is developed. Snke [16] introduced a new robot concept that aims at closing the gap between a manual assembly and a fully automatic assembly. It is intended to be used for handling and assembly of small parts in a highly agile production scenario, which employs both human workers and robots in the same line, with a frequent need for reconfiguration. The objective is to minimize the cost of the stations. This formulation is very similar to the rALB problem.

Gao and Gen [7] proposed a hybrid GA for solving rALB-2, in which different robots may be assigned to the assembly line tasks, and each robot needs different assembly times to perform a given task due to its capabilities and specialization. They focused on the genetic operators adapted to the specific chromosome structure and the characteristics of the rALB problems.

In this paper, we also consider a hybrid GA approach for solving rALB-2 problems. Different with prophase works [7], we not only focus on the design of GA to minimize the cycle time of the assembly systems, but also hammer at the key point of improvement of assembly system depended on the final result analysis. We propose a hybrid genetic algorithm (hGA) to solve the rALB-2. The genetic algorithm uses partial representation technique, that is, the coding space only contains a part of the feasible solutions, in which the optimal solution is included. New crossover and mutation operators are also developed to adapt to the specific chromosome structure and the nature of the problem. In order to strengthen the search ability, a local search procedure works under the framework of GA, this only investigates the neighbor solutions that have possibilities to improve the solutions of current population.

The rest of the paper is organized as follows. In Sect. 2, we formulate the mathematical model of rALB-2. The proposed GA for the problem is described in Sect. 3. In Sect. 4, introduce a local search procedure. In Sect. 5, we demonstrate effectiveness comparing with different GA approaches. This paper gives the conclusion in Sect. 6.

2 Robotic Assembly Line Balancing Problem

The assembly of each product unit requires the execution of n tasks (indivisible elements of work). Precedence constraints partially specify the order in which the tasks have to be performed. They can be represented by an acyclic precedence graph which contains nodes for all tasks. As mentioned above, the type II robotic assembly line balancing problem usually occurs when changes in the production process of a product take place. In this case, the robotic assembly line has to be reconfigured using the present resources (such as robots) so as to improve it efficiency for the new production process. The problem concerns how to assign the tasks to stations and how to allocate the available robots for each station in order to minimize the cycle time under the constraint of precedence relationships.

Let assembly tasks ($i = 1, 2, \cdots, 10$) assigned on 4 stations. Robots (R1, R2, R3, R4) are to be equipped on the 4 stations. The balancing chart of the solution was drawn for analyzing the solution. Figure 1 shows the idle time of the station 1, 2, 3 is very big, and it also means this line did not get the balancing for producing. In the real world, the assembly line is not just for producing one unit of the product. It should produce several units. We give the Gantt chart about 3 units for analyzing the solution just like Fig. 2.

We can see the waiting time occurs in the Fig. 2, and the waiting time means the idle time in the line. For example, the part waiting is occurred when the maximum processing time of the station, which is before the current station, is larger than the processing time of the current station. It means the current station will wait for the parts to process, which come from the anterior station. The processing waiting is occurred when the processing time of the current station is smaller than the processing time of the next station. It means the parts which were produced by the current station will wait for being processed

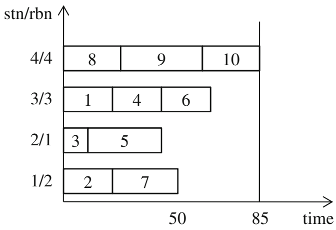

Fig. 1. Balancing chart of the feasible solution

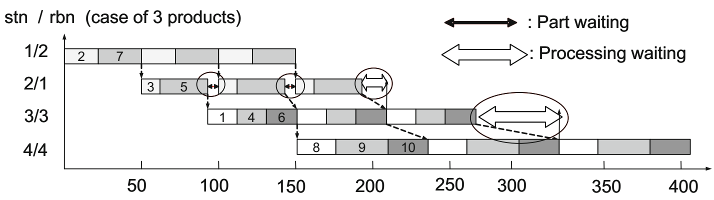

Fig. 2. Gantt chart for producing 3 units

by the next station. Both of the waiting time is the idle time of the assembly line. We want to reduce it by getting the balance of the line. The notation used in this section can be summarized as follows:

Indices:

i, j: index of assembly tasks, $i, j = 1, 2, \cdots, n$;
k: index of stations, $k = 1, 2, \cdots, m$;
l: index of robots, $l = 1, 2, \cdots, m$.

Parameters:

n: total number of assembly tasks;
m: total number of stations (robots);
t_{il}: processing time of the $i-th$ task by robot l;
pre(i): the set of predecessor of task i in the precedence diagram.

Decision variables:

$$x_{jk} = \begin{cases} 1, \text{ if task } j \text{ is assigned to work station } k \\ 0, \text{ otherwise;} \end{cases}$$

$$y_{jk} = \begin{cases} 1, \text{ if robot } j \text{ is assigned to work station } k \\ 0, \text{ otherwise.} \end{cases}$$

Problem Formulation:

$$\min\ C_T = \min_{1 \le k \le m} \sum_{i=1}^{n} \sum_{l=1}^{m} t_{il} x_{ik} y_{kl} \tag{1}$$

$$\text{s. t.} \sum_{k=1}^{m} kx_j k - \sum_{k=1}^{m} kx_{ik} \geq 0, \quad \forall j;\ i \in \text{pre}(i) \tag{2}$$

$$\sum_{k=1}^{m} x_{ik} = 1, \forall i \tag{3}$$

$$\sum_{l=1}^{m} x_{kl} = 1, \forall k \tag{4}$$

$$\sum_{k=1}^{m} x_{kl} = 1, \forall l \tag{5}$$

$$x_{ik} \in 0, 1, \forall k, i \tag{6}$$

$$x_{ik} \in 0, 1, \forall l, k. \tag{7}$$

The objective (1) is to minimize the cycle time (C_T). Inequity (2) represents the precedence constraints. It ensures that for each pair of assembly activities, the precedent cannot be assigned to a station behind the station of the successor, if there is precedence between the two activities. Equation (3) ensures that each task has to be assigned to one station. Equation (4) ensures that each station is equipped with one robot. Equation (5) ensures that each robot can only be assigned to one station.

3 Order-Based GA Design

Genetic algorithms (GAs) are powerful and broadly applicable stochastic search and optimization techniques based on principles from evolutionary theory [9]. GA's have been applied to solve various assembly line balancing problems [8,23,28]. We divide this algorithm into 3 phases. It is as follows:

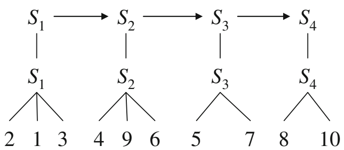

Fig. 3. Structure of example problem

Phase 1. Deciding Task Sequence

Phase 1.1 Order encoding for task sequence: A GA's structure and parameter settings affect its performance. However, the primary determinants of a GA's success or failure are the coding by which its genotypes represent candidate solutions and the interaction of the coding with the GA's recombination and mutation operators.

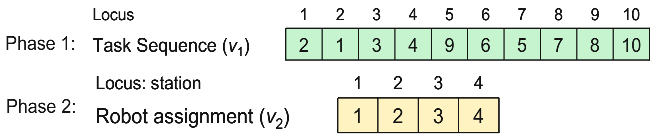

Fig. 4. Solution representation of a sample problem

A solution of the rALB problem can be represented by two integer vectors. Task sequence vector (v_1), which contains a permutation of assembly tasks, ordered according to their technological precedence sequence, and robot assignment vector (v_2). The solution representation method can be visually illustrated as in Figs. 3 and 4.

Phase 1.2 Reordering procedure: Considering precedence constraints, a task sequence may be infeasible since a precedent may appear before its successors. The reordering procedure will repair it into a feasible one before it is divided m parts to form a solution in the phase 1.

Phase 1.3 Breakpoint decoding: So, we use just one decoding procedure for phase 1, and the set of decoding procedure is to generate a feasible solution based on the task sequence and robot assignment schemes which are contained in the chromosomes. Then, the breakpoint decoding procedure inserts m points along the reordered task sequence vector to divide it into m parts, each of which corresponds to a station. The breakpoint decoding procedure consists of four main steps:

Step 1. Calculate the lower bound of the cycle time (C_{LB}) for the solution represented by the task sequence vector and robot assignment vector;

$$c_{LB} = \frac{1}{m} \sum_{i=1}^{n} \min_{1 \le l \le m} \{t_{il}\}; \tag{8}$$

Step 2. Find out a feasible cycle time as the upper bound of the cycle time (C_{UB});

Step 3. Find out the optimal cycle time via bisection method;

Step 4. Partition the task sequence into m parts with the optimal cycle time based on the robot assignment vector.

Here, a cycle time is said to be feasible if all the tasks can be allocated to the stations by allowing as many tasks as possible for each station under the constraint of the cycle time. The procedure to calculate the upper bound of cycle time is illustrated in procedure 2, and the bisection method to find out the optimal cycle time is shown in procedure 3. After calculating the optimal cycle time, it is easy to generate the breakpoints on the task sequence to divide it into m parts, each of which will correspond to a station, based on the robot assignment vector. Therefore, the tasks assigned for each station are determined according to a chromosome, and the cycle time can be calculated. An example of breakpoint decoding is showed in Fig. 5.

Phase 2. Assigning Robots to Station

Phase 2.1 Order encoding for robot assignment: A solution of the rALB problem can be represented by two integer vectors. In this phase, we code the robot assignment vector (v_2), which indicates the robot assigned for each station. The solution representation method can be visually illustrated as in Fig. 6. The coding space takes an exponential growth with the length of the chromosome; therefore, even one allele saved in the chromosome can decrease the coding space significantly. An obvious advantage to intentionally omit breakpoint vector, which is used in recently research, in the chromosome is that the coding space is dramatically decreased. As a result, the speed to find the global optimal is accelerated.

Phase 2.2 Breakpoint decoding: In this phase, this robot assignment vector (v_2) will decode into a solution with the task sequence vector (v_1), simultaneously by the breakpoint decoding procedure. It means when the tasks are assigned into each station, the robots will be assigned into each station at the same time. The illustration of the solution is shown in Phase 1.3.

Phase 3. Making a Schedule

Phase 3.1 Creating a schedule for the assembly line: We can make a schedule based on the chromosome (in Fig. 6) as fellow:

$$
\begin{aligned}
S = \{&(t_1, R_1 : 0-17), (t_2, R_1 : 17-38), (t_3, R_1 : 38-50), (t_4, R_2 : 50-71), \\
&(t_5, R_3 : 102-128), (t_6, R_2 : 71-89), (t_7, R_3 : 128-151), \\
&(t_8, R_4 : 151-176), (t_9, R_2 : 89-102), (t_{10}, R_4 : 176-202)\}
\end{aligned}
$$

Phase 3.2 Drawing a Gantt chart: Firstly, we draw a balancing chart for analyzing the solution (in Fig. 8). We can see the solution got the balancing for the line by comparing with the feasible solution from Fig. 2.

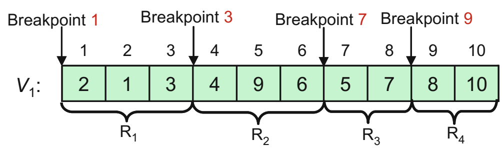

Fig. 5. Breakpoint decoding

In the real world, the assembly line is not just for producing one unit of the product. It should produce several units. So, we give the Gantt chart with 3 units for analyzing the solution just like Fig. 7, which is shown at the beginning. We can see the solution reduce the waiting time for the line by comparing with the feasible solution from Fig. 6. It also means the better solution got the balancing for the assembly line.

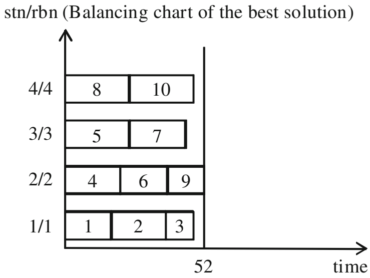

Fig. 6. The balancing chart of the best solution

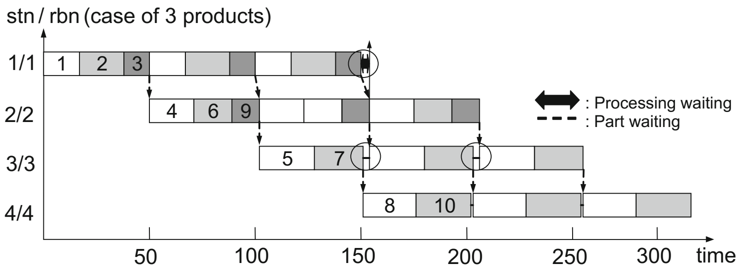

Fig. 7. Gantt chart for producing 3 units

3.1 Crossover Operators

In genetic algorithms, crossover recombines two chromosomes to generate a number of children. Offspring of crossover should represent solutions that combine substructures of their parental solutions [8]. In this paper, we use to kind of crossover methods: exchange crossover and mixed crossover. The detailed explanation of OX and PMX is introduced in [8].

(1) Exchange Crossover: A good schedule could be expected by exchanging task sequence and robot assignment schemes between a pair of parents. This kind of crossover is accomplished by selecting two parents and exchanging the task sequence vectors of the two parents to generate offspring.
(2) Mixed Crossover: The mixed order crossover consists of two crossover methods: Order Crossover (OX) and Partial-Mapped Crossover (PMX). For the rALB chromosome, the task sequence vector and the robot assignment vector are both of the style of permutation representation. Yet, the useful features of the task sequence vector and the robot assignment vector are different.

- For the task sequence vector, the useful feature of permutation representation to represent a rALB solution is the order information among the tasks.
- For the robot assignment vector, the acting feature is the number at each allele which indicates the robot no. assigned for a specific station.

3.2 Mutation Operators

In this study, two kinds of mutation operators are implemented: allele-based mutation and immigration mutation. For both the robot task sequence and robot assignment vectors, allele-based mutation randomly decides whether an allele should be mutated in a certain probability. Then, another position will be generated at random to perform exchange values with the mutated allele. In contrary to the canonical gene-by-gene mutation with very small probability at each generation, immigration mutation randomly generates one or more new members of the population from the same distribution as the initial population. This process prevents premature convergence of the population, and leads to a simple statement of convergence.

3.3 Fitness Evaluation

How to evaluate the fitness of chromosome is also key issue for GAs. In the most researches, objective function is used for fitness evaluation. However, the effective fitness function has to be different function and suitable to different problems. A central problem of fitness definition is how to guide to the most promising areas from the individuals of current generation. The characteristic of ALB problems are: ① We can calculate several different schedules with same cycle time. That means other conditions, such as idle time and total processing time are different, though the cycle time is same. For improvement of ALB, we also have to improve other conditions, not only cycle time. ② General, the solutions with better fitness of idle time and total processing time also can create better fitness of cycle time. We define the fitness function with considering not only the objective function (cycle time), but also idle time and total processing time. It is useful to guide to the most promising areas depending on the wide conditions from the individuals of current generation. We first define the fitness value $f_1(v)$ as the reciprocal of the cycle time $C_T(v)$ of the solution candidate v, the fitness values $f_2(v)$ as number of critical stations n_c and the fitness value $f_3(v)$ as the reciprocal of the standard deviation by the idle time of each station for balancing the workload of each station. t_k^W is the total processing time of each station. Then we give the adaptive weights for each fitness, where $w_1 + w_2 + w_3 = 1$. The special definition of fitness function is showed as follows:

$$f(v) = w(f(v)z^{\min}) + w(f(v)z^{\min}) + w(f(v)z^{\min}), \tag{9}$$

where

$$f_1(v) = \frac{1}{C_T(v)}, \tag{10}$$

$$f_2(v) = n_c(v), \tag{11}$$

$$f_3(v) = \frac{1}{m-1}\sum_{k=1}^{m}((C_T(v) - t_k^W(v)) - \frac{1}{m}\sum_{j=1}^{m}(C_T(v) - t_j^W(v))). \tag{12}$$

4 Local Search Procedure

Two individuals with high fitness values are likely to have dissimilar machine assignment and operation sequences, and the recombination may result in offspring of poor performance. This means that the genetic operations by themselves have limited ability in finding the global optimal solution. Many researchers have found that the convergence speed of simple GAs is relatively slow [7]. One promising approach for improving the convergence speed to the global optimum is the use of local search in GAs [17]. In this study, two local search methods are proposed to enhance the search ability of GA. Both the two local search methods are based on critical stations in order to improve their effectiveness and efficiency.

4.1 Task Sequence Search

Let $s(i)$ be the station to which task i is assigned. First we introduce the logical function $W_i(k)$ which return false if task i cannot be transferred from station $s(i)$ to station k, and true otherwise:

$$\begin{aligned} W_i(k) = &\text{false if} \\ &\quad s(i) > k \text{ and } j \in \mathrm{suc}(i), s(j) > k, \text{ or} \\ &\quad s(i) < k \text{ and } j; i \in \mathrm{suc}(j), s(j) < k \\ W_i(k) = &\text{true, otherwise.} \end{aligned}$$

For a pair of tasks i, j, if

$$W_i(s(j)) = W_j(s(i)) = \text{true} \wedge i \notin \mathrm{pre}(i)\ j \notin \mathrm{pre}(i),$$

then, the two tasks are said to be exchangeable. Let $R(i)$ be the robot which is allocated for station $s(i)$, and Tl be the total assembly time of station l. For a critical task i and task j which is not in $s(i)$, if

$$t_{j,s(i)} < t_{i,s(i)} \text{ and } T_s(j) - t_{j,s(j)} + t_{i,s(j)} < C_T,$$

then the exchange between tasks i and j is called worthwhile. The task sequence search is as follows:

Step 1. Decode the chromosome and identify a critical station l^*;
Step 2. For a task i that assigned to the critical station l^*, look for a task j that is not assigned to station l^*, and is exchangeable with task i.
Step 3. Repeat Step 2 until the exchange between tasks i and j is worthwhile or all the tasks in the critical station are tried.
Step 4. Repeatedly perform the above search steps until the chromosome cannot be improved any more.

4.2 Robot Assignment Search

Let $N(i)$ denote the set of machine assignment neighborhood of solution i. The enlarged two-pace machine assignment neighborhood is defined as the union of the neighborhood of each robot assignment neighbor of solution i

$$N^2(i) = \cup_{j \in N(i)} N(j). \tag{13}$$

During the robot assignment search, the local search will implement over two-pace neighborhood when it reaches the local optima of one-pace neighborhood, and is called two-pace robot assignment search. During the robot assignment search, when the local optima of two-pace robot assignment neighborhood is reached, the neighbors of the two-pace local optima are improved by the task sequence search to help the robot assignment search escape from the local optima. Since the size of the two-pace neighborhood is very large and the task sequence search is very computationally complex, to improve each neighbor solution by task sequence search needs a great computation time. Therefore, only those neighbor solutions that are local optimums of the two-pace robot assignment neighborhood are improved by task sequence search so as to save computation time.

5 Numerical Experiments

In the literature, no benchmark data sets are available for rALB. We collect 8 representative precedence graphs from [1], which are widely used in the sALB-1 literature [25]. These precedence graphs contain with 25-297 tasks. From each precedence graph, 4 different rALB-2 problems are generated by using different WEST ratios: 3, 5, 7, 10, 15. WEST ratio, as defined by Dar-EI [19], measures the average number of activities per station. For each problem, the number of station is equal to the number of robots, and each task can be processed on any robot. The task time data are generated at random, while two statistical dependence are maintained: (1) statistical dependence of task times on the task type, (2) statistical dependence of task times on the robot on which the task is processed.

To validate the effectiveness of our hybrid GA, we compare our approach with Levitin et al.'s two algorithms. Recently, Levitin et al. [18] develop an efficient approach for rALB problems. It is similar research with our purpose, aims to achieve a balanced distribution of work between different stations (balance the line) while assigning to each station the robot best fit for the activities assigned to it. Levitin et al. proposed two algorithms named as recursive assignment method and consecutive assignment method. If we look each robot as one type and deleting this type from the total types of robots when the robot is allocated for a station, Levitin et al.'s two algorithms can be adapted to solve the 32 rALB-2 problems here. Hence, the two algorithms proposed by Levitin et al. are also used to solve the 32 problems. The adopted parameters of the hGA are listed as following: maximal generations maxGen = 1000; population size popSize = 100;

Table 1. Performance of the proposed algorithm

Test problems			Cycle time (C_T)			Test problems			Cycle time (C_T)		
♯ of task	♯ of station	West ratio	Levitin et al.'s recursive	Levitin et al.'s consecutive	Proposed approach	♯ of task	♯ of station	West ratio	Levitin et al.'s recursive	Levitin et al.'s consecutive	Proposed approach
25	3	8.33	518	503	503	89	8	11.13	638	505	494
	4	6.25	351	330	327		12	7.42	455	371	370
	6	4.17	343	234	213		16	5.56	292	246	236
	9	2.78	138	125	123		21	4.24	277	209	205
35	4	8.75	551	450	449	111	9	12.33	695	586	557
	5	7.00	385	352	344		13	8.54	401	339	319
	7	5.00	250	222	222		17	6.53	322	257	257
	12	2.92	178	120	113		22	5.05	265	209	192
53	5	10.60	903	565	554	148	10	14.80	708	638	600
	7	7.57	390	342	320		14	10.57	537	441	427
	10	5.30	35	251	230		21	7.05	404	325	300
	14	3.79	243	166	162		29	5.10	249	210	202
70	7	10.00	546	490	449	297	19	15.63	1129	674	646
	10	7.00	313	287	272		29	10.24	571	444	430
	14	5.00	231	213	204		38	7.82	442	348	344
	19	3.68	198	167	154		50	5.94	363	275	256

exchange crossover probability $p_C = 0.20$; mixed crossover probability $p_M^1 = 0.80$; task sequence mutation probability $p_M^2 = 0.05$; robot assign. mutation probability $p_M^3 = 0.10$. Levitin et al.'s two algorithms used the same population size and maximal generations as the hGA.

Table 1 shows the experiment results of Levitin et al.'s two algorithms and proposed approach for 32 different scale test problems. As depicted in Table 1, all of results by proposed approach are obvious better than Levitin et al.'s recursive assignment method. And most results of proposed approach are better than and Levitin et al.'s consecutive assignment method, except to the test 25-3, test 35-7 and test 111-17. The differences of 32 test problems between proposed approach with Levitin et al.'s approaches are showed in Fig. 8.

To clearly see the convergence performance of proposed approach, we give the evolutionary process of proposed approach and Levitin et al.'s two methods by combining 3 different scale test problems: small-scale test 35-12, middle-scale test 111-17 and large-scale test 148-21. The evolutionary processes are showed in Fig. 9. As depicted in Fig. 9, the convergence of proposed approach is faster than each of other approaches. The difference of convergence increased with increasing the test problems size. Furthermore, though Levitin et al.'s consecutive found the same result with proposed approach for test 111-17, but the convergence speed of proposed approach was faster. The simulations show that propose hybrid GA with combining local search approach is computationally efficient and effective to find the best solution and convergence speed.

6 Conclusion

Robotic assembly line has been an important manufacturing system in the modern era. The objective of this work is to develop an efficient solution for the robotic assembly line balancing problem. This solution aims to achieve a balanced distribution of work between different stations and assign to each station the robot best fit for the activities assigned to it. The result of such solution would be an increased production rate of the line.

A new representation method adapting the GA to the rALB-II problem is proposed. Advanced genetic operators adapted to the specific chromosome structure and the characteristics of the rALB problem are used. In order to strengthen the search ability, two kinds of local search are integrated under the framework the genetic algorithm. The coordination among the three kinds of local search is well considered. The neighborhood structure of the local search can be adjusted dynamically. The balance between genetic search and local search is also investigated. The performance of proposed method is validated through simulation experiments. The simulation shows that our algorithm is computationally efficient and effective to find the best solution. The solution obtained by our algorithm outperforms the results from previous works.

Abstract. Owing to the development of internet finance in China, credit scoring is growing into one of the most important issues in the field of financial risk management. Quantitative credit scoring models are widely used tools for credit risk assessment in financial institutions. In this study, an AdaBoost algorithm model based on back-propagation neural network for credit scoring with high accuracy and efficiency is proposed. We first illustrate the basic concepts of back-propagation neural network and AdaBoost algorithm and propose a hybrid model of AdaBoost and back-propagation neural network, then two real-world credit data sets are selected to demonstrate the effectiveness and feasibility of the proposed model. The results show that the proposed model can get higher accuracy compared to other classifiers listed in this study.

Keywords: Credit scoring · AdaBoost model · Back-propagation neural network

1 Introduction

Credit scoring has grown an increasingly important issue of financial risk management in financial institutions since the 2008 financial crisis. It often calculates by following a set of decision models and other underlying technologies, does a great favor for lenders' judging whether an application of credit should be approved or rejected [27]. When some applicants fail to repay their debt, it leads to a direct economic loss for the lenders. In addition, the sub-prime mortgage crisis occurred in the USA has caused some financial institutions loss billions of dollars due to customers' default. However, if a credit-granting-institution rejects all applicants of loans even with good credit scores, it will suffer the potential revenues it can earn from the applicants in the future. Therefore, an efficient decision support with high accuracy becomes a clear need for financial institution.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_6

Due to the great importance of credit risk assessment, an increasing research stream is focusing upon credit risk assessment and credit scoring using different methods and models, approaches such as linear discriminant analysis (LDA) [1], logistic regression analysis LRA [26], k-nearest neighbor (KNN) [12,13] and decision tree [5] which uses the statistics disciplines. With the development of artificial intelligence(AI) techniques, artificial neural network (ANN) [3,8,14,21, 30,31], support vector machines (SVM) [2,11,25,34], genetic algorithm (GA) [7,22,28], rough set [4] and case-based reasoning [15–19] are used for credit scoring. Also some combined and ensemble approaches perform quite well with high accuracy and efficiency, including fuzzy system and artificial neural network [20,23], rough set and support vector machine [33], fuzzy system and support vector machines [29], case-based reasoning and support vector machines [19], neural network ensemble [32] etc.

Inspired by the combined and ensemble theories, this study attempts to purpose an ensemble AdaBoost model based on BP neural network for credit scoring. The main idea of AdaBoost algorithm is to maintain a distribution of weights over the training samples and adjust them after each basic classifier sorting cycle adaptively. In our study, we use ten single back propagation neural networks as the weak learners contends of a three-layer feed-forward network each, and the final strong ensemble classifier is constructed by the method of weighted voting associated with the performances of the weak learners. Based on the experimental results achieved from two public available credit data sets, our proposed AdaBoost model based on BP neural network obtains a good performance with higher accuracy efficiency compared to other models used in this study, which indicates a wide prospect usage in financial risk management.

The rest of this paper is organized as follows. Section 2 gives a brief formulation concerns about back propagation neural network and AdaBoost algorithm. Section 3 presents a hybrid model of AdaBoost and BP neural network. To verify the accuracy and effectiveness of the purposed model, empirical validation results of the model using the German credit data set and Australian credit data set are analyzed in Sect. 4. Finally, a short conclusion and discussion are presented in Sect. 5.

2 Methodology Formulation

2.1 Back-Propagation Neural Network Theory

Back-propagation neural network model was proposed by Rumelhart and Mccelland in 1985 [24], it is a kind of multi-layered forward feed type error counterbiography neural network. This model usually consists of input layer, output layer and hidden layer. Each layer includes certain nodes, and each node expresses a neuron. There exists interconnection among the nodes of different layers, but there is no connection among nodes in the same layer. Among them, the single hidden layer BP network's application is the most common. The typical structure of BP neural network is as shown in Fig. 1.

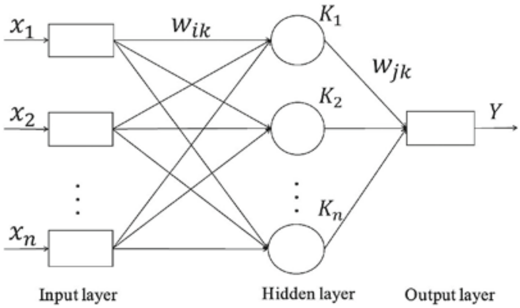

Fig. 1. Structure of single hidden layer BP neural network

The core thought of BP neural network can be described as following: training signal forward-propagating and error signal reverse dissemination. During the process of forward-propagating, the signal spreads from input layer, dealt with connection weights between input layer and hidden layer, then is transformed by the active function of hidden layer and transmitted to the output layer. If expected output can't be achieved from the output layer, then another process of error back propagation begins, which would continuously adjust the weights and bias of each layer in order to ultimately minimize the error of the network. This kind of signal forward-propagating and error back-propagating is to go iteration and iteration till the system output error is reduced to an acceptance degree or obtains the network constraints. Its concrete process is shown in Fig. 2.

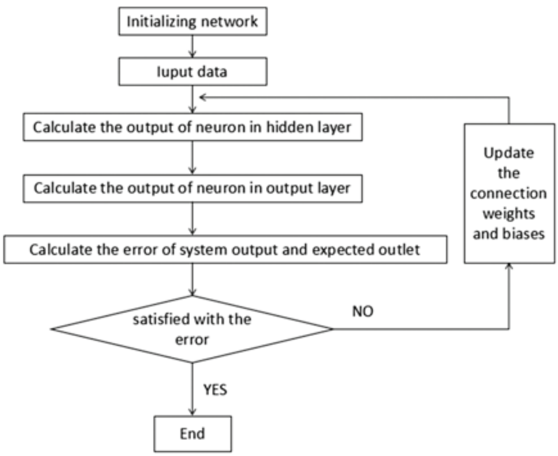

Fig. 2. Process of BP neural network model

2.2 Basic Theory of AdaBoost Algorithm

AdaBoost is a very popular boosting algorithm for binary classification, and it solved many practical difficulties of the earlier boosting algorithms. It was initially proposed by Yoav Freund and Robert Schapire in 1997 [10]. This algorithm constructs a high-quality compositive classifier by combining trained weak classifiers sequentially while putting more attention on those weak classifiers accompanied with good performance. There are several methods for combining results from base weak learners into one stronger predictor. Uniform voting, distribution summation, Bayesian combination, etc. are widely used for ensemble algorithms. Adaptive boosting algorithm has been applied in many fields such as speech recognition [9], moving vehicle classification based on images [6] and etc.

The main ideas of AdaBoost algorithm is to maintain a distribution of weights over the training samples and adjust them after each basic classifier sorting cycle adaptively. The weights of training data which are wrongly classified by current weak learner will be increased, otherwise, decreased if the samples are correctly classified. During the training process, the prediction error of the weak classifiers should be less than 0.5. And the voting weights of base classifiers will be increased while the decreasing of the prediction error, which means a larger voting weight this weak learner will take in the final ensemble output. Pseudocode for AdaBoost algorithm is shown in Fig. 3. As a series of base learners have been achieved, AdaBoost calculates a value α_t that is assigned to h_t, and the final hypothesis H is constructed via T weak classifiers using a weighted voting ensemble method.

AdaBoost Algorithm:

Given a training data set: $T = \{(x_1, y_1), \dots (x_i, y_i), \dots (x_n, y_n)\}$ $where$ $x_i \epsilon X, y_i \epsilon Y = \{-1, +1\}$

Initialize Distribution: $D_1(i) = \frac{1}{n}$, $i = 1,2, \dots, n$

For t = 1,2, … T:

•Train weak classifier using samples with distribution D_t

•Get weak hypothesis $h_t : X \to \{-1, +1\}$

•Calculate the error of h_t:

$$\varepsilon_t = \sum_{i=1}^{n} D_t(i) I_t(\mathrm{i})$$

$$\text{Where } I_t(\mathrm{i}) = \begin{cases} 1 & if \;\; h_t \neq y_i \\ 0 & if \;\; h_t = y_i \end{cases}$$

• Calculate the weight of current hypothesis: $\alpha_t = \frac{1}{2} * \ln(\frac{1-\varepsilon_t}{\varepsilon_t})$

•Update distribution: $D_{t+1}(i) = \frac{D_t(i)}{Z_t} \exp(-\alpha_t * y_i * h_t(xi))$

$$\text{Where } Z_t = \sum_{i=1}^{n} D_t(i) * \exp(-\alpha_t * y_i * h_t(xi))$$

Output final classifier:

$$H(x) = sign(\sum_{t=1}^{T} \alpha_t * h_t(x_i))$$

Fig. 3. Pseudocode for AdaBoost algorithm

3 Hybrid Model of AdaBoost and BP Neural Network

In this section, a hybrid model is constructed based on AdaBoost and BP neural network for credit scoring. According to the AdaBoost algorithm, the efficiency and accuracy of the ensemble predictor based on a series of weak classifiers largely depends on the accuracy of those base learners, the correlation coefficient of the ensemble predictor and the base classifiers is directly proportional. As BP neural network model is very fledged both in theory and practical applications with high accuracy and efficiency compared to other widely used models. So, in this study, BP neural network is selected as the weak classifier, and as the final ensemble classifier requires a certain method to combine those weak learners into an efficient ensemble system, we adopt the weighted voting method to combine the outputs of each weak classifier for the final outputs. The frame and pseudocode of hybrid model based on AdaBoost and BP neural network are shown in Figs. 4 and 5. The main steps used to construct ensemble predictor are shown as follows.

Step 1. Select the training samples randomly from the chosen databases with the method of 10-fold cross-validation, and each group training sample is assigned with the same weights:

$$\mathrm{T} = \{(x1, y1), \cdots, (xi, yi), \cdots, (xn, yn)\} \text{ while } xi \in X, yi \in Y = \{-1, +1\}.$$

The weights of this distribution on training samples on round t is denoted $D1(i)$. Initially, all weights are assigned with equal value $D1(i)$:

$$D1(i) = \frac{1}{n}, i = 1, 2, \cdots, n, \tag{1}$$

where n represents the total number of samples in the training data set;

Step 2. Parameters of the BP neural network, which include the structure of the network, neurons of each layer, expected goal, are set up according to the attributes of the input and output training samples. Then initialize the weights and biases of BP neural network.

Step 3. Training the BP neural network with the processed databases:

Step 3.1 Calculate input and output values of hidden layer: net_j, b_j

$$\mathrm{net}_j = \sum_{i=1}^{n} w_{ij} \times x_i - \theta_j, \tag{2}$$

$$b_j = f(\mathrm{net}_j), \tag{3}$$

where w_{ij} is the connection weights between input layer and hidden layer and θ_j represents the Threshold values of hidden layer, $f(x)$ represents the transfer function Sigmoid. Namely:

$$f(\mathrm{net}) = \frac{1}{1 + e^{-\mathrm{net}}}. \tag{4}$$

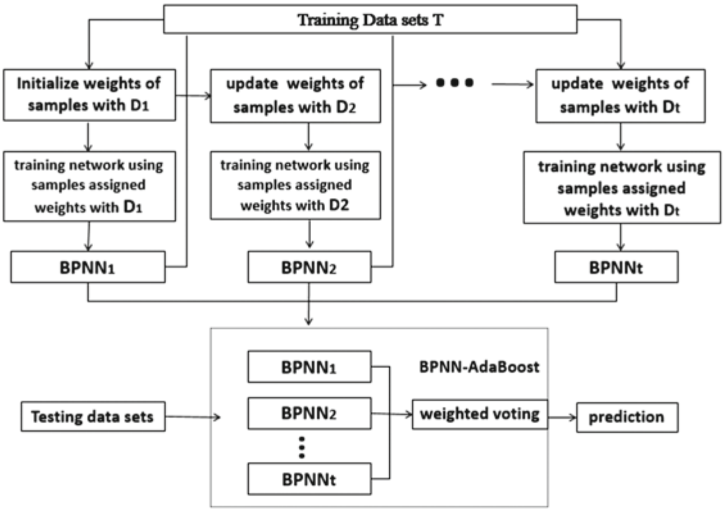

Fig. 4. The frame of hybrid model of AdaBoost and BP neural network

AdaBoost Model Based on BP neural network

Input: Training dataset $T = \{(x_1,y_1),\dots(x_i,y_i),\dots(x_n,y_n)\}$, where $x \in R^n, y_i \in \{-1,+1\}$
Weak classifier training algorithm (Back-Propagation algorithm)
Number of Learning Round: T
Initialize Distribution: $D_1(i) = \frac{1}{n}$, $i = 1,2,\dots,n$
For t=1: T Do

1. Select the subset training data drawn from the distribution $D_1(i)$.
2. Train the base classifier with the samples and obtain the hypothesis $h_t, h_t \in \{-1,+1\}$.
3. Calculate the classifying error of $h_t(x)$:

   $\varepsilon_t = \sum_{i=1}^{n} D_t(i) I(h_t(x_i))$ where $I(h_t) = \begin{cases} 1 & if\ h_t(x_i) \neq y_i \\ 0 & if\ h_t(x_i) = y_i \end{cases}$
4. Calculate the weight of current hypothesis h_t

   $\alpha_t = \frac{1}{2}\ln(\frac{1-\varepsilon_t}{\varepsilon_t})$
5. Update distribution $D_t(i)$

   $D_{t+1}(i) = \frac{D_t(i)}{Z_t}\exp(-\alpha_t * y_i * h_t(x_i))$

   Where Z_t is normalization constant for $D_{t+1}(i)$ become a proper distribution.

Output: Construct the final classifier based on the weak classifiers that have been trained using weighted voting method.

$$H(x) = sign(\sum_{t=1}^{T} \alpha_t * h_t(x))$$

Fig. 5. Pseudocode of hybrid model of AdaBoost and BP neural network

Step 3.2 Calculate input and output values of output layer:

$$\text{net}_i = \sum_{j=1}^{m} v_{jt} \times b_j - \gamma_i, \tag{5}$$

$$o_i = f(\text{net}_i), \tag{6}$$

where v_{jt} is the connection weights between hidden layer and output layer and γ_i represents the Threshold values of output layer. In this study, the hidden layer contains m neurons.

Step 3.3 Calculate the error d_i of each neuron of output using network's goal vector and its response output:

$$d_i = y_i - o_i, \quad (i = 1, 2, \cdots, n). \tag{7}$$

Step 3.4 Calculate the total error of the network $e(k)$:

$$e(k) = \frac{1}{2}\sum_{i=1}^{n}(d_i)^2. \tag{8}$$

Step 3.5 If the total error above is acceptable, the process stops. Otherwise, revise and. There are many ways of weight changes, we use the most common gradient descent method:

$$w_{ij}^{k+1} = w_{ij}^{k} + \Delta w_{ij}^{k} + \partial \Delta w_{ij}^{k-1}, \tag{9}$$

$$w_{jt}^{k+1} = w_{jt}^{k} + \Delta w_{jt}^{k} + \partial \Delta w_{jt}^{k-1}. \tag{10}$$

This process continuous till the system output error is reduced to an acceptance degree or obtains the network constraints.

Step 4. When training epochs go to round t, a base classifier $h_t(x)$ could be achieved with the weights distribution D_t and then calculate the weighted error ε_t from model:

$$\varepsilon_t = \sum_{i=1}^{n} D_t(i) \times I(h_t(x_i)), \tag{11}$$

where I$(h_t(x_i))$ is the indicator function, and its mathematical expression shows as below:

$$I(ht) = \begin{cases} 1, & \text{if } h_t(x_i) \neq y_i, \\ 0, & \text{if } h_t(x_i) = y_i. \end{cases} \tag{12}$$

Step 5. Calculate the weight of base classifier $h_t(x)$

$$a_t = \frac{1}{2}\ln\left(\frac{1-\varepsilon_t}{\varepsilon_t}\right). \tag{13}$$

As is shown above, if the prediction error of the samples is less than 0.5, the weight is bigger than zero, and with the decreasing of the prediction error, will be increased meanwhile, which means a larger voting weight of this weak learner in the final ensemble output.

Step 6. Update the weights of each samples in the training databases for the next iteration:

$$D_{t+1}(i) = \frac{D_t(i)}{Z_t}\exp(-a_t \times y_i \times h_t(x_i)), \tag{14}$$

where Z_t is normalization constant for $D_{t+1}(i)$ become a proper distribution:

$$Z_t = \sum_{i=1}^{n} D_t(i) \times \exp(-a_t \times y_i \times h_t(x_i)). \tag{15}$$

In this way, the weights of training data which are wrongly classified by current weak learner will be increased or decreased if the samples are correctly classified.

Step 7. As the training iteration goes on, a series of base classifiers will be obtained, then combine these classifiers during the processes:

$$f(x) = \sum_{t=1}^{T} a_t \times h_t(x). \tag{16}$$

A series of base classifiers with diversity are collected with loops from step 2 to step 5. Finally, an AdaBoost model based on the weak learners trained above is constructed:

$$H(x) = \mathrm{sign}(\sum_{t=1}^{T} a_t \times h_t(x)) \tag{17}$$

4 Empirical Analysis

In order to test the performance of the proposed AdaBoost algorithm based on BP neural network model, two available real world credit data sets with detailed input attributes description (German and Australian credit data sets) are used in this study. These two credit databases are available from open access UCI Machine Learning Repository. The German credit data set consists of 1000 instances with 700 samples labeled as creditworthy and 300 samples classified as poor credit. For each instance, there are 24 input variables described 19 attributes with 4 attributes changed to dummy variables. Also, the 25th variable is the label of the instance with two numerical descriptions, and label 1 stands for a worthy credit assessment of current instance, label 2, on the contrary, represents a bad credit evaluation. The meaning of original attributes are described in Table 1; The Australian credit data set is interesting because there is a good mix of attributes – continuous, nominal with small numbers of values, and nominal with larger numbers of values, which includes 690 instances in total with 383 samples classified as trustworthy and 307 samples labeled as poor credit. For each instance, 15 variables described 15 features of personal information and financial history of applicants, the last feature is labeled as approved (marked as 0) or rejected (marked as 1). All attribute names and values have been changed to meaningless symbols to protect confidentiality of the data.

Table 1. Original attributes in the German credit data set

Number	Description	Class
Attribute 1	Status of existing checking account	Qualitative
Attribute 2	Duration in month	Numerical
Attribute 3	Credit history	Qualitative
Attribute 4	Purpose	Qualitative
Attribute 5	Credit amount	Numerical
Attribute 6	Savings account/bonds	Qualitative

4.1 Experiment Design

In the experiment, the AdaBoost algorithm model based on BP neural network is used. The final classifier contents ten weak learners constructed with a three-layer feed-forward BP neural network model. As to the neurons in hidden of each weak learner, 9 nodes in hidden layer dealt with German data set and 20 nodes in hidden layer in Australian data set are set. For comparison purpose, some commonly used models, such as linear discriminant analysis (LDA), quadratic discriminant analysis (QDA), logistic analysis (Log A), K-Nearest neighbor (KNN), artificial neural network (ANN), back propagation neural network (BPNN), and least squares support vector machine (LSSVM) are also applied. In this study, training samples are selected by the method of 10-fold cross-validation to determine the model parameters. In BP neural network model, a common three-layer feed forward net trained by Levenberg-Marquartdt algorithm is employed, the transfer function in hidden layer is applied with Sigmoid function, and with Purelin function in output layer. In addition, three evaluation criteria, Type I Accuracy, Type II Accuracy and Total Accuracy are used, which are defined as follows [34]:

$$\text{Type I Accuracy} = \text{Specificity} = \frac{\text{number of both observed bad and classified as bad}}{\text{number of observed bad}}, \quad (18)$$

$$\text{Type II Accuracy} = \text{Sensitivity} = \frac{\text{number of both observed good and classified as good}}{\text{number of observed good}}, \quad (19)$$

$$\text{Total Accuracy} = \frac{\text{number of correct classification}}{\text{number of evaluation sample}}. \quad (20)$$

4.2 Experiment Result

As is shown in Tables 2 and 3, validation results for the German credit data set and Australian data set are achieved using the different algorithms and settings described above. The classification results of the first six classifiers in Tables 2 and 3 are from another article [35]. From Tables 2 and 3, several interesting findings can be drawn.

First of all, the total accuracy of the proposed AdaBoost model based on BP neural network is much better than other classifiers in both German and Australian data sets. Followed by the least squares support vector machine. Probable explaining reasons of the high accuracy achieved by AdaBoost model includes two aspects. For one thing, the accuracy of AdaBoost model depends much on the accuracy of the weak learners which it ensembles, and as we can see from Tables 2 and 3, BP neural network do a good credit classification compared to other commonly used models. For another reason, the main idea of AdaBoost system gives larger weights to those base classifiers with small prediction error, and as a result, the total accuracy of AdaBoost model get the best performance among all the classifiers compared in this study.

Second, referring to Type I Accuracy, the presented AdaBoost model based on BP neural network performs the best, compared to other classifiers employed in this study both in German credit data set and Australian credit data set. Followed by the linear discriminant analysis model in German data set and logistic analysis model in Australian data set.

Third, in terms of Type I Accuracy and Type II Accuracy, all models used in this study perform better with higher accuracy in Type II Accuracy than Type I Accuracy in general, which indicates that it's more difficult to classify customers with bad credit conditions from those of good credit evaluation cause of the complexity of credit risk.

Fourth, according to the Type II Accuracy shown in Table 2, our proposed model only ranks the fourth compared to other models for comparison. Supposed reason of this phenomenon may be the default of the AdaBoost algorithm, there is no exotic existence of noisy data in German data set, which will attract more attention of our AdaBoost model based on BP neural network on these noisy signals, as a result, the accuracy of our proposed model may not be satisfied as we wish and thus performs ordinarily in German credit data set.

Finally, compared with Tables 2 and 3, it's easy to find out that the performance of the German data set is worse than that of the Australian data set.

Table 2. Credit evaluation results comparison of different models for German credit dataset

Models	Type I Accuracy		Type II Accuracy		Total Accuracy	
	%	Rank	%	Rank	%	Rank
LDA	72	2	74.57	6	73.8	5
QDA	66.57	3	69.33	8	67.4	8
Log A	50.33	5	88.14	3	76.8	3
KNN	27	8	90.57	1	71.5	6
ANN	46.89	7	73.46	7	69.43	7
BPNN	63.83	4	79.36	5	75.8	4
LSSVM	49.67	6	88.86	2	77.1	2
BPNN_AdaBoost	78.7	1	84.19	4	83	1

Table 3. Credit evaluation results comparison of different models for Australian credit dataset

Models	Type I Accuracy		Type II Accuracy		Total Accuracy	
	%	Rank	%	Rank	%	Rank
LDA	80.94	6	92.18	2	85.94	5
QDA	66.12	8	91.38	3	80.14	6
Log A	85.9	2	86.32	6	86.09	4
KNN	81.72	5	54.4	8	69.57	8
ANN	72.56	7	83.61	7	78.94	7
BPNN	83.95	4	87.65	5	86.23	3
LSSVM	85.12	3	89.25	4	86.96	2
BPNN_AdaBoost	89.06	1	94.59	1	92.03	1

There are two possible reasons. On one hand, the credit market in Germany is more complex than that in Australia. On the other hand, there is more non-linearity in the German data set than in the Australian data set. Overviewing the above performance, one interesting phenomenon shows that there is a great capability raising of all three evaluation criteria both in the German data set and Australian data set compared BP neural network with the AdaBoost model based on BP neural network, from the viewpoint of Total Accuracy, there is a 9.5% raising in the German data set and a 6.7% raising in the Australian data set.

5 Conclusion

In this paper, a hybrid model of AdaBoost and BP neural network is proposed for credit risk evaluation. According to the empirical results, we find that our proposed hybrid model is the best one compared with other seven models for two publicly available credit data sets, which indicates that our proposed hybrid model of AdaBoost and BP neural network has a good practicability for credit scoring. In the future, we will use other method as base classifiers, for example, support vector machine and decision tree, and research other ensemble algorithm like bagging algorithm for credit risk assessment.

Abstract. Because the urban and rural residents' sports and leisure behaviors were different, to find out the factors influencing these differences was the purpose of this study. Therefore we selected urban and rural residents in Sichuan province as the research object to start our study. This study which was based on the Theory of Planned Behavior (TPB) used Structural Equation Modeling (SEM) as the research method. Firstly we constructed the conceptual model and put forward a series of assumptions. Then we used questionnaire survey to obtain first-hand information, at the same time we used ARMOS17.0 to work out the model. At last we verified our original assumption with the model. Research showed that: (1) The influence on the urban and rural residents' sports and leisure behavior from external objective factors (social atmosphere, venues, facilities, etc.) was much larger than that from the intrinsic objective factors (leisure time, income, physical condition, etc.); (2) The richness of sports and leisure activities, venues, facilities and the social atmosphere impacted the behavior of urban residents much more than that of rural residents; (3) The attitude to affirm and recognize sports and leisure had much more influence on urban residents; (4) While rural residents more cared about the views from family, friends even government.

1 Introduction

Under the Chinese specific dual social structure between urban and rural areas, social and economic activities, material conditions, living environment,

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_7

life style, cultural consciousness between urban and rural areas appear a huge differentiation [5, 24]. In terms of sports and leisure activity, social system differences between the urban and rural result in gaps which come from capital investment, facilities construction, social organization development and concepts. And the leisure sports behavior of urban and rural residents also shows difference. What's more, with the accelerating of urbanization process, urban and rural demographic differences will also expand the difference of leisure sports behavior [11]. Therefore, the purpose of this study is trying to find out the main factors which cause huge difference and gap between urban and rural residents, and to think about how to close the gap.

Sports and leisure behavior is a dynamic process that people try to meet their leisure needs to participate in sports activities spontaneously and get satisfaction from it. The purpose that people take part in leisure sports activities mainly includes physical aspect (exercise, beauty fitness, self-defense, etc.) and emotional aspect (entertainment, relieve pressure, thrill-seeking, social communication, etc.) [19]. Western researches about sports and leisure behavior is mainly focused on the influence of behavior by using various theories. Trans-theoretical Model (TTM), Self-efficacy, Self-determination Theory (SDT), Leisure Constrains Theory, Theory of Planned Behaviors (TPB) are the representative theories [3, 4, 6–9, 15, 16, 18]. In 2006, Xu [21] who published a paper "The Study on the characteristics of the Residents' Leisure Sports Behaviors" in the Journal of Guangzhou Sport University opened the prelude of the domestic sports and leisure behavior research. Qiu [10, 12–14] who published many articles in the Chinese authoritative core journals is very outstanding in the study of sports and leisure behavior. It is worth mentioning Yu [23], Zhao [25], Ye [22] and others who introduced the theory of planned behavior (TPB) into the sports and leisure behavior study. Overall, the domestic scholars' research mainly focused on cities and towns and little focused on rural areas and it caused the lacking of empirical studies in such areas.

It is very hard to find out a clear answer from existing researches in the face of the question what is the deep reason that causes sports and leisure behavior differences between the urban and rural residents. In order to answer this question better, we introduce the Theory of Planned Behavior (TPB) and Structural Equation Modeling (SEM) as our theoretical and method guide and choose Sichuan province as the sample to try to reveal the main influencing factors of sports and leisure behavior of urban and rural residents and to analyze the relationship between these factors. We try to work out a theoretical analysis framework to explain the differences between urban and rural residents' sports and leisure behavior and this framework should play an important role to enrich and expand the leisure science research. According to the results, we put forward corresponding countermeasures and suggestions to improve the policy environment effectively and promote the development of urban and rural integration better.

2 Theory and Hypothesis

2.1 Introduction to the Theory of Planned Behavior

Theory of Planned Behaviors (TPB) is one of the most famous theories about the relationship between attitude and behavior in the field of social psychology. Based on the Theory of Reasoned Action (TRA), Ajzen [1] published "The Theory of Planned Behavior" in 1991, it marked the born of the formal formation of Planned Behavior Theory. In the TPB, the Behavior is affected by the Behavior Intention or the Perceived Behavioral Control. And the Behavior Intention is affected by the Attitude toward the Behaviors, Subjective Norm and Perceived Behavioral Control, at the same time Behavioral beliefs, Normative beliefs and Control beliefs respectively affect the Behavioral Attitude, Subjective Norm and Perceived Behavioral Control.

The effects of sports and leisure behavior involve economic factors (income, consumption idea), cultural factors (leisure concept, leisure atmosphere, leisure time, etc.), environmental factors (Sports venues, policy guarantee, product promotion, service level, etc.), etc. In this study we analyze problems from the perspective of the TPB and give out the main factors which affect the urban and rural residents' behavior. Below are the main factors.

(1) Attitude
If people keep positive attitudes on the sports and leisure activity, they will actively participate in the activity. It is obvious that the attitude can affect the behavior.

(2) Subjective Norm
It refers to whether the views and practices of people around will affect residents' participation in sports and leisure activities.

(3) Perceived Behavioral Control
It refers to whether the past experience and current conditions of residents have influence on their sports and leisure behaviors.

(4) Behavior Intention
It refers to if the residents are more willing to participate in sports and leisure activities subjectively, the probability that they actually participate in sports and leisure activities is greater. And the significant positive correlation between behavior and intention is also confirmed by many relative researches.

(5) Other Objective Factors
According to interview results from Sichuan residents, the main reasons that people do not attend sports and leisure activities include lack of enough time, lack of appropriate sports ground, lack of specific skills for their favorite sports, lack of information and lack of partner, etc.

2.2 Conceptual Model and Assumptions

According to the TPB and the previous investigation results, we build our conceptual model (Fig. 1). According to the key points in the model, we make the following theoretical assumptions:

Hypothesis 1 (H1): The attitude of sports and leisure has a significant positive influence on the behavior intention.

Hypothesis 2 (H2): The attitude of sports and leisure plays an intermediary role between subjective norm and behavior intention.

Hypothesis 3 (H3): The attitude of sports and leisure behavior plays an intermediary role between perceived behavioral control and behavior intention.

Hypothesis 4 (H4): Subjective norm has a significant positive influence on the behavior intention.

Hypothesis 5 (H5): The perceived behavioral control has a significant positive influence on the behavior intention.

Hypothesis 6 (H6): The peripheral objective factors have a significant positive influence on the TPB system.

Hypothesis 6a (H6a): The peripheral objective factor has a significant positive influence on the subjective norm.

Hypothesis 6b (H6b): The peripheral objective factors have a significant positive influence on the attitude.

Hypothesis 6c (H6c): The peripheral objective factors have a significant positive influence on the perceived behavioral control.

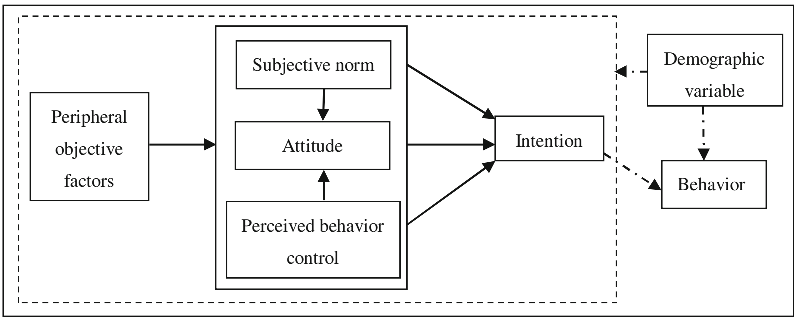

Fig. 1. The conceptual model of factors influencing sports and leisure behavior based on the TPB

3 Data Collection

3.1 Questionnaire Design

The influence factors of sports and leisure behavior mainly include the attitude, subjective norm, perceived behavioral control, peripheral objective factors and intention. The relevant information is collected through the questionnaire survey. This questionnaire chooses the Likert Scale, each question uses a measurement from strongly disagree (1 point) to strongly agree (5 points). All questions in Questionnaire come from the discussion of our team and the experts' suggestion. Below are the questions designed according to the conceptual model and the hypothesis (Table 1).

3.2 Data Collection

Empirical investigation in this study mainly involved Chengdu and other seventeen cities of Sichuan. We issued questionnaires two times. One is in spring of 2016 and the other is in summer of 2016.

For the first time, we mainly authorized students from Chengdu Sport Institute to issue the questionnaires in spring. During the vacation we issued 200 questionnaires through network and field investigation, and we received 62 effective questionnaires (43 ones from urban residents while only 19 ones from rural residents). Unfortunately, the effective recycling rate was very low and the reason was that: firstly, in the questionnaire we designed three filtering questions to filter bad ones; Secondly, the types of sports and leisure activities in rural areas are much less than these in urban areas, participation rate was also lower than that in town. In addition, in recent year rural migrant workers continued to increase in young adults, people left were only older and children. The older and children left were not able to finish questionnaire, so the amount of effective questionnaires was very small.

For the second time, we still authorized students from Chengdu Sport Institute to issue questionnaires in summer vacation. During the whole vacation we issued 400 questionnaires. This time we did some adjustments to issue more questionnaires to the rural residents. At last we recycled 168 effective questionnaires (83 ones from urban residents and 85 ones from rural residents).

To sum up, we issued 600 questionnaires out and recycled 230 effective ones at last. Among the effective questionnaires, 126 ones were from urban residents and the left 104 ones came from rural residents. Though sample size was not big enough but it could provide supports for this study.

3.3 Validity and Reliability Analysis

(1) Validity Analysis
Validity analysis of the questionnaire mainly uses the Factor Analysis method. We handle 20 questions in Table 1 as 20 variables which have influence on sports

Table 1. The questionnaire items assessing the TPB variables

Variables	Items (Question)
Attitude	a1. It is a pleasure to take part in sports and leisure activities
	a2. Sports and leisure activities are the best choice for entertainment and relaxation
	a3. Sports and leisure can help me to make more friends
	a4. Sports and leisure is an important part of my life
	a5. To participate in sports and leisure activities needs to insist on a long time, for which you are willing to give up some of the other things you like
Subjective norms	a6. The family supports me to participate in sports and leisure activities
	a7. Friends / colleagues / classmates support and appreciate me to participate in sports and leisure activities
	a8. When people see I take part in sports and leisure activities, they think I'm a man of life taste
	a9. The government encourages us to participate in sports and leisure activities
Perceived behavior control	a10. Enough time
	a11. Good income
	a12. Good physical condition
	a13. Enough information
	a14. It is very convenient to participate in sports and leisure activities
Peripheral objective factors	a15. The sports and leisure activities are abundant
	a16. Enough ground and facilities for sports and leisure activities
	a17. Good atmosphere of sports and leisure
Intention	a18. I am willing to participate in sports and leisure activities under the existing conditions
	a19. I will take part in sports and leisure activities in the future
	a20. I will persuade my family and friends together to participate in sports and leisure activities

and leisure behavior. By using SPSS19.0 software to calculate, Kaiser-Meyer-Olkin (KMO) is 0.871 and the significant probability of Bartlett Test of Sphericity statistic is 0.000 ($p < 0.01$), both of them indicate the data is suitable for factor analysis. Then we extract 5 common factors from the 20 variables, they can account for 63.876% of the total variation. Through rotary, we can see the factor-1 has a great influence on variables-a1, a2, a3, a4, a5, a18 and a19 (load value > 0.5); Factor-2 has a great influence on variables-a6, a7, a9 and a20; Factor-3 has a great influence on variables-a12, a15, a16 and a17; Factor-4 has a greater influence on variables-a10 and a13; and factor-5 has a great influence on variable-a11. While for variables a8 and a13, each of their load value on every common factor is less than 0.5, so we have reason to delete them. In the next step, we find that the item variable-a11 also should be removed through the tests for every common factor respectively.

(2) Reliability Analysis
We do the internal consistency test for the variables of every factor with Cronbach's alpha reliability analysis. And we find that 4 factors (attitude, subjective norm, periphery objective factors and intention) pass the test. If we delete the variables $a11$ and $a12$ in the factor-perceived behavioral control, the a-coefficient increases significantly to 0.698. In order to pass the internal consistency test, variables a11 and a12 should be deleted.

4 Modeling and Modification

4.1 Structural Equation Modeling

Structural Equation Modeling (SEM) is a common method in social science research. In the field of social science, the causal relationships among variables are complex sometimes, or these variables can't be observed directly, therefore traditional statistical methods can't solve this problem well. Since the 1980s, SEM has been developed quickly, it makes up for the deficiency of the traditional statistical method and becomes an important tool of multivariate data analysis [2,20]. SEM is a kind of multivariate analysis technology based on the regression. For it is of theory apriority, SEM is used to check the hypothesis between observed variables and latent variables, generally 5 samples are enough for every observed variable [17]. This research built the SEM of urban and rural residents' sports and leisure behavior influence factors with ARMOS17.0 software (Fig. 2).

4.2 The Urban Model

(1) Calculation and Correction
According to the SEM shown in Fig. 2, we take the 126 samples of the urban residents into the model. There are 5 paths that don't pass the significance test ($p < 0.01$) in the results and TLI index also fails in the inspection, so the model needs to be modified and optimized. After repeating the path correction, we delete the factors of perceived behavioral control, the results are obviously optimized (Tables 2 and 3). All indexes pass the test. Every variance estimation also passes the significance test ($p < 0.01$). In order to make the original model optimized better, we adopt Modification Index to fix the model again. We try

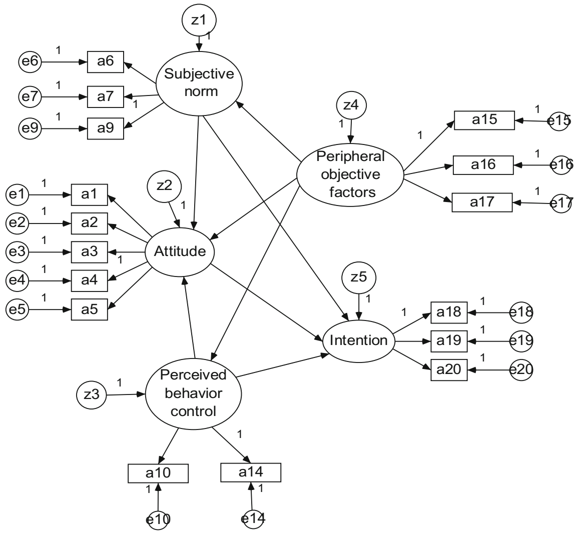

Fig. 2. Structural equation modeling

to modify the error terms of some observed variables by calculating MI value and find that it can optimize the index, but it can't improve the P value. On balance, we give up Modification Index and just keep the first adjusted result.

(2) Output
For the urban residents' sports and leisure behavior influence factor, we summarize the verification results of hypothesis 1 to 6 (Table 4). Then we can build out the SEM for urban residents.

4.3 The Rural Model

(1) Calculation and correction
According to the SEM shown in Fig. 2, we take the 104 samples of the rural residents into the model. 4 paths in the results don't pass the significance test ($p < 0.01$), and the AIC and EVCI indexes also fail in the test. It needs to correct the model. After repeating path correction, we delete the factor of perceived behavioral control and use Modification Index to revise the error terms of a4, a5 and a18 in the model. The results are optimized, all indexes pass the test, and every variance estimation also passed the significance test ($p < 0.01$). (Tables 5 and 6)

(2) Output
In view of the sports and leisure behavior influence factors of rural residents, we summarize the verification results of hypothesis 1 to 6 (Table 7). Then we can build out the SEM for rural residents.

5 Results

In view of the above empirical analysis, there are some differences between urban residents and rural residents in sports and leisure behavior influence factor.

From the perspective of direct effects (Table 8), the influence of peripheral objective factor that affected urban residents' sports and leisure attitude was larger 0.182 units than what affected rural residents, the influence of subjective norm on urban residents was larger 0.051 units than that on rural residents. For the influence of sports and leisure attitude on the intention, urban residents were higher 0.179 units than rural residents. The subjective norm only affected the intention of urban residents but did not affect their attitude, however subjective norm not only affected the intention of rural residents but also affected their attitude. The subjective norm had more influences on the intention of rural residents.

From the perspective of indirect effects (Table 8), the influence of peripheral objective factors on the intention of urban residents was 0.675 units, it was higher than that on rural residents. At the same time, the peripheral objective factors also indirectly affected the attitude of the rural residents. The subjective norm could indirectly affect the intention of rural residents through attitude, but it could not affect urban residents.

Table 8. Direct and indirect effect (Standardized results)

	Urban				Rural			
	Direct effect/Indirect effect				Direct effect/Indirect effect			
	Peripheral objective factors	Attitude	Subjective norm	Intention factors	Peripheral objective	Subjective norm	Attitude	Intention
Attitude	.764/	-	-	-	.582/.098	.257/	-	-
Subjective norm	.433/	-	-	-	.382/	-	-	-
Intention	/.675	.807/	.135/	-	/.537	.289/.162	.628/	-

a17	.586/	-	-	-	.575/	-	-	-
a16	.514/	-	-	-	.469/	-	-	-
a15	.686/	-	-	-	.698/	-	-	-
a1	/.543	.710/	-	-	/.550	/.208	.809/	-
a2	/.568	.743/	-	-	/.538	/.204	.791/	-
a3	/.436	.570/	-	-	/.411	/.156	.604/	-
a4	/.635	.831/	-	-	/.544	/.206	.799/	-
a6	/.373	-	.860/	-	/.335	.876/	-	-
a7	/.376	-	.867/	-	/.348	.911/	-	-
a9	/.245	-	.564/	-	/.187	.490/	-	-

From the perspective of total effects (Table 8), the influence of peripheral objective factors on the attitude, subjective norm and intention of urban residents was greater than that of rural residents. For the influence of attitude on the intention, it was larger for urban residents than for rural residents. For the influence of subjective norm on the intention, it was larger for rural residents than for urban residents. In addition, the subjective norm also affected the attitude of rural residents, but it did not affect the attitude of urban residents.

6 Discussion and Conclusion

The sports and leisure behavior of urban residents was affected by the intention, attitude, subjective norm and peripheral objective factors. The Subjective norm, attitude and intention were the intermediary variables. The subjective norm and the behavior attitude were two independent variables, besides, they were both affected by the peripheral objective factors, at the same time they indirectly affected the sports and leisure behavior by impacting behavioral intention. Sports leisure and behavior of rural residents was also affected by the intention, attitude, subjective norm and peripheral objective factors. The subjective norm, behavior, attitude and intention were the intermediary variables. The relationships among them were more complicated than the relationships of urban residents. The peripheral objective factors affected the subjective norm and attitude, at the same time they affected the sports and leisure behavior through behavioral intention. In addition, the subjective norm affected the attitude of rural residents, but it did not affect the attitude of urban residents.

After we calculated the path coefficient, we got a point of view about the total effect. The influence of peripheral objective factors on the attitude, subjective norm and intention of urban residents was higher than that of rural residents. For the influence of attitude on the intention, it was higher for urban residents than for rural residents. For the influence of subjective norm on the intention, it was higher for rural residents than for urban residents. That is to say, the influence of external objective factors (social atmosphere, sports ground, facilities, etc.) on the sports and leisure behavior of both urban and rural residents was much larger than the influence of intrinsic objective factors (personal leisure time, personal income, physical condition, etc.). The diversity and richness of sports and leisure activities, sports ground, facilities, and social atmosphere impacted urban residents more than rural residents. Admissive and positive attitude toward sports and leisure activities influenced urban residents more. While rural residents more cared about the view of their family, friends and even the government about their participation in sports and leisure activities.

Abstract. In this paper, a fast multiobjective hybrid evolutionary algorithm (MOHEA) is proposed to solve the multiobjective optimization problem (MOOP) in achieving a balance between convergence and distribution with computational complexity. The proposed algorithm, MOHEA, improves the vector evaluated genetic algorithm (VEGA) by combing a new sampling strategy according to the Pareto dominating and dominated relationship-based fitness function. VEGA is good at searching the edge region of the Pareto front, but it has neglected the central area of the Pareto front, and the new sampling strategy prefers the center region of the Pareto front. The mixed sampling strategy improves the convergence performance and the distribution performance while reducing the computational time. Simulation experiments on multiobjective test problems show that, compared with NSGA-II and SPEA2, the fast multiobjective hybrid evolutionary algorithm is better in the two aspects of convergence and distribution, and has obvious advantages in the efficiency.

Keywords: Evolutionary algorithm · Mixed sampling · Multi-objective optimization · Styling · Benchmark

1 Introduction

Multiobjective evolutionary algorithms (MOEAs) have been identified as very suitable for solving multiobjective optimization problems (MOP) [4]. MOEA is a heuristic method, and is useful for searching the Pareto optimal solutions of a MOP by global and local search between generations. From the results, MOEA can provide decision maker (DM) with a number of more practical solutions. So the DM can make decisions based on actual needs. In the optimization process of a single objective, the collaboration of other objectives should be considered at the same time. Meanwhile, maintaining the trend of simultaneous evolution

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_8

make the Pareto front solutions as close as possible. Simultaneously, the real Pareto optimal set is evenly distributed.

Moreover, a number of evolutionary algorithms have their own characteristics. Each algorithm is effective to solve the problem of limited areas of application. No algorithm can solve all the problems. How to mix these evolutionary algorithms to play their respective strengths has become one of the challenging research fields in evolutionary algorithms.

In order to compensate for the shortcomings of single MOEA, more researchers began to combine different algorithm to generate hybrid algorithm. In 2012, Zhang and Fujimura proposed an improved vector evaluation of genetic algorithm with archive (IVEGA-A) [6]. The IVEGA-A combines the strong convergence ability of the VEGA [7] method to the Pareto frontier boundary region [11] and the elite population updating mechanism based on the new fitness function to ensure the overall performance of the algorithm in the central region of the Pareto front. Zhang and Li introduced differential evolution strategy into MOEA/D [5].

In this paper, we propose a multi-objective hybrid evolutionary algorithm (MOHEA) to solve multi-objective optimization problem for improving the convergence, the distribution and reducing the computational time. The rest of the paper is organized as follows: An overview of sampling strategy is given in Sect. 2. MOHEA is summarized in Sect. 3. Section 4 presents experimental results to illustrate the efficiency of the algorithm.

2 Mixed Sampling Strategy

2.1 Pareto Dominating and Dominated Relationship-Based Fitness Function

In this paper, a new fitness function based on Pareto dominating and dominated relationship-based fitness function (PDDR-FF) is used to evaluate the individual. The fitness function value of an individual S_i is calculated by the following function:

$$\text{eval}(S_i) = q(S_i) + \frac{1}{p(S_i) + 1},\ i = 1, 2, \cdots, \text{popSize}, \tag{1}$$

where $q(S_i)$ is the number of individuals that dominate S_i, $p(S_i)$ is the number of individuals that dominated by S_i. popSize is the size of the population. If the individual S_i is non-dominated solution, $q(S_i) = 0$. Therefore, the fitness function of the non-dominated individual S_i is related to $p(S_i)$. The more individuals are dominated by S_i, the smaller the value of $1/(p(S_i) + 1)$, and the smaller the value of PDDR-FF. If $q(S_i) = 0$, $p(S_i) = 0$, the PDDR-FF value of S_i is 1. It means there is no individual dominates S_i and no individual is dominated by S_i. Therefore, the PDDR-FF value of the non-dominated solution will no more than 1. S_i is dominated individual, $q(S_i) \geq 1$; the less individuals that dominate S_i, the smaller $q(S_i)$. In addition, the more individuals that are dominated by

S_i, the bigger $p(S_i)$ and the smaller $1/(p(S_i)+1)$. Then, the value of PDDR-FF is smaller.

The smaller value of PDDR-FF means that the more individuals dominated by S_i and the less individuals dominating S_i. Therefore, the smaller the PDDR-FF value, the better. And besides, PDDR-FF can clearly identify the dominant and non-dominated solutions. If an individual is a non-dominant, the fitness function value is not more than 1. Even if the individuals are all non-dominated, the individuals with different number of dominant are endowed with different fitness function values. It is obvious that the fitness function value (close to 0) of the non-dominated individuals locating near the central area of the Pareto front having big domination area is smaller than the value (close to 1) of the individual in the edge region.

2.2 Mixed Sample Strategy of VEGA and PDDR-FF

The sampling strategy of PDDR-FF has the advantage of being able to converge to the central region of Pareto frontier. But the convergence of the edge region is not so good. Only using the PDDR-FF can cause the uneven distribution performance. Compared to the central area of Pareto frontier, the sampling strategy of VEGA is more preferred than the edge region, and the single use of VEGA sampling can also lead to the problem of the distribution performance. Therefore, the two sampling strategy can be combined to improve the overall performance of the algorithm and reduce the computation time.

3 Fast Multi-Objective Hybrid Evolutionary Algorithm

3.1 Detailed Process of MOHEA

The strong convergence capability of mixed sample strategy ensures that the MOHEA has ability to converge to the center and the edge region of true Pareto frontier. Meanwhile, different convergence regions ensure the distribution.

The specific algorithm flow of MOHEA is shown in Fig. 1.

The specific process of MOHEA is as follows:

Step 1. Initialization of algorithm parameters: The size of the population: popSize, the size of archive:archiveSize, the maximum number of calculation:maxEvaluations.

Step 2. Creating initial population $P(t)$ and initial archive $A(t)$.

Step 3. Loop $d)-g)$ step until the termination condition is satisfied: The number of the calculation achieves the maximum.

Step 4. Selection (VEGA sampling strategy) Using the VEGA sampling strategy to select good individuals as a part of the mating pool. For the two objectives of problem, at first all individuals in the population are ordered according to the value of object function 1 and select $\left|\frac{P(t)}{2}\right|$ individuals with replacement into the sub-population 1 in order. In a similar way, considering objective 2 and select $\left|\frac{P(t)}{2}\right|$ individuals with replacement into the sub-population 2.

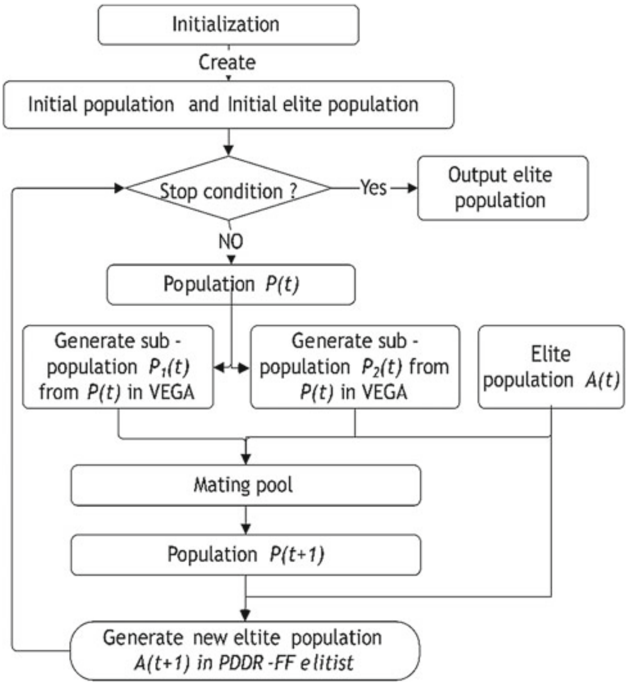

Fig. 1. The specific algorithm flow of MOHEA

Step 5. Generation of the mating pool: mixing the sub-populations and $A(t)$ to form the mating pool. In the mating pool, sub-population 1 stores the excellent individuals for the objective 1 and sub-population 2 keeps the excellent individuals for the another objective. The individuals with good PDDR-FF value are stored in $A(t)$. For the two objectives optimization problem, the size of these two sub populations and archive are set to the half size of the population. As a result, there are three parts in the mating pool, 1/3 of the individuals serve the objective 1, 1/3 of the individuals tend to the objective 2 and the remaining individuals obeys both the two objectives.

Step 6. Genetic operations: according to the selection operator, two individuals are selected from the mating pool as the parent and the new generation $P(t+1)$ is produced after genetic operations (crossing and mutation).

Step 7. The updating of the archive (PDDR-FF sampling strategy): mixing the new generation P(t+1) and the archive to form the temp population $A'(t)$. Calculate the fitness function value of all individuals in the population, according to the ascending order and individuals with the smallest of the $\mid A(t) \mid$ values are chosen as $A(t+1)$.

The overall procedure of MOHEA is described as the follows Fig. 2.

```
procedure: MOHEA
input: data set of problem, EA parameters
output: Pareto optimal solutions E
begin
    t ← 0;
    initialize P(t) by random key-based encoding routine;
    calculate two objectives by decoding routine;
    calculate fitness eval(P) by PDDR-FF approach;
    create Archive A(t) by PDDR-FF based updating routine;
    create Pareto E(t) by nondominated routine;
    while (not terminating condition) do
        create mating pool M(t) from P(t) by BTS routine;
        combine mating pool M(t) and Archive A(t) as M(t);
        create P(t+1) from M(t) by crossover routine;
        create P(t+1) from M(t) by mutation routine;
        calculate objectives by decoding routine;
        calculate fitness eval(P+1) by PDDR-FF approach;
        update Archive A(t+1) by PDDR-FF routine;
        update Pareto E(t) by nondominated routine;
        t ← t + 1;
    end
    output Pareto optimal solutions E(t)
end;
```

Fig. 2. The overall procedure of MOHEA

3.2 Genetic Encoding

The genetic code operating is real-coded in this paper. Each gene of the chromosome is consists of a random, evenly distributed, floating-point number in $[0, 1]$, or the true value of the decision variable. Each chromosome is a vector of a floating point type and the length of the chromosome is determined by the number of decision variables. Real coding makes the complex genetic operation easy to implement. It enhances the accuracy of the operation and strengthens the search ability of the algorithm to the large space.

For example, the number of benchmark test problem ZDT6 [10] decision variables is 10. Suppose vector $V = (0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1)$ is a set of ZDT6 solution, the vector V can be directly used as the chromosome corresponding gene coding sequence. Or the vector V' may be used as the gene sequence of the chromosome according to the mapping relationship in the Fig. 3.

3.3 Crossover Operator

The crossover operator used in this section is the Simulated Binary Crossover (SBX) proposed by Deb [1]. When the real-coded chromosomes are crossed by the SBX, the distribution parameter β of the parents need to be calculated by the equation:

$$\beta = \begin{cases} (2u)^{\frac{1}{\eta+1}}, & u \leq 0.5 \\ \frac{1}{2(1-u)}^{\frac{1}{\eta+1}}, & \text{othersize}, \end{cases} \tag{2}$$

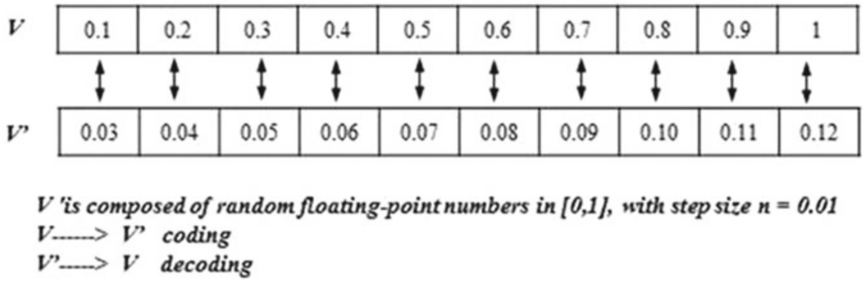

Fig. 3. Real-Coded mapping

where $u \in U(0,1)$, η represents the cross-distribution index and be determined by the decision maker. The larger the value, the smaller the distance between the progeny individual and the parents. Conversely, the greater the distance. Parent S_1 and S_2 can produce offspring s_1 and s_2 by the following equation:

$$\begin{cases} S_1 = 0.5\left[(1+\beta)\,S_1 + (1-\beta)\,S_2\right] \\ S_2 = 0.5\left[(1+\beta)\,S_1 + (1-\beta)\,S_2\right]. \end{cases} \tag{3}$$

3.4 Crossover Operator

The mutation operator used in this section is a polynomial variation proposed by Deb and Goyal [2]. The main forms of variation are:

$$S' = S + \delta\omega_{\max}, \tag{4}$$

where S is a normal individual and S' is a variant individual. ω_{max} is the maximum variable value of decision variables. δ is calculated as:

$$\delta = \begin{cases} (2v)^{\frac{1}{\gamma+1}} - 1, & v < 0.5 \\ 1 - [2(1-v)]^{\frac{1}{\gamma+1}}, & v \geq 0.5, \end{cases} \tag{5}$$

where $v \in V(0,1)$. $\gamma > 0$ represents the variance distribution index and be determined by the decision maker.

3.5 Selection Operator

In this study, NSGA-II [3] and SPEA2 [13] use binary contention selection as the selection operator. SPEA2 need to consider the dominance of the individual relationship. In this context, NSGA-II also needs to note the crowding distance of individuals. The mating pool of MOHEA consists of two parts: one is the individuals that are excellent for a single target. In the selection process, the individuals in the current population are first sorted according to the number of targets and the sub-population with excellent single-target value is selected in order. All sub-populations are included as part of the mating pool. The other is the non-dominated individuals in the elite population. In order to ensure sufficient information exchange between individuals in the two populations, it is necessary to randomly select two individuals from the mating pool during genetic manipulation.

4 Experiments and Discussion

The benchmark problem is used to test the MOHEA proposed in this paper. At the same time, two classical multi-objective evolutionary algorithms, NSGA-II and SPEA2, are tested and compared under the same conditions. The test function uses the ZDT and DTLZ problems that are currently used in the MOEAs domain. The algorithm is implemented in Java language. The hardware condition of the PC computer is: CPU Core 2, clock speed 2.8G, memory 2G, and operating system Windows XP.

4.1 Evaluation Index

Let S_j be the solutions of each algorithm ($j = 1, 2, 3$). In this study, the test considers two kinds of common convergence and distribution performance measures.

Coverage $C(S_1, S_2)$ is the percent of individuals dominated by S_1 in S_2 [12]. The bigger the $C(S_1, S_2)$ value, the better the convergence performance of S_1.

Spacing SP is the standard deviation of the closest distance of individuals in S_j [8]. The smaller value of SP means the better distribution performance.

The mathematically defined expressions for the 12 benchmark tests used in the experiment are shown in [10]. Among them, ZDT1, ZDT2 and ZDT3 have 30 decision variables, ZDT4 and ZDT6 have 10 decision variables. The decision variables and the number of targets of DTLZ problem can be expanded arbitrarily. For k and $\mid xk \mid$ values, if the target number is 2, then $k = 2$.

The parameters used in the three algorithms are as same as the original. The detailed values are shown in the following.

- Population size: 100
- Elite population size: 100
- Crossover rate: 0.4
- Mutation rate: 0.8
- Cross distribution index: 15
- Variation distribution index: 20
- Max generation: 500

The three algorithms have the same crossover and mutation operator. Fitness evaluation mechanism and the elite strategy is not the same. It should be pointed out that NSGA-II and SPEA2 need to select all non-dominated solutions from the elite as Pareto sets. MOHEA updates the Pareto set by choosing non-dominated solutions among the elite and the population. For the optimal stopping criterion of the algorithm, this paper uses the most widely used function evaluation number as the termination condition of the algorithm.

The performance evaluation index of the algorithm adopts the convergence index C and the distributed index SP. The results of the three algorithms running 30 times are compared. The time of each algorithm running is recorded. Thus the algorithm efficiency index CPU is obtained. A boxplot was used to evaluate the alignment results of the algorithm during 30 calculation results [9]. Box diagram is an important tool for statistical analysis. The image can clearly reflect the distribution of data. It is the most effective way to display EAs graphically. The upper line of the box represents the quartile line of the sample. The lower line indicates the lower quartile line of the sample. The middle line represents the bisector (mean). The top of the box represents the maximum value of the sample and the bottom is the minimum value. The gap in the middle of the box represents the confidence interval, and the other scatter points represent the outliers.

4.2 Discussion of the Results

The evaluation indexes C, SP and CPU obtained from MOHEA, NSGA-ii, and SPEA2 are shown in Fig. 3, and the average and variance of each index are shown in Tables 1 and 3. It can be concluded that MOHEA performs better on most problems than NSGA-II and SPEA2 in terms of convergence. On questions ZDT1, ZDT2, ZDT6 and DTLZ7, NSGA-II and SPEA2 performed well with MOHEA as shown in Table 1. For the distribution, it can be seen from Tables 2 and 3 that the distribution of MOHEA is better than the other two algorithms except for the problems ZDT1 and DTLZ6. Since the number of variables and the range of variables make the focus of the 12 test functions different, it is difficult for the same algorithm to perform optimally on all test functions.

The efficiency of the algorithm can be discussed from two aspects. M is the number of targets and N mean the population number. In terms of distance com-

DTLZ7	1.12e+052.0e+04	1.34e+041.9e+03	8.78e+031.1e+03

putation, the time complexity of NSGA-ii is $O\ (mN \log_2 N)$. The computational complexity of SPEA2 is $O\ (mN\ \log_2\mathrm{N})$. Since there is no distance mechanism in the MOHEA, the computational complexity of MOHEA is 0. In the calculation of the fitness value, the MOHEA needs $mN(N-1)/2$ comparisons to calculate PDDR-FF value, so the computational complexity of MOHEA is $O(mN \log_2 N)$. The computational complexity of NSGA-II is the same as SPEA2. The value is $O(mN^2)$. In summary based on the quantitative analysis of the complexity, the MOHEA is clarified faster than NSGA-II and SPEA2, and the experimental result are shown in Table 1.

5 Conclusions

In this study, a multi-objective hybrid evolutionary algorithm (MOHEA) based on mixed sampling strategy was proposed to solve the multi-objective optimization problem while improving the convergence and distribution performances, and reducing the computational time at the same time. The VEGA sampling strategy prefers the edge region of the Pareto front, but deviates from the search of the central region. The PDDR-FF sampling strategy makes up the shortcoming of VEGA. The mixed sample strategy could converge the multiply regions of Pareto front to improve the efficacy. Since no computation requirement for distance, the MOHEA could also improve the efficiency. Numerical comparisons indicated that the proposed MOHEA outperforms the classical MOEAs such as SPEA 2 and NSGA ii on convergence and distribution performance as well as computational time too.

Abstract. In this paper, we reviewed the current technology for the hydrogen fuel cells and got the light spots when 1271 papers related to hydrogen fuel cells were analyzed, which were focused on the hydrogen fuel cell technologies, hydrogen fuel cell application and solar hydrogen fuel cell. This paper had outlined these several types of the specific technology and confirmed that hydrogen fuel cells was an inevitable choice when faced to serious environmental pollution and energy structure's imbalance. And the solar-hydrogen fuel cell system that involved the hydrogen production, hydrogen storage and hydrogen application is of significant importance addressing the problem of the production of renewable energy, power generation and transportation pollution.

Keywords: Hydrogen fuel cell · Solar-hydrogen · FC vehicles · Zero-pollution

1 Introduction

Many environmental issues have been caused by or relate to the production, transformation and use of fossil energies, for example, acid rain, stratospheric ozone depletion and global climate change [5]. Energy is the material basis for the country's social development and progress of science and technology, but due to the constant use of the three large fossil energies, energy conservation and environmental problem became more and more serious. As a result of the badly exceeds bid of PM2.5, human beings got a warning of continuous haze weather. And the air pollution problem can be settled down when it is mainly closely related to fossil fuel combustion and transport industries. The increasing trend in world's energy need is expected to continue in the future. As a result, a growth in energy generation capacity will be needed [1]. Cars are important transport means in people's lives. However, the automobile exhaust is the important cause of increasingly serious environmental pollution. Therefore, we need to find an alternative fuel for the traditional fossil fuels.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_9

Hydrogen has high energy density, and the energy released is enough to make the vehicle's engine running. Hydrogen energy systems appear to be the one of the most effective solutions and can play a significant role in providing better environment and sustainability [4,14]. Hydrogen fuel cell vehicle itself works with no noise, no vibration, no loss, and long service life. The electrode is only working as the place of chemical reaction and conductive channel and it does not participate in chemical reactions. The fuel of hydrogen fuel cell is hydrogen and oxygen, and the product is clean water, with the prefect results of no CO and CO_2, and no sulfur and particulate exhaust. We could have a clear look at the advantages when compared to the thermal power as Table 1 shows. Therefore, hydrogen fuel cell vehicle can run with zero emissions, zero pollution in real sense and hydrogen is regarded as a perfect energy for vehicle. Fuel cell technology with the hydrogen energy is the core technology of the auto industry in the 21st century, and it takes revolutionary significance for the car industry.

Table 1. Comparison of atmospheric pollution between fuel cells and thermal power

Pollution components	Gas thermal power	Heavy oil thermal power	Coal thermal power	Fuel cells
SO_2	2.5–230	4550	8200	0–0.12
NO_2	1800	3200	3200	63–107
Hydrocarbon	20–1270	135–5000	30–10000	14–102
Dust	0–90	45–320	365–680	0–0.14

(unit: kg·10^{-6}(KWh)$^{-1}$)

In the face of oil price's rising, increasingly severe atmospheric environment, increasingly strict emission regulations and the pressing needs of light energy, fuel cell is the power generation device which can turn the chemical energy stored in the fuel and oxidant directly into electrical energy. It is considered to be the best choice as clean and efficient power generation technology in the 21st century because of its energy conversion is not limited by Carnot cycle [8], energy conversion efficiency can reach 90%, and the actual service efficiency is 2–3 times of internal combustion engine. And hydrogen fuel cell shows the unique superiority in such aspects as in the comprehensive energy efficiency, environment friendly and high reliability, so the hydrogen fuel cell will have broad market prospects as specific tools for the transition from fossil fuel based era to hydrogen economy-oriented society.

2 Literature Mining

Hydrogen fuel cell is a cutting-edge research problem in current society, but researches about this issue has certain basis and achievements. Based on these researches, literature mining has been shown to be a powerful method for elucidating major trends across time in published scientific literature so that topic maps can be built [2]. Garfield believed that the academic literature citation indexing was crucial when researching similar topic areas [7]. A citation index is a synthesized result based on journal articles, keywords, publication dates and abstracts and is able to separate and highlight the various influences in a specific field, allowing for the research with the greatest impact to be easily identified.

2.1 Data Analysis

Literature mining from published scientific literature allows for the discovery of key areas and trends [2]. CiteSpace is one of the latest development of a generic approaches to detecting and visualizing emerging trends and transient patterns in scientific literature. The work makes substantial theoretical and methodological contributions to progressive knowledge domain visualization. A specialty is conceptualized and visualized as a time-variant duality between two fundamental concepts in information science: research fronts and intellectual bases [3]. 1271 papers had been retrieved as "TI = HFC" been limited, and all the data was imported into the CiteSpace with a data process. Finally, 65 categories were formed after cluster, as Fig. 1 shows.

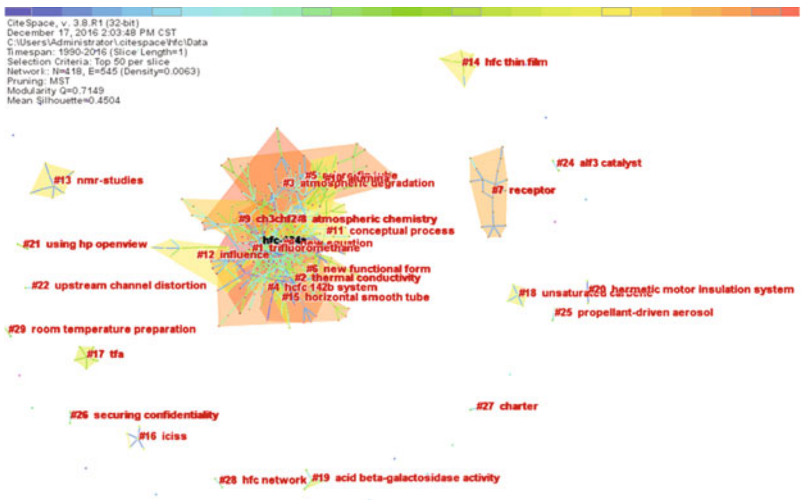

Fig. 1. Clusters of the hydrogen fuel cells

2.2 Results

Keywords are important index terms used to provide access to articles that have been published or presented in journals and conference databases and are essential for clearly identifying arange within a specified boundary. As Fig. 2 illustrates, keywords about hydrogen fuel cells have been shown from 1960 to 2016, which could be divide into three phases as timezone developed. And the first stage could be described as hydrogen fuel cell technologies in Sect. 3, the second could be extracted as hydrogen fuel cell application in Sect. 4, and the latest stage could be know as solar hydrogen fuel cell in Sect. 5, which is on behalf of the most frontier and hot issue on hydrogen fuel cells.

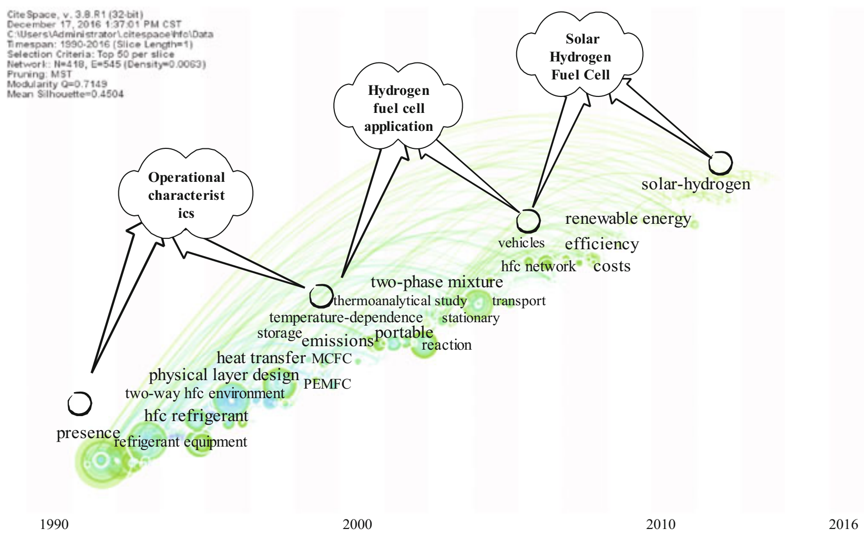

Fig. 2. Timezone of the hydrogen fuel cells

3 Hydrogen Fuel Cell Technologies

Hydrogen production has laid the basis for the development of fuel cells (FC) and the diffusion of associated technologies. The fuel cell technology mechanisms were discovered in 1838 by the German-Swiss chemist Christian Friedrich Schonbein and the British lawyer and natural scientist Sir William Grover [17]. The FC technologies have the potential to be the key technologies that contribute to the transition to a low carbon energy economy. The fuel cell and its application has become the most attractive and promising technology in the hydrogen energy utilization field. Because of its' promising clean and efficient power generation, as oil and the internal combustion engine displaced coal and the steam engine, FCs will make the transition in a similar way in the future.

3.1 Operational Characteristics

A fuel cell is similar to conventional battery but different, being composed of an anode, cathode and electrolyte. These components generate electricity through an electrochemical reaction in which the external oxygen supply source (usually air) and a hydrogen-rich fuel combine to form water as Eq. (2) show. The difference with a conventional battery is that no combustion occurs in FCs, as the energy to run the FCs is released electro-catalytically. This electrochemical reaction at the two electrodes is shown from Eqs. (1) to (2) respectively.

$$\text{Atanode:} \, H_2 \rightarrow 2H^{+}{+}2e^{-}., \tag{1}$$

$$\text{Atcathode:} \, 2H^{+}{+}2e^{-}{+}O_2 \rightarrow \text{H2O}. \tag{2}$$

As the schematic diagram in Fig. 3 shows, the fuel (hydrogen) and oxidizer (oxygen) dissociate to evolve electrons and ions, the ions separating from the pole move towards another under electrolyte conditions while the dissociated electrons are guided to an external electric circuit. The fuel (hydrogen) is supplied for the cathode, and the oxidizer for the anode. The hydrogen dissociates the H^+ and e^-, and the H^+ blends into the electrolyte while the e^-, tends towards the positive pole through an external circuit. The H^+ and oxygen in the air react at the positive pole to form water when absorbing e^-,. As long as the fuel and oxygen are supplied, there is a constant power output in the FCs.

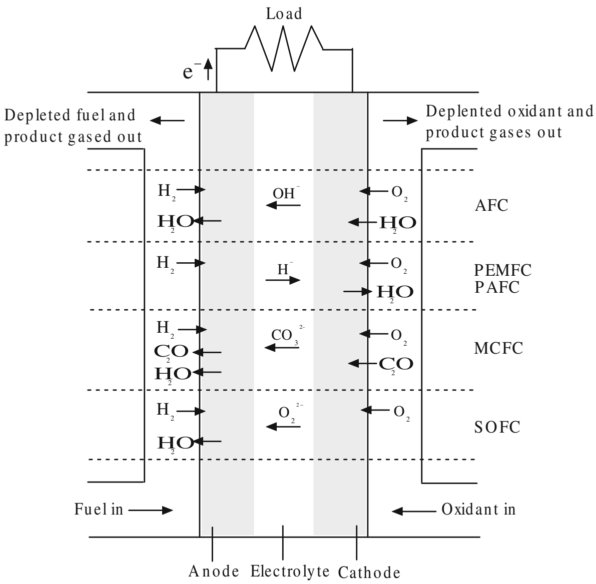

Fig. 3. The schematic diagram of FCs and different types FCs' operation principle

3.2 Outlook for Fuel Cell Technologies

FCs are classified by the kinds of electrolytes they use, which determines the kind of chemical reactions that take place in the cell, the kind of catalysts required, the temperature range in which the cell operates, the fuel required, and other factors. In turn, these chemical reaction condition characteristics affect the applications for which these cells are most suitable. There are six major types of fuel cells presently under development, each with its own advantages, limitations, and potential applications, as shown in Table 2. Respectively, they are proton exchange membrane fuel cells (PEMFC), alkaline fuel cells (AFC), phosphoric acid fuel cells (PAFC), molten carbonate fuel cells (MCFC), solid oxide fuel cells (SOFC) and direct methanol fuel cells (DMFC). The operating characteristics of these systems are highlighted in Table 2.

Table 2. Operating and applicable properties of FCs technologies

Styles	PAFC	MCFC	SOFC	PEMFC	AFC
Fuel	Natural gas, methane hydrogen peroxide, air	Natural gas methane gas, air, coal gas, hydrogen peroxide	Natural gas methane gas, coal gas, air, hydrogen peroxide,	Hydrogen, oxygen	Hydrogen, oxygen
Electrolyte	phosphate	Alkali metal carbonate fused mixture	Oxygen ion conductive ceramics	Proton exchange membrane	Potassium hydroxide solution
Operating temperature	160–220	620–660	800–1000	80	90
Electrochemical efficiency	55%	65%	60–65%	40–60%	60–70%
Power output	200KW	2MW–10MW	100KW	1KW	300W–5KW

AFCs use an aqueous solution of potassium hydroxide (KOH) as an electrolyte with a concentration ranging from 35% to 45%, a fuel of pure hydrogen, and typically operate at a low temperature of around 70° C. It is a one of the most developed technologies so far and has been used by NASA spacecraft. Because of the low operating temperature, instead of a platinum catalyst in the system, a variety of non-precious metals such as the most commonly used catalyst of nickel can be employed to speed up the reactions taking place at the anode and cathode in AFC units. Owing to the rate at which the chemical reactions take place, AFCs offer relatively high fuel to electricity conversion efficiencies, as high as 60% in some applications. The major advantage of AFCs is the quick start, but the disadvantage is that they are very sensitive to CO_2 which causes a slower reaction time and consumes the alkaline in the electrolyte, thereby limiting its commercial applications.

PEMFCs are considered to be a promising technology for clean and efficient power generation in the 21st century and are known for their high-power density delivery and short start up time compared with other fuel cells, characteristics which guarantee that the PEMFCs technology is competitive for transportation and commercial applications such as stationary, and portable power generation [13]. PEMFCs use a solid polymer electrolyte (Teflon-like membrane) which is an excellent conductor of protons and an insulator for electrons to exchange ions between two porous electrodes, and operate under a temperature of 100° C. The operating schematics are shown in Fig. 3. Therefore, the membrane is the key point in the PEMFCs technology and current research on PEMFCs also focuses on the development of a proton exchange membrane with high proton conductivity, low electronic conductivity, good thermal stability, and low cost.

Figure 3 shows that the working principles of the PAFCs and PEMFCs are similar even though the structures are different. PAFCs use liquid phosphoric acid as an electrolyte which is contained in a Teflon-bonded silicon carbide matrix, and works at about 150 to 200° C. Different from PEMFCs and AFCs, PAFCs are more tolerant and insensitive to any impurities in the hydrogen fuel. The advantages of PAFCs are that the metal catalysts required are much less than that of the AFCs and the reducing agent purity requirements are significantly lower allowing for up to 5% carbon monoxide. PAFCs are viewed as the "first generation" of modern FCs. According to the state development, these are the first mature cell types to be used commercially. The 100200 and 500 kW size plants are typically available for stationary power generation. A 1.3 MW system has already been tested in Milan and PAFCs have been installed at 70 sites in Europe, USA and Japan [16].

MCFCs are high-temperature (650° C) fuel cells which commonly use a molten carbonate salt, such as lithium carbonate, potassium carbonate or sodium carbonate, suspended in a porous ceramic matrix as the electrolyte. To date, this type has been developed in natural gas and coal based power plants for industrial and military use. The SOFCs' electrolyte is a hard, non-porous ceramic compound such as yttria stabilized zirconia which has a strong conductivity and operates at a much higher temperature of 800–1000° C [12]. SOFCs are considered to be around 50%–60% efficient at converting fuel to electricity and have rapidly increased in popularity in stationary applications in recent years.

Different from the five types fuel cells which fueled by hydrogen, DMFCs are powered by pure methanol or alcohol which can be generated hydrogen via reforming reaction as presented in Sect. 3. Direct methanol fuel cell technology is relatively new compared with that of fuel cells powered by pure hydrogen, and DMFCs research and development is roughly 3–4 years behind that for other fuel cell types [10]. The working principle and reaction equations are shown in Eqs. (3)–(4).

$$\text{Atanode: } CH_3OH + H_2O \rightarrow CO_2 + 6e^- + 6H^+, \tag{3}$$

$$\text{Atcathode: } \frac{3}{2}O_2 + 6e^- + 6H^+ \rightarrow 3H_2O. \tag{4}$$

4 Hydrogen Fuel Cell Application

Generally, today, the application of fuel cell technologies can be categorized in three directions. Respectively, there are portable fuel cells designed to be moved, including auxiliary power units (APU), stationary power fuel cells designed to provide power to a fixed location, and transport fuel cells providing either primary propulsion or range-extending capacity for vehicles as shown in Table 3.

Table 3. A brief summary of hydrogen energy application technical directions [11]

Application	Portable	Stationary	Transport
Definition	Units that are built into, or charge up, products that are designed ti be moved, including auxiliary power units (APU)	Units that provide electricity sometimes, but are not designed to be moved	Units that provide propulsive power or ranger extension to vehicle
Typical power range	5W–20KW	0.5KW–400KW	1KW–100KW
Typical technology	PEMFE, DMFC	MCFC, PAFC, PEMFC, SOFC	PEMFC, DEMFC
Examples	Non-motive APU (campervants, boats, lighting); military applications; portable products; small personal electronics	Large stationary combined heat and power; small stationary micro-CHP; uninterruptible power supplies(UPS)	Materials handing vehicles; fuel cell electric vehicles (FCEV); Trucks and buses

4.1 Portable Technological Direction

Using portable fuel cells can solve the low energy power capability and long charging time problems of current battery technology. Consequently, the global production of portable fuel cells has grown continuously on the basis of FC technology. In the 21st century, commercial portable units are being adopted rapidly in such areas as educational fuel cells and toys, auxiliary power units (APU), and consumer electronics [11]. With the many specific industrial niches that can benefit from fuel cells, the technology's use in APU has been an area of interest for fuel cell manufacturers and industry players alike. DMFCs are a relatively expensive cell technology and is most cost-effective in small, low-power stack configurations under 100 W. There are a number of products emerging for applications that require a higher APU output. The Danish company Serenergy uses methanol as a fuel, but processes it ahead of a 350 W high-temperature PEMFC (HT PEMFC), which it is marketing fora variety of applications.

The long-awaited launch of a number of fuel cell consumer electronics chargers in 2011 and 2012 has marked a turning point in this sector. For many years it proved too difficult to miniaturize fuel cell technology to a level where it could realistically compete with external battery supplies. Continued development is expected to result in units small enough to be integrated inside consumer devices and large multinational companies, such as Apple and Research In Motion, are patenting products in this field.

4.2 Stationary Technological Direction

Stationary units that provide electricity/heat are not designed to be moved. They are used for backup power, in remote locations, as stand-alone power plants for towns and cities, for distributed generation in buildings, and for co-generation [9]. Compared with traditional power stations, stationary fuel cells use is inevitable because of today's subtle change in energy structures and the breakthroughs in fuel cell technology.

In recent years, both small and large systems in residential, industrial and prime power applications have experienced a fast growth such as in the highly-advanced Japanese Ene-Farm residential micro-CHP plan and the emergence of similar schemes in Europe. Present fuel cell technology allows for a continued cost reduction and optimization of the technology. At the same time, the commercialization of backup power systems for the telecommunications industry has accelerated as the communication field expands with a significant interest emerging in China and elsewhere for both independent and grid-connected systems. The introduction of methanol-fuelled telecommunication backup locations, where delivering hydrogen is difficult, to take advantage of fuel cell technology. Large stationary fuel cell installations have gained increasing interest from multinational companies who are looking for ways to reduce their carbon footprint.

4.3 Transport Technological Direction

The global automotive industry sells in excess of 80 million vehicles per year, and for fuel cells a portion of this market remains the long-term prize in this sector. FCs are capable of replacing ICEs (internal-combustion engines) as they have the potential to achieve higher efficiency and lower GHG emissions. A typical application in vehicles varies from passenger cars, utility vehicles, to buses, with power ranges from 20 kW to 250 kW [15].

The production of regular automobiles increased steadily in the early 2000 s. In the past few years, the fuel cell light-weight vehicle market has been led by Honda, General Motors, and others. Honda has started shipping its FCX Clarity to Southern and Northern California. In 2007 General Motors, through its "Project Driveway" program, delivered over 100 units of its Chevrolet Equinox fuel-cell vehicles to California, Washington DC, and New York. Other fuel cell application technologies are in marine and unmanned aerial vehicles (UAVs), trucks, trains, and bicycles. Siemens has developed a fuel-cell-based air-independent propulsion system intended for use in submarines, such as the U212/214 type hybrid powered submarine manufactured by the German Howaldtswerke Deutsche Werft GmbH (HDW).

5 Solar Hydrogen Fuel Cell

Solar energy is a ubiquitous and rich source, also a kind of renewable energy sources with no environmental pollution. China has abundant solar energy resource, annual total solar radiation area is greater than 1050 kWh/m^2, which is more than 96% of the total land. There are several methods for producing hydrogen from solar energy. Currently, the most widely used solar hydrogen production method is to obtain hydrogen by electrolyzing the water at low temperature. Solar-hydrogen fuel cell power generation system was new-type energy which was based on the solar power for water decomposition, and it could generate electricity by electrochemical reaction using the hydrogen and oxygen produced. Countries are committed to carry on the development and application of solar-hydrogen fuel cell because of rich energy source, high energy conversion efficiency, and no pollution in the whole transformation process. In the future energy system, solar energy will become the main primary energy to replace the current energy such as the coal, oil and gas, and hydrogen fuel cell will become the clean energy to replace petrol, diesel and chemical battery.

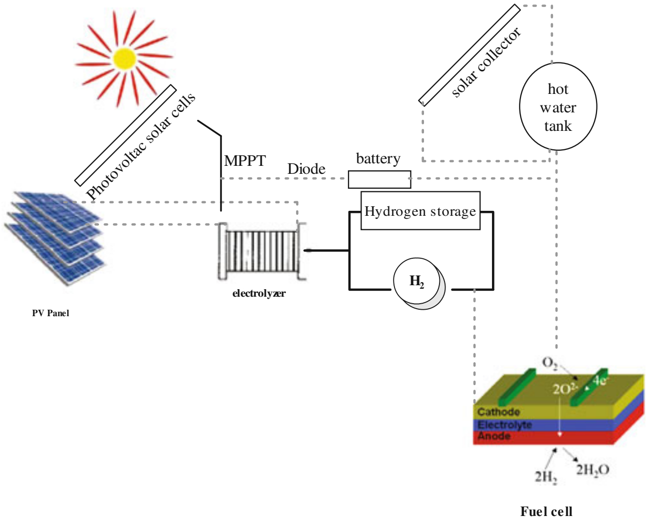

Fig. 4. Scheme of the solar-hydrogen system

As a reversible fuel cell, it gives you the freedom to invent your own clean energy applications using fuel cells and renewable hydrogen formed using sun and water. Figure 4 shows a schematic diagram of hydrogen production system that uses photovoltaic technology. The electrolysis of distilled water using electricity produced by the PV panel takes place in electrolyser unit and produces hydrogen and oxygen as the end product [6]. Through the study of solar-hydrogen fuel cell system's characteristics, we known that hydrogen fuel cell power generation efficiency could be as high as 36.4%, and solar cell power generation efficiency generally is in 15% to 18% range. Therefore, the hydrogen fuel cells not only greatly improve the efficiency of the power generation, also produce only water in the whole power generation process, which implement the clean, pollution-free and efficient, and will become a leader in the field of new energy in the 21st century.

6 Conclusion

Through the researches on the existing hydrogen fuel cell technologies and the application technologies, we learned that the real value of the hydrogen fuel cells is does not poor. Especially this particular and reversible solar-hydrogen fuel cell system is bright star prior to other styles with a steady stream of resources and the cycle of zero pollution. The direct hydrogen fuel cell vehicle is preferred, since it would be less complex, have better fuel economy, lower greenhouse gas emissions, greater oil import reductions and would lead to a sustainable transportation system once renewable energy was used to produce hydrogen. All countries need to increase comprehensive and multi-functional analysis and research on hydrogen fuel cell's characteristics if we want to keep in active status in the field of energy development in the 21st century.

Abstract. The technique of shift-share method [6] and GM(1.1) model [4] are applied for a dynamic assessment and predictive study of industries between the year of 2010 and 2015 in Leshan city, choosing Sichuan province as a background. With the actuality, some advice was put forward on how to adjust and optimize the development of industries of Leshan. The survey shows that the secondary industry is the key factor to the whole economic development of Leshan City. Leshan's tertiary industries had a weak competitiveness and will develop more slowly, department structure contributed a little to the rapid growth of economic total; Tourist industry and trade are lack of competitiveness, while the transportation industry industries ran on a small scale and contribute little to the growth of economic total. Hence, it's important and necessary to formulate the industry development strategy based on objective scientific analysis of Leshan's industries.

Keywords: GM(1.1) model · Shift-share · Leshan city · Industrial policy

1 Introduction

Shift-Share Method (SSM) was put forward by America scholars Dunn, Perloff, Lampard and Muth in the 60s, and it was summarized as the form which is widely acknowledged now by Dunn in the early 80s [2]. Shift-Share Method is widely applied in the assessment of regional economy and industrial analysis with high comprehensiveness and dynamic which is used mainly in analyzing regional economy efficiency. Due to the particularity of object, every practical application has its own referring value.

SSM was introduced to China in the 80s. Nowdays lots of domestic scholars study in inter-region with SSM widespread and some surveys already found that it is evident and suitable for the area of the industrial development assessment [1,5,9]. However, the utilizing of SSM by existing research is based on the analysis

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_10

of economic development, depending on the experience to predict the growing trend of the future whose forecast of the trend still has a high level of subjectivity. As a result, this text applies GM(1.1) model to predict the chief data of industrial development. To employ this predicative study to estimate the development of regional industry in the future on the basis of dynamically assessing industrial development with SSM.

Following a longitudinal study, we can explore the rule of industry development to provide the adjustment of regional industry organization and industry policy formulation with more scientific decision source.

Leshan city is a significant connection point and port of the economic zones of the southern Sichuan and Chengdu areas, also the west of Panzhihua which plays a vital role in economic development structure. On one hand, Leshan city has an outstanding advantage in agriculture, industry, tourism, transportation and business. On the other hand, the problems of inadequate use of ascendant resource still exist. From the view of whole Sichuan province, the overall economic development of Leshan city remains an upper medium level; in the perspective of industrial department, the superior industries are not obvious enough which cannot be judged by experience to find out the departments with advantages and growth potential. Energy-extensive consumption, high-emission and high-pollution still have an influence on the economic development of Leshan city. In this situation, if efforts are made in pursuit of long-term development, it will solve the problem of increasing load of resource and environment. Therefore, getting a clear understanding of industrial development trend will offer reliable evidence to the transformation of low-carbon industry. As a result, it is of great realistic significance to apply the technique of SSM, dynamic assessment and predictive study to industrial development of Leshan city.

2 Research Methods and Data Sources

2.1 Shift-Share Method and GM(1.1) Model

SSM regards regional economy as a dynamic process and views its locating region or whole country as a reference system. Then this method divides the variation of the regions' own economic aggregate into three subprojects, which are the national growth effect, the industry mix effect and the competitive effect to approve the reason of this region's economy development and recession. At the same time, it also can evaluate the strength of regional economic structure's competitiveness. $N_{ij} = b_{ij} \times R_j$ is called as national growth effect which means Department J's total quantity is distributed pro rata. The variation of Department J's scale in area "i" is the variation caused by regional industrial department for standardization in average growth rate of locating area or whole country. $P_{ij} = (b_{ij,0} - b_{ij}) \times R_j$ is marked as the industry mix effect (industry structure effect) which reflects the influence and contribution from the structure of department to the increase: the rate is greater and that contribution is greater. $D_{ij} = b_{ij,0} \times (r_{ij} - R_j)$ is named as the competitive effect (the local share effect) which shows the relative competitiveness of Department J, so that a greater rate means a greater effect to economic increase made by Department J's competitiveness, including $r_{ij} = \frac{b_{ij,t} - b_{ij,0}}{b_{ij,0}}$, $R_j = \frac{B_{j,t} - B_{j,0}}{B_{j,0}}$, $b_{ij} = \frac{b_{ij,0} \times B_{j,0}}{B_0}$. Introduce $K_{j,0} = b_{ij,0}/B_{j,0}$, $K_{j,t} = b_{ij,t}/B_{j,t}$ which means the relative department's share of the whole area or country at the beginning and at last. The relative increasing rate of area i, compared with its locating area or country, is $L = W \times U$,

$$W = \frac{\sum_{j=1}^{n} K_{j,0} \times B_{j,t}}{\sum_{j=1}^{n} K_{j,0} \times B_{j,0}} : \frac{\sum_{j=1}^{n} B_{j,t}}{\sum_{j=i}^{n} B_{j,0}}, \quad U = \frac{\sum_{j=1}^{n} K_{j,t} \times B_{j,t}}{\sum_{j=1}^{n} K_{j,0} \times B_{j,t}},$$

where W and U separately represent result the effect index and effect of regional competition index. If G_i is a little bit big while L is greater than 1, the regional increase is faster than another which is of locating area and whole country. If P_i is a little bit large while W is greater than 1, it proves the industry department with high-speed growth has major share. In this situation, the regional overall economic structure is a little bit good and the structure makes a great contribution to economic growth. If D_i is great and U is greater than 1, the increasing trend of every industry department is obvious with a strong competitiveness.

GM(1.1) model has part of the information known and partial information unknown. It can accurately describe the state and behavior of the social economic system. On one hand, this method can help avoid the Achilles' heel of the lack of relevant data. On the other hand, it also can avoid the subjective assume due to personal preference, experience, knowledge and macro policy which can better grasp the self-evolution law of the system.

GM(1.1) was modeled as follows:

(1) Set the original sequence $X^{(0)}$ and figure up the original sequence according to $x^{(1)}(i) = \sum_{m=1}^{i} x^{(0)}(m), i = 1, 2, \cdots, n$ to create a new sequence $X^{(1)}$;
(2) Create a winterization differential equation [12] GM(1.1) as predictive model to sequence $X^{(1)}$, that is $\frac{dX^{(l)}}{t} + aX^{(l)} = b$, a, b are undetermined parameter, separately as evolution parameter and gray action;
(3) Suppose $\hat{a}$ as undetermined parameter vector, with the help of least square method, to figure out $\hat{a}$ and get $\hat{a} = \begin{bmatrix} a \\ b \end{bmatrix} = (B^T B)^{-1} B^T X$;

$$B = \begin{bmatrix} -\frac{1}{2}[x^{(1)}(1) + x^{(1)}(2)] & 1 \\ -\frac{1}{2}[x^{(1)}(2) + x^{(1)}(3)] & 1 \\ \vdots & \vdots \\ -\frac{1}{2}[x^{(1)}(n-1) + x^{(1)}(n)] & 1 \end{bmatrix}, \quad X = \begin{bmatrix} x^{(0)}(2) \\ x^{(0)}(3) \\ \vdots \\ x^{(0)}(n) \end{bmatrix}$$

(4) Figure out GM(1.1) and get $\hat{X}^{(1)}(i+1) = (x^{(0)}(1) - \frac{b}{a})e^{-ai} + \frac{b}{a}$;
(5) According to Inverse Accumulated Generating Operation to calculate $x^{(0)}(i+1)$; Make a counter current to the predictive value $\hat{X}^{(0)}(i+1) = \hat{X}^{(1)}(i+1) - \hat{X}^{(1)}(i)$;
(6) Make an error checking to prediction model, including residual test, relational coefficient test and posterior-variance-test [11].

2.2 Definition of Indicator

In recent years, Leshan city's GDP has been maintaining a double-digit growth in 10 years whose comprehensive strength significantly strengthened. In 2009, the domestic GDP is 61.902 billion yuan–15.3% more than the number of the previous year. Three industries separately stimulate GDP growth by 0.5%, 11.1%, 3.7% whose contribution rate of economic growth separately are 3.1%, 72.6%, 24.3%. It is necessary to analyze the three industries and they are marked as GDP1, GDP2, GDP3 in the sections below. During The Eleventh Five-Year-Plan, by building "the transportation project with one hundred billion yuan", developing the economy of Culture & Tourisim, business, mountain area and port-surrounding, it promoted the position as a south-west hub and accelerated the development of economy and society. Leshan city is a vital city of industry and tourism of Sichuan province. At the same time, it belongs to the core area in Chengdu economic zone as an important city of business, so that its tourism, transportation industry and business are regarded as leading industries for economic development. Therefore, in the current study, based on the analysis of Leshan city's three industries, for further study, choose tourism, transportation and storage postal service, business industry from thrice industry to analyze. In consideration of data's access, the current study chooses Total Retail Sales of Consumer Goods as an alternative to reflect the prosperity degree of the business industry. Tourism is marked as GDP31 while transportation storage and transport the postal service is marked as GDP31. SXT shows Total Retail Sales of Consumer Goods.

2.3 Data Sources

The data come from *Leshan City Statistical Yearbook* (1999–2009) [3] and the documents from relevant departments; *Sichuan Province Statistical Yearbook* (1999–2009) [8]. The data are calculated in current prices.

3 The Analysis and Prediction of Industry Development Share-Shift

(1) The Prediction of Industry Development
According to GM(1.1) model, every index will be predicted and calculated to get Index Prediction as follow Table 1:

Get relative error sequence of every index $\Delta_i = \frac{\varepsilon(i)}{x^{(0)}(i)}$ and make a residual test to model. If average relative error is not more than 5%, its predicted value meets the precision requirement. Specific contents are as follows Table 2.

As shown in Table 2, the average relative error of the tourism industry in Sichuan province, the tourism, transportation storage and transport the postal service of Leshan are more than 5% which cannot pass the residual test. On the basis of the analysis of the relative error every year, the above three indicators in 2002–2004 relative error is a little bit obvious while the error of 2003 is

the largest–the prediction relative error between Leshan and Sichuan province in tourism is more than 20% due to the outbreak of SARS which makes a profound impact [7]. Above conclusion is also mentioned in previous studies and GM(1.1) model still cannot eliminate the phenomenon effectively. Therefore, on the basis of acknowledging prediction error and considering the reality, the three sets of predictive data meets the precision requirement.

Calculate the correlation coefficient, correlation degree (while $\rho = 0.5$, $\zeta > 0.6$ is satisfying), variance ratio (if $C < 0.35$, and $P \geq 0.95$, the forecasting precision is regarded as superior). The result shows as follow Table 3: the correlation degree of every index is greater than 0.6; the variance ratio of every index is less than 0.35; every small error possibility is 1. According to the inspection standard, this prediction accuracy is higher and predicted values have high credibility.

Table 3. GM(1,1) Correlation degree and Posterior-variance-test

(2)The Analysis of Industry Development Share-Shift
According to the SSM model and using Sichuan province as a reference area, analyze and predict the share-shift of Leshan industrial data from 2002 to 2015 and the results are showed as follow Tables 4, 5 and 6.

Table 4. 2002–2009 The SSM analysis of three industries of Leshan city

Index	Leshan	2002	2003	2004	2005	2006	2007	2008	2009
P_{ij}	GDP1	2.07	2.641	9.606	3.293	4.302	17.861	12.464	−4.083
	GDP2	5.159	10.399	19.066	21.633	26.034	32.233	43.85	29.615
	GDP3	3.449	4.776	9.516	8.173	9.469	13.221	12.258	21.453
W		1.0031	1.0028	1.0081	1.0086	1.004	1.0105	1.0011	1.0069
D_{ij}	GDP1	−1.15	1.224	1.969	−3.07	3.6	2.341	−3.404	2.807
	GDP2	2.678	14.409	3.758	−2.488	3.218	6.75	20.826	−30.634
	GDP3	3.035	0.494	−2.644	−0.083	−1.286	−1.924	5.429	9.524
U		1.0622	1.0086	0.9835	1.0127	1.0123	1.0321	0.9716	1.027
L		1.0655	1.0114	0.9915	1.0214	1.0164	1.0429	0.9727	1.0341

Table 4 indicates that during 2002 to 2003, 2005 to 2007, 2009, the regional economic growth is faster than the overall level of Sichuan province; the growth rate is lower than the overall level of Sichuan province in 2004 and 2008. The result from the Chart tells that the main reason is a decline in the industrial sector competitiveness ($U04 = 0.9835 < 1$, $U08 = 0.9716 < 1$). During 2002 to 2009, the effective index of industrial result W is always greater than 1 which indicates the industries with potential and high-speed increase are the majority in Leshan economy. Moreover, regional overall economic structure is fine and the structure makes a great contribution to economic growth while secondary and tertiary industries are in the proportion of the optimization process step by step. During 2002 to 2003, 2005 to 2007, 2009, the effect of regional competition index U is greater than 1 which indicates the overall increasing trend of every industrial department in Leshan is great. What's more, the competitiveness of secondary industry is more obvious while the primary industry and tertiary industry cannot provide support for the regional overall competitiveness, so that the overall competitive advantages are not clear enough. When the relative competitiveness of secondary industry is on decrease, the tertiary industry is unable to provide effective support. In this situation, the secondary industry makes a decisive effect on the overall competitiveness which means this region depends on the secondary industry too much.

Table 5. 2010–2015 The SSM prediction of three industries of Leshan city

Index	Leshan	2010	2011	2012	2013	2014	2015
P_{ij}	GDP1	20.446	13.502	15.463	17.703	20.26	23.178
	GDP2	55.822	61.718	73.567	87.624	104.291	124.038
	GDP3	18.011	23.898	28.195	33.268	39.259	46.332
W		1.006	1.006	1.006	1.006	1.0059	
D_{ij}	GDP1	0.222	1.159	1.316	1.493	1.695	1.924
	GDP2	32.094	5.082	6.242	7.665	9.414	11.561
	GDP3	−5.145	1.512	1.765	2.06	2.405	2.807
U		1.0071	1.0071	1.0071	1.0071	1.0071	
L		1.0131	1.0131	1.0131	1.0131	1.013	

Choose the structure deviation component P [10] as abscissa and the competitiveness deviation component D as ordinate to draw the SSM Picture of Leshan's three industries during 2010 to 2015.

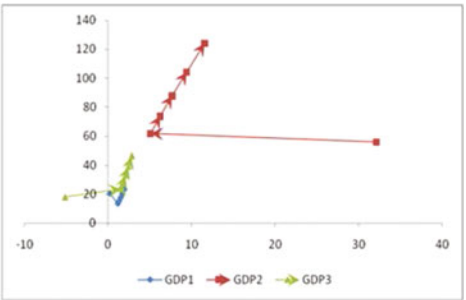

Fig. 1. 2010–2015 The SSM analysis Picture of three industries of Leshan city

Table 5 and Fig. 1 indicates: during 2010–2015, the relative growth rate (L) is greater than 1, meaning that the regional economic growth will be faster than the overall level of Sichuan province during the period of the Twelfth Five-year; W is always greater than 1 which indicates the regional overall economic structure will continue to the good development trend; further study of the structure deviation component of every industrial department find that the structure deviation component is the majority of economic part of every department. It proves that the structure of department make a great contribution to the economy growth and Leshan city already has some scale. At the same time, it is clear that compared with the secondary industry, the scale of tertiary industry has a growing difference. The effectiveness index of competitiveness shows every sector has a strong growth trend in total during the period of the Twelfth Five-year with a strong competitiveness. With the further study of the competitiveness deviation component, in addition to the obvious advantage of secondary industry, the primary industry and tertiary industry are in the average level of entire province without superiority. Still, this region depends on the secondary industry too much.

On the analysis of three industries of Leshan, we stress the further study of tertiary industry and get the SSM appraisal result of the tertiary industry during 2002–2009: the relative growth rate fluctuated, that is to say, there was no obvious advantage in its economic growth compared with the level of Sichuan province. The effect coefficient and the effect of regional competition index of every department are fluctuated too which proves that the advantages in the economic structure and competitiveness of tertiary industry are not obvious enough. With further study, we find that the competitiveness deviation component of tourism are negative generally which indicates the relative competitiveness of Leshan's tourism has not formed yet; there is a trend that the structure component of transportation industry is optimized step by step although the scale need to be further improved. Only in that way, an obvious economic effect will exists. From Table 6 and Fig. 2, the speed of growth of Leshan's tertiary industry will be slower than the level of Sichuan province in the next 5 years. We find out the result from the analysis of effect coefficient and the effect of regional competition index. The reasons are two: first, the departments in tertiary industry with high growth are minority; then, there is a non-performing growth trend of

Table 6. 2010–2015 The SSM prediction of tertiary industry of Leshan city

Index	Leshan	2010	2011	2012	2013	2014	2015
P_{ij}	GDP31	28.113	28.723	33.919	40.059	47.315	55.892
	GDP32	2.92	1.572	1.859	2.197	2.596	3.066

	GDP32	−1.302	2.782	3.278	3.863	4.552	5.364
	SXT	−2.206	−0.648	−0.761	−0.895	−1.051	−1.236
U		0.99993	0.99992	0.99991	0.9999	0.99989	
L		0.9949	0.994	0.9931	0.9921	0.9912	

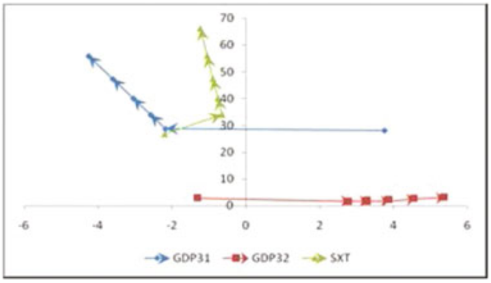

Fig. 2. 2010–2015 The SSM analysis Picture of three industries of Leshan city

every industrial department. With further analysis, the competitiveness deviation component of tourism and business are negative mainly which don't reach the average level of Sichuan province with a tendency of decrease year by year. By the study of structure deviation component, transportation and storage postal service make less contribution to economic growth with low level of structure and small scale.

4 Conclusion and Suggestion

Based on shift-share model to evaluate the industry development, we can predict the industrial development trend effectively with the help of GM(1.1) model. In this way, it can reflect the possible problems in the industrial development in the future more objectively and clearly which is convenient for related departments to plan ahead and formulate the specific targeted policies or measures. On the above analysis result, we suggest related departments to make some plans as follows:

(1) Make an accurate development orientation. It should further strengthen the development orientation of Leshan to be an important growth pole of economic development in Sichuan, a secondary transportation hub in the western, a southern core of Chengdu economic zone and an international tourist destination. The Twelfth Five-year Plan should be viewed as a period with breakthrough. Guided by the theory of low-carbon economy development, we can create a pattern of "low energy consumption, low emission, high benefit". If we speed up the pace of the adjustment of industrial structure, the industrial structure of low carbon, cycle, ecological and efficiency will formed quickly.

(2) Consolidate the leading status of secondary industry. Following with the theory that "following a new industrialization approach, developing modern industry system, promoting the combination of informatization and industrialization", we should set a core strategy of economic development in Leshan

which will promote the industrialization. Develop high-tech industry such as polysilicon, electronic information and biomedicine who have high scientific and technological content, low energy resources consumption and less pollution; Promote traditional superior industry and increase technology content; Develop low carbon economy and promote clean production which stick to the path to a new industrial city with high content of science and technology, good economic benefit, low resource consumption, less environment pollution and human capital advantage.

(3) Strengthen the competitiveness of tertiary industry. For the great increase in the proportion of the tertiary industry in the regional GDP, promote and optimize all kinds of service industries; Give full play to the unique and rich ecological tourism resources by developing ecological tourism; blossom the producer services such as information industry, green Trade and financial industry to build a new service system. Accelerate the implementation of "facilitate thousand billion transportation project and the construction of two flights four railways eight highways and one transportation hub" to build a fully functional integrated transportation system. Only in this way, the transport strength of Leshan will be promoted and the modern logistics services will be developed.

(4) Make full use of the resources rationally and promote tourism development of Leshan. Protect and make good use of the world cultural, natural heritage and bring this city's superiority into full play with famous mountain, famous Buddha, famous city and famous person. Prominent the three keys, like Buddhist culture, natural ecological tourism development and the construction management of scenic area. Improve the quality of ecological environment and the cultural taste of the city which improve the function of urban tourism. It's obvious that above actions will help speed up the process of the construction as a tourism city for Leshan.

Abstract. Scheduling in manufacturing systems is one of the most important and complex combinatorial optimization problems, where it can have a major impact on the productivity of a production process. Moreover, most of manufacturing scheduling models fall into the class of NP-hard combinatorial problems. In a real world manufacturing system, a plurality of worker who operates the machine exists, depending on the skill level by the workers for each machine and working time is different even if same work on the same machine in job-shop scheduling problem (JSP). Therefore, it is taking to account for differences in working time by the worker is scheduling problem with worker allocation. In this paper, in order to approach the more realistic model by dividing into several class workers and to determine the skill level for each machine for each class worker, we propose a new model that introduced the concept of class-type skill and demonstrate the effectiveness of the computational result by Hybrid Genetic Algorithm.

Keywords: Job-shop scheduling problem (JSP) · Scheduling problem for allocating worker (SPAW) · Class-type skill · Hybrid genetic algorithm

1 Introduction

Machine scheduling problem (MSP) arises in diverse areas such as flexible manufacturing system, production planning, computer design, logistics, communication, etc. A common feature of many of these problems is that no efficient solution algorithm is known yet for solving it to optimality in polynomial time. The classical job-shop scheduling problem (JSP) is one of the most well-known MSP models. Informally, the JSP model can be described as follows: there are a set of jobs and a set of machines. Each job consists of a chain of operations, each of which needs to be processed during an uninterrupted time period of a given length on a given machine. Each machine can process at most one operation at

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_11

a time. A schedule is an allocation of the operations to time intervals on the machines. The problem is to find a schedule of minimum length [14].

In real world manufacturing systems there are many combinatorial optimization problems (COP) imposing on more complex issues, such as complex structure, non-linear constraints, and multiple objectives to be handled simultaneously. Manufacturing scheduling is one of the important and complex COP models, where it can have a major impact on the productivity of a production process. Moreover, the COP models make the problem intractable to the traditional optimization techniques be-cause most of scheduling problems fall into the class of NP-hard combinatorial problems. In order to develop effective and efficient solution algorithms that are in a sense "good", i.e., whose computational time is small as within 3 min, or at least reasonable for NP-hard combinatorial problems met in practice, we have to consider three important issues: quality of solution, computational time and effectiveness of the nondominated solutions for multiobjective optimization problem (MOP) are very important issues [2,5,6].

In a typical job-shop scheduling problem (JSP), hitherto worker's ability has not been basically considered. Scheduling problem for allocating worker (SPAW) by introducing the concept of skill in JSP as a parameter, thereby taking into account the ability of the workers. And, it is defined as an objective function to minimize the sum of the delay time for the delivery time of the completion time of each job.

Generally JSP is known as NP-hard problem which cannot be calculated in actual SPAW [3,4]. When all the operator's skill level was 1.00, it can be considered equivalent to the JSP. In other words, SPAW can be said that the generalized problem of the JSP. So, the SPAW is also NP-hard. Recently Gen [8,9] surveyed multiobjective hybrid genetic algorithms for manufacturing scheduling. Therefore, genetic algorithm has been noted that a metaheuristic approach is as a solution to the problem of the SPAW in JSP. Then the solution methods have been proposed to solve the SPAW models [11,13,15].

In this paper, we propose a new model introduced the concept of skill value by Kitada [12] which used for the nurse scheduling problem (NSP) considering SPAW based on Iima [11]. And they used the GA algorithm as a solution of the model.

The paper is organized as follows: Sect. 2 presents Scheduling Problem for Allocating Worker (SPAW); Sect. 3 describes the detailed of SPWA with the class-type skill by hybrid genetic algorithm(HGA); Sect. 4 gives a numerical experiments results; finally, the conclusion are drawn in Sect. 5.

2 Scheduling Problem for Allocating Worker (SPAW)

2.1 Workers Skill Level

In the actual production site, there is a worker to operate the machine, and the difference in processing time of work is produced in accordance with skill level on the mechanical of each worker. We introduce a skill level as a parameter to account for the difference in processing time of the operation by the worker.

By using this parameter, each worker was placed in each machine, and it is possible to determine the processing time in consideration of the worker's abilities. In addition, we can create a more realistic schedule.

(1) Processing time in consideration of skill level

When assigning N workers $W_n(n = 1, 2, \cdots, N)$ to the I products $A_i(i = 1, 2, \cdots, I)$ using K machines $M_k(k = 1, 2, \cdots, K)$, skill level $S_n(k)$ for each worker W_n is set as the ability to operate the machine M_k.

In addition, for each product $A_i(i = 1, 2, \cdots, I)$, there are Ji operations written by each one $O_{ij}(j = 1, 2, \cdots, J_i)$ to be processed by the machine$M_{R_{ij}}(R_{ij} \in 1, 2, \cdots, K)$ which is determined in advance. The processing time given to each operation O_{ij} (processing time when the skill level is 1.00) is defined as the standard processing time PT_{ij}. The processing time pt_{ij}^n of operation O_{ij} by the worker W_n is represented by the following equation, and the actual processing time expands and contracts depending on the skill level [11]:

$$pt_{ij}^n = \frac{PT_{ij}}{S_n(R_{ij})}. \tag{1}$$

The proposed worker skill level in SPAW by Iima and Sannomiya [11] is determined in a range from 0.00 to 1.00 and are given in advance as skill level table. In addition, the value of the skill level for the worker of the machine is 0.00 cannot operate the machine. Processing time on each machine by each worker will be determined using the skill level table.

(2) Setting of the Worker Skill Level

Concept of worker's skill level is twofold. One is uniform proficiency type of skill level that has been proposed by Iima [11]. Another is variety proficiency type of skill level that has been proposed by Osawa [15].

Uniform proficiency type of skill level is different for each machine. On the other hand, variety proficiency type of skill level has a skill level that each worker is different for each machine. An example of the skill level table as shown in Fig. 1.

Uniform proficiency type of skill level

	M1	M2	M3
W1	1.00	1.00	1.00
W2	0.71	0.71	0.71
W3	0.85	0.85	0.85

Varuety proficiency type of skill level

	M1	M2	M3
W1	0.71	1.00	0.00
W2	0.90	0.83	0.78
W3	0.00	0.95	0.65

(W:worker M:machine)

Fig. 1. Setting an example of the skill level of worker

2.2 Placement of Workers

The overall schedule is divided into P periods $SP_p(p = 1, 2, \cdots, P)$ and it sets the length of one period T time. At this time, each worker working at some periods of the P number of periods. For placement of workers, the following constraints exist [11].

(1) Each worker can operate the machine only with placement period.
(2) Each worker can operate one machine only at the same time.
(3) The number of workers are placed equal to the total number of machine in each period.
(4) If the work is straddling the two periods, the rest of the work will be taken over in succession to the worker after the replacement. At this time, the interruption of work at the time of change is not taken into consideration.

In SPAW proposed by Iima [11], the entire schedule is dividing to 10 periods and the length of one period is set to 8 hours. If the worker is placed skill level of 0.00 against the machine, the worker cannot operate the machine. Thus, the scheduling becomes infeasible. In order to avoid this, Osawa and Ida [15] proposed an infeasible solution correction algorithm.

2.3 Set of Delivery Time

In this paper, it is defined as an objective function to minimize the total of the late delivery time of each job. In fact, delivery time of each job is set by consultation with the customer. However, when performing experiments with an existing instance, the customer is not present. Therefore, it is necessary to set the delivery time convenience. In this paper, we carried out the delivery time settings for each job by using a delivery time coefficient [1,16].

Delivery setting using the delivery time coefficient is a technique that is used in delivery time with JSP. The value obtained by multiplying the delivery time coefficient in total processing time of each job is set as the delivery time.

In Asano [1] and Singer and Pinedo [16] of the experiment is set to delivery time coefficient $F = 1.5$ and 1.6. In addition, it has given a late delivery penalty in the case of delay in delivery occurred in each job.

3 SPAW with the Class-Type Skill by HGA

3.1 Introduction of the Class-Type Skill

In SPAW, skill level has been set in the range of 0.00 to 1.00. Skill level setting can be considered only if processing time than standard processing time is longer. However, in actual production site, worker who can handle the work in a short period of time than the standard processing time is present. In this paper, we propose a new model, which was introduced the concept of skill value Kitada [12] was used for the NSP in SPAW that Iima [11] proposed.

Divided into several class workers, to determine the skill level for each machine in each worker for each class, considering the case that can handle jobs in a shorter time than the standard processing time.

In Kitada [12] skills value table used in the NSP, the nurse of the leader, veteran, mid-level, second year, newcomers has been divided into five classes. For this reason, divided workers into five classes in this paper, to set the range of skill level in each class. Range of skill level of each class, the leader from 1.00 to 1.40, a veteran from 0.90 to 1.30, mid-level from 0.80 to 1.20, second year from 0.60 to 1.00, newcomer from 0.30 to 0.60. To determine the skill level for each machine of the workers in each of the ranges for each class. In addition, the number of workers of each class was determined based on the number ratio of each class in the skill value table of Kitada [12].

3.2 Creating Worker Group in Consideration of Average Skill Level

In SPAW of Iima [11], workers who work in each period have been prepared in advance as the worker group, and the worker group is divided into three. However, the group who work in two period (16 hours) consecutive are present in the worker group created by the Iima [11]. This is not desirable from the viewpoint of the Labor Standards Law. If you create a worker group in advance, reduced diversity of individuals, and the possibility that initial convergence occurs is high. In this paper, we set the total number of workers is three times of the total number of machines, and three of the worker group without creating in advance, we set to be created for each individual in each trial.

The creation of the worker group to use the concept of uniform proficiency type of skill level proposed by Iima [11]. Therefore, the worker has a skill level for the worker group in each class. Skill level for the worker group of each class was set the leader 1.20, veteran 1.10, mid-level 1.00, second year 0.80, and rookie 0.50. In addition, in order to prevent bias in the class of workers for each worker group, the average skill level of the worker group became when less than 0.9 will be re-create a worker group. Showing the procedure of a worker group created in consideration of the average skill level of each period of the total number of periods P as follows:

Step 1. Set $i = 1$.
Step 2. Select one worker at random from the operator that is not arranged, and to place the selected workers in the period i.
Step 3. Exclude worker placed in Step 2 from the arrangement of the choices
Step 4. If the worker of the same number as the total machine numbers are arranged in period i, the process proceeds to Step 5. Otherwise, return to Step 2.
Step 5. If it is $i = 3$, the process advances to Step 6. Otherwise, as $i = i + 1$, and return to Step 2.
Step 6. If the periods 1 to 3 skill level average of all of the worker group was 0.9 or more, the process proceeds to Step 7. Otherwise, initialize the unplaced all workers which are disposed in the periods 1–3, and returns to Step 1

Step 7. Assign the worker group of the period from 1 to 3 in order to each period of the period from 4 to P, and exit when assigned a worker group to period P.

3.3 Decision of Machine Skill Level 0 in Consideration of the Class

In the actual production site, there is a worker who cannot operate the specific machine (skill level 0.00). To account for this, the Iima [11] and Osawa [15] was set percentage of a machine skilled level 0 in advance, and based on it, when performing experiments determines the machine each worker's skill level at random becomes 0.However, in this paper, there is more than one class to worker by introducing the Class-type skill. Therefore, when using a similar method as Iima [11] and Osawa [15], for example, leader may become greater the number of machines that cannot operate than newcomers, and it is not realistic setting. In this paper, to determine machine skill level 0 in consideration of the class of workers.

An example of skill level table of the class-type skill, including a machine of skill level 0 in consideration of the class shows in Table 1.

Table 1. Skill level table using a class type skill level

Class	M_1	M_2	M_3
Leader	1.01	1.28	1.15
Veteran	1.13	0.93	1.29
Mid-level	0	0.95	1.08
2nd year	0.66	0	0.98
Newcomer	0	0	0.5

In this paper, the leader and the veteran can operate all of the machine, and mid-level, second year, newcomer is set as the operator cannot operate the part of the machine (skill level 0). In the experiment, the proportion of the worker, mid-level 10–30%, second year 20–40%, and newcomer 40–60%, is determined at random in advance.

3.4 SPAW with the Class-Type Skill by GA

Recently, many researchers tried to adapt different metaheuristic approaches such as Genetic Algorithm (GA), Tabu Search (TS), Simulated Annealing (SA) for solving job-shop scheduling problem (JSP). Because of its inherent intractability, metaheuristic procedures are an attractive alternative (Gen [7]). To improve the efficiency for finding better solutions in searching space, some special technical local searches have been adapted in JSP. Osawa [15] reformed the traditional left shift to short the idle time, and formulated an algorithm called Eshift. Goncalves et al. proposed another technique based on the critical path to confirm the search space, and swapped the operations in critical block, and this approach can also improve the efficiency of algorithm for finding active schedule (Gen [7]).

In GA for SPAW, it represents one solution using two types of chromosomes. One is a job permutation chromosome representing a processing order for each task of a job, the other is a worker placement chromosome representing the arrangement of the worker to operate the machine at each period. Therefore, genetic operations such as crossover and mutation is carried out for each of the chromosome.

In this paper, we developed hybrid genetic algorithm (HGA) for solving scheduling problem to allocate worker with class-type skill in JSP as shown in a pseudo code in Fig. 2.

```
procedure: Hybrid Genetic Algorithm
input: problem data, GA parameters
output: the best schedule
begin
    t ← 0;                                                   // t: generation no.
    initialize P1(t) by job permutation based encoding routine;
    initialize P2(t) by worker group based encoding routine; // P(t)=[P1(t), P1(t)]: population
    check & repair all chromosome P(t) for the problem constraint;
    evaluate P(t) by decoding routine and keep best solution;
    while (not terminating condition) do
        create C(t) from P(t) by crossover routine;          // C(t): offspring
        create C(t) from P(t) by mutation routine;
        check & repair the precedence constraint for all offspring C(t);
        improve offspring C(t) by Eshift routine;
        evaluate C(t) by decoding routine and update best solution;
        reproduce P(t+1) from P(t) and C(t) by selection routine;
        t ← t + 1;
    end;
    output the best schedule
end;
```

Fig. 2. A pseudo code of HGA for SPAW with class-type skill

3.5 Initial Population

In Osawa [15] of the technique, the initial population of job permutation chromosome of each individual are randomly generated. In GA, superior solution can be obtained by repeating the genetic operations such as crossover and mutation. Therefore, it is required that to have diversity in the chromosome in the initial population stage, and eliminate the diversity operation is cause to cause initial convergence.

However, when starting the operation of GA from the chromosome of the initial population randomly generated, there is a possibility that the improvement of solution stagnates. Further, since the randomly generated, it is difficult to obtain stable and excellent solution.

In this paper, we propose the initial population generation method, including the two types of chromosomes. Type one is a chromosome to be stored in the random and priority from the early work of the delivery time, and type two is a chromosome to be stored in the random and priority from the slow work of the delivery time. Initial population is generated by these chromosomes by encoding routine is the proportion of each half. This initial population generation method, while maintaining the diversity of the initial population, it is possible to have the characteristics and trends for each chromosome. This technique, because improved based on the delivery time, which is a method that can be applied to general delivery time with JSP.

3.6 Genetic Operation

(1) Job Permutation Chromosome

Osawa [15], for the job permutation chromosome, is using the proposed 2-point crossover of Hirano [10] as a crossover method, and it uses a critical block mutation as a mutation. In this paper, we introduce the concept of delivery time to 2-point crossover of the Hirano [10], and use a crossover technique to store the large work of delivery time delay time on the left side of the chromosome. This technique, because improved based on the delivery time, which is a method that can be applied to general delivery time with JSP. In addition, mutations uses Osawa [15] same critical block mutation.

(2) Worker Placement Chromosome

Osawa [15] is using only the crossover method to worker placement chromosome. That approach uses a 2-point crossover of Hirano [10] like the job permutation chromosome. In this paper, it improved based on the 2-point crossover of Hirano [10] to worker placement chromosome. Its crossover technique has a method considering skill level and total processing time for each machine in each period.

4 Numerical Experiment

4.1 Experimental Data

Make a comparison experiments with the method (oGA) by Osawa [15] with using the proposed method (pGA) in this paper. Because the Osawa [15] approach had incorporated worker group as data, the creation of worker group is using the technique proposed in this paper.

Scheduling of instances considering variety of worker skill level, such as dealing with in this paper, does not exist as far as the authors know. Therefore, as an instance in this experiment, to use instances for JSP (10job-10machine problem la16-la20, ft10). Total machine number is 10, so the total number of workers is set 30. Upon the experiment, the worker's skill level is used a randomly generated skill level in the range specified by the class-type skill level. Worker ratio of each class will be set based on the number ratio of each class in the skill value table of Kitada [5].

If the skill level for the operator of the machine is zero, the method of Osawa [15] shown in Subsect. 3.3 is used. In addition, delivery time of each job is set using the delivery time coefficient F, F was defined as $F = 1.3$ by preliminary experiment.

Various parameters for the GA are set, the number of attempts 50 times, the population size 100, crossover probability 0.8, and mutation probability 0.2. Termination condition is when the number of evaluation individual has reached one million individuals, or delivery delay time total was set to when it becomes 0. Machine specifications are, Intel Core i5-4430 3.00 GHz, memory 8.00 GB. Experiments carried out in Microsoft Visual C++ 2010 on PC.

Performing a comparison by the minimum total delivery delay time (Best) in all the attempts and the average value of the minimum total delivery delay time (Average) obtained in each trial for each instance. The results were as shown in Table 2 (number in parentheses represents the number of times when the best solution is obtained more than once).

Table 2. Experimental result

Instance	Best		Average	
	oGA	pGA	oGA	pGA
la16	60	52	135	90
la17	5	1	36	17
la18	30	14	85	55
la19	26	7	77	39
la20	0(17)	0(47)	6	0

4.2 Consideration

From Table 2, significantly better solution than the method of Osawa [15] is obtained in all instances. Figure 3 shows a Gantt chart of the best solution for the most improved instance.

In particular, the instances, la18 and la19 has become delivery delay time following conventional half. In addition, it can be seen that from the experimental results of the Average, the solution accuracy of each attempt in all instances has been greatly improved. However, it is also true that still delivery delay time occurs in these instances. In particular ft10, the width of the delay in delivery compared with the other instance has become a big thing. This is thought to be due to features of ft10. ft10 is biased machine to be used in the processing of the first few of the work of the job. Thus, even if most job can protect delivery time, jobs that delivery delay time projecting to occur are present. Therefore, it is required improvement inconsideration of the characteristics of the instances.

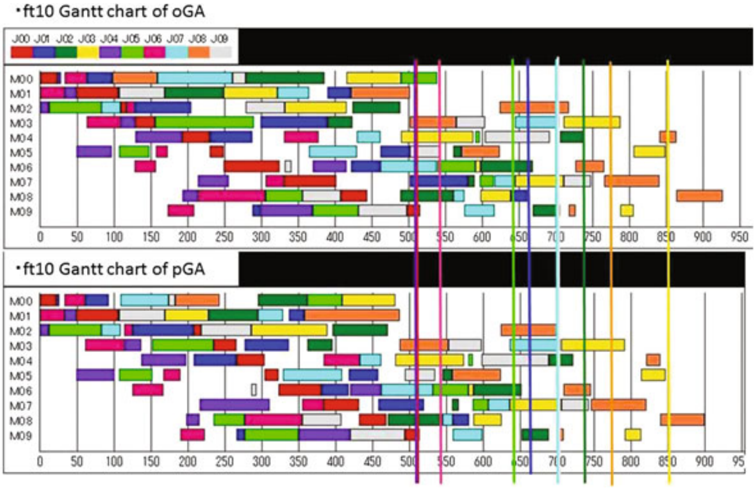

Fig. 3. ft10 Gantt chart b oGA and pGA

5 Conclusion

In this paper, scheduling problem for allocating worker (SPAW) with class-type skill in JSP expanded to the more realistic model by using Iima [11] and improvements were made of various types of algorithm using Osawa [15]. As a result, it was able to reduce the delivery delay time in all the instances that have occurred of delivery delay, and solving accuracy was able to present a schedule improved. Further, by introducing the class-type skill, divided into several class workers, to determine the skill level for each machine in each worker for each class, considering the case that can handle jobs in a shorter time than the standard processing time, and proposed SPAW of Iima [11] could be bought close to realistic models.

However, if the product had been completed earlier than the delivery time, in fact, there is a need to store the product until the delivery time. This leads to an extra cost, so it is necessary to consider in order to create a realistic schedule. The same applies to the total processing time. Therefore, after strictly to defend delivery time, it is necessary to introduce the inventory control as the second target and the total processing time as the third target.

Abstract. One of the optimization methods to solve the numerical association rule mining problem is particle swarm optimization (PSO). This method is popularly used in various fields such as in the job scheduling problem, evaluating stock market, inferring gen regulatory networks and numerical association rule mining optimization. The weakness of the PSO is often premature for searching the optimal solution because it traps in local optima when the best particle is being searched in every iteration. Combining the PSO with Cauchy distribution for numerical association rule mining problem (PARCD) is a solution because it is robust for finding the optimal solution in a large neighborhood. The important point in this proposed method is particle representation which to know the association between one attribute to another. Therefore, this study has the aim to determinate rules of numerical association rule mining and also to calculate the multi-objective function using combination of PSO and Cauchy distribution. The results show that all of them explain every attribute to formulate the rule well. In addition, the multi-objective function value of PARCD method generally produces results which better than the previous method, MOPAR.

Keywords: PSO · Cauchy distribution · Numerical association rule mining · Particle representation · Multi-objective functions · PARCD · MOPAR

1 Introduction

The issue of numerical association rule mining is interesting to discuss. This problem already solved by many researchers with many approaches. For instance discretization [14], distribution and optimization [1,2,6,13,18]. The last approach is the interesting one because it is said as the recent solution to overcome this problem.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_12

According to [6,18] revealed that this solution can find the multi-objectives function such as support, confidence, comprehensibility, interestingness, and amplitude without transformation of numerical dataset to categorical type.

One of the methods in optimization approach is MOPAR method [6]. This method used the PSO (particle swarm optimization) for solving the numerical ARM problem. This method already developed by Tahyudin and Nambo [18] by using combination of PSO and Cauchy distribution because of the weakness of PSO which trapped in local optima when the iteration goes to infinite then the velocity particle lead to 0. This condition make the PSO does not have capability to find the optimal solution [12]. Therefore, the combination of PSO with Cauchy distribution (PARCD) is the answer for the previous method.

The important step for this method is particle representation to determine the rules. This step as the initialization process before calculating the multi-objective function. There are two approach methods, firstly is Pittsburgh method which is determine the particle as the rule set and secondly, the Michigan approach method which explains that one particle refer to one rule [6]. This research uses the second method because of being appropriate with the kind of case. Moreover, the particle representation contains three main parts, they are ACN (antecedent, consequent and none of them), the lower bound and the upper bound. Hence, the aim of this research is to determine the rules and to calculate the multi-objective function values which are support, confidence, comprehensibility and interestingness using PARCD method.

The research is organized as follows: Sect. 2 reviews the literature of recent research; Sect. 3 presents the proposed method of combining PSO and Cauchy distribution for numerical association rule mining optimization (PARCD) and the procedure to determine the particle representation; Sect. 4 gives an experiment and discussion for determining of particle representation and also the result of multi objective function; finally, the conclusion and future work are given in Sect. 5.

2 Literature Review

Minaei-Bidgoli et al. [13] demonstrated that the numerical association rule problem can be solved by discretization, distribution and optimization. The discretization is performed by partitioning and combining, clustering and fuzzy logic routines [3,5]. Then, the optimization is approached by optimized ARM [20], differential evolution [2], Genetic Algorithm (GA) [10,13,15] and Particle swarm optimization (PSO) [1,6,9]. Using PSO techniques, the numerical data can be solved to attain the important information without the discretization process [4,6] and some methods can automatically determine the minimum support and minimum confidence based on the optimal threshold [15,17,20].

On the other hand, the PSO method has the weakness that the user has to specify the number of "best rules" and the time of complexity [17] and also it is not robust when used on large data sets [7,12]. One of the ways to diminish these weakness is revealed in [12], that the combination of PSO with Cauchy has approved can rise the leverage of result because the mutation process can reach wider and appropriate to a large database. In another research work [7] the combination of approaches has the ability to optimize two-stage reentrant flexible flow shop with blocking constraints. In addition, this combination can improve the interval solution by the average of 15.60% and then the performance of this combination higher than Hybrid Genetic Algorithm (HGA) [16]. Then, this combination was used to optimize the Integration of Process Planning and Scheduling (IPPS) and the result shows the effectiveness of the proposed IPPS method and the reactive scheduling method [21]. This hybrid method was developed by [7,16] to increase the wide search space in mutation process by using Cauchy distribution. His result shows that the method can enhance the evolutionary process with the wide search space.

3 Proposed Method

3.1 The Particle Representation

The rules of numerical association rule mining by PARCD will be obtained by the particle representation procedure. This study used Michigan method which determine for every particle referring to one rule [6], for which the data set will be extracted into ACN category, based on the value of lower bound and upper bound. Antecedent is pre condition and consequent is conclusion for describing a rule. The PARCD method can classify automatically the ACN based on the optimal threshold in every rules. This concept can be showed clearly by Fig. 1.

Attribute 1			Attribute 2			……			Attribute n		
ACN_i	LB_i	UB_i	ACN_i	LB_i	UB_i				ACN_n	LB_n	UB_n

Fig. 1. The particle representation

If the optimal procedure for one rule are $0 \leq \text{ACNi} \leq 0.33$ for antecedent, $0.34 \leq \text{ACNi} \leq 0.66$ for consequent and $0.67 \leq \text{ACNi} \leq 1.00$ for none of them. For instance, see Table 1.

Table 1. Example of particle representation

Attribute	ACN_i	LBi_i	UBi_i
A	0.32	2.4	6.7
B	0.14	1.7	27.8
C	0.71	0.23	135.1
D	0.66	0.11	78.9

According to the Table 1 the attribute A and B are the antecedent and the attribute D is consequent. The attribute C is not appearing because it not includes both of them. Therefore, the rule is $AB \rightarrow D$.

3.2 Objective Design

This study uses multi-objective function which are support, confidence, comprehensibility and interestingness. The support function measures the ratio of transactions in D containing X, or Support$(x) = |x(t)|/|D|$. Witten et al. [19] explained that support is refer to coverage utility. It means that the support function can calculate the percentage of number of attributes or their combination which have the association in every data set. The support of the rule $X \rightarrow Y$ is computed using the following equation.

$$\text{Support}(X \cup Y) = \frac{|X \cup Y|}{|D|}. \tag{1}$$

The confidence measures the quality of rule based on the number of transaction of an AR in the whole dataset. In other words, the confidence describes the accuracy [19]. The rule which often emerge in every transaction is considered to have a better quality because it leads to good accuracy [6].

$$\text{Confidence}(X \cup Y) = \frac{\text{Support}(X \cup Y)}{\text{Support}(X)}. \tag{2}$$

However, this criterion does not guarantee to obtain the appropriate AR, individually. In order to gain the suitable coverage and reliability the resultant rule must also be comprehensible and interesting. According to the previous research, the smaller number of conditions in the antecedent part of a rule, the more comprehensible or understandable is that rule [8]. Hence, the comprehensibility can be measured as below

$$\text{Comprehensibility} = \frac{\log(1 + |Y|)}{\log(1 + |X \cup Y|)}, \tag{3}$$

where $|Y|$ is the number of rules in the consequent the and $|X \cup Y|$ is the total number of rules in the consequent and antecedent rules.

The interestingness criterion is used for obtaining hidden information by extracting of such surprising rules. This criterion is based on the support count of both antecedent and consequent parts [8]. The equation is shown in Eq. (4).

$$\text{Interestingness} = \left[\frac{\text{Support}(X \cup Y)}{\text{Support}(X)}\right] \times \left[\frac{\text{Support}(X \cup Y)}{\text{Support}(Y)}\right] \times \left[1 - \frac{\text{Support}(X \cup Y)}{|D|}\right]. \tag{4}$$

This formula consists of three parts. In the first part, [Support$(X \cup Y)$/Support(X)], the generation probability of the rule is computed in terms of the antecedent part of the rule. In the second part, [Support$(X \cup Y)$/Support(Y)], the generation probability of the rule is computed in terms of the consequence part of the rule. Finally, in the third part, [$1 -$ Support$(X \cup Y)/|D|$], the section Support$(X \cup Y)/|D|$ shows the probability of generating the rule according to the total number of records in the dataset ($|D|$). So, its complement, [$1-$Support $(X \cup Y)/|D|$], means the probability of not generating the rule. Therefore, a rule with a high value of support count will be considered as a less interesting rule [6].

3.3 PSO

The PSO method discovered by Kennedy and Eberhart in 1995. They are animal psychologist and electrical engineer respectively which observed the swarming behaviors in flocks of birds, schools of fish, or swarms of bees, and even human social behavior [11].

The main concept of PSO is to initialize with a group of random particles (solutions) and then to search for optima by updating generations. During all iterations, each particle is updated by following two "best" values. The first one is the best solution (fitness) has achieved so far. This value is called "pBest". The other "best" value that is tracked by the particle swarm optimizer is the best value obtained so far by any particle in the population. This best value is a global best and is called "gBest". After finding the two best values; each particle updates its corresponding velocity and position [9]. Each particle p, at some iteration t, has a position $x(t)$, and a displacement velocity $v(t)$. The personal best (pBest) and global best (gBest) positions are stored in the associated memory. The velocity and position are updated using Eqs. (5) and (6) respectively [9,12].

$$v_i^{\text{new}} = \omega v_i^{\text{old}} + c_1 \text{rand}()(p\text{Best} - x_i) + c_2 \text{rand}()(g\text{Best} - x_i), \tag{5}$$

$$x_i^{\text{new}} = x_i^{\text{old}} + v_i^{\text{new}}, \tag{6}$$

here ω is the inertia weight; $v_i$old is the particle velocity of i^{th} particle before updating; $v_i$new is the particle velocity of i^{th} particle after updating; x_i is the i^{th}, or current particle; i is the particle's number; rand() is a random number in the range (0, 1); c_1 is the individual factor; c_2 is the societal factor; pBest is the particle best; gBest is the global best Particle velocities on every dimension are clamped to a maximum velocity $V_{\max}$ [9,12].

3.4 PSO for Numerical Association Rule Mining with Cauchy Distribution (PARCD)

PARCD is the proposed method to implement for solving numerical association rule mining problem. This combination generates the best result because the weakness of PSO has solved by Cauchy distribution so it can prevent the trap of local optima in best particle to gain the global best by long jump searching using Cauchy mutation.

$$v_i(t+1) = \omega(t) v_i(t) + c_1 \text{rand}()(p\text{Best} - x_i(t)) + c_2 \text{rand}()(g\text{Best} - x_i(t)), \tag{7}$$

$$u_i(t+1) = \frac{v_i(t+1)}{\sqrt{(v_{i1}(t+1)^2 + v_{i2}(t+1)^2 + \cdots + v_{iK}(t+1))^2}}, \tag{8}$$

$$s_i(t+1) = u_i(t+1) \times \tan(\pi/2 \cdot \text{rand}[0,1)), \tag{9}$$

$$x_i(t+1) = x_i(t) + s_i(t+1). \tag{10}$$

3.5 Pseudocode and Flowchart of PARCD

This pseudocode and flowchart depict that the algorithm begins by initializing the velocity vector and position randomly then it calculates the multi-objective functions as the current fitness. After that it runs by looping iteration to looking for pBest until it finds gBest value as the optimal solution.

Pseudocode of PSO [7] is shown as following, and flowchart is as Fig. 2:

Procedure: Combination of PSO and Cauchy distribution for Numerical ARM
Input: PARCD parameters
Output: Multi-objective results
Begin
$t \leftarrow 0$
initialize $x_i(t)$ by encoding routine;
calculate the multi objectives for all particles // current fitness
evaluate $x_i(t)$ by decoding routine and keep the best solution;
while (not terminating condition) do
  for each particle xi in swarm do
    update velocity $v_i(t+1)$ // using (7)
    update position $x_i(t+1)$ //using (10)
    calculate $u_i(t+1)$ and $s_i(t+1)$ //By Cauchy dist. using (8) and (9)
    evaluate $x_i(t+1)$ //using (10)
    if $f\big(x_i(t+1)\big) < f\big(pBest_i(t)\big)$ then // $pBest_i(t)$: historical best position
      update $pBest_i(t) = x_i(t+1)$; //update the best local position
end;
  $gBest(t+1) = argmin\{f(pBest\ k(t)), gBest(t)\}$ //update the global best position
  $t \leftarrow t+1$,
  end;
  output: the best solution $gBest$;
end;

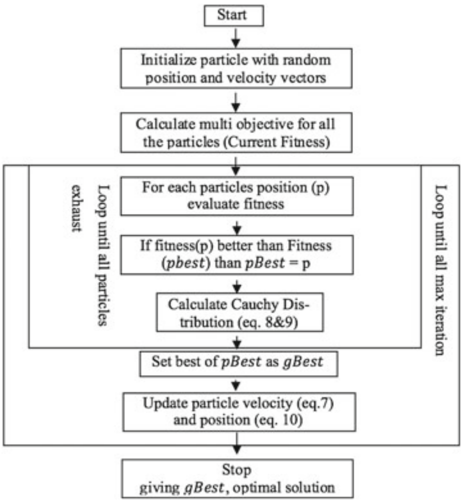

Fig. 2. Flowchart of PSO

4 Experiments and Discussion

4.1 Experimental Setup

This experiment uses benchmark datasets from Bilkent University Function Approximation Repository. There are five datasets which are used, Quake, Basketball, Body fat, pollution and Bolt (Table 2). This experiment is conducted on Intel Core i5, 8 GB main memory, running by Windows 7 and the algorithms are processed by using Matlab software.

We set up the variable of some values in the proposed algorithm such as parameter, population size, external repository size, number of iteration, the value of C_1 and C_2, W, velocity limit and xRank. They are average, 40, 100, 2000, 2, 0.63, 3.83, and 13.33 respectively. This parameters are referred according to the previous research of [6] reported in Table 3.

Table 2. Properties of the datasets

Dataset	No. of records	No. of attributes
Quake	2178	4
Basketball	96	5
Body fat	252	19
Bolt	40	8
Pollution	60	16

Table 3. The variable setup

Parameter	Population size	External repository size	Number of iteration	C_1 and C_2	W	Velocity limit	xRank
Average	40	100	2000	2	0.63	3.83	13.33

4.2 Experiments

(1) The output of particle representation
This output is generated by every running times. And then in this experiment shows the 20^{th} running time which in every running contains 2000 rules. The 20th running time is the last time so it produces the optimal solution. The results of ACN of quake data set which are the rule number, ACN and LB and UB in head title of table is shown in Table 4. According to the result in rule 1, the attributes as the antecedent are focal depth and latitude. This first rule result is same like the second rule then the last rule, rule 2000, the antecedent attributes are latitude, longitude and Richter. However, the consequent attributes are almost all none.

Table 4. ACN of quake dataset

Rule number (particle)	Antecedent, consequent, none of them (ACN)	Lower bound (LB) < attribute < Upper bound (UB)
Rule 1	Antecedent	290.028451 < Att1 < 316.467965 9.068816 < Att2 < 21.329102
	Consequence	None
Rule 2	Antecedent	290.028451 < Att1 < 316.467965 9.068816 < Att2 < 21.329102
	Consequence	None
...	...	...
...	...	...
Rule 2000	Antecedent	20.104086 < Att2 < 40.384987 33.959986 < Att3 < 71.573894 6.418029 < Att4 < 6.606453
	Consequent	None

Note: Att1 = focal depth, Att2 = latitude, Att3 = longitude, Att4 = Richter (target).

The result phenomena in Basket Ball Data set (Table 5) is almost similar to Quake data set, in which almost the rules have no consequent attributes. The first rule shows that the antecedent attributes are the number of assist per minute, height and time played. The result of second rule also shows the same as first rule, then the last rule shows that antecedent attributes are height and time played. The result of ACN in Quake and Basketball data set are interesting to study deeply, because generally the optimal solution has the antecedent and consequent attribute.

In Table 6 the result of ACN of Body Fat data set depicts the complete parameter either antecedent or consequent. In the rule 1 we see that there are eight attributes as the antecedent and three attributes as the consequents. In the rule 2 the number of antecedent and consequent attributes are the same as rule 1and in the last rule the number of antecedent and consequent attributes are six and two attributes respectively. The antecedent attributes in rule 1 are case number, Percent body fat using Siri's equation, density, age, adiposity index, chest circumference, Abdomen circumference and thigh circumference. Next, the consequent attributes are Percent body fat using Brozek's equation, height and hip circumference. Then, in rule 2 the antecedent and the consequent attributes are the same as rule 1. So that the rules 1 and 2 are if (att1, att3, att4, att5, att8, att11, att12, att14) then (att2, att7, att13). And then, in the rule 2000, the antecedent attributes are Percent body fat using Brozek's equation, Percent body fat using Siri's equation, density, height, neck circumference and knee circumference. Next, the consequent attributes are case number and weight. Therefore, the rule 2000 is if (att2, att3, att4, att7, att10, att15) then (att1, att6).

Table 7 explains the experiment result from Bolt data set which has eight attributes; run, speed, total, speed2, number2, Sens, time and T20 Bolt. Based on

Table 5. ACN of basket ball dataset

Rule number (particle)	Antecedent, consequent, none of them (ACN)	Lower bound (LB) < attribute < upper bound (UB)
Rule 1	Antecedent	0.093462 < Att1 < 0.149991 186.522680 < Att2 < 195.865376 14.763501 < Att2 < 20.155824
	Consequence	None
Rule 2	Antecedent	0.093462 < Att1 < 0.149991 186.522680 < Att2 < 195.865376 14.763501 < Att2 < 20.155824
	Consequence	None
...	...	...
...	...	...
Rule 2000	Antecedent	199.334064 < Att2 < 203.000000 24.076966 < Att3 < 39.254520
	Consequent	None

Note: Att1 = Assists_per_minute, Att2 = height, Att3 = time played, Att4 = age, Att5 = points_per_minute (target).

the table, two first rules show the same result both of antecedent and consequent. The antecedent attributes are total and time while the consequent attributes are run and speed1. Therefore, the rule is if (total, time) then (run, speed1).

The other rules do not report in this paper because they are so large, only three rules; the first, the second and the last one, rule 2000. So that, the rule 2000 shows that the antecedent attributes are run and speed 2. However, the consequent attribute is similar like quake and basket ball datasets, which is unknown. Hence. This rule can not be declared clearly because it does not have conclusion.

Table 8 depicts the result of rules from pollution dataset by particle representation PARCD method. The result from the first and the second rules are the same which the antecedent attributes are JANT, EDUC, NONW, WWDRK while the consequent attributes are PREC, JULT, OVR65, DENS and HUMID. So that, the rule is if (JANT, EDUC, NONW, WWDRK) then (PREC, JULT, OVR65, DENS and HUMID).

The rule 2000 has the ACN result which is different from the first and the second attributes. The antecedent attributes of rule 2000 are JANT, OVR65, HOUS, POOR, HC and HUMID while its consequent attributes are POPN, EDUC, DENS, NOX, SO@. The final rule is if (JANT, OVR65, HOUS, POOR, HC) then (POPN, EDUC, DENS, NOX, SO@).

(2) The output of multi-objective function
Table 9 reveals a comparison for the output of Multi-objective function among the proposed method, PARCD and MOPAR method. This table compares two objective functions which are support and confidence from both of methods in

Table 6. ACN of body fat dataset

Rule number (particle)	Antecedent, consequent, none of them (ACN)	Lower bound (LB) < attribute < upper bound (UB)
Rule 1	Antecedent	1.096724 < Att1 < 1.108900 57.988435 < Att3 < 69.574945 309.987803 < Att4 < 314.218245 55.294719 < Att5 < 66.896106 136.234441 < Att8 < 138.744999 40.927433 < Att11 < 41.562953 20.266071 < Att12 < 20.586850 22.220988 < Att14 < 23.180185

Note: Att1 = Case Number, Att2 = Percent body fat using Brozek's equation, $457/Density - 414.2$, Att3 = Percent body fat using Siri's equation, $495/Density - 450$, Att4 = Density (gm/cm^3), Att5 = Age (years), Att6 = Weight (lbs), Att7 = Height (inches)(target), Att8 = Adiposity index = $Weight/Height^2 (kg/m^2)$, Att9 = Fat Free Weight = $(1 - fraction\,of\,body\,fat) \times Weight$, using Brozek's formula (lbs), Att10 = Neck circumference (cm), Att11 = Chest circumference (cm), Att12 = Abdomen circumference (cm) "at the umbilicus and level with the iliac crest", Att13 = Hip circumference (cm), Att14 = Thigh circumference (cm), Att15 = Knee circumference (cm), Att16 = Ankle circumference (cm), Att17 = Extended biceps circumference (cm), Att18 = Forearm circumference (cm), Att19 = Wrist circumference (cm) "distal to the styloid processes".

Table 7. ACN of bolt dataset

Rule number (particle)	Antecedent, consequent, none of them (ACN)	Lower bound (LB) < attribute < upper bound (UB)
Rule 1	Antecedent	$11.911616 < Att3 < 16.259242$ $62.782669 < Att7 < 65.562550$
	Consequence	$23.688468 < Att1 < 31.295955$ $5.928943 < Att2 < 6.000000$
Rule 2	Antecedent	$11.911616 < Att3 < 16.259242$ $62.782669 < Att7 < 65.562550$
	Consequence	$23.688468 < Att1 < 31.295955$ $5.928943 < Att2 < 6.000000$
...	...	...
...	...	...
Rule 2000	Antecedent	$13.621221 < Att1 < 29.817232$ $1.761097 < Att4 < 2.325029$
	Consequent	None

Note: Att1 = RUN, Att2 = SPEED1, Att3 = TOTAL, Att4 = SPEED2, Att5 = NUMBER2, Att6 = SENS, Att7 = TIME, Att8 = T20BOLT (target).

column side, on the row side shows the five datasets which are quake, basket ball, body fat, bolt and pollution. According to the table the global result of PARCD method is better than MOPAR method except for the support value of Quake dataset.

The highest result of support value by PARCD method is at 250.84% (Bolt dataset) which is double value than the opposite method in the same dataset. On the other hand, the lowest one is 22.97% by PARCD method which is almost less twice from the MOPAR method also in the same dataset. Next, the remaining datasets; Basket ball, Body fat and pollution, show that the PARCD has better value than MOPAR method in which the gaps are almost 30%, 60% and 10% respectively.

Then, according to the Table 9, the confidence result there is the additional value of standard deviation because it shows the stability of confidence value. Based on the the result, the confidence value generally shows that the PARCD is better than MOPAR method. It can be seen from the whole datasets from Quake to pollution data set in which the gaps are by 4%, 0.02%, 40%, 8% and 10% respectively. Interestingly, the confidence and standard deviation values from basket ball dataset have the similar values as of both of methods.

The output of comprehensibility and interestingness function can be seen in Table 10. The comprehensibility function results that the PARCD is better than MOPAR method, because there are three datasets which the values are higher. They are basket ball, body fat and pollution which the gaps are almost 125%, 130% and 40% respectively. The comprehensibility means that the results from the method are easy to understand. So, the percentage of the result can be explained that both of the methods are better than the traditional method

Table 8. ACN of pollution dataset

Table 9. Output of support and confidence function

Dataset	Support (%)		Confidence (%)	
	PARCD	MOPAR	PARCD	MOPAR
Quake	22.97	46.26	86.73 ± 25.88	82.31 ± 28.91
Basket ball	61.04	32.13	92.69 ± 17.87	92.67 ± 16.65
Body fat	73.94	10.1	81.26 ± 30.67	43.59 ± 61.15
Bolt	250.84	107.29	96.88 ± 9.49	88.91 ± 9.49
Pollution	60.45	52.14	34.96 ± 43.91	23.02 ± 40.04

Table 10. Output of comprehensibility and interestingness function

Dataset	Comprehensibility (%)		Interestingness (%)	
	PARCD	MOPAR	PARCD	MOPAR
Quake	785.2 ± 37.72	786.14 ± 419.67	2.34 ± 9.30	4.67 ± 11.40
Basket ball	545.80 ± 167.74	424.65 ± 192.63	6.56 ± 21.16	4.99 ± 5.18
Body fat	333.49 ± 218.95	204.87 ± 235.46	10.61 ± 21.03	21.71 ± 9.30
Bolt	231.08 ± 168.35	271.25 ± 168.35	43.43 ± 39.68	23.70 ± 39.68
Pollution	110.63 ± 165.76	65.82 ± 130.49	9.51 ± 18.61	10.23 ± 27.88

(discretization approach). Conversely, the Interestingness result of the MOPAR is better than PARCD method which the datasets higher are quake, body fat and pollution. The gaps are about 2%, 10% and 1% respectively. Then the other data set shows that PARCD is better, using basket ball and bolt data sets by the gaps around 2% and 20% respectively.

5 Conclusions

The rules of PARCD from five data sets show the good result but there are two data sets which do not obtain the consequent, they are quake and basket ball dataset. This output is interesting to be studied continually because actually the optimal solution has the complete rule. In addition, by referring to the experiment, the output of multi objective functions which are support, confidence, comprehensibility, Interestingness, it is discovered generally that PARCD gives a better result than MOPAR method. For the future, since the problem of numerical association rule mining is still open to be improved, it will be nice to follow the research for instance by combining with other methods such as genetic algorithm or fuzzy algorithm.

weiqifeng15@cdut.edu.cn

Abstract. Whether the conflict coordination mechanism works effectively directly affects the achievement of the goal of the knowledge network, and is related to both the existence of the knowledge subject itself and the knowledge network. Based on principal-agent theory and game theory, a theoretical framework of conflict coordination mechanism for knowledge network is constructed in this paper, which divides the conflict coordination mechanism into three levels: contract mechanism, self-implementation mechanism and third-party conflict coordination mechanism, then this paper makes a mathematical analysis on the theoretical framework. Results indicate that the adaptive behavior of the knowledge subjects within knowledge network evolves along with the conflict coordination mechanism framework; the conflict coordination of knowledge network contract is mainly embodied in the two aspects of benefit distribution and knowledge division; the implementation of conflict coordination relies mainly on relational contract mechanism and the trust mechanism; when the first two fail, the third party helps to relieve the relationship and make value judgments with a neutral position, in order to solve the fierce conflict.

Keywords: Knowledge network · Conflict · Coordination mechanism · Behaviors

1 Introduction

The conflicts of knowledge network refer to the state of disharmony caused by the accumulation of contradictions to a certain extent, among two or more than two knowledge subjects, due to their incompatible behaviors or goals. According to Pondy [19], the American behavioral scientist, the generation and development of conflict could be divided into five stages: latent conflict, perceived conflict, felt conflict, manifest conflict and conflict aftermath, so as to construct the embryonic of organizational conflict theory. There are many reasons for the conflict of knowledge network, that's because there are many differences between different knowledge subjects in organizational goals, management modes and organizational cultures, which will cause disagreement and lead to conflict;

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_13

The nature and scope of interdependence among knowledge subjects, are often in a dynamic reset conditions, which enables conflict inevitable; And because of the complexity of the knowledge cooperation among organizations, the dislocation of objectives will also lead to the formation of conflict; In addition, due to a changing external environment of knowledge network, inconsistencies between subjects are long-standing. Moreover, the knowledge level, knowledge structure [20], organizational routines [1], differences of values [10,11], among the knowledge subjects, also lead to various conflicts inevitably.

Whether knowledge subjects within knowledge network could learn and improve the knowledge and skills of conflict management, and accurately or effectively implement conflict management, to control the conflict without harm, is directly affecting the goal, and also it is related to subject itself and the existence of knowledge network. Therefore, in the evolution process of conflict coordination mechanism, we should objectively face various conflicts, and adopt corresponding managerial strategies to conflicts with different natures. Obviously, in the process of the generation, development and operation of the conflict mechanism of knowledge network, as the carrier of management main body and objects, knowledge subjects not only have the characteristics of cooperate with the whole team to acquire a better implementation of conflict management, but also have the initiative to actively adjust and innovate the managerial behaviors. From the perspective of long-term development practices, the behavior routines and routine variation of knowledge subjects in the conflict management, is characterized by adaptation, which is specifically the behaviors adaptation under conflicts management mechanism of knowledge network.

2 Conflict Motivation and Behavioral Framework of Knowledge Subjects

The knowledge network is composed of many knowledge subjects, and the benefit distribution scheme among the subjects has both individual rationality and collective rationality. For any subject, cooperation is better than non-cooperation, and the higher benefit can be expected. Therefore, the cooperation among subjects is a cooperative game process. Take the benefit distribution conflict as an example, Gu and Li [7] proposed the n-person cooperative game model among the members of the knowledge chain. The knowledge network consists of several knowledge chains, and the cooperation among the knowledge subjects in the knowledge network inherits the inter-organization cooperative logic of the knowledge chain, so the model is also applicable here to explain. Quan [12] argued that the formation of conflict is mainly caused by three factors: intra-member, inter-member and environment. A three-dimensional conflict model of "benefit-structure-knowledge" is an effective means to explain the conflict of knowledge network (Fig. 1).

The rational organization has the expectation of greatest interests for itself, and conflicts are generated when the benefits of each other can't be coordinated. Based on the structuration theory, the "structure" is considered to be those

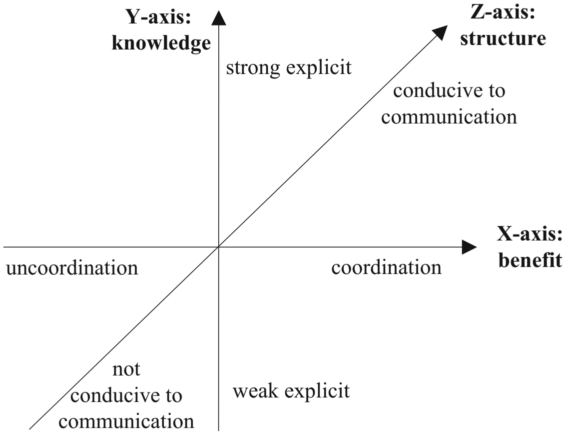

Fig. 1. "Benefit- structure - knowledge" Conflict Motivation Model

resources and institutions owned by the knowledge main body, which involves the organizational structure, organizational culture, social capital, human capital, capital, core competitive advantage and so on. The overlapping of the subjects is an important source of conflicts. Knowledge, as the basis of the operation and survival of knowledge network, determines the essence of value pursued by the knowledge subject. The development of the knowledge subject through knowledge network is to promote the knowledge creation, so as to form the knowledge advantage. Obviously, knowledge plays the central role in the conflict issue. Therefore, the conflict coordination of knowledge network also focuses on these three dimensions to operate management intervention. Wu et al. [22] argued that the problem of cooperation and conflict between knowledge subjects is actually a problem of creating and distributing income, including opportunism behavior control and benefit coordination, value creation mechanisms. The former includes a contract mechanism, a self-implementation mechanism and a third-party conflict coordination mechanism, while the latter includes a relationship adjustment mechanism and a knowledge collaboration mechanism [8]. And the framework of knowledge subject adaptive behaviors is also embedded in these mechanisms. The contract mechanism and the self-implement mechanism can effectively distribute the benefits of the knowledge network to avoid the opportunistic behavior of the knowledge subject, which is based on the coordination and interaction among the knowledge subjects. When the interaction can't solve the conflicts, then the third-party coordination mechanism is introduced to further resolve. In the mechanism of value creation, the regulation of relationship helps to improve the efficiency of cooperation among the knowledge subjects and increase the value of innovation. The mechanism of knowledge collaboration enhances the collaborative benefits of the knowledge subjects and further promotes the creation of knowledge to form the knowledge advantage.

3 The Contract Mechanism of Conflict Coordination Within Knowledge Network

According to the modern contract theory, the cooperative contract is designed to avoid opportunistic behavior and reduce transaction costs. In addition to this function, because of the characteristics of knowledge network cooperation model, the function of knowledge network contract is to promote the knowledge sharing among so as to realize the optimization of the cooperation value, which is significantly different from other types of cross-organizational consortia. For the contract design of knowledge network, the distribution of benefit and the division of knowledge are its core contents, and the conflict coordination is the important objective of those contents, that is, the rules of benefit distribution and knowledge division should effectively coordinate the possible conflicts in the process of network operation, if not, the existing benefit distribution and knowledge division rule is unscientific and unreasonable. According to the evolutionary theory, the knowledge subject has bounded rationality. Under the constraint of objective conditions, the knowledge subject tends to choose satisfaction strategy rather than the optimal strategy, which is also shown in the contract. During the operative process of knowledge network, the information asymmetry exists in the cooperation among the members, which contributes to the possibility that the information superiority side obtains the extra benefits through opportunism behaviors, thus aggravate the conflict of the knowledge network. Therefore, the design of knowledge network contract is also aimed to avoid this "rip off" problem. For the traditional contract overemphasizes partner opportunism prevention and behavior motivation, the contract of knowledge network emphasizes both cognitive and organizational coordination functions, which have a direct impact on the efficiency of knowledge network cooperation and conflict coordination. The function of knowledge-based inter-organizational cooperation contract is embodied in three aspects: motivation, coordination and cognition. The conflict coordination of knowledge network contract is mainly embodied in the two aspects of benefit distribution and knowledge division.

3.1 The Contract Mechanism of Conflict Coordination of Benefit Distribution

The design of the benefit distribution coefficient is the core issue of the conflict coordination of benefits, and the design of the contract also revolves around the core. As Wu and Gu et al. [7] stated, there are different approaches to contract optimization when considering knowledge spillovers. While the conflict of knowledge spillover is not considered, the input level of the knowledge subject is independent of the input level of the partner. In this type of contract design, the higher contribution to the overall network, the higher profit the knowledge subject should gain, which makes the incentive efficiency achieving the best, and effectively coordinate the conflict, so as to ensure the stable operation of knowledge network. Under the condition of knowledge spillover conflict, the knowledge spillover value is the important reason for the knowledge subject to choose whether to cooperate and adjust the level of knowledge input, yet the knowledge spillover loss is also the reason of the conflict formation. At this point, the input level of the knowledge subject depends on the input level of the partner, showing a positive correlation.

The study [23] revealed that, the effect of knowledge spillovers on the cooperation among knowledge subjects is a "double-edged sword", which effectively promotes cooperation but also brings conflict. On the one hand, the innovation value brought by knowledge spillovers is the driving force for deep cooperation. The stronger the knowledge absorptive capacity of knowledge subjects, the more benefits they could get from knowledge spillovers of partners, and the higher the level of knowledge input. On the other hand, because of the influence of knowledge spillover, the input level of knowledge subject is affected by the level of partner input, and the drop of knowledge input will affect the benefit from knowledge spillover. In addition, knowledge spillover may lead to the leakage of core knowledge assets, which will seriously affect the stability of knowledge network cooperation, because the huge potential value of knowledge spillover will stimulate the opportunistic behavior of the cooperators, resulting in conflict. By enhancing the level of cooperation transparency and enhancing the level of mutual trust among organizations, the observability of knowledge investment in the cooperation can be improved, which will effectively restrain opportunistic behaviors and enhance the interaction.

3.2 The Contract Mechanism of Conflict Coordination of Knowledge Division

What the knowledge division in knowledge network involves, is R&D of knowledge subject belongs to the issue of self-completion or principal-agent problem. That is, knowledge subject can do scientific research work by themselves, and make the technology development work outsourced to other subjects in the knowledge network; or both by other agency to complete. The operation mechanism of contractual mechanism of knowledge division conflict coordination includes two stages: knowledge division decision-making and multi-task principal-agent [8].

In the decision-making of knowledge division, the knowledge subject can choose independent R&D or principal-agent, and different decision-making behavior corresponds to different forms of contractual payment. Under the condition of principal-agent, in addition to receiving the entrusted payment, the entrusted entity can obtain the additional income from the technical capability growth. On the one hand, the higher the degree of R&D investment, the higher the R&D capacity gains. On the other hand, the fixed price paid by the entrusted agent represents the bargaining power in the contract conclusion, which reflects the technical capacity of the entrusted subject. From this point of view, it's clear that the higher the technical base is, the higher the additional benefits of growth will be. And because the principal does not participate in R&D, so the income is just the established distribution after the innovation success, but no additional revenue from the increase of technical capacity. According to the model of knowledge division decision-making constructed by Gu et al., the higher the coefficient of technical ability growth income, the higher the input level of the entrusted subject; the higher the payment price in contract, the higher the input level of entrusted subject. And finally the income level of principal is constructed as follows:

$$R_1^F = \frac{(1+k_1)V^2}{4}\left[\frac{\omega}{c_1^2}\right]^{\omega}\left[\frac{1-\omega}{c_2^2}\right]^{1-\omega}. \tag{1}$$

In formula (1), k_1 is the principal coefficient of technological capability growth; V is the value of the product after the success of innovation; ω is the importance level for the scientific research stage; $1-\omega$ is the level of importance for the technology development stage; the cost of the scientific research and technological development of the entrusted subject is respectively $\frac{c_1^2 e_r^2}{2}$ and $\frac{c_2^2 e_d^2}{2}$. and e_r mean e_d the level of knowledge input in two phases, $0 \le e_r \le 1$,$0 \le e_d \le 1$,$c_1^2 > 0, c_2^2 > 0$.

As the input level of the entrusted subject is positively related to its income, it can be seen that the higher the coefficient of technical capability growth, the more benefits the entrusted entity will gain. Therefore, in the decision of entrustment price, the principal will consider the technical capacity growth in the process of cooperation.

If the knowledge division uses partial delegation, that is, the knowledge subject only makes the technological development commissioned by the agent. The success of R&D depends on the degree of knowledge input and the efficiency of knowledge transfer from the stage of scientific research to technological development. Based on the model, the payment level of the principal is positively related to the importance of the development activities, that is, the more important R&D activities are, the higher the payment price will be. In addition, the higher the technical efficiency growth factor and knowledge transfer efficiency, the higher the input level of the principal. The principal's income level is as follows:

$$R_1^P = \mu^{2\omega}\frac{(1+k_2)}{2}V^2\left[\frac{\omega}{\eta^2 c_1^2}\right]^{\omega}\left[\frac{(1-\omega)^2}{2c_2^2}\right]^{1-\omega}. \tag{2}$$

In formula (2), k_2 is the coefficient of technological capability growth of subject; V is the value of the product after the success of innovation; ω is the importance level for the scientific research stage; $1-\omega$ is the level of importance for the technology development stage; μ is the knowledge transfer efficiency, $0 < \mu < 1$; η is the constant associated with R&D costs, $0 < \eta < 1$.

The choice on the form of knowledge division depends on the level of income. By comparing formulas (1) and (2), it can be seen that whether the subject of knowledge conducts the principal-agent of scientific research depends on the increase of technological capacity in R&D activities [8], the efficiency of knowledge transfer and the scientific research the importance relative to technological development.

When the knowledge subject entrust scientific research and technological development activities to other knowledge subjects, the conflict coordination becomes a multi-task principal-agent problem [9]. Based on the model of knowledge division, the model [8] considers the cost independence of R&D and the risk aversion problem of agent. In this case, the maximized deterministic equivalent income of the principal is confronted with two constraints: one is the participation constraint, the expected utility from the accepting contract is greater than or equal to the maximum expected utility when the contract is not accepted; another one is incentive compatibility constraint, when the principal is unable to follow the behaviors of the entrusted subject and the state of development, the entrusted subject always chooses a vector that maximizes its expected utility function. It can be seen that the utility behavior of any entrusted subject can only be realized through the maximization of the utility of the entrusted subject. Gu argued that the conflict coordination among knowledge subjects is affected by factors such as the profitability of entrusted subjects, the relevance of scientific research and technological development tasks, and the traceability of R&D activities.

In general, when the ability that the principal transferring the R&D results of the entrusted subject to the profit is stronger, then the degree of incentive on the entrusted subject to implement innovative behaviors is greater, which is derived from the larger profits will have more possibility for payment. When the cost of R&D is complementary, the entrusted subject will give higher motivation to the R&D task; and when the costs of R&D are substitutes for each other, if the degree of substitution is high, the degree of incentive on a single R&D task will not be too high. Similarly, if a higher incentive is given to technology development, the entrusted subject may neglect the input of scientific research activities, thus affecting the basis of product innovation; When the cost of R&D are completely independent, the incentive is related to the entrusted profit transformation ability, the marginal cost change rate, the degree of risk aversion, and the marginal cost variance and stochastic variance of another task.

4 The Self-implementation Mechanism of Conflict Coordination Within Knowledge Network

The self-implementation of conflict coordination within knowledge network is a kind of internal conflict resolution mechanism as opposed to third-party implementation. As the knowledge subject with the dominant information in the knowledge network performing "hitchhikes", "rip off" and some other acts, a series of conflicts among the organizations are triggered, although the contract effectively provides for the distribution details of innovation benefits, and to a certain extent, solve the conflict of knowledge division. However, due to the incompleteness of the contract, the prior arrangement of rights and the distribution of benefits cannot cover the content of "residual control" [25], which lead to the existence of controversy for the contract. The involvement of public relations departments, arbitration institutions, courts and other third-party conflict mediator is an optional way, but compared to the main subject of the conflict, the third-party management lacks information superiority, which leads to high management costs and diseconomy of the contractual mechanism. Therefore, it is the rational expectation of the knowledge subject to seek the maintenance and conflict coordination in the knowledge network. Dyer and Singh [4] have proposed to use self-imposed conventions to restrain opportunistic behavior. Focusing on long-term cooperative relationships in knowledge network, relational contracts among knowledge subjects can effectively reconcile possible conflicts. The relationship contract helps to make up for the short-sighted and incomplete defects of the formal contract, for instance, the conclusion of the contract can only be observed after the completion of the cooperation results, which ensures the smooth progress of knowledge cooperation. In addition, the trust among organizations is also a “dissolving agent” of the conflict. The self-implementation of the trust mechanism enhances the transparency of the knowledge subjects’ cooperation, enhances the special property investment and guarantees the openness of the communication among organizations, which is conducive to the coordination and settlement for conflict in the knowledge network.

4.1 The Relational Contract Mechanism of Cooperation and Conflict Coordination

The study of relational contract begins with the relational contract theory proposed by Macneil [15]. The theory holds that social transactions are embedded in complex relationships, thus, to study market transactions, we must make clear the various factors in social relations first, such as the specific personal relationships between contractors, the duration of the contract, the number of participants, the degree of difficulty in performing the contract, and so on. Baker and Gibbons et al. [3] argued that relational contracts are closely related to the relationship of ownership of assets, which is based on the value of future relations, it is the future relationship value based on the informal relationship. From this perspective, the purpose of the relational contract is to make the conflict subjects clear the loss of the future relationship and the loss of the direct benefit, so to change their behaviors, to promote the relaxation of the relationship to maintain the sustainable cooperation. From the perspective of contract theory, relational theory is based on the formation of asset specificity [21], whose main characteristic is “self-executing mechanism” [2]. Liu [14] even believed that the relational contract is the micro-foundation of formation and operation of the enterprise network, and the formation of the relational assets is derived from the common role of specific assets and individual social capital. Gu and Wu et al. [8] introduced the concept of relational contract to define the rent, the core enterprise and knowledge specific degree of agent organization of the relationship among the knowledge chain organizations, and analyzed the influences from discount factor and knowledge specific degree on the self-implementation of relational contract. The mechanism by which a relational contract can maintain cooperation among the contracting parties is that any breach by the other party will undermine long-term cooperative relations and thereby penalize the loss of future earnings. In order to maintain the self-implementation of the contract mechanism in the knowledge network and avoid the intervention of the third-party managers to increase the management cost, the rational knowledge subject in cooperation will adjust its behaviors from the factors closely related to the self-implementation, including relationship rent, discount factor and knowledge-specific level.

Usually, the principal and the entrusted subject cooperate to create the relationship. The more the rent is, the more the entrusted subject puts in the specific knowledge assets, the stronger the self-implementation of the relational contract is. The higher the discount factor set by the principal, the higher the input of the entrusted subject, and the stronger the self-implementation of the contract. Knowledge-specific degree refers to the relationship rent created by the unit-specific knowledge asset invested by the knowledge subject. The higher the degree of knowledge-specificity of the principal, the higher the degree of knowledge assets locked in the specific cooperative relationship with the entrusted subject, the replacement cost will be higher, so the self-implementation of relational contract is stronger; and when the principal commissioned into higher special assets, the principal must have a very high degree of knowledge in order to ensure the self-implementation of the relational contract, otherwise the subject may be subject to the implementation of opportunistic behavior to damage the benefits of the principal, thus the principal will spend more energy in the observation of the cooperative behavior of the entrusted subject.

4.2 The Trust Mechanism of Cooperation and Conflict Coordination

Network trust maintains high cooperation intensity among knowledge subjects and enhances the efficiency of knowledge transfer [18]. Trust also plays a very important role in cooperation and conflict coordination, that's because trust is the basis for establishing and maintaining intimate, cooperative, and efficient relationships and the devastation of trust due to deception and breaches can have devastating consequences for relations [24]. Trust is also a self-implementation mechanism for cooperation and conflict, based on informal rules of society, using mutual trust among organizations to make people willing to cooperate to eliminate conflicts [16,17]. The higher the degree of trust, the more significant the conflict resolution will be, on the contrary, the contradictions and conflicts will gradually increase. The role of trust in cooperation and conflict coordination among knowledge subjects in knowledge networks mainly lies in the following aspects: First, trust enhances the transparency of knowledge flow. Transparency between knowledge subjects is not high, mainly because of the vigilance on opportunistic behavior between each other, which usually lead to increased difficulty of knowledge sharing. Mutual trust can help reduce the fear of opportunistic behavior, and enhance the transparency of cooperation between organizations, thereby reducing the complexity of knowledge flow and uncertainty. Secondly, trust increases the investment in the specific assets of knowledge subjects. Specific asset investment refers to the existence of specific assets only for specific users, the knowledge subject once invest the specific asset, the bargaining power in cooperation will be reduced, which may face "rip off" behaviors. Therefore, under the condition of lack of confidence, the subject will generally choose universal asset investment rather than specific asset investment, but specific asset investment can create relational rent and help to improve performance [4]. In addition, trust helps to ensure the openness of communication among organizations. In-depth communication between organizations means that knowledge subjects have more comprehensive understanding the strategic vision, business objectives, resource allocation, financial status and other information, but deep communication between organizations must be based on a high degree of mutual trust as the prerequisite.

Trust mechanism for the cooperation between knowledge subjects and coordination of conflict, its essence is the trust game among organizations [8]. Under completely unconstrained conditions, suppose that there are two knowledge subjects, A and B, are cooperating. When they trust each other, the knowledge is fully shared. At this time, the two parties get the value of R_1 and R_2; when A trusts in B, while B is for the individual interests, bad faith and takes the opportunity to implement opportunistic behavior, so that the interests of A is damaged, $\Delta R > 0$, then the two sides get the benefits $R_1 - \Delta R$ and $R_2 + \Delta R$; If two sides do not trust each other, resulting in no knowledge sharing or knowledge sharing is in low efficiency, assuming that compared to mutual trust, the loss of benefits this time are both $2\Delta R$, so two sides respectively get $R_1 - 2\Delta R$ and $R_2 - 2\Delta R$. In the unconstrained condition, the game matrix of trust behaviors between knowledge subjects is shown in Table 1.

Table 1. Gaming matrix of trust behaviors of knowledge subjects without constraints

		Knowledge subject B	
		Trust	Distrust
Knowledge Subject A	Trust	R_1, R_2	$R_1 - \Delta R, R_2 + \Delta R$
	Distrust	$R_1 + \Delta R, R_2 - \Delta R$	$R_1 - 2\Delta R, R_2 - 2\Delta R$

As can be seen from Table 1, if knowledge subject A trusts knowledge subject B at the outset, he must bear the risk of opportunistic behavior that B is not trustworthy, and he cannot improve his condition as long as he does not change his behavioral strategy. Therefore, from the beginning, A doesn't trust B; vice versa, making the two sides into the Nash equilibrium distrust - distrust "prisoner's dilemma". The two sides of the knowledge subjects even starts from the rational assumption of self-interest purposes, the result is still detrimental to others, which is just the reason to strengthen communication to build mutual trust (Table 2).

When there are constraints, suppose knowledge subject A and knowledge subject B separately put specific assets r_1 and r_2 in cooperation. At the same

Table 2. Gaming matrix of trust behaviors of knowledge subjects with constraints

		Knowledge subject B	
		Trust	Distrust
Knowledge Subject A	Trust	R_1, R_2	$R_1 - \Delta R, R_2 + \Delta R - r_1 - p$
	Distrust	$R_1 + \Delta R - r_1 - p, R_2 - \Delta R$	$R_1 - 2\Delta R, R_2 - 2\Delta R$

time, the cooperation is influenced by informal social relations, including reputation, industry regulation and code of ethics. If someone abuses the trust to implement opportunistic behaviors, he will be punished with the loss of value p, therefore, in the presence of constraints, the payoff matrix of the trust game of knowledge subject becomes:

Compared with the income matrix in unconstrained condition, the difference exists in the losses from investment of specific assets and penalty, from a rational point of view, if $r_1 + p > \Delta R$, knowledge subject B will not choose to implement opportunistic behaviour, that is, when the extra income gained from opportunistic behaviour is less than the sum total of informal social relations punishments and specific assets input, knowledge subject B chooses to trust each other with no suspense, so that the game proceeds to the Nash equilibrium of trust-trust. Therefore, whether to knowledge subject A or B, in the consideration of the evolution of trust mechanism, negotiating the level of specific asset investment making clear social relations punishment are the main adaptive behaviours.

5 The Third-Party Conflict Management Mechanism Within Knowledge Network

The implementation of the third-party management mechanism of conflict in knowledge network is derived from the failure of the contract mechanism and the self-implementation mechanism of cooperation and conflict coordination. There is a serious disagreement among the knowledge subjects on the target and interests; it's unable to negotiate friendly. Only the third party independence institutions could help to relieve the relationship and make value judgments, to solve the fierce conflict in the knowledge network. The concept of "third party" comes from public economics, which can convey information to the conflicting parties in an impartial manner and attitude, and fairly adjudicates the conflict [13], the party is generally acted by the organization designated by government and industry associations, also, arbitration institutions and courts are often used as potential conflict resolution organizations, but its service cost is much higher.

The role of third party conflict management organization in coordinating the conflict among organizations is mainly reflected in [6,8]: to protect the benefits of the weaker subjects, to avoid the unreasonable distribution of interests, to appraise the performance of the knowledge subjects, to avoid the performance evaluation conflict of interest arising from subjective differences, and to investigate relevant conflict facts to determine the specific circumstances of the statement, so as to consider the dispute resolution. Specific functions include [13]: conflict evaluation, conflict level control, conflict resolution and conflict prevention. According to Elangovan [5], the strategy of third-party conflict control has five aspects, namely, means-control strategy (MCS), ends-control strategy (ECS), low control strategy (LCS), full control strategy (FCS), and part control strategy (PCS).

MCS mainly affect the formation process of the conflict solution, but not directly form the solution result. The final conflict resolution strategy is decided by the conflicting subject, so it is a strategy focusing on the process control, whose real form of expression is “mediation”. At this time, the adaptive behavior of knowledge subject tends to assist the management of the third party, strengthen the communication, consciously maintain the order of negotiation, discuss the solution with other conflict subjects under the witness of the third party and finally realize the reconciliation. The results of ECS is just the opposite, the strategy influences the outcome of the conflict resolution rather than the process to intervene in the dispute, directly deciding the conflict resolution, rather than trying to influence the negotiation process, the subject may positively and fully demonstrate the conflict content to a third party, the actual form of such strategies include “arbitration”, “judgment” and so on. LCS advocates using “negative” way to resolve the conflict, the third party organization only requests the conflict subject to shelve the dispute or provides the impetus to urge two sides to realize conflict self-reconciliation, rather than confront conflict itself, therefore the third-party doesn’t have the substantive involvement in conflict coordination process and the result either, For the knowledge subject, the adaptation behavior at this time is far away from conflict, shelving conflict, and achieving common development. FCS advocates the comprehensive intervention in the conflict coordination process, which resolves the conflict by influencing the way of expounding the cause of the conflict, the way of presenting the facts, and the final solution to resolve the conflict. In which the third party obtains information by asking the conflict subject about the conflict, that is, according to its own conflict resolution routines to actively search for and compile information about the conflict, and announce a conflict resolution plan to achieve the purpose, which as Elangovan stated is referred to as inquisitorial intervention or autocratic intervention, so as the parties to conflict, the knowledge subject cannot interfere in any aspect of conflict coordination, what they can only is just coordination. The last strategy PCS is a hybrid management approach, the third party implements the strategy of sharing the process of conflict-coordination and control of the strategy outcome, which is presented as: the third-party join the conflict negotiation to achieve consensus; and by facilitating the interaction and communication of the conflict subjects and arguing with the conflict subjects on the conflict event, to help think and evaluate the various options to select the best plan, recommend to convince the conflict subject to accept the preferred program to resolve conflicts, such as “arbitration after conciliation”, “collective discussion” and so on. In addition to actively cooperating with the third party to investigate and participate in collective discussion, the knowledge subject may try to find a solution to the conflict and obey the decision of the third party to eliminate conflicts. The third-party conflict intervention strategy chosen by knowledge network is mainly affected by fairness perception, satisfaction perception, effective perception and strategy implementation efficiency of knowledge subject.

6 Conclusions

The issue of conflict coordination for knowledge network, which is essential to knowledge network management, is directly influencing its effectiveness and performance. Due to this, the conflict coordination mechanism of knowledge network is studied in this paper, and an analytical framework is proposed afterwards. What's presented in this paper is: the conflict coordination of knowledge network is focusing on knowledge, benefits and structure. The contents of the cooperation and conflict coordination mechanism among knowledge subjects include contract mechanism, self-implementation mechanism and third-party conflict coordination mechanism. The framework of knowledge subject's adaptive behaviors is embedded in these mechanisms. The contract mechanism and the self-implement mechanism can effectively distribute the benefits of the knowledge network, to avoid the opportunistic behaviors of the knowledge subject, which is based on the coordination and interaction among knowledge subjects. When the interaction among the subjects cannot solve the conflict, the third-party coordination mechanism is introduced to further resolve.

Abstract. With the accelerated pace of life, more and more tourists' travel mode change from the traditional land travel into air travel. It has contributed to the rapid development of the aviation industry. But also produced some problems that troubled the airline. Among them, the flight delays problem has not been effectively addressed. The cost of flight delays is still high. This paper launches the research, analyze the cause of the cost of flight delays. For the factor of terminal area flight scheduling unreasonable to improve. Combined with the two-runway actual situation of Chengdu Shuangliu International Airport, minimize the cost of flight arrival delays, construct the model of flight arrival on two runways. At the same time, the coding method, selection strategy and fitness function of GEP are improved combined with the specific problem. Finally, IGEP and simulation are utilized to solve the practical problem. Compared with the traditional $FCFS$ rules, the cost of flight arrival delays is significantly reduced, the efficiency of flight arrival and runway utilization is improved, and the interests of airlines are guaranteed. It also shows the superiority of IGEP in addressing the issue of two-runway flight arrival.

Keywords: Flight arrival · Improved gene expression programming · Cost of flight delays · Two runways

1 Introduction

With the speeding up of life rhythm, people on the quality of travel requirements are getting higher and higher. Compared with ordinary land travel, people have a tendency to more efficient and better services' air travel. China's civil aviation passenger traffic for several years to maintain the growth rate of more than 8% [3]. In order to satisfy the needs of more passengers, major domestic airlines actively purchased aircraft, the number of aircraft China's civil aviation has been increasing for many years. At the same time, several domestic airports have built new runways for use by airlines. Two-runway airport is becoming more and more.

But the development of the aviation industry has also brought some problems cannot be ignored. Air traffic flow increases, airport traffic congestion and flight

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_14

delays are very common. According to statistics, the punctuality rate of flight in China has been lower than 80% for several years, and has a tendency to decline [4]. It is contrary to the pursuit of efficient travel. Flight delays led to some people confidence shook on the air travel, and then give up air travel, the airlines' revenue will reduce. In general, flight delays reach two hours, this flight will be a loss, the longer the delay, the higher the cost of delays. So how to control flight delays and decrease the cost of flight delays has become an urgent problem to be solved.

There are numerous reasons for flight delays, such as bad weather and aircraft faults, these accidental factors are unable to change. However, in many cases, unreasonable flight scheduling can also lead to flight delays. The data showed that nearly 40% of flight delays are related to flight scheduling. Unreasonable scheduling will aggravate flight delays, increase the cost of flight delays. On the contrary, reasonable flight scheduling can alleviate the problem of flight delays, reduce the cost of flight delays, protect the interests of airlines and improve the utilization of the runway. So how to make reasonable flight scheduling has become more and more attention by the airlines. Scholars in related fields have studied and made some achievements after noticing the importance of flight delays:

Hu and Xu [11] pointed out that flight delays and air traffic congestion due to the restriction of airport capacity, they used the ground maintenance strategy to solve the problem. Xu and Yao [19] established optimization model of multi-runway in the terminal area, and the genetic algorithm (GA) was used to solve the problem. Zhang et al. [20] constructed a dynamic multi-objective optimization model for arriving and departure flights on multiple runways. Then designed GA to solve the proposed model with the dynamic characteristics of receding horizon control strategy. Kafle and Zou [12] proposed a novel analytical-econometric approach, and built an analytical model to reveal the effects of various influencing factors on flight delays. Liang and Li [14] take flight departure time as the goal, and used improved gene expression algorithm (IGEA) to study the departure problem of single runway airport.

But the problem of two-runway flight arrival based on the cost of flight delays has not been solved. The traditional mode of flight arrival is first come first served (FCFS), without considering the impact on other flights, the advantage of this approach is completely fair between the various flights, and the scheduling is simple. It is more suitable in the early stage of China's aviation industry, the number of flights is less. With the increase in the number of flights, the shortcomings are also obvious leakage. Lack of scheduling lead to high cost of flight arrival delays, low runway utilization, cannot guarantee the interests of airlines, also cannot meet the requirements of travel time for passengers. So the traditional FCFS cannot adapt to the current flight arrival scheduling. There is an urgent need for new ways to improve the problem. Gene expression programming (GEP) is a new adaptive evolutionary algorithm based on biological structure and function [2]. It is evolved from GA and genetic programming (GP). It learns GA to encode chromosome into a fixed-length linear symbol string, and inherits the characteristics of GP to convert chromosomes into undefined expression trees. The genotype and phenotype were separated. Therefore, the use of genetic operators in terms of number and variety is not constrained. Meanwhile, mutation, insertion, and reorganization expands the search space of GEP. Using simple coding to address complex problems, make GEP greatly enhance the ability in solving specific problems. After the algorithm is proposed by Candida Ferreira, it has aroused great repercussions and became the focus of scholars in some fields. But the research of GEP is primarily focused on the prediction model and data mining [1,6,10,13]. Research on aviation management is still very limited. The application of GEP in flight arrival scheduling is more scarce. In view of GEP's powerful function, the problem of two-runway flight arrival scheduling based on IGEP is proposed in this paper. By using IGEP to solve the problem of two-runway flight arrival scheduling. The goal is to reduce the cost of flight delays, the corresponding model and IGEP were designed to optimize the problem. To ensure that the interests of airlines.

This paper is organized as follows. Section 1 introduce the reasons and influence of flight delays, discusses the study of flight scheduling, introduce the birth process and advantages of GEP, and IGEP was proposed to optimize the problem of two-runway flight arrival. Section 2 introduce the development of ZUUU and the specific problems of the flight arrival. Section 3 constructs the model based on the practical problem. In Sect. 4, some improvements of GEP are proposed, and describe the processes of IGEP. Section 5 application IGEP to solve practical case, and analyze the results of the problem; Sect. 6 is the conclusion and prospect.

2 Problem Description

Chengdu Shuangliu International Airport (ZUUU) is located in Sichuan Province, southwest of China. It was founded in 1938. After that, experienced several important expansion and development, and in November 1995 changed its name to "Chengdu Shuangliu International Airport". The second runway of the ZUUU was successfully completed and put into operation in 2009. It is located in the eastern part of the airport and connected to the first runway in the west. The aircraft can land independently on two runways. ZUUU plane diagram shown in Fig. 1:

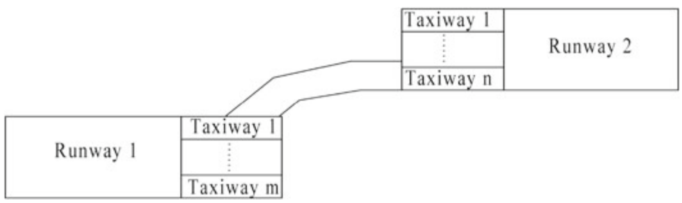

Fig. 1. ZUUU plane diagram

There are two runways in Fig. 1. Runway 1 is connected to m taxiways. Runway 2 is connected to n taxiways. For flight arrival, the runway serves as a buffer for the speed landing aircraft. Decelerated airplane slides into the taxiway, and the airplane enters the apron through the taxiway.

After the second runway put into use, the transportation capacity of ZUUU has been significantly improved, but in some cases the cost of flight arrival delays is still high. Among them, flight scheduling is the most important factor in the cost of flight arrival delays, and flight scheduling optimization mainly for the terminal area. The terminal area has two main functions. First, ensure orderly flight arrival and departure. Second, ensure safe separation and sequence between arrival flights. On the premise of flight safety, scheduling flight in the terminal area can reduce the time and cost of flight delays, improve runway utilization and ensure benefit of airlines.

Arrivaling is required after the flight reaches the terminal area. But at some point, due to the effects of bad weather and airport capacity constraints, the flight to reach the terminal area in a certain period of time will be restricted to arrival, these flights were forced to circle in the terminal area waiting to arrival. When the situation of the airport improved, these waiting flights were arranged on the runway in turn to arrival. But which flights arrival on runway 1 and which flights arrival on runway 2, as well as the sequence of flight arrival, related to the cost of flight delays. In order to minimize the total cost of flight arrival delays, these flights need to be sorted. So the problem can be transformed into the sequencing optimization problem of flight arrival. We can establish the scheduling model and design the appropriate algorithm to solve it. Flight arrival needs to consider safe wake vortex separation of the flight. Wake vortex separation is related to the aircraft type, and the cost of flight delays per unit time is not same for different aircraft types [5,7,17].

About wake vortex separation, according to the standards of international civil aviation (ICAO), all aircraft according to the maximum allowable takeoff weight is divided into three types. Heavy (H), medium (M) and light (L), and as a basis for the aircraft to set a safe wake vortex separation, ensure the safety of aircraft [8,15]. The safe wake vortex separation of ICAO is shown in Table 1.

Table 1. The ICAO safe wake vortex separation (Unit/min)

Aircraft types	Heavy (H)	Medium (M)	Light (L)
Heavy(H)	2	2	3
Medium(M)	2	2	3
Light (L)	2	2	2

In Table 1, the rows indicate the arrival flight in the front of a runway, the columns indicate the flight that is at the back on the same runway, the cross cells of row and column represent before and after the two adjacent arrival flights safe wake vortex separation on the same runway.

Table 2. The cost of flight delays per unit time for the three aircraft types

Aircraft type	The maximum allowable takeoff weight (t)	The cost of delays per unit time (yuan/min)
Heavy (H)	> 136	498
Medium (M)	7–136	236
Light (L)	≤ 7	92

About the cost of flight delays, according to the literature on the analysis of the cost of flight delays [18]. Table 2 shows the cost of flight delays per unit time for the three aircraft types, and the classification standards of aircraft type.

3 Model Construction

The total cost of flight arrival delays is minimized as the optimization goal, establish the scheduling model of flight arrival. In particular, to minimize the cost of delays in arrival flight on two runways, involved two runways, it is necessary to allocate runways to these flights, taking into account the sequence of flight arrival on the runway. The sequence of flight arrival is related to the safe wake vortex separation. The type of aircraft and the cost of flight delays per unit time is also required to consider. These factors affect the cost of flight arrival delays together.

In order to make the model more accurately describe the process of flight arrival, the following assumptions are made:

Assumption 1. The number of flights required to arrival during a certain period of time is N times, and these flights are now required to circle in the terminal area due to environmental impact and airport capacity constraints.

Assumption 2. From a certain moment, the waiting flight in the terminal area can in turn to arrival, this moment is remarked as 0.

Assumption 3. From 0 moment, the arrival flight can smoothly through the runway, taxiway into the apron. This is a continuous process. The allocation of flight on the taxiway and access to the apron does not have to be considered.

i : There are N flights circling in the terminal area waiting for arrival in a certain period of time, according to the sequence of arrival terminal area labeled as $i = 1{,}2, \cdots, N$;
j: Indicates a total of two runways $j = 1{,}2$;
k: According to the sequence of flight arrival on runway j, the flight is remarked as $k = 1{,}2, \cdots, M$, and $M \leq N$;
X_{ik}^{j}: If the $i-th$ flight in the terminal area is $k-th$ arrival on runway j, then $X_{ik}^{j} = 1$; else $X_{ik}^{j} = 0$;
u: Distinguish the aircraft types of flight. Heavy aircraft remarked as $u = 1$; medium aircraft remarked as $u = 2$; light aircraft remarked as $u = 3$;

W_u: Represents the cost of delays per unit time for the aircraft type u;
P^j_{ku}: If the $k-th$ flight arrival is the aircraft type on runway j, then $P^j_{ku} = 1$; else $P^j_{ku} = 0$;
$Q^j_{k,k-1}$: The safe wake vortex separation of adjacent flight on runway j;
T^j_k: The arrival time of the $k-th$ flight on runway j, it is also the time of flight delays;
$\triangle T^j_{k,k-1}$: The difference in arrival time between adjacent flights on runway j;
C: The total cost of flight arrival delays.

The objective function and constraints are as follows:

$$C_{\min} = \sum_{i=1}^{N}\sum_{j=1}^{2}\sum_{k=1}^{M}\sum_{u=1}^{3} P^j_{ku} Wu T^j_k X^j_{ik}, i = 1, \cdots N; j = 1, 2; k = 1, 2 \cdots, M; u = 1, 2, 3 \tag{1}$$

$$\sum_{j=1}^{2}\sum_{k=1}^{M} X^j_{ik} = 1, i = 1, 2, \cdots, N; j = 1, 2; k = 1, 2, \cdots, M \tag{2}$$

$$\sum_{i=1}^{N}\sum_{j=1}^{2}\sum_{k=1}^{M} X^j_{ik} = N, i = 1, 2, \cdots N; j = 1, 2; k = 1, 2, \cdots, M \tag{3}$$

$$\sum_{u=1}^{3} P^j_{ku} = 1, j = 1, 2; k = 1, 2, \cdots M; u = 1, 2, 3 \tag{4}$$

$$\sum_{u=1}^{3} P^j_{ku} Wu = P^j_{k1} W1 + P^j_{k2} W2 + P^j_{k3} W3, j = 1, 2; k = 1, 2, \cdots M; u = 1, 2, 3 \tag{5}$$

$$T^j_k - T^j_{k-1} = \varDelta T^j_{k,k-1}, j = 1, 2; k = 2, \cdots, M \tag{6}$$

$$\varDelta T^j_{k,k-1} \geq Q^j_{k,k-1}, j = 1, 2; k = 2, \cdots, M \tag{7}$$

$$T^j_1 = 0, j = 1, 2 \tag{8}$$

$$X^j_{ik} \in \{0,1\}, P^j_{ku} \in \{0, 1\}. \tag{9}$$

Among them, Eq. (1) is the objective function of the model, which represents the total cost of flight arrival delays; Eq. (2) shows that each flight can only arrival on one runway; Eq. (3) shows that there are N flights need to arrival at 0 moment; Eq. (4) indicates that each flight can only be one of three aircraft types; Eq. (5) shows the cost of delays per unit time of the k^{th} flight on runway j; Eq. (6) shows that the difference in arrival time between the adjacent flights on runway j is $\varDelta T^j_{k,k-1}$; Eq. (7) indicates that the difference in arrival time between adjacent flights on the same runway is not shorter than the safe wake vortex separation; Eq. (8) shows that the first flight arrival on the runway is at 0 moment and the time of delays is 0; Eq. (9) are the position and aircraft types selection variable. And then the specific algorithm is designed to solve the model.

4 Algorithm Design

FCFS has not been able to adapt to the flight arrival scheduling problem, and GEP as a new evolutionary algorithm, has a powerful function, compared with the traditional evolutionary algorithm, the ability to solve problems has been greatly enhanced. This chapter focusses on the design and process of IGEP.

4.1 IGEP

The IGEP are used to improve the problem of flight arrival on two runways and multiple taxiways. It is necessary to improve GEP according to the specific problem and model. It mainly adjusts the coding method, genetic operators design and so on of GEP, so that the algorithm is more simple and efficient in solving problems.

(1) Coding Method
Coding method around the problem, there are two runways mentioned on the model. In order to simplify the problem, it is possible to code the flight arrival on runway 1 as "1" and the flight arrival on runway 2 as "2", regardless of flight specific allocation on the taxiway. There are a total of m "1" and n "2", and N flights arrival on two runways. In accordance with the sequence of arrival, the flight arrival on runway 1 is encoded as "$A_1, A_2, \cdots, A_m$", the flight arrival on runway 2 is encoded as "$B_1, B_2, \cdots, B_n$".

(2) Mutation Operator
Mutation is the most efficient operator among all operators with the ability to modify. It can occur anywhere in the chromosome, and the chromosome structure was complete after mutation [16]. The root insertion, gene insertion, gene recombination not used in IGEP, excluding recombination and transposition. Utilising the mutation operator, the mutation probability P_m determines the point mutation in the chromosome. Since the coding used only contains the genotypes "1" and "2", the most effective mutation is to switch "1" and "2" of some genes. The gene pair represents the arrival flight on two runways, then it is easy to get the individual and population after mutation, simplify the process of GEP, increase the efficiency of solving the problem.

(3) Selection Strategy
In GEP, one of the most common selection strategies is roulette selection, in which the individual chooses according to their fitness through the roulette sampling strategy. Each individual with a round table of the disc to represent the fitness, the higher the individual fitness, the greater possibility it becomes the offspring. Instead of choosing this method, a strategy that is more suitable to solve the problem of flight scheduling is used in this paper. It preserves the individuals other than the optimal individual, and ensures that the population size remains constant.

(4) Fitness Function
The degree of fitness of the individual to the environment is expressed by the fitness, the individual fitness can be obtained by using the fitness function. The fitness function is the driving force of GEP population evolution, which directly affects the convergence speed of the algorithm and whether it can find the optimal solution [9]. In designing the fitness function, the analysis must be based on specific issues, clear objectives and accurate definition. Where the fitness function does not use the most common fitness function based on relative error. The improved fitness function is shown in Eq. (10):

$$f\left(c\right) = \frac{m+n}{C_{\min}}. \tag{10}$$

In Eq. (10), $C_{\min}$ represents the minimum total cost of flight arrival delays on two runways, m and n represents the number of arrival flights on two runways.

(5) Flight Retention Policy
The retention of the optimal flight is to retain the optimal individual and the optimal feasible individual. The optimal individual and the optimal feasible individual of the initial population are retained. Then the optimal individual and the optimal feasible individual of the first generation are compared with the individuals initially retained. If the individuals are better than the individuals originally retained, then the first generation of individuals will be retained. Otherwise individuals initially retained become the current generation. Then, in this manner successively selective substitution and retention.

4.2 IGEP Process

The IGEP steps are as follows:

Step 1. Randomly generate 50 chromosomes as the initial population;
Step 2. These chromosomes are translated into expression trees according to certain rules;
Step 3. According to the fitness function Eq. (10) to calculate the fitness of each individual;
Step 4. According to fitness value to determine whether the population to meet the requirements, if meet the requirements, the process is over; otherwise, proceed to step 5;
Step 5. Selecting the individuals according to the fitness, substitution and retention individual with selective;
Step 6. Genetic operations, the selected individuals are subjected to modified replication using genetic operators. Mutation probability is 0.05, so that the next generation to retain the new features, and then return to step 2.

The new population is subjected to the same development process described above, and the process is repeated until a satisfactory solution occurs, or iterates to a prescribed algebra, which is set to 500. According to the constructed model and the improved algorithm, the flowchart of IGEP is obtained, as shown in Fig. 2.

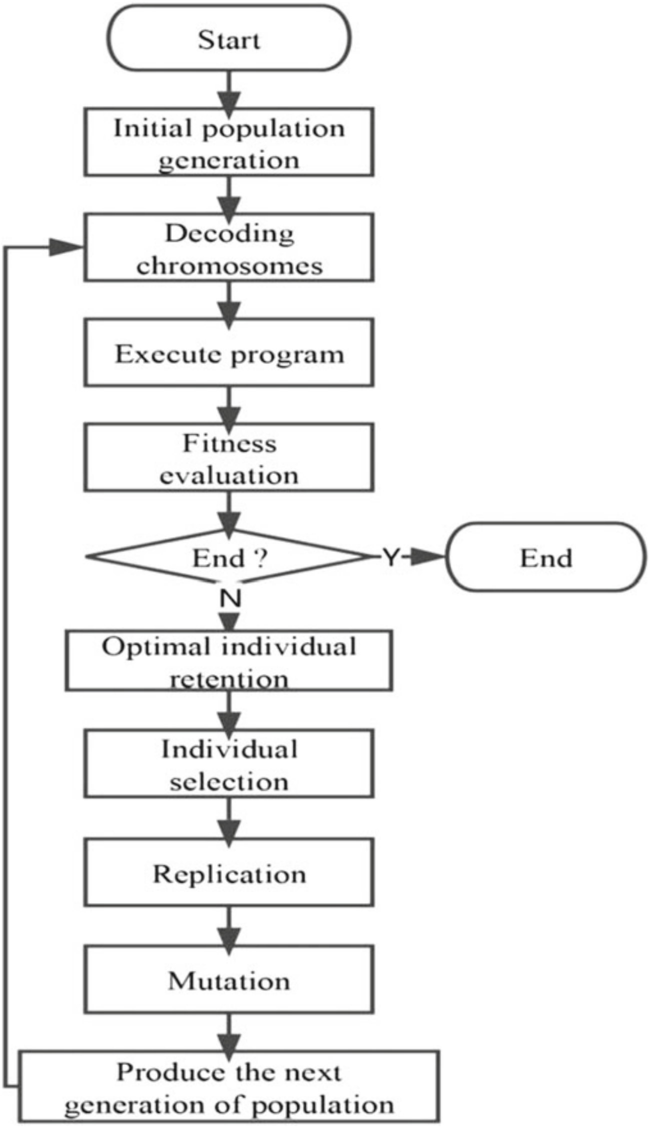

Fig. 2. Flowchart of IGEP

5 Case Simulation and Analysis

The case was developed using $C++$ and tested with multiple sets of data. The overall parameter design of IGEP is shown in Table 3.

Case taken from the ZUUU suffered a short period of time in a thunderstorm weather, resulting in flight delays, this period of time a total of 20 arrival flights were affected, leading to delay in arrival. Flights sequentially numbered 1–20

Table 3. The Parameter Design of IGEP

according to the sequence of arrival terminal area. In accordance with the FCFS rules, the odd-numbered flights arrival on runway 1 in sequence, and the even-numbered flights arrival on runway 2 in sequence, and two initial queues l_1 and l_2 are obtained according to the arrival sequence of the flight on two runways. Both queues contain 10 arrival flights, representing flights arrival sequence on runway 1 and runway 2 respectively, which is flight arrival sequence based on the FCFS rules and is also regarded as the initial flight arrival sequence L_0. According to L_0, obtained the total cost of flight arrival delays on two runways is C_0. Then the initial flight arrival sequence L_0 is optimized by IGEP according to the set parameters. When the algorithm reaches the termination condition, the optimized flight arrival sequence is L_n, and the total cost of flight arrival delays is C_n. After simulation, the flight arrival delays of the two schemes are obtained. As shown in Table 4.

Compare flight arrival delays of the two schemes in Table 4. It can be seen through optimization of IGEP. The total cost of flight arrival delays C has been significantly decreased. Compare with the traditional FCFS rules, the total cost of flight arrival delays decreased from 54,862 yuan to 30,716 yuan through the IGEP optimization. The total cost of flight arrival delays reduced 24,146 yuan, a decrease of 44.01%. The average delay cost of each flight from 2743.1 yuan down to 1535.8 yuan. The total time of flight arrival delays dropped from 43 min to 38 min, the total time decreased by 5 min, the average arrival time of each flight from 2.15 min down to 1.9 min, the flight arrival efficiency increased by 11.63%. The same flights arrival, reduced arrival time has proved that runway utilization has improved. According to the data in Table 4, the line chart of the cost of flight arrival delays on two runways are obtained, the abscissa represents the arrival sequence on the runway and the ordinate represents the total cost of flight arrival delays, as shown in Figs. 3 and 4.

As can be seen from Figs. 3 and 4, the cost of flight arrival delays on two runways has declined. The cost of flight delays on runway 1 decreased from 27406 yuan to 14590 yuan. The cost of flight delays on runway 2 decreased from 27456 yuan to 16176 yuan. Delay cost fell 12,816 yuan and 11,280 yuan respectively. The total cost of delays in airlines has significantly decreased, the income has been safeguarded, these have a positive impact on the development of airlines. At the same time, according to the trend of the line chart, we can see that when the

number of arrival flights reaches a certain scale, with the increasing number of arrival flights, the difference between the cost of flight arrival delays before and after optimization is greater, and the economic significance of the optimization of the flight arrival problem becomes more apparent.

6 Conclusion

The rapid development of social economy has promoted the change of passenger's travel mode. The demand for aviation industry has been growing. The development of aviation industry has also resulted in flight delays and high cost of flight delays, which impose higher demands on flight arrival scheduling. This paper studies the problem of flight arrival delays based on the results of domestic and international flight scheduling research. The total cost of flight arrival delays is minimized as the optimization goal, construct the scheduling model of flight arrival, and IGEP is designed according to the specific problem and model.

Through practical case studied of ZUUU, it was found that IGEP-optimized flight arrival scheme, compared with the traditional FCFS scheme, the cost of flight delays is significantly reduced, also reducing the arrival time of the flight, the efficiency of flight arrival and runway utilization are improved. It also showed the effectiveness of IGEP in solving the scheduling problem of flight arrival. For airlines, this approach is worth promoting. It can reduce the loss of the airlines in solving the scheduling problem of two-runway flight arrival, and ensure the interests of airlines. It also has a positive impact on the development of the aviation industry. The research work in the future can be associated with flight scheduling on the taxiway, improve the process of flight arrival. In the aircraft type, the three types can be more detailed division, accurate to each type, in order to get the conclusion more convincing.

Abstract. Climate change can make a profound impact on the entire ecosystem, and severely affects the stability of human society. The urban is the economic, political and cultural center of human society. The assessment of urban disaster vulnerability is of great significance to the disaster prevention system. Through the review of the relevant literatures on disasters vulnerability and the situations of Sichuan Province, the study establishes urban climate change actual vulnerability assessment systems. The vulnerability degrees of the five economic zones of Sichuan Province are evaluated by the improved mutation progression method based on the entropy method. The study shows that the urban disaster vulnerability of Southern Sichuan Economic Region is the most serious, and the degree of disaster vulnerability of Chengdu Economic Region is the lowest. Chengdu Economic Region should concern about the floating population. And Southern Sichuan Economic Region needs to create a good environment for enterprises to increase the number of enterprises within its jurisdiction.

Keywords: Climate change · Vulnerability · Sichuan province · Mutation progression method · Entropy method

1 Introduction

Climate change has already made a serious impact on human beings [1]. It not only makes social economy worse [3], increases the flood exposure of cities [6] and the difficulty of reservoir management [14], severely threaten the human health [11], but also destroys the diversity and the stability of ecosystem [2,9]. Therefore, climate change has been becoming an important issue related to the survival and sustainable development of human beings. To minimize the threat caused by climate change, effective measures need to be formulated.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_15

The vulnerability can comprehensively assess the impact of natural disasters [7], and provide a fundamental basis for effective adaptation to climate change [12]. And the vulnerability assessment of urban climate change disasters is an important link to enhance the ability of urban disaster response, and has important practical significance [8].

After years of development, foreign vulnerability research has acquired remarkable achievements. The Intergovernmental Panel on Climate Change (IPCC) has established a system of climate change vulnerability method, which has been applied to 24 countries [5]. The Tyndall Center constructed a national climate vulnerability assessment system [15]. China's relevant researches on the vulnerability of climate change disasters began in 1990s, which mainly were related to the impact of climate change on water resources and agricultural disaster, rarely including the regional composite system [17].

The influences caused by climate change are widespread and multi-level [11]. However, the current research focuses on the impact of climate change on the coastal cities [6], few of those studies of climate change in inland cities. In our study, Sichuan Province, an inland region of China, is regarded as the research object. The urban climate change vulnerability study of Sichuan five economical areas is based on catastrophe progression method. The result of our survey can provide objective statement of economical regions' urban vulnerability, and offer effective references to urban climate change response.

2 Method

The catastrophe progression method combines catastrophe theory and fuzzy mathematics [10]. And in order to make the sort of indicators more objective and reduce the influence of subjective factors, the evaluation indexes are ranked by the weight. The catastrophe progression method can be divided into 6 steps.

Step 1. Establish assessment systems.

The overall goal is divided into multi-level indicators. And the total number of the corresponding indicators is not more than four, which can be expressed by the parameter n.

Step 2. Identify the model of system.

$$f(x) = \begin{cases} x^3 + ax, & n = 1 \\ x^4 + ax^2 + bx, & n = 2 \\ \frac{1}{5}x^5 + \frac{1}{3}ax^3 + \frac{1}{2}bx^2 + cx, & n = 3 \\ \frac{1}{6}x^6 + \frac{1}{4}ax^4 + \frac{1}{3}bx^3 + \frac{1}{2}cx^2 + dx, & n = 4. \end{cases} \tag{1}$$

The $f(x)$ represents the potential function of the state variable x. And a, b, c represent the control variable of the state variable x.

Step 3. Data standardization.

$$x_{ij}{}^{*} = \begin{cases} x_{ij}/\max\limits_{j}(x_{ij}), & x_{ij} \in x_{ij}^{+} \\ \min\limits_{j}(x_{ij})/x_{ij}, & x_{ij} \in x_{ij}^{-}. \end{cases} \tag{2}$$

The x_{ij} means the evaluation index j of object i. The x_{ij}^{+} is a benefit attribute. The x_{ij}^{-} is a cost type attribute. The $\max_j(x_{ij})$ is maximum value of evaluation index j. The $\min_j(x_{ij})$ is minimum value of evaluation index j.

Step 4. Calculate the weight of each index by the entropy method, and rank the evaluation indexes based on the weights of evaluation indexes.

$$p_{ij} = x_{ij}^{*} \Big/ \sum_{i=1}^{m} x_{ij}^{*}, j = 1, 2, \cdots, n, \tag{3}$$

$$e_j = -\frac{1}{\ln m} \sum_{i=1}^{m} p_{ij} \ln p_{ij}, j = 1, 2, \cdots, n, \tag{4}$$

$$w_j = (1 - e_j) \Big/ \sum_{j=1}^{n} (1 - e_j), j = 1, 2, \cdots, n. \tag{5}$$

The m represents the number of evaluated objects. And n indicates the number of indicators. The value of w_j is the weight of each index.

Step 5. Confirm the normalized equation of each model.

$$x = \begin{cases} x_a = a^{1/2}, & n = 1 \\ x_a = a^{1/2}, x_b = b^{1/3}, & n = 2 \\ x_a = a^{1/2}, x_b = b^{1/3}, x_c = c^{1/4}, & n = 3 \\ x_a = a^{1/2}, x_b = b^{1/3}, x_c = c^{1/4}, x_d = d^{1/4}, & n = 4. \end{cases} \tag{6}$$

Step 6. Comprehensive evaluation.

According to the multi objective fuzzy decision theory, $T_1, T_2, \cdots, T_n$ can be regarded as a fuzzy goal for the same plan in the multi-objective situation. Then the ideal membership function is $u(x) = u_{T_1}(x) \cap u_{T_2}(x) \cap \cdots \cap u_{T_n}(x)$, of which $u_{T_i}(x)$ is the function of the fuzzy decision T_i. By unitary formula, the corresponding value of the state variable can be confirmed.

3 Case Study

Sichuan province is located in the hinterland of the China's southwest, and on the eastern of Qinghai-Tibetan plateau. Due to the unique geographical environment of the plateau, the climate change in Sichuan is very obvious. Meanwhile, Sichuan is located in the Longmen Shan Fault, in which geological disasters easily happen [13]. The sudden heavy rainfall caused by climate change led to the city water logging, and even geological disasters (e.g., landslide, debris flow). The basic situation of cities in each economic zone is shown in Fig. 1.

3.1 Construct the Index System

The vulnerability of urban disaster prevention system consists of response, sensitivity, resilience [4]. The related researches of vulnerability don't form a unified vulnerability assessment system, and the selection of vulnerability index

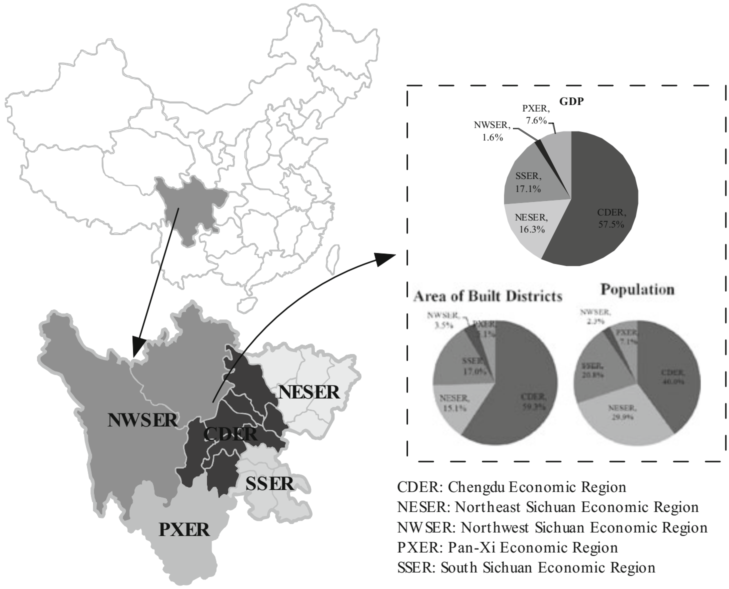

Fig. 1. Overview diagram of Sichuan Province

varies according to the real problems [16]. Sichuan Province is divided into five major economic zones, including Chengdu Economic Region (CDER), Northeast Sichuan Economic Region (NESER), Northwest Sichuan Economic Region (NWSER), Pan-Xi Economic Region (PXER), and South Sichuan Economic Region (SSER). In order to make the economic zone of the social vulnerability index objective and reasonable, the vulnerability assessment of urban climate change disaster is established based on actual situation of Sichuan (Table 1).

3.2 Assess the Urban Vulnerability of Climate Catastrophe

Our study regards Sichuan Statistical Yearbook (2015) as the source of the original data. According to Eqs. (2)–(6), the standard data and the importance of each indicator can be calculated. Table 1 shows the sorted result of each layer index.

In the assessment system, the number of each layer's indexes is not more than 4. According to the number of each level's indicators, the vulnerability of all levels' indicators can be calculated. The urban vulnerability of Sichuan economic zone is shown in Table 2. The larger the number of values in the table, the more serious the degree of vulnerability. As shown in Table 2, the disaster vulnerability of the CDER is the lowest, and the ability of disaster prevention and mitigation is the highest. The vulnerability of the SSER is the highest, whose ability of disaster prevention and reduction is the worst.

Table 1. Vulnerability assessment system and index importance of urban climate change disasters prevention system

The target layer	Criterion layer (Importance)	Index layer (Importance)	Measure (Importance)
Urban vulnerability of climate catastrophe	Capacity of coping A (0.6285)	Primary organization $A1$ (0.4811)	The number of Enterprises $A11$ (0.3190)
			The number of neighborhood committees $A12$ (0.1620)
		Traffic situation $A2$ (0.0873)	Per capita road area $A21$ (0.0579)
			Per capita car number $A22$ (0.0294)
		Awareness of disaster $A3$ (0.0404)	Per capita publicity expenditure $A31$ (0.0263)
			Per capita educational expenditure $A32$ (0.0141)
		Medical condition $A4$ (0.0197)	Per capita number of medical institutions $A41$ (0.0121)
			Per capita number of medical personnel $A42$ (0.0039)
			Per capita number of sickbeds $A43$ (0.0036)
	Sensitivity B (0.2125)	Urban status $B1$ (0.1240)	Drain pipe length $B11$ (0.1237)
			Per capita housing area $B12$ (0.0002)
			Greening rate $B13$ (0.0001)
		The structure of population $B2$ (0.0885)	Population ratio of Higher Education $B21$ (0.0499)
			Ratio of old people $B22$ (0.0223)
			Population density $B23$ (0.0062)
	Resilience C (0.1590)	Self rescue ability $C1$ (0.1304)	Institutional deposit amount $C11$ (0.1299)
			Per Capita disposable income $C12$ (0.0006)
		Social security $C2$ (0.0285)	Coverage rate of unemployment insurance $C21$ (0.0223)
			Coverage rate of medical insurance $C22$ (0.0062)

Table 2. Assessment and sorting of urban disaster vulnerability

Region	$A1$	$A2$	$A3$	$A4$	$B1$	$B2$	$C1$	$C2$	F	Rank
CDER	0.1656	0.4301	0.553	0.5751	0.4656	0.4836	0.3493	0.4725	0.6379	5
NESER	0.1917	0.5166	0.5923	0.6026	0.5081	0.6781	0.442	0.6049	0.6616	4
NWSER	0.5643	0.4379	0.3448	0.5118	0.5209	0.5456	0.6892	0.5062	0.8667	2
PXER	0.3514	0.4093	0.4762	0.5398	0.5687	0.4881	0.509	0.4058	0.7699	3
SSER	0.6636	0.6883	0.5596	0.5888	0.5209	0.5456	0.4379	0.5566	0.897	1

3.3 Evaluation Results and Comparative Analysis

The vulnerability distribution map, which is plotted according to the economic zones' vulnerability indexes, can visually help decision makers get regional vulnerability status and significant factors. Urban planning development and prevention of climate disasters can effectively reduce the city disaster vulnerability level. According to the calculation results of Table 2, our study draws the status of the disaster vulnerability, disaster response, sensitivity and resilience of each economic zone, as shown in Fig. 2.

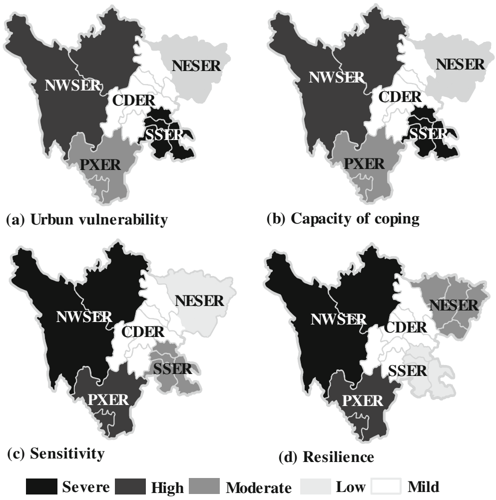

Fig. 2. Urban vulnerability of change-induced disasters

(1) Chengdu Economic Region (CDER)
CDER consists of 8 cities, including Chengdu, Deyang, Mianyang, Leshan, Meishan, Ziyang, Suining and Yaan. As shown in Fig. 1, the total GDP amount and urban built-up areas are more than half of the all urban corresponding indicators, the city's population of which is above one-third of

the total urban population. Therefore, the urban disaster vulnerability of CDER plays an important role in whole Sichuan urban climate disasters prevention systems.

Among all economic zones, the disaster vulnerability, coping ability, vulnerability, sensitivity and vulnerability resilience vulnerability indicators of the CDER all place in the lowliest place. The CDER's overall situation of climate disasters prevention is relatively benign. The value of the vulnerability index $A3$ and $A4$ is higher than other vulnerability indicators of CDER, which means disaster awareness and hospital conditions need to be improved. As the CDER is the core area of the entire Sichuan region, the overall level of medical care and economy is better than other economic regions. In the context of population mobility, the actual population of CDER is much larger than the data of the Yearbook, so the actual vulnerability is more serious than that in Table 2. And to minimize the urban vulnerability of the CDER, appropriate measures must be taken, especially on the disaster awareness and medical conditions. The urban management of CDER should offer much more attention to the floating population, and effectively improve the urban climate disaster vulnerability.

(2) Northeast Sichuan Economic Region (NESER)
The NESER includes 5 cities i.e., Guangyuan, Nanchong, Guangan, Dazhou and Bazhong. As shown in Fig. 2, the rank of the NESER's resilience vulnerability is more serious than that of coping vulnerability and sensitivity vulnerability. Disaster sensitivity of the NESER needs to be promoted, so that more energy should be put into the economic construction and the social security expenditure. Among them, the urban economic development is the most important link.

NESER is located in the northeast of Sichuan, which is an important channel to link Chengdu-Chongqing Economic Zone. NESER has rich mineral resources, especially natural gas reserves. The overall economic development level of ERSER is relatively backward; the communication and cooperation between cities in the region is poor, and at present there are no strong core cities to promote the economic development.

Relying on its geographical advantage and the construction of Chengdu-Chongqing Economic Zone, NESER can build wide-ranging and multi-level pattern of opening to the outside regions. The establishment of regional economic center will give priority to develop the core city, and injects impetus for economic development of the urban. These measures can not only promote the economic development of cities, but also can improve the disaster recovery, reduce the vulnerability of urban disasters, and increase the ability to withstand climate disasters.

(3) Northwest Sichuan Economic Region (NWSER)
NWSER is located in the northwest of Sichuan Province, of which the climate is plateau-climate. And the tourism resources and the natural resources are very rich. As a national autonomous region, the Northwest Economic

Zone covers a larger area than other economic zones. However, its urbanization process is slow. The ratio of the GDP, urban built-up area and urban population is much less than other areas (Fig. 1). As shown in Fig. 2, the sensitivity and vulnerability of the urban economic zone is very serious. The urban situation, the structure of population, self rescue ability and social security is poor.

In the vulnerability system, the population structure consists of higher education ratio, elderly population ratio and population density. And these indicators have a great relationship with local talent attractiveness, and the ratio of the young. In order to reduce the vulnerability, urban management departments need to increase investment in municipal construction, and improve urban facilities. On another hand, effective measures should be taken to make the urban appeal to the highly educated young and adults.

NWSER is an important tourist area in China, and its economy is mainly from agriculture sector. In view of these regional characteristics, the commercial organizations can build or upgrade related tourist facilities (e.g., the road, the gas stations and other infrastructure or public services), and make full use of these resources, so as to retain high-quality personnel and construct the ecological or tourist city.

(4) Pan-Xi Economic Region (PXER)
PXER is composed of Panzhihua and Liangshan. This economic region has a huge potential for economic development. As shown in Fig. 2, the overall urban vulnerability level of PXER is moderate in the five major economic zones. The root reasons of PXER's high vulnerability are similar to the causes of NWSER i.e., the less attractiveness and the shortage of relevant financial expenditure. And relative measures must be based on the improvement of the urban regional economic level.

In the background of that the central government of China strengthens the research of the vanadium and hydropower resources, this economic zone can take full of the mood of the time and transform the mainly strategic shift from the steel to the vanadium titanium new material with its abundant natural resources. To provide funding for municipal construction and enhance the attractiveness, the management of PXER should innovate the development model and increase revenue.

(5) South Sichuan Economic Region (SSER)
SSER is located in the upper reaches of the upper reaches of the Yangtze River, adjacent to Yunnan-Guizhou Plateau. The economic region is an important transportation hub, and has always been the most important materials trading center.

As shown in Fig. 2, the coping capacity vulnerability of SSER is the most serious among all economic zones, and need to be paid much more effort. The urban disaster response consists of grass-roots organizations, traffic conditions, disaster awareness and medical conditions, in which the importance of grass-roots organizations is higher than other indicators. In this assessment system, the primary organization is composed of enterprises and community committees. According to the data of Table 2, we can know that in order to reduce the urban vulnerability, the number of enterprises needs to be increased.

Although SSRS has a comprehensive transportation system, the level of development integration is low. And the overall advantages of this economic region can't be fully utilized in the long term. In addition, the transformation pace of the old industrial base is very slow.

By actively exploring new model of integration development, SSRS can slow the disaster vulnerability. The process of urban integration can be promoted by establishing the development fund of Southern Sichuan urban group. SSRS has a long wine culture. By supporting wine enterprises diversified development, intelligent manufacturing, upgrading of traditional manufacturing machinery and service oriented manufacturing transformation can be accelerated. Meanwhile, effective measures should be taken to develop high growth industry, and accelerate the exploration or development of shale gas. By various ways, enterprises can provide a good environment.

4 Conclusion

As an important part of disaster theory, vulnerability assessment is an important way to estimate the urban coping ability to disasters. To evaluate the urban vulnerability of climate change disasters, our study regards the five economic zones of Sichuan Province as objects and establishes the assessment systems.

Through data analysis and discussion, our study found that the economic zones should take appropriate measures based on its own characteristics to reduce the urban vulnerability. CDER needs to pay more attention to the floating population. By giving priority to the development of core cities, NESER can boost the whole urban economic development and enhance the disaster resilience. NWSER can make full use of its agriculture and tourism advantages, and provide much more support for enterprises engaged in deep processing of agricultural products or developing tourism resources. By the establishment of ecological cities, financial expenditure of NWSER can be guaranteed.

To slow the urban vulnerability, PXER needs to innovate the resource exploitation model, carry out the strategic transformation and increase the fiscal revenue. Relying on its rich history of wine culture, SSER can achieve the diversified development of wine enterprises. In addition, through creating a favorable environment for the development of enterprises, the disaster response capacity can be increased. And SSER can reduce the level of disaster vulnerability.

Abstract. This article puts forward a membership function of the customer satisfaction based on fuzzy random time windows in vehicle routing problems. The objective is to confirm that all the customers are satisfied in an acceptable degree by judging the vehicle arriving time. More specifically, time windows given by customers are taken as fuzzy random variables in this paper. And then, fuzzy random theory has been used to describe customers' time windows. Finally, a measure function has been given to calculate customers' satisfaction based on fuzzy random time windows.

Keywords: Vehicle routing optimization · Customer satisfaction · Time windows · Fuzzy random variable

1 Introduction

Generally, in the classical VRP, there is a set of customers, each of whom have their own demands. Vehicles in the same condition at the depot deliver goods to these customers, and they are required to start and end at the depot. The objective of the classical VRP is to minimize the total cost by designing an optimal delivery route for each vehicle. Nowadays, the VRP is a common problem in almost every industry such as supply chain management and transport planning. With the development of modern technology, customer satisfaction has become a hot issue in the VRP.

In the classical VRP, delivery vehicles usually need to meet the following conditions: (1) Serve all customers using a minimum of vehicles; (2) Each customer is served by only one vehicle once; (3) Each vehicle starts and ends at the depot; (4)Total customer demand on each route cannot exceed the load capacity of the vehicle. There are several VRP variants, such as the multi-depot VRP [1,9], the

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_16

Pickup and Delivery VRP [10], and the VRP with Backhauls [16] and so on. In addition, some problems have pre-set time constraints on the period of the day in which deliveries should take place. These are known as Vehicle Routing Problems with Time Windows (VRPTW) which is a well known variant of the VRP.

The VRPTW is classified into two types, namely a VRP with a hard time window (VRPHTW) in which the time windows are hard constraints and where a route is not feasible if the service for any customer does not start within the limits established by the time window [3], and a VRP with a soft time window (VRPSTW), which is a relaxation of the VRPHTW, where the delivery of goods is allowed outside the time windows if a penalty is paid [4,5,12]. There are many uncertainties in real-life applications where hard time windows can be violated, while the "soft time window" can deal with these situations [13,14]. The travel time on each road section cannot be determined because of many uncertainties, such as traffic incidents, vehicle breakdowns, work zones, special events, and driver skills and experience [6].

In the past, the research used to consider these uncertainties random variables [6,15], but recently, researchers have been increasingly applying fuzzy membership functions to characterize the service level issues associated with time window violation in a vehicle routing problem, called the VRP with fuzzy time windows (VRPFTW) [2,7,14]. This research has highlighted the fact that fuzzy factors and stochastic factors can exist at the same time in the VRPTM. In this paper, we propose to use fuzzy random theory to describe the VRPTW, namely VRPFRTM.

This paper is organized as follows. In Sect. 2, we describe the problem which includes fuzzy random time windows. And then, in Sect. 3, we discuss the methods for dealing with these uncertainties, and propose a procedure to handle fuzzy random time windows. Next, we proposed the membership function of the customer satisfaction based on the fuzzy random time windows in Sect. 4. Finally, some concluding remarks are outlined in Sect. 5.

2 Fuzzy Random Time Windows

The time windows in the traditional VRPTW can be described as follows. Each customer needs to be served in a certain time window, and no delay is permitted. This certain time window can be described as $[e, l]$, where e and l are the earliest and latest time which the customer can accept, respectively. As to vehicle routing problem with soft time windows (VRPSTW), the vehicle can provide service before e and also after l. Some researchers in this field believe that the violation adds some costs and these costs are related to the degree of the violation [14].

Adopting soft time windows often means loss in customer satisfaction. Soft time windows certainly can bring some economic benefits, while dissatisfaction causes customer defection in a long term, which leads to economic loss. It is necessary to maintain the customer satisfaction on a certain level and minimize the cost in the mean time. Some researchers have use fuzzy theory to describe the customer satisfaction level, such as [14]. In their research, it is believed that the customer satisfaction level is related to the start time. If a customer requires that the service should be started in $[e, l]$ in traditional VRP with hard time windows, earlier than e or later than l is unacceptable, and the satisfaction level is 0; otherwise, the customer is satisfied and the satisfaction level is 1. While considering the soft time windows, the service starts earlier than e or later than l is permitted in some extent, but no earlier than EET or later than ELT [14]. Hence, if service starts between e and l, customer satisfaction level is 1; if service starts between EET and e or between l and ELT customer satisfaction level is valued in $[0, 1]$; otherwise, customer satisfaction level is 0. The customer satisfaction level from hard to soft time windows can be seen in Fig. 1.

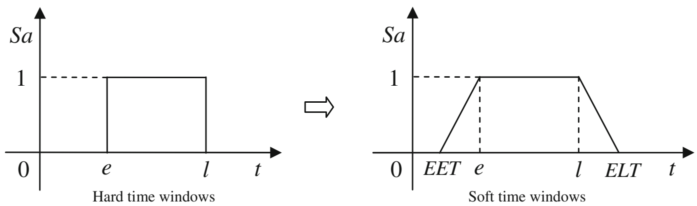

Fig. 1. The customer satisfaction level from hard to soft time windows

From previous studies, it can be seen that the EET and ELT are usually be treated as known and deterministic, while in practice, they can not usually be obtained as deterministic data. There are two common way to get the data, one is reasoning and the other is consulting the client. For reasoning, for example, the concreting in a construction project should be started at 9:00, and the process of unloading the concrete requires 10 min. By reasoning, the ELT is suppose to be 8:50, while actually the acceptable ELT to the project manager may be 8:30. As seen, reasoning often leads to false EET or ELT due to the lack of flexibility. As to consulting the client, deterministic data can not be obtained easily because the client usually gives a response including ambiguous information. The customer may make a statement, such as “not too early” or “no late than 10:00”. After getting these information, the specific data can not be acquired obviously, and if it is dealt as deterministic, the part of information which the customer provides will be lost. In sum, a response often not only includes some fuzzy information but also some random information. In this paper, the vehicle routing problem with fuzzy random time windows (VRPFRTM) is proposed and fuzzy random theory is chosen to describe the fuzzy random time windows. EET and ELT are considered to be fuzzy random, namely $\overline{\widetilde{EET}}$ and $\overline{\widetilde{ELT}}$.

3 Dealing with Fuzzy Random Variables

Uncertainty is absolute and certainty is relative. In practice, the fuzzy random variable has been applied in many areas. However, it is difficult to deal with uncertain variables, especially fuzzy random variables. Based on previous studies about fuzzy random theories, a method to transform a fuzzy random variable into a deterministic one is proposed in this paper. Take fuzzy random variable $\widetilde{\overline{EET}}$ as an example. The procedure of the transform operation can be described as follows:

Step 1. Consider the endurable earliness time of customer, $\widetilde{\overline{EET}}$, is fuzzy random variable. Through previous data and professional experience using statistical methods, estimate the parameters $[m]_L$, $[m]_R$, μ_0 and σ_0^2.

Step 2. Obtain the intermediate parameters by using group decision making approach, namely the decision-makers' degree of optimism. From Puri and Ralescu's definition in [11], a fuzzy random variable is a measurable function from a probability space to a collection of fuzzy variables. Roughly speaking, a fuzzy random variable is a random variable taking fuzzy values. In this paper, the fuzzy random variable $\widetilde{\overline{EET}}$ is denoted as $\widetilde{\overline{EET}} = ([m]_L, \rho(\omega), [m]_R)$, where $\rho(\omega) \sim N(\mu_0, \sigma_0^2)$ whose probability density function is $\varphi_\rho(x)$. Thus the expression of $\varphi_\rho(x)$ should be $\varphi_\rho(x) = \frac{1}{\sqrt{2\pi}\sigma_0 x} e^{-\frac{(x-\mu_0)^2}{2\sigma_0^2}}$. Suppose that σ is a probability level and $\sigma \in [0, \sup \varphi_\rho(x)]$, r is a possibility variable and $r \in [r_l, 1]$ where $r_l = \frac{[m]_R - [m]_L}{[m]_R - [m]_L + \rho_\sigma^R - \rho_\sigma^L}$, both of them reflect the decision-maker's degree of optimism.

Step 3. Let ρ_σ be the σ-cut of the random variable $\rho(\omega)$. According to Xu and Liu's lemma in [17], $\rho_\sigma = [\rho_\sigma^L, \rho_\sigma^R] = \{x \in R | \varphi_\rho(x) \geq \sigma\}$, and the value of ρ_σ^L and ρ_σ^R can be expressed as

$$\rho_\sigma^L = \inf\{x \in R | \varphi_\rho(x) \geq \sigma\} = \inf \varphi_\rho^{-1}(\sigma) = \mu_0 - \sqrt{-2\sigma_0^2 \ln(\sqrt{2\pi}\sigma_0\sigma)},$$

$$\rho_\sigma^R = \sup\{x \in R | \varphi_\rho(x) \geq \sigma\} = \sup \varphi_\rho^{-1}(\sigma) = \mu_0 + \sqrt{-2\sigma_0^2 \ln(\sqrt{2\pi}\sigma_0\sigma)}.$$

Step 4. Transform the fuzzy random variables $\widetilde{\overline{EET}} = ([m]_L, \rho(\omega), [m]_R)$ into the (r, σ)-level trapezoidal fuzzy variable $\widetilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)}$ by the following equation:

$$\widetilde{\overline{EET}} \to \widetilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)} = ([m]_L, \underline{m}, \overline{m}, [m]_R).$$

here, we have

$$\underline{m} = [m]_R - r([m]_R - \rho_\sigma^L) = [m]_R - r([m]_R - \mu_0 + \sqrt{-2\sigma_0^2 \ln(\sqrt{2\pi}\sigma_0\sigma)}),$$

$$\overline{m} = [m]_R - r([m]_L + \rho_\sigma^R) = [m]_L + r(\mu_0 - [m]_L + \sqrt{-2\sigma_0^2 \ln(\sqrt{2\pi}\sigma_0\sigma)}).$$

$\widetilde{\overline{EET}}$ can be specified by $\tilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)} = ([m]_L, \underline{m}, \overline{m}, [m]_R)$ with the membership function:

$$\mu_{\tilde{\omega}_{\widetilde{\overline{EET}}(x)}} = \begin{cases} 0 & \text{for } \; x > [m]_R \\ \frac{[m]_R - x}{[m]_R - \overline{m}} & \text{for } \; \overline{m} \le x \le [m]_R \\ 1 & \text{for } \; \underline{m} \le x \le \overline{m} \\ \frac{x - [m]_L}{\underline{m} - [m]_L} & \text{for } \; [m]_L \le x \le \underline{m} \\ 0 & \text{for } \; x < [m]_L. \end{cases}$$

The process of transforming fuzzy random variable $\widetilde{\overline{EET}}$ to the (r, σ)-level trapezoidal fuzzy variable $\tilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)}$ is illustrated in Fig. 2.

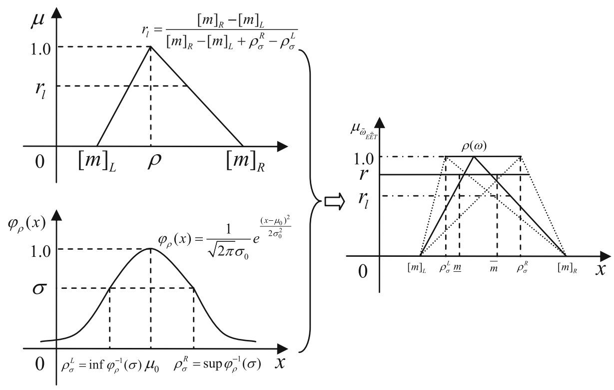

Fig. 2. The process of transforming fuzzy random variable

Step 5. Take expected value operator to convert (r, σ)-level trapezoidal fuzzy variable into a deterministic one. Based on the definition of fuzzy interval and expected value by Heilpern [8], suppose that there is a fuzzy number $\tilde{N} = (a, b, c, d)$, its membership function is:

$$\mu_{\tilde{N}}(x) = \begin{cases} 0 & \text{for } \; x < a \\ f_{\tilde{N}}(x) & \text{for } \; a \le x \le b \\ 1 & \text{for } \; b \le x \le c \\ g_{\tilde{N}}(x) & \text{for } \; c \le x \le d \\ 0 & \text{for } \; x > d. \end{cases}$$

where $f_{\tilde{N}}(x)$ and $g_{\tilde{N}}(x)$ are the upper and lower ends of the fuzzy number respectively. Then, the expected value of fuzzy variables $\tilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)}$ is as follows:

$$EV[\tilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)}] = \frac{1}{2}[(\underline{m} - \int_{[m]_L}^{\underline{m}} f_{\tilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)}}(x)dx) + (\overline{m} + \int_{\overline{m}}^{[m]_R} g_{\tilde{\omega}_{\widetilde{\overline{EET}}(r,\sigma)}}(x)dx)].$$

Based on the what has been discussed above, the fuzzy random time windows can be achieved, see Fig. 3.

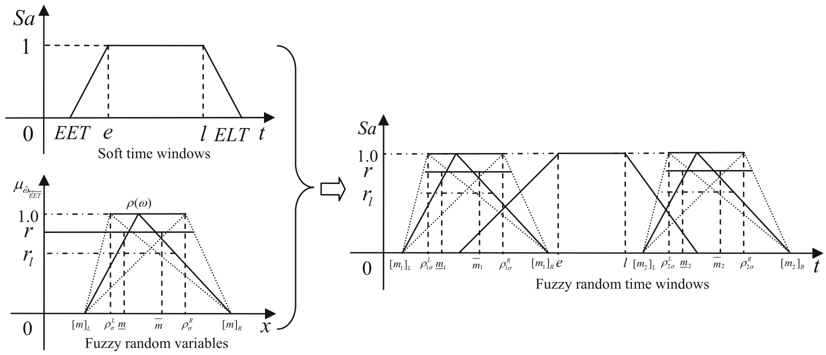

Fig. 3. The customer satisfaction level from soft to fuzzy random time windows

4 Customer Satisfaction by Fuzzy Random Time Windows

Finally, it comes how to define the customer satisfaction based on the fuzzy random time windows. In this paper, we suppose that there exists a least average customer satisfaction level Sa which is accepted by the customers [14].

$$\frac{1}{n}\sum_{i=1}^{n} L_i(t_i) \geq Sa, \tag{1}$$

where n is the number of customers. $L_i(t_i)$ is the satisfaction level serving customer i. Sa is the least average customer satisfaction level. The membership function of the satisfaction level, $L_i(t_i)$, is as below [14]:

$$L_i(t_i) = \begin{cases} 0, & t_i < \overline{\widetilde{EET}}_i, \\ \frac{t_i - \overline{\widetilde{EET}}_i}{e_i - \overline{\widetilde{EET}}_i}, & \overline{\widetilde{EET}}_i \leq t_i < e_i, \\ 1, & e \leq t_i < t, \\ \frac{\overline{\widetilde{ELT}}_i - t_i}{\overline{\widetilde{ELT}}_i - l_i}, & l_i \leq t_i < \overline{\widetilde{ELT}}_i, \\ 0, & t_i \geq \overline{\widetilde{ELT}}_i. \end{cases}$$

As discussed above, the service may start outside the time window $[e, l]$, and the bounds of acceptable earliness and lateness are described by $\overline{\widetilde{EET}}$ and $\overline{\widetilde{ELT}}$, respectively. Obviously, the earliness and lateness are closely related to the quality of service of the supplier. The response of a customer satisfaction level to a given service time may not be simply "good" or "bad"; instead, it may be between "good" and "bad". For example, the customer might say, "it's all right" to be served within $[\widetilde{EET}, e]$ or $[l, \widetilde{ELT}]$. In either case, the service level cannot be described by only two states (0 or 1).

5 Conclusion

In this paper, we focus on a special type of the VRPTW, the vehicle routing problem with fuzzy random time windows and multiple decision makers (VRPFRTW-MDM) which is seldom considered before. We present a membership function of the customer satisfaction based on fuzzy random time windows in vehicle routing problems. Since customer satisfaction is becoming more and more important for suppliers, the objective of this paper is to confirm that all the customers are satisfied in an acceptable degree by judging the vehicle arriving time. We also proposed a method to deal with the fuzzy random time windows based on the fuzzy random theory. In the end, we have given a measure function on how to obtain the customers' satisfaction based on fuzzy random time windows.

Abstract. In an intelligent manufacturing environment, process planning and scheduling (PPS) plays a very important role as a most complex and practical scheduling problem, which processes a set of prismatic parts into completed products by determining the optimal process plans and moments to execute each operation with competitive manufacturing resources. Many research works use multiobjective evolutionary algorithm (MOEA) to solve PPS problems with consideration of multiple complicated objectives to be optimized. This paper proposes a hybrid multiobjective evolutionary algorithm with differential evolution (HMOEA-DE) to solve the PPS problem. HMOEA-DE uses a special designed fitness function to evaluate the dominated and nondominated individuals and divides the population and elitism into two parts, which close to the center and edge areas of Pareto frontier. Moreover, differential evolution applied on elitism tries to improve the convergence and distribution performances much more by guiding the search directions through different individuals with different fitness function. Numerical comparisons indicate that the efficacy of HMOEA-DE outperforms the traditional HMOEA without DE in convergence and distribution performances.

1 Introduction

In an intelligent manufacturing system, a set of prismatic parts need to be processed into a products effectively and economically according to various resources constraints. The parts have operations with different features, which to be related with the machines, tools and tool access directions (TADs). Moreover, the precedence relationship constraints among operations must be satisfied with the technological and the geometrical considerations. Process planning

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_17

generates the optimal process plans, i.e. optimizes the operations (machine, tool, tool access direction) and their sequences. The scheduling assignments the most appropriate moment to execute each operation with competitive resources. The process planning and scheduling (PPS) optimizes of the optimal process plan and schedule simultaneously within the precedence relationship constraints and manufacturing resources. However, it is very difficult to efficiently find an optimal solutions from all of the combinations of all of the operations, manufacturing resources satisfying one and more specified objectives.

Since the complex and multi-resource constraints as well as multi-objective requirements of PPS problem, many researchers have addressed the evolutionary algorithms (EAs) method to deal with it while satisfying the single and multiple objectives [3,10,11,17,19]. Especially, multi-objective evolutionary algorithms (MOEAs) are well suitable for solving multi-objective optimizations (MOPs) [6,18]. In MOEAs, Vector evaluated genetic algorithm (VEGA) divides the population into several sub-populations according to the number of objectives, each of which evolves toward a single objective [14]. As two classical MOEAs, NSGA-II [5] and SPEA2 [20] have been proven to get better convergence and distribution performances in solving MOPs. NSGA-II uses the Pareto ranking and crowding distance mechanism to obtain better performances. SPEA2 proposes raw fitness assignment mechanism and density mechanism to guarantee the convergence and distribution performances. For solving the multi-objective PPS problem, Zhang et al., propose a hybrid sampling strategy-based multi-objective evolutionary algorithm (HSS-MOEA), which combines the sampling strategy of VEGA and the sampling strategy based on a new Pareto dominating and dominated relationship-based fitness function (PDDR-FF) [19]. The hybrid sampling strategies preserve both the convergence and the distribution performance while reduce the computational time.

As a real-parameter optimization method, Differential Evolution (DE) [16] has been also treated as a population-based approach, in which mutation and crossover are the variation operators used to generate new solutions. In DE, the mutation operator has been executed based on the differences of individuals to guide the search direction in the current population and the replacement mechanism uses to maintain the population. The effectiveness but simplicity of DE has attracted many research interests in single objective and multi-objective optimization [1,2,4,7–9,12,13,15]. Especially, Iorio and Li [8] proposed three DE variants incorporating the directional information to improve the optimization performance. The direction information among different individuals with same or different rank as well as different crowding distances could guide the search converge towards the Pareto frontier and/or prefers along the Pareto frontier to improve the convergence and distribution performances. Iorio and Li [8] provided an interesting topic to combine the DE with other MOEAs to improve the performance more especially for most complicated PPS problem, since only applies the DE on PPS problem could increase the computation time for practical optimization problem.

This paper proposes a hybrid multi-objective evolutionary algorithm with differential evolution (HMOEA-DE) to solve the multi-objective PPS problem that combines the DE with HSS-MOEA. The HSS-MOEA could generate the new individuals with traditional crossover and mutation operators, and update the elitism with special fitness function and strategy. The DE could enhance the performance on elitist population after applying the HSS-MOEA.

The paper is organized as follows: Sect. 2 presents the PPS problem and formulates the mathematical model; Sect. 3 describes the detailed HMOEA-DE approach; Sect. 4 gives a discussion and analysis of numerical experiments results; finally, the conclusion are drawn in Sect. 5.

2 Process Planning and Scheduling Problem

In PPS, there are many parts to be processed by a number of available machines with different tools and different TADs. Each part has several operations, and each operation can be processed on machines with different processing times. The PPS problem finally generates a proper process plan and schedule, which tells decision maker how, when and in which sequence to allocate suitable manufacturing resources to operations effectively.

The operation sequence of PPS should be decided firstly, then, the manufacturing resources should be assigned to each operation in operation sequence. After generating the process plan, the PPS determine the most appropriate moment to process each operation with competitive resources. The precedence relationship and resource constraints must be satisfied in deciding the process plan and schedule. Moreover, the process plan and schedule should also satisfy the multiple objectives requirements to maintain the feasibility.

Two important and frequently-used objectives are minimizing makespan and variation of workload for each machine.

The mathematical model of the problem is expressed in the following notations.
Indices:

i, k: indices of part, $(i, k = 1, 2, \cdots, I)$.
j, h: indices of operation for part, $(j, h = 1, 2, ..., J_i)$.
m: index of machine, $(m = 1, 2, \cdots, M)$;
l: index of tool, $(l = 1, 2, \cdots, L)$.
d: index of TAD, $(d = 1, 2, \cdots, D)$.

Parameters:

I: number of parts;
J_i: number of operations for part i;
M: number of machines;
L: number of tools;
D: number of TADs;
O: set of operations for part i, $O_i = \{o_{ij} | j = 1, 2, \cdots, J_i\}$;

o_{ij}: the j$^{\text{th}}$ operation of part;
m_m: the m$^{\text{th}}$ machine;
t_l: the l$^{\text{th}}$ tool;
a_d: the d$^{\text{th}}$ TAD;
M_{ij}: set of machines that can process o_{ij};
A_m: set of operations that can be processed on machine m;
S: operation sequence. $S = (s_1, s_2, \cdots, s_w, \cdots, s_W), s_w = o_{ij}, W = \sum_{i=1}^{I} J_i$;
r_{ijh}: precedence constraints. If o_{ij} is predecessor of o_{ih}, $r_{ijh} = 1$; otherwise, 0;
t_{mij}^{M}: machining time of $o^i j$ by machine m;
t^{MCI}: machine change time index. It is the same for each machine change.
t_{mij}^{MC}: machine change time of o_{ij} by machine m. A machine change is described in article by Zhang et al. [19]. Once machine change is occurred, $t_{mij}^{\text{MC}} = t^{\text{MCI}}$; otherwise, $t_{mij}^{\text{MC}} = 0$;
t^{TCI}: tool change time index. It is the same for each tool change;
t_{mij}^{TC}: tool change time of o_{ij} by machine m. A tool change is described in article by Zhang et al. [19] If tool change is occurred, $t_{mij}^{\text{TC}} = t^{\text{TCI}}$; otherwise, $t_{mij}^{\text{TC}} = 0$;
t^{SCI}: set-up change time index. It is the same for each set-up change;
t_{mij}^{SC}: set-up change time of o_{ij} by machine m. A set-up change is described in article by Zhang et al. [19] If set-up change is occurred, $t_{mij}^{\text{SC}} = t^{\text{SCI}}$; otherwise, $t_{mij}^{\text{SC}} = 0$;
t_{mij}^{PRE}: preparation time of operation o_{ij} by machine m. The preparation time for an operation consists of machine change time, tool change time and set-up time for the operation;
t_{mij}^{P}: processing time of operation o_{ij} by machine m.

$$t_{mij}^{\text{PRE}} = t_{mij}^{\text{MC}} + t_{mij}^{\text{TC}} + t_{mij}^{\text{SC}} \tag{1}$$

The processing time for an operation consists of the preparation time and the machining time for the operation.

$$t_{mij}^{\text{P}} = t_{mij}^{\text{PRE}} + t_{mij}^{\text{M}}, \tag{2}$$

where u_m is workload of machine m.

$$u_m = \sum\nolimits_{i=1}^{I} \sum\nolimits_{j=1}^{J_i} t_{mij}^{\text{M}} x_{mij}^{\text{M}}, \tag{3}$$

where $\bar{u}$: average workload of machine.

$$\bar{u} = {}^1\!/_M \sum\nolimits_{m=1}^{M} u_m, \tag{4}$$

where t_{mij}^{C}: completion time of $o_i j$ by machine m, it should satisfy the inequality $t_{m'i(j-1)}^{\text{C}} + t_{mij}^{\text{P}} \leq t_{mij}^{\text{C}}$ that means for every operation, its direct predecessor's completion time plus its processing time might be smaller that its completion time.

Decision variables:

$x_{mij}^{M} = \begin{cases} 1, \text{ if } o_{ij} \text{ is performed by machine} m, \\ 0, \text{ otherwise;} \end{cases}$

$x_{lij}^{T} = \begin{cases} 1, \text{ if } o_{ij} \text{ is performed by tool } l, \\ 0, \text{ otherwise;} \end{cases}$

$x_{dij}^{D} = \begin{cases} 1, \text{ if } o_{ij} \text{ is performed by TAD } d, \\ 0, \text{ otherwise;} \end{cases}$

$y_{ijkh} = \begin{cases} 1, \text{ if } o_{ij} \text{ is performed directly before } o_{kh}, \\ 0, \text{ otherwise;} \end{cases}$

$\Omega\left(X, Y\right) = \begin{cases} 1, \text{ if } X \neq Y, \\ 0, \text{ otherwise.} \end{cases}$

The mathematical model can be formulated as the following bi-criteria nonlinear mixed integer programming (NMIP) model:

$$\min \ t_M = \max_{m,i,j}\{t_{mij}^{C}\} \tag{5}$$

$$\min \ w_P = \sqrt{1/M \sum\nolimits_{m=1}^{M} \left(u_m - \bar{u}\right)^2} \tag{6}$$

$$\text{s. t.} \ \left(t_{mkh}^{\mathrm{C}} - t_{mkh}^{\mathrm{P}} - t_{mij}^{\mathrm{C}}\right) x_{mij}^{M} x_{mkh}^{M} y_{ijkh} \geq 0, \ \forall\left(i,j\right),\left(k,h\right),m \tag{7}$$

$$r_{ijh} y_{ihij} = 0, \ \forall(i,j), h \tag{8}$$

$$y_{ijij} = 0, \ \forall(i,j) \tag{9}$$

$$\sum\nolimits_{m=1}^{M} x_{mij}^{M} = 1, \ \forall(i,j) \tag{10}$$

$$x_{mij}^{M} = 0, \ \forall\left(i,j\right) \notin A_m, \forall m \tag{11}$$

$$y_{ijkh} \in \{0,1\}, \ \forall\left(i,j\right),\left(k,h\right) \tag{12}$$

$$x_{mij}^{M} \in \{0,1\}, \ \forall m, \left(i,j\right) \tag{13}$$

$$t_{mij}^{\mathrm{C}} \geq 0, \ \forall m, \left(i,j\right). \tag{14}$$

Equation illustrates the minimization of makespan. Makespan is the maximization of completion time among all the operations. Minimization of workload variance is defined as Equation. Workload variance is defined as standard deviation of workload of all the machines. The equations to impose the precedence relationship constraints, resource constraints and nonnegative condition.

3 Hybrid Multi-Objective Evolutionary Algorithm with Differential Evolution

The solution procedure of HMOEA-DE includes 5 phases.

Phase 1: Selection of Better Individuals with Objective Values

The sampling strategy of VEGA is used to select the better individuals from population $P(t)$ into part of mating pool (sub populations) according to their objectives value.

Phase 2: Generation of Mating Pool with Hybrid Sampling

The sub populations and elitist population $A(t)$ are combined to form a mating pool. In the mating pool, sub-pop-1 saves the good individuals for one objective, and sub-population 2 stores the good individuals for the other objective. The elitist population (archive) holds the individuals with good PDDR-FF values. Therefore, one-third of the individuals serve one objective, one-third the other objective, and the left one-third both the two objectives in the mating pool.

Phase 3: Reproduction with Traditional Crossover and Mutation Operators

Problem-dependent crossover and mutation operators are used to reproduce new individuals to form new population P(t+1). Moreover, a local search mechanism is proposed to improve the quality of individuals after the reproduction process. The details of reproduction and local search is described in article by Zhang et al. [19].

Phase 4: Archive Maintenance by PDDR-FF based Elitist Sampling Strategy

The individuals in $A(t)$ and $P(t)$ are combined to form a temporary archive $A'(t)$. Thereafter, the PDDR-FF values of all individuals in $A'(t)$ are calculated and sorted. If the individual is nondominated one, its fitness value will not exceed one. The fitness value of dominated individual will exceed one. Moreover, even the all nondominated individuals have also different PDDR-FF values. The nondominated individuals will be smaller values (near to 0) than the edge points (near to 1). After calculating the fitness function value, the smallest $|A(t)|$ individuals in $A'(t)$ are copied to form $A'(t+1)$.

Phase 5: Archive Enhancement by Combining DE

In this paper, the DE operators such as mutation, crossover and selection operators only apply on the temporary archive A'(t+1), which like a local search process to improve the performance of archive. After DE operator, the obtained solution set (temporary archive) $A''(t+1)$ and $A'(t+1)$ are combined to generate the last $A(t+1)$ according to the PDDR-FF values.

The DE/current/2 is used to generate new mutants and each individuals x_i in $A'(t+1)$ and three individuals r_1, r_2, r_3 are randomly picked up to do reproduction operators according to the following mutation operator.

$$\mathbf{v}_i = \mathbf{x}_i + K(\mathbf{r}_3 - \mathbf{x}_i) + F(\mathbf{r}_1 - \mathbf{r}_2), \qquad (15)$$

where $x_i \neq r_1 \neq r_2 \neq r_3$, eval($r_1$)< eval($r_2$) and eval($r_3$)<eval($x_i$), K and F are scale factors and $0 \leq K,\ F \leq 1$. eval(x_i) means the fitness function value of x_i. It is important to note that in PDDR-FF, the smaller value mean better and the fitness function of nondominated individual will not exceed one. The fitness value of dominated individual will exceed one. Moreover, the nondominated individuals locating around the central region of Pareto frontier have smaller values (near to 0) than the edge points (near to 1).

The mutation operator of DE will improve the performances as follows schemes according to the different fitness function of current and three random individuals.

Scheme 1: the current individual x_i is nondominated solution (eval(s_i) ≤ 1).

(1) If the eval(r_1) ≤ 1 and eval(r_2) ≤ 1, r_1, r_2 are nondominated solutions. This mutation means the search direction starts from the nondominated solution (x_i) and firstly follows the direction from edge region to center region(x_i locates in edge region and r_3 locates in center region) along the Pareto frontier, next, the search direction will guide from edge region to center region (r_2 locates in edge region and r_1 locates in center region) again. It will improve the distribution performance.
(2) If the eval(r_1) > 1 and eval(r_2) > 1, r_1, r_2 are dominated solutions. The search direction starts from the nondominated solution (x_i) and firstly follows the direction from edge region to center region(x_i locates in edge region and r_3 locates in center region) along the Pareto frontier, next, the search direction will guide from edge region to center region (r_2 locates in edge region and r_1 locates in center region) again. It will improve the distribution performance.
(3) If the eval(r_1) ≤ 1 and eval(r_2) > 1, r_1 is nondominated solutions and r_2 is dominated solutions. The search direction starts from the nondominated solution (x_i) and firstly follows the direction from edge region to center region(x_i locates in edge region and r_3 locates in center region) along the Pareto frontier to improve the distribution performance, next, the search direction will guide from dominated region to nondominated region (r_2 locates in the dominated region and r_1 locates in the nondominated region) towards the Pareto frontier to improve the convergence performance.

Scheme 2: the current individual x_i is dominated solution (eval(s_i) > 1) and r_3 is nondominated solution (eval(r_3) < 1).

(1) If the eval(r_1) ≤ 1 and eval(r_2) ≤ 1, r_1, r_2 are nondominated solutions. This mutation means the search direction starts from the dominated solution (x_i) and firstly follows the direction from dominated region to nondominated region (x_i locates in the dominated region and r_3 locates in the nondominated region) along the Pareto frontier to improve the convergence performance, next, the search direction will guide from edge region to center region (r_2 locates in edge region and r_1 locates in center region) to improve the distribution performance.
(2) If the eval(r_1) > 1 and eval(r_2) > 1, r_1, r_2 are dominated solutions. The search direction starts from the dominated solution (x_i) and firstly follows the direction from dominated region to nondominated region (x_i locates in the dominated region and r_3 locates in the nondominated region) along the Pareto frontier to improve the convergence performance, next, the search direction will guide from edge region to center region (r_2 locates in edge region and r_1 locates in center region) to improve the distribution performance.
(3) If the eval(r_1) ≤ 1 and eval(r_2) > 1, r_1 is nondominated solutions and r_2 is dominated solutions. The search direction starts from the dominated solution (x_i) and firstly follows the direction from dominated region to nondominated region (x_i locates in the dominated region and r_3 locates in the

nondominated region) along the Pareto frontier to improve the convergence performance, next, the search direction will guide from dominated region to nondominated region (r_2 locates in the dominated region and r_1 locates in the nondominated region) towards the Pareto frontier to improve the convergence performance more.

Scheme 3: the current individual x_i is dominated solution ($\text{eval}(s_i) > 1$) and r_3 also is dominated solution ($\text{eval}(r_3) > 1$).

(1) If the $\text{eval}(r_1) \leq 1$ and $\text{eval}(r_2) \leq 1$, r_2 are nondominated solutions. This mutation means the search direction starts from the dominated solution (x_i) and firstly follows the direction from edge region to center region(x_i locates in edge region and r_3 locates in center region) along the Pareto frontier, next, the search direction will guide from edge region to center region (r_2 locates in edge region and r_1 locates in center region) again. It will improve the distribution performance.
(2) If the $\text{eval}(r_1) > 1$ and $\text{eval}(r_2) > 1$, r_1, r_2 are dominated solutions. The search direction starts from the dominated solution (x_i) and firstly follows the direction from edge region to center region(x_i locates in edge region and r_3 locates in center region) along the Pareto frontier, next, the search direction will guide from edge region to center region (r_2 locates in edge region and r_1 locates in center region) again. It will improve the distribution performance.
(3) If the $\text{eval}(r_1) \leq 1$ and $\text{eval}(r_2) > 1$, r_1 is nondominated solutions and r_2 is dominated solutions. The search direction starts from the dominated solution (x_i) and firstly follows the direction from edge region to center region(x_i locates in edge region and r_3 locates in center region) along the Pareto frontier to improve the distribution performance, next, the search direction will guide from dominated region to nondominated region (r_2 locates in the dominated region and r_1 locates in the nondominated region) towards the Pareto frontier to improve the convergence performance.

From above analysis, the HSS-MOEA could improve the convergence and distribution performance, the combination of HMOEA and DE could much improve the performances more.

4 Experiments and Discussion

In this paper, 4 parts (each part having 20, 16, 14 and 7 operations, respectively) problem are used. All the simulations are run on Core i5 processor (2.6 GHz clock). The adopted parameters are listed as follows: population size = 100; maximum generation = 500; archive size = 50; crossover probability = 0.70; mutation probability = 0.30 and the scale factor K and F are assigned randomly within 0 to 1. HMOEA-DE and HSS-MOEA are run 30 times to compare the results.

Let S_j be a solution set for each method ($j = 1, 2$). PF^* is a known reference Pareto set which comes from combining all of the obtained Pareto set by

2 methods with 30 runs. In this study, Coverage $C(S_1, S_2)$, Average distance $AD(S_j)$, Hyper volume $HV(S_j)$ and Spacing $SP(S_j)$ are selected to compare the performances of algorithms.

Figure 1 shows the numerical comparison of the box-and-whisker plots for C, AD, HV, and SP by HMOEA-DE, and HSS-MOEA. From Fig. 1, it is easy to see that the HMOEA-DE is better than HSS-MOEA in terms of C measure. The AD measure also indicates that HMOEA-DE can get smaller value than HSS-MOEA. For HV measure, HMOEA-DE is better than HSS-MOEA. The distribution performances, SP, indicates that HMOEA-DE is better than HSS-MOEA. The PDDR-FF could give different values among nondominated and dominated solution in elitism, and the combination of DE for individuals in elitism could significantly improve the convergence and distribution performances.

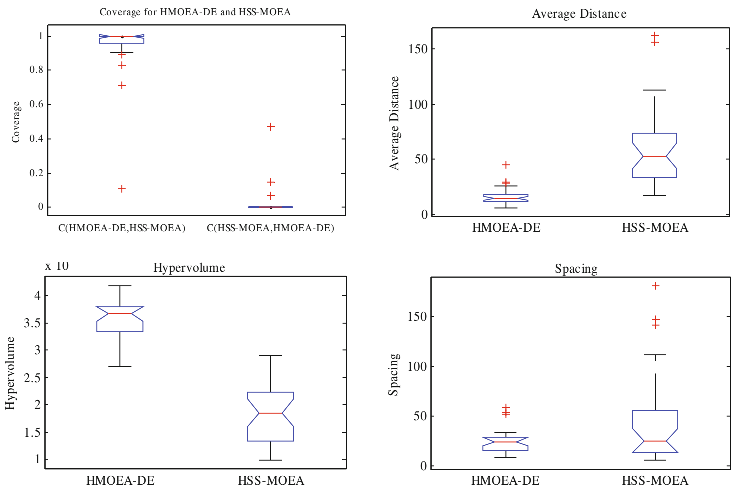

Fig. 1. C, AD, HV, and SP by HMOEA-DE, and HSS-MOEA

5 Conclusions

In this study, a HMOEA-DE approach was proposed to solve the multi-objective PPS problem with consideration of minimization of makespan and minimization of variation of machine workload simultaneously. The VEGA take a preference for the edge region of the Pareto front and the PDDR-FF-based elitism maintain mechanism has the tendency converging toward the center area of the Pareto front. Moreover, the hybrid DE operators for the elitism has the capabilities of improving the convergence and distribution performance much more. Numerical comparisons result demonstrated that HMOEA-DE outperformed the HSS-MOEA on convergence and distribution performance.

Abstract. In the present paper we introduce a numerical technique for solving fractional optimal control problems (FOCP) based on an orthonormal wavelet. First we approximate the involved functions by Sine-Cosine wavelet basis; then, an operational matrix is used to transfer the given problem in to a linear system of algebraic equations. In fact operational matrix of the Riemann-Liouville fractional integration and derivative of Sine-Cosine wavelet are employed to achieve a linear algebraic equation, in place of the dynamical system in terms of the unknown coefficients. The solution of this system, gives us the solution of original problem. A numerical example is also given.

Keywords: Fractional optimal control problem · Sine-Cosine wavelet · Operational matrix · Caputo derivative · Riemann-Liouville fractional integration

1 Introduction

Many application of the fractional calculus is in basic sciences and engineering. Many realistic model of physical [8] phenomenon which has dependence at both the time instance and on the previous time history, can be utter with fractional calculus. For example it can be applied in nonlinear oscillations of earthquakes, fluid-dynamic traffic [9], frequency dependent damping behavior of various viscoelastic materials [2], solid mechanics [18], economics [3], signal processing [17], and control theory [4].

One of the main difficulties is how to solve the fractional differential equations. The most commonly techniques proposed to solve them are Adomian decomposition method (ADM) [22], Variational Iteration Method (VIM) [20], Operational Matrix Method [19], Homotopy Analysis Method [6,7], Fractional Difference Method (FDM) [15] and Power Series Method [16].

A fractional optimal control problem is an optimal control problem in which the performance index or the differential equations governing the dynamic of the

system or both contains at least one fractional order derivative term [25]. Integer order optimal controls have already been well established and a significant amount of works have been done in the field of optimal control of integer order systems. Agrawal formulated and developed a numerical scheme for the solution of FOCP [1] in the Caputo sense. Biswas proposed a pseudo-state space representation of a fractional dynamical system, which is exploited to solve a fractional optimal control problem using a direct numerical method [21]. Sweilam et al. solved some types of fractional optimal control problem with a Hamiltonian formula using a spectral method based on Chebyshev polynomials [24]. Bernstein polynomials have been used for finding the numerical solution of FOCP by using Lagrange multipliers [10].

Approximation by orthogonal families of basis functions is widely used in science and engineering. The main idea behind applying an orthogonal basis is reduction of the problem under consideration into a system of algebraic equations. This is possible by truncating series of orthogonal basis functions for the solution of the problem and applying operational matrices. The orthogonal functions are classified into three main category [23]: the first one is sets of piecewise constant orthogonal functions such as the Walsh functions and block pulse functions. The second one is orthogonal polynomials such as the Laguerre, Legendre and Chebyshev functions, and the last one is sine-cosine functions. In one hand approximating a continuous function with piecewise constant basis functions results in a piecewise constant approximation, on the other hand, if a discontinuous function is approximated with continuous basis functions, the resulting approximation is continuous which cannot properly model the discontinuities. So, neither continuous basis functions nor piecewise constant basis functions, if used alone, can efficiently model both continuity and discontinuity of phenomena at the same time. In the case that the function under approximation is not analytic, wavelet functions will be more effective.

In this paper, we propose a computational method based on Sine-Cosine wavelet with their fractional integration and derivative operational matrix to solve the FOCP. The main idea is reduction the problem under consideration into a system of algebraic equations. To this end, we expand the fractional derivative of the state variable and the control variable using the Sine-Cosine wavelet with unknown coefficients.

The paper is organized as follows. In first section we will give the definitions of fractional calculus, then express a brief review of block pulse function and the related fractional operational matrices. In Sect. 4, we describe Sine-Cosine wavelets and its application in function approximation. In Sect. 5, operational matrices of fractional integration and derivative for considered wavelet is given. In Sect. 6, the proposed method is described for solving the underlying FOCP. In the last section the proposed method is applied for solving numerical example.

2 Preliminaries of Fractional Calculus

The Riemann-Liouville fractional integration and Caputo differential operator of a function f of order $\alpha \geq 0$ is defined in [13] as:

$$(I^{\alpha}f)(t) = \begin{cases} \frac{1}{\Gamma(\alpha)} \int_0^t (t-\tau)^{\alpha-1} f(\tau)d\tau & \alpha > 0 \\ f(t) & \alpha = 0, \end{cases} \tag{1}$$

$$\begin{aligned} D^{\alpha}f(t) &= \frac{1}{\Gamma(n-\alpha)} \int_0^t (t-\tau)^{n-\alpha-1} f^{(n)}(\tau)d\tau \\ &= I^{n-\alpha}f^{n}(t) \quad n-1 < \alpha \leq n. \end{aligned} \tag{2}$$

3 Review of Block Pulse Functions and the Related Fractional Operational Matrix

In this section first we introduce block pulse function (BPF), then it's operational matrix of fractional integration.

3.1 Definition of BPF

A set of BPFs $B_{m'}(t)$ containing m' component functions in the interval [0, T) is given by

$$B_{m'}(t) \triangleq [b_0(t)b_1(t)\cdots b_i(t)\cdots b_{m'-1}]^T. \tag{3}$$

The ith component of the BPF vector $B_{m'}(t)$ is defined as

$$b_i(t) = \begin{cases} 1 & \frac{iT}{m'} \leq t < \frac{(i+1)T}{m'} \\ 0 & O.W. \end{cases} \quad i = 0, 1, 2, \cdots, m'-1. \tag{4}$$

A square integrable function f can be expanded into a BPF series as

$$f(t) = [c_0c_1\cdots c_i\cdots c_{m'-1}]B_{m'}(t) = C^TB_{m'}(t), \tag{5}$$

$$c_i = \frac{1}{h}\int_{ih}^{(i+1)h} f(t)dt \quad h = \frac{T}{m'}. \tag{6}$$

3.2 Operational Matrix for Fractional Integration of BPF

Suppose that F^{α} be the block pulse operational matrix of fractional integration [12]. It is defined as follows,

$$F_{\alpha} = h^{\alpha}\frac{1}{\Gamma(\alpha+2)}\begin{bmatrix} 1 & \xi_1 & \xi_2 & \cdots & \xi_{m'-1} \\ 0 & 1 & \xi_1 & \cdots & \xi_{m'-2} \\ 0 & 0 & 1 & \cdots & \xi_{m'-3} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \xi_1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \tag{7}$$

$$\xi_k = (k+1)^{\alpha+1} - 2k^{\alpha+1} + (k-1)^{\alpha+1} \quad k = 1, 2, \cdots, m'-1. \tag{8}$$

4 Description of Sine-Cosine Wavelets and Its Application in Function Approximation

4.1 The Sine-Cosine Wavelet

Sine-cosine wavelets $\psi_{n,m}(t)$ are defined as follows [11],

$$\psi_{n,m}(t) = \begin{cases} 2^{\frac{k+1}{2}} f(2^k t - n) & \frac{n}{2^k} \le t \le \frac{n+1}{2^k} \\ 0 & o.w \end{cases} \tag{9}$$

with

$$f_m(t) = \begin{cases} \frac{1}{\sqrt{2}} & m = 0 \\ \cos(2m\pi t) & m = 1, 2, \cdots, l \\ \sin(2(m-l)\pi t) & m = l+1, \cdots, 2l \end{cases} \tag{10}$$

$n = 0, 1, \cdots, 2^k - 1, k = 0, 1, \cdots,$ where l is any positive integer.

4.2 Function Approximation

A function $f(t) \in L^2[0, 1)$ can be approximated as:

$$f(t) = \sum_{n=0}^{2^k-1} \sum_{m=0}^{2l} c_{n,m}\psi_{n,m} = C^T \Psi(t) = \Psi^T(t)C, \tag{11}$$

where $c_{n,m} = \langle f(t), \psi_{n,m}\rangle$ and $\langle ., .\rangle$ denotes the inner product as:

$$c_{n,m} = \int_{-\infty}^{+\infty} f(t)\psi_{n,m}(t)dt. \tag{12}$$

where $\Psi(t)$ represent considered wavelet. C and $\Psi(t)$ are $2^k(2l+1) \times 1$ matrices which are given by:

$$C^T = [c_{00}c_{01} \cdots c_{0,2l}, c_{10}, \cdots, c_{1,2l}, \cdots, c_{2^k-1,0}, \cdots, c_{2^k-1,2l}], \tag{13}$$

$$\Psi^T = [\psi_{00}\psi_{01} \cdots \psi_{0,2l}, \psi_{10}, \cdots, \psi_{1,2l}, \cdots, \psi_{2^k-1,0}, \cdots, \psi_{2^k-1,2l}]. \tag{14}$$

5 Operational Matrix of Fractional Calculus for Sine-Cosine Wavelet

In this section we find the operational matrix of fractional derivative for the considered wavelet using the operational matrix of fractional integration for BPF.

5.1 Express $\Psi(t)$ in Terms of BPF

$\psi_{n,m}(t)$ as a function can be express in terms of blockpulse function

$$\psi_{n,m} \simeq \sum_{i=0}^{m'-1} f_i b_i \quad m' = 2^k(2l+1), \tag{15}$$

$$f_i = m' \int_{\frac{i}{m'}}^{\frac{i+1}{m'}} \psi_{n,m}(x)dx = m' \int_{\frac{i}{m'}}^{\frac{i+1}{m'}} 2^{\frac{k+1}{2}} f_m(2^k x - n)dx. \tag{16}$$

Now we calculate f_i for different value of $i = 0, 1, \cdots, m'-1$

$$\begin{aligned} m = 0, \quad f_i = m' \int_{\frac{i}{m'}}^{\frac{i+1}{m'}} 2^{\frac{k+1}{2}} \times \frac{1}{\sqrt{2}} dx = 2^{\frac{k}{2}} \\ i = n(2l+1), \cdots, (n+1)(2l+1) - 1, \end{aligned} \tag{17}$$

$$\begin{aligned} m = 1, 2, \cdots, l, \quad f_i &= m' \int_{\frac{i}{m'}}^{\frac{i+1}{m'}} 2^{\frac{k+1}{2}} \cos(2m\pi(2^k x - n))dx \\ &= \frac{m'}{2^{\frac{k+1}{2}} m\pi} \left[\psi_{n,m+l}\left(\frac{i+1}{m'}\right) - \psi_{n,m+l}\left(\frac{i}{m'}\right) \right], \end{aligned} \tag{18}$$

$$\begin{aligned} m = l+1, \cdots, 2l, \quad f_i &= m' \int_{\frac{i}{m'}}^{\frac{i+1}{m'}} 2^{\frac{k+1}{2}} \sin(2(m-l)\pi(2^k x - n))dx \\ &= \frac{-m'}{2^{\frac{k+1}{2}}(m-l)\pi} \left[\psi_{n,m-l}\left(\frac{i+1}{m'}\right) - \psi_{n,m-l}(\frac{i}{m'}) \right]. \end{aligned} \tag{19}$$

For $m = 0$ we have

$$\psi_{n,m} = [\underbrace{0, \cdots, 0}_{n(2l+1)}, \underbrace{2^{k/2}, 2^{k/2}, \cdots, 2^{k/2}}_{2l+1}, 0, \cdots, 0] \times B_{m'}. \tag{20}$$

For $m = 1, 2, \cdots, l$

$$\begin{aligned} \psi_{n,m} = &\frac{m'}{2^{\frac{k+1}{2}} m\pi} \Bigg[\underbrace{0, 0, \cdots, 0}_{n(2l+1)}, \psi_{n,m+l}\left(\frac{n(2l+1)+1}{m'}\right) - \psi_{n,m+l}\left(\frac{n(2l+1)}{m'}\right), \\ &\cdots, \psi_{n,m+l}\left(\frac{(n+1)(2l+1)}{m'}\right) - \psi_{n,m+l}\left(\frac{n(2l+1)+2l}{m'}\right), 0, 0, \cdots, 0 \Bigg] \times B_{m'}. \end{aligned} \tag{21}$$

And for $m = l+1, \cdots, 2l$ we get

$$\begin{aligned} \psi_{n,m} = &\frac{-m'}{2^{\frac{k+1}{2}}(m-l)\pi} \Bigg[\underbrace{0, 0, \cdots, 0}_{n(2l+1)}, \psi_{n,m-l}\left(\frac{n(2l+1)+1}{m'}\right) - \psi_{n,m-l}\left(\frac{n(2l+1)}{m'}\right), \\ &\cdots, \psi_{n,m-l}\left(\frac{(n+1)(2l+1)}{m'}\right) - \psi_{n,m-l}\left(\frac{n(2l+1)+2l}{m'}\right), 0, 0, \cdots, 0 \Bigg] \times B_{m'}. \end{aligned} \tag{22}$$

Therefore we have $\Psi(x) = \Phi_{m' \times m'} B_{m'}(x)$ where $\Phi_{m' \times m'} = \text{diag}(\Phi_0, \Phi_1, \cdots, \Phi_{2^k-1})$, Φ_n is defined as follows, in the following matrix, $i = n(2l+1)$

$$\Phi_n = \begin{bmatrix} 2^{\frac{k}{2}} & \cdots\ 2^{\frac{k}{2}} \\ \frac{m'}{2^{\frac{k+1}{2}} 1\pi}(\psi_{n,1+l}\left(\frac{i+1}{m'}\right) - \psi_{n,1+l}(\frac{i}{m'}) & \cdots\ \psi_{n,1+l}(\frac{i+2l+1}{m'}) - \psi_{n,1+l}(\frac{i+2l}{m'})) \\ \vdots & \ddots\ \vdots \\ \frac{m'}{2^{\frac{k+1}{2}} l\pi}(\psi_{n,2l}\left(\frac{i+1}{m'}\right) - \psi_{n,21}\left(\frac{i}{m'}\right) & \cdots\ \psi_{n,2l}(\frac{i+2l+1}{m'}) - \psi_{n,21}(\frac{i+2l}{m'}))) \\ \frac{-m'}{2^{\frac{k+1}{2}} 1\pi}(\psi_{n,1}\left(\frac{i+1}{m'}\right) - \psi_{n,1}(\frac{i}{m'}) & \cdots\ \psi_{n,1}(\frac{i+2l+1}{m'}) - \psi_{n,1}(\frac{i+2l}{m'})) \\ \vdots & \ddots\ \vdots \\ \frac{-m'}{2^{\frac{k+1}{2}} l\pi}(\psi_{n,l}\left(\frac{i+1}{m'}\right) - \psi_{n,l}(\frac{i}{m'}) & \cdots\ \psi_{n,l}(\frac{i+2l+1}{m'}) - \psi_{n,l}(\frac{i+2l}{m'})) \end{bmatrix}. \tag{23}$$

5.2 Operational Matrix of Fractional Integration and Derivative for Sine-Cosine Wavelet

For finding operational matrix of fractional derivative of vector $\Psi(t)$, first of all we try to find the operational matrix of fractional integration.

$$(I^\alpha \Psi)(x) \simeq P^\alpha \Psi(x), \tag{24}$$

where P^α is the operational matrix of fractional integration, which calculate as follows

$$\begin{aligned} I^\alpha \Psi(x) &= I^\alpha \Phi_{m' \times m'} . B_{m'}(x) = \Phi_{m' \times m'} I^\alpha B_{m'}(t) = \Phi_{m' \times m'} F^\alpha B_{m'}(x) && (25) \\ &\Rightarrow P^\alpha \Psi(x) = P^\alpha \Phi_{m' \times m'} B_{m'}(x) = \Phi_{m' \times m'} F^\alpha B_{m'}(x) \\ &\Rightarrow P^\alpha = \Phi_{m' \times m'} F^\alpha \Phi^{-1}_{m' \times m'} \\ &\Rightarrow I^\alpha \Psi(x) \simeq \Phi_{m' \times m'} F^\alpha \Phi^{-1}_{m' \times m'} \Psi(x). && (26) \end{aligned}$$

Now we calculate operational matrix of derivative using P^α

$$D^\alpha f(x) = I^{n-\alpha} f^n(x) n-1 < \alpha \leq n n \in N, \tag{27}$$

$$D^\alpha x(t) = D^\alpha X^T \Psi(t) = X^T D^\alpha \Psi(t) = X^T I^{n-\alpha} \Psi^{(n)}(t). \tag{28}$$

For $\alpha \in$(0,1) we have $n = 1$ thus

$$\begin{aligned} D^\alpha x(t) &\simeq X^T I^{1-\alpha} D \Psi(t) = X^T D I^{1-\alpha} \Psi(t) \\ &= X^T D \Phi_{m' \times m'} F^{1-\alpha} \Phi^{-1}_{m' \times m'} \Psi(t), \end{aligned} \tag{29}$$

where D is operational matrix of derivative for $\Psi(t)$ which defined as $D = \text{diag}(w, w, \cdots, w)$, which is $2^k(2l+1) \times 2^k(2l+1)$ matrix and w is of size $(2l+1) \times (2l+1)$

$$w = 2^{k+1}\pi \begin{bmatrix} 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & -1 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & -2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & -l \\ 0 & 1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 2 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & l & 0 & 0 & \cdots & 0 \end{bmatrix}_{(2l+1)\times(2l+1)} . \tag{30}$$

6 Solution of the Fractional Optimal Control Problem by Sine-Cosine Operational Matrix

Consider the fractional optimal control problem with quadratic performance index

$$\min J = \frac{1}{2}X^T(1)SX(1) + \frac{1}{2}\int_0^1 (X^T(t)QX(t) + U^T(t)RU(t))dt \tag{31}$$

$$\text{s. t.} \quad D^\alpha X(t) = AX(t) + BU(t) \tag{32}$$

$$X(0) = X_0 \quad 0 < \alpha \leq 1, \tag{33}$$

where A and B are constant matrices with the appropriate dimensions, also in cost functional S and Q are symmetric positive semi-definite matrices and R is a symmetric positive definite matrix. In this section, the Sine-Cosine wavelet is used for solving the above problem. We approximate each $x_i(t)$ and $u_i(t)$, in terms of Sine-Cosine wavelets as

$$X(t) = [x_1(t), x_2(t), \cdots, x_s(t)]^T \quad x_i(t) = \Psi^T(t)X_i \text{ or } X_i^T\Psi(t), \tag{34}$$

$$X(t) = \hat{\Psi}_s^T(t)X \quad X = [X_1^T, X_2^T, \cdots, X_s^T] \quad \hat{\Psi}_s(t) = I_s \otimes \Psi(t), \tag{35}$$

$$U(t) = [u_1(t), u_2(t), \cdots, u_q(t)]^T \quad u_i(t) = \Psi^T(t)U_i \text{ or } U_i^T\Psi(t), \tag{36}$$

$$U(t) = \hat{\Psi}_q^T(t)U \quad U = [U_1^T, U_2^T, \cdots, U_q^T] \quad \hat{\Psi}_s(t) = I_s \otimes \Psi(t), \tag{37}$$

where X_i, U_i are vectors of order $2^k(2l+1)\times 1$, X and U are vectors of order $s2^k(2l+1)\times 1$ and $q2^k(2l+1)\times 1$ respectively. $\otimes$ denotes the kronecker product. By substituting the above mentioned relation into objective function

$$J = \frac{1}{2}X^T\hat{\Psi}_s(1)S\hat{\Psi}_s^T(1)X + \frac{1}{2}\int_0^1 [X^T\hat{\Psi}_sQ\hat{\Psi}_s^TX + U^T\hat{\Psi}_qR\hat{\Psi}_q^TU]dt. \tag{38}$$

Since considered wavelet is orthonormal, it means $\int_0^1 \Psi^T(t)\Psi(t)dt = I$, we can rewrite Eq. (38) as follows

$$J(X,U) = \frac{1}{2}X^T[S\otimes\hat{\Psi}(1)\hat{\Psi}^T(1)]X + \frac{1}{2}[X^T(Q\otimes I)X + U^T(R\otimes I)U]. \tag{39}$$

Similarly, we do the same method for Eq. (32)

$$X(t) = X^T I_s \otimes \Psi(t) \text{ or } (I_s \otimes \Psi^T(t))X, \tag{40}$$

$$\begin{aligned} D^\alpha X(t) &= I^{1-\alpha} X'(t) = I^{1-\alpha}(X^T(I_s \otimes \Psi(t)))' = X^T I^{1-\alpha}(I_s \otimes (D\Psi(t)))' \\ &= X^T I_s \otimes (I^{1-\alpha} D\Psi(t)) = X^T I_s \otimes [D I^{1-\alpha}(\Psi(t))] \\ &= X^T I_s \otimes (D\Phi_{m'\times m'} F^\alpha \Phi^{-1}_{m'\times m'} \Psi(x)) \end{aligned} \tag{41}$$

$$\begin{aligned} R(t) &= X^T I_s \otimes (D\Phi_{m'\times m'} F^\alpha \Phi^{-1}_{m'\times m'})\Psi(t) - AX^T I_s \otimes \Psi(t) - BU^T I_q \otimes \Psi(t) R(t) \\ &= [X^T I_s \otimes (D\Phi_{m'\times m'} F^\alpha \Phi^{-1}_{m'\times m'}) - AX^T I_s \otimes I_{2^k(2l+1)} \\ &\quad - BU^T I_q \otimes I_{2^k(2l+1)}] \otimes \Psi(t). \end{aligned} \tag{42}$$

As in a typical tau method [5] we generate $2^k(2l+1)-1$ linear equations by applying

$$\langle R(t), \psi_{n,m}(t)\rangle = \int_0^1 R(t).\psi_{n,m}(t)dt = 0. \tag{43}$$

Also, by substituting Eq. (35) in (33) we get

$$X(0) = X^T \hat{\Psi}(0) = X_0. \tag{44}$$

Equations (43) and (44) generate $2^k(2l+1)$ set of linear equations. These linear equations can be solved for unknown coefficients of the vectors X^T and U^T. Consequently, $X(t)$ and $U(t)$ can be calculated.

7 Illustrative Example

We applied the method presented in this paper and solved the undergoing example.

Example 1. Consider the following time invariant FOCP [14],

$$\begin{aligned} \min J =& \frac{1}{2}\int_0^1 (x^2(t) + u^2(t))dt \\ \text{s. t.}\ \ & D^\alpha x(t) = -x(t) + u(t) \\ & x(0) = 1. \end{aligned}$$

We want to find a control variable $u(t)$ which minimizes the quadratic performance index J. This problem is solved by proposed method with $\alpha = 1, m = 5$ and $n = 7$, the numerical value obtained for J is 0.1979, which is close to the exact solutions in the case $\alpha = 1(0.1929)$.

8 Conclusion

In this paper, we derive a numerical method for fractional optimal control based on the operational matrix for the fractional integration and differentiation. The procedure of constructing these matrices is summarized. An example is given to show the efficiency of method. The obtained matrices can also be used to solve problems such as fractional optimal control with delay. Moreover we could find these matrices using another set of orthogonal functions instead of BPFs, it seems if we use a set of continuous orthogonal function the numerical result will improve.

The Sustainable Interaction Analysis of Cause Marketing and Ethical Consumption in Electric Business Platform: Based on Game Theory and Simulation Analysis

Xu Zu and Weiping Yu(✉)

Business School, Sichuan University, Chengdu 610065, People's Republic of China
331382107@qq.com

Abstract. Based on evolutionary game theory and simulation analysis, the paper studies the sustainable interaction of cause marketing in electronic business platform, which constructs the evolutionary game model of cause marketing and ethical consumption, and studies the existence and stability of the equilibrium in the four situation interaction system, and also verifies results by Netlogo. The main contributions are that ethical consumption is the precondition of sustainable cause marketing development, reducing costs is the key to promote sustainable interaction development, electric business platform should vigorously promote social responsibility consciousness, and promote the policy support. Finally the paper constructs the theory frame for the realization of benign sustainable interaction.

Keywords: Cause marketing · Ethical consumption · The evolutionary game model · Simulated analysis

1 Introduction

In recent years, the development rate of China's e-commerce is 2–3 times of GDP (7% 9%). China's B2C online shopping market deals reached 609.67 billion yuan in the second quarter of 2016. With the rise of e-commerce, the businessman tried to introduce a cause marketing methods to get more customers focus on their homogeneous products, for example, some businesses join the public welfare plan of Taobao platform. Cause marketing dated from the public welfare activity of "Renovation of the statue of liberty" by the cooperation of American Express Company and Alice Island Foundation, and then it obtained the widespread attention and development. Nowadays, more and more traditional corporations have been successfully performed the corporate social responsibility by the form of cause marketing. The cause marketing is not only contributing to society, but also obtaining the business interests [1,8], for example, the cause marketing activity of "buy a bottle of water, donate a penny" improved Nongfu

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_19

spring's product sales, and Nongfu Spring raised more than 5 million yuan, 361° "ONE CARES ONE" also promoted sales of especially-made shoes and expanded brand influence. Cause marketing, also known as charity Marketing or cause-related Marketing, is a special form of donation. It depends on the purchasing behavior of consumers, and donates the amount of a certain percentage of business to the special public welfare project. Cause marketing has become one of the important way of charity enterprises to perform social responsibility in many countries. Cause marketing can promote sales, social responsibility image and brand awareness [9,13]. In E-commerce platform, corporations, which successfully continue to push the cause marketing, not only can achieve the aim of marketing businesses, but also can effectively promote the healthy development of Chinese social and economic. However, focusing on E-commerce situation, businesses joined the cause marketing activities in E-commerce platform, and didn't get a good response of consumers.

From the practice experience of western countries, the benign interaction between the enterprise and the consumer is the key to successfully propel the corporate social responsibility [12]. The concept of ethical consumption is that consumers not only consider the commercial value of product, but also consider the beneficial impact of their purchasing behavior on society, environment, and so on [5], that effectively promote the corporate cause marketing to fulfill the social responsibility better. The sustained interaction of cause marketing and ethical consumption can ensure that businessmen get more consumer approval ratings in order to cover cost and promote sales and corporate image. According to the survey in U.S. market, 78% of consumers are willing to buy products with cause marketing, 66% of consumers willing to switch brands to support cause marketing [3], and 96.6% consumers also incline to choose homogeneous products with good corporate social image [6] in China market. However, consumers are also "rational economic man". Because of the higher perceived risk in the E-commerce platform, consumers are not willing to fulfill the ethical consumption with much cost in order to balance the benefit and the cost [11], so there is often the inconsistent phenomenon about the consumer ethical attitude and behavior.

The relationship researches of cause marketing and ethical consumption mainly focus on two aspects: the first is the relationship of cause marketing and ethical consumption based on the investigation method and experiment method [1,9], the second is the cause of the inconsistent about consumers' ethical attitude and behavior based on the interview and other qualitative methods [2]. However, few scholars' researches focus on the interaction mechanism, especially the research of systemic balance and dynamic evolution in the E-commerce platform. It belongs to a kind of gambling behavior that cause marketing and ethical consumption. This research constructs the evolutionary game model based on evolutionary game theory and systematically explores the evolution rules. The research result not only enriches the existing theory research of cause marketing and ethical consumption, but also provides valuable advice on sustainable promoting the cause marketing and ethical consumption in the E-commerce platform.

2 Evolutionary Game Model Building

Evolutionary game theory emphasizes the dynamic equilibrium. It can real reaction behavior diversity and complexity of the body combined the game theory analysis and the dynamic evolution process analysis [7,10]. Based on evolutionary game theory, this research adopts the method that two kinds of group repeated game and replication dynamic evolutionary game, and puts forward the evolutionary game model to research like the assumptions:

Hypothesis 1: The two types of players are businesses and consumers in the E-commerce platform, and they are the rational "economic individuals". The businesses behavior sets are cause marketing and non cause marketing and the consumers behavior sets are ethical consumption and unethical consumption.

Hypothesis 2: The proportion of businesses with cause marketing is x, and the other is $1 - x$; the proportion of consumers with ethical consumption is y, and the other is $1 - y$.

Hypothesis 3: The product is homogeneous, the product cost for cause marketing is C_1 and product sales price is P_1, The endogenous utility, the brand image and perceived social contribution and so on, and the $E-$ commerce platform support utility are F; the product cost for non cause marketing is C_2 and product sales price is P_2, and C_1 is higher than C_2.

Hypothesis 4: The social responsibility consciousness of consumers is strengthened with the development of society, the ethical consumption not only meets the basic demand for products, but also makes consumers additional utility of social contribution, the utility is V, and K is the additional cost that consumers need to pay higher for ethical consumption than unethical consumption.

Based on the above assumptions, businesses' revenue is as follows:

(1) When businesses adopt cause marketing and consumers adopt ethical consumption, businesses' revenue is $P_1 - C_1 + F$;
(2) When businesses adopt cause marketing and consumers adopt unethical consumption, businesses' revenue is $-C_1 + F$;
(3) When businesses adopt non cause marketing and consumers adopt ethical consumption, businesses' revenue is $-C_2$;
(4) When businesses adopt non cause marketing and consumers adopt unethical consumption, businesses' revenue is $P_2 - C_2$.

Consumers' revenue is as follows:

(1) When consumers adopt ethical consumption and businesses adopt cause marketing, consumers' revenue is $V - K$;
(2) When consumers adopt ethical consumption and businesses adopt non cause marketing, consumers' revenue is $-V$;
(3) When consumers adopt unethical consumption and businesses adopt cause marketing or non cause marketing, consumers' revenue is 0. Payoff matrix for gaming revenue are shown in Table 1.

Table 1. Payoff matrix for gaming revenue about businesses and consumers.

	Type	Consumers	
		Ethical consumption (y)	Unethical consumption $(1-y)$
Businesses	Cause marketing (x)	$P_1 - C_1 + F, V - K$	$-C_1 + F, 0$
	Non cause marketing $(1-x)$	$-C_2, -V$	$P_2 - C_2, 0$

Expected returns of cause marketing and non cause marketing respectively are U_0^1, U_0^2, the average return of businesses is $\overline{U}_0$:

$$U_0^1 = y(P_1 - C_1 + F) + (1-y)(-C_1 + F) = yP_1 - C_1 + F, \tag{1}$$

$$U_0^2 = y(-C_2) + (1-y)(P_2 - C_2) = (1-y)P_2 - C_2, \tag{2}$$

$$\overline{U}_0 = xU_0^1 + (1-x)U_0^2. \tag{3}$$

Expected returns of ethical consumption and unethical consumption respectively are U_1^1, U_1^2, the average return of consumers is $\overline{U}_1$:

$$U_1^1 = x(V-K) + (1-x)(-V) = x(2V-K) - V, \tag{4}$$

$$U_1^2 = x \cdot 0 + (1-x) \cdot 0 = 0, \tag{5}$$

$$\overline{U}_1 = yU_1^1 + (1-y)U_1^2. \tag{6}$$

According to the above expressions, we can know the replicated dynamic equations respectively are:

$$\dot{x} = \frac{dx}{dt} = x(U_0^1 - \overline{U}_0) = x(1-x)\left[y(P_1 + P_2) + F - C_1 - P_2 + C_2\right], \tag{7}$$

$$\dot{y} = \frac{dy}{dt} = y(U_1^1 - \overline{U}_1) = y(1-y)\left[x(2V-K) - V\right]. \tag{8}$$

3 Evolutionary Game Model Analysis

3.1 Equilibrium Point and Stability Analysis

Make $\frac{dx}{dt} = 0$ and $\frac{dy}{dt} = 0$, based on results of replicated dynamic equation of the interaction between the businesses and the consumers, we can get five local equilibrium points: $(0,0)$, $(1,0)$, $(0,1)$, $(1,1)$ and (p^*, q^*), and

$$p^* = \frac{V}{2V-K}, \tag{9}$$

$$q^* = \frac{C_1 - F + P_2 - C_2}{P_1 + P_2}. \tag{10}$$

Friedman proposed that the stability of the equilibrium point of the evolution system can be obtained from the local stability analysis of the jacobian matrix (denoted by J) [4]. The jacobian matrix by the combination of Eqs. (7) and (8):

$$J = \begin{pmatrix} \frac{\partial \dot{x}}{\partial x} & \frac{\partial \dot{x}}{\partial y} \\ \frac{\partial \dot{y}}{\partial x} & \frac{\partial \dot{y}}{\partial y} \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}, \tag{11}$$

and

$$a_{11} = (1 - 2x)\left[y(P_1 + P_2) + F - C_1 - P_2 + C_2\right], \tag{12}$$

$$a_{12} = x(1 - x)(P_1 + P_2), \tag{13}$$

$$a_{21} = y(1 - y)(2V - K), \tag{14}$$

$$a_{22} = (1 - 2y)\left[x(2V - K) - V\right]. \tag{15}$$

Thus, we can get the numerical results about a_{11}, a_{12}, a_{21} and a_{22} under the five local equilibrium points, the results are shown in Table 2.

Table 2. The numerical results about a_{11}, a_{12}, a_{21} and a_{22} under the five local equilibrium points.

Equilibrium point	a_{11}	a_{12}	a_{21}	a_{22}
$(0, 0)$	$F - C_1 - P_2 + C_2$	0	0	$-V$
$(1, 0)$	$-F + C_1 + P_2 - C_2$	0	0	$V - K$
$(0, 1)$	$P_1 + F - C_1 + C_2$	0	0	V
$(1, 1)$	$-P_1 - F + C_1 - C_2$	0	0	$K - V$
(p^*, q^*)	0	A	B	0

And the expressions of A and B respectively are:

$$A = \frac{V}{2V - K}(1 - \frac{V}{2V - K})(P_1 + P_2), \tag{16}$$

$$B = \frac{C_1 - F + P_2 - C_2}{P_1 + P_2}(1 - \frac{C_1 - F + P_2 - C_2}{P_1 + P_2})(2V - K). \tag{17}$$

When the jacobian matrix satisfies the following conditions of the determinant value (denoted by $\det J$) and trace value (denoted by trJ), the local equilibrium of system is the stability and can be the evolutionary stable strategy (denoted by ESS).

Condition 1:

$$\det J = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{12}a_{21} > 0, \tag{18}$$

Condition 2:

$$trJ = a_{11} + a_{22} < 0. \tag{19}$$

Obviously, when the local equilibrium of system is (p^*, q^*), $a_{11} + a_{22} = 0$ do not meet condition 2, so it is not as ESS. The study needs to discuss the possibility that four local equilibrium points become ESS from different situations in the plane of $N = \{x, y\,|0 \le x, y \le 1\}$.

3.2 Result Discussion

Case 1: When $F > C_1 + P_2 - C_2$ and $V > K$, the stability of four local equilibrium points is as the Table 3 shown. We can get the ESS when $(1, 1)$ satisfies the conditions of $\det J > 0$ and $trJ < 0$.

Table 3. The stability analysis of local equilibrium point when $F > C_1 + P_2 - C_2$ and $V > K$.

Equilibrium point	$detJ$	trJ	Stability
$(0, 0)$	$-$	Indeterminacy	Saddle point
$(1, 0)$	$-$	Indeterminacy	Saddle point
$(0, 1)$	$+$	$+$	Instability point
$(1, 1)$	$+$	$-$	ESS

Case 2: When $F < C_1 + P_2 - C_2$ and $V > K$, the stability of four local equilibrium points is as the Table 4 shown, We can get the ESS when (0,0) and (1,1) satisfy the conditions of $\det J > 0$ and $trJ < 0$.

Table 4. The stability analysis of local equilibrium point when $F < C_1 + P_2 - C_2$ and $V > K$.

Equilibrium point	$detJ$	trJ	Stability
$(0, 0)$	$+$	$-$	ESS
$(1, 0)$	$+$	$+$	Instability point
$(0, 1)$	$+$	$+$	Instability point
$(1, 1)$	$+$	$-$	ESS

Case 3: When $F > C_1 + P_2 - C_2$ and $V < K$, the stability of four local equilibrium points is as the Table 5 shown, We can get the ESS when (1, 0) satisfy the conditions of $\det J > 0$ and $trJ < 0$.

Case 4: When $F < C_1 + P_2 - C_2$ and $V < K$, the stability of four local equilibrium points is as the Table 6 shown, We can get the ESS when (1,0) satisfy the conditions of $\det J > 0$ and $trJ < 0$.

4 Netlogo Simulation Modeling and Analysis

The study validates and analyzes the stability of equilibrium points with the aid of Netlogo modeling and simulation in the four situations. Netlogo is developed by the center of connectionist learning and computer modeling in northwestern university. It is based on multi-agent modeling, multi-agent parallel and asynchronous updating, and the whole system is dynamic with time. It can well study the macroscopic patterns of micro-individual interaction, and is especially suitable for modeling and simulating complex systems with time evolution. Based on the analysis of the stability of the equilibrium point in the evolutionary game model, this study sets the payment matrix from four cases and performs simulation verification and analysis. The horizontal axis represents the simulation time and the vertical axis represents the ratio that the number of subjects to the total number of game strategy in the simulation results chart. $X_1 Rate$ and $Y_1 Rate$ respectively are the cause marketing rate and ethical consumption rate, and the initial ratio is 1/2.

Case 1: From the stability analysis result of the replicated dynamic equation, (1,1) is ESS when $F > C_1 + P_2 - C_2$ and $V > K$. The study substitutes $F = 8$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$ and $K = 1$ into the simulation model, and the simulation result is as shown in Fig. 1.

The simulation results validate the deduction of the replicated dynamic equation. The evolution result is an ideal phenomenon that businesses, consumers and electric business platform are involved in social responsibility behavior. Consumers need to pay additional costs, but the additional utility of social contribution is always greater than the additional costs paid, consumers still choose ethical consumption strategy; cause marketing strategy will increase the cost of income, but a strong sense of social responsibility and good support and encouragement of electric business platform will increase the business additional benefits, so businesses still prefer to cause marketing strategy. Responsibility behavior of businesses and consumers will enter a good time of continuous interactive development.

Case 2: From the stability analysis result of the replicated dynamic equation, (1,1) and (0,0) are ESS when $F < C_1 + P_2 - C_2$ and $V > K$. The study respectively substitutes $F = 4$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$ and $K = 1$ and $F = 1$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$ and $K = 0.5$ into the simulation model, and the simulation result is as shown in Figs. 2(a) and 3(a).

The simulation results validate that there are two kinds of behavior patterns in the evolution system, namely [cause marketing, ethical consumption] and [non cause marketing, unethical consumption]. When the benefits from a good corporate brand image and self-perception of social contributions and commercial policy benefits make up for the loss of profits due to cause marketing, businesses will still choose cause marketing. Consumers, compensated for the additional cost, will still choose the ethical consumption strategy, so businesses and consumers are in a benign behavioral interaction process. When the additional benefits of cause marketing can not make up for the loss of profits, the system will quickly move toward a vicious direction: businesses will choose non cause marketing strategy, consumers will choose unethical consumption strategy. Social responsibility awareness of businesses and consumers is low and the system fails to achieve the sustainable social interaction due to lack of awareness and support of electric business platform.

Case 3: From the stability analysis result of the replicated dynamic equation, (1,0) is ESS when $F > C_1 + P_2 - C_2$ and $V < K$. The study substitutes $F = 8$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$ and $K = 4$ into the simulation model, and the simulation result is as shown in Fig. 4.

The simulation results validate that businesses will still keen on cause marketing although they can not sell products when the additional effect is greater than the sum of non cause marketing profits and the cause marketing cost. Consumers, as "economic man", can not pay too much extra expense for ethical consumption, and finally give up ethical consumption. The stability of system is based on policy support of the electric business platform and businesses own economic interests, if the electronic business platform reduce support and the economic benefits can not make up for cause marketing cost, then the system will be rapidly unbalanced.

Case 4: From the stability analysis result of the replicated dynamic equation, (0,0) is ESS when $F < C_1 + P_2 - C_2$ and $V < K$. The study substitutes $F = 1$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$ and $K = 4$ into the simulation model, and the simulation result is as shown in Fig. 5.

The simulation results validate that consumers can not use the extra utility of ethical consumption to make up for the extra cost, so they abandon the ethical consumption, and gradually choose unethical consumption through game learning. Although businesses get a certain income because of cause marketing,

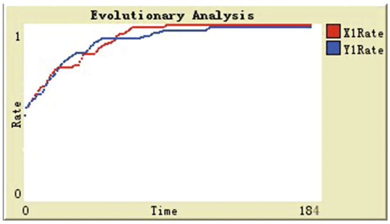

Fig. 1. The simulation result ($F = 8$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$, $K = 1$)

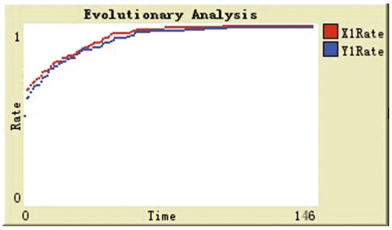

Fig. 2. The simulation result ($F = 4$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$, $K = 1$)

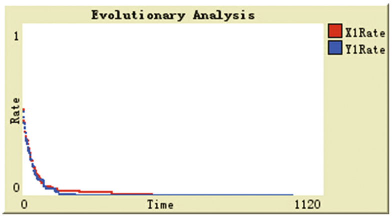

Fig. 3. The simulation result ($F = 1$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$, $K = 0.5$)

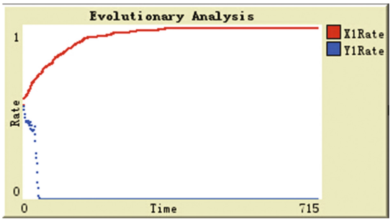

Fig. 4. The simulation result ($F = 8$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$, $K = 4$)

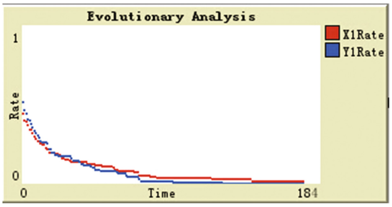

Fig. 5. The simulation result ($F = 1$, $C_1 = 4$, $P_2 = 5$, $C_2 = 2$, $V = 3$, $K = 4$)

businesses finally take non cause marketing strategy in order to sell products for profit without ethical consumption support, so the system will evolve to a vicious direction, and will be rapidly unbalanced.

5 Conclusion and Suggestion

From the perspective of evolutionary game, this paper uses replication dynamic evolutionary game method and Netlogo numerical simulation to analyze the sustainable interaction mechanism between cause marketing and ethical consumption, and obtains the positive and sustainable interaction conditions of cause marketing and ethical consumption.

(1) Ethical consumption is a prerequisite for the sustainable development of cause marketing. It's the safeguard for the sustainable development of cause marketing that consumers are willing to ethical consumption. Consumer cost affects choices of consumer behavior, low level of social responsibility awareness will directly increase the support burden of electric business platform to cause marketing, can not guarantee the product sales and achieve the good interaction of cause marketing and ethical consumption. Therefore, electronic business platform and businesses should implement the cause marketing, increase the cause marketing publicity to enhance consumer awareness of social responsibility, while reducing the time cost that consumer understand the specific content of cause marketing.

(2) Reducing cost is the key to promote sustainable development of cause marketing. Cause marketing cost is directly related to the sustainable interactive development of cause marketing and ethical consumption. Businesses should work from two aspects: First, reduce the cause marketing cost. The price of cause marketing product is not necessarily the same as the price of non cause marketing product, but it can not exceed the maximum afforded range of ethical consumption. The price should be combined with consumer's sense of social responsibility, at the same time, businesses should use other ways to reduce cause marketing cost. Second, businesses should indirectly reduce consumer ethical consumption cost. Businesses should accurately analyze consumer behavior, so as to accurately put cause marketing for advertising, really more convenient for consumers to understand the specific content of cause marketing, thereby reducing consumer spending on the time and other additional costs, better to achieve sustainable interaction of cause marketing and ethical consumption.

(3) Electronic business platform should vigorously promote the sense of social responsibility and promote the platform policy support. Businesses, as "economic man", always want their own additional endogenous utility and electric platform support for cause marketing to make up for opportunity cost and accounting cost. The platform should guide businesses to enhance the sense of social responsibility, so that the maximum expectation of policy support defined in the reasonable range of C1–C2. The specific work can be implement from two aspects: First, increase social responsibility propaganda. Only relying on the platform support policy is unable to maintain the sustainable development of cause marketing. Its important to increase the effectiveness of business and consumer social responsibility that improve the social responsibility sense in the electric business platform. Electric business platform should actively promote social responsibility concept to improve social responsibility awareness of businesses and consumers in order to increase the effectiveness of social responsibility. Second, improve the social responsibility incentive mechanism. Cause marketing will increase the cost of investment, electric business platform should speed up the development of policy incentives and other business incentives, to a certain extent make up the cost burden of business social responsibility, to better promote the sustainable development of cause marketing.

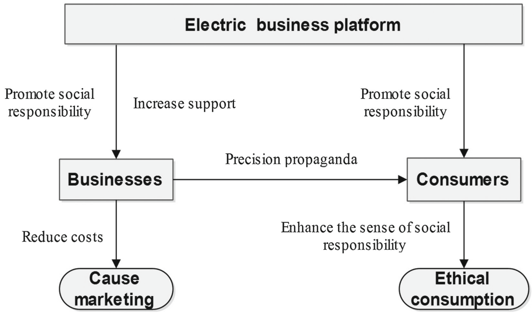

Fig. 6. The theoretical framework for the realization of benign and sustainable interaction.

Based on the above conclusions, this paper constructs a theoretical framework for the realization of benign and sustainable interaction between cause marketing and ethical consumption, as shown in Fig. 6:

Abstract. Financing efficiency in Public-Private Partnership (PPP) projects is a vital but impressionable aspect, whose likely consequence always influenced by inevitable uncertainties and confused the stakeholders. This study aims to investigate the methods for evaluating and predicting the relative efficiency of current financing scheme in PPP project, which surrounding with various uncertainties. The current study proposed a new algorithm for assessing the inancing efficiency and simulating the flexibilities in PPP projects simultaneously. Furthermore, it integrates DEA and Monte Carlo to provide the possible probability distribution of financing efficiency which takes the uncertainties in PPP. A case study is given to show its feasibility and practicability. It shows uncertainties in PPP projects considerably count for its deviation from the optimum value. This innovative model provides an avenue to predict the effects and possible outcome of an optimal scheme, which is important for financing scheme decision making.

Keywords: PPP · Monte Carlo · DEA · Financing efficiency

1 Introduction

Infrastructure constructions are essential to support the world economic development. Both in developed and developing countries, governments have dedicated a significant share of the public budget to develop and refurbish infrastructures [10]. While, with the global economy slows, the lack of economic resource can prevent further economic growth and the development of already planned infrastructure projects [5]. Infrastructure builders (always public sectors) are driven to attract private investment to take part in infrastructure constructions. This idea has elicited the generation of Public-Private Partnerships (PPP) mode.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_20

The development and popularization of PPP well bridge the gap between a need of infrastructures and a lack of budget. Worldwide, PPP grows into one of the most important procurement mechanisms of project development.

PPP mode holds numerable advantages, among which the financial efficiency is one of the main superiority. The British government directly name PPP projects as “Private Finance Initiative”, therefore its effect on financing is evidently reflected. The Asian Development Bank strong introduced PPP for constructing infrastructures at the beginning of its establishment, in order to reach the value of money and promote the efficiency of financing [1]. Many scholars studied the financing effects of PPP mode either from theoretical aspect or relating with practical application. Sastoque [12] concluded that it is one of the key characteristics of PPP to count private sector’s contribution on financial issues of public projects. Gatti indicated PPP is an efficient financing instrument acts through designing, structuring, and executing, as an important role in whole life cycle [6]. The high financing efficiency of PPP mode allows infrastructure projects obtain the best value for money.

However, stakeholders of PPP are in need of a benchmark to learn about the financing efficiency quantitatively; it is a necessary prerequisite for making a sensible decision before it simplement. Uncertainties implicated in PPP projects, like lengthy durations, high transaction costs and a lack of competition and transparency, always lead to inefficiencies and ineffectiveness [2], and further drag the financing efficiency down. Experts are trying to build a systematic model for the assessment of financing efficiency in PPP. While, PPP projects are multi-participation activities and multi-indicator processes which makes this work more complicated than traditional ones, let alone making predictions and selecting the optimal scheme.

Various methods have been proposed by scholars to settle this issue. The first family of methods universally used in the assessment of PPP projects is Fuzzy Synthetic Evaluation (FSE). Verweij [14] employed FSE to analysis satisfactory outcome of financing in 27 PPP road constructions in the Netherlands. FSE performs well in comparing existing options, however, fails to propose an optimum scheme and make prediction or simulation. The second family of methods for addressing the above problem is Analytic Hierarchy Process (AHP) analysis. Zhuang [21] applied AHP to research the fiscal control in PPP of city infrastructure. AHP suffered from the same limitation as FSE. Besides, it is easily influenced by the subjective rating of experts. Recently, an improved method had been proposed for achieving a comparison of the existing options, optimization of the inefficient ones, as well as eliminating subjective influence from human. It is Data Envelopment Analysis (DEA). In YuYuanchun’s study, DEA plays an important role in evaluating the technology transfer efficiency in industry-university-research institution [17]. Wang Hong investigated the efficiency of debt risk and fiscal expenditure of local government with an application of DEA [15]. Another strong point of DEA is that it supports target data of each indicator in relatively inefficient projects, which provides a reference for optimizing the original scheme. But it ignores the uncertainties and external influences in projects implement, which can be conducted by Monte Carlo (MC) approach.

The objective of this work is to propose a mathematical model to evaluate and predict the financing efficiency in PPP Projects. We apply DEA method to handle difficulties caused by multiple participators and factors, and integrate MC method to simulate uncertainties embraced in PPP projects. It is may offer a new insight and academic reference for related research.

2 Problem Statement

The motivation of the proposed method lies in the fact that the crude FSE and AHP method are limited in giving general evaluation and selecting the optimal scheme; moreover, they are vulnerable to anthropic rating [9]. These restrictions result in a series of dilemma in PPP projects, like hard to assess the potential influence of uncertainties, and lack of quantitative support for decision making of financing scheme. So, stakeholders in PPP projects are in an urgent need of a systematic model that offers data support for the decision of financing strategies, which should be uncertainties considering, optimum proposal providing, and free from artificial factors.

DEA is able to achieve all the mentioned goals except that it fails to take uncertainties in the implement and operation of PPP projects into account. The principle of Monte Carlo analysis is to run stochastic values of independent variable sand then simulate and identifies the possible distribution of outcomes [20]. A massive repetition of simulation processes counts the flexibility of changing environment, which supplement the flaw of DEA.

In this work, we try to propound an approach by exploiting Monte Carlo approach and integrating it with DEA. Monte Carlo works for simulating the uncertainties in PPP projects which facilitate the new method to systematically fulfill evaluation and optimization of financing efficiency in PPP Projects.

3 Monte Carlo and Its Application

Monte Carlo (MC) simulation is a computerized mathematical technique that allows people to simulate an approximate solution in quantitative analysis and decision making. The technique was first exploited by scientists who work in the nuclear technology field when they were facing with a 6-dimensional integral equation [20]. Calculating a result by repeated simulation was the only way to solve this complex multiple problem. Since then, MC was widely applied in the nuclear area, however, be confined to this area also because of the restriction of the capability of computing. As in projects, the related influence factor can be even more complex compared with in nuclear technology, a strong ability in computing and storage is needed [4]. With the booming development of computer in recent years, MC is widespread to various fields, for handling the simulation of multidimensional problems, especially in project decision making which constantly face with uncertainty, ambiguity, and variability. By using this method, the distribution of all possible outcome of an event is generated by running a model a large scale of times, and then prompts and assists the decision-making [11]. The main principle of MC is simulating the input of multiple independent variables, in accordance with their expected distributions, and drawing the proximate distribution and statistic data of dependent index. In the procedures of MC, it always involves determining the change rules of independent factors and exploring their interaction with dependent outcome. Then, the running of numerous simulations could identify the range and distribution of possible outcomes according to a number of scenarios. While managing a project, administrators always face up with difficulties when there is a list of alternatives for the project but lack of clues of their possible impact on the project. MC technique helps in forecasting the likely outcome of an event and thereby promotes making an informed decision. The method algorithm is shown in its succession interactive five steps [4,11,20]:

Step 1. Clearly defining the target problem y, and creating a parametric model composed by its influence factors $x_1, x_2, \cdots, x_q$, the model is noted as Eq. (1):

$$y = f(x_1, x_2, \cdots, x_q). \tag{1}$$

Step 2. On the basis of fitted or hypothetic distributions of influence factors, generating a random input set of data, $x_1, x_2, \cdots, x_q$;

Step 3. Adding the random set which is generated from step 2 into the model in step 1, obtaining an effective calculation and recording results as y_i;

Step 4. According to the accuracy requirement of specific research, determining the simulation times n, and repeating steps 2 and 3 for $i = 1$ to $i = n$ ($n = 1000$ in this work);

Step 5. Obtaining a distribution curve and analyzing the results by using statistic indicators generated from the simulation.

In the execution of PPP projects, forecasting the final financing efficiency is a complex and repeated issue. It always bewilders stakeholders because of its high degree of complexity and uncertainty. MC simulation assists in simulating likely scenarios and giving a probable distribution of objectives with taking the influence of risk factors and uncertainties into consider. In the model, we put forward in this study, DEA is applied to take the place of parametric model included in step 1. The key benefits and applicability of using the MC analysis in this research are listed below:

- MC simulation settles the uncertainties caused by multiple participators and complex influence factors in PPP projects well. Differing from the crude traditional model, MC exempts the complex mathematical calculation, and directly obtains likely outcomes by simulating a series of possible scenarios, which make it more operable and practical.
- MC overcomes the irreversibility involved in decision making, especially in significant determination as those in PPP projects. Simulation is a way to imitate results by running a large number of potential situations. MC simulation meets the need of foresight the possible outcome in advance.

- With the advanced computing technology, Monte Carlo simulation is easier to operate. It gains the availability and feasibility in practical application of PPP projects.

4 Model Establishment

Scholars have explored a number of avenues to calculate and optimize the productivity and operational efficiency issues. However, it is noteworthy that DEA is one of the most popular approaches in this area. It is more recent in applications among studies and it also draws more effective conclusions in comparison with some other methodologies like Stochastic Frontier Analysis (SFA) [13]. With a popularization of the PPP mode, employing DEA as modeling method is becoming more and more popular in latest decade [19]. While in the specific financing efficiency field of PPP projects, only a few scholars have gone into and DEA is scarcely used.

In this research, we first adopt DEA to evaluate the financing efficiency of specific PPP projects and get the initially optimized data. Due to the limitation of theoretical mathematical models, DEA ignores the uncertainties and all possible scenarios in PPP projects. Therefore, Monte Carlo is designed to play a role for filling in the vacancy. The integrated algorithm can be used to both give an assessment and practically optimized scheme and its efficiency.

4.1 Evaluation and Optimization of Financing Efficiency in PPP Projects

In the projects area, the application of DEA always embodies three main parts: selecting input and output indexes, forming the decision-making unit set, and finally analyzing from calculated outcome. For the efficiency of financing in PPP projects, it involves two major areas: raising funds in low cost and using funds efficiently. In addition, franchise and public service of public infrastructure are two characteristics in PPP project. Accordingly, five indicators are selected to measure the financing efficiency of PPP projects in this study: the ratio of capital funds, the duration, and the franchise as input indexes; social influence and the turnover ratio of total capital as output indexes.

Five indicators refer to five aspects of financing efficiency in PPP projects. Their names, definitions, notations and formulas for indicators are listed in Table 1.

For making up an effective decision-making unit set, the number of decision-making units should be no less than twice the number of a sum of the input and output indicators; otherwise its ability to distinguish efficiency will decline [7]. So, when measures the relative efficiency of a PPP project, the data of the other nine projects is needed to compose the decision-making unit set. Then input all indexes into DEA model and results can be generated. The calculating model is as Eq. (2) [8].

Table 1. The definition, notation, and calculation formula of five indexes in DEA model

Index	Notation	Meaning	Formulation
Ratio of capital funds	X_1	Percentage of capital amount contributed by partners in the total investment	$X_1 = \frac{\text{capital invested by partners}}{\text{total construction cost}}$
Duration	X_2	Construction time takes in PPP projects, which related to the value of money	$X_2 =$ construction time (month)
Franchise rights	X_3	Privilege the franchise of public infrastructure to co-enterprises	$x_3 = \sum_{t=1}^{m} \frac{B_t}{(1+i^t)}$
Social influence	Y_1	Analyze from the number of service users (μ_1) and related webpage (μ_2)	$Y_{1j} = \frac{\mu_{1j}}{\max\limits_{1 \leq j \leq n} \mu_{1j}} + \frac{\mu_{2j}}{\max\limits_{1 \leq j \leq n} \mu_{2j}}$
Turnover ratio of total capital	Y_2	Evaluate management quality and utilization efficiency of total capital	$Y_2 = \frac{\text{net operating income}}{\text{average total asset}}$

B_t: excess earnings in $t^{th}y$; m : duration of franchise; i: discount rates.

$$\min \left[\theta - \varepsilon\left(\sum_{k=1}^{K} s^{-} + \sum_{l=1}^{L} s^{+}\right)\right]$$
$$\text{s. t.} \begin{cases} \sum\limits_{j=1}^{n} X_{kj}\lambda_j + s^{-} = \theta x_{ko}, & k = 1, 2, 3 \\ \sum\limits_{j=1}^{n} Y_{lj}\lambda_j - s^{+} = y_{ko}, & l = 1, 2 \\ \sum\limits_{j=1}^{n} \lambda_j = 1 & \\ s^{-}, s^{+}, \lambda_j \geq 0, & j = 1, 2, \cdots, n. \end{cases} \quad (2)$$

Three indicators about efficiency can be obtained: technical efficiency θ, scale efficiency θ_{SE} and pure technical efficiency θ_{PE}. θ_{SE} and θ_{PE} separately show the financing efficiency of PPP projects in aspects of scale and pure technique. Only when θ_{PE} and θ_{SE} equal 1 at the same time, it means that the targeted project is in a relatively efficient level among other projects in this decision-making units set. A particular relationship among the three indictors is shown in Eq. (3).

$$\theta = \theta_{PE} \times \theta_{SE}. \quad (3)$$

In addition, the input redundancy s^{+} and the output deficiency s^{-} stem from DEA model indicate targets of every independent indicator for reaching a relative efficiency state. They fail to count uncertainties embodied in PPP projects, while are important raw data for MC simulation.

4.2 Monte Carlo for Simulating Uncertainties

The Integration of MC and DEA is able to build an avenue for simultaneously fulfilling the assessment and prediction of financing efficiency in PPP. Although DEA model have generated an optimal target for each parameter, it is presented

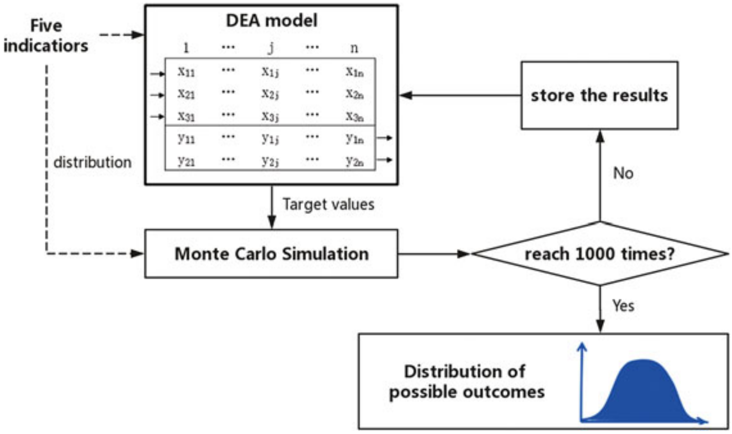

Fig. 1. The flowchart of simulation algorithm integrates Monte Carlo with DEA

as theoretical and fixed data. During the practical development and construction of a PPP project, all the changes in policy, economics, natural environment and project itself generate flexibilities and fluctuations. They may result in a deviation from the expected optimal scheme. MC analysis is strong at simulating realistic uncertainties by randomly sampling the possible parameters set based on their fitted distribution.

The simulation process is the vital part in Monte Carlo analysis. It contains defining distributions of independent parameter, inputting random sampling data set, and gathering results to generate a fitted distribution of dependent indicators. When integrates with DEA model, the sampled random date set need to be put in DEA model for running and giving the results of efficiency indicators, provided that the simulation times does not reach 1000 yet. An aggregation of all the results obtained from every simulation forms a possible financing efficiency distribution. Consequently, uncertainty is considered in the majorization. The flowchart of simulation process of the new model is shown in Fig. 1.

The innovative algorithm combines data processes of MC and DEA, which contribute to a complement of both methods. DEA creates raw data and algorithm for simulation in MC, and MC simulation bridge the gap between reality and theoretical values given by DEA. With the integrated algorithm, a probability distribution of financing efficiency with potential changes in implement will be drawn. It offers a quantitative reference for managers of PPP projects to analyze the feasibility and risk of the optimum proposal, and then make more evidence-based and financing efficient decision.

5 Case Study

5.1 Project Introduction

Australia Adelaide Water Utility project was developed to mitigate the water threat. PPP mode was applied to ally the public and private sector for supporting more efficient and quality service. The United Water Corporation (private sector) cooperated with the Water Company in South Australia (public sector) to construct the PPP project. The overall budget was 4.3 billion included 1.6 billion capital investments, which was raised from both main stakeholders and the others investment from banks and other social capital. During the negotiation stage, the government committed a 27 year franchise right. The completed water utility was expected to serve 5 million citizens and get 521 million's annual operating incomes.

5.2 Simulation and Optimization Analysis

In order to composing an effective decision-making unit, set for DEA analysis, we collected the related data of nine other PPP projects include Bird Nest and the Sydney Olympic Games Stadium. In order to guarantee their comparability, these projects shared similar scale and age of building; further, all the data is transform into the form of ratio of capital funds, duration, franchise rights, social influence and turnover ratio of total capital. The results of relative financing efficiency: pure technical efficiency θ_{PE}, scale efficiency θ_{SE} and technical efficiency θ are calculated with the application of DEA as listed in Table 2.

From the Table 2, a conclusion is drawn that, the financing efficiency is far away from relatively efficient state compared with the other projects in this decision-making unit set. When other projects almost reached 1, a relative efficient state, the pure technical efficiency, scale efficiency and technical efficiency of financing for Australia Adelaide Water Utility are separate to be 0.667, 0.454 and 0.303. Thus, an optimal scheme is in an urge need to improve the situation of relative inefficiency in Australia Adelaide Water Utility PPP project.

DEA model delivers an improvement strategy for relative inefficient units to reach an ideal level, namely a relative efficient financing efficiency state. For Australia Adelaide Water Utility, the initial input and final target given by DEA model are shown in Table 3.

Table 2. Financing efficiency of each project stem from DEA model

Project name	θ_{PE}	θ_{SE}	θ
Australia Adelaide Water Utility	0.667	0.454 irs	0.303
Bird Nest	1	1	1
Sidney Olympic Stadium	1	0.969 irs	0.969
Beijing no. 4 subway	1	1	1
South Africa Ekurhuleni high speed railway	1	0.894 irs	0.894
Perpignan-Figueras rail link	1	1	1
Sidney Harbour Tunnel	1	1	1
Kamchay Hydropower Station	0.725	0.993 irs	0.721
QingDao Sewage Treatment Works	1	1	1
Hong Kong Disneyland	1	1	1

Table 3. Comparison of initial and target data of Australia Adelaide Water Utility

Item	Ratioof capital funds	Duration	Franchise rights	Social influence	Turnover ratio of total capital
Initial input	0.37	36	77.28	0.18	0.12
Target value	0.21	24	11.5	0.27	0.3

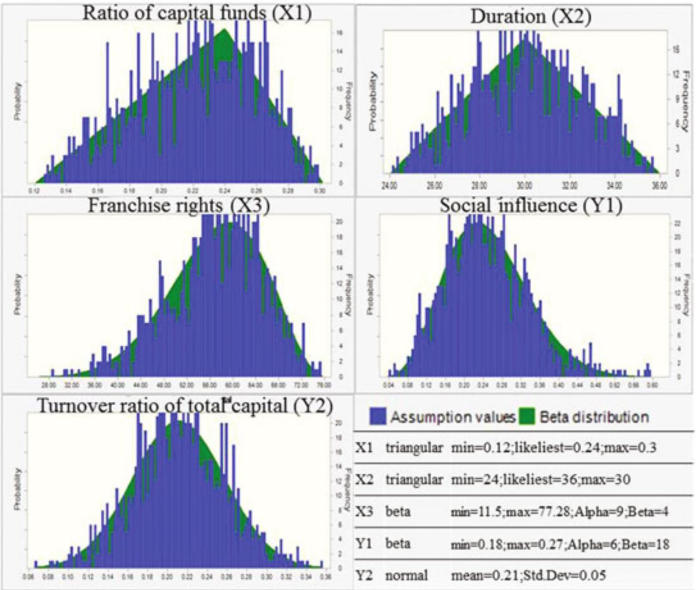

Fig. 2. The flowchart of simulation algorithm integrates Monte Carlo with DEA

The target values are more theoretical, rather than feasible and practical. For in the actual construction, it is surrounded by a changing environment all the time, any uncertainty can result in a deviation from the optimal target. If we predict and simulate all the possibility value of independent parameters, the possible value of dependent parameters can be obtained. MC is created to imitate this process. Ratio of capital funds, duration, franchise rights, social influence and turnover ratio of total capital are five independent parameters in this algorithm, we collect data from over hundred PPP projects so as to generate a fitting probability distribution for each parameter, and they are hypothesized as show in Fig. 2.

After sampling 1000 times in Monte Carlo simulation and running extracted data in DEA model, the crossover process finally generates the probability distribution of pure technical efficiency θ_{PE}, scale efficiency θ_{SE} and technical efficiency θ (Fig. 3). It shows the fitted probability curve for scale efficiency and technical efficiency are lognormal distribution; while for pure technical efficiency

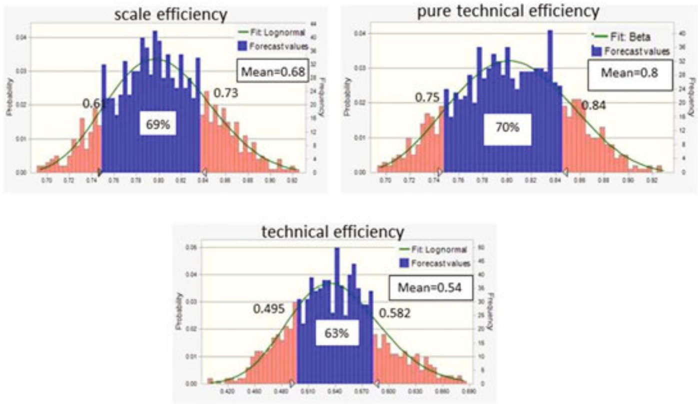

Fig. 3. The flowchart of simulation algorithm integrates Monte Carlo with DEA

is beta distribution. With setting the optimal scheme as a target, the expected value for the pure technical efficiency reaches 0.8, has a promotion over 20% than the initial value; for the scale efficiency reaches 0.68, get a considerable 50% improvement; for the technical efficiency meets 0.54, improves 80%. The blue area highlighted in graphs reveals the most probable range of financing efficiency value with a boundary set at the half of the maximum value.

Finally, we can make a conclusion that the practical implementation of an optimal scheme hardly fulfills the relative efficient state in the end, because of all the uncertainties and change of environment related with PPP projects. While the innovative algorithm proposed in this research offers an approach to predict possible outcomes and distribution of financing efficiency. It enables stakeholders make a better decision among financing strategies and prepare for probable consequences.

6 Conclusions

In this work, we propose an efficient and practical model for estimating and predicting financing efficiency in PPP projects. It integrates DEA and Monte Carlo approach to measure financing efficiency scientifically and objectively, as well as take the uncertainties embodied in PPP project into consider. The innovative model designs a crossover running between DEA and MC, which enable them to compensate for each other's weaknesses. DEA is an effective approach to measure the relative efficiency and delivered an optimal target to reach the relative efficiency state [19]. Wanke, Peter F also applied DEA to analyze scale efficiency of PPP projects in Brazilian ports [16]. While PPP projects are full of risks and uncertainties which will result in a fluctuation from the optimal target, the intrinsic restrictions of DEA fail to take it into consider. A number of scholars, like DijunTan and Yuzba Bahadr, use the features of Monte Carlo to quantify and visualize volatility and flexibility [3,18]. In this manuscript, the MC method is combined with DEA to handle uncertainties through a series of simulation. The proposed algorithm offers a comprehensive method to assess and forecast the financing efficiency in PPP projects.

In the case study of Australia Adelaide Water Utility project, one- thousand-time simulation forms the possible probability distribution of final pure technical efficiency, scale efficiency and technical efficiency of financing. It reveals the possible outcome of financing efficiency in this PPP project when set the optimal value derived from DEA as the target. It shows that, although uncertainties make the relative efficiency hardly to meet a perfectly financing efficient state, while the three efficiency parameters promoted 20%–80% than the initial financing scheme. This result enables the stakeholders to have a full preparation for the probable consequence.

The application of the new method which integrates MC and DEA is not limited in the financing efficiency of PPP projects. It can be extended to various fields whose assessment and simulation process involve multiple indicators and uncertainties. After making corresponding changes in input and output indexes and fit their possibility distribution, the innovative algorithm can be widely used in different areas.

7 Summary of Research Results and Future Study

This study proposed a new model to predict the financing efficiency with fluctuation caused by uncertainties in PPP projects, based on integration of DEA and MC. The case study of Australia Adelaide Water Utility project shows that this innovative method is capable to evaluate and predict flexibilities quantitatively and visually. It also indicates that the uncertainties in PPP projects make the target values in optimal scheme hard to reach, while in this specific project, it also realizes a considerable promotion in all three efficiency indicators.

Further research, such as a more comprehensive indexes system of DEA and subdivide uncertainties in to different categories, is necessary to delve more in-depth and practical in this topic. A more comprehensive and thorough investigation of related factors in DEA method will contribute to a more accurate outcome. Considering that the implementation of PPPs would be affected by economic, social and environmental conditions, sorted uncertainties can facilitate a more accurate calculation. Alternatively, a series of diversified case study need to be carried out in the future to verify and enrich the reliability and feasibility of this new model.

Abstract. The study presents an interactive and theoretical research model based on the economic theory of asymmetry behavior, which means labor costs are more likely to increase when activity increases greater than activity decreases. This paper aims to analyze the effect of capacity utilization on prior capacity changes and labor costs behavior. Study methodology tests the hypotheses of nonlinear relationships among variables in the proposed model using multiple regression analysis. Data have been collected from five factories of Iraqi cement firms by physical output data from 2006 to 2015 monthly. Findings reveal that degree of cost asymmetry of manufacturing, selling and administrative, and total labor is associated with capacity changes and that a moderating effect of capacity utilization strongly reveals the opposite pattern supported. Our results from Iraqi manufacturing provide a new evidence on labor costs behavior and contain important implications for both accounting and economic theories. The value of the paper is one of the earliest studies that empirically examine and explain the moderating effects of capacity utilization on employment capacity and labor costs behavior.

Keywords: Capacity utilization · Employment capacity · Labor costs behavior · Asymmetry theory

1 Introduction

Alternative behavior model is an important issue based on deliberate managerial decisions for cost accounting [1]. Underlying the traditional behavior model is based on the activity level that associates changes linearly and proportionately [30]. Many studies have documented an asymmetry behavior between costs and resources in various perspectives [15,22–25,36]. The variances between the level of costs to activity rise changes and the level of costs to activity fall changes called "asymmetry" as sticky, anti-stick costs [7]. Conversely, The asymmetric cost behavior is investigating the consequence cost stickiness on actual and forecast earnings [28].

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_21

Managers tend to save capacity when capacity is strained and demand falls then, add capacity when demand grows [7,13,16]. As optimistic expectations lead to saving idle capacity in the sales response to necessary declines but these predictions will make a sticky cost behavior [17]. The asymmetric slack maintenance does not automatically lead to cost stickiness, but if managers retained in response to a previous sales decrease, the significant is stickiness on a prior sales increase and anti-stickiness on a prior sales decrease [11]. These motivations lead us to question is "how capacity utilization moderate the relationship between labor costs and capacity changes?" Capacity utilization is a measurement of the percentage of firm productivity capacity that determine unused resources to total resources [31].

Unemployment fluctuations may make stickiness labor costs in structural parameters because the statistics of unemployment are replicated as well in sticky labor behavior [14]. Empirical implications created a counter cyclical wedge between the real labor and marginal rate [19]. Moreover, the significance of labor is not flexible or inflexible because it is necessary to manage cost structure [6]. Moderating model has certain guiding significance for the application of big data to management decision [37].

Prior studies identified that capacity changes asymmetrically impact on manufacturing labor, selling and administrative, and total costs [5,13]. However, Banker et al. [9] examined the moderating effect of prior periods on the relationship between sales changes and costs behavior. Yet, no research available in literature presents the impact of capacity utilization on asymmetric labor costs behavior.

This paper aims to analyze the impact of capacity utilization on the asymmetry behavior between labor costs and employment capacity, and to explain scientifically the differences without and within the interaction effects.

2 Related Studies and Hypothesis Development

Resources adjustment costs create asymmetry behavior in marginal costs because managerial expectations depend on optimism and pessimism about sales future [21]. Sometimes, uncompleted cost information generates asymmetric results [34]. It depends on how managers use resources and understand their mechanism [33]. Managerial optimism weakness on previous changes called cost sticky, and managerial pessimism weakness on previous changes called anti-sticky [2]. Asymmetry behavior is managerial practical because managers are expected reluctant to lower committed resources in periods of cost-effective growth [8,12]. Limitation of labor costs associated with operating's during sales changes [38]. In addition, high product competition has affected costs behavior that generates Stickiness costs or likely cost responsive [17]. This behavior of labor cost will generate a good control in future because the cost should match with managerial expectations that mean little variations [11]. Overall, The main reason of asymmetry behavior is cost response cannot be a rise or decline fast enough to combine changes in resources [4,30]. Few studies have considered the effect of asymmetric information on reporting decisions and analyze after demand realization under a decentralized setting [27].

The capacity problems and asymmetry behavior positively are associated with control on economics variables such as employees' intensity, production unit, workforce level [15,26,35,39], and machine level. There are behavioral differences between costs categories [24]. Dalla Via and Perego [18] indicated significant labor cost stickiness conditional on a prior sales changes for Italian companies listed. Chen et al. [15] studied the interaction effects among capacity, economics variables, sales changes, and selling and administrative costs. Their results indicate asymmetry behavior and find significant. Azeez et al. [5] examined the relationship of labor costs and employment capacity in which they activate, and discuss how they share to the growth and improvement rate of categories of labor cost with capacity. Banker et al. [11] used employment protection legislation to examine adjustment costs and employment resources in different countries. Their finding showed that costs respond to sales increase greater than sales decrease.

We summarize these predictions by three hypotheses as follows:

Hypothesis 1a (H1a): Conditional on a prior capacity utilization increases, change in manufacturing labor costs to capacity increase is greater than capacity decrease.

Hypothesis 1b (H1b): Moderating effects on a prior capacity utilization increases, change in manufacturing labor costs to capacity increase is less than capacity decrease.

Hypothesis 2a (H2a): Conditional on a prior capacity utilization increases, change in selling and administrative labor costs to capacity increase is greater than capacity decrease.

Hypothesis 2b (H2b): Moderating effects on a prior capacity utilization increases, change in selling and administrative labor costs to capacity increase is less than capacity decrease.

Hypothesis 3a (H3a): Conditional on a prior capacity utilization increases, change in total labor costs to capacity increase is greater than capacity decrease.

Hypothesis 3b (H3b): Moderating effects on a prior capacity utilization increases, change in total labor costs to capacity increase is less than capacity decrease.

3 Research Methodology

3.1 Sample Description

We have empirically investigated 600 practical observation from five factories across hundred twenty months each one from 2006 to 2015 of cement in national Iraqi company. We calculated all log-change using same months in years as indexes of study variables using OLS estimation for regression and the second stage we applied hierarchal moderation regression as function of results.

3.2 Model Development

Our research design is based on the established asymmetric labor costs model of Anderson et al. [1], and Azeez et al. [5], Banker et al. [9] as in equations:

$$\begin{aligned}\ln\left(\frac{MLC_{i,t}-MLC_{i,t-1}}{MLC_{i,t}}\right) = {} & \varphi_0 + \varphi_1 \ln\left(\frac{\mathrm{MEq}_{i,t}-\mathrm{MEq}_{i,t-1}}{\mathrm{MEq}_{i,t}}\right) \\ & + \varphi_2 \mathrm{DEC}_{i,t} \ln\left(\frac{\mathrm{MEq}_{i,t}-\mathrm{MEq}_{i,t-1}}{\mathrm{MEq}_{i,t}}\right) \\ & + \varphi_3 \ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right) \\ & + \varphi_4 \mathrm{DEC}_{i,t} \ln\left(\frac{\mathrm{MEq}_{i,t}-\mathrm{MEq}_{i,t-1}}{\mathrm{MEq}_{i,t}}\right) \\ & \times \ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right) + \varepsilon_{i,t},\end{aligned} \tag{1}$$

where $\mathrm{MLC}_{i,t}$ is a manufacturing labor cost for firm i at time t and is a non-linear function of independent variables ($\varphi_1, \varphi_2, \varphi_3$, and φ_4). ME is a manufacturing Capacity of employees by hours. $\mathrm{DEC}_{i,t}$ is an indicator set to 1 if $\mathrm{MEq}_{i,t} < \mathrm{MEq}_{i,t-1}$, and set to 0 otherwise. φ_0 is a parameter that estimates the asymmetric labor cost unassociated with employment capacity changes. φ_1 is a parameter that estimates the association between manufacturing labor cost and employment capacity changes increase. φ_2 is a Parameter of asymmetry measurement that estimates the association between manufacturing labor cost and employment capacity changes during increasing and decreasing. φ_3 is a moderating variable that estimates the association between labor cost and capacity utilization changes. φ_4 is a critical value that estimates how capacity utilization moderates the association between manufacturing employment capacity and labor costs behavior. $\varepsilon_{i,t}$ is an error term for variability in labor cost change estimation for firm i at time t.

The capacity utilization was computed for labor hour's measures of the unused and total capacity for each of the periods as in Eq. (2) below:

$$qu = 1 - \frac{\text{unused capacity}}{\text{total capacity}}, \tag{2}$$

where qu is employees Capacity Utilization for each activities. Unused capacity is that hours cannot exceed effective capacity. Total capacity is the maximum hours of output designed for the operation and facility other.

$$\begin{aligned}\ln\left(\frac{\mathrm{S\&ALC}_{i,t}-\mathrm{S\&ALC}_{i,t-1}}{\mathrm{S\&ALC}_{i,t}}\right) = {} & \theta_0 + \theta_1 \ln\left(\frac{\mathrm{SEq}_{i,t}-\mathrm{SEq}_{i,t-1}}{\mathrm{SEq}_{i,t}}\right) \\ & + \theta_2 \mathrm{DEC}_{i,t} \ln\left(\frac{\mathrm{SEq}_{i,t}-\mathrm{SEq}_{i,t-1}}{\mathrm{SEq}_{i,t}}\right) \\ & + \theta_3 \ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right) \\ & + \theta_4 \mathrm{DEC}_{i,t} \ln\left(\frac{\mathrm{SEq}_{i,t}-\mathrm{SEq}_{i,t-1}}{\mathrm{SEq}_{i,t}}\right) \\ & \times \ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right) + \omega_{i,t},\end{aligned} \tag{3}$$

where: $\mathrm{S\&ALC}_i$, is a selling and administrative labor cost for firm i at time t. $SEq_{i,t}$ is a selling and administrative Capacity of employees by hours, and all other variables were defined previously.

$$\begin{aligned}\ln\left(\frac{\mathrm{TLC}_{i,t}-\mathrm{TLC}_{i,t-1}}{\mathrm{TLC}_{i,t}}\right) = {} & \gamma_0 + \gamma_1 \ln\left(\frac{\mathrm{TEq}_{i,t}-\mathrm{TEq}_{i,t-1}}{\mathrm{TEq}_{i,t}}\right)\\ & +\gamma_2 \mathrm{DEC}_{i,t} \ln\left(\frac{\mathrm{TEq}_{i,t}-\mathrm{TEq}_{i,t-1}}{\mathrm{TEq}_{i,t}}\right)\\ & +\gamma_3 \ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right)\\ & +\gamma_4 \mathrm{DEC}_{i,t} \ln\left(\frac{\mathrm{TEq}_{i,t}-\mathrm{TEq}_{i,t-1}}{\mathrm{TEq}_{i,t}}\right)\\ & \times \ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right) + \alpha_{i,t},\end{aligned} \tag{4}$$

where TLC_i, is a total labor cost for firm i at time t. $\mathrm{MEq}_{i,t}$ is a total Capacity of employees by hours include all of the activities, and remainder of variables are defined previously.

To develop the concept of asymmetry labor costs about employment capacity structure (high utilization). The coefficients ϕ_1, and measure the average percentage increase in labor costs for one present increase in employment capacity, whereas the sum of coefficients $(\phi_1 + \phi_2)$, $(\theta_1 + \theta_2)$ and $(\gamma_1 + \gamma_2)$ in three models to measure the average percentage of decrease in labor costs for one present

Table 1. Definition of variables in empirical models

Variable/Calculation	Description
$\ln\left(\frac{\mathrm{MLC}_{i,t}-\mathrm{MLC}_{i,t-1}}{\mathrm{MLC}_{i,t}}\right)$	Log-change in manufacturing labor costs. All labor costs of manufacturing process and its supporting, payments of industrial activity
$\ln\left(\frac{\mathrm{S\&ALC}_{i,t}-\mathrm{S\&ALC}_{i,t-1}}{\mathrm{S\&ALC}_{i,t}}\right)$	Log-change in Selling & administrative labor costs. All labor costs of selling and administrative process, payments of selling, and administrative activity
$\ln\left(\frac{\mathrm{TLC}_{i,t}-\mathrm{TLC}_{i,t-1}}{\mathrm{TLC}_{i,t}}\right)$	Log-change in total labor costs. All labor costs of manufacturing, supporting, selling, and administrative activities
$\ln\left(\frac{\mathrm{MEq}_{i,t}-\mathrm{MEq}_{i,t-1}}{\mathrm{MEq}_{i,t}}\right)$	Log-change in manufacturing employment capacity. Total hours of employees in manufacturing and supporting activity
$\ln\left(\frac{\mathrm{SEq}_{i,t}-\mathrm{SEq}_{i,t-1}}{\mathrm{SEq}_{i,t}}\right)$	Log-change in selling employment capacity. Total hours of employees in selling, general, and administrative activity
$\ln\left(\frac{\mathrm{TEq}_{i,t}-\mathrm{TEq}_{i,t-1}}{\mathrm{TEq}_{i,t}}\right)$	Log-change in total employment capacity. Total hours of employees in the all activities
$\ln\left(\frac{qu_{i,t}-qu_{i,t-1}}{qu_{i,t}}\right)$	Log-change in capacity utilization. The percentage rate of each kind of actual capacity to design capacity

Manufacturing labor cost is collected from manufacturing, engineering & services, and quality control activities. Selling and administrative labor cost is collected from marketing and administration activities. Practical employees' capacity is collected from a dataset of the planning department. Unused employees' capacity is calculated based on differences between actual and practical employees capacity. Actual employees' capacity is calculated by divided labor costs on payment rates.

decrease in the employment capacity. The labor costs behavior is asymmetry when the average percentage increase in labor costs not equal the average percentage decrease in labor costs, that is, if labor costs decrease less when employment capacity fall than they increase when employment capacity rise [1,36]. Means the labor costs have sticky behavior (ϕ_1, θ_1 and γ_1, and will be positive, ϕ_2, θ_2 and γ_2, will be negative). The empirical hypothesis for sticky behavior means that $\phi_2 < 0$. This finding an empirical test of Hypotheses 1a, 2a, and 3a. In addition, the current study is exciting literature using the interactive effect of capacity utilization on the asymmetric relationship between employment capacity and labor costs behavior. *Hypotheses 1b*, *2b*, and *3b* imply ϕ_2, are negative and ϕ_4, are positive reflecting stickiness and anti-stickiness respectively [9]. The moderation role of capacity utilization implies that labor costs asymmetry will be less than in the case without the interactive effects. The variables definitions are defined in Table 1.

4 Findings and Discussion

In the current study, we estimate three models for each hypothesis of manufacturing labor costs, selling and administrative labor costs, and total labor costs (Tables 2, 3 and 4). For all of those categories, the estimates indicate significance levels and support our hypotheses. The evidence finds labor costs behavior is sticky on a prior capacity decrease and indicate significant anti-sticky behavior on a prior capacity decrease with interactive effects of capacity utilization (<0 and >0 continues to all models).

4.1 Asymmetric Labor Costs Response to Capacity Changes

In the regression analysis, we find a sticky behavior between labor costs and capacity changes for all of the labor costs categories but in different degrees, the estimates indicate that φ_1 is positive, φ_2 is negative and significant (see model (1) to each Tables 1, 2 and 3). The results found manufacturing, selling and administrative labor, total labor costs are sticky on average by magnitudes of prior employment capacity increase and decrease.

Table 2-panel A. presents a model (1), manufacturing labor costs response to capacity increase is statistically greater than capacity decrease ($\varphi 1 \succ \varphi_1+\varphi_2$). The coefficient is negative (-0.56%, $SE. = 0.18$) and significantly different from zero at the 1 % (t-statistics -3.176). On average, the manufacturing labor costs increase 0.74% per 1% increase in employment capacity (φ_1) and costs decrease by 0.18% per 1% decrease in employment capacity ($\varphi_1 + \varphi_2$). The results show that the adjusted R^2 is 0.71, the model is significant ($p < 0.001$) level. Means the behavior between employment capacity change and manufacturing labor cost is sticky (*H1a*). However, Selling and administrative labor costs response to capacity increase statistically is greater than capacity decrease ($\theta_1 > +\ 2$). The coefficient is negative and significant (-0.40%, $SE. = 0.12$, t-statistics -3.25). On average, the Selling and administrative labor costs increase 0.71%

per 1% increase in employment capacity (θ_1) and costs decrease by 0.31% per 1% decrease in employment capacity ($\theta_1 + \theta_2$), for which Selling and administrative labor costs expected to be sticky (*H2a*). The adjusted R2 is 0.70, where F-value is 475.99, the model is significant ($p < 0.001$) level. (Presented in Table 3-panel A.).

Finally, Table 4-panel A. in model (1), presented the empirical examination of the relationship between total labor costs and employment capacity changes. Total labor costs asymmetrically respond to capacity changes. The coefficient is negative and significant (-0.58%, $SE. = 0.08$, t-statistics -7.68). On average, the total labor costs increase by 0.67% per 1% increase in employment capacity (γ_1) and they decrease by 0.09% per 1% decrease in capacity ($\gamma_1 + \gamma_2$). The results show that the adjusted R^2 is 0.09, where F-value is 21.09, the model is significant ($p < 0.001$) level. The result is consistent with (*H3a*).

4.2 Moderation Analysis: Interactive Effects of Capacity Utilization

In extension analysis, we estimate interactive models for each of the main components of labor costs (manufacturing labor, selling and administrative labor, and total labor), for extending literature of asymmetric cost behavior. The estimates indicate significant stickiness conditional on a prior capacity decrease and significant anti-stickiness conditional on a prior capacity decrease with moderating effects of capacity utilization change ($\varphi_2 < 0$ and $\varphi_4 > 0$ respectively) suggesting that capacity utilization changes are related to the effects of employment capacity changes on labor costs behavior. These findings support *H1b*, *H2b*, and *H3b*.

Moderation test was conducted to examine the interacting effect of prior sales changes between sales changes and asymmetric cost behavior [9]. The labor costs exhibit significant stickiness without the interactive effects of capacity utilization ($\varphi_2 = -0.22\%$, $SE. = 0.34$, t-statistics -0.65), ($\theta_2 = -0.19\%$, $SE. = 0.05$, t-statistics -3.67), and ($\gamma_2 = -0.48\%$, $SE. = 0.06$, t-statistics -7.51) respectively, but the labor costs reveal the opposite pattern of significant anti-stickiness within the interactive effects of capacity utilization ($\varphi_4 = 0.11\%$, $SE. = 0.02$, t-statistics 6.05), ($\theta_4 = 0.28\%$, $SE. = 0.04$, t-statistics 6.81), and ($\gamma_4 = -0.13\%$, $SE. = 0.06$, t-statistics 2.16). These results document that labor costs are description of a broader pattern of asymmetric cost behavior, which extends to all the major components of labor costs for physical input quantity (employment capacity) for labor costs behavior.

In additional, Banker et al. [9] indicated that costs respond to activity increase is greater than activity increase within the moderation effects, which estimated parameter of total employees costs increase equal 0.62 stronger than 0.42 within the interactive effects. Whereas our finding indicate that coefficients of asymmetry measure less than within the interactive effects ($\varphi_2 = 0.56, \theta_2 = -0.40, \gamma_2 = -0.58$) $>$ ($\varphi_2 = -0.22, \theta_2 = -0.19, \gamma_2 = -0.48$) respectively and capacity utilization change was observed to strengthen the relationship between capacity changes and labor costs behavior ($\Delta R^2 = 0.017$, $\Delta R^2 = 0.021$, $\Delta R^2 = 0.009$, $p < 0.001$). The results also underscore the value-added of interactive analysis of capacity utilization, which in the moderation models of categories of labor costs are important for drawing accurate implications about the natural of costs behavior. While Banker et al. [9] considered the moderation of two-period analysis is value- added for theory of asymmetric cost behavior.

Table 4. Validation test of the sticky behavior: Nonlinear analysis of moderation test among employment capacity, capacity utilization, and total labor costs change

Variable	Parameter	Parameter estimate	Standard error	Parameter significance (t-statistics)
Panel A: Regression analysis: direct effects C model 1 Dependent variable = total labor cost (TLC)				
Intercept	γ_0	0.66	0.29	0
		(?)	−2.24	
$\ln\left(\frac{\mathrm{TEq}_{i,t}-\mathrm{TEq}_{i,t-1}}{\mathrm{TEq}_{i,t}}\right)$	γ_1	0.67	0.09	0
	Asymmetric behavior	(+)		−7.16
$\ln \mathrm{DEC}_{i,t}\left(\frac{\mathrm{TEq}_{i,t}-\mathrm{TEq}_{i,t-1}}{\mathrm{TEq}_{i,t}}\right)$	γ_2	−0.58	0.08	0

4.3 Discussion

This research was conducted to analyze the moderation effects of capacity utilization changes as they related to asymmetric costs behavior at manufacturing sector firms in Iraq. Until recently, most studies have been conducted to investigate why change in labor costs behavior to activity is asymmetry [3,8,18,20,29], specially Banker et al. [9] conducted on moderating effects but they ignored the important dimension of capacity utilization and also focused on multiple periods analysis for same variables to overcome these issues, this research has presented an interactive model based on data collection from multiple and different variables. Maintenance management is necessary an effective system to display the surface temperature to reduce the capacity losses [32].

From the variable is used in the theoretical research model, three nonlinear relationships were proposed and tested. The results found capacity utilization changes can affect asymmetric cost behavior. Conversely, labor costs and their categories have associated with employment capacity changes in different degrees such as significant stickiness conditional on a prior capacity decrease and significant anti-stickiness conditional on an interaction of capacity decreases with capacity utilization increases. Finally, capacity utilization can decrease the degree of sticky measure. The results from the nonlinear relationships tested to confirm and align with the existing literature [1,3,5,9].

Anderson et al. [1] Documented that behavior between costs and resources changes is asymmetry because costs respond to resources increase greater/less than resources decrease that rejected the traditional models about fixed and variable changes. However, costs behavior is sticky when prior sales increase, whereas costs behavior is anti-sticky when prior sales change decrease. The costs are anti-sticky when capacity utilization is unusually low [9]. On the other hand, Azeez et al. [5] examined the labor costs behavior when employment capacity change is increasing and decreasing for existing asymmetric cost behavior by using physical output data. Finally, the results found capacity utilization is able to moderate the relationship between capacity change and labor costs behavior, and suggest new avenues of exploration for future studies.

5 Conclusion

Significance of the relationship between costs behavior and resources changes has been an extension of the asymmetric cost behavior. Asymmetry phenomenon is a new thinking created by [1] but it still under discussion because they did not use many drivers, their findings used sales revenues change only and ignored a physical output data for two reasons: physical data is not available, and sales revenues typically is a more an appropriate empirical measure for activity than physical data [10]. The current study provides an empirical examining that added a new dimension for explaining how capacity utilization change moderates the relationship between capacity changes and labor costs behavior. In addition, our findings showed a complex fundamental design of asymmetric cost behavior that combines two roles: labor costs behavior is sticky on a prior capacity increase without the interaction of capacity utilization changes. Second, labor costs behavior is anti-sticky on a prior capacity increase within the interaction of capacity utilization changes, means the moderation effects of capacity utilization made the opposite of the standard predictions.

The findings of the current study have revealed that capacity utilization changes significantly have affected labor costs behavior. Furthermore, these predictions explain the influence of managerial expectations for future on firm resources such as the general structure of optimal decisions with resources adjustment costs, which generate asymmetry behavior. Finally, using capacity utilization changes with asymmetric relations can decrease the degree of sticky behavior between labor costs and capacity change, interaction capacity utilization changes with a prior capacity decrease can converse the asymmetry degree from sticky to anti-sticky. The results of moderation are unique and would provide productive avenues for future studies.

Abstract. At this stage, changing the mode of economic growth and optimizing the industrial structure is the important content for China's economy restructuring and steady growth, so the adjustment of industrial structure is imminent, especially manufacturing. This paper describes the present situation of China's technology innovation and the development of manufacturing, and analyzes the problems of manufacturing upgrading, and then uses the data of China' 27 manufacturing sub-sectors from 2005 to 2014 and establishes the regression model. The results showed that technical innovation has a positive role in promoting the upgrading of China's manufacturing, but its effect is still affected by certain factors, and the differences on technical innovation are obvious. Finally, in view of the problems found in the research, the paper puts forward some policy suggestions for the upgrading of China's manufacturing industry, such as increasing R&D investment, building system of financial support, and establishing a technical alliance about industrial-academic-research.

Keywords: Technical innovation · Manufacturing upgrading · Labor-intensive industry · Capital-intensive industry · Technology-intensive industry

1 Introduction

The manufacturing industry reflect a country's productivity level, as well as present the national competitiveness. It is the cornerstone of the realization of social progress and national prosperity. With the advantage of reform and opening policy, the labor force, some other natural resources and other factors, China' manufacturing industry has created a miracle and continued growth of economy. In 2010, China's manufacture value added exceeded the United States, becoming a manufacturing country, is worthy of the name. As shown in Fig. 1.

Since the financial crisis in 2008, the development of the real economy has been paid more and more attention by the countries all over the world. Therefore,

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_22

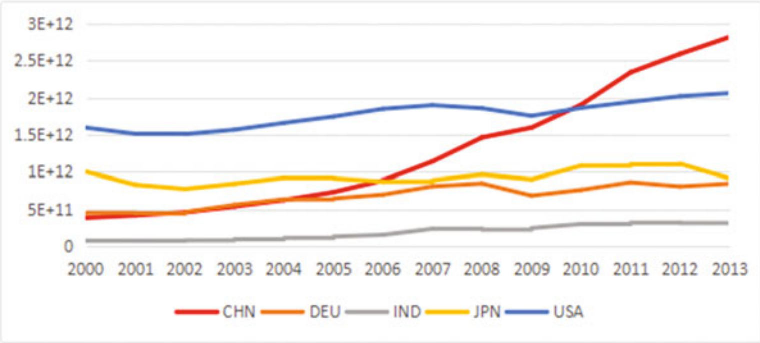

Fig. 1. Comparison of manufacturing value added (dollar)

the development of manufacturing industry and the expansion of exports are the key to the transformation of the world economic structure. The developed countries have taken measures to revitalize the manufacturing sector. For instance, the USA wishes "re industrialization" once again to opened the gap with the developing countries, to further promote its economic and social development, to enhance its competitiveness in the international manufacture. Germany issued "industry 4.0" which was proposed to establish an information physics system network in 2013, making itself the creator and supplier of advanced intelligent manufacturing technology. It provides the opportunities of technological innovation for China's implementation of "made in China 2025". At the same time, some developing countries take advantage of opportunities of the new round of international industrial transfer, promote the industrialization process, thereby exacerbating China's manufacturing competitive environment.

With China's rising labor costs and resource depletion, the advantage of traditional manufacturing relying on cheap labor and resources is gradually lost. In a word, we must rely on technological innovation to speed up the restructuring of China's manufacturing and the transformation of development mode. But how does technological innovation affect the manufacturing upgrading of different factors intensive industrial structure? This is an urgent problem in the process of China's industrialization. In view of this, based on the status of manufacturing upgrading and the thinking of upgrading power, this paper focuses on the effect of technical innovation on manufacturing upgrading.

2 Literature Review

Foreign scholars have carried on the thorough discussion on the technology innovation and the industrial structure evolution, but it mostly based on the industrial level. Guan [4] analyzed the relationship between technological innovation and industrial competitiveness in the ability of R&D personnel's learning and knowledge acquisition, research and development ability, and the research showed that technology innovation is the key way to promote the competitiveness of the industry. Castellacci [2] studied the relationship between the external innovation environment of technology innovation and industrial competitiveness, the results show that the economic policies based on market oriented and institutional arrangements will directly affect the innovation mode, and play the role in industry competitiveness. Cohen [3] considered the Schumpeterian hypotheses relating innovation to market structure and firm size, and considers in more depth the role of firm characteristics and industry-level variablesłbroadly characterized as reflecting demand, technological opportunity, and demand conditionsłin affecting firms' innovative activity and performance. Adak [1] focused on the influence of technological progress and innovation on the Turkish economy, and got the result that a significant effect of technological progress and innovation on economic growth. Hong et al. [5] found that government grants exert a negative influence on innovation efficiency of high-tech industries. However, the impact of private R&D funding is significant and positive. In view of the problem of upgrading the structure of manufacturing industry, this paper will not discuss it in detail.

Domestic scholars focus on the research on the mechanism and path of technological innovation to upgrade the manufacturing industry. Sun and Ye [6] analyzed the role and mechanism of innovation for transformation and upgrading of manufacturing industry based on the connotation of the innovation drive, and considered innovation driven to give impetus to manufacturing from three aspects of power dimension, elements dimensions and competition dimension. Zhao and Qiao [8] studied the upgrading mode of Shanghai' manufacturing industry, and pointed out that Shanghai needed to promote technology improvement and innovation of the traditional manufacturing, and created growth industry through the industrialization of high and new technology industry, and pushed on the dynamic integration of producer services and advanced manufacturing technology, all of which strengthen policy guidance so that it can realize comprehensively manufacturing upgrading.

From what has been discussed above, the existing literature on the analysis of the technology innovation's influence on manufacturing upgrading, which was mostly based on regional classification, and there is less research based on manufacturing industry so that it failed to reveal the impact of technological innovation on Internal structure changes in manufacturing industry. Based on the panel data model, the paper made an empirical analysis of the differences in the impact of scientific and technical personnel, R&D internal expenditure, sales revenue of new products, the number of effective invention patent, cost of technical renovation, main business profit on the manufacturing upgrading of labor-intensive industry, capital-intensive industry and technology-intensive industry. Through the analysis of the technology innovation's influence on different kinds of different factors intensive industries, that can provide guidance for our country to make the corresponding different incentive policy on technological innovation, and avoid invalid policy, and make the technological innovation to better play its role so to realize the upgrading of the manufacturing structure. It has certain practical significance.

3 Theoretical Basis

According to the classification standards of the National Bureau of Statistics, the manufacturing industry is divided into 31 categories, due to the lack of data during some years, this paper chooses 27 Subdivision manufacturing industry of national above-scale industrial as the research object. Referring to the classification method of the factor intensity and Wang and Dong' classification method [7] based on the structure of the manufacturing, the 27 Subdivision industry of China's manufacturing industry is divided into labor-intensive industry, capital intensive industry and technology intensive industry. The specific classification is shown in Table 1:

Table 1. Classification of different factors intensive industries

Manufacturing industry type	Industrial distribution
Labor-intensive industry	Agricultural food processing industry, food manufacturing, beverage and refined tea industry, tobacco industry, textile industry, textile and apparel and footwear products industry, leather and feather industry, Wood processing industry
Capital-intensive industry	Furniture manufacturing, paper making and paper products, printing and recording media copying, Stationery industry, Oil processing, coking & nuclear fuel processing, Chemical Fiber Industry, Rubber and plastic products industry, non-mental mineral product industry, Ferrous metal smelting and rolling processing industry, Non-ferrous metal smelting and rolling processing industry, Metal products manufacturing
Technology-intensive industry	Pharmaceutical Industry, the manufactures of chemical materials and products, General Equipment Manufacturing sector, Special Equipment Manufacturing Sector, Electronic and Communication Equipment Manufacturing Sector, Electrical machine equipment manufacturing, Transportation Manufacturing, instruments and cultural office machinery

4 Empirical Analysis

4.1 Index Selection

(1) Manufacturing Upgrading Index Selection
In existing research, the value added rate of manufacturing industry is generally considered as a comprehensive reflection of the economic benefits and growth quality of the manufacturing industry. There are also some scholars having used industrial profit and tax amount, but the main business profit of the Subdivision manufacturing industry is chosen as an index to measure the manufacturing upgrading. The reason why the author choose main business profit is that manufacturing upgrading means improving the competitiveness and profitability of enterprises. On the other hand, choosing the main business profit instead of net profit ratio, that can eliminate government subsidies which enterprises receive from government and other non-recurring profit, at the same time, taking into account the availability of data, this paper chooses main business profit as the variable of manufacturing upgrading.

(2) The Index Selection of Technological Innovation
In the measurement of technological innovation by domestic scholars, scientific and technological personnel, R&D investment intensity and other indicators are generally accepted evaluation indicators. However, considering the transformation and application of technological innovation achievements, this paper chooses scientific and technical personnel, R&D internal expenditure, sales revenue of new products, the number of effective invention patent, cost of technical renovation to measure the level of technology innovation according to the availability of data. The author tend to specifically study the impact of technological innovation on the manufacturing upgrading, and don't just use a single indicator of technological innovation.

(3) The Selection of Control Variable
In this paper, adding the input of labor and capital which his regarded as control variables into the model, that can reflect the impact of technical innovation and factor input on the changes of manufacturing added value. The net value of fixed assets of industrial enterprises above designated size approximately represent material capital investment, and annual average number of employed persons in all sectors of the manufacturing industry means the number of workers in the manufacturing.

4.2 Data Description

The data which is used in the paper come from the "Statistical yearbook in China", "Industrial Statistics Yearbook in China", "Labor Statistics Yearbook in China", "Statistical yearbook of scientific and technological activities of industrial enterprises", Some of the data are compiled according to the original data of the statistical yearbook.

(1) Comparison of Scientific and Technical Personnel of Various Types of Manufacturing Industry in China
As shown in Fig. 2, all kinds of scientific and technical personnel of manufacturing industry of our country from 2005 to 2008 has maintained steady growth, due to the financial crisis in 2008, from 2008 to 2009 it showed a downward trend, various types of science and technology personnel began to increase slowly after 2009, at the same time, China's scientific and technical personnel of labor-intensive industry and capital -intensive industry has been lagging behind in technology-intensive industry and the total is about half.

(2) Comparison of R&D Internal Expenditure of Various Types of Manufacturing Industry in China
As shown in Fig. 3, General speaking, among 2005–2014, China's various types of R&D internal expenditure of manufacturing industry is up forwards except among 2008–2009. However, R&D internal expenditure of labor-intensive industry and capital-intensive industry is slower than the growth of technology-intensive industry.

(3) Comparison of Sales Revenue of New Products of Various Types of Manufacturing Industry in China
As shown in Fig. 4, China's sales revenue of new products of technology-intensive industry grew so slowly and it almost unchanged. It shows that China's technology-intensive industry has poor ability of technology transformation, and the scientific and technological achievements can not be effectively translated into practical productive forces. But the capital intensive manufacturing and labor-intensive manufacturing industry has maintained a steady growth. Though the number of effective invention patent of capital and labor intensive manufacturing is far less than the technology intensive industry, the latter continuing innovation investment will make the sales revenue of new products greatly improved.

(4) Comparison of Effective Invention Patent Number of Various Types of Manufacturing Industry in China
As shown in Fig. 5, the number of effective invention patent in China's technology-intensive industry went through a growth spurt, and those of labor-intensive industry and capital-intensive industry increased much slower. Perhaps China's technology-intensive industry more and more pay attention to innovation output and the other two industries funding for innovation is not enough.

(5) Comparison of Cost of Technical Renovation of Various Types of Manufacturing Industry in China
As shown in Fig. 6, cost of technical renovation in China's labor-intensive industry grew slowly, until the peak reached early 2013, after that it was a downward trend. While cost of technical renovation in China's technology-intensive industry basically is on the rise from 2005 to 2010, and exceeded the cost of technical renovation capital- intensive industry in 2010, then it began to decline in 2011, finally it reached at the same level as capital-intensive industry in 2014.

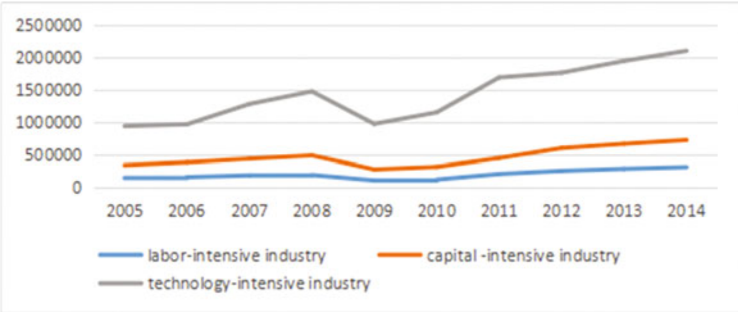

Fig. 2. Comparison of scientific and technical personnel

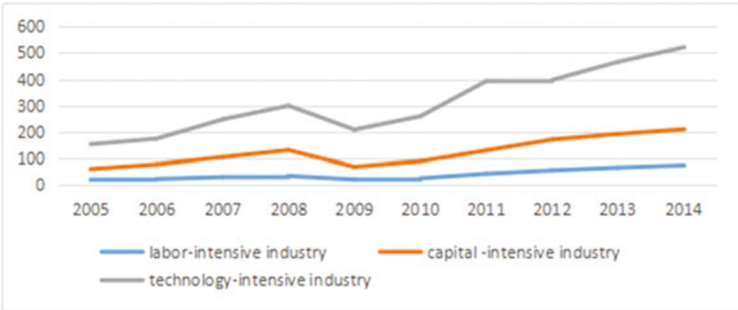

Fig. 3. Comparison of R&D internal expenditure (billion)

(6) Comparison of Main Business Profit of Various Types of Manufacturing Industry in China
As shown in Fig. 7, main business profit in the three kinds of China's manufacturing overall were rising, and those of technology-intensive manufacturing is much more profitable than capital-intensive industry and labor-intensive industry, but capital and labor intensive manufacturing industry's main business profits are similar.

4.3 The Construction of the Model

According to the selected model variables, based on the augmented Cobb Douglas production function, this paper establishes econometric model as follows:

$$Y_{it} = e^{c+\delta_1 \ln RD_{it}+\delta_2 \ln ST_{it}+\delta_3 \ln EP_{it}+\delta_4 \ln PS_{it}+\delta_5 \ln TR_{it}+u_{it}} K_{it}^{\alpha} L_{it}^{\beta}. \quad (1)$$

Among them, Y_{it} represents the main business profit of manufacturing during t period i industry; K_{it}, L_{it} represents fixed capital investment and the amount of labor during t period i industry respectively; RD_{it}, ST_{it}, EP_{it}, PS_{it} and

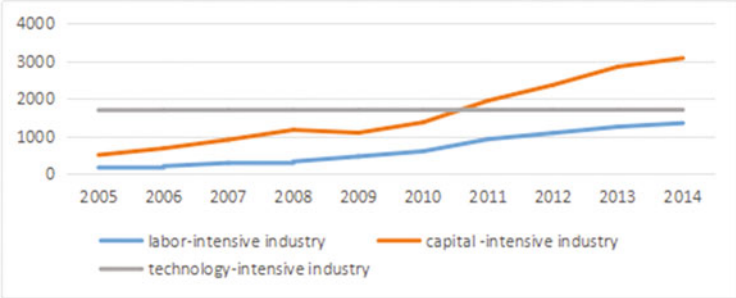

Fig. 4. Comparison of sales revenue of new products (billion)

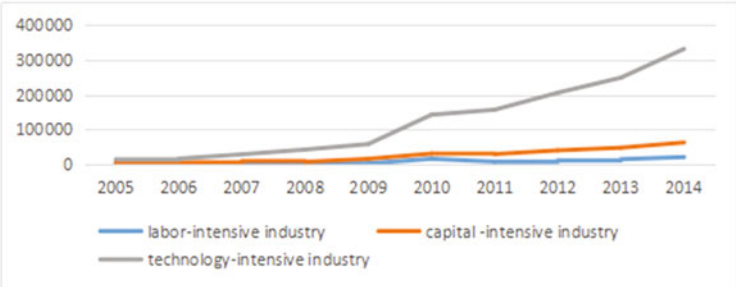

Fig. 5. The number of comparison of effective invention patent

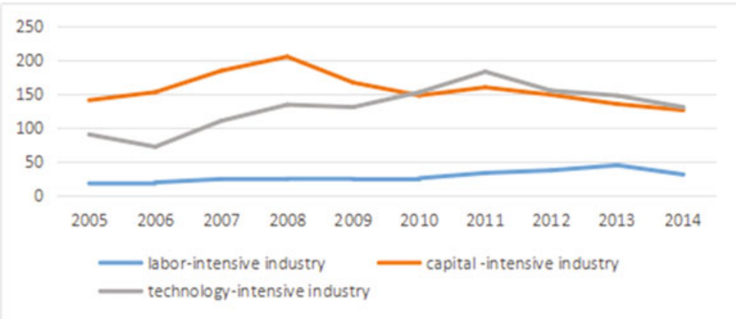

Fig. 6. Comparison of cost of technical renovation (billion)

TR_{it} represents R&D internal expenditure, scientific and technical personnel, the number of effective invention patent, sales revenue of new products, cost of technical renovation during t period i industry, u_{it} represents the random error.

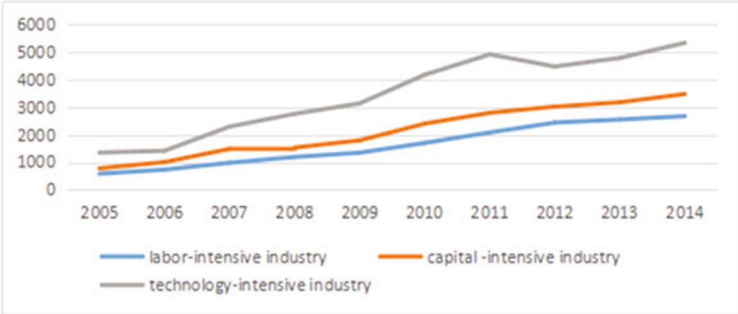

Fig. 7. Comparison of main business profit (billion)

Before testing the data of model, the Eq. (1) on both sides are processed into logarithmic for linear regression model, the model as follows:

$$\begin{aligned} \ln Y_{it} = & \; c + \alpha \ln K_{it} + \beta \ln L_{it} + \delta_1 \ln RD_{it} + \delta_2 \ln ST_{it} + \delta_3 \ln EP_{it} + \delta_4 \ln PS_{it} \\ & + \delta_5 \ln TR_{it} + u_{it}. \end{aligned}$$

4.4 Variable Inspection

(1) Correlation Analysis of Variables
The following is the correlation analysis of selected variables, and from Table 2 we can see that independent variables were significantly correlated with the dependent variable. Specifically, the stronger technique innovation capability is, the higher the main business profit of the industry is. Besides, the capital and labor input is in positive correlation with the operating profits. At the same time, the respective variables are also highly relevant. The explanatory variables including scientific and technical personnel, R&D internal expenditure, sales revenue of new products, the numbers of effective invention patents and cost of technical renovation was significantly correlated in 1% level, and the correlation coefficient is greater than 0.8. It reveals that these indicators selection of technical innovation is over-repeated, and the correlation is very strong.

(2) Empirical Results
After multicollinearity inspection of several variables, we found that VIF is 20.72 in average, more than 10, which shows that there is serious multicollinearity between variables. Via detecting x_3 and x_4 linear with other explanatory variables exist serious, so they should be removed in the model. The value of VIF is less than 10 after deletion. So the final determination of the independent variable is x_1, x_2, x_5 and x_6 in this paper.

Because different manufacturing industries with individual differences and mixed OLS cannot reflect individual differences, it is imperative to use fixed effects and random effects model for regression. Considering the upgrading of industrial structure with inertia index, this paper uses dynamic panel model

Table 2. Correlation analysis table

	y	x_1	x_2	x_3	x_4	x_5	x_6	x_7
y	1							
x_1	0.671^{***}	1						
x_2	0.713^{***}	0.644^{***}	1					
x_3	0.707^{***}	0.685^{***}	0.822^{***}	1				
x_4	0.739^{***}	0.747^{***}	0.758^{***}	0.973^{***}	1			
x_5	0.751^{***}	0.724^{***}	0.692^{***}	0.883^{***}	0.939^{***}	1		
x_6	0.716^{***}	0.585^{***}	0.651^{***}	0.809^{***}	0.814^{***}	0.841^{***}	1	
x_7	0.600^{***}	0.760^{***}	0.523^{***}	0.764^{***}	0.845^{***}	0.813^{***}	0.575^{***}	1

and apply the system of GMM estimation to eliminate endogenous for further analysis. In this paper, the regression model is as follows, model 1 is on behalf of the panel data model, and model 2 is on behalf of the dynamic panel model.

$$\text{Model 1} \quad y_{it} = \alpha_i + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_5 + \beta_4 x_6 + \mu_{it},$$
$$\text{Model 2} \quad y_{it} = \alpha_i + \gamma y_{it-1} + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_5 + \beta_4 x_6 + \mu_{it}.$$

Model 1 is the result of fixed effect, model 2 is he result of random effect. The result of Houseman test showed that Chi2(4) $=$ 7.22, the value of P is 0.1249, that can't refuse null hypothesis of Houseman test, so random effects model should be used. It can be seen from model 2, the technical innovation ability can really promote the upgrading of industrial structure for the manufacturing industry. In particular, sales revenue of new products increased by 1%, the industry's main business profit increased 0.222%; cost of technical renovation increased by 1%, the industry's main business profit increased 0.17%. Because of the diversification of products and competition, the invention of new products and the input of technological transformation can increase brand influence and competitiveness in a highly competitive market environment, thus increasing corporate profits. From the point of control variables, net value of fixed assets increased by 1%, the industry's main business profit increased 0.173%; average number of employees in manufacturing industry increased by 1%, the industry's main business profit increased 0.323%.

After the testing, the best model for dynamic panel is model 3 after the introduction of the second order. It is found that the equation is over identified and the value of P is 0.4130, which shows that the instrumental variable is effective, So the model is tenable. The lagged items of the explanatory variables entered into the model and the author found that the lagged items had a significant impact. Specifically, a lag of the main business profit increased by 1%, the current main business profit will be reduced by 0.342%; two lag of main business profit increased by 1%, the current main business profit will be reduced by 0.301%; it can be seen that three lag of main business profits will increase the current main business profit from the model 4. Perhaps it was related to the

manufacturing industry in our country which is mainly processing enterprises, and many of which is low value-added industries. Companies tend to increase plant equipment investment in the current or in the next period to increase the profits in the future when the current operating profit increased (Table 3).

5 Conclusion

In this paper, it can be seen from the empirical results that the invention of new products and technological innovation can increase the main business profits and promote the upgrading of manufacturing industrial structure. China is a big manufacturing country, whose economic growth is mainly driven by the second industry at present, and China's manufacturing industry accounted for the largest proportion of the second industry. At the same time, the manufacturing industry can absorb a lot of labor force. The development of the manufacturing industry is of great significance to the increase of the employment rate, reduction of the gap between the rich and the poor and the stability of the society. Therefore, the government should support the technological innovation of manufacturing industry, the enterprise itself also should actively seek innovation to make themselves invincible in the tide of marketization and internationalization.

Abstract. This paper aims to develop a crash counts by severity based hotspot identification method by extending the traditional empirical Bayes method to a generalized nonlinear model-based mixed multinomial logit approach. A new safety performance index and a new potential safety improvement index are developed by introducing the risk weight factor and compared with traditional indexes by employing four hotspot identification evaluating methods. The comparison results reveal that the new safety performance index derived by the generalized nonlinear model-based mixed multinomial logit approach is the most consistent and reliable method for identifying hotspots. Finally, a regional map based analytical platform is developed by expanding the safety performance module with the new safety performance index and potential safety improvement functions.

Keywords: Hotspot identification · Crash severity · Safety performance index · Potential safety improvement index · Regional map based analytical platform

1 Introduction

The identification of crash hotspots, also referred to as hazardous road locations, high-risk locations, accident-prone locations, black spots, sites with promise, or priority investigation locations, is the first step of the highway safety management process [10]. Hotspot identification (HSID) is of great importance to land transport authorities in their efforts to improve the safety of highways. There is a fairly extensive body of literature focused on methods for HSID [1,2,11].

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_23

There are papers that discuss methods based on accident count or frequency [3], papers that employ both accident rate (AR) and rate quality control [13], and others that adopt the joint use of accident frequency and rate to flag sites with promise [7]. To correct for the regression-to-the-mean bias associated with typical HSID methods [4], some researchers have suggested using the empirical Bayes (EB) techniques [5]. This method combines clues from both the accident history of a specific site and expected safety of similar sites, and has the advantage of revealing underlying safety problems which otherwise would not be detected.

Some recent studies indicated that the severity of crashes should not be neglected in the hotspot identification (HSID) process [12]. The hotspots corresponding to high crash risk locations can be quite different when considering the crash frequency by different levels of crash severity. It is particularly important to take into account crash severities in site ranking, because the cost of crashes could be hugely different at different severity levels. This means that, for instance, a road segment with higher frequency of fatal accidents may be considered more hazardous than a road segment with fewer fatal accidents, but more severe or minor injury accidents. Therefore, it is necessary to consider crash severity when identifying hotspots.

While the equivalent property damage only (EPDO) method [15] is a way of comparing severity types among each other, inconsistencies can occur when evaluating the HSID methods in different time periods, since the traditional EPDO method overemphasizes sites with a low frequency of fatal or severe crashes [10]. As a result, a risk weight factor is developed in this research by combining the average crash cost with the corresponding probability for each type of crash severity. In order to develop a new safety performance index (SPI) and a new potential safety improvement index (PSII), a generalized nonlinear model-based mixed multinomial logit approach is introduced to extend the traditional empirical Bayes method for estimating the probability of crashes in different severity levels. The new method developed in this paper is compared with other hotspot identification methods by employing four hotspot identification evaluating methods and applied on a regional map based analytical platform.

2 Crash Counts by Severity Prediction Model

The EB method requires the use of pertinent crash prediction models. For the purpose of the study, in order to account for unobserved heterogeneity and nonlinear effects of variables to extract more complex relationship, a refinement of the generalized nonlinear model-based (GNM-based) mixed multinomial logit (MNL) approach developed by Zeng et al. [17] was used.

2.1 GNM-based Mixed MNL Model

In this research, three categories are considered for the crash severity (i.e., property damage only (PDO) ($k = 1$), injury ($k = 2$), and fatal ($k = 3$)). The crash severity type, denoted by Y, was the response variable, whereas contributing factors for roadway geometric characteristics, traffic characteristics, and weather conditions were the independent variables denoted by x_{ij} $(j = 1, 2, \cdots, J)$, where i denotes the observation and J denotes the number of independent variables. Y is then defined as follows:

$$Y = \begin{cases} 1, & \text{if crash is PDO,} \\ 2, & \text{if crash is injury,} \\ 3, & \text{if crash is fatal,} \end{cases} \tag{1}$$

Ye and Lord [16] demonstrated that fatal crashes should be set as the baseline severity for the mixed MNL model. To minimize the bias and reduce the variability of a model, in this paper, fatal crashes were used as the baseline severity category for comparison with the other categories.

In order to account for the unobserved heterogeneity, let $\Omega = (\omega_1, \omega_2, \omega_3)$, as discussed previously, and note that the Ω vector has a continuous density function $f(\Omega|\Gamma)$, where Γ is a vector of parameters charactering the density function, $\omega_k = [\omega_{k1}, \omega_{k2}, \cdots, \omega_{kJ}]^T$ is the coefficient vector for the kth category of the predictor vector. According to [6,9,14], the resulting mixed MNL crash severity probabilities are as follows:

$$Pr(Y_i = K) = \int \frac{1}{1 + \sum_{k=1}^{K-1} e^{U_{ki}\omega_k + \beta_{k0}}} f(\Omega|\Gamma) d\Omega, i = 1, 2, \cdots, n, \tag{2}$$

$$Pr(Y_i = k) = \int \frac{e^{U_{ki}\omega_k + \beta_{k0}}}{1 + \sum_{k=1}^{K-1} e^{U_{ki}\omega_k + \beta_{k0}}} f(\Omega|\Gamma) d\Omega, i = 1, 2, \cdots, n; k = 1.2, \cdots, K-1, \tag{3}$$

where $Pr(Y_i = k)$ is the probability of crash severity type k; $U_{ki} = [U_{ki1}(x_{i1}), U_{ki2}(x_{i2}), \cdots, U_{kiJ}(x_{iJ})]$ is the nonlinear predictor vector of observation i for contributing factors (i.e., roadway geometric characteristics, traffic characteristics, weather conditions); β_{k0} is an intercept term specific to crash severity type k. Since U_{ki} is considered as a nonlinear predictor vector of observation i for contributing factors, Eqs. (2) and (3) are called the prediction functions of the GNM-based mixed MNL approach.

2.2 Predicting Crash Counts in Different Severity Levels

Based on the statistical approaches available to address the unobserved heterogeneity [8], the expected crash density in a roadway segment i can be estimated as below:

$$d_i = \int e^{U_i \omega + \beta_0} f(\omega|\varphi) d\omega, i = 1, 2, \cdots, n, \tag{4}$$

where $d_i = \mu_i / L_i y_i$ is the crash density of roadway segment i during a certain time period; μ_i is the expected crash frequency (or rate) along segment i during a certain time period; L_i is the segment length in miles; y_i is the time period length (years) of crash frequency of roadway segment i; $\omega = [\omega(1), \omega(2), \cdots, \omega(J)]^T$ is the coefficient vector for $U_i = [U_1(x_{i1}), U_2(x_{i2}), \cdots, U_J(x_{iJ})]$ when estimating the expected crash density.

According to Eqs. (2)–(4), the expected crash density for different severity levels can be estimated as follows.
(1) Expected PDO crash density:

$$\begin{aligned} d_{i1} &= d_i \cdot Pr(Y_i = 1) \\ &= \int e^{U_i\omega+\beta_0} f(\omega|\varphi)d\omega \cdot \int \frac{e^{U_{1i}\omega_1+\beta_{10}}}{1+\sum_{k=1}^{2} e^{U_{ki}\omega_k+\beta_{k0}}} f(\Omega|\Gamma)d\Omega,\ i = 1, 2, \cdots, n, \end{aligned} \tag{5}$$

where d_{i1} is the expected PDO crash density along segment i during a certain time period.
(2) Expected injury crash density:

$$\begin{aligned} d_{i2} &= d_i \cdot Pr(Y_i = 2) \\ &= \int e^{U_i\omega+\beta_0} f(\omega|\varphi)d\omega \cdot \int \frac{e^{U_{2i}\omega_2+\beta_{20}}}{1+\sum_{k=1}^{2} e^{U_{ki}\omega_k+\beta_{k0}}} f(\Omega|\Gamma)d\Omega,\ i = 1, 2, \cdots, n, \end{aligned} \tag{6}$$

where d_{i2} is the expected injury crash density along segment i during a certain time period.
(3) Expected fatal crash density:

$$\begin{aligned} d_{i3} &= d_i \cdot Pr(Y_i = 3) \\ &= \int e^{U_i\omega+\beta_0} f(\omega|\varphi)d\omega \cdot \int \frac{1}{1+\sum_{k=1}^{2} e^{U_{ki}\omega_k+\beta_{k0}}} f(\Omega|\Gamma)d\Omega,\ i = 1, 2, \cdots, n, \end{aligned} \tag{7}$$

where d_{i3} is the expected fatal crash density along segment i during a certain time period. Based on Eqs. (5)–(7), a crash counts by severity based hotspot identification (CCS-based HSID) method is developed in the following section.

3 Crash Counts by Severity Based Hotspot Identification Method

In this section, a CCS-based HSID method is developed by employing the GNM-based MNL approach discussed above. A new SPI and a new PSII are developed by introducing the risk weight factor.

3.1 Safety Performance Index

Based on Eqs. (5)–(7), the EPDO crash frequency measure is modified and employed to weight crashes according to severity (fatal, injury, and PDO) to develop a combined crash density and severity score (CCDSS) for each site [15]. The weight factors are based on PDO crash costs. An EPDO value summarizes the crash costs and severity.

In the calculations, weight factors were assessed from the crash cost estimates developed by WSDOT in the Annual Collision Data Summary Reports (2011–2014). Using average crash costs for motorways, fatal crashes ($2,227,851) have a weight factor equal to 981, injury crashes ($20,439) have a weight factor equal to 9, and PDO crashes ($2,271) have a weight factor equal to 1. However, if we only consider the average crash costs to be the weight factor, inconsistencies can occur when evaluating the HSID methods in different time periods, since the traditional EPDO method overemphasizes sites with a low frequency of fatal or severe crashes [10]. As a result, a risk weight factor is developed in this research by combining the average crash cost with the corresponding probability for each type of crash severity. Let F_w denote the fatality risk weight factor, I_w, the injury risk weight factor, and P_w, the PDO risk weight factor, then they are defined by using the following equations:

$$F_w = \frac{c_F \cdot \eta_F}{c_P \eta_P}, \;\; I_w = \frac{c_I \cdot \eta_I}{c_P \eta_P}, \;\; P_w = 1, \tag{8}$$

where $c_F = \$2,227,851$, $c_I = \$20,439$, and $c_p = \$2,271$ are the average costs for fatal, injury, and PDO crashes; η_F, η_I, and η_P are the probabilities of occurrence for fatal, injury, and PDO crashes.

Based on the preceding analysis, the expected CCDSS (ECCDSS) for roadway segment i can be defined as:

$$\text{ECCDSS}_i = d_{i1} F_w + d_{i2} I_w + d_{i3} P_w, \;\; i = 1, 2, \cdots, n. \tag{9}$$

Equation (9) is regarded as a safety performance function (SPF). In fact, the ECCDSS is an extension of the expected crash density based on the GNM. When the fatality weight factor and the injury weight factor are both equal to 1 (i.e., $F_w = I_w = 1$), the ECCDSS will degrade to an expected crash density based on the GNM. The EB method is a statistical method that combines the observed crash frequency with the predicted crash frequency using the SPF to calculate the expected crash frequency for a site of interest. The EB method pulls the crash count towards the mean, accounting for the regression to the mean (RTM) bias. A lot of studies have proved that the EB approach is the most consistent and reliable method for identifying sites with promise [2,10]. In this research, the EB method is employed to develop the new SPI as shown in the following:

$$\text{SPI}_i = \lambda_i \text{ECCDSS}_i + (1 - \lambda_i) \text{OCCDSS}_i, \;\; i = 1, 2, \cdots, n, \tag{10}$$

where OCCDSS_i is the observed combined crash density and severity score (OCCDSS) for roadway segment i and is defined as below:

$$\text{OCCDSS}_i = \sigma_{i1} F_w + \sigma_{i2} I_w + \sigma_{i3} P_w, \;\; i = 1, 2, \cdots, n, \tag{11}$$

where σ_{i1}, σ_{i2}, σ_{i3} are the observed fatal, injury, and PDO crash density along segment i during a certain time period respectively; λ_i is a weighting factor that is calculated through the following equation:

$$\lambda_i = \frac{1}{1 + \alpha_i \text{ECCDSS}_i}, \tag{12}$$

where α_i is the over dispersion parameter, which is a constant for a given model and is derived during the regression calibration process.

3.2 Potential Safety Improvement Index

The PSII was developed as the difference between the SPI and the ECCDSS, as follows:

$$\begin{aligned}\mathrm{PSII}_i &= \lambda_i \mathrm{ECCDSS}_i + (1-\lambda_i)\mathrm{OCCDSS}_i - \mathrm{ECCDSS}_i \\ &= \mathrm{SPI}_i - \mathrm{ECCDSS}_i,\ \ i = 1, 2, \cdots, n,\end{aligned} \tag{13}$$

when the PSII value is greater than zero, a site experiences a higher combined frequency and severity score than expected; when the PSII value is less than zero, a site experiences a lower combined frequency and severity score than expected.

4 Case Study Data

This study was performed based on crash data records collected in Washington State from January 2011 to December 2014 (i.e., a four-year period). The data were obtained from the Washington State Department of Transportation (WSDOT), Highway Safety Information System (HSIS), and the Digital Roadway Interactive Visualization and Evaluation Network (DRIVE Net) platform at the University of Washington (UW). Four major datasets are included in this study: crash data, roadway geometric characteristics, traffic characteristics, and weather conditions. These datasets detail all of the information regarding crash frequency, locations, severities, roadway segment length, average number of lanes (NOL), horizontal curve type (HCT), curvature of the segment (COS), average width of outer shoulder (WOS), average width of inner shoulder (WIS), average width of median (WM), dominant lane surface type (DLST), dominant outer shoulder type (DOST), dominant inner shoulder type (DIST), dominant median type (DMT), average speed limit (ASL), AADT, AADT per lane, road surface conditions (RSC, i.e., dry, wet, snow/ice/slush), and visibility (good, bad).

In this research, we consider using the proportion of the crash frequency for each type of severity based on the collected crash data of 21,396 road segments along I-5, I-90, I-82, I-182, I-205, I-405 and I-705 in Washington to represent the probability of crash occurrence for each severity level in this area. Based on the crash counts after data quality control, the total number of crashes recorded during the data collection period was 47,657, including 134 fatal crashes, 13,824 injury crashes, and 33,699 PDO crashes. Thus, we can calculate that $\eta_F = 0.0028$, $\eta_I = 0.29$, $\eta_P = 0.7072$; then, the values of the risk weight factors are obtained by employing Eq. (8) as $F_w = 3.884$, $I_w = 3.691$, $P_w = 1$.

5 Test Results and Discussion

In order to demonstrate the effectiveness of the SPI and PSII as developed in this research, they are compared with six reference performance indexes, which include the expected crash density based on the conventional safety performance function from the Highway Safety Manual (HSM) (i.e., NB GLM), expected crash density based on the GNM, EB estimated crash density based on the NB GLM,

Table 1. Results of site consistency test of various HSID methods

HSID method index (h)	HSID method name	Parameter Settings			
		$\gamma = 0.01$		$\gamma = 0.05$	
		$SCT_{h,t}$ Period 1 (2011–2012)	$SCT_{h,t+1}$ Period 2 (2013–2014)	$SCT_{h,t}$ Period 1 (2011–2012)	$SCT_{h,t+1}$ Period 2 (2013–2014)
1	SPI	22943.06	21521.79	46310.12	44251.68
2	PSII	22198.11	20879.23	45389.79	43921.56
3	CD (NB GLM)	21036.33	20105.38	43897.54	42868.83

EB estimated crash density based on the GNM, ARP based on the NB GLM, and ARP based on the GNM.

Cheng and Washington [2] have developed four new evaluation tests for HSID. In this research, the site consistency test, method consistency test, total rank differences test, and the total score test are employed to evaluate the effectiveness of the developed safety performance indexes and reference performance indexes.

The evaluation experiment uses the following procedure, which closely mimics how reactive safety management programs are conducted in practice:

(1) For the purpose of comparing alternate HSID approaches, the 4-year accident data were separated into two periods, Period 1 (Year 2011–2012) and Period 2 (Years 2013–2014).
(2) Road sections (intersections, ramps, two-lane rural roads, etc.) are segregated so that the safety of similar sites can be fairly compared. In this evaluation, the analysis is based on the analysis of nine functional classifications of road sections.
(3) For each HSID method, similar road sections are sorted in descending order of estimated safety (noting that the four HSID methods rank sites according to different criteria).
(4) Sections with the highest rankings are flagged as hotspots (in practice these sites will be further scrutinized). Typically, a threshold is assigned according to safety funds available for improvement, such as the top 1% of sites. In this evaluation, both the top 1% and 5% of the locations are used as experimental values.

5.1 Site Consistency Test

The site consistency test (SCT) measures the ability of an HSID method to consistently identify a high-risk site over repeated observation periods. The test rests on the premise that a site identified as high risk during time period i should also reveal an inferior safety performance in a subsequent time period $t+1$, given that the site is in fact high risk and no significant changes have occurred at the site. The method that identifies sites in a future period with the highest crash frequency is the most consistent. In this research, the SPI developed above is employed as the safety performance criterion in the subsequent time period. The test statistic is given as:

$$\mathrm{SCT}_{h,t+1} = \sum_{q=n-n\gamma+1}^{n} \mathrm{SPI}_{q,h,t+1},\ h = 1, 2, \cdots, H, \tag{14}$$

where h is the HSID method index being compared; n is the total number of roadway segment, γ is the threshold of identified hotspots (e.g., $\gamma = 0.01$ corresponds with top 1% of n roadway segments identified as hotspots, and $n\gamma$ is the number of identified hotspots).

From the site consistency test, it is shown in Table 1 that the SPI method outperforms other HSID methods in identifying both of the top 1% and 5% of hotspots with highest SCT values, 21521.79 and 44251.68, in Period 2, followed closely by the EB CD (GNM) method. The ARP (NB GLM) performs the worst in both cases, with the identified hotspots experiencing the lowest number of SCT values, say, 19034.25 and 42106.73, respectively (although the ARP is based on reduction potential, so the total count can be misleading).

5.2 Method Consistency Test

The method consistency test (MCT) evaluates a method's performance by measuring the number of the same hotspots identified in both time periods. It is assumed that road sections are in the same or similar underlying operational state and their expected safety performance remains virtually unaltered over the two analysis periods. With this assumption of homogeneity, the greater the number of hotspots identified in both periods the more consistent the performance of the HSID method. The test statistic is given as:

$$\mathrm{MCT}_h = \{s_{n-n\gamma+1}, s_{n-n\gamma}, \cdots, s_n\}_{h,t} \bigcap \{s_{n-n\gamma+1}, s_{n-n\gamma}, \cdots, s_n\}_{h,t+1},\ h = 1, 2, \cdots, H, \tag{15}$$

here, only segments $\{s_{n-n\gamma+1}, s_{n-n\gamma}, \cdots, s_n\}$ identified in the top threshold γ are compared. Table 2 shows the number of similarly identified hotspots identified by alternate HSID methods over the two periods. The SPI method is superior in this test by identifying the largest number of the same hotspots in both cases of $\gamma = 0.01$ and $\gamma = 0.05$, with 124 and 546 roadway segments, respectively. In other words, the SPI method identified 124 segments in 2011–2012 that were also identified as hotspots in 2013–2014. The ED CD (GNM), which performs slightly better than the ED CD (GLM) method, places 2nd with identifying 118 consistent hotspots (in the case of $\gamma = 0.01$) and 472 consistent hotspots (in the case of $\gamma = 0.01$). The ARP (NB GLM) performs worst, with the lowest number of consistent hotspots identified in the two periods. Again, the SPI method outperforms the other HSID methods. Also shown in Table 2 are differences between percentages (shown in the parentheses) of Column 3 and Column 4 for the eight methods. There is a consistent drop in percentages as threshold values drop. The explanation is that the top segments suffer from greater random fluctuations in crashes, and thus the higher is the threshold, the larger are the random fluctuations and the likelihood of not being identified in a prior period.

Table 2. Results of method consistency test of various HSID methods

HSID method index (h)	HSID method name	Parameter settings	
		$\gamma = 0.01$	$\gamma = 0.05$
1	SPI	124 (60.7%)	546 (53.5%)
2	PSII	103 (50.5%)	452 (44.3%)
3	CD (NB GLM)	92 (45.1%)	406 (39.8%)
4	CD (GNM)	101 (49.5%)	423 (41.5%)
5	EB CD (NB GLM)	109 (53.4%)	441 (43.2%)
6	EB CD (GNM)	118 (57.8%)	472 (46.3%)
7	ARP (NB GLM)	83 (40.7%)	382 (37.5%)
8	ARP (GNM)	88 (43.1%)	393 (38.5%)

5.3 Total Rank Differences Test

The total rank differences test (TRDT) takes into account the safety performance rankings of the road sections in the two periods. The test is conducted by calculating the sum of the total rank differences of the hotspots identified across the two periods. The smaller the total rank difference, the more consistent the HSID method. The test statistic is given as:

$$\mathrm{TRDT}_h = \sum_{q=n-n\gamma+1}^{n} |R(q_{h,t}) - R(q_{h,t+1})|, \;\; h = 1, 2, \cdots, H, \tag{16}$$

where $R(q_{h,t})$ is the rank of segment q in period t for method h. The difference in ranks is summed over all identified segments for threshold level γ for period t. Table 3 illustrates that the SPI method is superior in the total rank differences test. In both the $\gamma = 0.01$ and $\gamma = 0.05$ cases, the SPI method has significantly smaller-summed ranked differences, by about 22.6% (in the case of $\gamma = 0.01$) and 16.9% (in the case of $\gamma = 0.05$) compared with the EB CD (GNM), and by about 75.1% (in the case of $\gamma = 0.01$) and 77.4% (in the case of $\gamma = 0.05$) compared with the ARP (NB GLM). This result suggests that the SPI method is the best HSID method (of the eight evaluated here) for ranking roadway segments consistently from period to period.

5.4 Total Score Test

The total score test (TST) combines the site consistency test, the method consistency test, and the total rank difference test in order to provide a synthetic index. The test statistic is given as:

$$\mathrm{TST}_h = \frac{100}{3}\left[\left(\frac{\mathrm{SCT}_{h,t+1}}{\max_h\{\mathrm{SCT}_{h,t+1}\}}\right) + \left(\frac{\mathrm{MCT}_h}{\max_h\{\mathrm{MCT}_h\}}\right) + \left(1 - \frac{\mathrm{TRDT}_h - \min_h\{\mathrm{TRDT}_h\}}{\max_h\{\mathrm{TRDT}_h\}}\right)\right],$$
$$h = 1, 2, \cdots, H, \tag{17}$$

where the test assumes that the SCT, MCT, and TRDT have the same weight. The former three tests provide absolute measures of effectiveness, whereas the total score test gives an effectiveness measure relative to the methods being compared. If method h performed best in all of the previous tests, the TST value is equal to 100. If method h performed worst in all of the tests, the TST value is positive since all three components of the test have a positive value. Indeed, SCT and MCT, which should be maximized by the HSID methods, are weighted

Table 3. Results of total rank differences test of various HSID methods

HSID method index (h)	HSID method name	Parameter settings	
		$\gamma = 0.01$	$\gamma = 0.05$
1	SPI	2354	10237
2	PSII	3031	12798
3	CD (NB GLM)	3672	14781
4	CD (GNM)	3298	13587
5	EB CD (NB GLM)	3158	13016
6	EB CD (GNM)	2887	11973
7	ARP (NB GLM)	4123	18167
8	ARP (GNM)	3887	17105

Table 4. Results of total score test of various HSID methods

HSID method index (h)	HSID method name	Parameter settings	
		$\gamma = 0.01$	$\gamma = 0.05$
1	SPI	100	100
2	PSII	87.89	89.31
3	CD (NB GLM)	78.55	82.07
4	CD (GNM)	85.37	85.83
5	EB CD (NB GLM)	88.63	88.14
6	EB CD (GNM)	93.81	92.12
7	ARP (NB GLM)	70.82	73.82
8	ARP (GNM)	75.16	77.02

in relation to the maximum values in the tests, whereas TRDT, which should be minimized by the HSID methods, is weighted in relation to its difference from the minimum value in the test. Table 4 illustrates the results of total score test of the eight HSID methods, in which SPI performed best in both $\gamma = 0.01$ and $\gamma = 0.05$ cases, and was followed closely by EB CD (GNM) method with 93.81 score (in the case of $\gamma = 0.01$) and 92.12 score (in the case of $\gamma = 0.05$). ARP (NB GLM) performed the worst in both cases, with 70.82 score and 73.82 score respectively.

Overall, the four tests reveal that the SPI method is the most consistent and reliable method for identifying hotspots. Although it can only be applied to roadway segments where the crash data for different levels of severity are available, with the rapid development of intelligent transportation systems and data collection technologies, this method could become quite useful in identifying high-risk road sites. On several criteria, the SPI outperforms other methods by a wide margin. This evaluation suggests that the SPI method (of the methods compared) has a potential to become the industry standard.

6 Application on Regional Map Based Analytical Platform

A regional map based analytical platform was developed on the DRIVE Net system to highlight the methodology developed under this project. Ultimately, the existing safety performance analysis function under the "Safety Performance" module was expanded. The SPI developed in the preceding is used to color-code the regional map based on safety performance. The PSII is employed to highlight potential safety improvements on the map. By combining the two indices on the regional map, one can easily identify accident hotspots and the key influencing factors to consider in an improvement package.

The interface of the safety performance module in the regional map based analytical platform is illustrated in Fig. 1. There are three sub-functions implemented on this panel: Incident Frequency (NB GLM), Estimated Crash Mean and Potential Safety Improvement Index (ARP NB GLM). The new SPI and PSII were added as expended safety performance analysis options. As stated in the previous modeling part of this report, within a selected time range and corridor, the SPI shows a more comprehensive view of safety performance on a given corridor. The accident/incident data is from Washington Incident Tracking System (WITS) database. The SPI level ranges from Level A to Level F, where Level A (light green) corresponds to the highest safety performance and Level F (dark red) corresponds to the lowest safety performance expected as shown in Fig. 1.

The PSII implements the EB method in the modeling part. In this function, both the historical incident data and the characteristics of the selected corridor are used as model inputs. The output format still uses the six different colors representing Level A to Level F to show the potential safety improvement index on the map, where Level A shows the segment has the least potential to improve

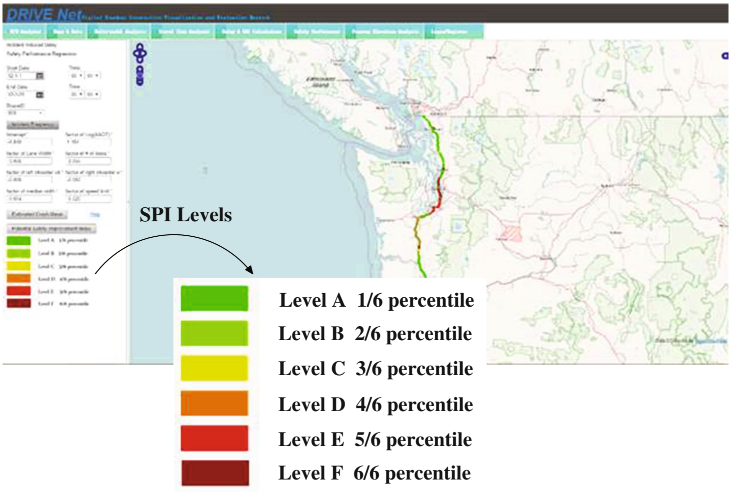

Fig. 1. SPI level ranges from Level A to Level F in the safety performance module

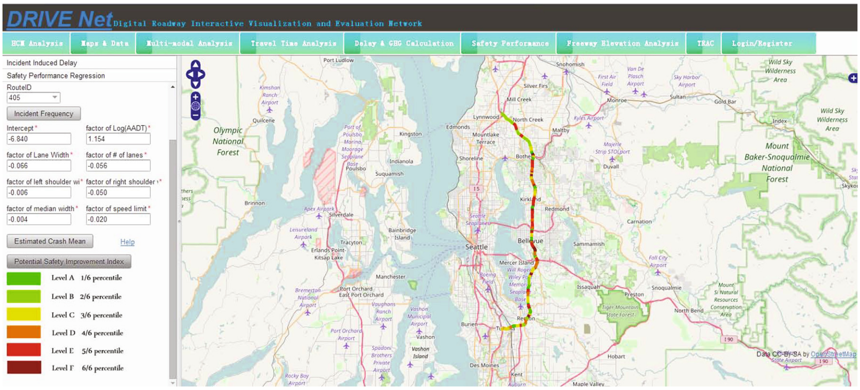

Fig. 2. An example of the PSII function

its safety, and Level F shows the segment has the most potential to improve its safety. Figure 2 shows an example of this function.

7 Conclusions

A CCS-based HSID method is developed by extending the traditional EB method to a GNM-based mixed MNL approach in this paper. A new SPI and a new PSII are developed by introducing the risk weight factor and compared with traditional indexes by employing four HSID evaluating methods, including the site consistency test, method consistency test, total rank differences test, and the total score test. The test results showed that the new SPI derived by the

GNM-based mixed MNL approach is the most consistent and reliable method for identifying hotspots. Finally, the new CCS-based HSID method was applied on a regional map based analytical platform.

Abstract. A network traffic utilization in order to support teaching and learning activities are an essential part. Therefore, the network traffic management usage is requirements. In this study, analysis and clustering network traffic usage by using K-Means and Fuzzy C-Means (FCM) methods have been implemented. Then, both of method were used Euclidean Distance (ED) in order to get better results clusters. The results showed that the FCM method has been able to perform clustering in network traffic.

Keywords: Network traffic · K-Means · Fuzzy C-Means · Clustering

1 Introduction

A bandwidth usage monitoring management in a network traffic at university is indispensable. Therefore, a recording and analysis of bandwidth usage by network administrators is very beneficial. It aims to make use of the bandwidth can be well controlled, stable access, and gives users convenient access. Therefore, mapping or cluster of bandwidth usage in order to support the network administrator performance analysis is required.

In this study, the cluster method based on intelligence algorithm are proposed in bandwidth usage, such as Self-Organizing Maps (SOM), K-Means, Fuzzy C-Means, etc. For that reason, these algorithms have been widely used by researchers in order to solve cluster data problems in a variety of fields, including economics [5], supply chain [2], engineering [6], hydrology [1,4], internet and social media [3,8], pattern recognition [7], and so forth. Many research results have shown that the algorithms are able to provide accurate information in solving the clustering problem.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_24

Afterward, two intelligence algorithms is K-Means and Fuzzy C-Means (FCM) for cluster bandwidth usage data has been implemented. The purpose of this study are compared the feasibility of two clustering methods and how it works in the real world problems particularly subject on network traffic. Thus, the expected results of network traffic clustering are coordination schemes that support resource management [8]. Furthermore, this paper will apply two models, namely K-Means and Fuzzy C-Means (FCM) that have been developed and compared in order to cluster the network traffic usage. Section 2 describes the architectures of K-Means and FCM clustering models are proposed. Section 3 describes the analysis and discussion of the results. Finally, conclusions are summarized in Sect. 4.

2 Research Method

In this section, a brief information of K-Means and FCM models are presented.

2.1 Principle of K-Means Method

K-means clustering is an unsupervised learning classified. This algorithm is based on the determination of the distance between the centroid and the training data. Then, the number of cluster centroid based on the number desired. Meanwhile, the initialization centroid randomly generated by considering the data training. In other words, the centroid should be in the training data space. Then, a couple of training data is from the attributes of the data patterns to be planned. In each iteration, the distance of each training data with each centroid to be calculated. It means that any training data will have a centroid distance. At the same time, members of the cluster indicated by the smallest distance from the corresponding centroid. Then, a new centroid value is calculated based on the average value of each member of the cluster. If the cluster member does not change then the iteration is stopped, Fig. 1.

The following data clustering techniques using the K-Means algorithm as follows.

- Determine the number of clusters K.
- The Initialization of K cluster centers can be done randomly and used as initial cluster centers.
- Allocate all data/objects to the nearest cluster. The proximity of the two objects is determined by the distance of the object. To calculate the distance of all the data to the cluster center point using the Euclidean distance theory formulated as follows:

$$T_{(x,y)} = \sqrt{(T_{1x} - T_{1y})^2 + (T_{2x} - T_{2y})^2 + \cdots + (T_{kx} - T_{ky})^2}, \tag{1}$$

where, $T_{(x,y)}$ is distance data of x to the cluster center of y; T_{kx} is i-data on attribute data of k; T_{ky} is the center point of j on the attribute of k.

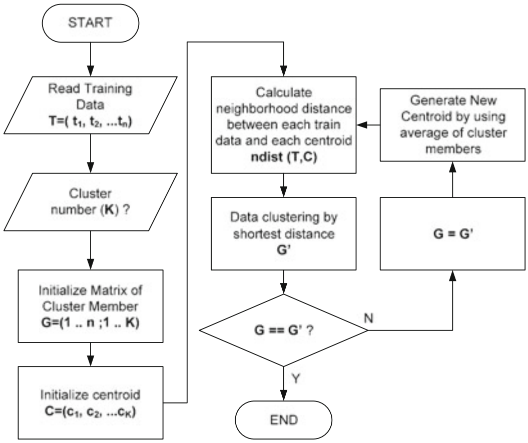

Fig. 1. K-Means algorithm

- Recalculate the center of the cluster with the new cluster membership. This is computed by determining the centroid/center cluster.
- Assign each object to put on the new cluster center, if the center of the cluster changed, back to 3, otherwise clustering is complete.
- Analyze the results in the clustering process.

2.2 Principle of Fuzzy C-Means Method

Other advanced techniques clustering in machine learning model come from the Dunn in 1973, and improved by Bezdek in 1981, called Fuzzy C-Means (FCM) clustering was developed by Dunn in 1973, and improved by Bezdek in 1981. In principle, FCM clustering process is based on a partition of a set of data into a number of clusters with minimum similarity between different clusters [2]. Since the introduction of the fuzzy set theory in 1965 by Zadeh, it has been applied in a variety of fields. FCM is a flexible fuzzy partition that an improvement of common C-Means algorithm [5]. At FCM, each feature vectors valued between [0–1] by using the membership function, because FCM is based on the criteria of distances numbers between clusters. In other words, FCM clustering is based on Point-Prototype Clustering Model with output centroid most optimal partition. Where, partition optimization centroid is obtained by minimizing the objective function. The formula is given by:

$$J_{\mathrm{FCM}}(U,V) = \sum_{j=1}^{N}\sum_{i=1}^{C}(u_{ij})^{q}(d_{ji})^{2},$$

where
$U =$ Fuzzy datasets K-partition;
$V =$ Set of prototype centroid;
$V = \{v_1, v_2, \cdots, v_C\} \subset R^P$;

$$(d_{ji})^2 = \|x_j - v_i\|^2 = \sqrt{\left(x_{j\,(\text{row})} - v_{i\,(\text{row})}\right)^2 + \left(x_{j\,(\text{col})} - v_{i\,(\text{col})}\right)^2}. \tag{2}$$

Euclidean Distance between x_j and v_i;
$X = \{x_1, x_2, \cdots, x_n\} \subset R^P$;
$v_i =$ Centroid cluster to i;
$u_{ij} =$ Membership level x_j in cluster to i;
$N =$ Total data;
$C =$ Total cluster;
$q =$ Fuzzifier parameter, $q > 1$.

Afterward, all of the objects in each cluster has a certain degree of proximity or similarity. Meanwhile, the FCM processes consists of five stages. First, to determine the cluster is set become a center cluster location marker on average for each cluster. Second, calculate the distance between feature vector (X) and the centroid vector $(V)[X \to V]$. In this experiment, Euclidean Distance (ED) was implemented. Third, Calculate membership level. Fourth, Calculate new centroid. Lastly, recalculated the new centroid, if criterion between [0–1] is reached then stop the iteration. In this study, the FCM Clustering algorithm is as follows:

Step 1. Initialization Vector centroid, v_i (prototypes).
Step 2. Calculate the distance between feature vector (X) and the centroid vector $(V)[X \to V]$. Feature vectors with the closest distance to one of the centroid vectors then expressed as a cluster member.
Step 3. Calculate membership level of all feature vectors in all clusters by using the formula:

$$u_{ij} = \frac{1}{\sum_{k=1}^{K}\left[\frac{(d_{ji})^2}{(d_{jk})^2}\right]^{1/(q-1)}} = \frac{\left[\frac{1}{(d_{ji})^2}\right]^{1/(q-1)}}{\sum_{k=1}^{K}\left[\frac{1}{(d_{jk})^2}\right]^{1/(q-1)}}. \tag{3}$$

Step 4. Calculate new centroid using Eq. (4).

$$\hat{V_i} = \frac{\sum_{j=1}^{N}(u_{ij})^q X_j}{\sum_{j=1}^{N}(u_{ij})^q}. \tag{4}$$

Step 5. Recalculate the step 4, $u_{ij} \to \hat{u}_{ij}$ If, $\max_{ij}|u_{ij} - \hat{u}_{ij}| < \varepsilon$, where ε is termination criteria between 0 and 1. Then, the iteration process is stopped. If not go back to step 5. The FCM algorithm can be seen in Fig. 2.

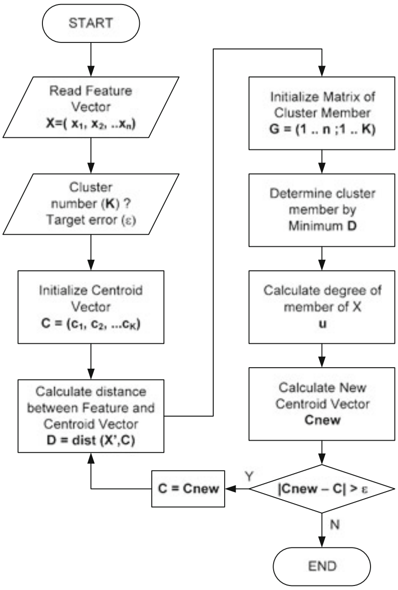

Fig. 2. Fuzzy C-means algorithm

(1) Initialization Centroid

Centroid is used as a central member of the cluster that expected to be an average of all the cluster members. If k cluster is formed, the number k centroid is necessary. There are various ways of doing initialization centroid, such as the random generation and the average spread. For example, interval data is [mindata$\cdots$maxdata]. Centroid random initialization is done with formula $C = \text{mindata} + (\text{maxdata} - \text{mindata}) \times \text{rand}\,()$. In this study, the initialization centroid for K-Means and FCM are used the average spread then the formula as follows:

$$\begin{aligned}
&\text{cluster number} \;=\; k \\
&s = (\text{maxdata} - \text{mindata})\,/k \\
&m = \text{mean}\,(\text{data}) \\
&C = [(m - s^*(k)) \;\; (\cdots) \;\; (m - s^*(1)) \;\; (m) \;\; (m + s^*(1)) \;\; (\cdots) \;\; (m + s^*(k))]
\end{aligned}$$

(2) Calculated Distance Neighborhoods

Neighborhoods distance is the distance between a centroid to each data that expressed by Eq. (2). According to [9] "an important step in most clustering is to select a distance measure, which will determine how the similarity of two elements is calculated". Thus, there are some varieties of distance function in clustering, including Euclidean distance (ED), Manhattan distance, Mahalanobis distance, and Hamming distance. In this study, K-Mean and FCM clustering using ED distance.

(3) Generated New Centroid
In this study, generating new centroid both of K-Means and FCM are based on the average all members cluster values. As an illustrated, for training data is as follows.

$$T = \begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 & x_5 & x_5 \\ y_1 & y_2 & y_3 & y_4 & y_5 & y_6 \end{bmatrix}.$$

Next, the clustering results in an iteration is as follows.

$$G = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} = \begin{bmatrix} 1\,0\,1\,1\,0\,0 \\ 0\,1\,0\,0\,1\,1 \end{bmatrix}.$$

Then, the new centroid is as follows.

$$c_1 = \frac{x_1 + x_3 + x_4}{y_1 + y_3 + y_4} \quad c_2 = \frac{x_2 + x_5 + x_6}{y_2 + y_5 + y_6}.$$

Meanwhile, in FCM, generating new centroid by using the COA (Center of Area) formula, Eq. (4).

2.3 Datasets

In this study, 152 days (from January–May 2016) daily network traffic usage of four client datasets from ICT unit were captured. Then, the data are analyzed by using MATLAB R2013b. The real dataset can be seen in Table 1 (Fig. 3).

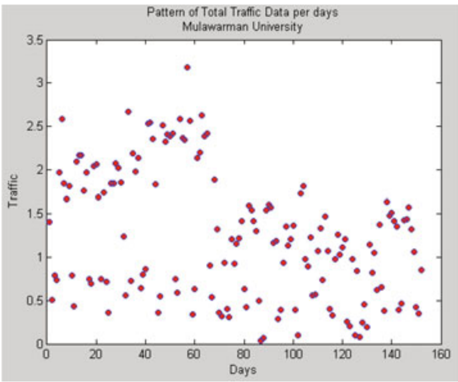

Fig. 3. Plot of network traffic per days

Table 1. The real of daily network traffic data (January–May 2016)

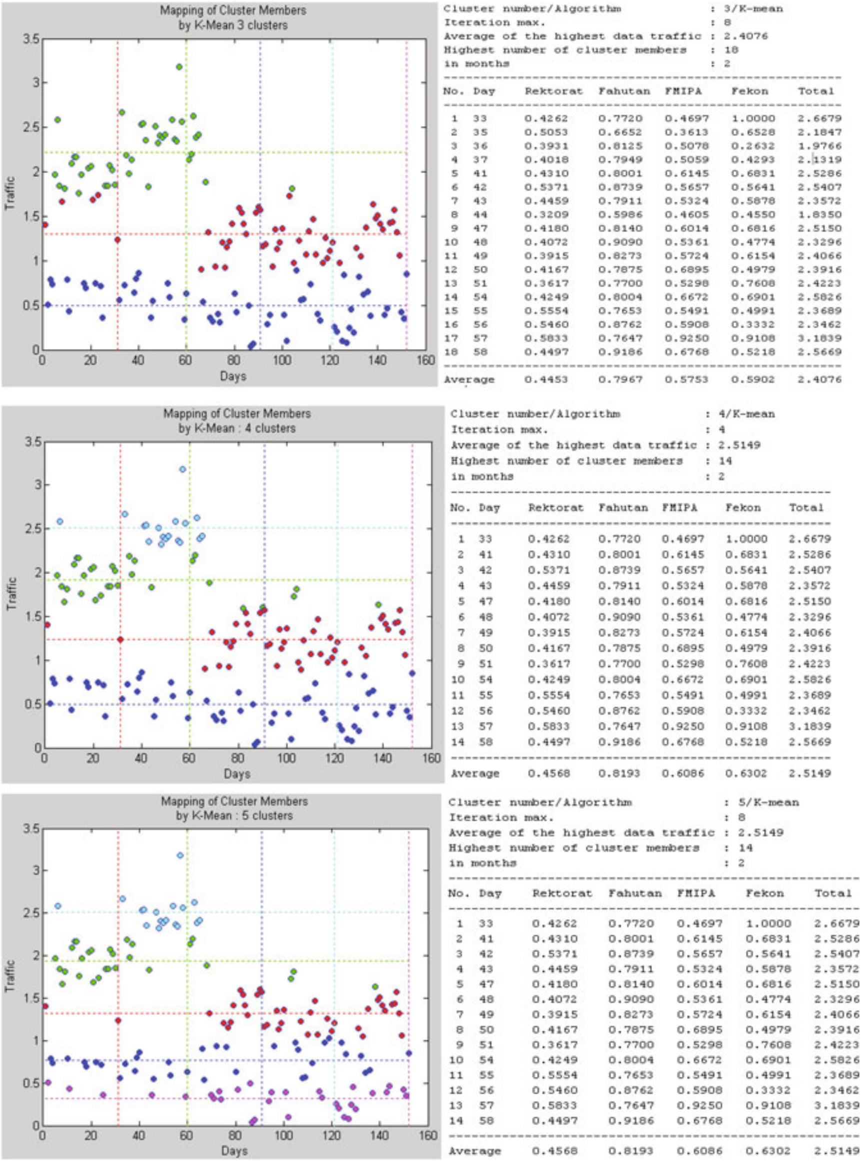
3 Results and Analysis

This section presents the empirical work and compares the experimental results of the K-Means and FCM algorithms on highest average usage network traffic problems. The performances are measured by the objective function value given by Eq. (1).

3.1 Analysis of K-Means

In this experiment, the scheme used is to classify the training data into 3, 4, and 5 cluster grouping patterns in order to observe the good cluster. The average data value is used as one of the centroid values. Then, for another centroid value is determined randomly in the space of data training. The results of K-Means are shown in Fig. 4.



Cluster number/Algorithm : 3/K-mean
Iteration max. : 8
Average of the highest data traffic : 2.4076

3.2 Analysis of Fuzzy C-Means

In this experiment, the scheme used is to classify the training data into 3, 4, and 5 cluster grouping patterns in order to observe the good cluster. The average data value is used as one of the centroid values. Then, for another centroid value is determined randomly in the space of data training. In this test, the FCM

initial parameter values were implemented, (a). Number of clusters 3, 4, and 5; (b). Maximum iterations = 50; and (c). Stopping Criteria (ξ) = 10^{-5}. In this research, applied testing scheme is the amount of usage per day of data network traffic from the four parts (rectorate, forestry, science, and economic). Then, the

Table 2. Results comparison K-means and FCM methods

Cluster	Methods	Highest cluster members number	Average of network traffic usage	Highest of network traffic usage month
3	KCM	18	2.4076	2
	FCM	18	2.4076	2
4	KCM	14	2.5149	2
	FCM	17	2.4412	2
5	KCM	14	2.5149	2
	FCM	16	2.4703	2

highest, middle and lowest data values are obtained. The results of FCM are shown in Fig. 5.

In this study, the accuracy level in order to get the centroid value by using FCM method is quite careful than K-Means method, Table 2.

4 Conclusion

In this paper we presented a comparison of K-Means and FCM methods then compared the centroid accuracy by using various performance criteria. This research was used network traffic usage from four units; rectorate, forestry, science, and economic. In clustering, the examining of 1 parameter of centroid value is 3 centroid values. Our experiment showed that the FCM method is better results analysis in clustering than K-Means. Nevertheless, we have also concluded that FCM algorithm was slower than K-Means. As future work, an optimizing methods in order to get good accuracy between centroids is proposed.

RDEU Evolutionary Game Model and Simulation of the Network Group Events with Emotional Factors

Guoqiang Xiong(✉), Xian Wang, Ying Yang, and Yuxi Liu

School of Business Administration, Xi'an University of Technology,
Xi'an 710054, People's Republic of China
xgq168@163.com

Abstract. At present, network communication becomes more efficient and geographical restrictions barely exist. However, the network mass incidents tend to be multiple and frequent, which are mostly unexpected. In this paper, we point at studying the limitations of the traditional game theory in the players' rational assumptions, and consider the influence of the irrational factors on the netizens behavior. Based on RDEU theory and evolutionary game theory, a RDEU evolutionary game model of group events on network is constructed. In addition, we studied the evolution mechanism of game Nash equilibrium under different emotional conditions and the numerical simulation of the model, which is carried out by using the numerical simulation method of Matlab. After that, the evolutionary equilibrium state of the game between the netizens in different emotional states of the network group events is analyzed. Finally, research results show that emotional factors have a great impact on the network behavior of group events; when the emotions of netizens are pessimistic, the game participants are more inclined to confrontational behavior, and will have both the conflicting herd effect, more prone to network mass incidents. In this case, it is more likely to produce group events on network.

Keywords: Network group event · RDEU evolutionary game model · Emotion · Simulation

1 Introduction

Generally, the whole Society is in the period of social transformation filled with various contradictions and social conflicts, including the increasing number of network mass incidents and the negative influence from that. We often find a simple network information will attract tens of millions of click rate in a short period, an infectious emotion may spread out of control like a virus, thus causing emotional excitement. That is to say, the development of the group events on networks is often due to the interaction between social and human factors.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_25

The evolution of this interaction has the derivative harmfulness, easily leading to systemic economic and social crisis. Thus, social stability is facing a severe challenge. Therefore, keeping in touch with the emotional state of netizens in time is of great significance to grasp the law of the evolution in the behavior of netizens group and monitor the occurrence of early warning derivative events.

At present, a majority of researchers of the network mass incidents focused on the aspects of the network conflict. Morales [5] believed that network mass incidents refer to the large-scale pooling of netizens' opinions in the network for specific hotspot problems, thus affecting the real-life group events. Levine [2] argued that cyberspace disputes and conflicts, which expand the interaction of people, can activate the public awareness of the society in order to create a new public realm, and provide new environmental resources for democracy, effectively avoid autocratic. In addition, there are some research focus on the function of network conflict, the conflict on real society and democratic system. Post [6] pointed out that the traditional legal control tools are confronting severe network conflict challenges. Technicians cannot depends on the traditional management policy to effectively restrict network environment and reconstruct the rules' system of cyberspace. Qiu [7] summarized three types of network mass incidents: First, some incidents occur in the Internet but exerts substantial influence on the real society; the second type of incidents happens in the reality with the virtual online organization as the intermediary; the third one happens through offline interaction that is based on the online communication. Some scholars proposed corresponding strategies to solve the problem about unexpected group incidents from different perspectives. From the view of communication studies, Zhu et al. [13] emphasized that the fundamental effect of faith on the public opinion and the guidance of the "opinion leader" for the direction of public opinion. From the social and psychological point of view to investigate the social struggle, Sidney et al. [10] argued it was the existence of a sense of deprivation of the individual that resulted in resentment, thus forming a collective behavior. It follows that the present scholars' research on network unexpected group incidents mostly applies the qualitative, canonical approaches and comes from the single perspective but seldom establishes mathematical models based on the theories of management science to make relevant research. At present, a few scholars as Liu [3,4], Deng et al. [1], Xie [12], Wang [11] and Sun [9] made research on traditional unexpected group incidents. Aiming at the conflict evolutionary mechanism of unexpected group incidents, they established the models of unexpected group incidents and initially revealed the mechanism of such incidents. Although evolutionary game models of unexpected group incidents deepened the research concerning the conflict evolutionary mechanism by dividing up the social groups into advantaged groups and vulnerable groups, they did not consider the influence of emotional factor on the state of evolutionary game equilibrium in decision-making in the game.

All in all, the study of the evolution mechanism of the group events on networks is still in its infancy, and only qualitative methods have been used to analyze the causes, types and countermeasures of the events. There are little research on the evolution mechanism of the group events on networks, especially we lack the direct research on game model of endogenous factors like emotion to further explore the evolution of the event. Based on the Quiggin's RDEU theory (Rank-dependent expected utility) [8], this paper constructs the RDEU evolutionary game model of the group events on networks and studies the evolvement process of netizens' strategy selection under different emotional states, and provides emergency decision support for policy selection of the group events on networks. There are four sections in this paper. In the second section, we introduce the emotional function which reflects the psychological activities of netizens and establish the RDEU game model of the behavior mechanism of the group events on networks. The third section, according to the different emotions of netizens, adopts Matlab's numerical simulation analysis of evolution equilibrium on the netizens RDEU game model under six evolutionary scenarios (for example, netizens of one party are rational, while the other party is pessimistic, netizens are both pessimistic, etc.). The fourth section is the summary of the full text.

2 The RDEU Evolutionary Game Model among Netizen Group

2.1 The Method of Constructing the Netizen Game Model

In the network unexpected group incident, the strategy sets of the netizen groups can be divided into: "fight" (represented by F) and "peace" (indicated by P), the former refers to radical articles or comments while the latter refers to quiet observation of the course of events without taking any radical actions. In that game, there are three different situations: (1) When both of the two groups of netizens adopt the sheep-flock strategy to "F"; the influence of the incident may be accordingly expanded, and both of interactive objects may respectively gain interaction revenues represented by "V"; extraneous revenues is implied by "S"; paying the costs is implied by "C". Then, both sides should pay the costs and make extraneous and interaction revenues; (2) When two netizen groups adopt different strategies, the principal party of "P" can make interaction revenues without paying "C" while the principal party of "F" pays "C" and makes "V" and "S"; (3) When both groups apply the peaceful sheep-flock strategy, namely, as onlookers or passers-by, neither of them gain any revenue or deliver any contribution to the incidents, make any "S" or pay any costs, so they spend no cost and gain no benefit. Table 1 shows the revenue matrix in the game of the netizen's sheep-flock effect in the network unexpected group incidents.

Table 1. Revenue matrix in the game of the netizen

		Netizen B	
		Fight (F) q	Peace (P) $1-q$
Netizen A	Fight (F) p	$2V+S-C, 2V+S-C$	$V+S-C, V$
	Peace (P) $1-p$	$V, V+S-C$	0, 0

Table 1 shows that the netizens pay a little price when they forward or comment the article in most case. To be concluded, the fight brings more benefits than peace, obviously $S > C$, so the size relation between parameters is: $2V + S - C > V + S - C > V > 0$.

2.2 Establishing the RDEU-Based Evolutionary Game Model for the Netizen Groups

The dynamic game model was basically built on the basis that the netizens were entirely rational. However, when the social economic environment and the decision problems are more complicated, people's rationality will be obviously limited. For this reason, in a move to ensure the application value of game analysis, the netizen game of limited rationality must be analyzed. Consequently, the following part will discuss the evolutionary game model among netizen groups in a drive to analyze the game under the analytical framework of repeated random-pair game among netizens of low rationality. Suppose that the netizens adopting "F" occupy the proportion of "p" of the netizen group A and the counterparts adopting "P" account for $(1 - p)$; the netizens adopting "F" take up a proportion of "q" of the netizen group B and the counterparts adopting "P" account for $(1 - q)$, where $p, q \in [0, 1]$.

Network unexpected group incidents have displayed distinctive characteristics from traditional group incidents chiefly in terms of emotional extremity in these years. Because of lack of authoritative review mechanism in communication, some features, such as popularization and randomness arose. It is correspondingly difficult for the governmental institutions to control. At the same time, because of some problems like enlarging gap of wealth, soaring house prices and inappropriate governmental behaviors, the netizens tend to show sympathy to the disadvantaged groups. When the incident object relates to social unfairness, the netizens are evidently easier to get agitated or go to extremes. To reflect the emotional status of both parties of the game in strategy selection, the paper hereby applies the RDEU theory to include the emotional factors of the netizen groups into the above game model of the netizen's sheep-flock effect. Suppose the emotional function of netizen group A and netizen group B is respectively $w_A(p) = p^{r_1}$ and $w_B(q) = q^{r_2}$ and $r_1, r_2 > 0$, called the emotional index of the netizens respectively.

In the RDEU theory, we can get that the probabilities of different revenues made by netizen group A and B when they adopt different strategies and the rank of the revenue value of different strategy portfolio among all the revenue values. It can be called the rank of corresponding revenue. If the rank of a strategy portfolio is higher, it is less possibility that the revenues of other strategy portfolios can exceed it. That is the implication of "high revenue and low probability". The corresponding decision weights are calculated with probabilities and ranks of different revenues, as listed in Tables 2 and 3.

Table 2. The probability distribution, rank and decision weights of netizen group A's revenue

The revenue of Netizen group A x_i	$2V+S-C$ (F)	$V+S-C$ (F)	V (P)	0 (P)
Probability p_i	pq	$p(1-q)$	$(1-p)q$	$(1-p)(1-q)$
Rank RP_i	1	$1-pq$	$1-p$	$(1-p)(1-q)$
Decision weights $\pi(x_i)$	$w_A(pq)$	$w_A(p)-w_A(pq)$	$w_A(p+q-pq)-w_A(p)$	$1-w_A(p+q+pq)$

Table 3. The probability distribution, rank and decision weights of netizen group B's revenue

The revenue of Netizen group A x_i	$2V+S-C$ (F)	$V+S-C$ (F)	V (P)	0 (P)
Probability p_i	pq	$(1-p)q$	$p(1-q)$	$(1-p)(1-q)$
Rank RP_i	1	$1-pq$	$1-q$	$(1-p)(1-q)$
Decision weights $\pi(x_i)$	$w_B(pq)$	$w_B(q)-w_B(pq)$	$w_B(p+q-pq)-w_B(q)$	$1-w_B(p+q+pq)$

U_{AF} and U_{AP} represent the expected revenues of netizen group A adopting "*F*" and "*P*" respectively in the network unexpected group incidents.

$$U_{AF} = V(pq)^{r_1} + (V+S-C)p^{r_1},$$
$$U_{AP} = V(p+q-pq)^{r_1} - Vp^{r_1}.$$

The RDEU expected revenues of netizen group A as:

$$U_A(p,q;w) = U_{AF} + U_{AP} = V(pq)^{r_1} + V(p+q-pq)^{r_1} + (S-C)p^{r_1}. \quad (1)$$

Similarly, U_{BF} and U_{BP} are taken to represent the expected revenues of netizen group B adopting "*F*" and "*P*"

$$U_{BF} = V(pq)^{r_2} + (V+S-C)q^{r_2},$$
$$U_{BP} = V(p+q-pq)^{r_2} - Vq^{r_2}.$$

The RDEU expected revenues of netizen group B as:

$$U_B(p,q;w) = U_{BF} + U_{BP} = V(pq)^{r_2} + V(p+q-pq)^{r_2} + (S-C)p^{r_2}. \quad (2)$$

$\overline{U_A}$ is taken to represent the average revenue of netizen group A, then

$$\begin{aligned}\overline{U_A} =& p^{r_1}U_{AF} + (1-p^{r_1})U_{AP} = Vp^{2r_1}q^{r_1} - Vp^{r_1}(p+q-pq)^{r_1} \\ &+ (2V+S-C)p^{2r_1} + V(p+q-pq)^{r_1} - Vp^{r_1}. \quad (3)\end{aligned}$$

The limited rationality of the netizen groups indicates that people will find better strategies by learning in the game instead of finding the best strategy at the beginning. According to the theory of replicated dynamics for biological evolution, the game player who adopts strategies yielding lower revenues will change the strategy and turn to (simulate) the strategies yielding higher revenues. For this reason, the proportion of group members who apply different strategies may change, then the speed of proportion change and the proportion of specific strategies have positive relation with the margin of its revenue over the average revenue. Consequently, the speed of change of "p" of the netizens resorting to "F" among the above netizen group A can be shown in the replicated dynamic equation as follows:

$$\begin{aligned}\frac{dp}{dt} &= p^{r_1}(U_{AF} - \overline{U_A}) = p^{r_1}(1 - p^{r_1})[V(pq)^{r_1} \\ &\quad + (2V + S - C)p^{r_1} - V(p + q - pq)^{r_1}].\end{aligned} \tag{4}$$

At the same time, is taken to represent the average revenue of netizen group B, so

$$\begin{aligned}\overline{U_B} &= q^{r_2}U_{BF} + (1 - q^{r_2})U_{BP} = Vp^{r_2}q^{2r_2} - Vq^{r_2}(p + q - pq)^{r_2} \\ &\quad + (2V + S - C)q^{2r_2} + V(p + q - pq)^{r_2} - Vq^{r_2}.\end{aligned} \tag{5}$$

When the netizen group B take the "fight" behavior, the change of speed of netizen number's proportion can be represented as the below replicator dynamics equation as

$$\begin{aligned}\frac{dq}{dt} &= q^{r_2}(U_{BF} - \overline{U_B}) = q^{r_2}(1 - q^{r_2})[V(pq)^{r_2} \\ &\quad + (2V + S - C)q^{r_2} - V(p + q - pq)^{r_2}].\end{aligned} \tag{6}$$

Simultaneous integration of the replicated dynamic equations of netizen group A and B may help to build the replicated dynamic model for the evolutionary game of netizen group A and B applying changing strategies as time changes.

$$\begin{cases}\frac{dp}{dt} = p^{r_1}(1 - p^{r_1})[V(pq)^{r_1} + (2V + S - C)p^{r_1} - V(p + q - pq)^{r_1}] \\ \frac{dq}{dt} = q^{r_2}(1 - q^{r_2})[V(pq)^{r_2} + (2V + S - C)q^{r_2} - V(p + q - pq)^{r_2}].\end{cases} \tag{7}$$

3 Numerical Simulation of RDEU-Based Evolutionary Game Model

Because of the numerous parameters in Formula 7 and the uncertainty of the parameter values, this part adopts the approach of numerical simulation to further discuss the afore-mentioned model in order to reflect how emotions influence the behaviors of netizens. To facilitate the operation, we suppose V = 6, S = 8 and C = 4 and rewrite the replicated dynamic model into:

$$\begin{cases}\frac{dp}{dt} = p^{r_1}(1 - p^{r_1})[6(pq)^{r_1} + 16p^{r_1} - 6(p + q - pq)^{r_1}] \\ \frac{dq}{dt} = q^{r_2}(1 - q^{r_2})[6(pq)^{r_2} + 16q^{r_2} - 6(p + q - pq)^{r_2}].\end{cases} \tag{8}$$

After that we assume r_1 and r_2 which the emotional indexes of the netizens be divided into six kinds of conditions, then the conditions simulation software named matlab7.0 will be applied to simulate the changes of the strategies of the network groups in network unexpected group incidents and analyze the different conditions to reach the state of evolutionary equilibrium. Assuming the initial ratio of p and q is (0.2, 0.7). When t = 0, the proportion of netizens of group B applying "*F*" is higher than that of group A.

Situation 1: Both sides of netizen groups are rational, namely $r_1 = r_2 = 1$.

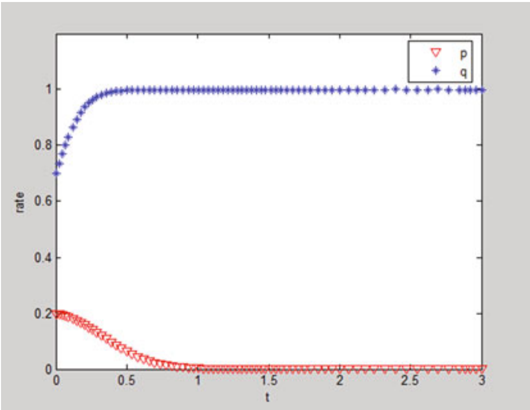

Fig. 1. The result of simulation when $r_1 = 1$, $r_2 = 1$

Figure 1 shows that the evolutionary result of the experiment when all the parameters conform to situation 1. The result manifests that when both the netizen group A and netizen group B are rational, the system will eventually evolve to be "*F*" of group B and "*P*" of group A.

Situation 2: One of the netizen groups is rational while the other is optimistic.

$r_1 = 1$ and $r_2 \in (1, +\infty)$ or $r_1 \in (1, +\infty)$ and $r_2 = 1$, suppose $r_1 = 1, r_2 = 1.7$ or $r_1 = 1.7, r_2 = 1$

Figure 2 describes the evolutionary results of the system when all the parameters satisfy to situation 2. The result shows that when netizen group A and group B are optimistic or group A are optimistic and group B are rational, the system will finally evolve to be "*F*" of Group B and "*P*" of Group A.

Situation 3: One party of the netizen groups is rational while the other is pessimistic. $r_1 = 1$ and $r_2 \in (0, 1)$ or $r_1 \in (0, 1)$ and $r_2 = 1$, suppose $r_1 = 1, r_2 = 0.9$ or $r_1 = 0.9, r_2 = 1$.

Figures 3(a) and (b) indicate that the evolutionary results of the system when all the parameters conform to situation 3. The result shows that when netizen group A are rational and group B are pessimistic or group A are pessimistic and group B are rational, the system will finally evolve to be "*F*" of group B and "*P*" of group A.

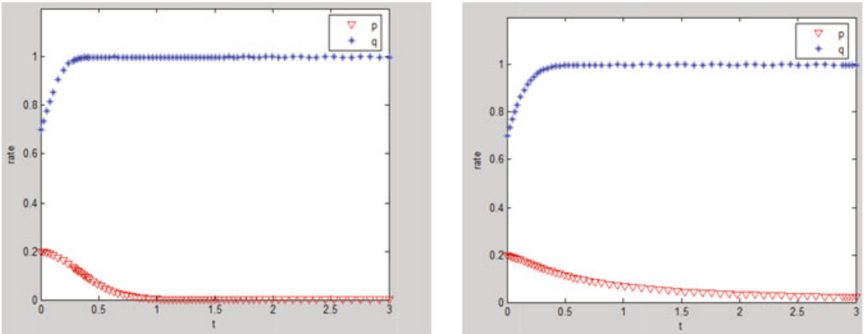

Fig. 2. (a) The result of simulation when $r_1 = 1$, $r_2 = 1.7$; (b) The result of simulation when $r_1 = 1.7$, $r_2 = 1$

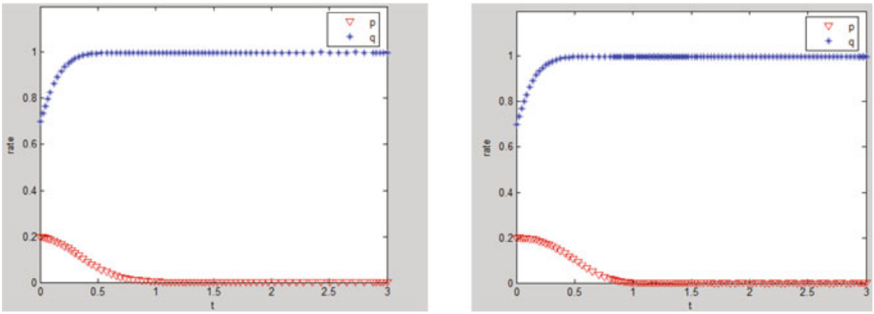

Fig. 3. (a) The result of simulation when $r_1 = 1$, $r_2 = 0.9$; (b) The result of simulation when $r_1 = 0.9$, $r_2 = 1$

Situation 4: Both sides of netizen groups are pessimistic, as $r_1 \in (0, 1)$ and $r_2 \in (0, 1)$, suppose $r_1 = 0.5, r_2 = 0.6$.

Figure 4 describes that the evolutionary result of the system when all the parameters conform to situation 4. The result shows that when netizen group A and B are both pessimistic, the system will finally evolve to generate the sheep-flock effect that both sides apply "F" because netizen group A simulates netizen group B.

Situation 5: Both sides of netizen groups are optimistic, as $r_1 \in (1, +\infty)$ and $r_2 \in (1, +\infty)$, suppose $r_1 = 1.2, r_2 = 1.3$.

Figure 5 depicts the evolutionary result of the system when all the parameters conform to situation 5. The result shows that when netizen group A and B are both optimistic, the system will finally evolve to be the "F" of netizen group B and the "P" of netizen group A.

Situation 6: One party of the netizen groups is optimistic while the other is pessimistic, namely, $r_1 \in (0, 1)\, and\, r_2 \in (1, +\infty)$ or $r_1 \in (1, +\infty)\, and\, r_2 \in (0, 1)$, suppose $r_1 = 0.9, r_2 = 1.1$ or $r_1 = 1.1, r_2 = 0.9$

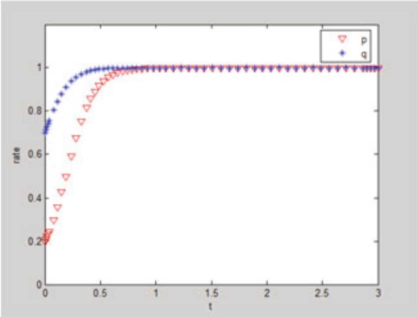

Fig. 4. The result of simulation when $r_1 = 0.5$, $r_2 = 0.6$

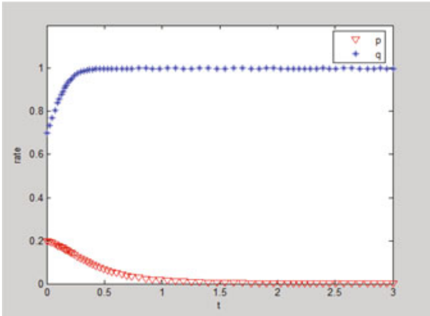

Fig. 5. The result of simulation when $r_1 = 1.2$, $r_2 = 1.3$

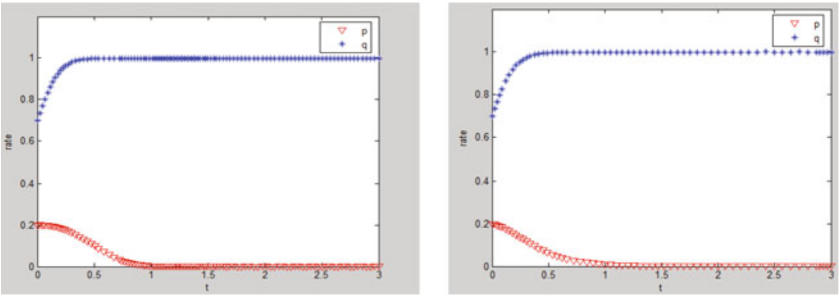

Fig. 6. (a) The result of simulation when $r_1 = 0.9$, $r_2 = 1.1$; (b) The result of simulation when $r_1 = 1.1$, $r_2 = 0.9$

Figure 6(a) and (b) describe the evolutionary results of the system when all the parameters conform to situation 6. The result shows that when netizen group A and group B are optimistic or group A and group B are pessimistic, the system will finally evolve to be of Group B and of group A.

4 Conclusion

Based on the shortcomings of the existing literature on the research of group events on networks and the new RDEU theory, this paper establishes RDEU game model of group events on network. Under the six evolutionary scenarios, it analyzes the extent and condition of influence of different emotions on netizens' game behavior. This paper overcomes the limitations of the traditional game model which on the basis of "full rationality" hypothesis of netizens, and considers the influence and mechanism of endogenous factors such as netizen emotion on the evolution of the group events on networks. It also reveals the deeper root of the outbreak and expansion of group events on networks. The results show that emotional factors have an important influence on the choice of the game strategies of the group events on networks. When some netizens has a “pessimistic” emotion, they tend to “antagonistic” behavior, and the higher the degree of pessimism, the more likely they choice a risk strategy; When some netizens has a “optimistic” emotion, they are easy to commit “concessions” behavior; When the netizens are pessimistic in both groups, the event is likely to evolve into a conflict effect with the herd effect.

The conclusion of this study can provide some reference and inspiration for the emergency management and prevention and control measures of network mass incidents. Government departments or social media should increase the response mechanism for the interests and wishes of netizens, strengthen netizens’ emotion monitoring and analysis and provide psychological intervention and emotional counseling for them timely.

Effects of Internet Word-of-Mouth of a Tourism Destination on Consumer Purchase Intention: Based on Temporal Distance and Social Distance

Mo Chen(✉) and Jingdong Chen

Faculty of Economy and Management, Xi'an University of Technology, Xi'an 710054, People's Republic of China
chenmo19921201@foxmail.com

Abstract. The proportion of tourists who referencing the Internet word-of-mouth increased. Hence, tourism destinations' online word-of-mouth has an practically significant effect on the willing of purchase. Due to an increasing trend about the proportion of tourists referencing Internet word-of-mouth (IWOM) for, making a study of tourism destination online word-of-mouth influence on purchase intention has practical significance. The purpose of this article is to provide marketing advises in different temporal and social distance. The research methods of this article is dividing 110 college students into two groups. All the students are allowed to read online word-of-mouth about two destinations, and this is for measuring consumers' tourism consumption which under different temporal distance and social distance categories. The conclusion is that quality of word-of-mouth exercise a greater effect for the consumers when they will travel in the far future. And the quantity of word-of-mouth influence nearly future purchase intention of consumers more prominently. For far Social distance between reader and IWOM witter, purchase intention is more significantly affected by the quality of word-of-mouth. On the contrary, purchase intention is more significantly influenced by the quantity word-of-mouth, when they feel they are close.

Keywords: Internet · Word-of-Mouth (IWOM) · Consumers purchase intention · Temporal distance · Social distance

1 Introduction

The context of traveling getting increasingly popular, prospects is taking on prosperity and potential is substantial for the traveling sector in China, with online consumption in doing sightseeing projected to reaching RMB 800 Billion. In 2014, this country had a transaction scale of RMB 3250 Billion, in which the E-market of tourism represents 11.3% to 367 Billion, a 45.6% rise compared to last year.

The reason why Chinese marketing has good developing prospects is great influence of WOM. As the consequence surveyed by Market research company

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_26

GfK shows that more than half of Chinese travelers rely on personal contact to obtain travel information, including friends, family and colleagues, which is same as online reading. In terms of actual booking, online instead of offline, there are 63% of visitors choosing online payment, which means that they are unavoidable to read some online information about destinations. 80% of consumers said they buy, influenced by the Internet word-of-mouth IWOM, implying that researching the tourism destination IWOM is of practical significance. At the same time, customer get tourism information platforms and ways, which are more diverse, because the Internet and mobile phone mobile client widely are used. The IWOM regarding tourism destinations in platforms such as ctrip, weibo or other tourism BBS or APP spread more widely, showing it exerts a great influence.

On the one hand, because the time intervals from customers reading IWOM to the actual purchase is different, leading to their purchase will be different. Customers will have a psychological judgment when they read online word-of-mouth. The judgment of the psychological distance between customers and the author of IWOM will also change the customer's purchase intention. Therefore, this paper starts from the difference of the influence of the word-of-mouth in the different temporal distance and social distance, observes the performance of consumers' purchasing intention and explains the influence of online word-of-mouth.

2 Literature

2.1 Word-of-Mouth Research

Arndt [1] first raised word-of-mouth in marketing research significance and showed word-of-mouth as a third party's influences on consumer behavior. And early studies tended to probe into the reason for word of mouth research [7]. With the development of the Internet and the increase of its scale, word-of-mouth research started in the Internet-word-of-mouth. In research, Internet-word-of-mouth (IWOM) [24], electronic word-of-mouth (ewom) [22], and electronic reputation refer to the same concept. In the study of IWOM, scholars [6,13] thought the IWOM is that customers or potential customers in the network community or BBS put forward for the product or business the positive and negative. Dong dahai defined the concept of IWOM [8], and considered IWOM has three main differences compared to traditional word-of-mouth: ① Spread more broadly. ② Connection between the receivers and senders is not determined [4]. In addition to the strong relationship between circles of friends, there is also a weak relationship. ③ commercial uncertainty. Due to some reasons such as the anonymity of the Internet behavior, Internet word of mouth will be controlled by some enterprises or business organizations. So, examining IWOM is different from traditional marketing and this makes word-of-mouth a fresh meaning.

From the beginning of the 21st century's China, research on word-of-mouth started to be increasing gradually. Domestic study about word-of-mouth for consumers to buy has two directions. One direction is discovering the emotional

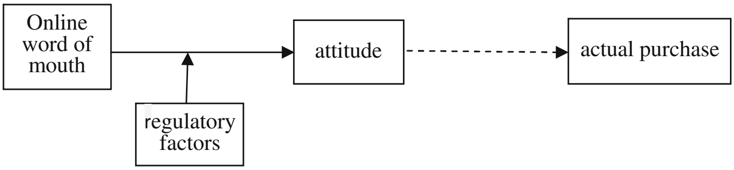

Fig. 1. Word-of-mouth and attitude theoretical model

factors of word-of-mouth. Guo [10] put forward the theoretical model of word-of-mouth for consumer attitudes, as shown in Fig. 1. After the model raised, A lot of research around the positive word-of-mouth and negative word-of-mouth. They believe that the emotion behind IWOM influence actual purchase through attitude. Baber et al. [2] found that the positive online word-of-mouth can bring positive change on consumers' purchase intentions. Bailey [3] proved that negative reviews have a significant impact on customers decision. Based on the original model studied, concentrated on regulating variables, which joined the adjustment factors such as trust and relationship strength. Balaji [22] found that the relationships among language divergence effect positive word-of-mouth intentions.

On the other hand, Zuo [20] put forward a model concerning the consumer purchase intention affected by word-of-mouth's quantity and quality. The existing literature has proved quality and quantity of word-of-mouth influencing intentions of consumers purchase [23]. This studies focus on the transmission of information. Balajia [4] mentioned information quality in the article about language divergence in WOM. This article in also refer to interaction quality and relationship quality.

2.2 Temporal Distance and Social Distance

Research on consumers' behavior and psychology research on time distance and social distance in recent years also have attracted more attention. With the development of the theory of psychological explanation level, researchers began to define the temporal distance and social distance from the Angle of cognitive. Reference point means the subject is located in someplace at the moment, the distance between the location of reference point and object is vague [19]. Time distant refers to people's feeling about the interval from an event occurrence to now [5], while social distant is they feeling about the relationship between relevant person and them [5].

Many studies probe into social distance and time distance with purchase intention of literature. Junghye's [15] conclusions are drawn that with the time interval between intention formation and the action becoming longer, and the greater the spatial distance to a destination is, the non-travelers have higher the probability to change behaviors. Xu [14], through experiment to measure the temporal distance and social distance for the interaction of the virtues and vices products, proved discrepancy in customers' preferences for the product under different situations. Zhang [21] proved the temporal distance effect on consumers' impulse consumption. Zou [25] found that the customers emphasis desirability or feasibility differently, when the consumer choose financial products under different temporal distances.

The preliminary study shows that temporal and social distance have an effect on consumer purchase intention. In short, combined with psychology and word of mouth is also a relatively new research.

3 The Experimental Research

3.1 Research Hypothesis

Internet word-of-mouth has one of the biggest differences compared with the traditional word of mouth, whose access is of diversification, so the quantity of electronic word-of-mouth is substantial. In terms of tourism destination's IWOM, consumers can collect and obtain, from several ways like tourism network BBS, blog, Micro-blog, instant messaging (We-chat, qq), network video, Wikipedia and travel quiz, tourist IWOM. Liu [16] proved that the movie aspect through word-of-mouth affects the relationship between the number of product sales and reputation. The study of the quantity of word-of-mouth, with the development of the network, from the original single-platform to cross-platform research, at present, has developed [11] swiftly, so the total quantity of IWOM is measured from the viewpoint of cross-platform.

The quality of word-of-mouth in essence refers to the content of word of mouth. In terms of tourist destination of IWOM, word-of-mouth quality evaluation is mainly from the correlation of word of mouth to convey information, professional degrees, and the vitality of comprehensive evaluation on the quality of word-of-mouth. In the texts of existing research on tourism destination's IWOM, online word-of-mouth interesting and vivid impact on the quality of word of mouth are great, illustrating IWOM which has high quality in the customer in the heart of higher quality [12].

Comprehensive quality and quantity of word-of-mouth's related research, Grant [9], proved that the total effect of word-of-mouth quantity and quality is the most significant, especially the quality of word of mouth, which is different from the path on the purchase intention. So the theoretical model of its influence on purchase intention action is (as shown in Fig. 2).

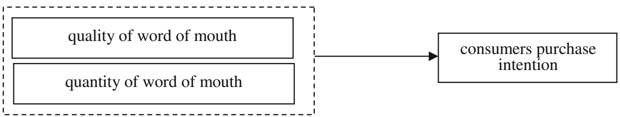

Fig. 2. Word-of-mouth and purchase intention model

This basis the paper puts forward the following two assumptions:

Hypothesis 1: Consumers purchase intention is more significantly affected by the quality of word-of-mouth in far future and the quantity of word-of-mouth influence nearly future purchase intention of consumers more prominently.

Hypothesis 2: When there is far social distance between receivers and senders, the receivers' purchase intention is more significantly affected by the quality of word-of-mouth; When they have nearly social distance, customers' purchase intention is more significantly influenced by the quantity word-of-mouth.

3.2 Design of Experiment

(1) Subjects

The participants were senior undergraduate and graduate students, between the age of 21 to 25 years old, a total of 110 people, is divided into two groups, each group divided into 55 people. There are 28 women, and 27 men in each group. Choosing college students as subjects is mainly based on the following reasons: first, according to the survey of 2013, we found that 85.43% of college students surveyed said "I like traveling". And college students often use the Internet and like to travel. Second, college students and postgraduates with high homogeneity, can effectively control the contrast group and control group of demographic heterogeneity.

(2) Experiment Preparation

Experiment on all testers to get on the Internet first hand tourist information platform and channel was tested. These platforms for tourist destination's IWOM, including Ctrip, Qyer and Ma Feng Wo, the tourism BBS, post tourist experience. There are 90.9% testers, who collect information from those platform. 89.1% from weibo, 60% form We-chat's moment and subscription account, 1.8% from other ways. Due to the W-chat moment's privacy, word-of-mouth authors have close social distance with word-of-mouth readers. So that the experience of travel sites post and micro-blog platform simulation scene, which measures the participants' purchase intention in the different temporal and social distance.

First of all, by reading the study of word-of-mouth, the author summarized main export tablets in quality and quantity of several attributes. Word-of-mouth quantity evaluation is mainly from three aspects [18]: ① multiple online platform to see multiple destinations related IWOM appear; ② the common platform to see multiple destinations IWOM; ③ the IWOM of destination has a lot of forwarding. Measurement of word-of-mouth quality is from the relevance, integrity, interesting and professional comprehensive evaluation.

On this basis, the author collected the related tourism destination online network of word of mouth. To avoid the destination names, which interfere the subjects of purchase intention, we use A and B represent to tourist destination, and both are simulating the ancient town tour relevant scenic spots, this ruling out consumer preferences' disturbance. The IWOM of Destination A reflect word-of-mouth quantity, and tourist destination B's IWOM reflect word-of-mouth quality. Word of mouth simulates the situation in three network platforms like weibo, ctrip and Ma Feng Wo. The tester would be shown 12 items IWOM about A and 3 items IWOM about B. The IWOM about B is 1 item IWOM in each platform, and the IWOM about A is 4 items IWOM in each platform. At the same time the experiment obscures the names of related sites.

(3) Experimental Design

Experiment is divided into two steps: the first measuring different temporal distance and the second experiment measuring different social distance. Measuring subjects for tourism destination A and B different purchase intention, and the scale basis by using three items, designed by Mr Schiff (Schiffman et al.) [17]: ① I am willing to travel to the area; ② I would like to recommend to others the region tourism; ③ I'd be happy to try to travel to the area.

Before answering questionnaire, subjects need to read the IWOM which simulates the IWOM's model of tourism BBS and Micro-blog. Scale takes 7 likert scale from "strongly disagree" to "strongly agree" assignment 1 to 7, recycling questionnaire by examining Cronbach's Alpha $= 0.767 > 0.7$, certificating validity within a reasonable range.

Because tourism is different from the retail purchase, it needs to cooperate with holiday, so the writer has been testing the latest holiday time for the recent test used in measuring temporal distance experiment. One is "weekend" and another is "one year", which are two different time distance measurements. Experiment announced by two word of mouth the identity of senders, 53-years-old workers and 23-year-old college student, respectively.

3.3 The Results

Experiment 1: using SPSS19.0 for data analysis and processing. In the study of the demographic variables such as gender, age did not produce any significant effect, therefore not included in the model. Mixed repeat test analysis of variance, the BOX 'sM inspection results $F(2, 108) = 0.174 > 0.05$, co-variance matrix through the homogeneity test, in the error variance equality Levene test, word-of-mouth quality $P = 0.937$, word-of-mouth quantity $P = 0.094$ were greater than 0.05 through inspection. Through the following Table 1 descriptive statistics analysis, it can be seen that word-of-mouth obvious interaction between quality and quantity exists.

Internet word of mouth and the interaction of the distance and time ($Eta = 0.645$, $p > 0.645$) can better account for the variation model. As shown in Table 1 and Fig. 3, in the distant future buying situation, the purchase intention of subjects who read the IWOM of tourism destination B (reflect word-of-mouth quality), are significantly higher than that of tourism destination A (reflect word-of-mouth quantity); In near future purchase situations, the purchase intention of testee who read destination A (reflect word-of-mouth quantity), is significantly higher than of destination B (reflect word-of-mouth quality). *Hypothesis 1* is validated.

Because of social distance perception differences, the experiment by controlling the reviewers with different background information realizes the control of

Table 1. The results of experiment one

Temporal distance	Online-word-of-mouth				Paired-sample t test	
	Quality		Quantity		t-value	Degree of freedom
	Mean	Standard deviation	Mean	Standard deviation		
Near future	3.18	1.335	4.35	1.377	3.734***	54
Distant future	4.24	1.319	2.47	1.052	7.251***	54

*** is $p < 0.001$

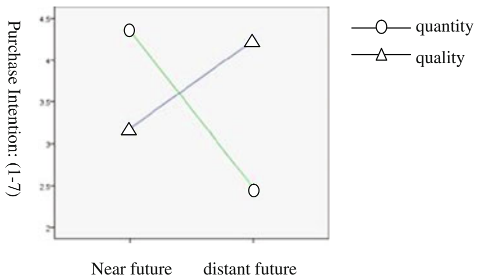

Fig. 3. Impact of word-of-mouth quality and quantity on purchase intention of consumers in different temporal distances

social distance. In the social distance situation in the group, we told the participating commentators, 53-year-old workers (social identities and differences in subjects); Then in the social situation in the group closer, we told participating reviewers, 23-year-old college students (high degree of social identity is similar to the participants).

Social distance measure takes the following scale: (1) I think of myself and word-of-mouth authors similar; (2) I think of myself and word-of-mouth authors psychological distance; (3) I think of myself and word-of-mouth authors belonging to the same group. Adopting likert scale at 7 level produces The result of social distance is that a 23 of college students ($M = 5.26$) is significantly higher than a 53 office worker ($M = 3.44$), showing that the social distance control experiment is effective.

BOX'sM inspection results $F(2, 108) = 0.100 > 0.05$ in Levene test, word-of-mouth quality $P = 0.803$, the word-of-mouth quantity ($P = 0.07$ were greater than 0.05 through inspection. And the interaction of the Internet word of mouth and social distance ($Eta = 0.531$, $p > 0.531$) can better explain the variation model.

As shown in Table 2 and Fig. 4, when the social distance is far between the senders and receivers of IWOM, the subjects' purchase intention of tourism destination B (reflect word-of-mouth quality), are significantly higher than that of tourism destination A (reflect word-of-mouth quantity); When the reader feel

Table 2. The results of experiment two

Social distance	Online-word-of-mouth				Paired-sample t test	
	Quality		Quantity		t-value	Degree of freedom
	Mean	Standard deviation	Mean	Standard deviation		
Far social distance	3.55	1.212	4.51	1.611	5.185^{***}	54
Close social distance	4.80	1.311	2.65	1.181	6.885^{***}	54

*** is $p < 0.001$

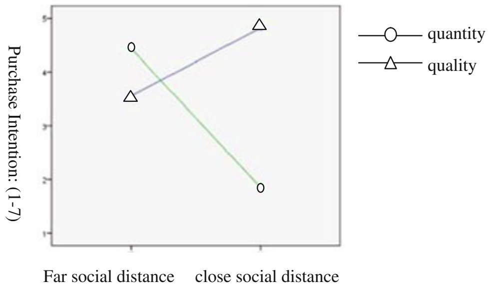

Fig. 4. Impact of word of mouth quality and quantity on purchase intention of consumers in different social distances

they have close social distance, which means that they believe that they have a similar social identity, the purchase intention of destination A (reflect word-of-mouth quantity), is significantly higher than B ((reflect word-of-mouth quality). *Hypothesis 2* is validated.

4 Results, Discussion and Limitations

In this paper, tourism destination online word-of-mouth can be divided into two different measures, including the quality and the quantity of word-of-mouth. This paper, through two experiments, tests the quantity and quality of IWOM influencing on consumer purchase intention under different temporal distance and the social distance situation. The conclusion is as follows:

(1) Quality of Internet word-of-mouth for the forward travel consumer buying may exercise a greater effect and the quantity of IWOM influence on recent purchase intention of consumers more prominently. This suggests that if the time interval between reading and buying is far, the customers' decision-making depends on IWOM quality. It because the customer's high level interpretation will be easily activated, when the cognitive and purchase time interval is far. That means high levels of explanation of IWOM more easily

by cognitive quality and low levels of explaining IWOM quantity will be weakened.

(2) The far social distance between the word-of-mouth authors and readers, consumers purchase intention is influenced significantly by the quantity of word-of-mouth. This suggests that when customers and word-of-mouth authors are far in social distance, the customers' decision-making depends on IWOM quality. It because the customer's high level explanation is easy to be activated. That means high levels of explanation of IWOM quality theory is more easily cognitive and low explaining IWOM quantity will be weakened.

(3) The average of quality of word of mouth influencing on consumers' willingness to buy is higher than word quantity, which means the high-quality IWOM have more extensive and more lasting influence.

In this paper, the study of online word-of-mouth, expands the research contents of psychological explanation level about social distance, and also provides inspiration for tourist destination choice.

First, the relevant tourism destination management on tourism propaganda should choose who have closer social distance with destination target customers. At the same time, the high quality tourism strategy and the relevant evaluation can attract more consumers. The platform of their own tourism official weibo, also should share more high-quality tourist guides, and, release illustrated weibo.

Second, when it is tourist season, the relevant tourism management department can propaganda through multiple platforms, and form a certain scale of word-of-mouth, to attract more attention from people.

Finally, because the study take the simulation experiment method, in the simulation of situation and realistic scenarios exist certain differences. In the future, we should be in the real scene to verify this conclusion.

jianchenghu@163.com

Abstract. In recent years, with the acceleration of population aging, the development of population structure is an important factor that influences economy and social development of China. This paper studied the future trend of population in Sichuan of China by establishing a population development equation. Taken the statistical data of census in 2010 in Sichuan, some important factors, such as survival rate, fertility mode and gender ratio etc. are considered to estimate the population structure, especially the proportion of older people, in Sichuan. The model is utilized to predict the population aging trend and aging index in the case of different total fertility rate and to provide reference for the government to make corresponding social and economic decisions.

Keywords: Population aging · Population development equation · Aging index · Total fertility rate

1 Introduction

Population aging is a phenomenon that occurs when the median age of a country or region increases due to rising life expectancy and/or declining fertility rates. Population aging is becoming one of the global problems of the modern times, but with different features from region to region and from country to country. Recent declines in fertility rates and increases in life spans are producing a significant shift in the age distribution of population [4]. Aging of population is closely associated with increased life expectancy, which was mainly determined by better quality health services, new discoveries in pharmaceutics, children diseases treatment. Recent research by the United Nations reveals that the proportion of people aged 60 and over is growing faster than any other age group and it is expected to reach 1 billion by 2020 and almost 2 billion by 2050 (representing 22% of the global population). The proportion of individuals age 80 or over is projected to rise from 1 to 4% of the global population by 2050 [5]. Figure 1 shows the change in the age structure of the world's population over time. Each shaded section reveals the age distribution at one point in time. The elderly share will be much higher in 2050 than it is now.

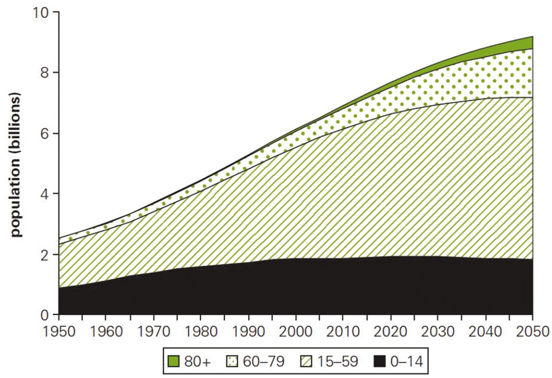

Fig. 1. World population by age group in 1950–2050

Population aging is one of the important factors that influence social and economic development of a country. Since different age groups have different economic needs and productive capacities, a country's economic characteristics may be expected to change as its population ages. Therefor correct forecast on the future population trend has significant guiding to the economic plan of overall country and local government.

In recent years, many articles have been paying more and more attention to population aging prediction and family policy to deal with the aging population problem, such as using gray dynamic model with equal dimension forest theory [9], overlapping generations model [1,7], logistic population model [2], predator-prey population model [8,11,12], stochastic differential equations [10] and so on. In order to analyze and predict the population trend of Sichuan, China, population development equation model is presented and applied to analyze the population of China [3,6].

The United Nations' old standard maintains that a country with more than10% of its population over 60 years old is an aging society. The new standard presents the population of 65 years and above people exceeds 7% of the total population. In fact, according to census of population, there were 88.11 million population aged over 65 years in Chinese mainland, accounting for 6.96% of the total population till November, 2016; while the number turned to 130 million and 10.20% when it came to the population aged over 60 years.

This paper takes the 6th census data in Sichuan as the accordance, and uses a population development equation model to predict the population development in Sichuan. The model is utilized to analyse the population aging trend in the future in Sichuan from a short period, and further predict the long-term population development trend and aging population change condition in Sichuan in the case of different total fertility rate.

2 Population Development Equation

2.1 Continuous Model of Population Development Equation

Let $p(r,t)$ expresses the population density of r years in the year of t, considering the population in the age interval $[r, r+\Delta r)$ from year of to $t+\Delta t$, survival population turns into age interval $[r+\Delta t, r+\Delta r+\Delta t)$, and the number of dead population is $\mu(r,t)p(r,t)\Delta r\Delta t$, which $\mu(r,t)$ is mortality rate of r years population in the year of t. Then we have

$$p(r,t)\Delta r - p(r+\Delta t, t+\Delta t)\Delta r = \mu(r,t)p(r,t)\Delta r\Delta t \tag{1}$$

or

$$\frac{p(r+\Delta t, t+\Delta t) - p(r, t+\Delta t)}{\Delta t} + \frac{p(r, t+\Delta t) - p(r,t)}{\Delta t} = -\mu(r,t)p(r,t), \tag{2}$$

when time increases Δt, the age also increase Δt, that is $\Delta t = \Delta r$. Let $\Delta t = \Delta r \to 0$ in Eq. (2), then

$$\frac{\partial p(r,t)}{\partial r} + \frac{\partial p(r,t)}{\partial t} = -\mu(r,t)p(r,t). \tag{3}$$

Given the initial and boundary conditions, that is, initial population density function $p(r,0) = p_0(r)$ and fertility rate $p(0,t) = f(t)$, the continuous model of population development equation can be obtained

$$\begin{cases} \frac{\partial p(r,t)}{\partial r} + \frac{\partial p(r,t)}{\partial t} = -\mu(r,t)p(r,t), & 0 \le r \le r_m, t \ge 0 \\ p(r,0) = p_0(r), & 0 \le r \le r_m \\ p(0,t) = f(t), & t \ge 0 \\ p(r_m,t) = 0, & t \ge 0, \end{cases} \tag{4}$$

where the r_m is the maximum age of population. Equation (4) is difficult to solve, but in ideal situation, such as stable society circumstance, short time interval etc., the mortality rate and fertility rate are independent with time t, the solution of Eq. (4) can be obtained.

2.2 Discrete Model of Populat1ion Development Equation

In order to study the dynamical population of different ages at any time, the Eq. (4) should be discreted respect to variables r and t. Based on Eq. (1), the r years population $N_r(t)$ in the year of t can be written

$$N_{r+1}(t+1) = s_r(t)N_r(t), r = 0, 1, 2, \cdots r_m - 1 \tag{5}$$

and by virtual of initial condition, also have

$$N_0(t) = s_0(t)b(t), \tag{6}$$

where $s_r(t)$ and $s_0(t)$ are the survival rate of r years population in the year of t and infant survival rate respectively, which can be calculated by the statistical data of population census. $b(t)$ is the population born in the year of t. Concerning the reproductive age interval $[r_1, r_2]$, $b(t)$ can be described as

$$b(t) = \sum_{r=r_1}^{r_2} b_r(t)k_r(t)N_r(t), \tag{7}$$

where $b_r(t)$ is the fertility rate of childbearing age female at r years old in the year of t, i.e. the average number of infant born by each r years old female in the year of t, $k_r(t)$ is gender ratio, the ratio of r years old female in the total population in the year of t.

By representing the population of each age in the year of t as a vector of size r_m, let

$$N(t) = [N_0(t), N_1(t), \cdots, N_{r_m}(t)]^T, \tag{8}$$

the population development Eqs. (5) and (6) can be written as

$$N(t+1) = A(t)N(t) + \beta(t)B(t)N(t), \tag{9}$$

where

$$A(t) = \begin{bmatrix} 0 & 0 & \cdots 0 & 0 \\ s_1(t) & 0 & \cdots 0 & 0 \\ 0 & s_2(t) & \cdots 0 & 0 \\ \vdots & \vdots & \ddots \vdots & \vdots \\ 0 & 0 & 0 \quad s_{r_m-1}(t) & 0 \end{bmatrix}, \tag{10}$$

$$B(t) = \begin{bmatrix} 0 \cdots 0 & b^*_{r_1}(t) & \cdots & b^*_{r_2}(t) & 0 \cdots 0 \\ 0 \cdots 0 & 0 & \cdots & 0 & 0 \cdots 0 \\ \vdots \ddots \vdots & \vdots & \ddots & \vdots & \vdots \ddots \vdots \\ 0 \cdots 0 & 0 & \cdots & 0 & 0 \cdots 0 \end{bmatrix}, \tag{11}$$

$$b^*_r(t) = s_0(t)s_r(t)k_r(t)h_r(t), r = r_1, \cdots, r_2, \tag{12}$$

and the total fertility rate

$$\beta(t) = \sum_{r=r_1}^{r_2} b_r(t), \tag{13}$$

which is the average number of infants born by each female in the year of t. Define the female's fertility mode $h_r(t)$, which is r years old female's fertility weighted factor and satisfied $\sum_{r=r_1}^{r_2} h_r(t) = 1$. Then $b_r(t)$ can also written as

$$b_r(t) = \beta(t)h_r(t). \tag{14}$$

3 Model Establishment and Solution

As Sichuan has come into aging society, in order to make clearly the future population aging trend, we use population development equation to predict the population in a short period and analyze the change trend of future population aging speed. At the same time, predicting the long-term population development process of Sichuan in the case of different total fertility rate, and trying to seek for a relatively good total fertility rate not only can control too fast population growth but also ease the population aging condition.

3.1 Prediction of Population Structure

As the data information provided by the 6th census in Sichuan is limited, and the factors that influence population development are various, it is relatively difficult to get the rule that mortality rate function and fertility mode changes as the time changes. The population fertility policy will not change in a relatively short period; in the condition of stable society, we usually suppose that survival rate $s_r(t)$, fertility mode $h_r(t)$ and gender ratio $k_r(t)$ relatively do not change. The data published from the 6th census in Sichuan shows the total fertility rate of women $\beta(t) = 1.075$ at present. Under the supposition above, we use the data of the 6th census in 2010 in Sichuan as the cardinal number to predict the population in the future six years in Sichuan. The prediction result is shown as Table 1.

From the prediction results, we can see that the population in Sichuan is still increasing. After Guangdong, Shandong and Henan, Sichuan is ranked fourth big province in the whole country population, also aging serious provinces. Although the data of the census shows the population fertility rate is relatively low, and the total population still continuously grows.

From Table 2, we can see from the calculation result of population proportion at each age section that the proportions of aged people and children still continuously increase, but the proportion of adults continuously decreases. In 2010, people under the age of 14 years accounts for the total population of 16.97%, 0.37% points higher than the national average level; 15–64 year old population account for the total population of 72.08%, 2.45% points lower than the national average; the population aged 65 years account for the province's total population of 10.95%, 2.08% points higher than the national average.

3.2 Aging Index

The aging index (AI, sometimes referred to as the elder-child ratio) is a common indicator of changes in age structure, which is defined as the number of people aged 65 and over per 100 young people aged 0–14 years [10]. In 2000, only a few countries (Germany, Greece, Italy, Bulgaria, and Japan) had more elderly than youth (aging index above 100). To date, aging indexes are much lower in developing countries than in the developed world, but the proportional rise in the

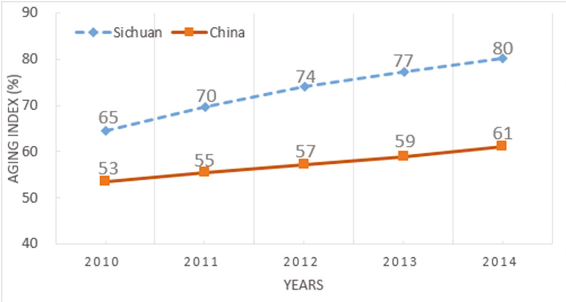

Fig. 2. Aging index of Sichuan and China in 2010–2014

aging index in developing countries is expected to be greater than in developed countries.

In 2010, the AI in China was approximately 53, meaning that there were 53 people aged 65 and over for every 100 persons aged 0–14 years, while the AI in Sichuan was approximately more than another 12. As Fig. 2 shown, the AI in both China and Sichuan increased progressively from 2010 to 2014, and the increment of AI in Sichuan is more than that of China in studied period from 65(2011) to 80(2014).

3.3 Total Fertility Rate Analysis

In the late-1970s started the family planning policy which implemented, especially in the urban only child policy, China effectively was suppressing the population growth, the fertility rate dropped continually, and in recent years, the fertility rate has remained at 1.4%–1.5% level for a long time, which have also accelerated the aging of population. In order to promote the balanced development of population, adhere to the basic state policy of family planning, improve the population development strategy, China fully implement two-children policy, that is, a couple can have two children. Two-children policy appropriate to slow down the population aging process, help to solve the aging population.

From the short term, the family planning policy will not influence the population structure of Sichuan temporarily, however, from the long term, it will have played a positive role on easing the aging population. In the population analysis and decision-making, the total fertility rate is an important index and parameter for the prediction of population. It can be directly used to compare different periods of women's fertility level, which has important reference to the long-term macro decision of the population. In order to study population fertility policy, the following supposes that the other factors do not change in the future years, and predicts the population structure of Sichuan in different total fertility rate. Following, we will suppose that the total fertility rate $\beta(t)$ is respectively at 1.5, 2.0 and 2.5, and predict the total population and the proportion of 65+ years old population in the future 50 years in Sichuan. The prediction results are shown as Figs. 3 and 4.

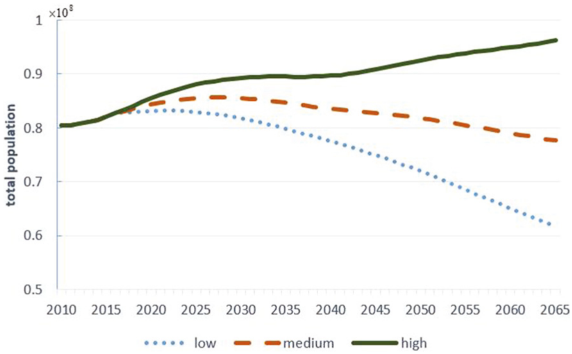

Fig. 3. Prediction of total population in 2010–2065

From Fig. 3 we can find that the total population quantity in the future will increase continuously in the case of high total fertility rate. When the total fertility rate maintains the low level, the total population has a short term growth, and soon will decrease steadily. In the case of medium total fertility rate, the total population will maintain stable in the future 50 years. Meanwhile, the prediction of aging population proportion in the future 65 years is shown as Fig. 4.

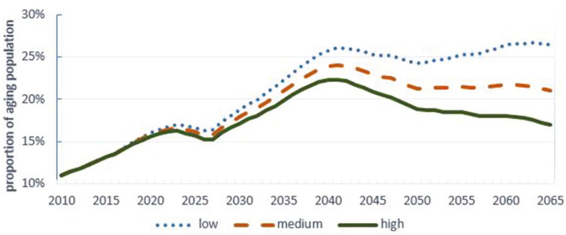

Fig. 4. Proportion of population at 65+ years old in 2010–2065

As Fig. 4 shown, in the case of low total fertility rate, the proportion of aging population will continuously increase and finally exceed 25% in 2060. In the case of medium total fertility rate, the aging population increase slowly, and stabilizes around 22% after 30 years. When the total fertility rate is high, the proportion of aging population is relatively slow, and gradually stabilize and maintain in the below 20% after 30 years of growth.

From the prediction results, we can find that the relatively high fertility rate will make the population aging keep at a relatively low level, but will cause the rapid population growth. For example, considering the proportion of aging population and the total population in the period of 2020–2040, the proportion of aging population changes from 16% to 26% and the total population decreases from 83 million to 77 million in the case of low total fertility rate. Meanwhile, the proportion of aging population only increases 6% from 16% and the total population increases 13 million from 83 million in the case of high total fertility rate. The prediction indicates that only when the total fertility rate keeps at 2.0 can a relatively good result appear.

The rate of population aging may also be modulated by migration. Immigration usually slows down population aging, because immigrants tend to be younger and have more children. On the other hand, emigration of working-age adults accelerates population aging. The 6th census shows that in 2010 the population mobility rate of Sichuan was 18.92%, lower than the national average only 0.59% points. Among them, the emigration rate of Sichuan was 23.24%, and the immigration rate was 14.59%.

4 Conclusions

This paper predicts the population structure in the future six years in Sichuan by establishing the population development equation. And the results show that total population in Sichuan will continuously increase and the aging population is increasingly aggravated. The population aging is an inevitable population problem. The aging population increase will be a series of problems to society, we can not only solve it through population policy but also old-age supporting policy, and social security policy, and regulating economic structure, etc.

In order to analyze the effect of fertility rate on the aging of the population, we predict the population structure in the future 50 years in Sichuan in the case of different fertility rate. And the results indicate that appropriate fertility rate will help to regulate population structure and ease the population aging. When the total fertility rate is 2.0, the population development in the future in Sichuan will be relatively stable and the trend of population aging will slow down and finally keep at the level of 22%.

Evaluation of Progressive Team Intervention on Promoting Physical Exercise Behavior

Xinyan Guo(✉)

Economy and Management Faculty in Chengdu Sport Institute,
Chengdu 610041, People's Republic of China
sindystory@163.com

Abstract. Focusing on parts of urban residents, which were divided into two groups, intervention group (165 people) and control group (178 people), a "5As" physical exercise behavior intervention process (Ask, Access, Advice, Assist and Arrange) was applied to the intervention group people with auxiliary materials including intervention manuals and exercise prescriptions. The baseline data and the tracking data of the two groups were collected and analyzed by descriptive statistics, comparison of means, analysis of variance and correlation analysis to study the effectiveness of intervention. The results of tracking survey showed that residents had better acceptance for the use of intervention. Before and after the intervention, there was a certain change about the residents' physical exercise behavior and there were significant differences in the behavior variables ($P < 0.05$). Physical exercise behavior belongs to preventive innovation which requires corresponding health education and intervention. The research adopts a step by step mode to implement targeted intervention measures, and peer groups make it easier to accept and prove to be efficient for the individuals. And the research provides a new idea and method for the physical exercise intervention.

Keywords: Physical exercise behavior · Progressive intervention · Tracking survey · Urban resident

1 Introduction

In the modern society, sports and human survival and development are more and more closely related, its significance and function far exceeded the original concepts and categories. Physical activity can effectively change people's way of life, prevent all kinds of chronic diseases, and moderate physical activity is one of the most simple ways to improve and maintain health [3,17,18]. People pay much more attention to living environment, living styles and the consequent changes of morbidity and mortality rates [16]. Researches on health management and promotion show a close relationship between residents' living style and physical health.

In Japan, less than 30% of Japanese do frequent (usually one year or more) and regular (30 min per time, twice a week) physical exercises. A survey in

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_28

Australia showed that 53% of the adults didn't take regular exercises with their sitting time being 4.7 h per day or more [10]. High income countries like U.S. and U.K. showed the same results. According to the survey, in U.K., only 39% male and 29% female adults were doing exercises regularly, moreover, the participation rate declined with the change of age, work and family [1,11,12].

There are many exercise behavioral intervention studies. Geoff et al. (2010) conducted a pre-post survey research to 200 British female undergraduates who did not attended any physical exercises, and analyzed the benefits and cognitive disorders [13]. This study indicated that interventions should give priority to solve the disorders of participating physical exercises which can be perceived by individual. On the other hand, interventions should emphasize this cognition that physical exercises are beneficial to health, thereby promoting modifications of cognition and behavior for participating physical exercises. In order to study the influence of PE class to students' physical activities, Sallis et al. designed a trial that it made 338 senior undergraduates to attend randomly intervention credit courses or control credit courses [19]. The results demonstrated that the total volume of activities including leisure time, strength exercises and flexible exercises in female group was increased due to interventions, which facilitated female to participate healthy physical exercises. However, there was not significant in male group, because male students were more like sports than female found in basic survey. About the applied studied of stage-based intervention, Marcus et al. performed an exercise intervention the Imagine Action campaign for community volunteers to research the results between pre-exercises and post-exercises, and this study indicated that 30% of participants in Contemplation and 60% of participants in Preparation moved into Action, while 31% in Contemplation moved into Preparation. This study also indicated that less expensive and intensive exercise intervention can be adopted significantly [14]. Bogdan et al. evidenced the effectiveness of stage-based intervention in their study which aimed at exercises behavioral intervention for 560 orthotic patients [2]. Other researchers also proved the advantages of stages-matched intervention to stages-non-matched intervention using other approaches such as Internet aided intervention [4].

However, to make it function well, coordination and cooperation are needed between individuals, family, society and various departments (such as health, education etc.). At the same time, it also depends on the scientific method of promoting behavior to intervene [5,7].

In this paper, Progressive Intervention is adopted to understand the individual characteristics, strengthen the awareness of individual self-management and help individuals form a good behavior habits. Then through baseline data and tracking data, the effectiveness of intervention was analyzed to provide operational framework and theoretical guidance for the health promotion, especially for the "sub health" status of the population.

2 Objects and Methods

2.1 Participants

Stratified random sampling method was used to select the urban residents participants from the fitness clubs, parks, squares, community focus points etc. And they include volunteer solicitation, recruitment network, and random samples through the local network. Sample size for the baseline survey was 343. Samples were randomly divided into two groups: intervention group and control group, 165 in the intervention group, and 178 in the control group (Tables 1 and 2).

Table 1. Gender of respondents (baseline data) $N = 343$

Gender	%
Male	47.1
Female	52.9

Table 2. Age of respondents (baseline data) $N = 343$

Age	≤18	18–29	30–39	40–49	50–59	≥60
(%)	6.5	10.8	25.7	28.1	19.2	9.7

To ensure the quality of the intervention, staff training was carried out before the test to ensure that the intervention process was completely. And all these works are taken out accordance with the framework of the theory hypothesis.

2.2 Test Instruments

The related testing instruments used in the study include the test scale, the intervention manual and the experiment site, and so on.

The test scale is mainly used to measure the process and the result of the residents' physical exercise behavior. This study integrated the health belief theory and the theory of planned behavior and propose that the exercise behavior outcome of urban resident can be predicted by some factors including behavioral attitude, body norm, perceived subjective control, perceived susceptibility, perceived severity, perceived behavior benefit, perceived behavior disorder, behavior clue and behavior intention. The scale is based on the integration of relevant theory [8]. A self-designed questionnaire was formed on the combination of the theory of planned behavior and health belief model, the questionnaire contain 4 items of personal basic information (including gender, age, occupation, education etc.), perceived susceptibility, perceived severity, perceived barriers, perceived benefits, behavioral cues, behavioral attitude, subjective norm, perceived behavioral control, behavioral intention and behavior, a total of 33 items.

Scale by Li Kete five point scale scoring methods: among them, perceived barriers project assigned the remaining items reverse, positive score, namely "strongly disagree" for 1 points, "disagree" for 2 points, "not sure" for 3 points, "agreed" for 4 points, "strongly agree" for 5 points.

The effectiveness of the physical exercise behavior at the present stage (including the action stage and the intensity of action) and the related characteristics were measured [6].

Based on exercises behaviors traits and stages of residents, the invention handbook was composed of introduction, interpretation and suggestion. The content is as follow:

(1) Health, sub-health and diseases
The aim of this part is to provide some essential concepts about their physical fitness for residents so that lay a good foundation for healthy life style. For example, health can be divided into three states, namely health, sub-health and diseases. A state of sub-health is either non-health or non-diseases. The symptoms of sub-health include lack of energy and other weakness, but these symptoms cannot be diagnosed by clinical examinations.

(2) Introduction of scientific exercise methods
In the part, the benefits of regular exercises will be introduced, including the improvement of physical fitness, adjustment of psychological factors and so on. And then to introduce what is regular exercises, how to control the amount of exercises, how to warm-up and how to eliminate fatigue quickly.

(3) The common exercise methods aerobic exercise
The most common exercise is aerobic exercise that is to improve the cardio respiratory fitness and physical fitness. Furthermore, methods and skills of aerobic exercise will be introduced in this part.

(4) Other exercise methods
These exercise methods do not need complex techniques, fitness facilities, and extra costs, at the same time these methods are effective, feasible and popular for public. For example, jogging, running, bicycle riding, aerobics and fitness path.

(5) Exercise methods of different population
People should perform suitable exercises based on their physical and psychological conditions such as ages, gender and vocation. The main contents of this part is to provide distinct advices for different population.

2.3 Test Procedure

The study is a quasi-experimental design due to the large sample size and the certain range of exercise behavior intervention. In order to ensure the rationality and integrity of data analysis, the empirical research is divided into two stages: the first stage is baseline survey data analysis, and the second stage is tracking data analysis. The test procedure is shown in Fig. 1.

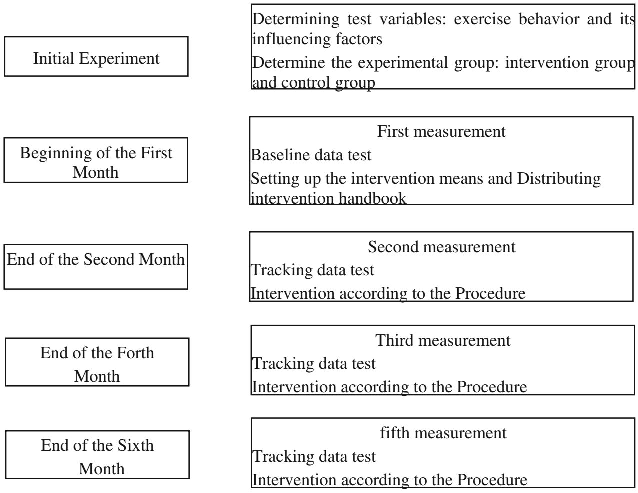

Fig. 1. Intervention procedure

Firstly, the baseline survey was performed with the permission of subject individuals. The questionnaire was distributed to the residents, and the characteristics of the physical exercise behavior and basic information were measured, then the experimental group of residents were carried out by the intervention staff.

After six month behavior intervention, behavioral tests were carried out every two months, four times totally. Both groups use the same questionnaire scale. The survey was conducted in a narrative way of step-by-step introduction, explanation and recommendations.

3 Intervention Process

3.1 Intervention Evaluation

Firstly, Epi Data was used to establish a database, and all the data were checked after the entry. Then the modeling and analysis of the related research can be carried out only after the examination of the normal distribution, in which the reference value of all samples were within the reference range of criteria. And the absolute value of Skewness coefficient and kurtosis coefficient should be in the 0 to 1 range, and the S-W test P value is greater than 0.05, which demonstrated that the formal sample can meet the requirements of normal distribution [15].

Urban residents of Sichuan randomly selected for the survey sample (n = 343), and the two subjects showed no significant difference in the results of exercise behavior and behavioral characteristics variables ($p > 0.05$).

3.2 Follow-up

Complete physical exercise behavior intervention points can be summed up in 5 words: Ask, Access, Advice, Assist and Arrange (5As).

Ask is to inquire about the individual residents to participate in physical exercise and understand their health status; assess is to measure individual residents' intention of participating physical exercise, behavior characteristics and the behavior of the stage; advice is to provide targeted exercise recommendations, support and help based on the individual physical exercise behavior; at last follow-up (shown in Fig. 2).

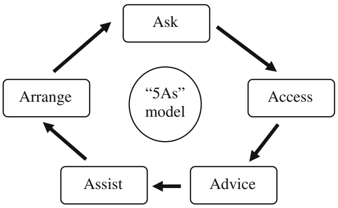

Fig. 2. "5As" Intervention flow chart of physical exercise behavior

After the beginning of intervention, according to the experimental arrangement, "Arrange" is set up in the four follow-up tests. The main purpose is to understand if the residents still persist in physical exercises, congratulate the residents who have maintained physical exercise and encourage them to continue to persist; and give the affirmation to those who maintained a period of time and then give up, and encourage them to start exercise behavior again. At the same time, according to the interview, guidance and help are given, in case of giving up.

4 Intervention Outcome

Based on the theoretical hypothesis, the exercise behavior intervention experiment is implemented to analyze the changes of physical exercise behavior between intervention group and the control group before and after the test period.

Firstly, the slope homogeneity of the covariance analysis is tested. The variance analysis model were analyzed in which the variables of behavioral characteristics after intervention were dependent variables, the group variables (1 = intervention group and 2 = control group) were independent variables. The result showed that the interaction between independent variables and covariates was not significant ($P > 0.05$), that is, the assumption of the slope homogeneity (Table 3).

The result showed that the effectiveness is not significant from previous perceived susceptibility, previous perceived severity, previous perceived benefits, previous perceived barriers, previous behavioral attitude, previous subjective norm and previous perceived behavioral control variable ($P > 0.05$). But some variables' effectivenesses are significant ($P < 0.05$), such as previous behavioral cues and previous behavioral intention. Results are shown in Table 4.

Table 3. Covariance pre-analysis results (interaction)

Source of variance	P value
Group* Previous behavioral cues	0.363
Group* Previous perceived susceptibility	0.627
Group* Previous perceived severity	0.351
Group* Previous perceived benefits	0.094
Group* Previous perceived barriers	0.126
Group* Previous behavioral attitude	0.521
Group* Previous subjective norm	0.438
Group* Previous perceived behavioral control	0.095
Group* Previous behavioral intention	0.766

*The difference is significant at 0.05 level.
**The difference is significant at 0.01 level.

Table 4. Covariance pre-analysis results (Intervention effectiveness)

Source of variance	P value
Previous behavioral cues	0.044*
Previous perceived susceptibility	0.426
Previous perceived severity	0.233
Previous perceived benefits	0.068
Previous perceived barriers	0.091
Previous behavioral attitude	0.084
Previous subjective norm	0.258
Previous perceived behavioral control	0.086
Previous behavioral intention	0.032*

*The difference is significant at 0.05 level.
**The difference is significant at 0.01 level.

Therefore, the exercise behavior variables of the two groups were compared and analyzed (Tables 5 and 6). The results indicated that the exercise behavior of the intervention group was significantly higher than that of the control group, which means the progressive intervention is effective to promote the formation of physical exercise.

Table 5. Comparative analysis of the effectiveness before and after the intervention

Variable	Intervention group	Control group	P value
Perceived susceptibility	$3.35 \pm 0.0.583$	$2.83 \pm 0.0.518$	0.032*
Perceived severity	2.89 ± 0.167	$2.49 \pm 0.0.273$	0.050*
Perceived benefits	$3.05 \pm 0.0.267$	$3.68 \pm 0.0.415$	0.021*
Perceived barriers	$3.58 \pm 0.0.326$	$2.94 \pm 0.0.572$	0.006**
Behavioral attitude	$4.25 \pm 0.0.597$	$3.92 \pm 0.0.486$	0.006**
Subjective norm	$4.15 \pm 0.0.278$	$4.00 \pm 0.0.436$	0.000**
Perceived behavioral control	$4.83 \pm 0.0.352$	$4.70 \pm 0.0.492$	0.000**

*The difference is significant at 0.05 level.
**The difference is significant at 0.01 level.

Table 6. Difference analysis of adjusted mean

Variable	(I) Group	(J) Group	Mean difference (I–J)	P Value
Behavioral cues	Intervention group	Control group	0.42	0.022*
Behavioral intention	Intervention group	Control group	0.36	0.003**

*The difference is significant at 0.05 level.
**The difference is significant at 0.01 level.

5 Discussion

The subject was intervened by progressive intervention, and the effectiveness of the intervention was confirmed by the comparative analysis of the intervention group and the control group.

The influence factors of urban residents' exercising behavior are multidimensional, including 9 factors: behavioral attitude, subjective norm, perceived behavioral control, perceived susceptibility, perceived severity, perceived benefits, perceived barriers, behavioral cues and behavioral intention. Perceived susceptibility and perceived severity of physical exercise have effects on perceived benefits and behavior attitude: perceived susceptibility, perceived severity, behavior barriers and perceived benefits have a positive impact on behavior attitude; perceived benefits have a negative role in behavior barriers but positive in behavior attitude; behavior attitude, subjective norm and perceived behavioral control function positively to behavior intention and behavior attitude does positive role to perceived behavioral control at the same time; behavior intention, perceived behavioral control, perceived benefits, barriers and cues exerts positive effects on behavior itself. Based on the survey results, in the baseline data, the majority of urban residents are aware of the benefits from physical exercise, but they are not necessarily involved in the fitness. In other words, the promoting effect which perceived benefits impacted on behavior intention is still to be strengthened. For there are more worried about, such as ways of physical exercises and strength, physical training environment, time cost, etc.

In addition, although the residents hold a positive attitude for physical exercise benefits, but due to the limited understanding of their own physical condition and the relevant authority on argument, there is no clear subjective feeling for the contrast effect not to participate in fitness activities, and actively participate in fitness activities. But the intervention group was improved in these aspects.

In the four follow-up tests, according to the time schedule, the main purpose set of the "Arrange" is to understand whether the residents are still persist in this behavior or not [9]. In the process of behavior intervention, the people who did not participate in physical exercise should be divided into stages to carry out the work, such as conducting appropriate in-depth interviews with individuals, giving psychological guidance, emphasizing the importance of exercise behavior in their consciousness, at the same time, enhancing the confidence of physical exercise by demonstration role or embodiment contrast, and helping them realize the change of behavior as early as possible. In order to pursue a better cooperation of individual residents, access to information about physical exercise, intervention staffs may need to make some special arrangements for the environment of the conversation. For example, put some health handbooks or posters about physical exercise, display some sports souvenirs on desk, to help residents receive health intervention, and let them feel about that physical exercise is a very important work in the process of communication.

6 Conclusions

This study indicated that individual had different psychological cognitive status and behavior intention level, and faced different difficulties and obstacles. Based on the survey results, in the baseline data, the majority of urban residents are aware of the benefits from physical exercise, but they are not necessarily involved in the fitness. In other words, the promoting effect which perceived benefits impacted on behavior intention is still to be strengthened. For there are more worried about, such as ways of physical exercises and strength, physical training environment, time cost, etc. In addition, although the residents hold a positive attitude for physical exercise benefits, but due to the limited understanding of their own physical condition and the relevant authority on argument, there is no clear subjective feeling for the contrast effect not to participate in fitness activities, and actively participate in fitness activities. But the intervention group was improved in these aspects.

National fitness activities is mass fitness activities, to promote physical and mental health. Urban residents as the main subject of national fitness activities, their views of the community sports, support and participation in decision-making, directly impact on the mass sports development. Using progressive intervention mode can make people to clear the relationship between physical exercise and promote the health, to deepen the understanding of physical exercise behavior. in this study the intervention based physical exercise behavior intervention points (5As), and the result meant progressive intervention is effective to promote the formation of physical exercise.

Abstract. Environmental issues are harmful effects of human activities on the biophysical environment. More and more citizens are engaged in the open data movement for different purposes, in particular, emerging private companies are being built on Open Government Data (OGD) to predict extreme weather events for environmental protection, to satisfy more social requirements (e.g. job creation) and to make economic profits, simultaneously. Emerging companies are utilizing OGD to generate values. Building on a synthesis of the OGD literature and established theories of value generation, we develop a structural equation modelling (SEM)-based model to explore the causal relationship between OGD and value generation. This study constructs the conceptual structural equation model and lays a foundation for the upcoming research.

Keywords: SEM · Value generation · Open government data · Environment/weather sector

1 Introduction

Environmental issues are harmful effects of human activities on the biophysical environment. Major current environmental issues may include *climate change*, pollution, environmental degradation, and resource depletion etc. Global warming, or *climate change* as it's now commonly referred to, is the greatest environmental threat we've ever faced. There is little doubt that climate change is contributing to the extreme weather disasters we have been experiencing, such as worsening air quality, searing heat, and more frequent extreme weather events (e.g. raging storms, ferocious fires, severe droughts, and punishing floods). It threatens our health, communities, economy, and national security [7], for example, the climate change-related heat mortality in the first half of 2012 is a part

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_29

of a deadly trend. In 2011, at least 206 people died from extreme heat, up from 138 fatalities in 2010 and nearly double the 10-year average, according to the National Oceanic and Atmospheric Administration [8]. If we don't do more to reduce fossil fuel emissions and other heat-trapping greenhouse gases that are making heat waves more intense, more than 150,000 additional Americans could die by the end of this century due to excessive heat. Heat-related death is just one deadly side effect of extreme weather tied to climate change [7]. Other extreme events also have side effects, such as storms can cause drowning, contaminate drinking water and result in outbreaks of infectious diseases; heat and ozone smog increases respiratory diseases (e.g. asthma) and worsens the health of people suffering from cardiac or pulmonary disease.

According to NRDC (2015), the global warming has mainly six side effects on human health, including more vector-borne disease, more water-borne illness, longer allergy seasons, declining crops, air pollution and more heatwaves [7]. Therefore, as we work to stop climate change and prevent those associated impacts, we are also developing policies to minimize human suffering.

At present, worldwide nations have begun taking steps to combat this growing threat, working toward an international agreement in which every country on earth plays its part. Many of the world's largest polluters have stepped up with significant commitments, amplified by efforts from cities, businesses, sports leagues, non-governmental organizations (NGOs), and many other individuals and groups that have responded to the urgent need for a climate action. For example, since carbon pollution fuels climate change, drives extreme weather, threatens communities and cuts too many lives short, the U.S. Environmental Protection Agency has developed the Clean Power Plan, which sets the first national limits on carbon pollution from power plants and provides states with the flexibility to meet them.

The NRDC has suggested more solutions to address the global warming issues, such as setting limits on global warming pollution; investing in grean jobs and clean energy; driving smarter cars; creating green homes and buildings; as well as building better communities and transportation networks. These solutions will motivate our lawmakers to quit ignoring climate change and start limiting carbon pollution that is heating our planet and increasing the intensity of extreme weather. However, the government cannot be expected to do everything to protect the environment. In cooperating with the private sector as a partner can make sense based on the principle of partnership and appropriate process. Opening data is recognized as a driver of efficiency and a vehicle for increasing transparency, citizen participation and innovation in society. Open data can help improve food security, healthcare, education, cities, the environment, and other public and private services that are critical to development. Taiwan environment protection agency (TEPA) views environmental data as a strategic asset to protect our environment. *At present, more and more citizens are engaged in the open data movement for different purposes, in particular, emerging private* *companies are being built on Open Government Data or Open Environmental Data to predict extreme weather events for environmental protection, to satisfy more social requirements (e.g. job creation) and to make economic profits, simultaneously.*

Today, we are generating and storing more data than at any other time in history. The public sector and especially the various government branches are one of the main sources of data. Government data has traditionally been accumulated in protected repositories and registries as public record and a matter of civil order. Consequently, over centuries, archived government data has had limited access via proprietary interfaces and often cumbersome fee-based procedures. With time going on, governments have started to look into the prospects of providing open access to their data repositories. The concept of Open Government Data (OGD) refers to government data defined as "data and information produced or commissioned by government or government controlled entities" that are opened up for use and re-use by public and private agents alike [3]. These data encompass both scientific data about the environment (from Earth Observation and other fields) and other public sector information, including diverse topics such as demographics, health and crime. In the current-used terminology, OGD does not include data that are subject to valid privacy, security or privilege limitations, as governed by other statutes. Government data sets are an interesting subset of open data because such subsets have already been collected for specific use, have been paid for by taxpayers, are relevant and offer value beyond what is captured from the originally intended use. When opened up, government data become a common, shared resource (i.e., public good) that is provided by the government. In our digital age, opening up government data to everyone puts power in the hands of citizens [3]. Making environmental data open is an effective method to guide the local agencies for policy-making and decision-making, and to increase the citizen participation for environmental protection.

Under the OGD circumstances, many private companies are set up to make business values in various sectors, such as business & legal services, data & technology, education, energy, finance & investment, lifestyle & consumer. It becomes common to observe that data itself has no value, the value comes from how data is used and analyzed in particular businesses. Specifically, private sectors, non-government organizations, businesses and APP developers in the environment/weather are encouraged to use the datasets already published to create economic, social values, and in particular environmental values (Sustainable Objectives). Many pioneering companies are using OGD as a key resource to generate values, for example, OGD-driven business models are proposed to evaluate how OGD is used as a key resource to understand the value generation process in e-business industry. The Open Data 500 Global Network is an international network of organizations that seek to study the use and impact of open data. Coordinated by the Governance Lab (GovLab) the OD500 Global Network enables participating organizations to analyze open data in their country in a manner that is both globally comparative and domestically specific. The OD500 Global Network starts from the assumption that only by mapping the use of open data within and across countries, can new approaches for understanding the economic and social impact of open government data be generated. The Open Data 500 U.S.A is the first comprehensive study of U.S. companies that use OGD to generate new business and develop new products and services [6]. Similarly, the Open Data 500 Korea, the Open Data 150 Canada, the Open Data 500 Australia, the Open Data 500 Mexico, the Open Data 500 Italy projects have been launched. Many companies from different sectors (e.g. healthcare, food and agriculture, finance etc.) are developed and generate value based on OGD from department of defense, department of energy etc. Our study show that around many environmental companies uses OGD to generate value, including the economic, social and environmental values.

Despite the potential significance of OGD, emphasized by an abundance of anecdotal evidence, we could not identify many studies on how OGD will contribute to value generations. To-date, the economic and social impact of open-data policies remains largely unclear, and there are scant empirical data available on the effects of the various policy approaches, thus leaving policy makers without the facts they need to assess and improve these policies. Some studies were conducted to illustrate how data are used as a key resource to enhance their core values [5,9,10]. However, more studies are needed to figure out how OGD is used as a key resource to generate values in specific domains, such as the environment/weather sector.

2 Research Motivation and Approach

Although a lot of anecdotal evidence has demonstrated the potential importance of OGD, it is still a mystery that how OGD will contribute to value generations in various sectors. Accordingly, our research on Open Government Data for Value Generation aims to address the question: How can use of OGD stimulate value generation in environment/weather companies? Building on a synthesis of the OGD literature and established theories of value generation, we develop a structural equation modelling (SEM)-based model to explore the causal relationship between OGD and value generation. The model is proposed to provide some guidance for the establishment of more companies to address more environmental issues. This research is planned in three phases. In the first phase the global open government data landscape in environment/weather sector is surveyed using secondary data from Open Data 500 projects. Accordingly, a conceptual SEM model is to be established for further research. In the second phase, questionnaires are designed and investigations conducted to collect data for model calculation and validation. In the third phase of this research, we plan to propose and implement appropriate OGD-driven companies in other countries to assist the governments for environmental protection.

This paper, however, only looks into the first phase of the planned research where it attempts to survey the landscape of OGD-driven environmental companies in USA, Australia and South Korea and establish a conceptual structural equation model for further validation.

3 OGD-Driven Companies in Environment/Weather Sector: The Current Situation

Many countries are entering the mainstream of open data movement. A number of open data benchmarks have been developed such as the World Bank's Open Data Readiness Assessment (ODRA), World Wide Web Foundation's Open Data Barometer (ODB, 2015), Open Knowledge Foundation Network's (2014) Open Data Index (ODI) and Capgemini Consulting's (2013) Open Data Economy (ODE), to name few global and widely used benchmarks. However, each of these benchmarks serves a different purpose and focus. Susha et al. (2014) suggest that ODB provides a more comprehensive perspective since it not only includes measures at various stages like readiness, implementation, and impact but also highlight the importance of involvement of major stakeholders and challenges throughout the open data process [9]. According to ODB (2016), a scaled score is an indication of how well a country is doing against other countries in getting the basics of open data readiness, implementation and impact [4]. According to the ODB (2014) technical handbook, When evaluating the ODB score, the openness of environmental data (D14 element) is considered based on the data on one or more of: carbon emissions, emission of pollutants (e.g. carbon monoxides, nitrogen oxides, particulate matter etc.), and deforestation. This study take 34 companies from US, Australia and South Korea into consideration due to the following two reasons. On one hand, the ODB rankings (as demonstrated in Fig. 2) show that US, Australia and South Korea are in the top ten countries in terms of open data readiness, implementation and impact. On the other hand, due to the high data openness in US, Australia and South Korea, many environmental companies participated in the Open Data 500 USA project, the Open Data 500 Australia project, and the Open Data 500 Korea project.

The 34 OGD-driven companies in environment/weather sector are surveyed and partially shown in Table 1, which present social impact, revenue (economic impact), and environmental impact of different companies. It is noted that the 34 companies use OGD from various official sources and their main purposes are to address severe environmental issues. The environmental issues to be addressed and other missions to be accomplished are also listed.

The aim of this study is to understand the causal relationship of why the OGD is beneficial for value generation from the environmental, social and economic aspects (Table 2).

Table 1. OGD-driven companies in environment/weather sector (Part 1)

No	Company name	City state country	Environmental impacts	Social impacts	Revenue sources	Data sources	Purposes	Websites
1	AccuWeather	State College_PA_US	Environmental protection, Climate change prevention	Environment and climate change	Subscriptions	National Weather Service, Monitoring stations	(1) Provide weather forecasts (2) Deliver enterprise solutions (3) Cooperate relationships between government weather agencies and the weather industry	http://www.accuweather.com
2	CoolClimate	Berkeley_CA_US	Environmentally sustainable development	Cleaner living environment	Data analysis for clients, Database licensing, User fees for web or mobile access	Multiple government open data sources (e.g. environmental records, land use information)	(1) Provide decision-making tools and programs (2) Design tailored climate solutions (3) Motivate low-carbon choices (4) Design climate actions and programs	http://coolclimate.berkeley.edu
3	Earth Networks	Germantown_MD_US	Extreme weather (e.g. tornadoes, cyclones), Climate change detection	Environment and climate change	Weather data analysis for organizations	Neighborhood-level sensors, National Oceanic and Atmospheric Administration, National Weather Service	(1) Operate weather observation, lightning detection and climate (green gas) networks (2) Enable enterprises and consumers to make informed decisions	www.earthnetworks.com
4	Environmental Data Resources	Milford_CT_US	Environmental problem report	Environment and climate change	Data collection outsources, Data management for clients	U.S. Environmental Protection Agency, Multiple government open data sources (e.g. environmental records, land use information)	(1) Provide robust data (2) Provide smarter workflow tools for data management	http://www.edrnet.com

4 SEM Conceptual Model for Value Generation

OGD-driven companies in environment/weather sector apply OGD as a key resource in their business to generate sustainability values. Accordingly, it is necessary to reflect the causal relationship between OGD and the generated values. In the research, the SEM is proposed as a cause -and-effect diagram to illustrate how OGD is used to generate values.

4.1 Basic Structural Equation Modeling

Since Bentler's appeal to apply the technique to handle latent variables (i.e. unobserved variables) in psychological science, structural equation modeling (SEM) has become a quasi-routine and even indispensable statistical analysis approach in the social sciences. The emergence and development of SEM was regarded as an important statistical development in social sciences in recent decades and this "second generation" multivariate analysis method has been widely applied in theoretical explorations and empirical validations in many disciplines. Structural Equation Models with latent variables are extensively in measurement and hypothesis testing [1,2]. Compared with other statistical tools such as factor analysis and multivariate regression, SEM carries out factor analysis and path analysis simultaneously, since it can (1) measure and accommodate errors of manifest variables (i.e. observed variables); (2) represent ambiguous constructs in the form of latent variables (i.e. unobserved variables) by using several manifest variables; and (3) simultaneously estimate both causal relationships among latent variables and manifest variables. In addition, SEM can also provide group comparisons with a holistic model, resulting in much more vivid impressions than traditional ANOVA. SEM can also handle longitudinal designs when time lag variables are involved.

As introduced above, SEM describes and tests relationships between two kinds of variables – latent variables (LVs) and manifest variables (MVs). Latent variables cannot be observed directly due to their abstract character. In contrast, observed variables contain objective facts and easier to measure. Several observed variables can reflect one latent variable. As presented in Fig. 2, a structural equation model usually consists of two main components, a structural model and several measurement models. A simple measurement model includes a latent variable, a few associated observed variables and their corresponding measurement errors. The structural model consists of all LVs and their interrelationships. For model development purposes, some researches aim to validate their assumptions of a dimensional framework of one or several discriminant LVs, while others aim to elicit the causal relationship between the LVs. Confirmatory factor analysis (CFA) with correlating latent variables satisfies the former purpose, while these correlations need to be replaced by directional relationships for the latter.

Figure 4 provides a simple example of a structural equation model investigating the effect of LVs ξ_1, ξ_2 and ξ_3 on LVs η_1, η_2 and η_3, and where several MVs are used to represent the LVs. The MVs are shown in rectangles, the LVs in ellipses, measurement errors in circles and with arrows indicating the direction of the effects. If directional arrow between ξ and η is replaced by a correlation two-way arrow, the model is a CFA and its purpose is to test whether MVs can represent LVs well (i.e. convergent validity) and whether ξ and η are different (i.e. discriminant validity). The basic concepts and principles of SEM are now well established with the help of early explorations by researchers, structured textbooks, well developed soft programs (e.g. LISREL, EQS and AMOS).

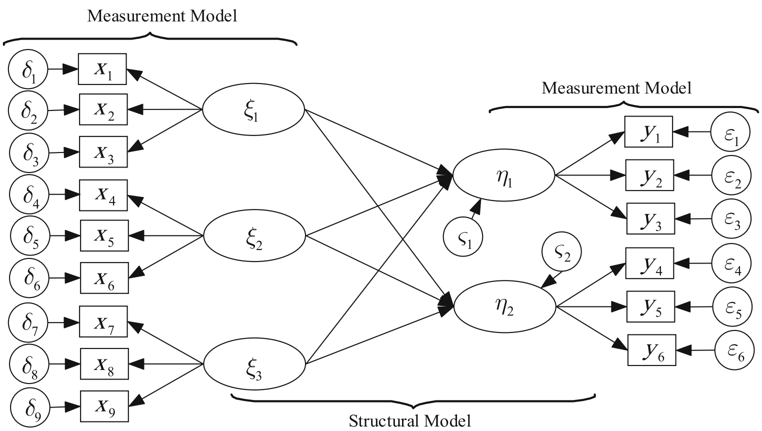

Fig. 2. A structural equation model diagram

4.2 Model Path Analysis

In order to establish a cause -and-effect diagram to illustrate how OGD is used to generate values, a path analysis is conducted, along with which we decide necessary latent variables and manifest variables based on a large amount of literature reviews.

(1) Constructs of OGD that are important in value creation
According to data-intensive science, data is prone to generate value through a value chain of big data, including value capture, value curation, value analysis and value visualization. To make sure that decision makers are able to produce information, knowledge or wisdom by utilizing various data analytics techniques and technologies. OGD is applied as a core resource for creating economic profits for themselves, bringing social values for the society and promoting environmental protection. In order to find out in what aspects OGD is important when firms use OGD to guide decision making or enhance transparency for value generation. The following features of data are essential for whether or not they are able to create values.

① Data quality & Integrity
OGD exposes data to public view in a way that allows for crowdsourced and quality control. Poor quality data can mislead for decision for environmental data-driven companies.

② Data disaggregation
OGD has many elements of being disaggregated and being highly accessible to many or even any party that wishes to use it. To some extent, disaggregated data can provide a better comparative picture of what works and help inform and promote evidence-based policy-making or decision making in environment/weather sector.

③ Data timeliness
OGD allows for private-sector and citizen contributions to open datasets that can make data more timely and relevant. In order to achieve real-time weather report, the data cycle has to match the decision cycle for better decision-making. Environmental data timeless in environment/weather sector is quite important for firms to make decisions, produce new products or provide new services.

④ Data transparency and openness
The promotion of OGD and tightened feedback loops between data users and data suppliers (namely government or government-governed entities). Publicly-funded datasets, as well as data on public spending, should be available to other public ministries or the general public. With high data transparency and openness, data should be made public in ways that encourage greater use and be complete, machine-readable, freely available for reuse without restrictions, and transparent about underlying assumptions. Environmental data transparency and openness in environment/weather sector is quite important for firms to make decisions, produce new products or provide new services.

⑤ Data usability and curation
Through OGD roundtables and similar events, data users can provide feedback on open datasets that makes them more accessible and useful. Data architecture should place great emphasis on user-centered design and user-friendly interfaces. Communities should be fostered to develop new tools that can translate raw data into something meaningful to a broader constituency of non-technical potential users.

⑥ Data protection and privacy
The challenge of opening government datasets while anonymizing sensitive information on health or environment sets a high bar for developing data privacy safeguards. Clear international norms and must be developed to protect data. The data protection is quite important when environmental companies utilize data in their daily business for weather forecast or policy suggestions.

⑦ Data governance and independence
The open data charter, open government partnership, and other international efforts are beginning to provide a governance structure for open data. Data quality should be protected and improved to ensure they are functionally autonomous, and independent of political influence.

⑧ Data resource and capacity
National statistical systems should be established that are capable of producing high quality statistics in line with global standards and expectations. Under these circumstances, people can make sure that the companies are able to provide reliable suggestions and conduct right measures for environmental protection.

(2) Constructs of value creation mechanisms
With rapid development of the society, data has become an important resource for creating values and we have entered the big data era. Most firms are utilizing big data for creating values and data-intensive science has become a new discipline. Data, in nature, has no value and data analysts aim to extract values, information, knowledge and wisdom by applying various techniques learning, data mining and technologies. It is the job of computer scientist to develop tools, but it is the practitioners' job to make decisions, provide new offerings or enhance transparency for creating values. The complementarity between the superior computational capabilities provided in the data analytics process and the higher judgmental capabilities of firm managers is quite important for realizing values from big data. Our study mainly consider three value creation mechanism based on literature reviews, and they are guiding decision makings, providing new offerings and enhancing transparency.

① Decision making
Decision making is quite important for firms to create values. By making better decisions based on data analytics, managers are able to achieve more economic or social values. Data-driven decision-making positively affects value through generation of new information, knowledge and wisdom.

② New offerings
Innovation is the source of value creation in Schumpeter's economic theory, bringing about novel combinations of resources, new production methods, as well as new products and services, which, in turn, lead to the transformation of markets and industries, thus increasing value. Data-driven innovation positively affects value through generation of new knowledge, new processes, services and products, and new businesses.

③ Transparency & accountability
Most definitions of transparency recognize the extent to which an entity reveals relevant information about its own decision processes, procedures, functioning and performance. However, opening access to chosen public documents does not necessarily contribute to a transparent government. By utilizing OGD for companies in environment/weather sector, it is important to promote the transparency and accountability of OGD from the environment sector.

(3) Constructs of values for OGD-driven companies in environment/weather sector
Two types of value are frequently discussed: economic value, defined as the worth of a good or service as determined by the market, and social value, which is created when resources, inputs, processes or policies are combined to generate improvements in the lives of individuals or society as a whole. The main difference is that our research emphasizes the environmental impacts of those companies from the environment/weather sector as the 34 companies make great contributions to environmental protection and disaster prevention. The environmental, economic and social values are combined to achieve the sustainability goal of the world, as shown in Fig. 3. The environmental impacts mainly include pollution reduction, natural resource conservation and climate change resilience.

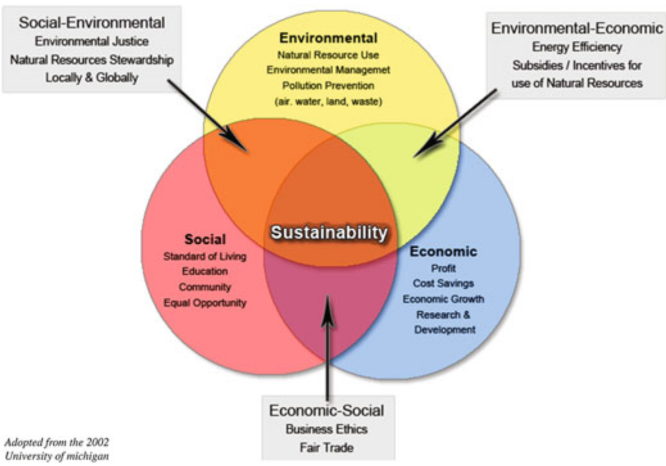

Fig. 3. Constructs of values

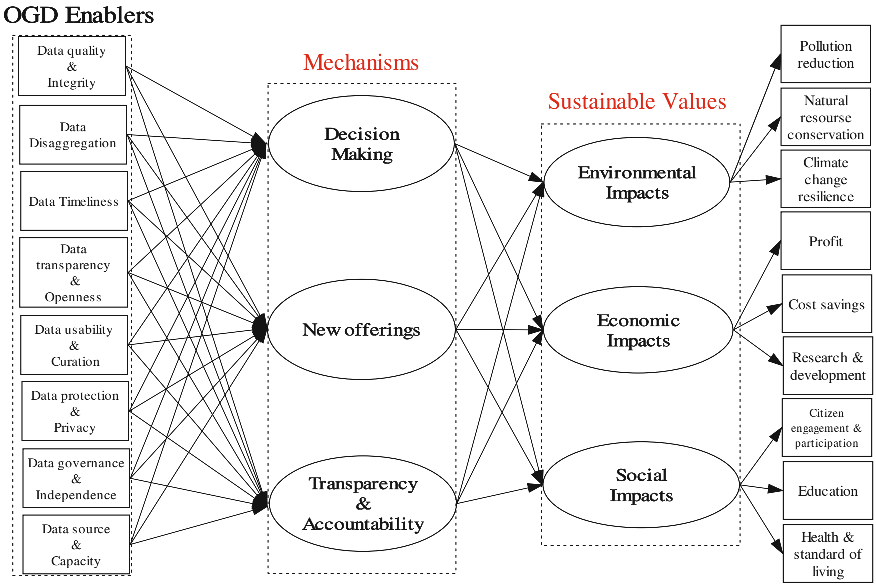

Fig. 4. Path analysis

The economic impacts are reflected in profits, cost savings, and research & development. The social impacts are categorized as citizen engagement & participation, education, and health & standard of living.

As previously discussed, the conceptual SEM model-based value generation methodology is established in Fig. 1.

5 Conclusions and Recommendations

Intensive research has been conducted to figure out the importance of big data or massive OGD, among which value chain analysis approach and value stream mapping method are extensively used. Both technical workers and management practitioners are key actors in finding out how big data or OGD contributes to value generations in various sectors. The beginning stage of our research on Open Government Data for Value Generation aims to address the issue of how OGD stimulates value generation in environment/weather companies. We attempt to analyze the causal relationship between OGD and sustainable values driven by OGD based on a structural equation model.

This paper, however, only looks into the first phase of the planned research where it attempts to survey the landscape of OGD-driven environmental companies in USA, Australia and South Korea and establish a conceptual structural equation model for further validation. Further research is needed to further enrich the current study.

Impact of Management Information Systems Techniques on Quality Enhancement Cell's Report for Higher Education Commission of Pakistan

Faraz Ullah Khan and Asisf Kamran(✉)

Management and Social Science Department,
Institute of Business and Technology, Karachi, Pakistan
asifkamrankhan@gmail.com

Abstract. The way to achieve high quality education is through the quality affirmation. Higher education Commission has developed processes for the evaluation of the scholastics program's quality. The department of Quality Assurance has set up Quality Enhancement Cell which works under indicated Criterions. The point is to compose gathered information to produce useful information for QA clients. At present QEC is setting Self-Assessment Report through their predefined Performa and manual of models to help scholarly foundations. The fundamental issue of setting up this report is the utilization of manual strategies, which is the reason for delivering reports with repetitive errors and clearly, lumbering to oversee. The proposed solution for this issue is, as one may have seen in this time, fast move towards automation. MIS techniques will be applied by utilizing software development tools and database integration and broadly utilized reporting tools. Utilizing above mentioned tools and techniques will empower QA and clients to play out their job viably, reduce the repetitive information, save clients time and upgraded clarity. A more easy to understand Graphical User Interface helps client to accomplish more exact data for the decision making which will help them complete their tasks in impressively less time. This procedure have a major space for system enhancement system management more graphical reports more auxiliary changes by the assistance of software development tools.

Keywords: Self-Assessment Report · Higher education commission · Automation · Quality Enhancement Cell · Quality assurance · Management information systems

1 Introduction

Quality is a term which has always be confused with other concepts. The word quality has a Latin word "quails" its meaning is 'what sort of'. It has a range

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_30

of different meanings. Quality is something for you knowingly known. But there are things that are better than others. A high evaluation accorded to an educative process [11]. Where it has been demonstrated that, through the process, the students' educational development has been enhanced not only have they achieved the particular objectives set for the course but, in doing so, they have also fulfilled the general educational aims of autonomy of the ability to participate in reasoned discourse, of critical self-evaluation, and of coming to a proper awareness of the ultimate contingency of all thought and action [15].

Through above examinations, you will comprehend that esteem is undefined and setting focused. It stretches out from meaning "standard" to 'flawlessness'. Both are significantly settled in their different qualities operationalize in independent, institutions, and, the national practice will be visualize later. "Values can be justified in as a lowest 'threshold' by which the accuracy is judged" [4]. It is quite possible to have higher education institutions to have a common understanding in formulating to have teaching and research standards with high quality.

The administration measurement of value is most likely more likened to the instructive methodologies. We realize that not at all like physical products, administrations are vaporous to the degree that they can be expended just the length of the action or the methodology proceeds. Prominent issue of quality had been identified in the higher education in the Medium Term Development Framework (MTDF) [12]. Therefore, to enhance the quality of output and efficiency of the higher education learning systems, a mechanism of establishment of QECs has been developed by the Quality Assurance Committee to improve the standards of quality of higher education in an organized way with consistency across institutions. QEC prepared SAR to assess a systematic process of collecting, reviewing and using relevant quantitative/qualitative data and information from multiple and diverse sources about educational programs, for the purpose of improving student learning, and evaluating academic and learning standards. With a specific end goal to accomplish the subsequent reports the way toward finishing SAR is complicated [2]. The fundamental issue of setting up this report is the utilization of manual techniques, which is the reason for creating reports with repetitive errors and obviously, unwieldy to oversee. The answer for this issue is, as one may have seen in this time, quick move towards automation [13]. Applied MIS techniques by utilizing software development tools and database integration and generally utilized reporting tools. Utilizing above mentioned tools and techniques will empower QA and clients to perform their job effectively, lessen the repetitive data, save clients time and enhanced clarity [3].

1.1 Self-Assessment Report Manual by HEC (Document Prepared By: Dr. Abdul Raouf)

Criterion: Program Mission, Objectives and Outcomes

Each program must have a mission, measurable objectives and expected outcomes for graduates. Outcomes include competency and tasks graduates are expected to perform after completing the program. A strategic plan must be in place to achieve the program objectives. The extent to which these objectives are achieved through continuous assessment and improvements must be demonstrated [10].

Standard 1: The program must have documented measurable objectives that support Faculty/College and institution mission statements.

- Document institution, college and program mission statements.
- State program objectives. Program educational objectives are intended to be statements that describe the expected accomplishments of graduates during the first several years following graduation from the program.
- Describe how each objective is aligned with program, college and institution mission statements.
- Outline the main elements of the strategic plan to achieve the program mission and objectives.
- Provide for each objective how it was measured, when it was measured and improvements identified and made. Table 1 provides a format for program objectives assessment.

Table 1. Program objectives assessment

Objective	How measured measured	When measured	Improvement identified	Improvement made
1.				
2.	- do -			
3.	- do -			
4.	- do -			
5.	- do -			

Standard 2: The program must have documented outcomes for graduating students. It must be demonstrated that the outcomes support the program objectives and that graduating students are capable of performing these outcomes.

- Describe how the program outcomes support the program objectives. In Table 3 show the outcomes that are aligned with each objective..

- Describe the means for assessing the extent to which graduates are performing the stated program outcomes/learning objectives. This should be accomplished by the following (Table 2):

– Conducting a survey of graduating seniors every semester.
– Conduct a survey of alumni every two years.
– Conduct a survey of employers every two years.

Table 2. Outcomes versus objectives

Program objectives	Program outcomes			
	1	2	3	4
1.				
2.				
3.				

– Carefully designed questions asked during senior projects presentations. These questions should be related to program outcomes.
– Outcomes examinations.

The data obtained from the above sources should be analyzed and presented in the assessment report.

It is recommended that the above surveys should be conducted, summarized and added to the self-study assessment report. Departments should utilize the results of the surveys for improving the program as soon as they are available. An example follows:

1.2 Example (Program Objectives-Program Outcomes)

An example of program objectives and program outcomes is given below.

(1) Program Objectives (as developed by the department)

- Foundation
- Skills and Tools
- Awareness and Professional Ethics

① Objective 1
To provide students with a strong foundation in engineering sciences and design methodologies that emphasizes the application of the fundamental mathematical, scientific and engineering principles in the areas of engineering.

② Objective 2
To provide students with skills to enter the workplace well-prepared in the core competencies listed below:

- Design and modeling experience
- Open-ended problem solving ability
- Experimental and data analysis techniques
- Teamwork experience
- Oral written and multimedia communication skills
- Experience with contemporary computing systems and methodology

③ Objective 3
To provide students with knowledge relevant to engineering practice, including ethical, professional, social and global awareness, the impact of engineering on society, the importance of continuing education and lifelong learning in both technical and non-technical areas.

(2) Program Outcomes (as developed by the department)
Degree of skills and capabilities that will reflect on their performance as engineers:

- Students shall have an ability to apply knowledge of mathematics science and fundamental engineering to mechanical engineering problems.
- Students shall have an ability to identify, formulate and solve practical engineering problems.
- Students shall have an ability to design components, processes and systems to meet desired needs.
- Students shall have an ability to conduct engineering experiments to study different engineering systems, including various modes of operation, performance evaluation, properties of materials and manufacturing techniques, as well as to use laboratory instruments and computers to analyze and interpret data.
- Students shall have an ability to use modern tools, techniques, and skills necessary for practicing mechanical engineering including computational tools, statistical techniques, and instrumentation.
- Students shall have an ability to work in a professional engineering environment, and to understand the associated economical considerations.
- Students shall have an ability to communicate effectively in written, oral, and graphical forms, including the use of professional quality visual aids.
- Students shall have an ability to work effectively in teams including multidisciplinary teams to solve engineering problems relevant to their field.
- Students shall have an understanding of the professional and ethical responsibilities of engineers.
- Students shall have an understanding of the impact of engineering on society and environment.
- Students shall have recognition of the need and an ability to engage in life long learning of engineering.
- The program outcomes are the by products of the program objectives and are interrelated. An example of interrelation between the program objectives and the program outcomes is shown in the following table.

Standard 3: The results of program's assessment and the extent to which they are used to improve the program must be documented.

- Describe the actions taken based on the results of periodic assessments.
- Describe major future program improvements plans based on recent assessments.

Table 3. Relationship between Program objectives and Program outcomes

Program objectives	Program outcomes

Legend: ◎ Denotes substantial contribution to the objective and ⊖ denotes moderate contribution to the objective. . Denotes no contribution to the objective.

- List strengths and weaknesses of the program.
- List significant future development plans for the program.

Standard 4: The department must assess its overall performance periodically using quantifiable measures.

- Present students enrolment (undergraduate and graduate) during the last three years indicating percentages of honor students, student faculty ratio, average graduating grade point average per semester, average time for completing the undergraduate program and attrition rate.
- Indicate percentage of employers that are strongly satisfied with the performance of the department's graduates. Use employer's survey.
- Indicate the median/average student evaluation for all courses and the % of faculty awarded excellence in teaching award.
- Present performance measures for research activities. These include journal publications, funded projects, and conference publications per faculty per year and indicate the % of faculty awarded excellence in research award.
- Present performance measures for community services. This may include number of short courses per year, workshops and seminars organized.
- Indicate faculty and students satisfaction regarding the administrative services offered by the department. Use faculty and students surveys.

2 Problem Statement

The main problem of preparing this report is the use of manual methods, which is the cause of producing reports with repetitive errors and obviously, cumbersome to manage. The proposed solution to this problem is, as one may have observed in this era, rapid move towards automation.

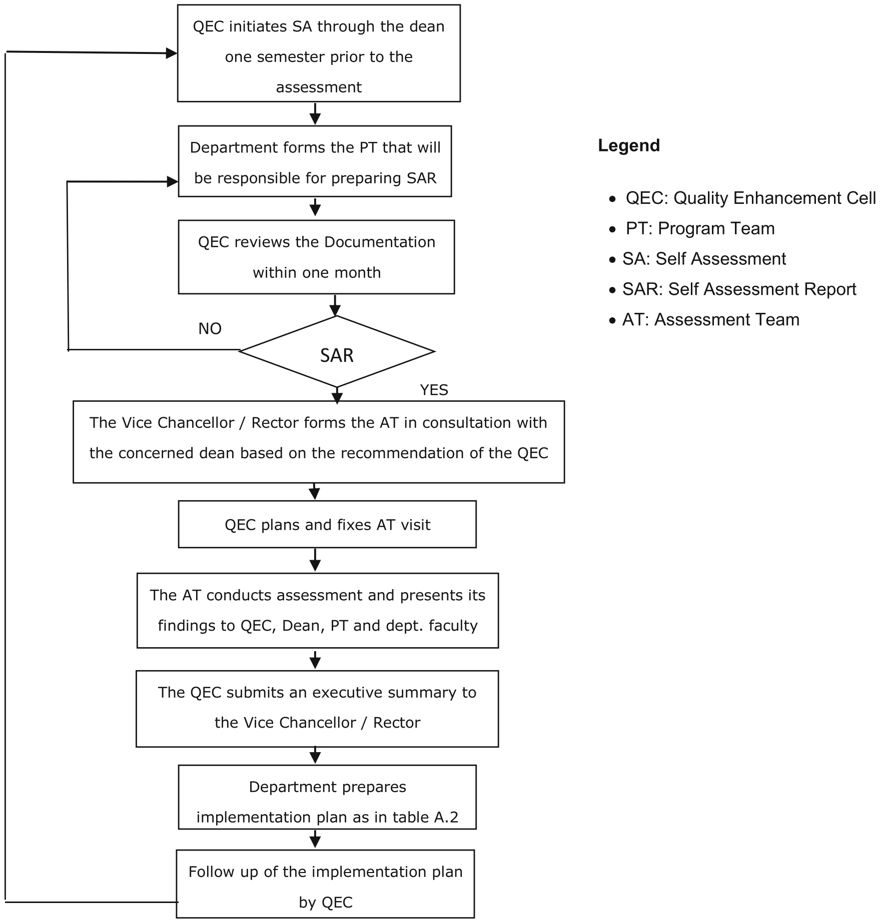

Fig. 1. Self-Assessment procedure

3 Method of Research

This research is aimed that of the process of Self-Assessment Report gets automated by using technology, for example through user friendly software then this will help in enhance the process of QA Reporting for HEC. Therefore this research is a Descriptive Research in which the method of research is Observational Research. Since the respondents in this research work in a natural environment, this method is convenient in assessing multiple users performing their jobs.

Using detailed investigation methodology adds a lot for the investigation, for instance:

- Detailed research reveals difficulties as well as excessive ailments to ensure that remedial procedures may be instituted. This might assistance in presenting ideas for predicaments exactly where progress may be required.
- Detailed exploration facilitates the particular prediction of the future by results about existing disorders, effects and by persons in the direction of a particular matter.
- Detailed exploration provides a much better and much deeper comprehension of any trend by an in-depth study from the trend.

3.1 Research Methodology

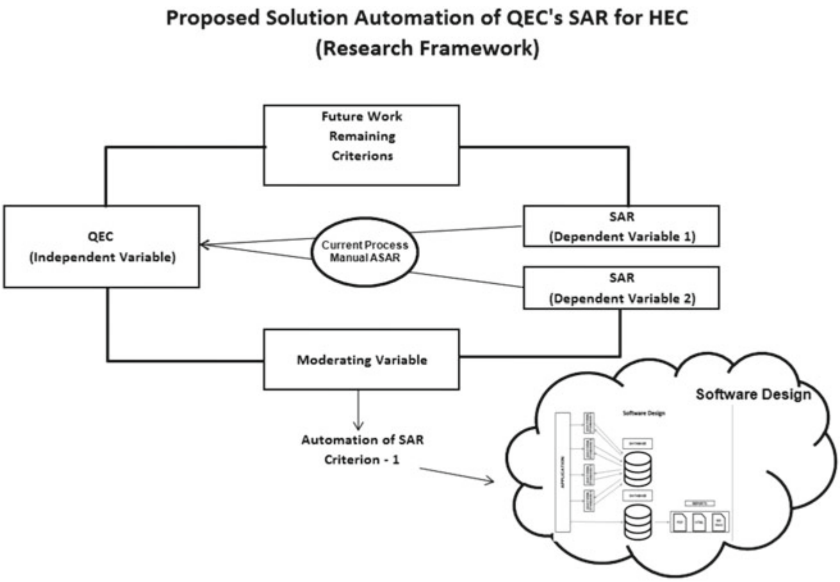

Fig. 2. Proposed solution automation of QEC's SAR for HEC

3.2 Design of Research

In view of these variables and hypothesis, the Research Design followed for this thesis is Qualitative Research Design. Reasons for choosing this design:

- This design helps in identifying & controlling extraneous factors also.
- This design is efficient in using available resources.

3.3 Techniques & Instrument of Research

Research instruments included a single List of questions. The set of questions was structured. Various factors relevant to the study have been integrated from the set of questions. There were 20 issues in which concerned numerous qualities in addition to considerations. The set of questions was made in view from the study ambitions. The options from the set of questions derive from Contract by making use of Liker Range.

- Strongly Agree
- Agree
- Disagree

3.4 Target Population

The sample of the SAR user is selected for the research, those who are working for QEC. Those individual SAR users who are preparing their report by manual method. On a whole we have taken almost 61 responses from different institutions.

3.5 Data Analysis

The purpose of the research is to analyze the aspects which are affecting the adoption of Automation of QEC's SAR. The researcher selected the questionnaire for collecting the responses. The average graph of respondents is showing high requirement for the automation of SAR.

3.6 Research Methodology

The representation of the operation sequence uses job-based encoding [13], and the length of the chromosome equals the total number of operations. The job number denotes the operation of each job, and the $l-th$ occurrence of a job number refers to the $l-th$ operation in the sequence of this job. Figure 1 presents an example considering a rescheduling with a 4 jobs and 3 machines.

3.7 Impact of Research Question

The study will apply the following impacts, when the SAR will automate.

- Time saving
- Process
- Error Reduction

Figure 3(a) shows the significance of Automation of Self Assessment Report by high requirement of respondents. Figure 3(b) shows the significance of process Improvement viewed by respondents. Figure 3(c) shows the significance of Time saving can be viewed by the positive responses. Figure 3(d) shows the magnitude of error reduction is shown by the positive responses.

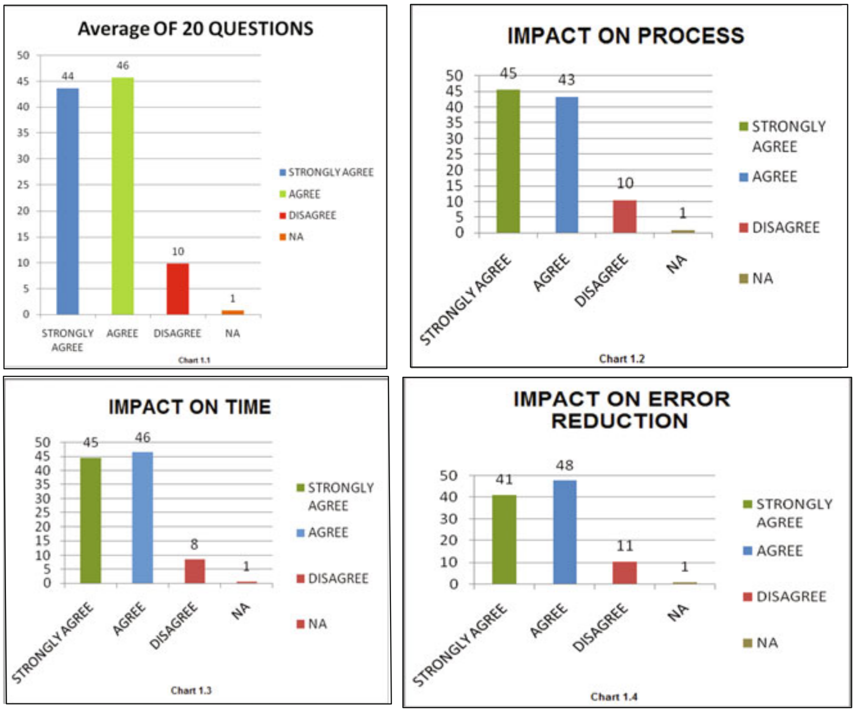

Fig. 3. Questionnaire graphical analysis

4 Conceptual Model

The above given diagram is a conceptual model of all entities participating in the process of making SAR. This model only shows how the whole process works currently without having being automated. From this diagram one can start to figure out how the software can be evolved in the system to provide or achieve the outcomes which are supposed to be achieved.

The process starts when an institution wishes to approve its program by HEC. QEC personal sends a request to HEC which in return supplies 'SAR Manual' in order to prepare SAR Report. QEC user inserts MISSION OBJECTIVES & OUTCOMES based on the CRITERION-1 in Self Assessment Report Manual. Finally report is generated as per the format of HEC.

4.1 Waterfall Models

There are different models used for software life cycle the one which is suitable in SAR is Waterfall Model. As this model distinguishes the whole process into distinct phases.

"A software requirements specification (SRS) is a description of a software system to be developed, laying out functional and non-functional

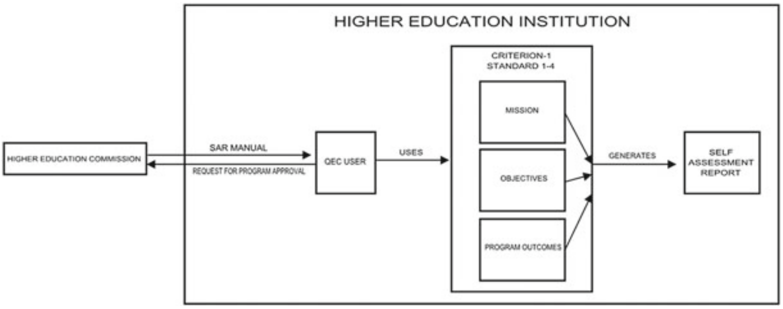

Fig. 4. Conceptual model

requirements" [8]. This model is used as a frame work or it provides a specified format to develop any software in a predefined phases. It starts from gathering requirements from users and then moves on to produce software design. Later this design will be implemented after unit testing. The last two phases may not need very much consideration in SAR.

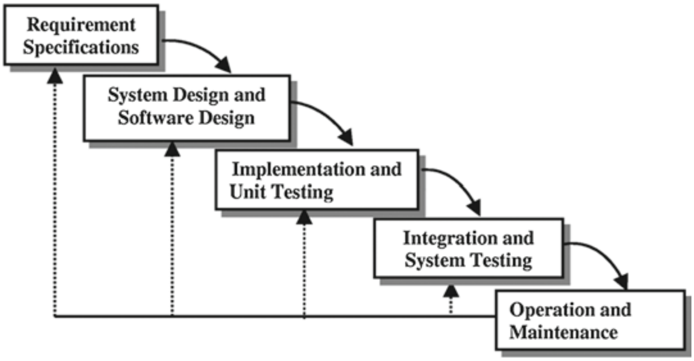

Fig. 5. Waterfall models

4.2 Languages

For the above purpose, C# & VB Languages have been selected to process SAR Report. C# & VB is usually a multi-paradigm programming language encompassing strong typing, essential, declarative, sensible, universal, object-oriented (class-based), and also component-oriented programming disciplines. C# & VB is one of the programming languages designed for the Common Language Infrastructure.

4.3 Programming Methodology

Object-Oriented Programming has the following advantages over conventional approaches [7]:

Provides a clear modular structure for programs which makes it good for defining abstract data types where implementation details are hidden and the unit has a clearly defined interface.

- Makes it easy to maintain and modify existing code as new objects can be created with small differences to existing ones.
- Provides a good framework for code libraries where supplied software components can be easily adapted and modified by the programmer. This is particularly useful for developing graphical user interfaces [1].

4.4 Platform

Visual Studio is a complete set of development tools for building C# & VB applications, XML Web Services, desktop applications, and mobile applications. Visual Basic, Visual C#, and Visual C++ all use the same integrated development environment (IDE), which enables tool sharing and eases the creation of mixed-language solutions [14].

4.5 Database

A Relational database is a computerized database whose association is focused around the Relational model of information, as proposed by E.f. Codd in 1970. This model arranges information into one or more tables (or "relations") of columns and sections, with a Primary key for each one line [6]. By and large, every element sort portrayed in a database has its own particular table, the lines speaking to occurrences of that substance and the segments speaking to the characteristic qualities depicting each one occurrence (Education Indicators [9]. Since each one column in a table has its own particular interesting key, pushes in different tables that are identified with it can be connected to it by putting away the first line's one of a kind key as a characteristic of the optional line (where it is known as a "remote key"). Codd [6] demonstrated that information connections of subjective unpredictability can be spoken to utilizing this straightforward set of ideas. The different programming frameworks used to keep up social databases are known as Relational Database Management Systems (RDBMS).

Essentially all Relational database frameworks use SQL (Structured Query Language) as the dialect for questioning and keeping up the database.

A good choice would be "Microsoft SQL Server is a relational database management system developed by Microsoft. As a database, it is a software product whose primary function is to store and retrieve data as requested by other software applications, be it those on the same computer or those running on another computer across a network (including the Internet)" [17].

Fig. 6. Types of reporting tool

4.6 Reporting Tool

The Visual Studio Report Designer provides a user-friendly interface for creating robust reports that include data from multiple types of data sources [5] (Fig. 6).

'Visual Studio' reports let you slice and dice your data and present it in detail or summary form regardless of how the data is stored or sorted in the underlying tables. It offers a great deal of power and flexibility to analyze and present results [16].

4.7 Software Architecture

User authentication and password protection Managers and QEC directors given the authorization to change all the aspects of SAR report the director is working with are also given the authorization to access the whole report but with the exception of few section which are in read only mode.

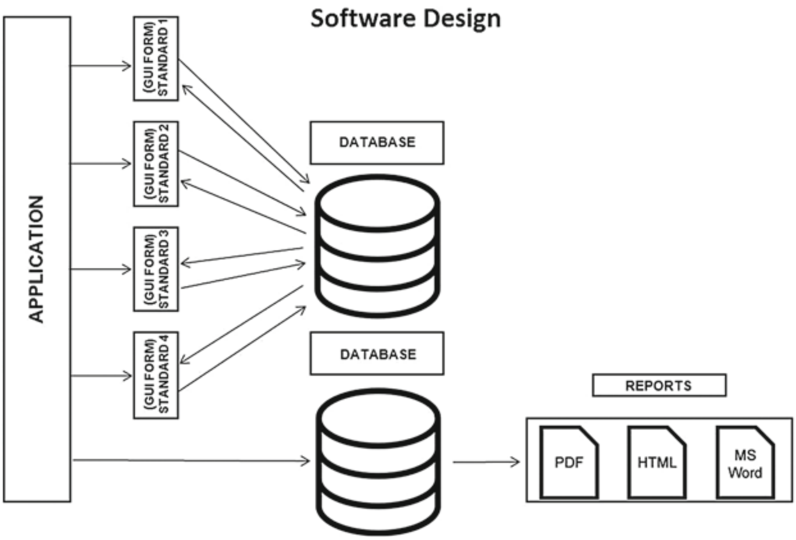

Fig. 7. Software design

4.8 Software Design

Is the process by which an agent creates a specification of a software artifact, intended to accomplish goals, using a set of primitive components and subject to constraints. Software design usually involves problem solving and planning a software solution [17]. The figure explains main components of ESAR Design. Application interacts with the four graphical user interfaces (GUI) sequentially. GUI component establishes two way communication with database components (that comprises related tables) once all the required data is stored in database, user initiates the process of generating report (an ultimate components of ESAR) this final result will also be saved (Fig. 7).

5 Result

- Figure 2 illustrates the research framework and demonstrate the function of moderate variable.
- Figure 4 shows the process of Self-Assessment Report through conceptual model.
- Figure 5 demonstrates the software design of Self-Assessment Report.
- TIME: the process of ESAR will significantly save the user's time.
- MIS Techniques: the above advantages of results may well be achieved MIS techniques.
- REDUCTION OF REPEATION ERRORS: using RDBMS.
- FLEXIBILITY IN FUTURE MODIFICATION: can be achieved using OOP techniques.

6 Conclusions

Quality assurance is a portal to "High quality education". With a specific end goal to evaluate the programs quality Higher Education Commission" has created predefine Criterions forms. The department of Quality Enhancement Cell which works under those predefined Criterion. This Criterion is met utilizing frames with applicable information. Thusly, this will bring about an enhanced interaction with QA clients utilizing E-SAR. One of the other major advantages of it will be as better organized report. In this manner, the real issue for QA clients of following QEC procedures can extensively be all around encouraged utilizing the proposed solution. Infect, repetitive errors are better managed with it. A well designed application is most suitable to accomplish the proposed results for future work. In future, alternative design technique of HCI can be utilized to furnish client with more upgraded collaboration in SAR making.

In order to discuss the process of QEC's SAR, we clearly observe that the whole process is currently based on manual work. There is a dire need to automate SAR process which reflects from the survey data analysis, collected from the QEC users. The remaining Criterion of SAR can easily be considered by applying MIS technology and software development tools in order to automate.

Abstract. Network design is one of the most important and most frequently encountered classes of optimization problems. It is a combinatory field in combinatorial optimization and graph theory. A lot of optimization problems in network design arose directly from everyday practice in engineering and management. Furthermore, network design problems are also important for complexity theory, an area in the common intersection of mathematics and theoretical computer science which deals with the analysis of algorithms. Recent advances in evolutionary algorithms (EAs) are interested to solve such practical network problems. However, various network optimization problems typically cannot be solved analytically. Usually we must design the different algorithm for the different type of network optimization problem depending on the characteristics of the problem. In this paper, we investigate the recent related researches, design and validate effective priority-based genetic representations for the typical network models, such as shortest path models (node selection and sequencing), spanning tree models (arc selection) and maximum flow models (arc selection and flow assignment) etc., that these models covering the most features of network optimization problems. Thereby validate that EA approaches can be effectively and widely used in network design optimization.

Keywords: Evolutionary Algorithm (EA) · Shortest path model · Spanning tree model · Maximum flow model · Bicriteria network design

1 Introduction

Many real-world problems from operations research (OR)/management science (MS) are very complex in nature and quite hard to solve by conventional optimization techniques. Since 1960s, there has been being an increasing interest in imitating living beings to solve such kinds of hard optimization problems. Simulating natural evolutionary process of human beings results in stochastic optimization techniques called evolutionary algorithms (EAs) that can often outperform conventional optimization methods when applied to difficult real-world

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_31

problems. EAs mostly involve metaheuristic optimization algorithms such as: genetic algorithm (GA) [18,21], evolutionary programming (EP) [12], evolution strategies (ES) [36,39], genetic programming (GP) [27,28], learning classifier systems (LCS) [22], swarm intelligence (comprising ant colony optimization (ACO) [9] and particle swarm optimization (PSO) [25,26]. Among them, genetic algorithms are perhaps the most widely known type of evolutionary algorithms today and load more stuff again.

Network design is one of the most important and most frequently encountered classes of optimization problems [2]. It is a combinatory field in graph theory and combinatorial optimization. A lot of optimization problems in network design arose directly from everyday practice in engineering and management: determining shortest or most reliable paths in traffic or communication networks, maximal or compatible flows, or shortest tours; planning connections in traffic networks; coordinating projects; and solving supply and demand problems. The most of network design problems where even one cost measure must be minimized are often NP-hard [14]. However, in practical applications, it is often the case that the network to be built is required to multiobjective. In this paper, we introduce three kinds of major bicriteria network design models. These models are the core multi-criteria network design models and extensively used in practical applications. (1) Bicriteria shortest path (bSP) model is one of the basic multi-criteria network design problems. It is desired to find a diameter-constrained path between two specified nodes with minimizing two cost functions. Hansen presented the first bSP model at 1979 [19]. Recently, Hao and Gen [20] examined an effective multiobjective EDA for bi-criteria stochastic job-shop scheduling problem; Shokrollahpour and Zandieh [47] presented A novel imperialist competitive algorithm for bi-criteria scheduling of the assembly flowshop problem. (2) Bicriteria spanning tree (bST) model play a central role within the field of multi-criteria network modes. It is desired to find a subset of arcs which is a tree and connects all the nodes together with minimizing two cost functions. Craveirinha et al. [4] presented a bi-criteria minimum spanning tree routing model for MPLS/overlay networks, and Steiner [41] Computing all efficient solutions of the biobjective minimum spanning tree problem.

2 Multiobjective Genetic Algorithms

Optimization deals with the problems of seeking solutions over a set of possible choices to optimize certain criteria. If there is only one criterion to be taken into consideration, it becomes to single objective optimization problems, which have been extensively studied for the past 50 years. If there are more than one criterion which must be treated simultaneously, we have multiple objective optimization problems [1,6,42]. Multiple objective problems arise in the design, modeling, and planning of many complex real systems in the areas of industrial production, urban transportation, capital budgeting, forest management, reservoir management, layout and landscaping of new cities, energy distribution, etc. It is easy to find that almost every important real world decision problem involves multiple and conflicting objectives which need to be tackled while respecting various constraints, leading to overwhelming problem complexity. The multiple objective optimization problems have been receiving growing interest from researchers with various background since early 1960 [23]. There are a number of scholars who have made significant contributions to the problem. Among them, Pareto is perhaps one of the most recognized pioneers in the field [11]. Recently, GAs have been received considerable attention as a novel approach to multiobjective optimization problems, resulting in a fresh body of research and applications known as evolutionary multiobjective optimization (EMO).

2.1 Fitness Assignment Mechanism

GAs are essentially a kind of meta-strategy methods. When applying the GAs to solve a given problem, it is necessary to refine upon each of the major components of GAs, such as encoding methods, recombination operators, fitness assignment, selection operators, constraints handling, and so on, in order to obtain a best solution to the given problem. Because the multiobjective optimization problems are the natural extensions of constrained and combinatorial optimization problems, so many useful methods based on GAs developed during the past two decades. One of special issues in the multiobjective optimization problems is fitness assignment mechanism. Since the 1980s, several fitness assignment mechanisms have been proposed and applied in multiobjective optimization problems [7,8,13,15,16,24,38,40,49]. Although most fitness assignment mechanisms are just different approach and suitable to different cases of multiobjective optimization problems, in order to understanding the development of multiobjective GAs, we classify algorithms according to proposed years of different approaches:

2.2 Performance Measures

Let S_j be a solution set $(j = 1, 2, \cdots, J)$. In order to evaluate the efficiency of the different fitness assignment approaches, we have to explicitly define measures evaluating closeness of S_j from a known set of the Pareto-optimal set S*. For example, the following common 3 measures are considered that already used in different moGA studies [24]. They provide a good estimate of convergence if a reference set for S* (i.e., the Pareto optimal solution set or a near Pareto optimal solution set) is chosen.

(1) Number of Obtained Solutions $|S_j|$

Evaluate each solution set depend on the number of obtained solutions.

(2) Ratio of Nondominated Solutions $R_{\mathrm{NDS}}\ (S_j)$

This measure simply counts the number of solutions which are members of the Pareto-optimal set S^*. The $R_{\mathrm{NDS}}(S_j)$ measure can be written as follows:

$$R_{\mathrm{NDS}}(S_j) = \frac{|S_j - \{x \in S_j\, |\exists r \in S^* : r \prec x\}|}{|S_j|},$$

where $r \prec x$ means that the solution x is dominated by the solution r. The $R_{\mathrm{NDS}}(S_j)$ =1 means all solutions are members of the Pareto-optimal set S^*, and $R_{\mathrm{NDS}}(S_j) = 0$ means no solution is a member of the S^*. It is an important measure that although the number of obtained solutions $|S_j|$ is large, if that the ratio of nondominated solutions $R_{\mathrm{NDS}}(S_j)$ is 0, it may be the worst result. The difficulty with the above measures is that although a member of S_j is Pareto-optimal, if that solution does not exist in S^*, it may be not counted in $R_{\mathrm{NDS}}(S_j)$ as a non-Pareto-optimal solution. Thus, it is essential that a large set for S^* is necessary in the above equations.

(3) Average Distance D1R(S_j)

Instead of finding whether a solution of S_j belongs to the set S^* or not, this measure finds an average distance of the solutions of S_j from S^*, as follows:

$$D1_R(S_j) = \frac{1}{|S^*|} \sum_{r \in S*} \min\{d_{rx} \,|x \in S_j\},$$

where d_{rx} is the distance between a current solution x and a reference solution r in the 2-dimensional normalized objective space. f_i means the objective function for each objective $i = 1, 2, \cdots, q$.

$$d_{rx} = \sqrt{\sum_{i=1}^{q} (f_i(r) - f_i(x))^2}.$$

The smaller the value of $D1_R(S_j)$ is, the better the solution set S_j is. This measure explicitly computes a measure of the closeness of a solution set S_j from the set S^*.

(4) Reference Set S^*

For making a large number of solutions in the reference set S*, the first step calculates the solution sets with special GA parameter settings and much long computation time by each approach which used in comparison experiments, the second step combine these solution sets to calculate the reference set S^*. In the future, a combination of small but reasonable GA parameter settings for comparison experiments will be conducted. Thus, ensure the effectiveness of the reference set S^*.

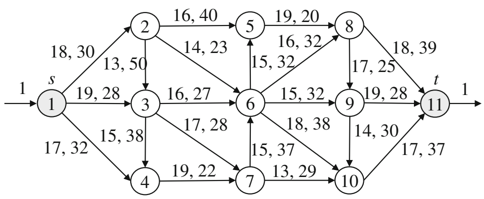

Fig. 1. A simple network with 11-node/ 22-edge

3 Bicriteria Shortest Path (bSP) Model

Routing problem is one of the important research issues in communication network fields. As B-ISDN standards and ATM networks emerge, modern networks are expected to provide a wide range of services and guarantee various end-to-end Quality of Service (QoS). Traditionally, the routing problem has been a single objective problem having as goal the minimization of either the total distance or travel time. However, in practical applications of communication network, create an effective route consider not only cost or travel time, but also requirements of social and economic environment. In other words, it is necessary to take into account that many real-world problems are multiobjective in nature. The objective functions related to cost, time, accessibility, environmental impact, reliability and risk are appropriated for selecting the most satisfactory ("best compromise") route in many communication network optimization problems [3].

3.1 Mathematical Formulation

Let $G = (N, A)$ be a directed network, consisting of a finite set of nodes $N = 1, 2, \cdots, n$ and a set of directed arcs $A = \{(i, j), (k, l), \cdots, (s, t)\}$ joining m pairs of nodes in N. Arc (i, j) is said to be incident with nodes i and j, and is directed from node i to node j. Suppose that each arc (i, j) has assigned to it nonnegative numbers c_{ij}, the cost of (i, j) and d_{ij}, the transmission delay of (i, j). Let x_{ij} is a 0-1 Decision variables the link on an arc $(i, j) \epsilon$ A. The bSP problem is formulated as follows, in which the objectives are to minimizing total cost z_1 and minimizing transmission delay z_2 form source node 1 to sink node n.

$$\min z_1 = \sum_{i=1}^{n} \sum_{j=1}^{n} c_{ij} x_{ij} \tag{1}$$

$$\min z_2 = \sum_{i=1}^{n} \sum_{j=1}^{n} d_{ij} x_{ij} \tag{2}$$

$$s.t. \sum_{j=1}^{n} x_{ij} - \sum_{k=1}^{n} x_{ki} \begin{cases} = 1, & i = 1 \\ = 0, & i = 2, 3, \cdots, n-1 \\ = -1, & i = n \end{cases} \tag{3}$$

$$x_{ij} = 0 \text{ or } 1, \quad (i, j = 1, 2, \cdots, n), \tag{4}$$

where constraint (3), a conservation law is observed at each of the nodes other than s or t. That is, what goes out of node i, $\sum_{i=1} x_{ij}$ must be equal to what comes in $\sum_{k=1} x_{ki}$.

3.2 GA Approaches for bSP Model

How to encode a solution of the network design problem into a chromosome is a key issue for GAs. In Holland's work, encoding is carried out using binary strings. For many GA applications, especially for the problems from network design problems, the simple approach of GA was difficult to apply directly. There two special difficulties by using GAs for creating a path: (1) different path contains variable number of nodes; (2) a random sequence of nodes usually does not correspond to a path.

Zhang et al. [48] extended this variable-length chromosome for solving the SPR problem. But crossover may generate infeasible chromosomes that generating loops in the routing paths. It must be checked that none of the chromosomes is infeasible at each generation, and is not suitable for large networks or unacceptable high computational complexity for real-time communications involving rapidly changing network topologies. An example of generated variable-length chromosome and its decoded path are shown in Fig. 2(a) and (c), respectively for the directed network shown in Fig. 1.

We proposed a priority-based encoding method. As it is known, a gene in a chromosome is characterized by two factors: locus, i.e., the position of gene located within the structure of chromosome, and allele, i.e., the value the gene takes. In this encoding method, the position of a gene is used to represent node ID and its value is used to represent the priority of the node for constructing a path among candidates. A path can be uniquely determined from this encoding. An example of generated priority-based chromosome is shown in Fig. 2(b). At the beginning, we try to find a node for the position next to source node 1. Nodes 2, 3 and 4 are eligible for the position, which can be easily fixed according to adjacent relation among nodes. The priorities of them are 1, 10 and 3, respectively. The node 3 has the highest priority and is put into the path. The possible nodes next to node 3 are nodes 4, 6 and 7. Because node 6 has the largest priority value, it is put into the path. Then we form the set of nodes available for next position and select the one with the highest priority among them. Repeat these steps until we obtain a complete path, (1-3-6-5-8-11). Considering the characteristic of priority-based chromosome, they proposed a new crossover operator, called weight mapping crossover (WMX) and adopted insertion mutation and immigration operators.

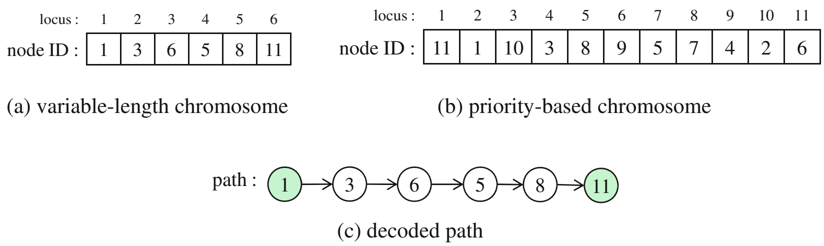

Fig. 2. An example of chromosome and its decoded path

3.3 Experiments and Discussion

In this subsection, the first experiment examines the different chromosome representations. We compare priority-based encoding with Ahn and Ramakrishna's variable-length encoding. Then to validate the multiobjective evolutionary approaches for solving bSPR problems, we compare our i-awGA with 3 different fitness assignment approaches (spEA, nsGA II and rwGA). All test network topologies were constructed by Beasley and Christofides [31]. Costs and delay are represented as random variables depend on the distribution functions.
(1) Different Encoding Methods
In order to evaluate the results of each test, we use the single objective by minimizing total cost, and combine average of the best solutions (ABS). In addition, we demonstrate the difference among the quality of solutions obtained by various GA parameter settings and our auto-tuning strategy. There are 3 kinds of different GA parameter settings:

Para 1: popSize = 10, $p_c = 0.3$, $p_M = 0.7$, $p_I = 0.30$
Para 2: popSize = 10, $p_c = 0.5$, $p_M = 0.5$, $p_I = 0.30$
Para 3: popSize = 10, $p_c = 0.7$, $p_M = 0.3$, $p_I = 0.30$.

In addition, two different stopping criteria are employed. One of them is the number of maximum generations, maxGen = 1000. Another stopping criteria is $T = 200$. That is, if the best solution is not improved until successive 200 generations, the algorithm will be stopped.

Table 1 shows the ABS of 50 runs by different GA parameter settings with different genetic representations respectively. As depicted in Table 1, most results of ABS of 50 runs by priGA with auto-tuning operator proposed are better than each of the other combinations, except to the test 4, test 6 and test 8.
(2) Different Fitness Assignment
In the second experimental study, we demonstrate the performance comparisons of multiobjective GAs for solving bSP problems by different fitness assignment approaches, there are spEA, nsGA II, rwGA and i-awGA. In each GA approach, priority-based encoding was used, and arithmetical crossover, swap mutation, immigration and auto-tuning operators were used as genetic operators.

As depicted in Table 2, most results of ABS of 50 runs by i-awGA are better than each of the other fitness assignment approach. In addition, we do not say the efficiency of the approach, only depend on the performance measure $|S_j|$ or $R_{\mathrm{NDS}}(S_j)$. We can have worst results when compared to another run with a low $R_{\mathrm{NDS}}(S_j)$. Therefore, we show the proposed i-awGA outperform another approach with the efficiency both of the performance measure $|S_j|$ or $R_{\mathrm{NDS}}(S_j)$. In Table 3, the values of $|S_j|$ are given as rational numbers, though the value of $|S_j|$ was defined as the integer number. Because we give an average of $|S_j|$ with 50 runs for comparing the different approaches. Furthermore, the values of $|S_j|$ increases (or decreases) depended on the characteristic of different testing data.

Table 1. The ABS of 50 runs by different ga parameter settings with different genetic representations

		ahnGA			priGA

4 Bicriteria Spanning Tree (bST) Model

Modeling and design of large communication and computer networks has always been an important area to both researchers and practitioners. The interest in developing efficient design models and optimization methods has been stimulated by high deployment and maintenance costs of networks, which make good network design potentially capable of securing considerable savings [33].

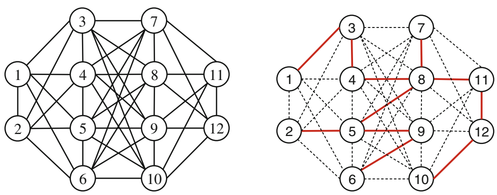
The Minimum Spanning Tree (MST) problem is one of the best-known network optimization problems which attempt to find a minimum cost tree network that connects all the nodes in the communication network. The links or edges have associated costs that could be based on their distance, capacity, quality of line, etc.

In the real world, the MST is often required to satisfy some additional constrain for designing communication networks such as the capacity constraints on any edge or node, degree constraints on nodes, and type of services available on the edge or node. This additional constraint often makes the problem NP-hard. In addition, there are usually such cases that one has to consider simultaneously multicriteria in determining a MST, because there are multiple attributes defined on each edge, has become subject to considerable attention. Almost every important real-world decision making problem involves multiple and conflicting objectives [17].

In this paper, we are considering a bicriteria spanning tree (bST) model. The bST is to find a set of links with the two conflicting objectives of minimizing communication cost and minimizing the transfer delay and the constraint of network capacity is met. This problem can be formulated as the multiobjective capacitated minimum spanning tree (mcMST) problem, and is a NP-hard.

4.1 Mathematical Formulation

The communication network is modeled using an edge-weighted undirected graph $G = (V, E, C, D, W)$ with $n = |V|$ nodes and $m = |E|$ edges, $c_{ij} \epsilon C = [c_{ij}]$, $d_{ij} \epsilon D = [d_{ij}]$ and $w_{ij} \epsilon W = [w_{ij}]$ represent the cost, delay and weight of each edge $(i, j) \epsilon E$, where the variable is restricted to be a nonnegative real number, respectively. And u_i is given weight capacity of each node i. Figure 3 presents a simple network with 12 nodes and 40 arcs.



(a) a simple network (b) a spanning tree

Fig. 3. A simple network with 12 nodes and 40 edges

The decision variables in the bicriteria communication spanning tree problem (bSTP) are the minimum cost z_1 with minimum delay z_2. Mathematically, the problem is reformulated as a constrained Minimal Spanning Tree (MST) problem is as follows:

$$\min\ z_1(x) = \sum_{i=1}^{n}\sum_{j=1}^{n} c_{ij}x_{ij} \tag{5}$$

$$\min\ z_2(x) = \sum_{i=1}^{n}\sum_{j=1}^{n} d_{ij}x_{ij} \tag{6}$$

$$\text{s. t. } \sum_{i=1}^{n}\sum_{j=1}^{n} x_{ij} = n-1 \tag{7}$$

$$\sum_{i=1}^{n}\sum_{j=1}^{n} x_{ij} \leq |S| - 1 \text{ for any set } S \text{ of nodes} \tag{8}$$

$$\sum_{j=1}^{n} w_{ij}x_{ij} \leq u_i, \forall i \tag{9}$$

$$x_{ij} \in \{0,1\}, \forall i,j. \tag{10}$$

In this formulation, the 0-1 variable x_{ij} indicates whether we select edge (i,j) as part of the chosen spanning tree (note that the second set of constraints with $|S| = 2$ implies that each $x_{ij} \leq 1$). The constraint (7) is a cardinality constraint implying that we choose exactly $n-1$ edges, and the packing constraint (8) implies that the set of chosen edges contain no cycles (if the chosen solution contained a cycle, and S were the set of nodes on a chosen cycle, the solution would violate this constraint). The constraint (9) guarantees that the total link weight of each node i does not exceed the upper limit W_i.

4.2 GA Approaches for bST Model

Recently, GA and other Evolutionary Algorithms (EAs) have been used extensively in a wide variety of communication network design problems. For example, Mathur [32] Voβ, Stefan et al. [46] gave the EAs for the capacitated MST problem occurring in telecommunication applications, Ruiz and Duhamel [10,37] investigated the different encoding methods and gave the performance analyzes for the degree-constraint MST problem in communication network, respectively. Liang [29], Torkestani et al. [43], Rezaei et al. [45] investigated the multicriteria communication design problems with GA approaches and other EAs. GAs were also applied to solve other communication network design problem such as two graph problem, one-max tree problem and communication spanning tree problem [44].

We need to consider these critical issues carefully when designing an appropriate encoding method so as to build an effective GA. How to encode a spanning tree T in a graph G is critical for developing a GA to network design problems, it is not easy to find out a nature representation. We summarized the several kinds of classification of encoding methods as follows:

Characteristic Vectors-based Encoding: Davis et al. [5], Piggott and Suraweera [34] have used binary-based encoding method to represent spanning trees in GAs.

Edge-based Encoding: Edge-based encoding is an intuitive representation of a tree. General, an edge-based encoding requires space proportional to n and the time complexities is $O(m)$. Edge-based encoding and binary-based encoding have very similar performance in theory. However, there are $2n(n-1)/2$ possible values for a tree, and only a tiny fraction of these chromosomes represents feasible solutions, and weaken the encoding heritability.

Prefer Number-based Encoding: Many researchers have encoded spanning trees as Prüfer numbers in GAs, called Prüfer number-based encoding for a variety of problems. These include the degree-constrained MST problems, leaf-constrained MST problem, and multicriteria MST problems, etc.

Predecessor-based Encoding: Abuali et al. [35] proposed a predecessor-based encoding that applies to spanning trees. It is a more compact representation of spanning trees by the predecessor or determinant encoding, in which an arbitrary node in G is designated the root, and a chromosome lists each other node's predecessor in the path from the node to the root in the represented spanning tree: if pred(i) is j, then node j is adjacent to node i and nearer the root. Thus, a chromosome is string of length $n-1$ over $1, 2, \cdots, n$, and when such a chromosome decodes a spanning tree, its edges can be made explicit in time that is O(nlogn).

PrimPred-based Encoding: We improved the predecessor-based encoding that adopted Prim's algorithm in chromosome generating procedure. Prim's algorithm implements the greedy-choice strategy for minimum spanning tree. Starting with an empty tree (one with no edges), the algorithm repeatedly adds the lowest-weight edge (u, v) in G such that either u or v, but not both, is already connected to the tree. Considering the characteristic of predecessor-based encoding, they proposed a new crossover and mutation operators. These operators offer locality, heritability, and computational efficiency. An example of generated PrimPred-based chromosome and its decoded spanning tree are shown in Fig. 4 for the undirected network shown in Fig. 3.

node id k:	2	3	4	5	6	7	8	9	10	11	12
chromosome $v(k)$:	5	1	3	8	9	8	4	5	12	8	11

$T = \{(1, 3), (2, 5), (3, 4), (4, 8), (5, 8), (5, 9), (6, 9), (7, 8), (8, 11), (10, 12), (11, 12)\}$

Fig. 4. An example of the Prim Pred-based chromosome

4.3 Experiments and Discussion

In this section, first, the proposed PrimPred-based GA is compared with Prefer Number-based Encoding, Edge-based Encoding for solving several large scale minimum spanning tree problems. Afterwards, compare the different fitness assignment approaches by multiobjective GA for solving bSTP.

(1) Different Genetic Representations
For examining the effectiveness of different encoding methods, we applied Prefer Number-based encoding method and Edge-based encoding method on 6 test problems [30]. We are combining the Prefer Number-based encoding with one-cut point crossover and swap mutation, and combining the Edge-based encoding using two kinds of mutation operators which included in [48], and for initializing the chromosomes based on the edge set, we combining the Raidl and Julstrom's PrimRST (Prim Random Spanning Tree). Each algorithm was run 20 times using different initial seeds for each test problems. The GA parameter is setting as follows:

Population size: popSize = 10;
Crossover probability: $p_C = 0.30, 0.50$ or 0.70;
Mutation probability: $p_M = 0.30, 0.50$ or 0.70;
Maximum generation: maxGen = 1000;

The experimental study was realized to investigate the effectiveness of the different encoding method; the interaction of the encoding with the crossover operators and mutation operators; and the parameter settings affect its performance. Table 3 gives computational results for four different encoding methods on six test problems by tree kinds of parameter settings, where, edge-based 1 and edge-based 2 were considered with different mutation operators of Raidl and Julstrom's approach [35].

When we compare with columns of the best cost of four encoding methods, it is possible to see that whereas the Prefer number-based approach is the fastest than others, it is difficult to consist mostly of substructures of their parents' phenotypes (poor heritability), and the results is very far from the best one. The two kinds of mutation is used in edge-based encoding, the second one (depends on the cost) gives better performance than the first one. For considering the computational cost (CPU time), because of the LowestCost mutation in proposed approach, spend the most CPU times to find the edge with lowest cost, it is always longer than other algorithms. However, our algorithm developed in this study gives best cost than other algorithms.

(2) Different Fitness Assignment Approaches
The second experimental study, we show performance comparisons of multiobjective GAs for solving bSTP by different fitness assignment approaches, there are spEA, nsGAII, rwGA and i-awGA. The data in test problem was generated randomly. In each GA approach, PrimPred-based encoding was used, and Prim-based crossover and LowestCost mutation were used as genetic operators. GA parameter settings were taken as follows:

Population size: popSize = 20;
Crossover probability: $p_C = 0.70$;
Mutation probability: $p_M = 0.50$;
Stopping criteria: evaluation of 5000 solutions.

We compare i-awGA with spEA, nsGAII and rwGA trough computational experiments on the 40-node/1560-arc test problem under the same stopping condition (i.e., evaluation of 5000 solutions). Each algorithm was applied to

each test problem 10 times and gives the average results of the 3 performance measures (i.e., the number of obtained solutions $|S_j|$, the ratio of nondominated solutions $R_{\mathrm{NDS}}(S_j)$, and the average distance D1R measure). In Table 4, better results of all performance measures were obtained from the i-awGA than other fitness assignment approach.

5 Conclusion

In this paper, we investigated with a broad spectrum of bicriteria network optimization models, analyze the recent related researches, design and validate effective EA approaches for the typical network models: bicriteria shortest path (bSP) model, bicriteria spanning tree (bST) model, bicriteria network flow (bNF) model. Focus on the broad applications of proposed evolutionary algorithms (EAs) to network design with large-scale optimization.

For bSP model, we introduced an efficient genetic representation using the priority-based encoding method; based on the characteristic of this representation, we propose a new crossover operator, called weight mapping crossover (WMX), adopt insertion mutation and immigration operator. We gave effective analysis of different evolutionary approaches for bSP model dedicated to calculate nondominated paths for the minimum total cost and the minimum transmission delay. For bST model, we investigated different GA approaches for solving minimum spanning tree (MST) problems, and introduced a new genetic representation using the PrimPred-based encoding method. And we also introduced a local search technique into GA loops, called a LowestCost mutation operator. For bNF model, we introduced a new multiobjective genetic algorithm (moGA) to solve the problem with two conflicting objectives to minimize the total cost and maximize the total flow simultaneously. We combine the priority-based encoding method with a special decoding to overcome the special difficulties of bNF model.

Abstract. The county government plays a fundamental role in the Chinese governance. The e-government system of it can directly reflect the quality and efficiency of its service. Thus, it's significant to evaluate the efficiency of the e-government at county level. Nowadays, there're plenty of methods to do this kind of evaluation. This paper mainly uses principal component analysis to establish the index system, and adopts the CCR and BCC models, two of the data envelopment analysis DEA, to reflect the current input and output efficiency of 147 counties' e-government in Sichuan Province. The analysis reveals that most of the e-governments' comprehensive efficiency, technical efficiency and scale efficiency are non-DEA effective in county level governments of Sichuan Province, and the differences in development among them are quite distinctive. What's more, the local governments' information department should embark on improving their investment scale and technical efficiency in order to enhance the efficiency of e-government.

Keywords: E-government · County government · Data envelopment analysis · Efficiency

1 Introduction

The county government has long been the basis of administration management and state governance in China. It faces to the grass-roots and serves them directly. Thus, the efficiency of its operation can greatly influence the overall quality of people's life and production. Nowadays, as an effective way of improving administrative efficiency and transparency, the e-government has been praised highly by many countries. And China has also launched the Government Online Project since 1999. In fact, the construction of e-government within the county level is a very important part of China's e-government development, as well as the terminal node to the provincial level e-government, and governments should pay great attention to e-government construction at county level for constructing mature e-government system structure [7]. To promote the healthy and

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_32

sustainable development of a county e-government, an evaluation of its efficiency which may help improve its service quality is strongly required.

Evaluation systems like the Global E-government Evaluation from the UN [11], the "eEurope" Strategic Assessment System from the EU [3] and the Overall e-government Maturity Assessment from the Accenture company [1] are international representatives. While in China, it also has assessment models like the CCW Research [12], the China Software Testing Center [4], the CCID Consulting [5] and the CCTC [2].

According to the actual situation, the E-government efficiency evaluation index system was constructed from different perspectives and the corresponding analysis methods are used to evaluate the efficiency of the E-government. Extraordinary representatives: Luo and Shi [10] introduced genetic algorithm optimized to BP neural network weights and thresholds after reducing the established evaluation index system by rough set, and established e-government website evaluation model based on genetic neural network algorithm; Rorissa, Demissie and Pardo [13] used benchmarking to assess the strengths and limitations of six frameworks for computing e-government indexes; Luna et al. [9] used data envelopment analysis (DEA) to show how efficient are Mexico state governments in their use of certain inputs to produce high quality e-government portals; Zdjelar [17] measured efficiency of Croatian regional government implementation by Balanced Scorecard Method; Song and Guan [14] utilized a super efficiency slack-based measure (SBM) model to evaluate the e-government performance of environmental protection administrations in the 16 cities of Anhui Province; Kao [8] evaluated the e-government of 21 European countries based on the concept of Pareto optimality and developed a compromise programming model to rank these nations; Wu and Guo [15] used method of DEA to evaluate e-government performances of 31 provincial government websites in China and concluded that most of these provincial government websites operated at an inefficient level and in a bad manner.

To sum up, the achievements of researches on the e-government's efficiency provide a useful reference to the study. However, the evaluation of Chinese e-government's efficiency has not yet had a uniform index system. Most researches are focusing on the overall efficiency of the provincial research objects and few investigate the input-output efficiency of e-government from the perspective of e-government at county level. Therefore, this paper attempts to use principal component analysis to build the evaluation index system of county level e-government's efficiency, and adopt the DEA model to evaluate the efficiency of e-government in 147 counties (including county level cities) of Sichuan Province to provide decision-making reference for the promotion of county level e-government's efficiency.

The remainder of this paper is organized as follows. In the first half of Sect. 2, we briefly discuss the principle of principal component analysis and the practical application value of it. In the second half of Sect. 2, we narrate the construction of CCR model and BCC model of DEA which will be used for e-government efficiency evaluation. The process of e-government efficiency evaluation is presented in Sect. 3 which includes the samples selection, data collection, the establishment of evaluation index system and the model solution. On the basis of the solution, the analysis of the current situation in Sichuan Province and the suggestions for the ineffective county level government are given in Sect. 4. Finally, we conclude with a summary of this paper and prospect about evaluation of e-government in Sect. 5.

2 The Method of E-Government Efficiency Evaluation

2.1 Principal Component Analysis

On the premise of the least information loss, principal component analysis is a statistical procedure that uses the thought of dimension reduction to convert a set of multiple indexes with possible correlation into a few linearly uncorrelated comprehensive indexes.

The basic principles of principal component analysis are as follows:

We assume that there are p objects that each object is described by n indexes. In this way, we can constitute a data matrix:

$$X = \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & & \vdots \\ x_{p1} & x_{p2} & \cdots & x_{pn} \end{pmatrix} = (X_1, X_2, \cdots, X_n). \tag{1}$$

$X_1, X_2, \cdots, X_n$ are defined as original variable indexes and $F_1, F_2, \cdots, F_m (m \le n)$ are defined as new variable indexes. By using the n vectors $X_1, X_2, \cdots, X_n$ of data matrix to make a linear combination, then we can get:

$$\begin{cases} F_1 = a_{11}X_1 + a_{12}X_2 + \cdots + a_{1n}X_n \\ F_2 = a_{21}X_1 + a_{22}X_2 + \cdots + a_{2n}X_n \\ \qquad\qquad \cdots \qquad \cdots \\ F_m = a_{m1}X_1 + a_{m2}X_2 + \cdots + a_{mn}X_n \end{cases} \tag{2}$$

Coefficient a_{ij} meets:

- F_i is linearly independent with $F_j (i \neq j; i, j = 1, 2, \cdots, n)$;
- F_1 has the greatest variance of the linear combination of $X_1, X_2, \cdots, X_n$ mentioned above. F_2 has the greatest variance of the linear combination of $X_1, X_2, \cdots, X_n$ which are independent with F_1. The rest could be deduced in this way. F_m has the greatest variance of the linear combination of $X_1, X_2, \cdots, X_n$ which are independent with $F_1, F_2, \cdots, F_{m-1} (m \le n)$.

New variable indexes $F_1, F_2, \cdots, F_m (m \le n)$ are called the first, second, $\cdots$, m^{th} principal component respectively.

2.2 Data Envelopment Analysis

Based on the relative efficiency concept, the data envelopment analysis is a non-parametric statistical method employing convex analysis and linear programming as tools to calculate the relative efficiency between the same type of multi-input and multi-output decision making units. The relative efficiency is used to evaluate whether the decision-making unit is effective.

(1) CCR Mode
Assume that there are n decision-making units (hereinafter referred to as DMU), each DMU has n inputs and m outputs. The input vector of DMU_j is $X_j = (x_{1j}, x_{2j}, \cdots, x_{mj})^T \geq 0, X_j \in R^+$ while output vector is $Y_j = (y_{1j}, y_{2j}, \cdots, y_{sj})^T \geq 0, Y_j \in R^+$ Building a model with a non-Archimedes infinitely small to evaluate the relative efficiency of the DMU_j:

$$\min\left[\,\theta - \varepsilon(e_1^T s^- + e_2^T s^+)\right]$$
$$s.t.\ \begin{cases} \sum\limits_{j=1}^{n} \lambda_j x_j + s^- = \theta x_0 \\ \sum\limits_{j=1}^{n} \lambda_j y_j - s^+ = y_0 \\ \lambda_j \geq 0, j = 1, 2, \cdots, n \\ s^+ \geq 0, s^- \geq 0 \end{cases} \tag{3}$$

ε is non-Archimedes infinitely small. s^- is the slack variable while s^+ is the remaining variable. Assuming that Eq. (3) has the best solution $\theta_0, \lambda_0, s_0^-, s_0^+$ for DMU_{j0}. If $\theta_0 < 1$, DMU_{j0} will be non-DEA effective. If $\theta_0 = 1$ and s_0^- or $s_0^+ \neq 0$, DMU_{j0} will be weakly DEA effective. If $\theta_0 = 1$ and DMU_{j0} will be DEA effective.

(2) BCC Model
BCC model is the extension of fixed scale benefit data envelopment analysis. Adding the convexity condition $\sum_{j=1}^{n} \lambda_j = 1$ to the linear programming under fixed scale benefit model (CCR model) is the BCC model:

$$\min\left[\,\theta - \varepsilon(e_1^T s^- + e_2^T s^+)\right]$$
$$s.t.\ \begin{cases} \sum\limits_{j=1}^{n} \lambda_j x_j + s^- = \theta x_0 \\ \sum\limits_{j=1}^{n} \lambda_j y_j - s^+ = y_0 \\ \sum\limits_{j=1}^{n} \lambda_j = 1 \\ \lambda_j \geq 0, j = 1, 2, \cdots, n \\ s^+ \geq 0, s^- \geq 0. \end{cases} \tag{4}$$

3 The Process of E-Government Efficiency Evaluation

3.1 Samples, Indexes and Data Collection

The decision-making units in DEA should have the same type of characteristics. In order to evaluate the relative effectiveness of e-government at the county level in Sichuan Province, this paper selects the 147 districts and counties (including county level cities) in Sichuan Province as the objects of the research.

In accordance with the requirements of the DEA method, we need to establish an index system of input and output based on the comprehensive consideration of region informatization level, economic development, cultural and educational level and other factors. There are nine categories of input indexes in this paper which specifically include fixed telephone subscribers, the number of mobile phone users, the value of the tertiary industry income, GDP, total fiscal revenue, governmental investment in science and education, the proportion of urban population, the number of students in colleges and universities, the number of colleges and universities. These index data are mainly obtained from "Sichuan Province Statistical Yearbook" (2014) [16] and "The Statistics Bulletin of the National Economy and Social Development" (2013) issued by the various districts and counties (including county level cities).

To select proper output indicators, we referenced the objective indexes derived from CCID consulting assessment of government website performance and The United Nations for the global objective of e-government assessment. This study revolves around the authoritative evaluation results to screen the indexes. The five main evaluation indexes consist of government information publicity, work services, public participation, the website management, application of new technology. Output index data are mainly obtained from "The total Report of the Sichuan Government Website Performance Evaluation" (2013) [6].

3.2 Principal Component Analysis

The principal component analysis of 9 input indexes and 5 output indexes data were conducted by SPSS software (Tables 1 and 2).

According to extracts of the principal component to calculate the principal component load, the formula is:

$$l_{ij} = p(z_i, x_j) = \sqrt{\lambda_i} a_{ij} (i = 1, 2, \cdots, k, k \text{ as main composition}, \quad j = 1, 2, \cdots, 147) \tag{5}$$

Then we can get the principal component index data of inputs and outputs.

On account of that the result of the principal component analysis is negative number, and DEA model requires that the data is not negative, so the results of the principal component calculated by poor transformation normalized to [1, 10] interval. The range transform formula is:

$$n_{\text{new}} = 1 + 9 \times [(n - n_{\min})/(n_{\max} - n_{\min})], \tag{6}$$

where $n_{\max}$ and $n_{\min}$ represent the maximum and minimum values of the column data respectively (Tables 3 and 4).

3.3 The Solution of the DEA Model

According to the principal component analysis method, the main components of input and output index data are obtained. After that, we use the DEAP 2.1 to solve 147 counties' (including districts' and cities') input-output efficiency of e-government with CCR and BCC model, and we obtain the comprehensive efficiency, pure technical efficiency and scale efficiency of all counties' (including districts' and cities') e-government. All results are shown in Table 5.

4 Analysis of the Result

Through the analysis of *CCR*, it appears that Wuhou District in Chengdu and Gongxian County in Yibin have achieved a full effectiveness of comprehensive efficiency (CCR = 1.000) among 147 counties, districts, or cities of Sichuan Province, which indicates that they have obtained a fully efficient outcome. However, two districts, Jinjiang and Chenghua in Chengdu, are in the position of a light level of non-DEA effective degree ($0.700 \leq \text{CCR} < 1.000$). For those of a light level of non-effective degree, the development of electronic administration requires focusing more on the control and management of details and proper distribution of the investment, as there's still some room for improvement. Meanwhile, most of counties (including districts and cities) are in a severe level of non-DEA effective degree ($\text{CCR} \leq 0.500$), which suggests that most counties' e-government development in Sichuan province don't work out. The overall development gap is huge, and most of objects have not achieved the comprehensive effectiveness. The input of the e-government construction has not acquired the desired results. On the one hand, the technical inefficiency leads to the comprehensive ineffectiveness. On the other hand, the low scale efficiency also affects the improvement of the comprehensive efficiency. Therefore, the government should make a huge effort to find out the route to suit the situation, so as to surmount the problem fundamentally. The counties and districts with the lowest CCR, Jinyang County and Butuo County in Liangshan, Rangtang County in Tibetan Qiang Autonomous Prefecture of Aba, Qingshen county in Meishan, Dawu County in Tibetan Autonomous Prefecture of Garze, Aba County in Aba Tibetan and Qiang Autonomous Prefecture, correspond to their relatively weak national economy and social development, as well as the influence of little capital invested by the government on information construction. Thus, problems should be solved and development should be sped up in the future construction of e-government.

The pure technical efficiency results obtained by the BCC model show that Jinjiang district, Wuhou District and Pixian County of Chengdu are with pure technical effective (BCC = 1.00). It indicates that their services systems of e-government run well, and the resources invested can develop productivity efficiently. The pure technical efficiency of 132 counties, districts or cities are lower than 0.5, and it appears that these local governments' technical outcomes are not enough. The last 5 counties, districts or cities with the lowest BCC successively are Hongya County in Meishan, Peng'an County in Nanchong, Qingshen County in Meishan, Pengxi County in Suining, Chaotian District in Guangyuan. It indicates these governments didn't distribute the resources legitimately, and they need more technological innovation to improve the service abilities of e-government from technology level.

From the point of view of scale efficiency, there are 9 counties or districts of Sichuan Province in full scale efficiency. They are Wuhou District, Qingbaijiang District and Shuangliu County in Chengdu, Gongxian County in Yibin, Dachuan District and Xuanhan District in Dazhou, Fucheng District in Mianyang, Lizhou District in Guangyuan and Bazhou District in Bazhong.

These governments input resources in e-government are proper, and returns of scale remain unchanged. The rest 138 counties, districts or cities are not in full scale efficiency, it manifests that these governments waste some resources during the construction of e-government. In the future, the governments need to increase the investment in information technology and science and education, for speeding up the process of urbanization and informatization. What's more, the governments should allocate resources more reasonably to improve the level of government information disclosure, services and websites management. Besides, governments should make more and more people participate in the construction of e-government in order to take better use of the resources.

5 Conclusions

Due to the wave of the informatization and popularization of the network, the construction of e-government in the human condition is getting better and better. Governments at all levels are also vigorously investing money and human resources for the construction of e-government to promote the informatization. To guide the construction of e-government, how to accurately evaluate and scientifically observe the efficiency of e-government is a hotspot and difficulty in the field of current e-government. Although there are a lot of foreign standards being references, different countries may have different national conditions. The real effective e-government construction has to be combined with the actual situation. According to the views of scholars and organizations at home and abroad, based on observation and thinking, we use different indexes and principal component analysis and DEA model to evaluate the e-government construction efficiency of all districts and counties of Sichuan Province. We hope to be able to scientifically evaluate the comprehensive efficiency of various districts and counties of Sichuan Province in the construction of e-government. On the whole, the local government's information department should focus on improving their investment scale and technical efficiency to enhance the efficiency of e-government.

However, this paper also has some limitations. Firstly, we take both input and output into consideration which also have been rotated, extracted and standardized. Therefore, this paper couldn't use the projection algorithm to get the improvement solutions which give the target value and scope for the non-DEA effective. Secondly, DEA focus on the relative efficiency. It means that different evaluation range may have different result. So how to choose the evaluation range is a project worth exploring. In later study, we will commence on diminishing the limitations above and optimize the solution.

Acknowledgements. We would like to express our sincere appreciation to the reviewers for their insightful comments, which have greatly aided us improving the quality of the paper. This research was supported by the Soft Science Research Project of Chengdu (Grant 2016-RK00-00041-ZF).

Comparing Visitors' Behavior Through Mobile Phone Users' Location Data

Masahide Yamamoto(✉)

Faculty of Foreign Studies, Nagoya Gakuin University, Nagoya, Japan
myama@ngu.ac.jp

Abstract. In recent years, so-called "big data" have been attracting the attention of companies and researchers. This study aims to identify the number of visitors of each period and their characteristics based on the location data of mobile phone users collected by the mobile phone company. The study sites of this survey are tourist destinations in Ishikawa Prefecture and Toyama city, including Kanazawa city, which became nationally popular after the Hokuriku Shinkansen opened in 2015. The opening of the Hokuriku Shinkansen brought more visitors to many areas. However, it also led to fewer visitors in some areas. The positive effect was remarkable in Kanazawa.

Keywords: Mobile phone · Location data · Tourism

1 Introduction

In Japan, many people have struggled to promote tourism in their regions to vitalize their local economies. The low-cost carriers have boosted competition in the transportation industry, and domestic transportation costs have declined in several regions. Therefore, tourism is likely to become increasingly important to local economies. Initially, Japan's tourism industry suffered significant volatility in demand depending on the season and day of the week. In addition, there was significant loss of business opportunities because of congestion during the busy season.

To cope with such volatility, various events have been held to eliminate the seasonal gap. Many events are newly launched. To date, it has been difficult to accurately grasp the extent to which these events attract visitors and the types of people who visit. However, by employing the recently provided Information and Communication Technology (ICT) services, it is possible to verify the number and characteristics of visitors to a particular event.

This study attempts to identify the number of visitors in different periods and their characteristics based on the location data of mobile phone users collected by the mobile phone company. In addition, it also attempts to demonstrate an alternative method to more accurately measure the number of visitors attracted by an event.

2 Method

This study used "MOBILE KUUKAN TOUKEI^{TM}" (mobile spatial statistics) provided by NTT DoCoMo, Inc. and DoCoMo Insight Marketing, Inc. to collect the location data of mobile phone users in order to count the number of visitors at specific tourist destinations and examine their characteristics. MOBILE KUUKAN TOUKEI^{TM} is statistical population data created by a mobile phone network. It is possible to estimate the population structure of a region by gender, age, and residence using this service of a particular company.

Table 1. Survey areas and regional mesh codes

	Survey areas	Regional mesh code	Type of codes
Kanazawa	Kanazawa Station	5436-6591-2	1/2
	Kenrokuen	5436-6572 + 5436-6573-1, 5436-6573-3	Tertiary, 1/2
	Higashi Chayagai	5436-6583-3	1/2
Nanao	Wakura Hot Springs	5536-5703	Tertiary
	Nanao Station	5536-4757	Tertiary
Kaga	Yamanaka Hot Springs	5436-2299, 5436-2390	Tertiary
Wajima	Wajima	5636-0772	Tertiary
Toyama	Toyama Station	5537-0147-1	1/2

Note: A regional mesh code is a code for identifying the regional mesh, which is substantially divided into the same size of a square (mesh) based on the latitude and longitude in order to use it for statistics. The length of one side of a primary mesh is about 80 km, and those of secondary and tertiary meshes are about 10 Km and 1 km respectively.

The sites studied in this survey are tourist destinations in Ishikawa Prefecture and Toyama city, including Kanazawa city, which became nationally popular when the Hokuriku Shinkansen (high-speed railway) opened in 2015. Moreover, the locations and characteristics of the individuals obtained herein are derived through a non-identification process, aggregation processing, and concealment processing. Therefore, it is impossible to identify specific individuals.

The survey areas are presented in Table 1 and Fig. 1. A regional mesh code is a code for identifying the regional mesh. It stands for an encoded area that is substantially divided into the same size of a square (mesh) based on the latitude and longitude in order to use it for statistics. With regard to regional mesh, there are three types of meshes: primary, secondary, and tertiary. The length of one side of a primary mesh is about 80 km, and those of secondary and tertiary meshes are about 10 Km and 1 km respectively.

In addition, split regional meshes also exist, which are a more detailed regional division. A half-regional mesh is a tertiary mesh that is divided into two equal pieces in the vertical and horizontal directions. The length of one side is about 500 m. Furthermore, the length of one side of a quarter and 1/8 regional meshes is about 250 m and 125 m respectively.

Fig. 1. Survey areas

This study analyzed the location data collected from NTT DoCoMo, Inc. to consider the effect of the opening of the Hokuriku Shinkansen on the survey areas.

3 Previous Research

Previous tourism marketing research has primarily focused on the ways service promises are made and kept, mostly generating frameworks to improve managerial decisions or providing insights on associations between constructs [4]. Big data have become important in many research areas, such as data mining, machine learning, computational intelligence, information fusion, the semantic Web, and social networks [3]. To date, several attempts have been made to use large-scale data or mobile phone location data in tourism marketing studies.

Most studies dealing with big data in tourism were published after 2010. Fuchs et al. [5] presented a knowledge infrastructure that has recently been implemented at the leading Swedish mountain tourism destination, Åre. Using a Business Intelligence approach, the Destination Management Information System Åre (DMIS-Åre) drives knowledge creation and application as a precondition of organizational learning at tourism destinations. Xiang et al. [9] tried to apply big data to tourism marketing. The study aimed to explore and demonstrate the utility of big data analytics to better understand important hospitality issues, namely, the relationship between hotel guest experience and satisfaction. Specifically, the investigators applied a text analytical approach to a large number of consumer reviews extracted from Expedia.com to deconstruct hotel guest experiences and examine the association with satisfaction ratings. These studies are similar to this study in that they attempted to utilize big data in tourism. However, the research methods and objectives of these studies are different from that of the present study.

Studies on using mobile phone location data for tourism surveys can be traced back to 2008. Ahas et al. [2] introduced the applicability of passive mobile positioning data for studying tourism. They used a database of roaming location (foreign phones) and call activities in network cells: the location, time, random identification, and country of origin of each called phone. Using examples from Estonia, their study described the peculiarities of the data, data gathering, sampling, the handling of the spatial database, and some analytical methods to demonstrate that mobile positioning data have valuable applications for geographic studies. Japan Tourism Agency conducted a similar study using international roaming service in December 2014 [1].

Since the creative work of Ahas et al. [2], several studies employing location data have emerged. Liu et al. [7] investigated the extent to which behavioral routines could reveal the activities being performed at mobile phone call locations captured when users initiate or receive voice calls or messages. Using data collected from the natural mobile phone communication patterns of 80 users over more than a year, they assessed the approach via a set of extensive experiments. Based on the ensemble of models, they achieved prediction accuracy of 69.7%. The experiment results demonstrated the potential to annotate mobile phone locations based on the integration of data mining techniques with the characteristics of underlying activity-travel behavior.

Alternative related studies have also been conducted. Gao and Liu [6] attempted to examine the methods used to estimate traffic measures using information from mobile phones, accounting for the fact that each vehicle likely contains more than one phone because of the popularity of mobile phones. Steenbruggen et al. [8] used mobile phone data to provide new spatio-temporal tools for improving urban planning and reducing inefficiencies in current urban systems. They addressed the applicability of such digital data to develop innovative applications to improve urban management.

As described above, this study surveyed previous related research. Among those studies, the present study could be characterized as similar to Ahas et al. [2]. However, Ahas et al. [2] is based on results obtained by analyzing data roaming activity. Mobile phone users in the study are obviously limited. Therefore, whether the knowledge gained applies to the average traveler is not clear. In the present study, I analyzed data provided by NTT DoCoMo, Inc., which is the largest mobile phone service provider in Japan. Therefore, their data should be more reliable in that the parameter is quite large.

4 Results

In general, the number of visitors has been increasing since the Hokuriku Shinkansen was launched on May 14, 2015, with the exception of Nanao station.

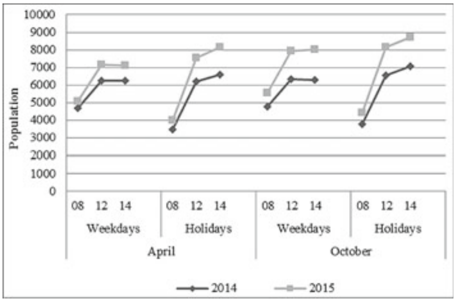

Fig. 2. Visitor transitions at Kanazawa station

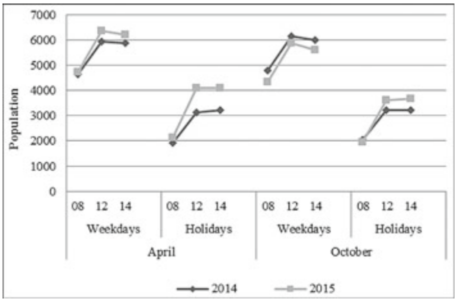

Fig. 3. Visitor transitions at Toyama station

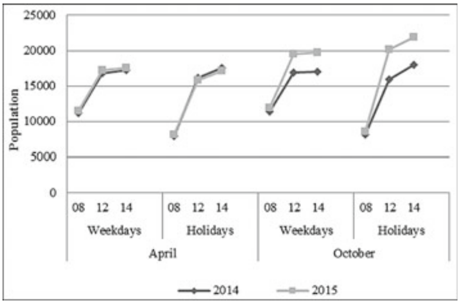

Fig. 4. Visitor transitions at Kenrokuen

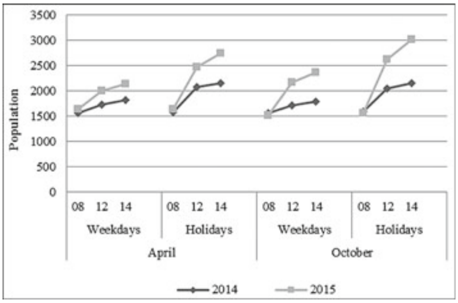

Fig. 5. Visitor transitions at Higashi Chayagai

It should be noted that these "visitor" also include the residents living there, because the data cannot exclude them. Of course, I tried to exclude residential areas as much as possible when I specified the regional mesh codes. However, it was rather difficult to do that, because the mesh codes are square-shaped.

First, I compared the results of two larger cities, Kanazawa and Toyama (see Figs. 2 and 3). Both these cities have a station at which the Hokuriku Shinkansen stops. It should be noted that Kanazawa city and Toyama attracted more visitors in the afternoons, whereas Wakura and Wajima, which are located on the Noto Peninsula, had more visitors in the mornings (8:00 a.m.–9:00 am). Visitors to Toyama Station demonstrated approximately the same trend as those visiting Kanazawa Station. However, there were fewer visitors on holidays than on weekdays in Toyama.

I then examined the data of Kanazawa city (see Figs. 4 and 5). There were three survey areas in this city: Kanazawa station, Kenrokuen Park and Higashi Chayagai.

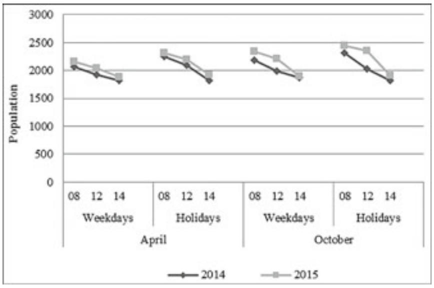

Fig. 6. Visitor transitions at Wajima

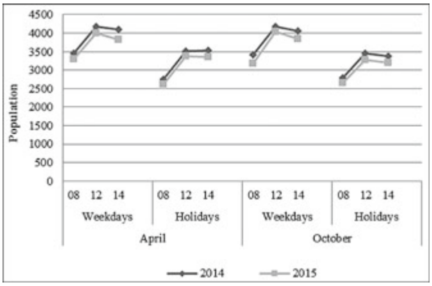

Fig. 7. Visitor transitions at Nanao station

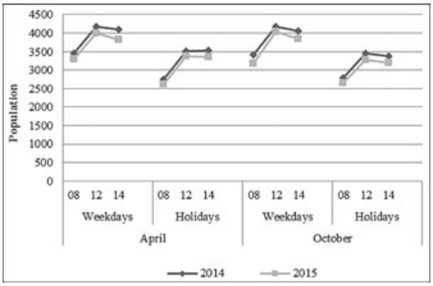

Fig. 8. Visitor transitions at Wakura hot springs

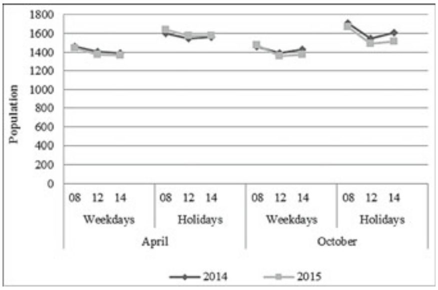

Fig. 9. Visitor transitions at Yamanaka hot springs

Wajima is famous for its Asaichi (morning market). Presumably, visitors enjoy shopping at the Noto Shokusai market near Nanao Station during the daytime, move on to Wakura hot springs later in the day, and then return to the morning market the next day (see Figs. 6, 7 and 8).

Wajima is also the setting for a TV drama "Mare", which was broadcasted nationwide from April to September 2015. Visits to Wajima have slightly increased in 2015. The increase in visits could be attributed to this TV drama rather than the opening of the Hokuriku Shinkansen, because Nanao attracted fewer visitors in 2015 than in 2014 in spite of being a better location and nearer to Kanazawa.

Regarding Yamanaka hot springs, there was no significant difference in visits between different periods. Some visitors might have spent more than one night in Yamanaka hot springs (see Fig. 9).

Although both Wakura and Yamanaka hot springs are a little far from Kanazawa, their results were contrary. The TV drama might have increased the number of tourists in Wakura (Figs. 10 and 11).

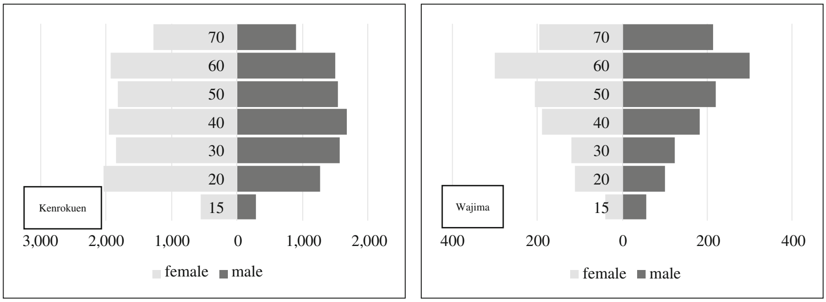

Fig. 10. Visitors' gender distribution at Kenrokuen and Wajima (12:00 a.m.–1:00 p.m. on holidays in October 2015)

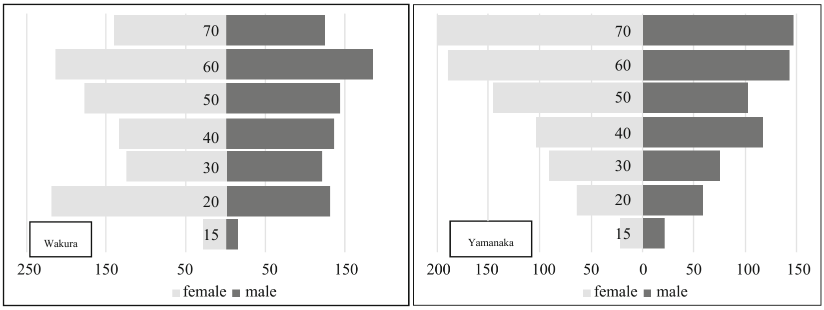

Fig. 11. Visitors' gender distribution at Wakura hot springs and Yamanaka hot springs (12:00 a.m.–1:00 p.m. on holidays in October 2015)

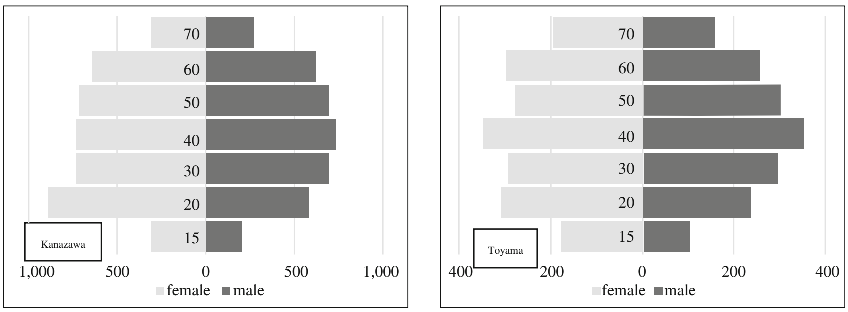

Fig. 12. Visitors' gender distribution at Kanazawa station and Toyama Station (12:00 a.m.–1:00 p.m. on holidays in October 2015)

Kanazawa city (particularly Kenrokuen) attracted a variety of visitors, including many female visitors.

On the other hand, many elderly people (over 60 years old) visited the hot springs and the Noto Peninsula. I presume that the local people account for a large proportion of these visitors.

A comparison of visitors at Kanazawa Station with those at Toyama Station found that Kanazawa Station attracted visitors from a wider area of Japan. Mobile phone users around Kanazawa Station were from 235 municipalities, including Ishikawa Prefecture, whereas those at Toyama Station were from 43 municipalities, including Toyama Prefecture (12:00 a.m.–1:00 p.m. on holidays in October 2015) (Fig. 12).

Although the Hokuriku Shinkansen stops at both stations, the results suggest that Kanazawa has been more successful so far in attracting visitors (see Table 2). The number of visitors from Tokyo (gray column) increased in both the cities.

Table 2. Visitors' residential distribution at Kanazawa Station and Toyama Station(12:00 a.m.–1:00 p.m. on holidays in October 2014 and 2015)

Kanazawa station			Toyama station		
Residence	2015	2014	Residence	2015	2014
Toyama, Toyama Pref.	131	147	Kanazawa, Ishikawa Pref.	67	60
Takaoka, Toyama Pref.	93	94	Fukui, Fukui Pref.	18	13
Fukui, Fukui Pref.	91	80	Setagaya-ku, Tokyo	16	n/a
Myoko, Niigata Pref.	47	n/a	Suginami-ku, Tokyo	15	n/a
Nanto, Toyama Pref.	34	31	Yamagata, Yamagata Pref.	14	n/a
Setagaya-ku, Tokyo	34	17	Takayama, Gifu Pref.	14	n/a
Imizu, Toyama Pref.	34	42	Nakamura-ku, Nagoya, Aichi Pref.	13	n/a
Oyabe, Toyama Pref.	33	39	Minami-ku, Niigata, Niigata Pref.	13	n/a
Sakai, Fukui Pref.	32	30	Gifu, Gifu Pref.	12	n/a
Omachi, Nagano Pref.	30	n/a	Hakusan, Ishikawa Pref.	12	20
Ota-ku, Tokyo	28	12	Ota-ku, Tokyo	12	n/a
Tsubame, Niigata Pref.	28	n/a	Himeji, Hyogo Pref.	12	n/a
Bunkyo-ku, Tokyo	27	n/a	Nagano, Nagano Pref.	12	n/a
Nagano, Nagano Pref.	24	n/a	Nerima-ku, Tokyo	11	n/a
Hiratsuka, Kanagawa Pref.	24	n/a	Shinagawa-ku, Tokyo	11	n/a
Sanda, Hyogo Pref.	23	n/a	Hida City, Gifu Pref.	11	10
Tonami, Toyama Pref.	23	26	Joetsu, Niigata Pref.	11	n/a
Suginami-ku, Tokyo	22	16	Kawaguchi, Saitama Pref.	10	n/a
Nerima-ku, Tokyo	22	10	Adachi-ku, Tokyo	10	n/a
Tsu, Mie Pref.	22	n/a	Takatsuki, Osaka	10	n/a

Note: The figures above do not include visitors from Ishikawa Pref. for Kanazawa Station and Toyama Pref. for Toyama Station. Numbers less than ten are represented as "n/a"

Despite the fact that Toyama is nearer to Tokyo than Kanazawa, the latter successfully attracted more visitors from Tokyo.

Regarding the two prefectures, Ishikawa and Toyama, they both do have many wonderful tourist attractions. However, as for the two cities, it seems that Kanazawa is more attractive to tourists.

5 Conclusion

This study attempted to identify the number of visitors at two points in time at various places in Japan and their characteristics using the location data of mobile phone users collected by the mobile phone company.

As explained above, the opening of the Hokuriku Shinkansen increased the number of visitors to many areas. However, it also led to fewer visitors in some other areas. Its positive effect was remarkable in Kanazawa.

Numerous events have been recently held in Japan to attract visitors. In addition to using the "MOBILE KUUKAN TOUKEI^{TM}", combining it with other ICT services, such as Google Trends, can help better predict the number of visitors at new events. Specifically, by combining the "MOBILE KUUKAN TOUKEI^{TM}" and the transition of the search results for a particular tourist destination, it would be possible to more accurately predict the number of tourists. If we can realize more accurate demand forecasting, it would be possible to optimize the necessary goods and number of non-regular employees in advance. Moreover, understanding consumers' characteristics beforehand could enable us to optimize the services, which could influence customer satisfaction.

Abstract. Queueing phenomenon is prevalent in all areas of society and a reasonable queueing design can improve service efficiency and customer satisfaction. In order to adapt to the new requirements of web service system, this paper studies a Geo/Geo/1 retrial queue with working vacation interruption and nonpersistent customers. Firstly, a series of assumptions about the queueing system are put forward and the corresponding transition probability matrix is obtained. Then the stationary condition of the queueing system is derived. After that, the stationary distribution and the performance measures are obtained by using the matrix-analytic method. Finally, numerical analysis is conducted to discuss the effect of parameters on performance measures, furthermore, the performance of the queueing model is optimized to obtain the best parameters and the minimum cost.

Keywords: Web service · Discrete-time queueing system · Retrial · Working vacation interruption · Nonpersistent customers

1 Introduction

With the development of the internet, the internet-based web service industry is growing explosively, and web service of higher quality is required. The basic application structure of web service is shown in Fig. 1. In the system, users can request services according to their own needs through the internet. After their service requests are passed to web server, the web server will interact with application server and database server for different requests, and process various requests properly. Finally, the results of the requests will be returned to the users. The function of the application server is to guarantee the business logic in the activities and coordinates the information exchange among the users. The task of the database server is to complete query, storage, modify and other functions of web service data in the database.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_34

Web service system needs to use the adapted queueing model in dealing with the order of the users, but the traditional queueing model cannot accurately deal with this scene. When the arriving user finds the server is temporarily unable to provide service, he will leave the server and repeat requests after a while, which is called retrial strategy. Considering the utilization of server, managers often allow server to serve at a relatively low rate when there are no users in the system, but when the number of the users requesting service increases in the system, the service rate needs to return to a higher level immediately, which is called working vacation interruption strategy. Besides, users who conduct business on the internet tend to give up receiving service and leave the service system because they don't want to wait too long, which is called nonpersistent customers strategy. Scholars have studied the above three cases separately, but there are no studies of the queueing model which possess these three strategies at the same time. This paper tries to study the combination of these three strategies, and solve the construction of the queueing model of web service system under these conditions.

This paper is organized as follows. In Sect. 1, relevant literatures are reviewed. Section 2 is dedicated to formulate a queueing model to solve the problem mentioned above. In Sect. 3, a series of numerical analyses are presented and the performance of the model is optimized. Section 4 gives some conclusions.

2 Literature Review

Queueing theory studies the working process of random service system. It originated from the telephone conversation in the early 20^{th} century. In 1909–1920, Erlang, the Danish mathematician and electrical engineer, studied the problem of telephone conversation using the method of probability theory, which created this subject of applied mathematics. Queueing system is divided into continuous-time queueing system and discrete-time queueing system. Compared with the former, the research of discrete-time queueing system started relatively late and

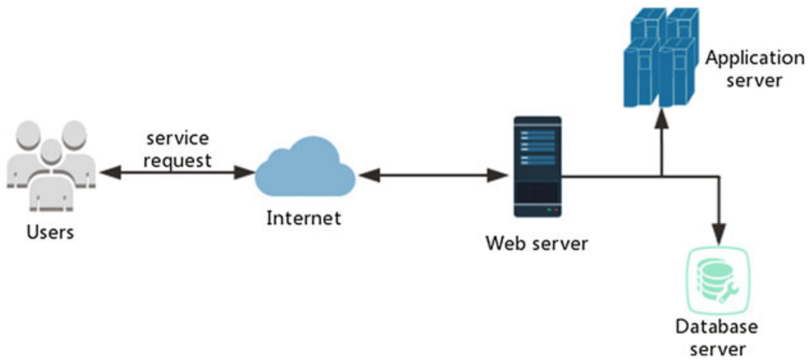

Fig. 1. The basic application structure of web service

the early research results about the discrete-time queueing system are few. But with the development of computer and communication in which time is slotted, the discrete-time queueing system has become one of the research hotspots of queueing theory in recent years. Meisling [10] made a pioneering work on the discrete-time queueing system, and then a series of studies have deepened and developed the analysis of this classical model. Kobayash and Konheim [3] studied the application of the discrete-time queueing system in the field of computer communication network, and pointed out that the discrete-time queueing system is more suitable for the modeling and analysis of computer networks, which has played a positive role in the research and application of the discrete-time queueing system.

Retrial queueing system is an important part of queueing theory research. The characteristic of retrial queueing system is that customer who requests service will enter a queue called orbit and retry after a random time when he finds all servers are busy. Kosten [4] first proposed a retry service system. Yang and Li [18] were the first to study a discrete-time retrial queue, they studied the steady-state queue size distribution of the discrete-time Geo/G/1 retrial queue. Then retrial queueing system is widely used in telephone switching systems, computer networks and communications networks. So far, these research areas are still vibrant. Some of the latest developments regarding retrial queueing systems are Dimitriou [2], Rajadurai [13] and so on. If the server is occupied, the customer retrying from the orbit may leave the queueing system or return to the orbit, which is called nonpersistent customers phenomenon. Palm [11] first proposed the issue of nonpersistent customers. Then, many scholars introduced nonpersistent customers into various queueing systems. Liu and Song [9] introduced nonpersistent customers to a Geo/Geo/1 retrial queue with working vacations. Phung-Duc [12] introduced two types of nonpersistent customers into a M/M/c/K ($K \geq c \geq 1$) retrial queues. These models are also widely used in real life. In fact, the introduction of nonpersistent customers is of great significance to imitate the impatience characteristic of customers in reality.

The queueing systems with vacation and working vacation have always been a research hotspot. Queueing system with vacation is an extension of the classical queueing system, which allows server not to serve customers at certain time called vacation. For more information about queueing system with vacation, see Tian and Zhe [16]. If server does not completely stop serving on vacation, but rather serve at a slower service rate than the rate of regular busy period, this vacation policy is called working vacation. Servi and Finn [14] first introduced the queueing system with working vacation when they studied the model of communication network. They introduced the working vacation mechanism into the M/M/1 queue. Then, many scholars introduced working vacation into various queueing system. Tian et al. [17] studied a discrete-time queueing system with working vacation. Li and Tian [7] studied a discrete-time Geo/Geo/1 queue with single working vacation. On the basis of working vacations, working vacation interruption strategy was introduced, which means that once a certain indicator (such as the number of customers in the system) reaches a certain value on working vacation, server can stop working vacation and return to normal service level immediately. Li and Tian [6] first proposed working vacation interruption strategy. They introduced working vacation and vacation interruption into M/M/1 queue, then they studied the corresponding discrete-time queue [5]. Recently, studies on working vacation interruption are continued. Li et al. [8] introduced working vacation interruption into discrete-time Geo/Geo/1 retrial queue, Gao et al. [15] studied an M/G/1 queue with single working vacation and vacation interruption under Bernoulli schedule.

Previous studies can't address the real-world scenes of web service that are mentioned. So, this paper considers introducing working vacation interruption and nonpersistent customers to discrete-time Geo/Geo/1 retrial queue to provide the solution.

3 Method

In order to deal with retrial, working vacation interruption and nonpersistent customers phenomena in web service, this section constructs an adapted queueing model and studies the queueing system. Section 3.1 put forwards a series of assumptions about the queueing model (for convenience of study, assume that the number of server is one) and obtains the corresponding transition probability matrix for subsequent derivation. The research of queueing system needs to be based on the stability of the system, so Sect. 3.2 derives the condition under which the system is stable, and the rate matrix R for the derivation of stationary distribution. The main purpose of the research of queueing system is to study the states and the indexes when the system is stable, so Sect. 3.3 derives the stationary distribution and some performance measures using matrix-analytic method.

3.1 Model

The Geo/Geo/1 retrial queue with working vacation interruption and nonpersistent customers is assumed as follows:

First of all, the rules of service and customer arrival are assumed. Assume the beginning and ending of service occur at slot division point $t = n, n = 0, 1, \cdots$. The service time S_b in a regular busy period follows a geometric distribution with parameter μ_b. The service time S_v in a working vacation period follows a geometric distribution with parameter μ_v. Note that $0 < \mu_v < \mu_b < 1$. Assume customer arrivals occur at the slot $t = n, n = 0, 1, \cdots$. Inter-arrival time, which is an independent and identically distributed sequence, follows a geometric distribution with parameter during a regular busy period and a geometric distribution with parameter λ_b during a working vacation period. Also Note that $0 < \lambda_v < \lambda_b < 1$.

Then, assume the rules of retrial and nonperisistent customers strategies. Customer from the orbit of infinite size requests retrial at the slot $t = n, n = 0, 1, \cdots$. And the time between two successive retrials follows a geometric distribution with parameter α. If the customer arrival and retrial occur at the same instant when the server is not occupied, we assume that the arriving customer receives the service. And, due to the introduction of nonpersistent customers strategy, suppose the probability that the retrial customer leaves system is $q(0 < q < 1)$, and the probability that retrial customer returns to the orbit is $1 - q$.

Finally, working vacation and vacation interruption are assumed. The server begins a working vacation each time when there is no customer in the system, i.e., the server is free and there is no customer in the orbit. Assume the beginning and ending of working vacation occur at the slot $t = n^+, n = 0, 1, \cdots$. At the end of each working vacation, the server begins a new vacation only if there is no customer in the system. And the vacation time V follows a geometric distribution with parameter θ, $(0 < \theta < 1)$. If the service is complete at slot t = n$^-$ and there is customer in the system at slot $t = n^+$, the server will stop the working vacation immediately and return to the normal service level, i.e., working vacation interruption strategy.

In this paper, for any real number $x \in [0, 1]$, denote $\overline{x} = 1 - x$. Assume that interarrival time, service time, and working vacation time are mutually independent.

After completing the above assumptions, the occurring order of the random events can be described in Fig. 2 using number axis.

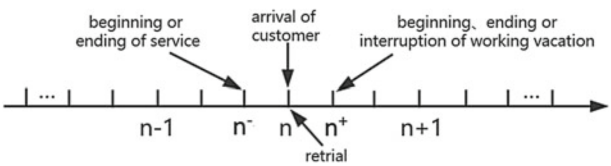

Fig. 2. The occurring order of the random events

Meanwhile, the structure of the queueing model in web service can be shown in Fig. 3. User accesses the web server through the internet. He joins the orbit if the web server is busy, or else he receives service immediately and leaves the system after the service is completed. The retrial user from the orbit receives service immediately if the web server is free, otherwise he may leave the system or come back to the orbit.

Let Q_n be the number of customers in the orbit at the slot n^+, and J_n the state of server at the slot n^+. There are four possible states of the server as follows:

(1) The state $J_n = 0$ denotes the server is free in a working vacation period at the slot n^+.
(2) The state $J_n = 1$ denotes the server is busy in a working vacation period at the slot n^+.
(3) The state $J_n = 2$ denotes the server is free in a regular busy period at the slot n^+.

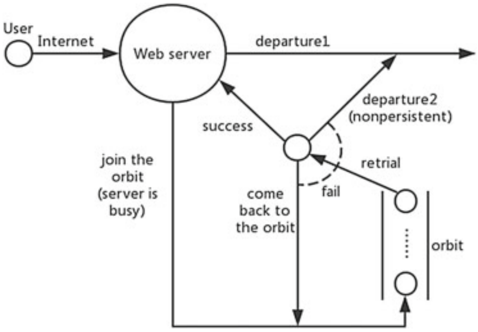

Fig. 3. The structure of the queueing model in web service

(4) The state $J_n = 3$ denotes the server is busy in a regular busy period at the slot n^+.

Then, $\{Q_n, J_n\}, n \geq 0$, is a Markov chain with state space $\Omega = \{(k, j), k \geq 0, j = 0, 1, 2, 3\}$. Note that, the probability that the server is free in a regular busy period is zero when there is no customer in the orbit.

Using the lexicographical sequence for the states, the transition probability matrix of $\{Q_n, J_n\}$ can be written as:

$$P = \begin{pmatrix} B_1 & B_0 & & \\ A_2 & A_1 & A_0 & \\ & A_2 & A_1 & A_0 \\ & & \ddots & \ddots & \ddots \end{pmatrix},$$

where

$$B_0 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \bar{\mu}_v \lambda_v \bar{\theta} & 0 & \bar{\mu}_v \lambda_v \theta \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \bar{\mu}_b \lambda_b \end{pmatrix}, B_1 = \begin{pmatrix} \bar{\lambda}_v & \lambda_v \bar{\theta} & 0 & \lambda_v \theta \\ \mu_v \bar{\lambda}_v & \bar{\mu}_v \bar{\lambda}_v \bar{\theta} & 0 & \mu_v \lambda_v + \bar{\mu}_v \bar{\lambda}_v \theta \\ 1 & 0 & 0 & 0 \\ \mu_b \bar{\lambda}_b & 0 & 0 & \mu_b \lambda_b + \bar{\mu}_b \bar{\lambda}_b \end{pmatrix},$$

$$A_0 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \bar{\mu}_v \lambda_v (\bar{\alpha} + \alpha \bar{q}) \bar{\theta} & 0 & \bar{\mu}_v \lambda_v (\bar{\alpha} + \alpha \bar{q}) \theta \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \bar{\mu}_b \lambda_b (\bar{\alpha} + \alpha \bar{q}) \end{pmatrix},$$

$$A_1 = \begin{pmatrix} \bar{\lambda}_v \bar{\alpha} \bar{\theta} & \lambda_v \alpha \bar{q} \bar{\theta} + \lambda_v \bar{\alpha} \bar{\theta} & \bar{\lambda}_v \bar{\alpha} \theta & \lambda_v \bar{\alpha} \theta + \lambda_v \alpha \bar{q} \theta \\ 0 & \bar{\mu}_v \bar{\lambda}_v (\bar{\alpha} + \alpha \bar{q}) \bar{\theta} + \bar{\mu}_v \lambda_v \alpha q \bar{\theta} & \mu_v \bar{\lambda}_v \bar{\alpha} & (\mu_v \lambda_v + \bar{\mu}_v \bar{\lambda}_v \theta)(\bar{\alpha} + \alpha \bar{q}) + \bar{\mu}_v \lambda_v \alpha q \theta \\ 0 & 0 & \bar{\lambda}_b \bar{\alpha} & \lambda_b (\bar{\alpha} + \alpha \bar{q}) \\ 0 & 0 & \mu_b \bar{\lambda}_b \bar{\alpha} & (\mu_b \lambda_b + \bar{\mu}_b \bar{\lambda}_b)(\bar{\alpha} + \alpha \bar{q}) + \bar{\mu}_b \lambda_b \alpha q \end{pmatrix},$$

$$A_2 = \begin{pmatrix} 0 & \lambda_v \alpha q \bar{\theta} + \bar{\lambda}_v \alpha \bar{\theta} & 0 & \lambda_v \alpha q \theta + \bar{\lambda}_v \alpha \theta \\ 0 & \bar{\mu}_v \bar{\lambda}_v \alpha q \bar{\theta} & 0 & (\bar{\mu}_v \bar{\lambda}_v \theta + \mu_v \lambda_v) \alpha q + \mu_v \bar{\lambda}_v \alpha \\ 0 & 0 & 0 & \lambda_b \alpha q + \bar{\lambda}_b \alpha \\ 0 & 0 & 0 & (\bar{\mu}_b \bar{\lambda}_b + \mu_b \lambda_b) \alpha q + \mu_b \bar{\lambda}_b \alpha \end{pmatrix}.$$

It can be seen from the block structure of the transition probability matrix that is a quasi-birth and death (QBD) process.

3.2 Stability Condition and Rate Matrix R

In this section, after using the matrices A_0, A_1 and A_2 to get the matrix A, derive the stability condition of the queueing system using the matrix A.
Let $A = A_0 + A_1 + A_2$, then,

$$A = \begin{pmatrix} \bar{\lambda}_v \bar{\alpha} \bar{\theta} & \alpha \bar{\theta} + \lambda_v \bar{\alpha} \bar{\theta} & \bar{\lambda}_v \bar{\alpha} \theta & \alpha \theta + \lambda_v \bar{\alpha} \theta \\ 0 & \bar{\mu}_v \bar{\theta} & \mu_v \bar{\lambda}_v \bar{\alpha} & \bar{\mu}_v \theta + \mu_v \lambda_v + \mu_v \bar{\lambda}_v \alpha \\ 0 & 0 & \bar{\lambda}_b \bar{\alpha} & \lambda_b + \bar{\lambda}_b \alpha \\ 0 & 0 & \mu_b \bar{\lambda}_b \bar{\alpha} & \bar{\mu}_b + \mu_b \lambda_b + \mu_b \bar{\lambda}_b \alpha \end{pmatrix}.$$

Theorem 1. *The QBD process $\{Q_n, J_n\}$ is positive recurrent (stable) if and only if $\bar{\mu}_b (\bar{\lambda}_b \bar{\alpha} - 1)(\alpha q - \lambda_b) < \mu_b (\bar{\lambda}_b + \lambda_b q) \alpha$.*

Proof. Since A is reducible, according to Theorem 1 in Latouche and Ramaswami [1], know that the QBD process is positive recurrent if and only if

$$v \begin{pmatrix} 0 & \lambda_b \alpha q + \bar{\lambda}_b \alpha \\ 0 & \bar{\mu}_b \bar{\lambda}_b \alpha q + \mu_b \bar{\lambda}_b \alpha + \mu_b \lambda_b \alpha q \end{pmatrix} e > v \begin{pmatrix} 0 & 0 \\ 0 & \bar{\mu}_b \lambda_b (\bar{\alpha} + \alpha \bar{q}) \end{pmatrix} e,$$

where v is the stationary probability vector of

$$\begin{pmatrix} \bar{\lambda}_b \bar{\alpha} & \lambda_b + \bar{\lambda}_b \alpha \\ \mu_b \bar{\lambda}_b \bar{\alpha} & \bar{\mu}_b + \mu_b \lambda_b + \mu_b \bar{\lambda}_b \alpha \end{pmatrix},$$

e is a column vector with all elements equal to one. By solving

$$\begin{cases} v \begin{pmatrix} \bar{\lambda}_b \bar{\alpha} & \lambda_b + \bar{\lambda}_b \alpha \\ \mu_b \bar{\lambda}_b \bar{\alpha} & \bar{\mu}_b + \mu_b \lambda_b + \mu_b \bar{\lambda}_b \alpha \end{pmatrix} = v \\ ve = 1 \end{cases},$$

get

$$v = \left(\frac{\mu_b \bar{\lambda}_b \bar{\alpha}}{1 + \mu_b \bar{\lambda}_b \bar{\alpha} - \bar{\lambda}_b \bar{\alpha}}, \frac{1 - \bar{\lambda}_b \bar{\alpha}}{1 + \mu_b \bar{\lambda}_b \bar{\alpha} - \bar{\lambda}_b \bar{\alpha}}\right).$$

Then take v into the inequation above, after a series of algebraic operations, the QBD process $\{Q_n, J_n\}$ is positive recurrent if and only if $\bar{\mu}_b(\bar{\lambda}_b\bar{\alpha}-1)(\alpha q-\lambda_b) < \mu_b(\bar{\lambda}_b+\lambda_b q)\alpha$, i.e., the stability condition of the queueing system.

Next, before deriving the stationary distribution of the system, need to obtain the minimal non-negative solution R which satisfies the matrix quadratic equation

$$R = R^2A_2 + RA_1 + A_0. \tag{1}$$

Theorem 2. *If* $\bar{\mu}_b(\bar{\lambda}_b\bar{\alpha}-1)(\alpha q-\lambda_b) < \mu_b(\bar{\lambda}_b+\lambda_b q)\alpha$*, the matrix equation above has the minimal non-negative solution*

$$R = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & r_1 & r_2 & r_3 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & r_4 & r_5 \end{pmatrix},$$

where

$$r_1 = \frac{1-\bar{\mu}_v\bar{\lambda}_v(\bar{\alpha}+\alpha\bar{q})\bar{\theta}-\bar{\mu}_v\lambda_v\alpha q\bar{\theta}-\sqrt{D}}{2\bar{\mu}_v\bar{\lambda}_v\alpha q\bar{\theta}}, \; r_2 = \frac{\mu_v\bar{\lambda}_v\bar{\alpha}r_1+\mu_b\bar{\lambda}_b\bar{\alpha}r_3}{1-\bar{\lambda}_b\bar{\alpha}},$$

$$r_3 = \frac{Mr_1{}^2+Nr_1+\bar{\mu}_v\lambda_v(\bar{\alpha}+\alpha\bar{q})\theta(1-\bar{\lambda}_b\bar{\alpha})}{(1-\bar{\lambda}_b\bar{\alpha})[1-L-F(r_1+r_5)-(\lambda_b\alpha q+\bar{\lambda}_b\alpha)r_4]-G},$$

$$r_4 = \frac{\mu_b\bar{\mu}_b\lambda_b\bar{\lambda}_b(\bar{\alpha}+\alpha\bar{q})\bar{\alpha}}{\bar{\mu}_b\bar{\lambda}_b\alpha q-\bar{\mu}_b\bar{\lambda}_b\alpha\bar{\alpha}q+\mu_b\bar{\lambda}_b\alpha+\mu_b\lambda_b\alpha q},$$

$$r_5 = \frac{\bar{\mu}_b\lambda_b(\bar{\alpha}+\alpha\bar{q})(1-\bar{\lambda}_b\bar{\alpha})}{\bar{\mu}_b\bar{\lambda}_b\alpha q-\bar{\mu}_b\bar{\lambda}_b\alpha\bar{\alpha}q+\mu_b\bar{\lambda}_b\alpha+\mu_b\lambda_b\alpha q},$$

$$D = [\bar{\mu}_v\bar{\lambda}_v(\bar{\alpha}+\alpha\bar{q})\bar{\theta}+\bar{\mu}_v\bar{\lambda}_v\alpha q\bar{\theta}-1]^2-4\bar{\mu}_v{}^2\bar{\lambda}_v\lambda_v\alpha q(\bar{\alpha}+\alpha\bar{q})\bar{\theta}^2,$$

$$M = (\bar{\mu}_v\bar{\lambda}_v\alpha q\theta+\mu_v\bar{\lambda}_v\alpha+\mu_v\lambda_v\alpha q)(1-\bar{\lambda}_b\bar{\alpha})+\mu_v\bar{\lambda}_v\bar{\alpha}(\lambda_b\alpha q+\bar{\lambda}_b\alpha),$$

$$N = [(\mu_v\lambda_v+\bar{\mu}_v\bar{\lambda}_v\theta)(\bar{\alpha}+\alpha\bar{q})+\bar{\mu}_v\lambda_v\alpha q\theta](1-\bar{\lambda}_b\bar{\alpha})+\mu_v\bar{\lambda}_v\lambda_b(\bar{\alpha}+\alpha\bar{q})\bar{\alpha},$$

$$L = (\mu_b\lambda_b+\bar{\mu}_b\bar{\lambda}_b)(\bar{\alpha}+\alpha\bar{q})+\bar{\mu}_b\lambda_b\alpha q,$$

$$F = \bar{\mu}_b\bar{\lambda}_b\alpha q+\mu_b\bar{\lambda}_b\alpha+\mu_b\lambda_b\alpha q,$$

$$G = \mu_b\bar{\lambda}_b\bar{\alpha}r_1(\lambda_b\alpha q+\bar{\lambda}_b\alpha)+\mu_b\bar{\lambda}_b\lambda_b(\bar{\alpha}+\alpha\bar{q})\bar{\alpha}.$$

Proof. Notice the structure of A_0, A_1 and A_2, assume $R = \begin{pmatrix} R_{11} & R_{12} \\ 0 & R_{22} \end{pmatrix}$, where R_{11}, R_{12} and R_{22} are all 2×2 matrices. Taking R into Eq. (1), have

$$
\begin{cases}
R_{11} = {R_{11}}^2 \begin{pmatrix} 0 & \lambda_v \alpha q \bar{\theta} + \bar{\lambda}_v \alpha\theta \\ 0 & \bar{\mu}_v \bar{\lambda}_v \alpha q \bar{\theta} \end{pmatrix} + R_{11} \begin{pmatrix} \bar{\lambda}_v \bar{\alpha} \bar{\theta} & \lambda_v \alpha \bar{q} \bar{\theta} + \lambda_v \bar{\alpha} \bar{\theta} \\ 0 & \bar{\mu}_v \bar{\lambda}_v (\bar{\alpha} + \alpha \bar{q}) \bar{\theta} + \bar{\mu}_v \lambda_v \alpha q \bar{\theta} \end{pmatrix} \\
+ \begin{pmatrix} 0 & 0 \\ 0 & \bar{\mu}_v \lambda_v (\bar{\alpha} + \alpha \bar{q}) \bar{\theta} \end{pmatrix} \\
R_{12} = {R_{11}}^2 \begin{pmatrix} 0 & \lambda_v \alpha q\theta + \bar{\lambda}_v \alpha\theta \\ 0 & \bar{\mu}_v \bar{\lambda}_v \alpha q\theta + \mu_v \bar{\lambda}_v \alpha + \mu_v \lambda_v \alpha q \end{pmatrix} \\
+ (R_{11}R_{12} + R_{12}R_{22}) \begin{pmatrix} 0 & \lambda_b \alpha q + \bar{\lambda}_b \alpha \\ 0 & \bar{\mu}_b \bar{\lambda}_b \alpha q + \mu_b \bar{\lambda}_b \alpha + \mu_b \lambda_b \alpha q \end{pmatrix} \\
+ R_{11} \begin{pmatrix} \bar{\lambda}_v \bar{\alpha} \theta & \lambda_v \bar{\alpha} \theta + \lambda_v \alpha \bar{q} \theta \\ \mu_v \bar{\lambda}_v \bar{\alpha} & (\mu_v \lambda_v + \bar{\mu}_v \bar{\lambda}_v)(\bar{\alpha} + \alpha \bar{q}) + \bar{\mu}_v \lambda_v \alpha q\theta \end{pmatrix} \\
+ R_{12} \begin{pmatrix} \bar{\lambda}_b \bar{\alpha} & \lambda_b (\bar{\alpha} + \alpha \bar{q}) \\ \mu_b \bar{\lambda}_b \bar{\alpha} & (\mu_b \lambda_b + \bar{\mu}_b \bar{\lambda}_b)(\bar{\alpha} + \alpha \bar{q}) + \bar{\mu}_b \lambda_b \alpha q \end{pmatrix} \\
+ \begin{pmatrix} 0 & 0 \\ 0 & \bar{\mu}_v \lambda_v (\bar{\alpha} + \alpha \bar{q})\theta \end{pmatrix} \\
R_{22} = {R_{22}}^2 \begin{pmatrix} 0 & \lambda_b \alpha q + \bar{\lambda}_b \alpha \\ 0 & \bar{\mu}_b \bar{\lambda}_b \alpha q + \mu_b \bar{\lambda}_b \alpha + \mu_b \lambda_b \alpha q \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & \bar{\mu}_b \lambda_b (\bar{\alpha} + \alpha \bar{q}) \end{pmatrix} \\
+ R_{22} \begin{pmatrix} \bar{\lambda}_b \bar{\alpha} & \lambda_b (\bar{\alpha} + \alpha \bar{q}) \\ \mu_b \bar{\lambda}_b \bar{\alpha} & (\mu_b \lambda_b + \bar{\mu}_b \bar{\lambda}_b)(\bar{\alpha} + \alpha \bar{q}) + \bar{\mu}_b \lambda_b \alpha q \end{pmatrix}
\end{cases}
$$

From the first and third equations, get$R_{11} = \begin{pmatrix} 0 & 0 \\ 0 & r_1 \end{pmatrix}$ and $R_{22} = \begin{pmatrix} 0 & 0 \\ r_4 & r_5 \end{pmatrix}$ respectively. Then, taking R_{11} and R_{22} into the second equation, finally obtain $R_{12} = \begin{pmatrix} 0 & 0 \\ r_2 & r_3 \end{pmatrix}$ are as shown in Theorem 2.

3.3 Stationary Distribution and Performance Measures

If $\bar{\mu}_b(\bar{\lambda}_b \bar{\alpha} - 1)(\alpha q - \lambda_b) < \mu_b(\bar{\lambda}_b + \lambda_b q)\alpha$, Let $\{Q, J\}$ be the stationary limit of the $\{Q_n, J_n\}$. And denote

$$
\begin{aligned}
\pi_k &= (\pi_{k0}, \pi_{k1}, \pi_{k2}, \pi_{k3}), k \geq 0, \\
\pi_{kj} &= P\{Q = k, J = j\} = \lim_{n \to \infty} P\{Q_n = k, J_n = j\}, (k, j) \in \Omega.
\end{aligned}
$$

Note that, $\pi_{02} = 0$.

Theorem 3. *If* $\bar{\mu}_b(\bar{\lambda}_b \bar{\alpha} - 1)(\alpha q - \lambda_b) < \mu_b(\bar{\lambda}_b + \lambda_b q)\alpha$, *the stationary distribution of* Q, J *is given by*

$$\begin{cases} \pi_{k0} = 0, & k \geq 1 \\ \pi_{k1} = \pi_{01} {r_1}^k, & k \geq 0 \\ \pi_{k2} = \pi_{01}(r_2 {r_1}^{k-1} + \frac{r_3 r_4}{r_5 - r_1}({r_5}^{k-1} - {r_1}^{k-1})) + \pi_{03} r_4 {r_5}^{k-1}, & k \geq 1 \\ \pi_{k3} = \pi_{01} \frac{r_3}{r_5 - r_1}({r_5}^k - {r_1}^k) + \pi_{03} {r_5}^k, & k \geq 0, \end{cases} \tag{2}$$

where

$$\pi_{00} = \left[1 + (\frac{1 + r_2}{1 - r_1} + \frac{r_3(1 + r_4)}{(1 - r_1)(1 - r_5)})Y + \frac{1 + r_4}{1 - r_5} U\right]^{-1},$$

$$Y = \frac{\lambda_v \bar{\theta}}{1 - \bar{\mu}_v \bar{\lambda}_v \bar{\theta} - \bar{\mu}_v \bar{\lambda}_v \alpha q \bar{\theta} r_1}, U = \frac{\lambda_v(1 - \bar{\lambda}_v \bar{\theta}) - \bar{\mu}_v \bar{\lambda}_v \lambda_v \alpha q \bar{\theta} r_1}{\mu_b \bar{\lambda}_b(1 - \bar{\mu}_v \bar{\lambda}_v \bar{\theta} - \bar{\mu}_v \bar{\lambda}_v \alpha q \bar{\theta} r_1)},$$

$$\pi_{01} = \frac{\lambda_v \bar{\theta}}{1 - \bar{\mu}_v \bar{\lambda}_v \bar{\theta} - \bar{\mu}_v \bar{\lambda}_v \alpha q \bar{\theta} r_1} \pi_{00}, \pi_{03} = \frac{\lambda_v(1 - \bar{\lambda}_v \bar{\theta}) - \bar{\mu}_v \bar{\lambda}_v \lambda_v \alpha q \bar{\theta} r_1}{\mu_b \bar{\lambda}_b(1 - \bar{\mu}_v \bar{\lambda}_v \bar{\theta} - \bar{\mu}_v \bar{\lambda}_v \alpha q \bar{\theta} r_1)} \pi_{00}.$$

Proof. Using the matrix-analytic method [1], have

$$\pi_k = (\pi_{k0}, \pi_{k1}, \pi_{k2}, \pi_{k3}) = \pi_0 R^k = (\pi_{00}, \pi_{01}, 0, \pi_{03}) R^k, k \geq 0. \tag{3}$$

Taking

$$R^k = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & {r_1}^k & r_2 {r_1}^{k-1} + \frac{r_3 r_4}{r_5 - r_1}({r_5}^{k-1} - {r_1}^{k-1}) & \frac{r_3}{r_5 - r_1}({r_5}^k - {r_1}^k) \\ 0 & 0 & 0 & 0 \\ 0 & 0 & r_4 {r_5}^{k-1} & {r_5}^k \end{pmatrix}, k \geq 1$$

into Eq. (3), then Eq. (2) is obtained. Meanwhile, π_0 satisfies the following two equations

$$\pi_0(B_1 + R A_2) = \pi_0, \tag{4}$$

$$\pi_0(I - R)^{-1} e = 1. \tag{5}$$

From Eq. (4), get π_{01} and π_{03} as shown in Theorem 3. Then, taking $\pi_{01}, \pi_{02} = 0$ and π_{03} into Eq. (5), obtain π_{00} as shown in Theorem 3. So far, Theorem 3 is proved.

Using the stationary distribution derived above, some performance measures can be obtained as follows.

(1) The probability that the server is busy

$$P_b = \sum_{k=0}^{\infty} \pi_{k1} + \sum_{k=0}^{\infty} \pi_{k3} = \frac{1 - r_5 + r_3}{(1 - r_1)(1 - r_5)} \pi_{01} + \frac{1}{1 - r_5} \pi_{03}.$$

(2) The probability that the server is free

$$P_f = \sum_{k=0}^{\infty} \pi_{k0} + \sum_{k=1}^{\infty} \pi_{k2} = \pi_{00} + \frac{r_2 - r_2 r_5 + r_3 r_4}{(1-r_1)(1-r_5)}\pi_{01} + \frac{r_4}{1-r_5}\pi_{03}.$$

(3) The probability that the server is in a regular busy period

$$P_r = \sum_{k=0}^{\infty} \pi_{k2} + \sum_{k=0}^{\infty} \pi_{k3} = \frac{r_2 + r_3 - r_2 r_5 + r_3 r_4}{(1-r_1)(1-r_5)}\pi_{01} + \frac{1+r_4}{1-r_5}\pi_{03}.$$

(4) The probability that the server is in a regular busy period

$$P_v = \sum_{k=0}^{\infty} \pi_{k0} + \sum_{k=0}^{\infty} \pi_{k1} = \pi_{00} + \frac{1}{1-r_1}\pi_{01}.$$

(5) The mean number of customers in the orbit

$$\begin{aligned} E[L] &= \sum_{k=1}^{\infty} k(\pi_{k1} + \pi_{k2} + \pi_{k3}) \\ &= \pi_{01}\frac{(r_1+r_2)(1-r_5)^2 + r_3 r_4(2-r_1-r_5) + r_3(1-r_1 r_5)}{(1-r_1)^2(1-r_5)^2} + \pi_{03}\frac{r_4+r_5}{(1-r_5)^2}. \end{aligned}$$

(6) The mean number of customers in the system

$$E[\widetilde{L}] = \sum_{k=1}^{\infty} k\pi_{k2} + \sum_{k=0}^{\infty} (k+1)(\pi_{k1} + \pi_{k3}) = E[L] + P_b.$$

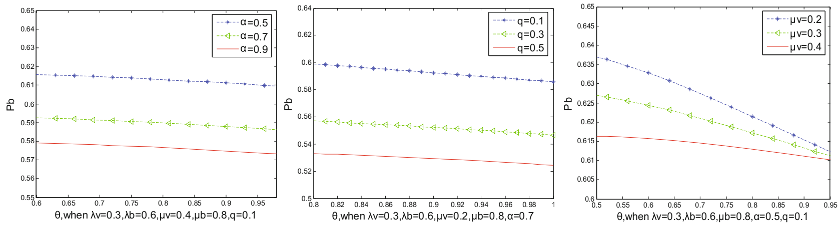
3.4 Empirical Research

This section provides some numerical examples to illustrate the effect of varying parameters on the performance measures of the system. Assume λ_v equals 0.3, λ_b equals 0.6 and μ_b equals 0.8. Under the condition that $\bar{\mu}_b(\bar{\lambda}_b\bar{\alpha} - 1)(\alpha q - \lambda_b) < \mu_b(\bar{\lambda}_b + \lambda_b q)\alpha$, plot Figs. 3, 4, 5, 6, 7, 8, 9 and 10, which illustrate the effect of vacation period rate θ, retrial rate α, departure rate q and service rate μ_v on the performance measures P_b and $E[L]$.

Remark 1. Considering the constraint of the stationary condition and the display of the graph, the values of the parameters are the most suitable.

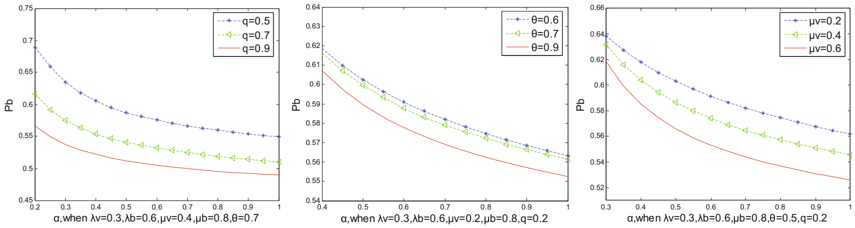
(1) The numerical analysis of P_b
Figures 4, 5, 6 and 7 illustrate the effect of parameters on the probability that the server is busy. The effect and the reasons which cause the effect are discussed.

Figure 4 illustrates the effect of θ on the probability that the server is busy. Figure 4(a) is for different α, Fig. 4(b) is for different q and Fig. 4(c) is for different μ_v. Obviously, whether in Fig. 4(a), (b) or (c), the probability P_b decreases



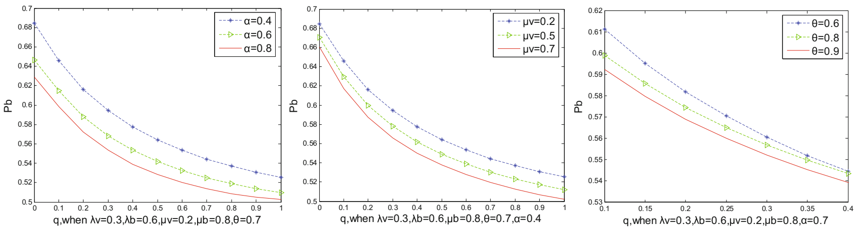
(a) (b) (c)

Fig. 4. (a) The probability that the server is busy versus θ for different α (b) The probability that the server is busy versus θ for different q (c) The probability that the server is busy versus θ for different μ_v



(d) (e) (f)

Fig. 5. (d) The probability that the server is busy versus α for different q (e) The probability that the server is busy versus α for different θ (f) The probability that the server is busy versus α for different μ_v

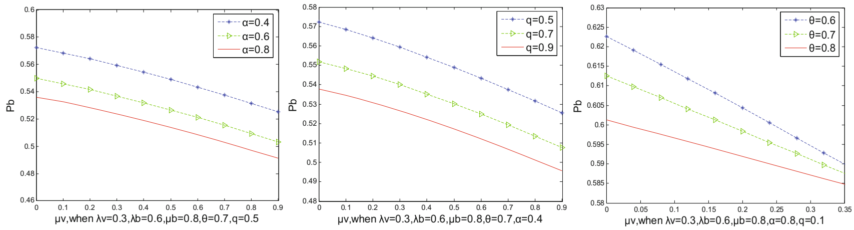


(g) (h) (i)

Fig. 6. (g) The probability that the server is busy versus q for different α (h) The probability that the server is busy versus q for different μ_v (i) The probability that the server is busy versus q for different θ

gradually with the rate θ increasing regardless of the change of α, q and μ_v. What causes this trend is the fact that the average service rate becomes smaller with θ increasing. Note that the effect of θ on P_b becomes weaker with μ_v increasing. Meanwhile, because $P_b + P_f = 1$, the probability that the sever is free P_f should show the opposite trend of change (the same below).

Figure 5 illustrates the effect of α on the probability that the server is busy. Figure 5(d) is for different q, Fig. 5(e) is for different θ and Fig. 5(f) is for



(j) (k) (l)

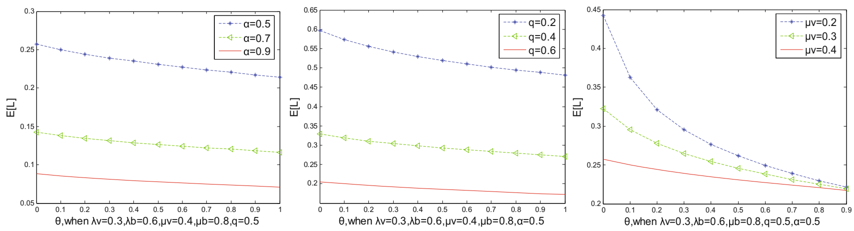
Fig. 7. (j) The probability that the server is busy versus μ_v for different α (k) The probability that the server is busy versus μ_v for different q (l) The probability that the server is busy versus μ_v for different θ

different μ_v. Among these three figures, P_b decreases with the rate α increasing regardless of the change of α, q and μ_v. This is because the number of the customers who give up receiving service increases with μ_v increasing.

Figure 6 illustrates the effect of q on the probability that the server is busy. Figure 6(g) is for different α, Fig. 6(h) is for different μ_v and Fig. 6(i) is for different θ. Obviously, P_b decreases with the rate q increasing among these three figures. This is because the number of the customers who leave the system due to the failure of retrial increases with q increasing.

Figure 7 illustrates the effect of v on the probability that the server is busy. Figure 7(j) is for different α, Fig. 7(k) is for different q and Fig. 7(l) is for different θ. Obviously, P_b decreases with the rate μ_v increasing. This is because the average service rate increases with μ_v increasing. From the change of the other three parameters, this trend is consistent. Besides, the effect of μ_v on P_b also becomes weaker with θ increasing.

(2) The numerical analysis of $E[L]$
Figures 8, 9, 10 and 11 illustrate the effect of parameters on the mean number of customers in the orbit. The effect and the reasons that cause the effect are also discussed.



(m) (n) (o)

Fig. 8. (m) The mean number of customers in the orbit versus θ for different α (n) The mean number of customers in the orbit versus θ for different q (o) The mean number of customers in the orbit versus θ for different μ_v

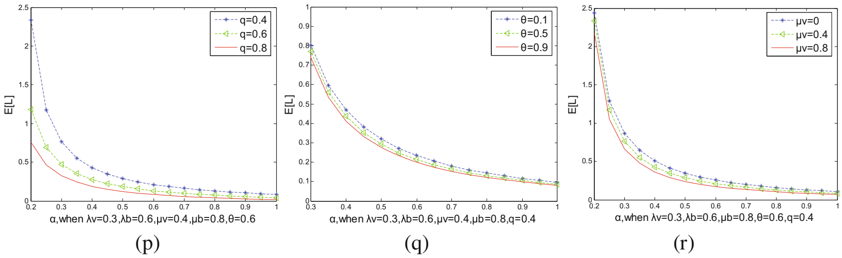


Fig. 9. (p) The mean number of customers in the orbit versus α for different q (q) The mean number of customers in the orbit versus α for different θ (r) The mean number of customers in the orbit versus α for different μ_v

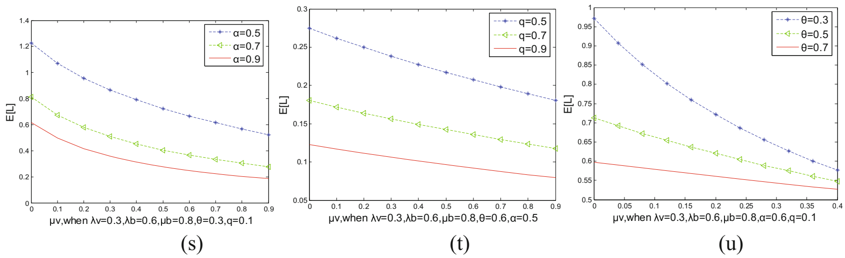

Fig. 10. (s) The mean number of customers in the orbit versus μ_v for different α (t) The mean number of customers in the orbit versus μ_v for different q (u) The mean number of customers in the orbit versus μ_v for different θ

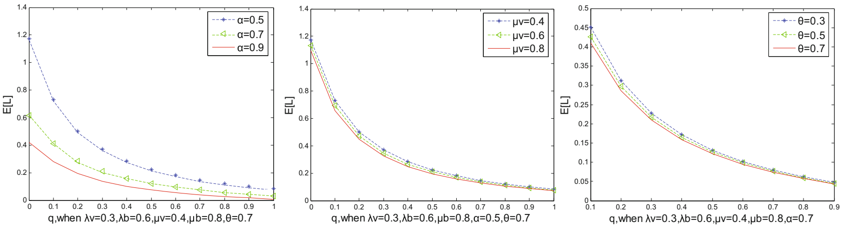
Figure 8 illustrates the effect of θ on the mean number of customers in the orbit. Figure 8(m) is for different α, Fig. 8(n) is for different q and Fig. 8(o) is for different μ_v. With the rate θ increasing, the time during which the sever is in a working vacation period is reduced, then the average service decreases, which leads to the decreasing trend of the mean number of customers $E[L]$ as shown in the figures. It is worth noting that the effect of θ on $E[L]$ becomes weaker with μ_v increasing, which is consistent with the effect of θ on P_b in the Fig. 4(c).

Figure 9 illustrates the effect of α on the mean number of customers in the orbit. Figure 9(p) is for different q, Fig. 9(q) is for different θ, Fig. 9(r) is for different μ_v. For the same q, θ and μ_v, $E[L]$ decreases with α increasing. It is because the number of the customers who leave the orbit due to success or failure of retrial increase with the retrial rate α increasing. Furthermore, with α increasing, the effect of it on $E[L]$ becomes weaker.

Figure 10 illustrates the effect of μ_v on the mean number of customers in the orbit. Figure 10(s) is for different α, Fig. 10(t) is for different $q$and Fig. 10(u) is for different θ. Obviously, no matter how α, q and θ change, $E[L]$ decrease with μ_v increasing. This is because the average service rate increases with μ_v increasing. From Fig. 10(u), we can see that the effect of μ_v on $E[L]$ becomes



(v) (w) (x)

Fig. 11. (v) The mean number of customers in the orbit versus q for different α (w) The mean number of customers in the orbit versus q for different μ_v (x) The mean number of customers in the orbit versus q for different θ

smaller with θ increasing, which is consistent with the effect of μ_v on P_b in the Fig. 7(l).

Figure 11 illustrates the effect of q on the mean number of customers in the orbit. Figure 11(v) is for different α, Fig. 11(w) is for different v and Fig. 11(x) is for different θ. With q increasing, the number of customers who leave the system due to failure in retrial increases, which leads to the decreasing trend of $E[L]$ as shown in the figures. Besides, the effect of q on $E[L]$ becomes weaker with q increasing. And the lager α is, the smaller the effect of q on $E[L]$ becomes, which means that the departure rate of customers will diminish the impact on the mean number of customers in the orbit when the load of the orbit becomes lighter.

(3) Performance optimization

Using the performance measures derived in Sect. 3.3, this section designs a cost function, i.e., the average total cost of the system per unit time, and establishes an optimization model on the basis of the cost function. Then we use the optimization model to optimize the queueing model established in Sect. 3.1 under the environment of web service system, and obtain the optimal parameters and the minimum average total cost per unit time.

To design the cost function, the cost structure is defined firstly. Assume there are two costs in the system, one is the waiting cost, and the other is the service cost. Assume the average waiting cost of each customer per unit time is c, the average service cost of each server in a regular busy period per unit time is a_r, and the average service cost of each server in a working vacation period per unit time is a_v Then, the average total cost of the system per unit time M can be expressed as

$$M = cE[\widetilde{L}] + a_r P_r + a_v P_v, \tag{6}$$

i.e., cost function. Based on Eq. (6), establish an optimization model as

$$
\min = cE[\widetilde{L}] + a_r P_r + a_v P_v
$$
$$
s.t. \begin{cases} \bar{\mu}_b(\bar{\lambda}_b \, \bar{\alpha} - 1)(\alpha q - \lambda_b) < \mu_b(\bar{\lambda}_b + \lambda_b q)\alpha \\ E[\widetilde{L}] \geq 0 \\ 0 < P_r, P_v < 1 \\ 0 < \mu_v < \mu_b < 1, 0 < \theta, \alpha < 1. \end{cases}
$$

Then, consider using the optimization model above to optimize the Geo/Geo/1 retrial queue with working vacation interruption and nonpersistent customers established in Sect. 3 under the environment of web service system. Assume the average waiting cost of each customer per unit time is 5, the average service cost of each server in a regular busy period per unit time is 10, the average service cost of each server in a working vacation period per unit time is 6, the probability that the user requests service during a regular busy period is 0.6, the probability that the user requests service during a working vacation period is 0.3, the retrial rate is 0.6 and the probability that the user gives up receiving service due to the failure of retrial is 0.2. Taking these parameters into the optimization model and using LINGO to solve it, get $\mu_v = 0.277, \mu_b = 0.739, \theta = 0.125, M = 11.359$. The result means that the average total cost of the system per unit time is 11.359, i.e., the minimum sum of the average waiting cost and the average service cost per unit time, now, the service rate in a regular busy period and the service rate in a working vacation period are 0.739, 0.277 respectively, and the vacation period rate θ is 0.125. That is to say, in order that the performance of the web service system is the best, managers should adjust the actual service capabilities of the server to guarantee that the service time in a regular busy period follows a geometric distribution with parameter 0.739, the service time in a working vacation period follows a geometric distribution with parameter 0.277 and the working vacation time follows a geometric distribution with parameter 0.125.

4 Conclusions

With the development of the internet, the web service industry has put forward many new requirements to the design of queueing model. This paper provides a queueing solution for web service. After presenting three practical problems that web service encounters in real life, a queuing model which can deal with these problems is constructed and a series of necessary researches are carried out on the model. Then, based on the results of the researches, the numerical analysis and model optimization are conducted, which provide some valuable consultations for the web service management under the corresponding circumstances. In addition, since the model proposed in this paper is a single server, which is somehow discrepant with the reality of multi-server web service, the number of services can be pending in the future research to better cope with the actual situation.

Pan-Tourism Urbanization Model Based on System Dynamics: A Case Study of Barkam

Lin Hu, Lu Gan(✉), and Qian Yang

College of Architecture and Urban-Rural Planning, Sichuan Agricultural University, Dujiangyan 611830, People's Republic of China
ganlu_soarpb@sicau.edu.cn

Abstract. With the rapid development of urbanization, tourism-driven urbanization process has become an important development strategy in China. There are many examples of the tourism urbanization, however, the integration with industries is scarce. In order to describe the characterization of the industrial clusters system, this paper uses SPSS [8] to analyze the data. And it also uses DYNAMO simulation language and Vensim [2] to establish the pan-tourism urbanization model based on the theory of industrial cluster and system dynamics. Simultaneously, taking Barkam city in the northwestern Tibetan area of Sichuan as an example, this paper analyzes the operation mechanism of pan-tourism urbanization mode to find the optimal system structure, which can provide corresponding scientific basis and theoretical support for promoting the development of urban and rural areas, improving the level of new urbanization and building new towns.

Keywords: System dynamics · Pan-tourism · Industrial cluster · Simulation

1 Introduction

In recent years, the model of new urbanization has been widely concerned. Tourism industry and related industries develop interactively in order to promote the new urbanization and the coordinated development of new rural construction. Therefore, the model of pan-tourism industry integration and industrial cluster development is an effective way to promote the development of urbanization, which is proposed by experts and scholars at home and abroad.

Some scholars have made some research ideas. Alexandrova [1] aims to review tourism cluster initiatives in Russia, particularly, tourism cluster formation processes. Jackson [6] takes four towns in Australia as an example, exploring the effectiveness of correlation factors of these four regions, and studying the competitive advantage of cluster theory. However, they only concentrate on the research of the existing tourism industrial clusters evaluation and focus on using descriptive language to assess or predict which lacks a practical and objective evaluation system.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_35

Jackson [5] probes into the development of regional tourism clusters, and he finds the correctness in theory of the Porter's [12] model. Tourism cluster may become a way to convert comparative advantage into competitive advantage and make better use of existing tourism resources in China. It can be more adapted to the characteristics of Chinese region. Qian [13] questions Mullins's [10] classical theory of tourism urbanization, and he shows the idea that the process of urbanization driven by modern tourism is not the product of post-modernization of urban cultural expression, however, it is the product of tourism-related services based on relatively standardized regulations. The two scholars focus on the comparative analysis of relevant theoretical models and existing data. The research model they put forward has positive effects on the development of domestic tourism, but they ignore the systematic description of tourism urbanization.

This paper is organized as follows. In Sect. 2, the pan-tourism urbanization is introduced and then we proposed a differential pan-tourism system model with industrial clusters theory. In Sect. 3, on the basis of pan-tourism system with the actual situation in Barkam, we investigate the relevant data, including the number of tourists, tourism revenue and other data about urbanization. Once we have carried out regression analysis, we can get simulation results for pan-tourism urbanization system. And we analyze the results and give recommendations. In Sect. 4, we make a conclusion about the effectiveness of such a model and discuss the shortcomings of this model.

2 Modeling

2.1 Concept Model

System dynamics is a science of dynamic complexity of the system developed by the Professor Forester of MIT, which emphasizes the overall consideration of the system and the interaction of each composition of the system. It is designed to deal with the problems of high order, nonlinear and multiple feedbacks in complex system [17]. Based on the method of qualitative and quantitative analysis and the system dynamic simulation experiments, which can forecast the dynamic change, the decision makers can observe the simulation results and take different measures in various contexts.

In this paper, the process of system dynamics modeling can be divided as follows: firstly, according to the characteristics of problems, we realize the purpose of modeling and determine the system boundaries to avoid the system architecture which will be too large or too small; secondly, we analyze the system structure to divide the system hierarchy and sub modules, determine the causal feedback loop and define the interaction mechanism among elements; thirdly, through the regression analyzing of the data, we establish the system dynamic mathematical model completely; finally, we analyze the simulation results which are obtained from the model running and evaluate the model in order to identify the problems and improve the model.

Based on the feedback control theory and the concept of industrial cluster development, this paper constructs the dynamic analysis model of pan-tourism

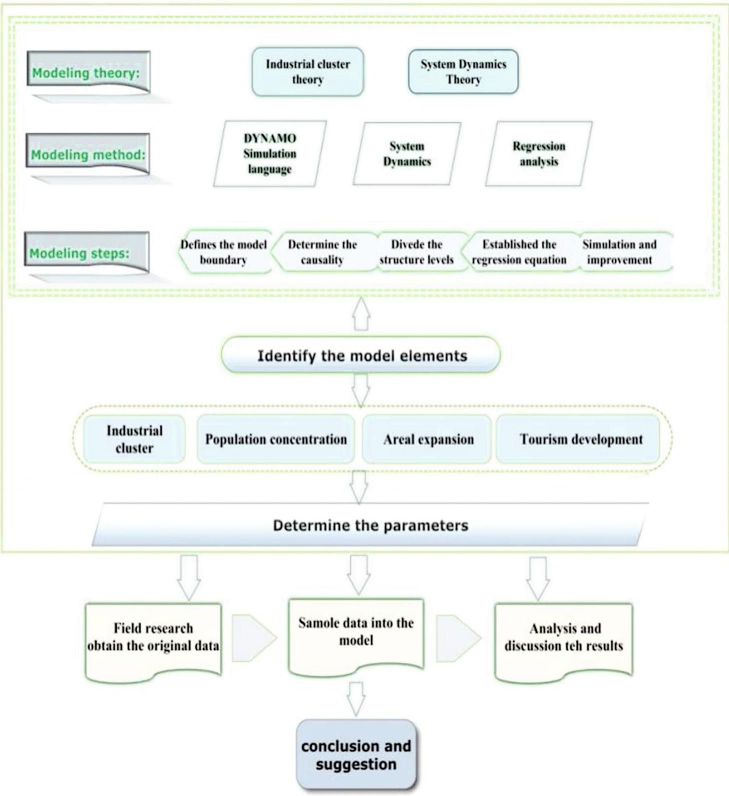

Fig. 1. Flow chart for research process

urbanization system to find out the basic reasons, key factors, changing rules and internal relations further. The research ideas are shown in Fig. 1.

2.2 System Elements Determination

System dynamics believes that the fundamental power and the direct cause of the whole socio-economic development come from the inner system, which determines the behavior pattern and characteristics. Besides, the system boundaries define the minimum number of units. Only defining the boundaries can the system solve structural problems [15]. Traditional tourism is only a single industry with simple form, while the pan-tourism urbanization model is the integration of pan-tourism industry development.

Pan-tourism industrial clusters have three main modes, such as the feedback, promotion and interaction modes [4]. The first one is the feedback model, referring to the non-profit service industries, which provide the tourism industry with resourceful and environmental infrastructures. They receive economic benefits from tourism and make themselves developing stably and healthily with tourism. The second promotion model means industries which cannot integrate with the tourism to produce new products or formats, but their development will be promoted when tourism developed vigorously. For instance, the lodging, catering and transportation industry can supply support elements for the tourism while the wholesale and retail trade, real estate, warehousing postal services, construction and industry which offering corollary facility to tourism. The third one is the interaction mode, referring to integration of agriculture and tourism, which can form a new tourism products and formats, rich tourism content and enhance the value of tourism products. Not only further does the mode develop the new tourism market, but also it promotes the industry and tourism industry to develop collaboratively.

The development of tourism industry leads to the development of related industries and forms pan-tourism industrial clusters, therefore it brings about the agglomeration of population and elements, and promotes the process of urbanization in local area. Urbanization is the process of the evolution of the economic structure, mode of production, life style and social concept after rural population and various factors constantly gathered to the city. The level of urbanization is usually measured by the proportion of urban population to total population.

Actually, urbanization is not just a regional change in the nature of the population. The connotation of urbanization is very abundant which means a regional change process based on the non-agricultural population and non - agricultural economy [16], and it's overgeneralization if the urbanization level only measured by the population ratio. This paper references to Fang [3], Sun [14] and other scholar's defining of urbanization degree and combines with the development characteristics of pan-tourist urbanization to define urbanization degree of pan-tourism urbanization system by using two indicators of urbanization and economic urbanization.

The population urbanization rate is usually used to measure the level of urbanization, and it is an important symbol to measure a country's level of economic development [7]. The integration development of tourism and related industries influence the changes of the industrial structure, reduce the employees of the primary industry continuously and increase the employees of the second and tertiary Industry. In addition, the urban employment increases through the transfer of labor, while gradually realizing the transformation of farmers' identity, then completing the population in situ urbanization.

The economic urbanization rate reflects the non-agricultural process of the overall economic structure, characterized by the proportion of the second and third industries gradually increased while proportion of primary industry gradually decreased. Tourism drives pan-tourism industrial clusters, whose output values are calculated from the second and third industrial output values, location entropies and the contribution rates [18]. The economic urbanization rates are the proportion of cluster output values to GDPs.

2.3 System Causality Analysis

Pan-tourism urbanization system includes three subsystems: tourism subsystem, industrial cluster subsystem and urbanization subsystem. This paper chooses the relevant variables from the perspective of pan-tourism industrial cluster and urbanization, and analyzes the system elements from the perspective of tourism driven urbanization.

The pan-tourism industrial clusters and urbanization interactive development system consist of three basic feedback loops: firstly, tourism drives pan-tourism cluster through industrial integration, increasing the cluster output values and improving the level of urbanization; secondly, industrial cluster increases employment in the second and third industries. The transfer of the labor also increases the urban population and raises the urbanization level; thirdly, the development of region economy and the increase of urban population promote urban construction, thus enhancing tourism reception capacity and developing the tourism industry. The causal relationship is shown in Fig. 2.

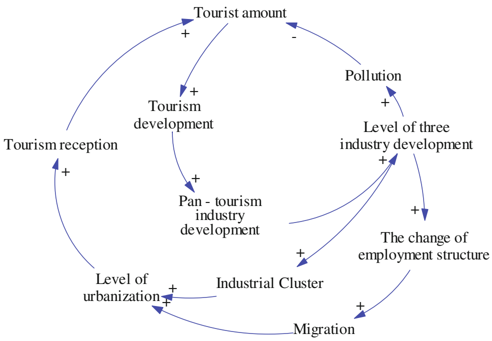

Fig. 2. Pan-tourism urbanization causality graph

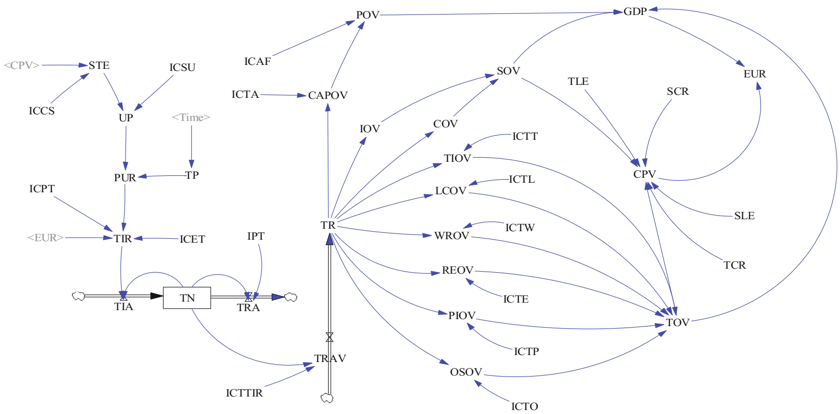

Fig. 3. Pan-tourism urbanization system flow diagram

Table 1. Meaning of the main variables and influence factors

Notation	Variable name	Unit
TN	Number of tourists	10^4 persons

2.4 System Flow Diagram and Parameter Equation

(1) System Flow Diagram

As shown in Fig. 3, two flow variables, three rate variables and multiple auxiliary variables are selected to construct the system flow diagram based on the causal feedback map. The meaning of the main variables and influence factors in this model is shown in Table 1.

(2) Index System and Parametric Equation

The parametric equations are determined according to the logical relationship between system variables. There are two level variables named number of tourists and tourism revenue, and the three rate variables are tourist increase amount, tourist reduction amount and tourism revenue added value. The auxiliary variables are logically related to the level and rate variables. The constants include the influence coefficients, the contribution rates, the location entropy, and the total population expressed by the table function. The main parameters and equations are shown in Table 2.

Table 2. Main variables and equations

Variable type	Variable name	Equation
Level variable	TN	INTEG (TIA − TRA, Initial value)
	TR	INTEG (TRAV, Initial value)
Rate variable	TIA	TN × TIR
	TRA	TN × IPT
	TRAV	ICTTIR × TN
Auxiliary variable	TIR	ICETEUR+ICPTPUR
	CAPOV	TR × ICTA
	IOV	ICTI × TR
	COV	ICTC × TR

Constant	SLE, TLE, SCR, TCR	No dimension
	TP	Table function

3 Case Analysis

3.1 Data Sources

In this paper, Barkam city in northwest Tibetan area of Sichuan is selected as the study object. The urbanization mode driven by tourism has been well reflected at here. Based on the actual situation of Barkam, the pan-tourism urbanization system is simulated [9]. The primary data is collected from Barkam's statistical yearbook and Sichuan Province statistical yearbook. Although there are some uncertain values, such as the total population and urban population, which are strongly affected by the social environment and natural disasters, it can be explained reasonably to make the model reflect the general trend of pan-tourism system.

The simulation step length of this model is set to 1 year, and the simulation year is from 2011 to 2025. The initial values for 2011 are determined based on the Barkam's statistical yearbook: the number of tourists was 505,800; tourism revenue is 434.48 million Yuan. Table 3 shows the values of parameters determined by regression analysis, table function and other methods.

Table 3. Parameter's value

Parameter	Value	Explanation
SLE	0.354	(Regional secondary or tertiary industry output/Regional GDP)/(national secondary or tertiary industry output/GDP)
TLE	1.654	
SCR	0.15	The contribution degree of urban secondary and tertiary industry to regional GDP
TCR	0.75	
ICET	0.172	Regression equation:
ICPT	4.85	$TIR = (0.172099 \times EUR - 4.85 \times PUR) + 2.4092$
ICT	0.964, 0.996, 0.486, 1.164, 2.094, 0.151	Regression equation: $TOV = 0.964 \times TIOV + 0.996 \times LCOV$ $+0.486 \times WROV + 1.164 \times REOV$ $+2.094 \times PIOV + 0.151 \times OSOV$
ICSU	0.42, −1.788	Regression equation: $UP = -1.788 \times STE + 0.42 \times STE^2 + 4.616$
ICCS, ICTTIR, ICTA,	0.514, 101.277, 0.225,	Regression analysis determines the parameters
ICTI, ICTC, ICTT,	0.298, 0.068, 0.384,	
ICTL, ICTW, ICTE,	0.316, 0.081, 0.154,	
ICTP, ICTO	1.662, 0.788	
IPT	0.04	The extent of the impact of pollution on the reduction of visitors
TP	Table function	With Lookup (([(2011,5.9)-(2015,5.9)],(2011,5.9),(2012,5.9),(2013,5.9),(2014,5.9),(2015,5.9))

3.2 Validity Test

(1) Historical Inspection

In this paper, the comparison of simulation results with actual data is conducted to test the effectiveness of the model. The simulated data, actual data and error rate for 2011–2015 are shown in Table 4. These data show that the error rate is kept within the 10% controllable range, which indicates the model can forecast the running state of the real system with good fitting degree.

(2) Operation inspection

The step length of these fitting values of tourism revenue is 1 year, and thus we select the step length of 0.5 years and 0.25 years to make comparison. It can be seen that curve of tourism revenue of Barkam changes implicitly under different step lengths of simulation. And the average error rate is less than 10%, which means the analogue system is stable (see Fig. 4).

3.3 Simulation Results

(1) Tourists and Tourism Revenue

Figures 5 and 6 show the simulation results of the tourists and the tourism revenue in Barkam City. The number of tourists of Barkam will increase steadily

Table 4. Historical data and simulation results analysis

Variable name	Value type	2011	2012	2013	2014	2015
$TN/10^4$ persons	Actual value	50.58	64.57	77.3	85.74	92.02
	Simulation value	50.58	60.8498	73.1725	86.4152	99.9342
	Error rate/%	0	−5.761	−5.34	0.787	8.601
$TR/10^4$ yuan	Actual value	43448	57725	69642	76572	84565
	Simulation value	43448	57023.2	64819.7	73864.2	84249.9
	Error rate/%	0	−1.216	−6.924	−3.536	−0.373

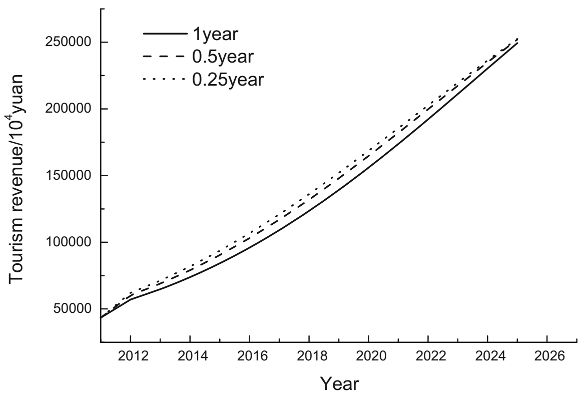

Fig. 4. Barkam's tourism revenues under different step simulation

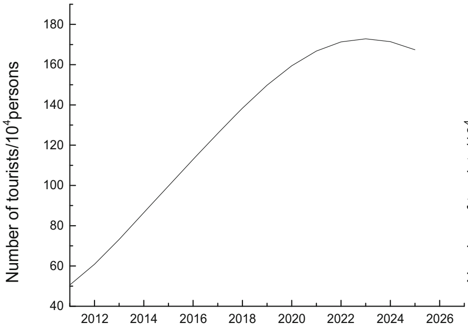

Fig. 5. Barkam's number of tourists simulation

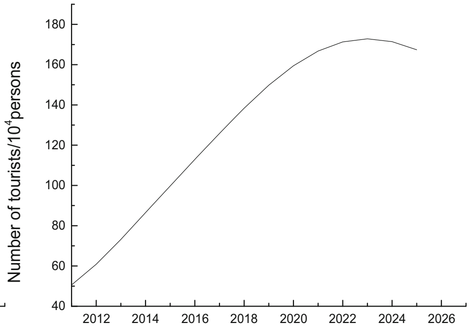

Fig. 6. Barkam's tourism revenue simulation

from 2011 to 2023, reaching 1.5 million by 2019 and having a peak at the end of 2023. After that, there will be a slight decline. The speculative reason is that pollution caused by the industrial clusters may affects the tourists' enthusiasm to travel to Barkam, while the development of the pan-tourism industry is driven by tourism. At the same time, Barkam's tourism revenue is also growing steadily and it will exceed 20 billion Yuan by 2022. We can see that the booming tourism industry of Barkam will be in a steady upward trend in the next decade from the simulation results. Therefore, in order to maintain the vitality of tourism industry and promote the development of industry clusters to propel urbanization, the government should pay more attention on the tourism industry meantime to concentrate on the impact of resource depletion and pollution from local industrial development [11].

(2) Simulation Analysis of Economy

As the Fig. 7 shown, the three industrial output values grow steadily in the period from 2011 to 2025. It is speculated that tertiary industry output values of Barkam will exceed 3 billion Yuan, while the GDP will exceed 4 billion Yuan.

Contrasting the primary and secondary industries, the tertiary industry output values increased significantly. The main reason is that tourism promote the development of related industries, such as transportation, lodging and catering industry and related social public services, so that the tertiary industry become the leading industry.

On the contrary, the growth rate of the primary industry is very slow, presumably due to the destruction of the local ecological environment and the obstruction of rural construction in the process of realizing urbanization. Local governments should take corresponding measures to strengthen the linkage of the tourism industry with the primary and secondary industry, promote the development of agricultural tourism and industrial tourism vigorously, extend the chain of business opportunities strenuously, and create an advantage platform to promote economic development effectively.

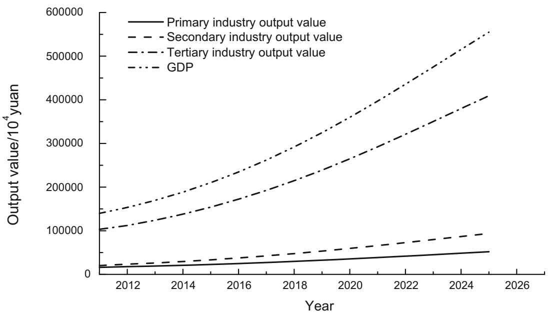

Fig. 7. Barkam's output value simulation

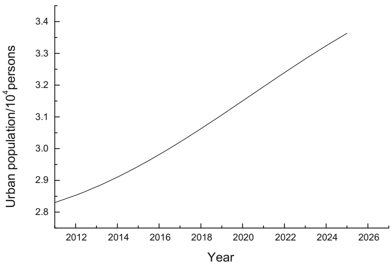

Fig. 8. Barkam's urban population simulation

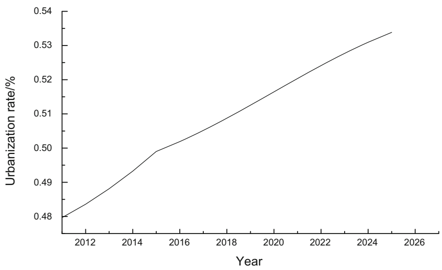

Fig. 9. Barkam's urbanization rate simulation

(3) Population Simulation

The simulation results of the employment population, the urban population and the urbanization rate are shown in Figs. 8 and 9. According to simulation results, the number of urban population will reach 33,000 while the urbanization rate of population will reach 53% by 2025, and both of them are in a steady rising state.

The main reason for the increase is the development of local tourism, driving the development of the tertiary industry such as services and circulation industries. These industries require low technical and easy to realize the labor force transfer.

Furthermore, the process of rural population to non-agricultural population is accelerated, and the in-situ urbanization of farmers is achieved which constantly improve the level of urbanization. From the data we can see that although the level of urbanization has increased year by year, the growth rate is relatively slow, mainly due to the fact that Barkam is located in the Tibetan area of northwest Sichuan, and the residents have long been engaged in agriculture and animal husbandry. The process of local urbanization has been speeded up by tourism, but some remote farmers still use the traditional agricultural mode, which affects the local urbanization process.

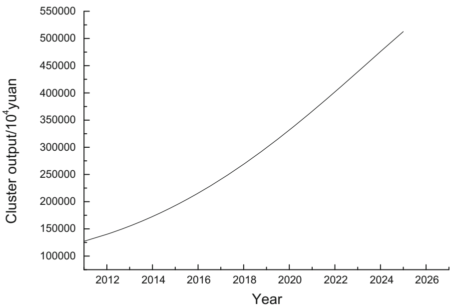

Fig. 10. Barkam's cluster output simulation

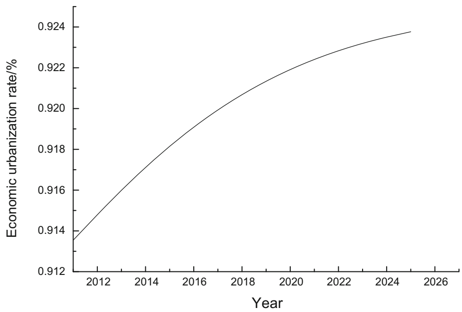

Fig. 11. Barkam's economic urbanization rate simulation

(4) Cluster Simulation

Cluster output value and economic urbanization rate simulation results shown in Figs. 10 and 11.

This paper refers to the definition of cluster output value by scholar Xiaoye Zhou [18], whose economic meaning is the development of secondary and tertiary industry in the region, relating to the entire country. As the Fig. 10 shows, the cluster output increased year by year from 2011 to 2025, which will exceed 5 billion Yuan in 2025. The stable increase in cluster output values means that the local secondary and tertiary industries are booming, which will lead to overall economic development of Barkam. Economic urbanization rate is defined as the proportion of cluster output values of GDP. The current urbanization rate of Barkam city has reached more than 90%, which shows that local industrial clusters have reached a high level. Figure 11 speculates that the Barkam's economic urbanization rate will be improved steadily in the next decade.

It can be concluded that the tourism industry of Barkam will develop rapidly in the next decade and the output values of industrial clusters will increase steadily. The urban GDP and urban population are also increasing. With the development of industrial clusters driven by tourism, the urbanization rate of Barkamis gradually increased, and the level of urbanization has laid a foundation for the local tourism development and industrial clusters. Meanwhile the development of tourism in Barkam has higher requirements for the whole urban system from the external to the internal connection service, which promotes the development of local construction, transportation, lodging catering and social public services, etc. The direct effect of tourism on the evolution of local urbanization has increased the attractiveness of cities and towns, and accelerated the process of Urbanization. In addition, we find that the growth rate of local agricultural output value is smaller than other two industries, which is not conducive to the coordinated development of various industries and the optimization of industrial structure. Therefore, the local government should maintain the smooth development of tourism and pay attention to the integration of tourism and related industries so that the development of the local three industries will be promoted harmoniously.

4 Conclusion

In this paper, the quantitative relationship was analyzed by SPSS, and the DYNAMO language and Vensim are used to establish the system dynamic model of pan-tourism urbanization. The three subsystems about tourism, industrial cluster and urbanization are interrelated through the visitor numbers, tourism revenue, and clusters output value and employment population. The interactive development relationship among the three reflects the industrial cluster driven by tourism development and the process of rural labor transfer. This model systematically analyzes pan-tourism urbanization operation mechanism, and it provides the corresponding scientific basis and theoretical support to promote urban and rural development, improve the level of characteristic urbanization and the construction of new towns. Because the selected city of Barkam has certain particularity, the system elements may not be comprehensive. In addition, as the difference of local development and economic level, the pan-tourism urbanization model may not be suitable for all cities and towns, so it is necessary to adjust specific elements and coefficients in a specific place in order to make a more scientific analysis.

A Study on the Three Different Channel Models in Supply Chain Under the Network Externalities

Jinjiang Yan, Jiankai Xing(✉), Kai Zhu, and Ke Liu

Business School, Sichuan University,
Chengdu 610065, People's Republic of China
mukaimu@163.com

Abstract. With the rapid developments of Internet, many manufacturers and retailers choose not only the offline channel but also the online channel. According to the choices of different channels, this paper models three types of channel models in supply chains. Considering the presence of the network externalities, the degree of substitution between online and offline channels and consumers' preference for two entities (the manufacture and the retailer), we study the effect of retailer's choice to online channel and the differences among the three different channel models. Our main findings are that compared to the first two models, the sales price of unit product will be smaller and in contrast the market size will be bigger in the third model. Also, when the entities make the best strategies, the retailer's profit and the total profit of the channel can reach the maximum. The study shows that the introduction of online channel can create more social values, which is why the dual-channel model of retailers is so widespread. In the end, a numerical example is given to verify the conclusions.

Keywords: Network externality · Supply chain · Online channel · Offline channel

1 Introduction

With the rapid development of the Internet, on the one hand, online sales have become a mode in which the manufacturers and retailers can increase sales. On the other hand, more and more products have gradually affected by the network externality. The introduction of online channel for the manufacturer can increase their sales and avoid the large retailers' monopoly of the offline channel. At the same time, it can provide opportunities for the retailer to expand the market and increase sales. Many well-known manufacturers (such as Lenovo, Apple, etc.) chose to introduce the online channel based on the offline channel. However, a lot of famous retailers (such as Alibaba, Wal-Mart Stores, etc.) had also introduced the online channel one after another. Nevertheless, most studies of dual-channels

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_36

focused on the choice of the manufacturer, the internal channel coordination and channel pricing, but ignored the impact of network externalities and the choice of retailers in dual-channel situation.

The network externality means that the customer can obtain more utilities when more suppliers are willing to join in the network and opposite situation is similar. In making strategies for channel markets, however, sellers (including the manufacturer and the retailer) have typically relied on assumptions and paradigms that apply to business without network effects. Therefore, the strategy that they make may not match the economics of their changing industries. Many literatures studied the pricing strategy for the dual-channel. Liu [13] pointed that compared to the traditional single channel, when the manufacturer brings in the online channel, pricing strategies will have different effects on the channel. Leider [9] studied experimentally bargaining in a multiple-tier supply chain with horizontal competition and sequential bargaining between tiers. They found that the structural issue of cost differentials dominates personal characteristics in explaining outcomes, with profits in a tier generally increasing with decreased competition in the tier and increasing with decreased competition in alternate tiers. Naeem, Charles and Rafay [3] considered a dynamic problem of joint pricing and production decisions for a profit-maximizing firm that produced multiple products. They presented a solution approach which is more general than previous approaches that require the assumption of a specific demand function. Chuang and Yang [7] modeled the deteriorating goods pricing strategy with reference price effects and solved the dynamic problem by obtained theoretical results.

Some scholars carried out their research from the aspect of dual-channel coordination. Shamir [14] studied the operational motivation of a retailer and showed that by making forecast information publicly available to both his manufacturer and to the competitor, a retailer is able to credibly share his forecast information-an outcome that cannot be achieved by merely exchanging information within the supply chain. Yang and Zhuo etc. studied a two-period supply chain that consists of a retailer and a supplier and found that a revenue sharing contract significantly affects the retailer's payment behavior and supplier's wholesale price [16]. Zhong, Xi and Jing [17] analyzed the coordinating mechanisms for a single-period supply chain comprising of one supplier and one retailer. They pointed that the transfer payment plus a contract could mitigate the down side risk effect on the supply chain performance. Yue and Allen, etc. [15] studied a supply chain consisting of one supplier and n retailers and pointed the pricing strategy under different situations. Wenyi et al. [6] presented an integrated model of marketing choices and supply chain design decisions and developed the closed-loop supply chain. Yulan and Stein, etc. reviewed operational models in service supply chain management (SSCM) and examined the definitions of SSCM [6]. Panda et al. [12] analyzed coordination of a manufacturer-distributer-retailer supply chain, where the manufacturer exhibited corporate social responsibility [12]. They built a manufacturer-Stackelberg game setting to propose a contract-bargaining process and resolved channel conflict. Jing, Hui and Ying [5] analyzed the channel effects of four kinds of dual-channels' pricing strategies. Aimin and Liwen analyzed the stochastic demand, joint promotion, the price competition and coordination problems between the manufacturer and the retailer [1]. Ravi and Rajib [11] studied the co-opetition between differentiated platform in two-sided markets. In their study, they highlighted the importance of technology. They pointed that collaboration might provide incentives for a dominant platform. In this paper, we consider the platform/channel ownership is independent, not belonging to the seller or the consumer.

Some scholars focus on the study of network externalities for the competitive strategy. Blocher [4] showed that amplifying network externalities among mutual funds could explain substantial flow-based effects documented in the literature. Liu [10] identified the valid mechanism for the alternative range of profit-sharing contracts and analyzed the effect of product substitutability coefficient and network externalities on the alliance and profit-sharing contract. Hagiu and Spulber [8] presented first-party content and coordination in two-sided markets and they found that the strategic use of first-party content by two-sided platform was driven by two key factors: the nature of buyer and seller expectations. Edward and Anderson researched the platform performance investment in the presence of network externalities [2]. They carried out a full analysis of three distinct settings: monopoly, price-setting duopoly and pricing-taking duopoly. They concluded that the conditions under which offering a platform with lower performance but greater availability of content can be a winning strategy.

These literatures have analyzed the pricing and coordination strategies of the dual-channels and the influence of network externalities on pricing and competitive strategy of enterprises respectively. We can conclude that the main problem of pricing and coordination is to coordinate the distribution of benefits between manufacturers and retailers in the structure of the manufacturer's choice of dual channel. The network externality can increase the strength of the sharing economy, bring about a positive cycle effects, and provide guidance for pricing and coordination of enterprises. However, from the two aspects of researches, there exists the following deficiencies.

The retailer's behavior can also have a great impact on the dual-channel in the supply chain system. But most of the studies about the dual-channel and the network externalities are limited to the behavior of the manufacturer. In addition, the network externalities also have a great influence on the pricing and decision making. Many literatures about the dual-channel have largely ignored the effect of network externalities on consumers and the whole supply chain system. Many studies about the network externalities simply consider the effect of network externalities on the single channel mode, not using it to dual-channel mode.

With the premise that both entities' (including the manufacturer and the retailer) optimal profits must greater than zero, this paper considers the products with the network externalities and builds three channel models under the condition that the retailer is the leader in the structure models. This paper names them as single channel model (SCM), the dual-channel model of manufacturers

(DCMM) and the dual-channel model of retailers (DCMR) respectively. First, this paper analyzes the optimal product pricing and strategy for the manufacturer and the retailer under three different channel models. Then we analyze the differences among the three models and their effect on the local supply chain. At last, this paper uses the numerical examples to demonstrate the conclusions.

2 Model Assumptions and Notations Description

Assumed that the manufacturer only produces a kind of product with network externality. Considering that the sale period is not too long, consumers only buy the goods from the manufacturer or the retailer on the channel and there is no intersection between the consumption of different channels.

The retailer is the leader in the structure in all models. In the single channel model, firstly, according to the retailer's own marginal profit m_1, the manufacturer decides the wholesale price ω_1 to maximize their own profits. Then, the retailer adjusts its revenue to maximize its own marginal profit according to the wholesale price. Further, the retailer sets the sales price of the product $p_1 = \omega_1 + m_1$. In the dual-channel model of manufacturers, firstly, according to the retailer's own marginal profit m_2, the manufacturer decides the wholesale price ω_1 and the sale price p_{22} on online channel to maximize their own profits. Second, the retailer adjusts its revenue to maximize its own margin according to the wholesale price. At last, the retailer sets the sales price of the product. Similar to the dual-channel model of manufacturers, in the dual-channel model of retailers, the manufacturer decides the wholesale price and the sale price ω_2 on online channel p_{22}. The main difference is that the retailer needs to decide the sale price on online channel p_{22}.

Consumers can buy goods through different channels, but they will have different utilities and the estimated value of the product on offline or online channels will also be different. For example, In the physical store, consumers can immediately get product information and then purchase products. While through the network channel, consumers can get more products no matter how far it is. With the development of modern logistics, waiting time will become very short. So we denote the degree of substitution or monopoly between online and offline channels by $\beta\,(0 \le \beta < 1)$, so $1-\beta$ indicates the degree that the online channel cannot monopolize. While refers to the manufacturer's credit tendency in the mind of the consumer, so does the $1-\gamma$.

In the single channel model, the consumer's estimation value of the product on the offline channel is V_{11}; in the dual-channel model of manufacturers, the consumer's estimation value of the product on the offline and online channels are V_{21}, V_{22}; in the dual-channel model of retailers, the consumer's estimation value of the product on the offline channel is V_{31}, while the consumer's estimation value of the manufacturer's and the retailer's product on the online channel are V_{32}, V_{33}.

The consumer will select the channel only when their utilities are greater than zero. Without loss of generality, assume the customer is heterogeneous and subject to uniform distribution. In model one, θ_{11} refers to the consumers' preference distribution on offline channel. It represents the consumer's measure for each potential transaction; In model two, we use θ_{21} instead of θ_{11} and denote the consumer's preference distribution for manufacturers of online channel by θ_{22}. In model three, we use θ_{31}, θ_{32} instead of θ_{21}, θ_{22} and denote the consumer's preference distribution for manufacturers of online channel by θ_{32}.

The sales cost of unit product for the manufacturer on offline channel can be interpreted by c_1, while for the retailer is c_2. Because the cost of online channel is lower than the offline channel, so define k_1 as the manufacturer's allocation efficiency relative to the offline channel, while for the retailer is k_2. The smaller the k, the lower the cost. To be more representative, we can get $k \in (0, 1)$. α_1 expresses the strength of network effects of consumers who select retailer's offline channel; α_2 expresses the strength of network effects of consumers who select manufacturer's online channel; α_3 expresses the strength of network effects of consumers who select retailer's online channel. Without loss of generality, $\alpha \in (0, 1)$.

In the single channel model, A_{11} represents the largest potential market demand on offline channel, N_{r1}denotes the number of retailers on offline channel. In the dual-channel model of manufacturers, use A_{21}, N_{r2} instead of A_{11}, N_{r1}, A_{22} represents the largest potential market demand on online channel, N_{s2} denotes the number of manufacturers on online channel. Due to the widening of the market, we can conclude $A_{21} + A_{22} > A_{11}$. At the same time, because the manufacturer adds the online channel, and appeal some consumers, so it will inevitably lead to a decrease in the number of retailers. So $N_{r2} \le N_{r1}$. In the dual-channel model of manufacturers, similar to model two, A_{31} can instead of A_{21}; A_{32} represents the largest potential market demand for the manufacturer on online channel; A_{33} represents the largest potential market demand for the retailer on online channel; denotes the number of retailers on online channel; N_{s3} denotes the number of manufacturers on online channel; N_{r4} denotes the number of retailers on offline channel; Similarly, $A_{32} + A_{33} > A_{22}$, $N_{s3} \le N_{s2}$ and $N_{r4} \le N_{r2}$.

3 The Model

3.1 The Single Channel Model (SCM)

Based on the above assumptions, we study the single channel model firstly. The supply chain mode is shown in Fig. 1.

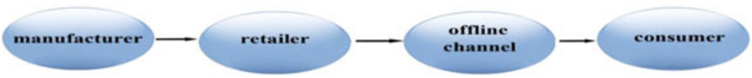

Fig. 1. The single channel mode (SCM)

Assume that the utility function of the consumer on the single channel is:

$$U_{11} = V_{11} + N_{r1}\theta_{11}\alpha_1 - p_{11}. \tag{1}$$

According to Eq. (1), for this channel, the consumer's individual rationality (participation) constraint is:

$$U_{11} \geq 0. \tag{2}$$

So

$$\theta_{11} \geq \frac{p_{11} - V_{11}}{N_{r1}\alpha_1}. \tag{3}$$

As a result, according to Eq. (3), the number of consumers who join the retailer's offline channel is:

$$D_{11} = A_{11}\int_{\frac{p_{11}-V_{11}}{N_{r1}\alpha_1}}^{1} d\theta = \frac{(N_{r1}\alpha_1 - p_{11} + V_{11})A_{11}}{N_{r1}\alpha_1}. \tag{4}$$

And it must satisfy:

$$D_{11} \geq 0. \tag{5}$$

(1) The manufacturer's profit is:

$$\varPi_{M1} = (\omega_1 - c_1)D_{11} = A_{11}(\omega_1 - c_1)\frac{N_{r1}\alpha_1 - \omega_1 - m_1 + V_{11}}{N_{r1}\alpha_1}. \tag{6}$$

Proposition 1. *The manufacturer's profit function is a concave function of the wholesale price, so when the manufacturer's profit reaches the maximum, the price's optimal value is:*

$$\omega_1^* = \frac{N_{r1}\alpha_1 - m_1 + c_1 + V_{11}}{2}. \tag{7}$$

(2) The retailer's profit of offline platform is:

$$\varPi_{\mathrm{R1}} = (p_{11} - \omega_1 - c_2)D_{11} = A_{11}(m_1 - c_2)\frac{N_{r1}\alpha_1 - m_1 - c_1 + V_{11}}{2V_{11}\alpha_1}. \tag{8}$$

Proposition 2. *The retailer's profit function is a concave function of the earning of unit product on offline channel, so when the retailer's profit reaches the maximum, the margin's optimal value is:*

$$m_1^* = \frac{N_{r1}\alpha_1 - c_1 + c_2 + V_{11}}{2}. \tag{9}$$

In the single channel model, the final optimal values for these parameters are as following:

$$\omega_1^* = \frac{N_{r1}\alpha_1 + 3c_1 - c_2 + V_{11}}{4}, \tag{10}$$

$$p_{11}^* = \frac{3N_{r1}\alpha_1 + c_1 + c_2 + 3V_{11}}{4}, \tag{11}$$

$$\Pi_{M1}^* = \frac{(N_{r1}\alpha_1 - c_1 - c_2 + V_{11})^2 A_{11}}{16N_{r1}\alpha_1}, \tag{12}$$

$$\Pi_{R1}^* = \frac{(N_{r1}\alpha_1 - c_1 - c_2 + V_{11})^2 A_{11}}{8N_{r1}\alpha_1}, \tag{13}$$

$$\Pi_1^* = \Pi_{M1}^* + \Pi_{R1}^* = \frac{3(N_{r1}\alpha_1 - c_1 - c_2 + V_{11})^2 A_{11}}{16N_{r1}\alpha_1}. \tag{14}$$

3.2 The Dual-Channel Model of Manufacturers (DCMM)

Based on the above assumptions and the first model, we study the dual-channel model of manufacturers next. The supply chain mode is shown in Fig. 2.

Fig. 2. The dual-channel model of manufacturers (DCMM)

As consumers have their own preferences for online and offline channels, assume that the utility function of the consumer on the offline channel and online channel respectively are:

$$U_{21} = V_{21} + N_{r2}\theta_{21}\alpha_1 - p_{21} - (1-\beta)V_{21}V_{22}, \tag{15}$$

$$U_{22} = V_{22} + N_{s2}\theta_{22}\alpha_2 - p_{22} - \beta V_{21}V_{22}. \tag{16}$$

On the basis of Eqs. (15) and (16), the consumer's individual rationality (participation) constraints for these two channels are:

$$U_{21} \geq 0, \tag{17}$$

$$U_{22} \geq 0. \tag{18}$$

So

$$\theta_{21} \geq \frac{p_{21} + (1-\beta)V_{21}V_{22} - V_{21}}{N_{r2}\alpha_1}, \tag{19}$$

$$\theta_{22} \geq \frac{p_{22} + \beta V_{21}V_{22} - V_{22}}{N_{s2}\alpha_2}. \tag{20}$$

As a result, according to Eqs. (19) and (20), the numbers of consumers who join retailer's offline channel and online channel respectively are:

$$D_{21} = A_{21}\frac{N_{r2}\alpha_1 - p_{21} - (1-\beta)V_{21}V_{22} + V_{21}}{N_{r2}\alpha_1}, \tag{21}$$

$$D_{22} = A_{22}\frac{N_{s2}\alpha_2 - p_{22} - \beta V_{21}V_{22} + V_{22}}{N_{s2}\alpha_2}. \tag{22}$$

And they must satisfy:

$$D_{21} \geq 0, \tag{23}$$

$$D_{22} \geq 0. \tag{24}$$

The manufacturer decides the wholesale price and the online channel's price of unit product to maximize their own profits. The manufacturer's profit is:

$$\Pi_{M2} = (\omega_2 - c_1)D_{21} + (p_{22} - k_1c_1)D_{22}. \tag{25}$$

Proposition 3. *The manufacturer's profits function is a concave function of the wholesale price and the online channel's price of unit product, so when the manufacturer's profit reaches the maximum, the optimal values of the prices are:*

$$p_{22}^* = \frac{N_{s2}\alpha_2 - \beta V_{21}V_{22} + k_1c_1 + V_{22}}{2}, \tag{26}$$

$$\omega_2^* = \frac{N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} - m_2 + c_1 + V_{21}}{2}. \tag{27}$$

At the same time, the retailer's decision-making is the same as the single channel model. The retailer's profit of offline platform is:

$$\begin{aligned}\Pi_{R2} &= (p_{21} - \omega_2 - c_2)D_{21}\\ &= A_{21}\frac{m_2 - c_2}{2}\frac{N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} - m_2 - c_1 + V_{21}}{N_{r2}\alpha_1}.\end{aligned} \tag{28}$$

Proposition 4. *The retailer's profits function is a concave function of the earning of unit product on offline channel, so when the retailer's profit reaches the maximum, the margin's optimal value is:*

$$m_2^* = \frac{N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} - c_1 + c_2 + V_{21}}{2}. \tag{29}$$

So in the dual-channel model of manufacturers, the final optimal values for these parameters are as the following:

$$\omega_2^* = \frac{N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} + 3c_1 - c_2 + V_{21}}{4}, \tag{30}$$

$$p_{21}^* = \frac{3N_{r2}\alpha_1 - 3(1-\beta)V_{21}V_{22} + c_1 + c_2 + 3V_{21}}{4}, \tag{31}$$

$$p_{22}^{*} = \frac{N_{s2}\alpha_2 - \beta V_{21}V_{22} + k_1 c_1 + V_{22}}{2}, \tag{32}$$

$$\begin{aligned} \Pi_{M2}^{*} = & A_{21}\frac{\left[N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} - c_1 - c_2 + V_{21}\right]^2}{16N_{r2}\alpha_1} \\ & + A_{22}\frac{\left(N_{s2}\alpha_2 - \beta V_{21}V_{22} - k_1 c_1 + V_{22}\right)^2}{4N_{s2}\alpha_2}, \end{aligned} \tag{33}$$

$$\Pi_{R2}^{*} = A_{21}\frac{\left[N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} - c_1 - c_2 + V_{21}\right]^2}{8N_{r2}\alpha_1}. \tag{34}$$

Finally, consider the prerequisite: the manufacturer's profit in this model should be greater than in model one (Because only in this condition, the manufacturer will choose to introduce online channel). So for the manufacturer, their optimal profit must be satisfied:

$$\Pi_{M2} \geq \Pi_{M1}. \tag{35}$$

Let $\frac{(N_{r1}\alpha_1 - c_1 - c_2 + V_{11})^2 A_{11}}{16N_{r1}\alpha_1} = C_1$, $A_{21}\frac{[N_{r2}\alpha_1 - (1-\beta)V_{21}V_{22} - c_1 - c_2 + V_{21}]^2}{16N_{r2}\alpha_1} = C_2$ and $\beta V_{21}V_{22} - k_1 c_1 + V_{22} = C_3$. So according to formula (35), we can get:

$$\alpha_2 \geq \frac{\frac{4(C_1 - C_2)}{A_{22}} + 2N_{s2}C_3 + \sqrt{\left[\frac{4(C_1 - C_2)}{A_{22}} + 2N_{s2}C_3\right]^2 - 4N_{s2}^2 C_3}}{2N_{s2}^2}. \tag{36}$$

3.3 The Dual-Channel Model of Retailers (DCMR)

In the end, we analyze the dual-channel model of retailers. According to the above analysis, the supply chain mode is shown in Fig. 3.

Fig. 3. The dual-channel model of retailers (DCMR)

In the case of this model, consumers have not only different choices of channels, but also preferences for the entities in the channels. Therefore, the net utilities to a consumer on the retailer's offline platform, the manufacturer's online platform, the retailer's online platform are given by:

$$U_{31} = V_{31} + N_{r4}\theta_{31}\alpha_1 - p_{31} - (1-\beta)V_{31}(V_{32} + V_{33}), \tag{37}$$

$$U_{32} = V_{32} + N_{s3}\theta_{32}\alpha_2 - p_{32} - \beta\gamma V_{31}(V_{32} + V_{33}). \tag{38}$$

Similarly, the numbers of consumers who join retailer's offline channel, manufacturer's online channel and retailer's online channel respectively are:

$$D_{31} = A_{31}\frac{N_{r4}\alpha_1 - p_{31} - (1-\beta)V_{31}(V_{32}+V_{33}) + V_{31}}{N_{r4}\alpha_1}, \tag{39}$$

$$D_{32} = A_{32}\frac{N_{s3}\alpha_2 - p_{32} - \beta\gamma V_{31}(V_{32}+V_{33}) + V_{32}}{N_{s3}\alpha_2}, \tag{40}$$

$$D_{33} = A_{33}\frac{N_{r3}\alpha_3 - p_{33} - \beta(1-\gamma)V_{31}(V_{32}+V_{33}) + V_{33}}{N_{r3}\alpha_3}. \tag{41}$$

According to the actual situation, they must satisfy:

$$D_{31} \geq 0, \tag{42}$$

$$D_{32} \geq 0, \tag{43}$$

$$D_{33} \geq 0. \tag{44}$$

Similar to the model two, the manufacturer decides the wholesale price and the online channel's price of unit product to maximize their own profits. The manufacturer's profit in this model is:

$$\Pi_{M3} = (\omega_3 - c_1)D_{31} + (p_{32} - k_1 c_1)D_{32}. \tag{45}$$

Proposition 5. *The manufacturer's profits function is a concave function of the wholesale price and the online channel's price of unit product, so when the manufacturer's profit reaches the maximum, the optimal values of these prices are:*

$$p_{32}^* = \frac{N_{s3}\alpha_2 - \beta\gamma V_{31}(V_{32}+V_{33}) + k_1 c_1 + V_{32}}{2}, \tag{46}$$

$$\omega_3^* = \frac{N_{r4}\alpha_1 - (1-\beta)V_{31}(V_{32}+V_{33}) - m_3 + c_1 + V_{31}}{2}. \tag{47}$$

Different from the model two, the retailer not only decides the earning of unit product on offline channel, but also the online channel's price of unit product. The retailer's total profit in this model is:

$$\Pi_{R3} = (p_{31} - \omega_3 - c_2)D_{31} + (p_{33} - k_2 c_2)D_{33}. \tag{48}$$

Proposition 6. *The retailer's profits function is a concave function of the earning of unit product on offline channel and the online channel's price of unit product, so when the retailer's profit reaches the maximum, the optimal values are:*

$$m_3^* = \frac{N_{r4}\alpha_1 - (1-\beta)V_{31}(V_{32}+V_{33}) + c_2 - c_1 + V_{31}}{2}, \tag{49}$$

$$p_{33}^* = \frac{N_{r3}\alpha_3 - \beta(1-\gamma)V_{31}(V_{32}+V_{33}) + k_2 c_2 + V_{33}}{2}. \tag{50}$$

Therefore, in the dual-channel model of retailers, the final optimal values for these parameters are as the following:

$$
\begin{aligned}
\omega_3^* &= \frac{N_{r4}\alpha_1 - (1-\beta)V_{31}(V_{32}+V_{33}) - c_2 + 3c_1 + V_{31}}{4}, && (51)\\
p_{31}^* &= \frac{3N_{r4}\alpha_1 - 3(1-\beta)V_{31}(V_{32}+V_{33}) + c_2 + c_1 + 3V_{31}}{4}, && (52)\\
p_{32}^* &= \frac{N_{s3}\alpha_2 - \beta\gamma V_{31}(V_{32}+V_{33}) + k_1c_1 + V_{32}}{2}, && (53)\\
p_{33}^* &= \frac{N_{r3}\alpha_3 - \beta(1-\gamma)V_{31}(V_{32}+V_{33}) + k_2c_2 + V_{33}}{2}, && (54)\\
\Pi_{M3}^* &= A_{33}\frac{[N_{r4}\alpha_1 - (1-\beta)V_{31}(V_{32}+V_{33}) - c_1 - c_2 + V_{31}]^2}{16N_{r4}\alpha_1}\\
&\quad + A_{34}\frac{[N_{s3}\alpha_2 - \beta\gamma V_{31}(V_{32}+V_{33}) - k_1c_1 + V_{32}]^2}{4N_{s3}\alpha_2}, && (55)\\
\Pi_{R3}^* &= A_{33}\frac{[N_{r4}\alpha_1 - (1-\beta)V_{31}(V_{32}+V_{33}) - c_1 - c_2 + V_{31}]^2}{8N_{r4}\alpha_1}\\
&\quad + A_{35}\frac{[N_{r3}\alpha_3 - \beta(1-\gamma)V_{31}(V_{32}+V_{33}) - k_2c_2 + V_{33}]^2}{4N_{r3}\alpha_3}. && (56)
\end{aligned}
$$

Finally, consider the prerequisite: the manufacturer's profit in this model should be greater than in model one and the retailer's profit in this model should be greater than in model two. So for the manufacturer, their optimal profit must be satisfied:

$$\Pi_{M3} \geq \Pi_{M1}. \tag{57}$$

Let $A_{33}\frac{[N_{r4}\alpha_1-(1-\beta)V_{33}(V_{34}+V_{35})-c_1-c_2+V_{33}]^2}{16N_{r4}\alpha_1} = C_4$ and $\beta\gamma V_{31}(V_{32}+V_{33}) + k_1c_1 - V_{32} = C_5$. So:

$$\alpha_2 \geq \frac{4(\frac{C_1-C_4}{A_{32}}) + 2N_{s3}C_5 + \sqrt{[4(\frac{C_1-C_4}{A_{32}}) + 2N_{s3}C_5]^2 - 4N_{s3}^2C_5}}{2N_{s3}^2}. \tag{58}$$

At last, for the retailer, their optimal profit must be satisfied:
Let $\beta(1-\gamma)V_{31}(V_{32}+V_{33}) + k_2c_2 - V_{33} = C_6$. According to formula (57)

$$\alpha_3 \geq \frac{8(\frac{C_2-C_4}{A_{33}}) + 2N_{r3}C_6 + \sqrt{[8(\frac{C_2-C_4}{A_{33}}) + 2N_{r3}C_6]^2 - 4N_{r3}^2C_6}}{2N_{r3}^2}. \tag{59}$$

Comparing the three models and when these prerequisites are met, we can get the following conclusions. With manufacturers and retailers choose the online channel in turn, it can be seen that the price of unit product on offline channel gradually reduces. In model three, the online channel's price of unit product for the manufacturer and the retailer both lower than the online channel's price in model two. With the introduction of online channel, the wholesale price is gradually reduced and the number of consumers who join retailer's offline channel will decrease. As the retailer chooses the online channel, the number of consumers who join manufacturer's online channel will also decrease, but the total number of consumers will increase. Compared to the model one, when the manufacturer chooses the online channel, their profit gets to the maximum, then when the retailer uses online channel, the manufacturer's profit reduced, but is higher than in the model one. In model two, when the manufacturer chooses the online channel, the retailer's profit gets to the minimum, then when they choose the online channel, their profits will increase and higher than in model one. Along with the introduction of the online channel, the overall profit of the channel will increase.

4 Numerical Example

This section presents numerical simulations to clarify the findings which is not easy to understand. First, we maintain the following assumptions over the simulations. For the case of the single channel model, in order to achieve profitability, some variables need to meet some restrictions: $A_{11} \geq p_{11} \geq \omega_1 \geq c_1$. In model two, in order to prevent retailers ordering goods from online channels and be able to make profit, they need to meet $A_{21} \geq p_{21} \geq \omega_2 \geq c_1$, $p_{22} \geq \omega_2 \geq c_1$ and $A_{22} \geq p_{22} \geq k_1 c_1$. Similar to model two, in model three, $A_{31} \geq p_{31} \geq \omega_3 \geq c_1$, $p_{32} \geq \omega_3 \geq c_1$, $A_{32} \geq p_{32} \geq k_1 c_1$, $p_{33} \geq \omega_3 \geq c_1$ and $A_{33} \geq p_{33} \geq k_2 c_2$.

According to formula $A_{11} \geq p_{11} \geq \omega_1 \geq c_1$, $A_{21} \geq p_{21} \geq \omega_2 \geq c_1$, $A_{31} \geq p_{31} \geq \omega_3 \geq c_1$ and formulas (2), (21), (22), (42), (43) and (44), the prerequisite is:

$$\alpha_1 \geq \frac{c_1 + c_2 + (1-\beta)V_{31}(V_{32}+V_{33}) - V_{31}}{N_{r4}}. \tag{60}$$

According to formula $p_{22} \geq \omega_2 \geq c_1$, $A_{22} \geq p_{22} \geq k_1 c_1$, $p_{32} \geq \omega_3 \geq c_1$, $A_{32} \geq p_{32} \geq k_1 c_1$ and formulas (21), (22), (36), (42), (43), (44) and (57), the prerequisite is:

$$\alpha_2 \geq \frac{N_{r4}\alpha_1 + (\beta - 1 + 2\beta\gamma)V_{31}(V_{32}+V_{33}) + (3-2k_1)c_1 - c_2 + V_{31} - 2V_{32}}{2N_{s3}}. \tag{61}$$

According to formula $p_{32} \geq \omega_3 \geq c_1$, $A_{32} \geq p_{32} \geq c_1$, $p_{32} \geq p_{32} \geq k_1 c_1$ and formulas (42), (43) and (44), and controlling other variables constant, the prerequisite is:

$$\beta \leq \frac{2N_{r3}\alpha_3 - N_{r4}\alpha_1 + V_{31}(V_{32}+V_{33}) + (2k_2+1)c_2 - 3c_1 + 2V_{33} - V_{31}}{(3-2\gamma)V_{31}(V_{32}+V_{33})}. \tag{62}$$

So according to previous assumptions, these parameters' values can be set: $A_{11} = 16$, $V_{11} = 0.35$, $\alpha_1 = 0.7$, $c_1 = 0.5$, $c_2 = 0.3$, $N_{r1} = 10$, $A_{21} = 14$, $A_{22} = 13$, $V_{21} = 0.5$, $V_{22} = 0.37$, $\alpha_2 = 0.6$, $\beta = 0.7$, $k_2 = 0.5$, $N_{r2} =$, $N_{s2} = 0.6$, $A_{32} = 10$, $A_{31} = 13$, $A_{32} = 12.5$, $V_{31} = 0.6$, $V_{31} = 0.6$, $V_{32} = 0.4$, $V_{33} = 0.5$, $\gamma = 0.6$,

$k_2 = 0.1$, $\alpha_3 = 0.5$, $N_{s3} = 5$, $N_{s3} = 5.5$ and $N_{r4} = 7$. According to formulas (60), (61) and (62), and controlling other variables constant, these prerequisites are $0.052 \le \alpha_1 \le 1$, $0.569 \le \alpha_2 \le 1$, and $0 \le \beta \le 0.782$. So the prices of unit product on different channels can be shown in Fig. 4.

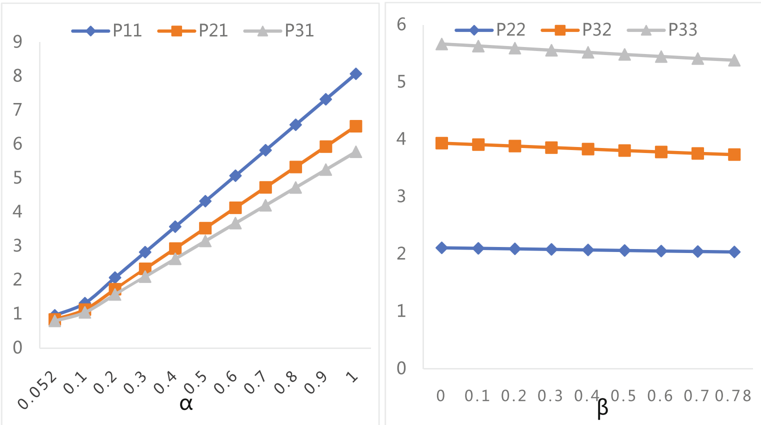

Fig. 4. The prices of unit product

As shown in Fig. 4, under the premise that manufacturers and retailers can choose the online channel, we can conclude that the price of the retailer's unit product on offline channel gradually decrease; the manufacturer's and the retailer's online channel's prices of unit product are also lower than in single channel model. That means consumers are very favorable when the manufacturer and the retailer both choose the online channel.

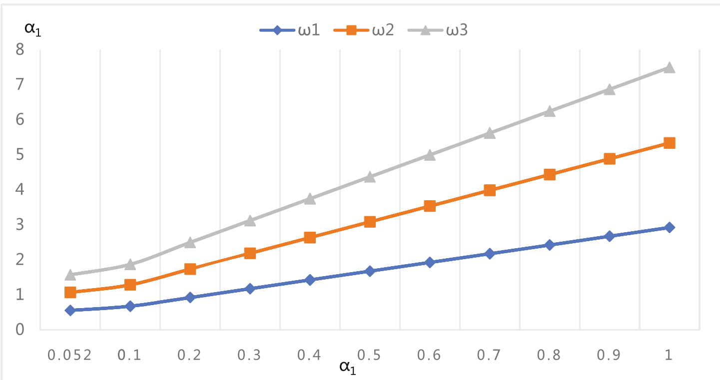

Fig. 5. The wholesale price of unit product

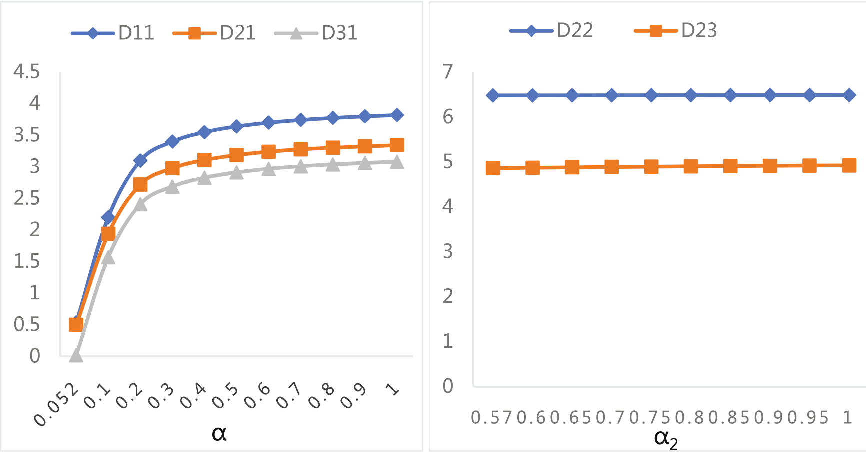

Fig. 6. The number of consumers

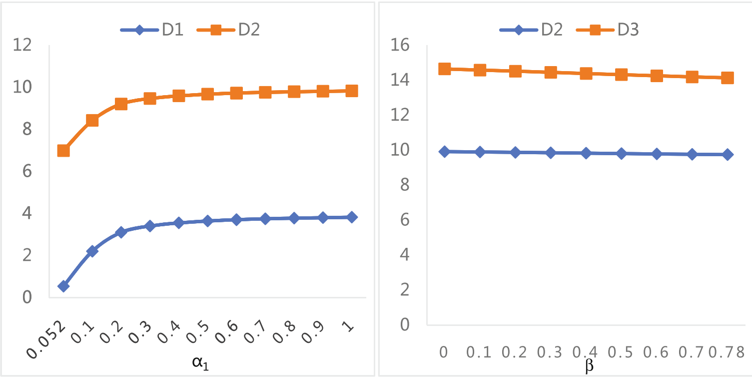

Fig. 7. The number of consumers

Compared the three models, the wholesale price of unit product is gradually reduced with the introduction of online channel. It's benefit for the retailer (Figs. 6 and 7).

With the increase of the network externality, the number of consumers who join the offline and online channels are all increasing in the three modes. Compared the three modes, due to the introduction of online channel, some consumers transfer to online channel. So the number of consumers who join the offline channel will decrease. When the retailer chooses to introduce the online channel, the number of consumers who join the manufacturer's online channel will also decrease. As shown in Fig. 7, the total number of consumers is increasing with the increase of network externalities and decreasing with the degree of substitution or monopoly between online and offline channels. With the introduction of online channel, the total number of consumers is increasing in turn. The

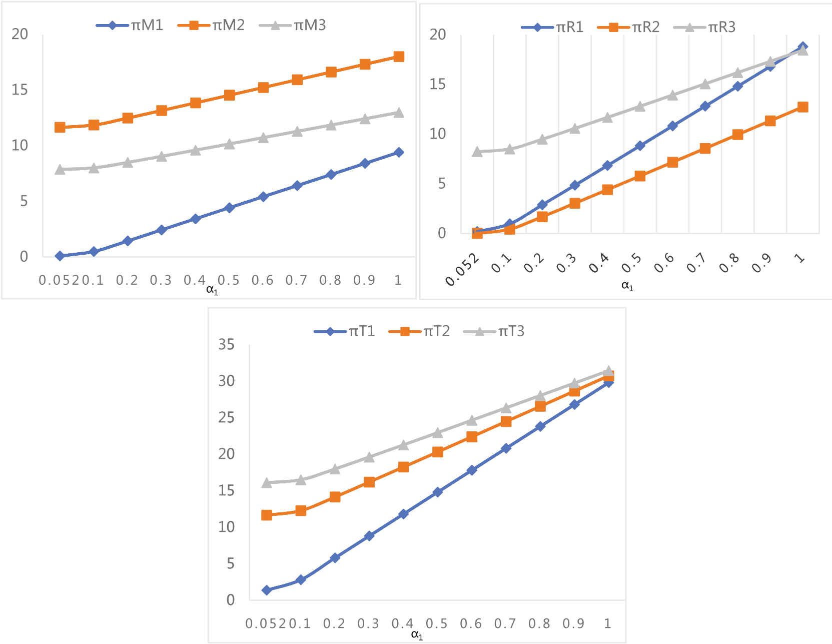

Fig. 8. The profit

total number of consumers can increase with the introduction of online channel. At the same time, consumers have more channels to choose, manufacturers and retailers have more demand for products, and thus these behaviors can increase consumption and create more social values.

We can see from Fig. 8, with the increase of the network externalities all profits are increasing. In model one, the profit of the manufacturer is the lowest. In model two, as the manufacturer chooses the online channel their profits reach the maximum. In model three, as the retailer chooses the online channel, their profits somewhat reduce but higher than in model one. On the contrast, in model one, the profit of the retailer is lower than in model three but higher than model one. In model two, as the manufacturer chooses the online channel, their profits reach the minimum. In model three, as the retailer chooses the online channel, their profits increase and reach the maximum. The total profit is increasing with the introduction of online channel. That means when manufacturers and retailers both choose to use online channel, they will create more social values.

5 Conclusions

This paper considers the choice of the retailer based on the choice of the manufacturer under the network externalities. We focus on the influence when the entities have different choices. By contrasting the single channel model, the dual-channel model of manufacturers and the dual-channel model of retailers, the introduction of online channel is benefit to the local supply chain.

Our study of channel performance under the affecting of the network externalities has yielded several important insights that should be of managerial interest. There are certain conditions for the manufacturer's and retailer's selection of the online channel. When manufacturers or retailers introduced the online channel first, the other one will make the same choice. With the introduction of online channel, the whole price will decrease but the number of consumers and the total profit will increase. That is why the dual-channel model of retailers is so widespread.

In developing our models, there are a few simplifying assumptions. For example, consistent with many literatures, we only study a single-period model and assume the consumer can only choose one channel. While we believe the intuition of our results applies to cases with different assumption, future research might investigate how such assumptions (e.g., independent of retailers' utility) affect the conditions in the proposition. Finally, future research could divide the channel into monopoly channel and competitive channel, so we can further discuss the choice of the manufacturer and the retailer between two channels or among three channels. There also might conduct a comprehensive analysis of manufacturers' or retailers' decisions which include different first-party content, technology and market share.

Abstract. Braille books follow a process of deterioration different from ordinary printed books. Braille is a reading letter and visually impaired people touch the boss with the finger's belly. Therefore, in Braille books that are frequently read, Braille is dirty with aged use, holes open, and they collapse. In old Braille books, braille collapses and deteriorates due to pressure from left and right books in the library. Therefore, in this research, we convert Braille books into machine-readable electronic data. First, a Braille book is scanned by an image. Next, we detect braille by image recognition technology one by one from braille page. And we classify and identify Braille. Furthermore, we correct errors such as misdetection of braille and misidentification. Finally, we save the result as character code.

Keywords: Braille · Old boo · Restoration · Deep learning

1 Introduction

In this section we briefly explain Braille and degraded braille.

1.1 Braille and Braille Library

The origin of Braille is old. In 1825, Braille [3] invented Braille in France. In 1879, Megata introduced Braille to Japan. In 1890, Ishikawa devised Japanese braille. This is the beginning of Japanese Braille. Since then Braille has been used as a character for the blind.

Braille consists of six embossed or flat points. These six points constitute one cell with two by three shape, which represents one character or a modifier of 63 kinds. With the modifier, characters more than 64 kinds are represented. In Japanese braille, each of voiceless sounds is represented by a plain cell and other characters such as syllabic nasals, voiced consonants, semi- voiced consonants, numerals, alphabets and so on are represented by a modifier and subsequent cell(s). In Fig. 1, Japanese Braille has a blank space for each clause like English.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_37

Some Japanese Braille are constructed with a prefix as last three examples in Fig. 1. Though Japanese is vertical writing or horizontal one, Japanese braille is horizontal writing only.

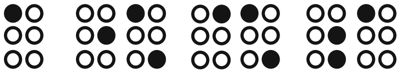

Fig. 1. Japanese Braille

The most primitive tool for writing braille is the slate and stylus. To use it, the user presses the tip of the stylus down through the small rectangular hole to make braille dots. Therefore the user is required to punch the braille dots with mirror image in reverse order. Nowadays, for publishing a book in braille, texts are input according to the braille grammar by using a braille text editor, are revised, and are printed in braille, as Fig. 2.

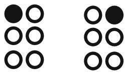

Fig. 2. Normal dot and mirrored one

In 1988, IBM opened "Tenyaku Hiroba (Field of Braille Transcription)", that was the Braille information network system, and digitization of braille had become widespread. The books in braille before the IBM's project are stored as they are without being converted into electronic data. Even if they have high storage value, the braille books are bulky, so braille libraries in various places are struggling to save. Each library has been forced to decide whether to discard them in recent years or to leave them.

In the earlier days when the Braille code was still in the research phase and there was no Windows, no personal computer, no internet, Shimomura et al. [1] studied coding of Braille.

Braille books are stored in the braille libraries throughout the country. The braille libraries registered in National Association of Institutions of Information Service for Visually Impaired Persons have about 100 libraries. Braille books. Braille books are borrowed from the braille libraries and public libraries via the braille libraries. In addition, many braille books are provided from the WEB braille library.

1.2 Degraded Braille

Braille is a tactile reading system. One reads tangible points with a finger's belly. Figure 3 is a typical page of Braille book. The braille books that are frequently

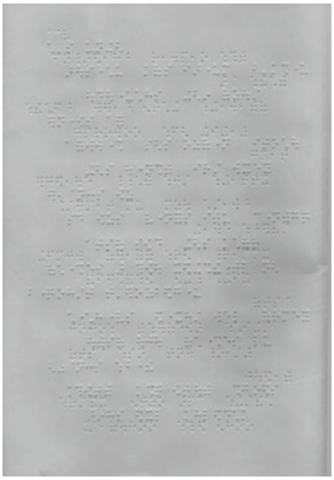

Fig. 3. Page of Braille book

read are dirty, holes are opened in dots, and dots collapse. Figures 4 and 5 show fresh dots and a part of a page that both normal cells and mirror images of cells, respectively. Figures 6, 7, 8 and 9 show the degraded braille cells, where the collapsed cell, the hole opened one, the dirty one and the distorted one is presented, respectively. Tears, creases and stains in pages are shown in Figs. 10, 11 and 12, respectively.

Fig. 4. Cell

Fig. 5. Normal and mirrored cell

Shimomura et al. [2] also studied restoration of the degraded Braille by shadow of Braille using fuzzy theory. In that study, the extraction of Braille was made by hand and computer programs executed the determination of existence of Braille. In this project, we extract Braille from scanned page images, which contain the degraded Braille, by computer programs, recognize them and restore the pages.

2 Restoration System

In this subsection we explain our project of the restoration system for old books written in Braille.

(1) Page scanning.
(2) Determination of whether scanned dot is normal or mirrored.
(3) Extraction of cells and classification into 63 categories.
(4) Error correction by using a scanning redundancy, that one cell is read twice as the normal image and the mirror image.
(5) Error correction by using Braille grammar.
(6) Interpretation Braille into Japanese.
(7) Error correction by using Japanese grammar.

As noted above, the system has two main components, a machine learning system for recognition of Braille and an error correction system.

Fig. 13. Normal dot image

Fig. 14. Mirrored dot image

Fig. 15. Background image

2.1 Preparation of Braille Images for Machine Learning

To detect degrade cells by machine, we must prepare many image of degrade cells. We have already scanned many the old braille books with resolution of 200 dpi, extracted each cell into 54 $\times$ 36 pixel by hand, and have obtained about 15000 cell images. These images were classified into 63 normal categories and 63 mirror ones. Next, we cut each call images into 6 dot areas by a tiny application program and got about 45000 dot images and 45000 flat (non dot) ones. The followings are the normal image, the mirrored dot one and the background one for the machine learning (Figs. 13, 14 and 15).

2.2 Dot Recognition by OpenCV

OpenCV is a famous computer vision library and has functions of object detection. Some detectors such as face, eye, mouth and so on are prepared, and one also can make detectors for arbitrary objects. To make the object detector, one prepares many images one wants to detect and execute the machine learning. In the machine learning, characteristics are extracted from the many images of the object, and the machine learns the characteristics. The set of images and characteristics learned by the machine is called a cascade classifier. OpenCV has some algorithm to make the classifier. In our system, we adopt train the cascade routine with LBP characteristic to search dots in scanned page.

As the cells are regularly aligned on paper, by using the gradient of dots or the edge of paper we can correct the gradient of page. The distribution of detected dots determines row lines in page.

2.3 Scanning of Old Braille Books

It is necessary to treat the old Braille books carefully because of the degradation of cells in them as mentioned above. Therefore we do not adopt flatbed scanners but adopt a noncontact type of scanner, Fujitsu ScanSnap SV600, which operates by taking an elevated view (see Fig. 16), with resolution of 600 dpi and grey scale.

If a Braille book is printed on both side and all pages are scanned, all Braille printed is scanned twice. They are read as the normal image and the mirror image. This gives us a redundancy for interpretation of cells.

The next step is the dot detection by OpenCV mentioned above. The result is given in Figs. 17 and 18.

Fig. 16. ScanSnap SV600

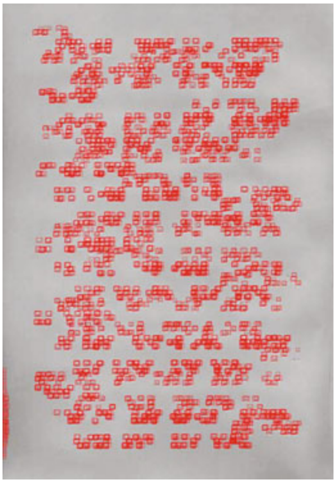

Fig. 17. Dot detection by OpenCV

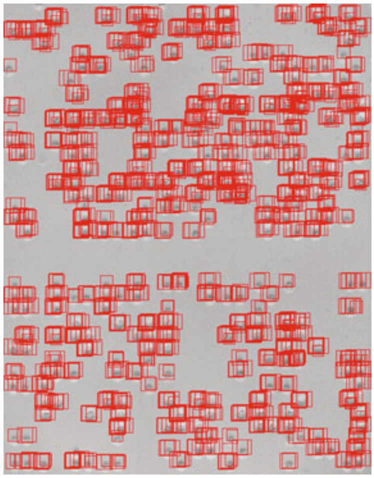

Fig. 18. Close up of detected dots

2.4 Normal and Reverse Dot Classification by Deep Neural Network

To detect degrade cells by machine, we must prepare many image of degrade cells. We have already scanned many the old braille books with resolution of 200 dpi, extracted each cell into 54 × 36 pixel by hand, and have obtained about 15000 cell images. These images were classified into 63 normal categories and 63 mirror ones. Next, we cut each call images into 6 dot areas by a tiny application program and got about 45000 dot images and 45000 flat (non dot) ones.

The deep learning is the one of technique of machine learning based on a deeply structured and hierarchical neural network. This technique is applied on the image recognition, the sound recognition and so on. In our project, we use this technique.

As usual Braille books are printed on both side, we must distinguish between the normal dots and the mirror ones. The both cell image are give again in Figs. 19 and 20. We have already obtained many dot images for them, so we use the images as reference data for the dot classification in the deep neural network.

This procedure gives us a normal dot distribution and a mirrored distribution. By converting the mirrored distribution into left-side right, we obtain the second candidate of the normal dot distribution.

Fig. 19. Normal cell

Fig. 20. Mirror cell

2.5 Cell Classification

As Braille is regularly aligned, the coordinate of dots tells us the starting point of cells. From this point, the dot images are sequentially analyzed, recognized and classified as cells by the deep neural network learned with 15000 cell images. Figures 20, 21, 22, 23, 24, 25 and 26 are binary aligned cell images. According to the classification, a character code is assigned to the cell image and is stored into database with a page number, a line number in the page, a word number in the line and a character number in the word. If the cell image has no character code, a flag of scanning error is also stored in the database.

2.6 Error Correction by Scanning Redundancy

When a Braille book is printed on both side and all pages are scanned, all pages become to be scanned twice. The character codes obtained from the normal images and ones from mirrored images are stored in the database and the codes obtained from normal and mirror images, for examples both shown in Figs. 16 and 17, are identical each other. By collating these codes and finding discrepancies, we have possibility to correct the scanning error.

2.7 Error Correction by Braille Grammar

Braille has own grammar. The character codes stored in the database are analyzed according to the grammar. In Japanese Braille, for example;

Fig. 25. "12345x" cell

Fig. 26. "123456" cell

A postposition "ha" is translated into "wa".
There is not the postposition "ha" following numeric characters.
A long sound written with kana character is translated into a macron and so on. When unacceptable sequence of characters is found, a flag of Braille grammatical error is stored in the database. If a probable code can be presumed by the grammar, the code is also stored as a candidate in the database.

2.8 Error Correction by Japanese Grammar

According to Japanese grammar, we check the sequence of code, set flags of Japanese grammatical error for ungrammatical expressions and correct the codes to probable codes if possible. Typical grammatical errors are as follows;

- A sequence of punctuation marks;
- A sequence of contracted sounds;
- Non-correspondent parentheses Incorrect sonant marks.

2.9 Output and Correction by Hand

Finally the codes are converted into ink-spots expressing Braille and are output (See Fig. 27). For codes with the error flag, the ink-spots and candidates of Japanese character are output, and are corrected by hand.

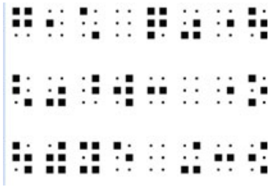

Fig. 27. Ink-spots expressing Braille

3 Concluding Remarks

In this paper, we explain our project to restore old Braille books by converting Braille books into machine-readable electronic data. The Braille book is scanned by an image. With the machine learning Braille are detected by image recognition technology, classified and identified. Furthermore, the error corrections are executed. Finally, the machine-readable character codes are stored.

Shimomura and colleagues have studied Braille 35 years before. The resumption of our study of Braille is because a request by the Japan Braille Library and Ishikawa Braille Library. In recent years, Braille books have been converted into electronic data and stored, and printed by computer processing. However the previous books are not converted into electronic data and are left as Braille books as it is. There are Braille books where the original is not found and without the original. The request was to convert Braille books into digital data before they became degraded and they became unreadable. Responding to this request, we resumed our research. We want to quickly restore degraded Braille books.

Acknowledgement. We would like to thank the staff of the following organizations for enabling us to research the actual condition of old Braille books: Ishikawa Association for Providing Facilities for the Visually Impaired and Japan Braille Library.

Abstract. This paper presents a method for discriminating personal opinions from commercial speech. Today many personal opinions such as complaints about a particular product can be found on the Web. Mining useful information from these opinions is important for a wide range of applications. Personal opinions on the web, however, are often contaminated with commercial speech. Commercial speech is generated by companies and individuals for the intent of making a profit. The data cleaning process that discriminates personal opinions from commercial speech is important for obtaining useful results in opinion mining. As a data cleaning method, we propose a language-independent method for discriminating personal opinions from commercial speech based on subjectivity of text. Assuming that subjective words frequently occur in personal opinions rather than commercial speech, we define the subjectivity score of each word. Estimating the total subjectivity score of a given text, the proposed method identifies whether the given text expresses personal opinions or commercial comments. From experiments using texts datasets written in different languages, we have found over 90% of personal opinions can be correctly discriminated from commercial speech by the proposed method.

Keywords: Personal opinions · Commercial speech · Data mining · Data cleaning · Information filtering

1 Introduction

Gathering personal opinions such as complaints about a particular product is an important task for a wide range of applications. For example, in marketing, it helps identifying the potential revenues, judging the success of a new product launch, improving the quality of customer service, reducing the development cost of a next product, etc. Today, many personal opinions can be found on websites

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_38

of individuals, social networking services like Twitter and customer review pages in E-commerce sites. Owing to the importance of personal opinions on the Web, many opinion mining techniques have been proposed [3,5–9]. One of the major topics in opinion mining is to identify the polarity of a given text whether the expressed opinion in a text is positive, negative, or neutral.

However, texts collected from web sites are often contaminated with commercial speech. Commercial speech is generated by companies and individuals for the intent of making a profit, which is essentially different from personal opinions. Therefore, differentiating between personal opinions and commercial speech is important for obtaining useful results in opinion mining.

In our previous study, we proposed a method for discriminating personal opinions from commercial speech [1,2]. In the previous study, we assumed that subjective expressions such as negative meaning words like "bad" and emoticons like ":)" are more likely to be used for describing personal opinions than commercial speech. Under the assumption, we modeled the total subjectivity score of a given text for discriminating between personal opinions and commercial speech. However, in the previous method, the dictionary of subjective expressions was generated by human labor and it was strongly dependent on the Japanese grammar. It is, therefore, difficult to apply the method to other languages.

In this paper, we propose a language-independent method for discriminating personal opinions from commercial speech. The proposed method focuses on the statistical difference of appearance ratio of each word between personal opinions and commercial speech corpora. Based on the difference, the subjectivity of each word is estimated. Assuming that words having high subjectivity are frequently used in personal opinions, the proposed method judges whether a given text is personal opinions or commercial speech.

The rest of the paper is organized as follows. In Sect. 2, we explain the outline of related works. In Sect. 3, we describe the details of the proposed method. In Sect. 4, we explain experiments using corpora written in different languages. In the section we show that the proposed method can accurately discriminate the two types of documents independently from languages.

2 Related Works

The process of opinion mining can be divided into three phases: data collection, polarity analysis and post processing such as visualization of mining results. In this paper we focus on the data collection phase. In many studies on opinion mining aims at analyzing the polarity (positive, negative or neutral) of a given sentence or text [3,5–9]. Text corpora using in these studies are collected from various sources such as social networking service sites like Twitter and the customer review pages of E-commerce sites. These studies implicitly assume that all the analyzing documents are regarded as personal opinions. However, the texts gathered from these sources are often contaminated with commercial speech. There is obvious difference between minds of writers in personal opinions and commercial speech. Therefore, for people who want to collect real public impressions about subjects, personal opinions should be discriminated from commercial speech.

In our previous study [1,2], we proposed a method for discriminating personal opinions from commercial speech. In the previous method, in order to discriminate the two types of documents, we focused on the four kinds of subjective expressions: negative meaning expressions, sentence-final particles, interjections, and specific symbols such as emoticons. Measuring the appearance ratios of these expressions, we defined the subjectivity score of a given text. Using the scoring model, we judged texts having high subjectivity scores as personal opinions. However, the four kinds of subjective expressions were selected by human labor and these words are strongly dependent on the Japanese Grammar. Therefore, it is difficult to apply the previous method to other languages.

In this paper, we propose a language-independent method, where the dictionary of subjective expressions is automatically generated by analyzing two kinds of corpora: texts of personal opinions and ones of commercial speech. Based on statistical difference of appearance ratio of each word between the two corpora, the subjectivity score of each word is defined. Subjective words frequently occurring in personal opinions can be automatically detected. Since the scoring model is independently from languages, the proposed method can be applied to any languages by just chaining corpora.

3 Proposed Method

In order to discriminate personal opinions from commercial speech, the proposed method focuses on the difference of appearance ratios of words between two text corpora: corpus C_p and corpus C_n. Here, corpus C_p consists of text documents describing personal opinions and corpus C_n consists of text documents describing commercial speech. Using the two corpora, the subjectivity score of word w is defined as

$$s\left(w\right) = s_p\left(w\right) - s_n\left(w\right), \tag{1}$$

where $s_p(w)$ and $s_n(w)$ are defined as

$$s_p\left(w\right) = \frac{r_p\left(w\right)}{r_p\left(w\right) + r_n\left(w\right)}, \tag{2}$$

$$s_n\left(w\right) = \frac{r_n\left(w\right)}{r_p\left(w\right) + r_n\left(w\right)}, \tag{3}$$

here, $r_p(w)$ and $r_n(w)$ are the appearing ratios of word w in the corpus C_p and C_n, respectively. $r_p(w)$ and $r_n(w)$ are respectively defined as follows:

$$r_p\left(w\right) = \frac{\sum_{d \in C_p} f\left(w, d\right)}{\sum_{d \in C_p} \sum_{w' \in W(d)} f\left(w', d\right)}, \tag{4}$$

$$r_n\left(w\right) = \frac{\sum_{d \in C_n} f\left(w, d\right)}{\sum_{d \in C_n} \sum_{w' \in W(d)} f\left(w', d\right)}, \tag{5}$$

here, $W(d)$ is the set of words occur in document d, and $f(w, d)$ is the frequency of word w in document d.

Since subjective words like negative-meaning words are more frequently used in personal opinion rather than commercial speech [1,2], $s_p(w)$ is expected to be larger than $S_n(w)$ if word w is a subjective expression. The subjective scores of such words are expected to be positive ($s(w) > 0$). On the other hand, the subjective scores of words used in commercial speech tend to be negative.

Eliminating extremely-common words from a document is an important pre-process for text mining because these words give little meaningful information. In order to detect such common words, the document frequency of each word in a corpus is calculated. If word w occurs in over 99% documents in both corpus C_p and corpus C_n, the frequencies $f_p(w)$ and $f_n(w)$ are set as 0s.

Based on the subjective scores of words, the total subjectivity of a document d can be calculated as follows:

$$S\left(d\right) = \frac{1}{\left|W\left(d\right)\right|} \sum_{w \in W(d)} s\left(w\right), \tag{6}$$

where $W(d)$ is the set of words which appear in document d. If the subjectivity of a document is positive ($S(d) > 0$), the proposed method judges the text as personal opinions; if otherwise ($S(d) \leq 0$), the method judges the text as commercial speech.

4 Experimental Results

In order to confirm that the proposed method works independently from languages and subjects, we conducted 6 kinds of tasks (T1–T6) using different corpora. As corpus C_p (personal opinions) and corpus C_n (commercial speech) used in each task, we collected texts from different websites. Table 1 shows the source websites, the number of documents in each corpus, the language of the texts, and the topic of the texts. As shown in the table, in task T2, T3 and T4, the texts in corpus C_p and corpus C_n (personal opinions and commercial speech) were collected from the same websites. In these websites, documents are categorized into user reviews and professional reviews. In these tasks, the user reviews were assigned as the texts of corpus C_p (personal opinions) and the professional reviews were assigned as the texts of corpus C_n (commercial speech). There is obvious difference between minds of writers of the two types of documents. Professional writers tend to emphasize positive comments about subjects for their sponsors and seldom report negative comments about them. On the other hand, personal writers report any comments about subjects. For people who want to collect real public impression about subjects, user reviews would be more useful than professional comments. Therefore, professional reviews were regarded as commercial speech in the tasks.

The purpose of the experiments is to confirm whether the texts in corpus C_p (personal opinions) and the text in corpus C_n (commercial speech) were

Table 1. The details of corpora used in each task

Task	Language	Topic	♯ of documents	Sources of corpora
T1	Japanese	Product	C_p: 1980	Amazon.co.jp (https://www.amazon.co.jp/)
			C_n: 1975	Impress Watch (http://www.watch.impress.co.jp/)
T2	Japanese	Movie	C_p: 1496	映画.com (http://eiga.com/)
			C_n: 1706	映画.com (http://eiga.com/)
T3	English	Product	C_p: 4900	CNET.com (https://www.cnet.com/)
			C_n: 3803	CNET.com (https://www.cnet.com/)
T4	English	Movie	C_p: 990	Rotten Tomatoes (https://www.rottentomatoes.com/)
			C_n: 999	Rotten Tomatoes (https://www.rottentomatoes.com/)
T5	French	Product	C_p: 1147	Amazon.fr (https://www.amazon.fr/)
			C_n: 953	CNET France (http://www.cnetfrance.fr/)
T6	French	Movie	C_p: 692	SensCritique (https://www.senscritique.com/)
			C_n: 3093	Critikat (http://www.critikat.com/)

correctly classified by the proposed method. In addition, in order to clarify how the classification with the proposed method will generalize to an independent dataset, we used the technique of 10-fold cross validation [4]. That is, the texts in each corpus are divided into 10 subsets. By using 9 subsets as a training set, the subjectivity score of each word is defined by Eq. (1). Based on the subjectivity scores obtained with the training set, the classification is conducted for the texts in the remaining one subset. The training and classification are repeated 10 times by changing the combination of subsets for the training and test sets. Finally, the average performance across the 10 rounds is calculated.

For each round, the performance of classification results is evaluated with the F-value. The F-value is defined as follows:

$$F = \frac{2PR}{P + R}. \tag{7}$$

The F-value is the harmonic mean of the precision P and the recall R. The precision P and the recall R are defined as

$$P = \frac{|D_{\text{relevant}} \cap D_{\text{classified}}|}{|D_{\text{classified}}|}, \tag{8}$$

$$R = \frac{|D_{\text{relevant}} \cap D_{\text{classified}}|}{|D_{\text{relevant}}|}, \tag{9}$$

where D_{relevant} is the set of relevant texts, i.e., the texts of personal opinions in the test set, and $D_{\text{classified}}$ is the set of documents classified as personal opinions by the proposed method.

Table 2. The performances (F-values) of the proposed method in each task

Task	Maximum	Minimum	Average
T1	0.95	0.93	0.94
T2	0.93	0.88	0.90
T3	0.99	0.98	0.98
T4	0.99	0.97	0.98
T5	1.00	0.99	0.99
T6	0.98	0.96	0.97

The experimental results are shown in Table 2. In the table, the minimal, maximal and average F-values across the 10 rounds are shown for each task. From the table, we can confirm that in all the tasks (T1–T6), the high classification performances ($\bar{F} \geq 0.90$) were obtained. These results indicate that the proposed method can discriminate personal opinions from commercial speech independently from languages and subjects.

Figure 1 shows the distributions of subjectivity scores of the texts in corpus C_p and corpus C_n in used in each task. As shown in the figure, personal opinions and commercial speech can be clearly separated by the subjectivity score. These results indicate the effectiveness of the proposed scoring.

We analyzed frequently occurring words in personal opinions and commercial speech, respectively. Table 1(a) and (b) shows typical words in personal opinions and commercial speech, respectively. We have found that the words listed in Table 1(a) have high subjectivity scores and the words in Table 1(b) have negative subjectivity scores. As shown in the table, in personal opinions, subjective expressions, sentence-final particles (in Japanese), emoticons (in Japanese), and first-person singulars (in English and French) frequently occur. On the other hand, in commercial speech first-person plurals (in English and French) and neutral expression such as words just explaining the specification of a product. While negative-meaning expressions such as “bad” frequently occur in personal opinions regardless of its language, the appearance ratios of these words are

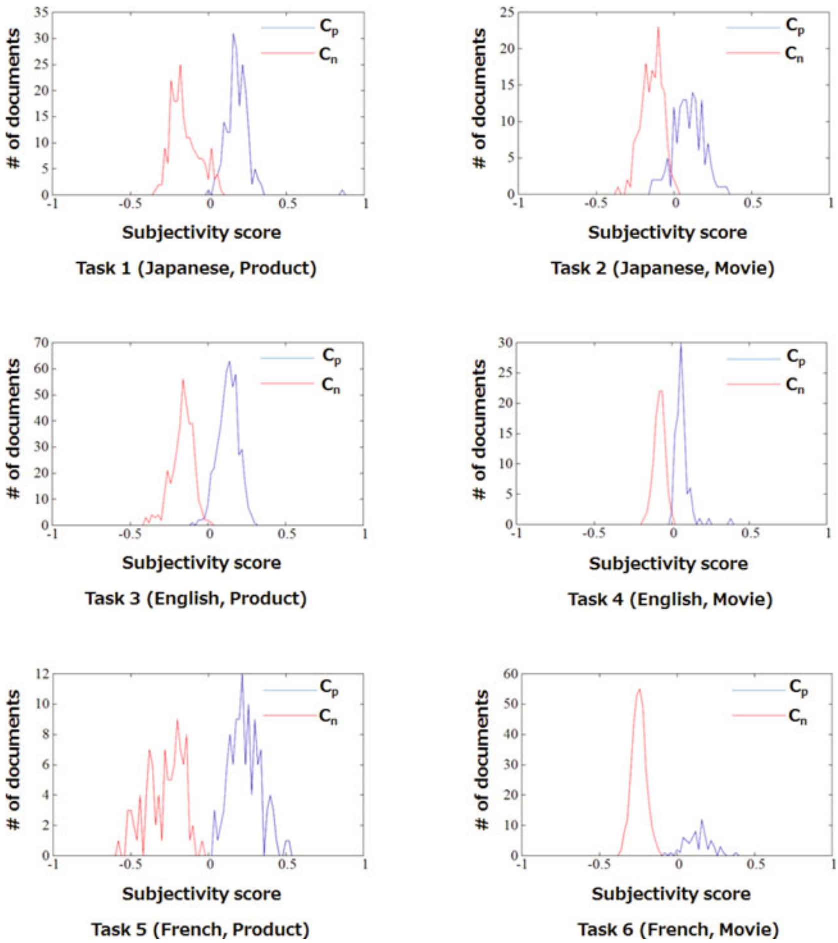

Fig. 1. The distributions of the subjectivity scores of the texts in corpus C_p (personal opinions) and corpus C_n (commercial speech) used each task

extremely lower in commercial speech. Sentence-final particles occur at the end of a sentence expressing linguistic modality. We have found sentence-final particles have high subjectivity scores, which indicate these words are useful for differentiating between personal opinions and commercial speech. Sentence-final particles are used in Asian languages including Japanese and Chinese. Further experiments applying the proposed method to other languages including Chinese texts remain as a future work (Table 3).

In the Indo-European languages including English and French, the subjects of sentences are helpful for differentiating personal opinions and commercial speech. For example, first-person singular is used in personal opinions but first-person plural is often used in commercial speech. These characteristics cannot be found

Table 3. Words frequently occurring in personal opinions and commercial speech

	(a) Personal opinions	(b) Commercial Speech
Japanese	**Subjective expressions** 悪い、良い **Sentence-final particles** かな、か、だな **Emoticons** (^^)/	**Neutral expressions** 液晶、搭載、監督、脚本
English	**Subjective expressions** good, bad, too **First person singular** I, my	**Neutral expressions** model, speed, drama, comedy **First person plural** We, our **Second person plural** You, your
French	**Subjective expressions** parfait, bon **First person singular** Je	**Neutral expressions** systeme, fiction **First person plural** Nous **Second person plural** Vous

in Japanese. This is because in Japanese the subject of a sentence is often absent. Although there is different usage of words in each language, with the proposed scoring method, informative words helping for decimation of personal opinions and commercial speech can be found automatically regardless of languages.

5 Conclusion

In this paper, we have presented a language-independent method for discriminating personal opinions from commercial speech. From the results of experiments using corpora written in different languages, we have confirmed that with the proposed method personal opinions can be effectively separated from commercial speech. Further experiments using other languages remain as a future work.

Opinion mining contributes to improve various phases in product-life cycle management such as improving the quality of customer service, creating new products, identifying the potential revenues, reducing the development cost, etc. The proposed method can be used as a method for data cleaning processing of opinion mining. Combining the proposed method with other post processing techniques in opinion mining such as sentiment analysis and visualization, we are planning to develop a comprehensive framework for opinion mining.

Abstract. During the last couple of decades, ICT sector became the most innovative service sector that affected the living standards of human beings all over the world. In the beginning of the 21st century, some of the Asian countries made reforms in the ICT sector and spent an enormous amount for the progress of this sector. On the other hand, developed countries in the European Union (EU) faced different crises which badly affected the dissemination of this sector. Consequently, EU countries lost their hegemony in the field of information technology and resultantly, some of the emerging Asian countries like China, India, and South Korea got supremacy over the EU in this field. Currently, these countries have a strong IT infrastructure, R&D sector, IT research centers working for the development of ICT. Moreover, this paper investigates reasons for the shifting of the balance of digital power from Europe to Asia.

Keywords: Information and communication technology (ICT) · Infrastructure · R&D · One belt · One road · Game changer · Supremacy

1 Introduction

The global economy is facing many challenges as advanced economies are declining and emerging economies continue to expand their grounds. The level and duration of these developments are unprecedented. Also, recent developments in the field of information and telecommunication technology (ICT) such as cloud computing affects the trend of economies. We can define the trend as a shift in the regional balance of power. As the world's economic balance of power is shifting quickly, this trend has been accelerated due to the global recession. China overtakes the United States as the world's largest economic power and India enters the race of these two countries as another big economy. After the great

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_39

global recession, the world's balance of economic power in term of gross domestic product (GDP) was gradually shifted to the South and East [9]. Currently, the western industrialized countries are trying to get the growth momentum after the recession tragedy but they haven't fully recovered yet. On the other hand, the developing nations including Asian countries suffered comparatively less than the industrial countries and recovered rapidly after the recession. In the next years, the developing Asian countries accelerated their industrial growth, particularly in information and communication sector [12,25].

A steep decline has seen with the occurrence of 9/11, which resulted in the steady attrition of economic certainty that finally concluded with the great geopolitical obstruct of the western financial crisis [1,7]. It has now become the truth of the 21st century that the western world (Europe) is rapidly losing its superiority in the field of ICT and is replaced by a new international system shaped by geographical entity known as Asia [7]. Asia has the greater most number of internet users around the world and it covers almost half of the whole world. On the basis of internet usage and population statistics, Asia covers 45.7% of the world internet users, while rest covers the remaining 54.3% (See Table 1 and Fig. 1).

Table 1. Analysis of internet usage in Asia and rest of the world

Region	Population Est. 2016	% Population of the world	Internet users on 30/06/2016	Penetration (% Population)	% Internet users
Asia	4,052,652,889	55.20%	1,846,212,654	45.60%	50.20%
Rest of world	3,287,506,603	44.80%	1,829,612,159	55.70%	49.80%
World total	7,182,406,565	100%	3,035,749,340	42.30%	100%

Source: Internet World Stats, (www.internetworldstats.com/stats.htm)

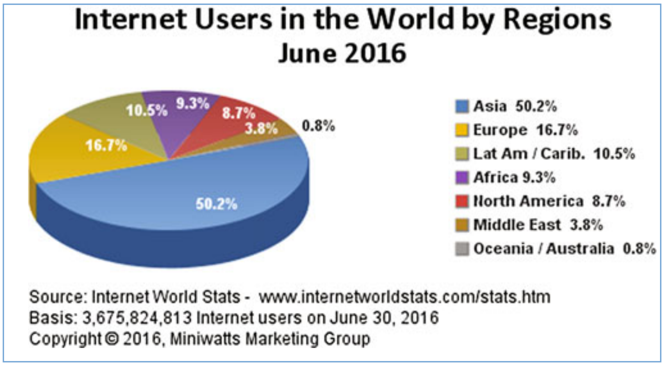

Fig. 1. Internet users in the world by regions

The above analysis shows the internet penetration and usage in Asia and rest of the world. The figures clearly describe the shift of technology towards Asia. Although due to low GDP and poverty, many people in Asian countries do not have access towards internet but the figures show richer tendency for these countries. China has one of the biggest communication network in Asia, as well as in the whole world. The ICT semiconductor industry has become one of the key industry of People Republic of China and has a huge potential to do business in ICT. This industry has undergone a rapid change of growth and development during the past decade [15]. The ICT sector in Asia includes goods and services that process, transmit or receive information. It includes technologies such as hardware, software, computer services, microelectronics, e-learning, e-business, e-health, multimedia, as well as emerging technologies such as photonics, fixed and mobile network convergence, life sciences, environmental sciences, Internet of Things, mobile internet, cloud computing and digital imaging [26].

2 Research Background

2.1 Literature Review

According to realist approach, the potential for clashes among great powers is an old story in the international system [4,8,19]. European Commission research scholars in EU Monthly Magazine predicted about the multi-polar world in 2025. It described that it is likely for the world to become truly multi-polar and reflecting the new balance of power, and the loss of US leadership. It further predicted that if the US remains the first military power, the scientific and technological advancement of some Asian states in new irregular war tactics like cyber-war and cyber-attacks will weaken the hegemony of US in information and communication technology [4,6,11,23]. Some authors give much importance to ICT even four decades before and predicted that the rise of a post-industrial society would be information centered and marked by a shift from production to service job [18,27,31].

The world's economic balance of power is shifting rapidly from North to South, and the trend has been accelerated by the global recession [1,9,30]. Kenichi Ohmae developed a concept of a "Triad", he predicted that the world economy including the information technology will be led by the United States, Japan, and the European Union [13]. But in present circumstances, the concept of Kenichi seems to have become concealed by a new order consisting of China, United States, and India in the field of ICT. Uri Dadush presented a model in a chapter of book "Handbook of Emerging Economies", in which he argued that the shift of technological balance from North to South is increased after the global recession. He considered technology as the most important element than the other factors for economic growth of both groups [16,24].

2.2 Conceptual Framework of ICT

The conceptual framework can be observed from the Fig. 2 which classifies economic and social benefits of ICT as well as the poverty outcomes. It clarify the concept that how ICT can promote economic and social benefits in a society.

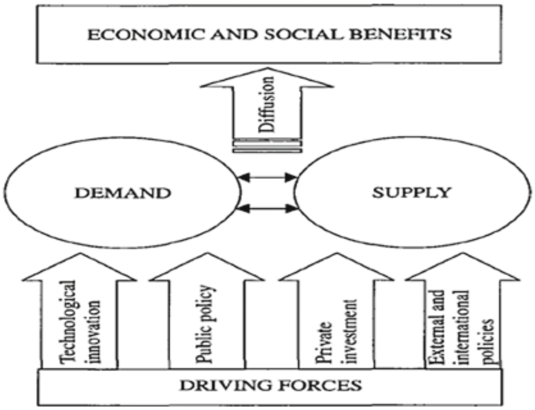

Fig. 2. A conceptual framework of ICT and development

The diffusion of ICTs, like other innovative technologies, proceed with three particular stages introduction, growth and maturity [17]. The ICT skills and infrastructure vary from country to country and is analyzed according to these three stages.

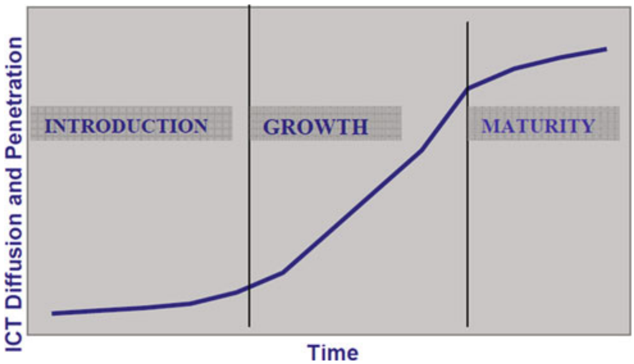

Fig. 3. ICT diffusion at three stages

Figure 3 shows that if a country developed, not only the mass of ICT users and practitioners increased but the necessary infrastructure for ICT must be developed. During the growth stage the diffusion rate is fast and is continuous until the maturity has been attained. The conceptual model of ICT diffusion will able the government and policy makers to adjust their goals and strategies in order to move from one stage to another stage. The proposed model will help the policy makers to improve the ICT skills and infrastructure in a way that it will reach to the next stages of the model.

3 A Comparative Analysis of Emerging Asian Economies and Europe

The recent development in ICT in the Asian region has accelerated the GDP growth of emerging Asian countries. Furthermore, the Asian region receives massive investments in the field of ICT, including both local and foreign investments. Most of the Asian countries attract massive investment through the sector of ICT. In this regard, the People Republic of China is on the top among the other emerging states followed by Russia, Brazil, and India. China is the biggest supplier of ICT equipment, while India has developed IT city called Silicon City (Bangalore).

The share of ICT in GDP has been decreasing gradually from the last several years in Europe, which dropped from 6.6% in 2009 to 5.9% in 2013. While the situation in emerging countries (mostly Asian and Asia pacific countries) in 2009 have accounted for third of the telecom services revenue and in 2013 it received almost 40% of the total world telecom revenue [3,5]. As a result, the gap in the growth rate and development of ICT between the developed countries and emerging countries became wider in 2013. In 2013, the balance in power regarding ICT kept on shifting to emerging countries continuously and become shared 80% of global growth contributing almost more than third of the world ICT market [29]. The comparison of ICT market growth and GDP are shown n the Table 2.

Table 2. Comparison of growth rates in advanced and emerging Asian countries

		2010	2011	2012	2013	2014
Advanced economies	Digiworld market growth	2.60%	1.30%	1.00%	1.10%	2.40%
	GDP growth	4.20%	3.70%	3.10%	2.60%	3.90%
Emerging Asian economies	Digiworld market growth	9.70%	10%	7%	7.70%	7.90%
	GDP growth	15.70%	13.20%	9.30%	10.10%	10.30%

4 Factors Influencing the Transfer of Digipower to Asia

The following are the some key reasons that cause the shift of balance of ICT in the favor of Asia from Europe.

- Single Telecommunication market (Monopoly)
- Fragmentation of digital market in Europe
- Influence of financial crisis in early years of 21st century
- Complex ICT Regulations that cause decrease in investment
- Economic Crisis
- Coalition against "war on terror"

Table 3. Global digiworld market by region

Billion ϵ	2012	2013	2014	2015	2018

The Table 3 shows the breakdown of digiworld in the region, it also have some predictions about the ICT market globally. The Fig. 4, also give a graphical picture of the percentage share of ICT market contribution throughout the world. The Figure clearly shows that the emerging Asian countries surpass the Europe in ICT market share following US.

4.1 Transfer of Digipower to Asia

Some scholars also state that the rise of Asia, particularly China will enable Beijing to pressurize US and the other western countries, not only through military power, but in the field of technology as well, which will lead to an "open and intense geopolitical rivalry". China will rise and become a new power throughout Asia [10,22,28]. According to the analysis of European Commission Joint Research Centre, China, Korea and Taiwan are the three highly specialized countries in ICT manufacturing, who have continued to strengthen their positions in the global ICT market [14]. China is the most obvious power on the rise in the present world scenario regarding ICT. In this study, China is the subject matter, because it not only belongs to the group of emerging economies growing very rapidly [2]. China took the lead among other regional states due to both its specialization in manufacturing of IT equipment and its economic size. Moreover,

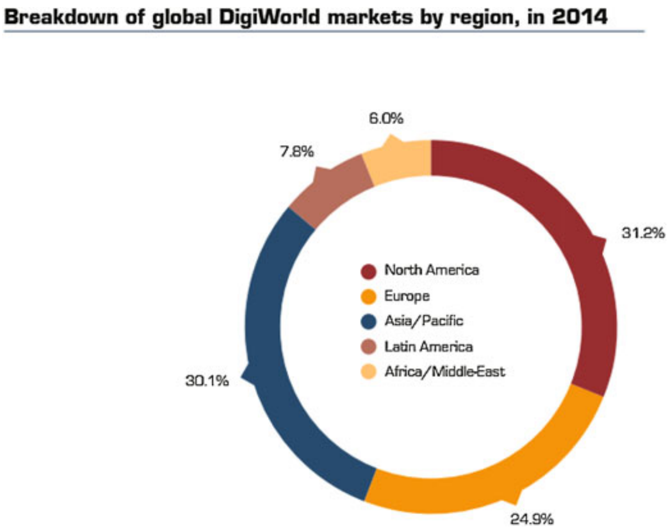

Fig. 4. Breakdown of global ICT market by region

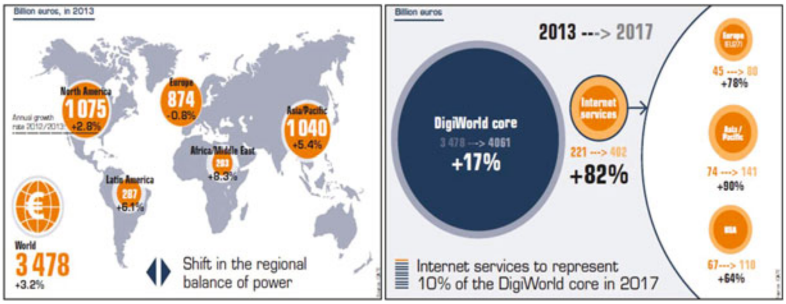

Fig. 5. Shift in the regional balance of power from Europe to Asia (ICT)

India and other emerging Asian states, which are now promoting their ICT sector, and can possibly surpass few major western states in the upcoming decades. The transfer of digital power ICT from West to Asia is getting velocity and may soon change the perspective for dealing with the global challenges. West is already aware of Asia's increasing potency in ICT.

The key lesson learnt from the international point of view is that, China, Korea and Taiwan having a large ICT manufacturing sector, have an important potential for growth, particularly, as the important resources like expenditures and qualified staff. In other words they have strengthened the ICT and R&D sector. While the US has dominance over EU due to its high productivity level of manufacturing as well as high R&D resources in order to retain its competitiveness in global ICT market [20, 21]. The detailed comparison and contribution of Asian countries and Europe in the world market (in ICT sector) are given in Fig. 5.

5 Conclusion

The facts and figures outlined in this paper show that the balance of power in information and communication technology (ICT) is drifting slowly and gradually towards Asia from Europe. Asia is a densely populated region with more than 2.8 billion people, living in a land fertile for IT and communication industry, with cheap labor and capital, rich raw resources and tremendous absorbing capacity for new technologies and developments. All these factors are molding the situation in favor of emerging Asian countries and shifting the regional balance of power in ICT towards Asia. The development of ICT has been the main objective of most of the Asian countries in changing the global environment towards the Asian region in terms of communication and technology. New Silk Road is an example of this strategy. Besides, US as the ICT giant has its own strategies towards occupying the information and communication market. This will require the sacrifice of core national interests in the short run. At the same time, China and other Asian emerging countries can get the dominancy in ICT sector only if these could ensure the interests of other countries according to their own ways in the long run.

Abstract. This study investigates the impact of rent-seeking behavior, political connections, and government science and technology (S&T) subsidies on the research and development (R&D) of private listed enterprises. Based on empirical data of China's private listed enterprises between 2008 and 2012, this paper performs validation at three levels and obtains suggestive conclusions. First of all, the purpose to obtain more S&T subsidies motivates private listed enterprises to take rent-seeking activities which can facilitate them in establishing political connections (PCs). Secondly, rent-seeking activities could eventually result in crowing-out effect of the R&D input, especially for the local PCs. Thirdly, the side effect of rent-seeking is more significant for enterprises located in provinces of high corruption levels, which weakens the availability of government S&T subsidies. The improper intervention of government distorts the market resources allocation.

Keywords: Rent-seeking · Political connections · Government subsidy · Research and development

1 Introduction

During the "supply-side reform", China's economic development mode is transforming from "factor-driven" to "innovation-driven", so it is critical to strengthen the R&D of enterprise innovations. But funding and policy restraints make it difficult for small and medium-size private enterprises to carry out project research. Since the process of research and innovation is a long high-risk investment period, it is necessary for governments to provide various incentives and subsidies so as to promote enterprises R&D. However, through the economic transition, private listed enterprises, especially small ones, suffered from

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_40

"explicit" or "hidden" discrimination in policies especially in terms of financial resources and government subsidies.

Plenty researches have recognized that enterprise can promote development by political connections, benefiting from the government subsidies, financing convenience, and tax preference [2,6,21]. Since PCs can bring huge economic benefits, enterprises are intent to ingratiate with government officials by rent-seeking activities for the purpose of getting more S&T subsidies [17]. There are many studies investigating the effects of the PCs and government subsidies on the enterprise performance. Wu [22] finds the state-owned enterprises can receive more subsidies than private enterprises, which points out that PCs can help enterprises obtain S&T subsidies. Meuleman and Maeseneire [16] found the government subsidies promote enterprises to innovate. Xu [25] analyze the signal effect of the government subsidies. But on the other side, S&T subsidies will crowd out the enterprise R&D input [26]. Some empirical results indicate that political connections are more likely to serve a binding function [28]. However, beyond that, it still lacks detailed discussions of how PCs and S&T subsidies affect the R&D input, fairly clear explanations of why the S&T subsidies failed to make effects, and intuitive evidences of the crowding-out effect of rent-seeking corruptions on R&D input.

In order to enrich the research of this field, this paper designs the three levels of verification: first, to test if rent-seeking activities help maintain the PCs; second to verify if it will crowd out the enterprise R&D input; lastly, to investigate if corruption levels in enterprise provinces will make a difference and whether it will ruin the utility of S&T subsidies.

The contributions of this study are as follows. Firstly, it provides empirical evidence of the economic consequences of establishing political connections and obtaining S&T subsidies on the enterprise R&D input. Secondly, it enriches the explanation for the failure of government subsidies. It is found that although rent-seeking activities facilitate establishing PCs and makes it easier to get government S&T subsidies, it reduces the utility of government subsidies. Thirdly, this study also provides microcosmic evidence that government S&T subsidies may distort the social resource allocation under certain conditions.

2 Theoretical Analysis and Research Hypothesis

2.1 Rent-Seeking and Political Connections

Political connections mean close connections between the internal personnel of the enterprise and government officials, or participation in political affairs. However, political connections do not mean corruption [6]. The existing financial and legal systems in China still cannot fully meet the various needs of the transition of economic development patterns, and the distribution of resources is mainly driven by the government, which all lead to the current situation that enterprises scramble for more opportunities by seeking for informal ways under the development pressure [1,15]. Under the special period of "adjusting structure and transition of patterns", and increasingly drastic market competition in China, enterprises are trying to gain more financial resources or policy welfares through such "recessive capitals", namely the PCs [23,29,30].

In these situations, enterprises in China must have strong motivation to establish PCs by rent-seeking [4]. Therefore, the following hypothesis is proposed:

Hypothesis 1: Rent-seeking can help enterprises establish PCs.

2.2 Rent-Seeking and Enterprise R&D

Now, the formal institutions are weak in China [5]. Corruption and rent-seeking distort fiscal and monetary policy [3,8]. Entrepreneurs are more likely to spend time and resources on rent seeking rather than on productive activities in order to influence governments [4]. Under weak institutional contexts, enterprises have to satisfy government's requirements, which aggravates burden on enterprises [14]. In this condition, government subsidies can deteriorate corporate performance. Quevedo [7] proposed that government S&T subsidies have a negative effect on the R&D expenditure, namely the crowding-out effect. Huang [9] made a case study on Chinese listed companies between 2001 and 2007, finding that PCs have a promoting effect on the performance of SOEs, but negative impact on private listed enterprises.

Following the normal logic of enterprise behavior, the following hypothesis is proposed:

Hypothesis 2: Enterprises are intent to establish PCs by rent-seeking for obtaining more government S&T subsidies, but it will lead to crowding-out effect on R&D input.

2.3 S&T Subsidies and Enterprise R&D

As is recognized, government S&T subsidy are important for enterprises, which can alleviate market failures in R&D activities [11,24]. Levin and Reiss [13] studied the relationship between government subsidies and R&D output on the micro level, finding that government subsidies have a remarkable role in promoting R&D. Lee and Cin [12] drew the same conclusions by considering different country samples and selecting panel data for several years. The government R&D subsidies contribute to both green innovations [19] and sustainable innovations [10]. Yet, there are opposite opinions. Zhang [27] found subsidies, in long and short terms, have significant positive effect on the financial performance of wind energy manufacturing companies. In renewable energies sector, subsidy policies could cause adverse consequences to a certain extent [20]. The current economic transition period in China, is combined with a serious rent-seeking phenomenon and ethical risks, so the establishment of PCs may consume a tremendous amount of manpower and material resources for enterprises and thus fail to improve the performance.

Therefore, the following hypothesis is proposed.

Hypothesis 3: In provinces with serious corruptions, the rent-seeking results in more significant crowding-out effect, frustrating the availability of government S&T subsidies.

3 Research Design and Sample Selection

3.1 Sample

The original sample contains the non-financial private A-share companies listed in Shanghai and Shenzhen Stock Exchange during 2008–2012. The final sample keeps 361 companies listed 1614 totally after basic sample processing.

The major data used in the empirical part includes: the detailed government subsidies data, PCs data, basic enterprise data, post crime data at the provincial level and the excess administration expense data. The data was derived from the CSMAR and WIND database, the China inspection yearbook and China statistical yearbook. Most of them need manual calculation.

3.2 Model Setup and Variable Definition

To test *Hypothesis 1*, we set up the following probit regression model

$$P_{\mathrm{Poli},i,t} = \alpha + \beta_1 \times \mathrm{Rent}_{i,t} + \beta_2 \times X_{i,t} + \varepsilon_{i,t}. \tag{1}$$

To illustrate the robustness of conclusions we also set up the following logistic model:

$$\log\left(\frac{P_{\mathrm{Poli},i,t}}{1 - P_{\mathrm{Poli},i,t}}\right) = \alpha + \beta_1 \times \mathrm{Rent}_{i,t} + \beta_2 \times X_{i,t} + \varepsilon_{i,t}. \tag{2}$$

Here, $P_{\mathrm{Poli},i,t}$ is the probability that company i established political connections in year t. Correspondingly, $\mathrm{Poli}_{i,t}$ represents the dummy variable of PCs in year t while Loca represents the dummy variable of central PCs. Then, referring to the treatment methods proposed by Yu et al. [17], the participation in the politics of private listed companies is depicted by whether the directors and senior executives of listed companies have held a position in the National People's Congress (NPC), Chinese People's Political Consultative Conference (CPPCC) or government sectors. Specifically, $Poli_{i,t}$ is defined as 1 if the directors or senior executives have been the members of the NPC or CPPCC, or held a position at a government sector, otherwise it is 0. $\mathrm{Loca}_{i,t}$ is the same way defined for the local NPC, CPPCC, or local government sectors.

$\mathrm{Rent}_{i,t}$ represents the excess administration expense of company, a proxy variable of rent-seeking, which should be calculated as with a regression process introduced by RichardsonM [18]. The excess administration expense is the in-sample forecast residuals of the regression between the ratio (management cost/operating income) with a series of factors based on the historical data.

To verify *Hypothesis 2*, we set up the following model:

$$\log \mathrm{Devlpexp}_{i,t} = \alpha + \beta_1 \times \log \mathrm{SciSubsiby}_{i,t} + \beta_2 \times \mathrm{Rent}_{i,t} + \beta_3 \times X_{i,t} + \varepsilon_{i,t}, \tag{3}$$

where $\log \mathrm{Devlpexp}$ is the logarithm of corporate R&D investment; $\log \mathrm{SciSubsidy}$ represents the enterprises' S&T subsidies from government.

To verify *Hypothesis 3*, we set up the following model:

$$\begin{aligned}\log \mathrm{Devlpexp}_{i,t} = \alpha &+ \beta_1 \times \log \mathrm{SciSubsiby}_{i,t} + \beta_2 \times \mathrm{Rent}_{i,t} \\ &+ \beta_3 \times Poli_{i,t} + \beta_4 \times X_{i,t} + \varepsilon_{i,t}.\end{aligned} \tag{4}$$

On the basis of model (3), model (4) adds the PCs variable Poli, and the sub-sample regression for local PCs companies. In addition, the regression is divided into different groups according to the corruption level in the provinces. The corruption level is depicted by the corruption and bribery cases registered every 10 thousand public officers, which is exactly the ratio of registered post criminal cases at the provincial level to the number of civil servants.

In the model (1) & (2), X is a multiple vector of control variables including: the logarithmic company size ($\log$ Asset), rate of asset (ROA), debt-to-assets ratio(Dbassrt), establishment years (EstAge), the logarithm of top three executive compensations (LogMane3Pay), the duality of CEO and chairman

Table 1. Descriptive statistics of variables from groups with different PCs (10,000 yuan)

	Companies without PCs			Companies with PCs			Companies with local PCs		
	Mean	sd	Med	Mean	sd	Med	Mean	sd	Med

Top three executive compensation	1.18	1.17	0.9	1.34	1.36	1.05	1.16	0.9	0.97
Excess administration expense	−0.01	0.12	−0.01	0	0.15	−0.01	0	0.07	−0.01
Top three directors' compensation	1	0.97	0.75	1.27	1.61	0.88	1.04	1.03	0.79
The proportion of independent directors	0.37	0.05	0.36	0.36	0.05	0.33	0.36	0.04	0.33
The duality of CEO and chairman	0.19	0.39	0	0.18	0.38	0	0.24	0.43	0
Corruption level	24.08	5.67	24.31	24.52	6.78	24.31	24.4	7.34	24.31

(Chairman&CEO is defined as 1 for duality), the proportion of independent directors (IndeDirRatio), year control variable, industry control variable (Industry is defined as 1 if the company belongs to the national key support, highly regulated or monopoly industries, otherwise 0 [17].

3.3 Descriptive Statistics

It can be seen from Table 1, politically connected companies obtain more government S&T subsidies in average which is consistent with the previous literatures view that political connections help obtain the government subsidies. At the same time, the politically connected enterprises have relatively higher overheads and excess administration expense, indicating that rent-seeking may exist.

Table 2. Descriptive statistics of variables between groups with different excess administration expense

	Low excess administration expense			High excess administration expense		
	Mean	sd	Med	Mean	sd	Med
S&T subsidies (10,000 yuan)	5.87	24.78	0	10.47	51.32	0
T&D input (10,000 yuan)	44.51	107.41	16.34	148.96	359.71	41.77
Overheads (10,000 yuan)	192.9	230.08	130.62	531.86	773.28	287.51
R&D input/Overheads	0.21	0.23	0.11	0.23	0.26	0.13
Operating income (10,000 yuan)	3903.8	6600.95	2171.7	11630.4	18952.16	4605.86
Overheads/ Operating income	0.07	0.04	0.06	0.13	0.27	0.07
Total asset (10,000 yuan)	5773.42	10141.05	2899.96	11278.23	17493.17	5611.22
Top three executive compensation (10,000 yuan)	1.18	0.89	0.96	1.54	1.83	1.14
Top three directors' compensation (10,000 yuan)	1.1	1.28	0.8	1.36	1.9	0.93
The proportion of independent directors	0.37	0.05	0.33	0.36	0.05	0.33
The duality of CEO and chairman	0.16	0.37	0	0.13	0.33	0

On the basis of Table 2, though the enterprises with high excess administration expense can obtain more S&T subsidies, they do not show any significantly higher ratio of R&D input/overheads but get higher ratio of the overheads/operating income. It may be caused by the crowding out effect from the rent-seeking behaviors, namely the existence of corruption and rent-seeking reduce the efficiency of the use of government S&T subsidies.

4 Empirical Results and Analysis

4.1 Rent-Seeking Behavior and Political Connections

Note: Robust standard errors in parentheses, ***Significant at 0.01, **Significant at 0.05, *Significant at 0.1.

ical connections. The regression results of probit model reflect a significantly positive coefficients of Rent and the first-lagged Rent as well. It suggests that excess administration expense can help enterprises establish political connections, which is companied with hysteresis effect. To maintain the robustness of the conclusion, the logistic model is conducted at the same time and the results are basically the same as the probit models, which shows a robust estimating conclusion.

4.2 Rent-Seeking Behavior and Enterprise R&D Input

Based on the results of the *Hausman* test and *Wald* test, corresponding regression models are applied to test the influences of government S&T subsidies and excess administration expenses on enterprise R&D input. Table 4 contents the regression results of groups with different political connections. Comparing the regression in columns 1 and 2, the coefficient of *Rent* is significantly negative for companies with PCs, indicating that high excess administration expense will probably reduce the R&D input. Overall, test results of the Hypothesis 1 draw the conclusion that enterprises are intend to establish political connections through rent-seeking which makes it easier to acquire government S&T subsidy. According to the motivation of establishing PCs, we can infer that the pursuance of government S&T subsidies will stimulate more rent-seeking activities which eventually result in crowding-out effect on the primary business performance.

Under the fiscal decentralization system in China, local governments are empowered with great administrative power and relatively weak financial power since the tax reform. When local governments try to obtain more resources through extra-budgetary way with less supervision, it is prone to create rent-seeking corruptions between local governments and enterprises. At the same time, the local governmental officials have strong discretionary power in science subsidy and financial support (including rewards) which has no explicit restriction in laws or regulations. So the difference between enterprises with and without local political connections are further investigated as regression results in columns 3 and 4. The variable Rent has a significantly larger negative coefficient than total sample in columns 1, which suggests that local PCs will cause higher rent-seeking cost and worse impact on the enterprise's performance.

4.3 R&T Subsidies and Corporate R&D

Following the *Hausman* test and *LR* test, corresponding regression models are applied to test the hypothesis 3 and results are listed in Table 5. Compared to the low corruption group, high corruption group in columns 1 and 2 showed distinctly negative effect of variable Rent. The figures illustrate that rent-seeking behavior will lead to substantial crowding-out impact on the R&D of enterprises in provinces with serious corruptions. On the other hand, coefficients of log SciSubsidy are almost significantly negative in columns 1 and 2, but positive in columns 3 and 4. Thus for high corruption group, the government S&T subsidies probably cause negative impact on the enterprise R&D. It is because enterprises have to invest great manpower and resources for rent-seeking, which will fail the fulfill use of S&T subsidies and crowd out scientific research innovation input. In addition, the coefficient of Loca is significantly negative in column 2, suggesting that the local PCs will strengthen such side effect, which is consistent with the results in Table 4.

Table 4. Test results of the Hypothesis 2

Variable	log Delpexp

4.4 Robustness Analysis

To guarantee the robustness of conclusions, we build logistic and probit models. Considering the possible endogenous problems, the lagged excess administration expense is added into the test of Hypothesis 1, As for hypothesis 2 and 3, we use the current and previous budget of technology spending from enterprise‘s local government as the instrumental variable to conduct two-stage least squares regressions, the exogeneity of the government budget avoid the two-way causality problem. The results are basically consistent, indicating the reliability of conclusions.

5 Research Conclusions

We find evidence that rent-seeking behavior facilitate private listed enterprises in establishing PCs and thus obtaining more S&T subsidies. However, it is proved that rent-seeking activities will finally result in crowing-out effect of the R&D input, especially for the enterprises located in the province of higher corruptions. For such companies, the PCs are closely related to the S&T subsidies, which breeds severe rent-seeking corruption and weakens the availability of subsidies. Our results support the idea that PCs can result in rent-seeking corruption, because enterprises are motivated to ingratiate with government officials by rent-seeking activities for the purpose of getting more S&T subsidies. And it turns out that the crowding-out effect of such activities will eventually fail the availability of subsidies. The PCs and S&T subsidies cannot effectively promote corporate performance or improve the development of the whole society, but only serve for a few entrepreneurs and politicians. The government should regulate the allocation of government subsidies, and have a reasonable control over local government powers to improve the efficiency of the whole market and stimulate the enthusiasm of enterprise innovation.

Abstract. A location arc routing problem (LARP) is an important issue that finds the best locations of depots and routing simultaneously. It deals with a routing problem, in which demands are on arcs instead of nodes. Additionally, parameters may not be deterministic in real problems. Thus, this paper addresses an uncertain LARP through developing a deterministic mathematical model regarding to the respective literature and employing two scenario-based approaches. The objectives of the model are to minimize the maximum regret and minimize the mean and deviation of the objective function value (OFV). A numerical example is generated and the results analyze the performance of scenario-based models.

Keywords: Location arc routing · Mathematical model · Scenario-based · Regret

1 Introduction

An important cost of the most of companies is their logistic costs. It can be reduced through appropriate planning and designing supply chains. In fact, distribution networks in supply chains are highly important [9]. The location problem aims at finding optimal locations for facilities or centers. In fact, one of the most important factors in the success of a production unit is determining appropriate locations of sites and also, on a smaller scale, production facilities. Therefore, finding optimal or near-optimal solutions is essential. Vehicles routing, on the other hand, is among the most challenging issues in supply chain management. These two issues affect the cost of networks and supply chains. Hence, the location-routing problem (LRP)is defined to determine the location and routing decisions in at the same time. It is a combination of both location and routing optimization problems, whose decisions are made at the same

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_41

time. In recent years, several LRPs were presented. Considering the LRP, better logistics could be designed [4].

In general, routing issues may be defined on a graph of number of nodes and arcs. The LRP deals with routing problems where demands are on nodes. One related issue which has been considered in recent years by some researchers is the routing problem when demands belong to arcs instead of nodes. Arc routing is a special type of routing problems. In this content, researchers have taking into account the conditions and restrictions in real applications, a variety of models, and methods for solving these problems. Ghiani and Laporte [5] addressed a problem and solved it based on the concept of the rural postman problem (RPP) as one the earliest studies on arc routing problems. There are many researches in this filed. For example, Pia and Filippi [8] addressed a capacitated arc routing problem (CARP) to consider a waste collection problem and Beullens et al. [1] employed some heuristics for a periodic CARP.

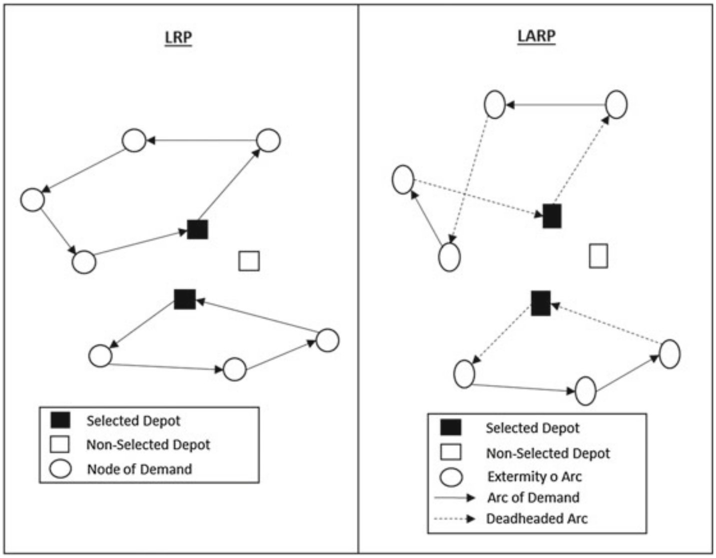

Fig. 1. LRP versus LARP

The location arc routing problem (LARP) is emerged when arc routing decisions are made along with location ones. The difference between the LRP and the LARP is displayed by Fig. 1. Waste collection, mail delivery, and telecommunication network design is among most well-known problems in which LARP could be addressed [7]. Also, some node routing problems could be considered as an arc routing one. For instance, when there are supermarkets as the nodes of demand, one can convert a node routing to an arc routing problem; because the street with N supermarkets is an arc with an aggregated demand from them. It might reduce the complexity of the problem. It means that a LARP could be defined for a lot of real applications. Firstly, Levy and Bodin [2] considered a LARP by which a mail delivery problem is taken into account. Then, Ghiani and Laporte [6] employed some heuristics to deal with a LARP. Lopes et al. [11] developed a mathematical model for LARP. In addition, Hashemi and Seifi [3] developed two mathematical models for single-depot and multiple-depot LARPs, respectively. One the latest works is what Riquelme-Rodrłguez et al. [10] presented which deals with a LARP with inventory constraints.

The paper on hand addresses a LARP by developing a mathematical model. Also, according to the uncertain nature of the data and information in the real world, we intend to build our research based on this fact. In our best of knowledge there is a gap in considering uncertainties in LARP. So, two scenario-based approaches are employed in the developed mathematical model. Section 2 defines the problem and notations and develops a deterministic mathematical model for LARP. Section 3 deals with two scenario-based approaches and modifies the mathematical model for each. In Sect. 4 a numerical example is analyzed based on the mathematical models. Finally, we conclude the paper.

2 Deterministic LARP Model

There is a complete graph $G = (V, A)$ where V and A denotes the set of vertices and set of arcs, respectively. V is consisted of K as the set of potential depots and R as the set of extremities of arcs, $\mathrm{V} = \mathrm{R} \cup K$. Each arc denoted by (i, j) which means that the arc begins form vertex i and ends at j. There is a given number of homogenous vehicles for each potential depot in a set called P. Then each depot is able to have $|P|$ separate tours. Some arcs have positive demands and the demand of arc(i, j) equals the demand of arc(j, i). This means that both of them are not required to be serviced and it is sufficient to meet the demand of one of them. The problem is finding optimal depots among the potential ones, assign vehicles and arcs to them, and traverse those arcs in an optimum routing. It is assumed that arcs with positive demands must be serviced once by a vehicle and also split delivery of demands is not allowed. Number of deadheaded traversing in each arc is not limited. In addition, tours must begin from a depot and end to the same one. In the deterministic model are parameters are given in advance. Following notations are introduced to develop the mathematical model.

Parameters:

F_k: Establishment cost of depot k;
C_{ij}^{k}: Servicing cost of required arc (i, j) by depot k;
H_{ij}^{k}: Deadheading cost of required arc (i, j) by depot k;
W: Hiring cost of each vehicle;
D_{ij}: Demand of arc$(i, j) \in R$;
Q: Vehicle's capacity;
B_k: Capacity of depot k.

Variables:

x_{ij}^{pk}: Binary variable which equals 1 if required arc(i, j) is served by vehicle p of depot k;
y_{ij}^{pk}: Number of deadheaded traverses in arc(i, j);
f_{ij}^{pk}: Departed flow form arc(i, j);
v_{ij}: Binary variable which equals 1 if arc(i, j) has a positive demand;
q_{pk}: Binary variable which equals 1 if vehicle p of depot k is established;
g_{pk}: Departed flow form depot k by vehicle p;
z_k: Binary variable which equals 1 if depot k is established.

Regarding the assumptions and notations the mathematical model for the deterministic LARP is developed as below. As a matter of fact, this model is inspired by what is developed in [3].

$$\min \theta = \sum_{k} z_k F_k + \sum_{i,j,p,k} x_{ij}^{pk} C_{ij}^{k} + \sum_{i,j,p,k} y_{ij}^{pk} H_{ij}^{k} + \sum_{p,k} q_{pk} W \tag{1}$$

$$\text{s.t.} \sum_{k \in K, p \in P} (x_{ij}^{pk} + x_{ji}^{pk}) = v_{ij}, \forall (i, j) \in R \tag{2}$$

$$\sum_{k \in K, p \in P} (x_{ij}^{pk} + x_{ji}^{pk}) = 0, \forall (i, j) \in K \tag{3}$$

$$\sum_{i \in V} (x_{ij}^{pk} + y_{ij}^{pk}) - \sum_{i \in V} (x_{ji}^{pk} + y_{ji}^{pk}) = 0, \forall j \in V, \forall p \in P, \forall k \in K \tag{4}$$

$$q_{pk} \leq z_k, \forall p \in P, \forall k \in K \tag{5}$$

$$\sum_{j \in R} (x_{kj}^{pk} + y_{kj}^{pk}) = q_{pk}, \forall p \in P, \forall k \in K \tag{6}$$

$$\sum_{j \in R} (x_{jk}^{pk} + y_{jk}^{pk}) = q_{pk}, \forall p \in P, \forall k \in K \tag{7}$$

$$x_{ij}^{pk} + y_{ij}^{pk} \leq M q_{pk}, \forall (i, j) \in V, \forall p \in P, \forall k \in K \tag{8}$$

$$x_{ii}^{pk} + y_{ii}^{pk} = 0, \forall i \in V, \forall p \in P, \forall k \in K \tag{9}$$

$$\sum_{i \in K, i \neq k} y_{ij}^{pk} = 0, \forall p \in P, \forall k \in K \tag{10}$$

$$x_{ij}^{pk} \leq D_{ij}, \forall (i, j) \in R, \forall p \in P, \forall k \in K \tag{11}$$

$$D_{ij} \leq M v_{ij}, \forall (i, j) \in R. \tag{12}$$

$$\sum_{p \in P} q_{pk} \leq |P|, \forall k \in K \tag{13}$$

$$g_{pk} \geq \sum_{i,j} D_{ij} x_{ij}^{pk} - M(1 - q_{pk}), \forall p \in P, \forall k \in K \tag{14}$$

$$g_{pk} \leq \sum_{i,j} D_{ij} x_{ij}^{pk} + M(1 - q_{pk}), \forall p \in P, \forall k \in K \tag{15}$$

$$g_{pk} \leq Q q_{pk}, \forall p \in P, \forall k \in K \tag{16}$$

$$\sum_{p \in P} g_{pk} \leq B_k, \forall p \in P, \forall k \in K \tag{17}$$

$$\sum_{i} f_{ij}^{pk} - \sum_{i} f_{ji}^{pk} = \sum_{i} D_{ji} x_{ji}^{pk}, \forall (i,j) \in V, \forall p \in P, \forall k \in K \tag{18}$$

$$f_{ij}^{pk} \leq Q(x_{ij}^{pk} + y_{ij}^{pk}), \forall (i,j) \in V, \forall p \in P, \forall k \in K \tag{19}$$

$$\sum_{j} f_{kj}^{pk} = g_{pk}, \forall j \in V, \forall p \in P, \forall k \in K \tag{20}$$

$$\sum_{j} f_{ik}^{pk} = 0, \forall i \in V, \forall p \in P, \forall k \in K \tag{21}$$

$$x_{ij}^{pk}, v_{ij}, z_k, q_{pk} \in \{0,1\}, \forall (i,j) \in V, \forall p \in P, \forall k \in K \tag{22}$$

$$y_{ij}^{pk} \geq 0 \& Integer, \forall (i,j) \in V, \forall p \in P, \forall k \in K \tag{23}$$

$$f_{ij}^{pk}, g_{pk} \geq 0, \forall (i,j) \in V, \forall p \in P, \forall k \in K. \tag{24}$$

Objective function (1) minimizes the total costs of opening depots, traversing, and hiring vehicles. Constraint (2) guarantees that required arc(i,j) must be served by one vehicle form one depot in one direction, i.e. from i to j or j to i. Constraint (3) ensures that traveling between depots is not allowed. Constraint (4) represents the continuity of tours, and Constraint (5) is in charge of vehicle assignments to depots could be considered if that depot is opened. Constraint (6) indicates that one arc must leave the depot to one arc of its tour at the beginning of the tour and, on the other hand, Constraint (7) shows that arc must enter the depot form one arc of its tour at the end of the tour. In Constraint (8) it is mentioned that x_{ij}^{pk} and y_{ij}^{pk} can be equal to 1 if they are assigned to the vehicle p of depot k, where M is a big sufficient positive number.

Constraint (9) guarantees that there is not any arc between one vertex and itself. Constraint (10) declares that tours are not allowed to end at a different depot from which they begin. Also, Constraints (11) and (12) find the arcs with positive demands. Regarding Constraint (13), maximum number of assigned vehicles to each depot cannot exceed the total number of vehicles. Constraints (14) and (15) measure the total amount of demands for each vehicle of each depot if it is opened. Constraints (16) and (17) regard the capacity limitations for opened depots and selected vehicles. Constraint (18) guarantees that the existing flows from arc(i,j) equal the entering ones to that arc minus its demand if there is one servicing traveling for that arc in that tour. Also, Constraint (19) shows that flows of arc(i, j) are zero if there is not any traversing. Although, flows are not required to be determined, Constraints (18) to (21) ensure not to have sub-tours. Finally, Constraints (20) and (21): existing flow form each opened depot by each vehicle equals the total amount of demands of that tour and entering flow to that depot is zero.

3 Scenario-Based LARP

Regarding the real problems in the world, data might not be exactly given. So, many problems have uncertain parameters. The paper on hand aims at employing two scenario-based approaches to consider uncertainties: (i) Minimization of maximum regret, (ii) Minimization of mean and deviation of objective function value. The scenario-based LARP is called SLARP in this paper. So the first Approach is named SlARP^{R} and the second one is named SlARP^{MD}. Also, let s denotes the index of scenarios form its set S from now on.

3.1 SlARP^{R} Mathematical Model

This approach begins with employing the LARP model to solve the problem under each scenario separately. Then an integrated mathematical model is required to obtain a unique solution which meets all requirements of all scenarios. Developing the integrated mathematical model, following variables are introduced.

$r^{\max}$: Maximum regret;
f_{ijs}^{pk}: Departed flow form arc (i, j) under scenario s;
g_{pks}: Departed flow form depot k by vehicle p scenario s.

In fact, despite of other variables, flows are dependent on scenarios. Let θ_s^* indicates the optimum value for objective function under scenario s $\in S$. In addition θ_s is the obtained OFV for scenario s $\in S$ when the integrated model is solved, Eq. (25). Then, the regret of scenario sS is the difference between θ_s^* and θ_s. $\theta_s \geq \theta_s^*$ for each scenario s $\in S$.

$$\theta_s = \left(\sum_k z_k F_{ks} + \sum_{i,j,p,k} x_{ij}^{pk} C_{ijs}^k + \sum_{i,j,p,k} y_{ij}^{pk} H_{ijs}^k + \sum_{p,k} q_{pk} W_s \right), \forall s \in S. \quad (25)$$

Considering LARP model, Eq. (25), and new variables, following model is developed as the integrated model for SLARP^{R}.

$$\min \ \theta^R = r^{\max}, \quad (26)$$

$$\text{s.t. } r^{\max} \geq \theta_s - \theta_s^*, \forall s \in S \quad (27)$$

$$x_{ij}^{pk} \leq D_{ijs}, \forall (i,j) \in R, \forall p \in P, \forall k \in K, \forall s \in S \quad (28)$$

$$D_{ijs} \leq M v_{ij}, \forall (i,j) \in R, \forall s \in S \quad (29)$$

$$g_{pks} \geq \sum_{i,j} D_{ijs} x_{ij}^{pk} - M(1 - q_{pk}), \forall s \in S \tag{30}$$

$$g_{pks} \leq \sum_{i,j} D_{ijs} x_{ij}^{pk} + M(1 - q_{pk}), \forall s \in S \tag{31}$$

$$g_{pks} \leq B_{ks}, \forall p \in P, \forall k \in K, \forall s \in S \tag{32}$$

$$g_{pks} \leq B_{ks}, \forall p \in P, \forall k \in K, \forall s \in S \tag{33}$$

$$\sum_{i} f_{ijs}^{pk} - \sum_{i} f_{jis}^{pk} = \sum_{i} D_{ijs} x_{ij}^{pk}, \forall j \in V, \forall p \in P, \forall k \in K, \forall s \in S \tag{34}$$

$$f_{ijs}^{pk} \leq Q_s (x_{ij}^{pk} + y_{ij}^{pk}), \forall (i,j) \in V, \forall p \in P, \forall k \in K, \forall s \in S \tag{35}$$

$$\sum_{j} f_{ijs}^{pk} = g_{pks}, \forall (i,j) \in V, \forall p \in P, \forall k \in K, \forall s \in S \tag{36}$$

$$\sum_{i} f_{ijs}^{pk} = 0, \forall (i,j) \in V, \forall p \in P, \forall k \in K, \forall s \in S \tag{37}$$

$$f_{ijs}^{pk}, g_{pks} \geq 0, \forall (i,j) \in V, \forall p \in P, \forall k \in K, \forall s \in S. \tag{38}$$

Constraints (2–10), (13), (22), (23).

Objective function (26) minimizes the maximum regret among all scenarios measured by Constraint (27). Other constraints are similar to those presented for the LARP model. Some of them (i.e., Constraints (28) to (38)) are required to be considered for each scenario separately.

3.2 SlARP^{MD} Mathematical Model

This approach is similar with SlARP^R in beginning with solving problems under scenarios separately and takes all of them into account in an integrated model. Its main difference with SlARP^R is in its objective function. Also, SlARP^{MD} needs to know the probability of occurrence of each scenario, P_s. SlARP^{MD} aims at minimizing the mean of OFV, $\overline{\theta}$, and its deviation form, σ_θ^2, where $\overline{\theta} = \sum_s P_s \theta_s$ and $d_\theta = \sum_s P_s \left|\theta_s - \sum_{s'} P_{s'} \theta_{s'}\right|$. So, this approach minimizes $\overline{\theta} + d_\theta$ in its integrated model. It is worth mentioning that deviation could be differently important for the different decision makers. Therefore, the weight λ is introduced for it. Now the integrated model minimizes $\overline{\theta} + d_\theta$ which is $\sum_s P_s \theta_s + \lambda \sum_s P_s \left|\theta_s - \sum_{s'} P_{s'} \theta_{s'}\right|$. The deviation term results in having a non-linear objective function. As a result to non-negative variables are employed to linearize the objective function: e_{1s} and e_{2s}. Now the term $\left|\theta_s - \sum_{s'} P_{s'} \theta_{s'}\right|$ in objective function is replaced with $e_{1s} + e_{2s}$ when $\theta_s - \sum_{s'} P_{s'} \theta_{s'}$ equals to $e_{1s} - e_{2s}$. Following model is the integrated model for SlARP^{MD}.

$$\min \ \theta^{MD} = \sum_{\mathrm{s}} P_s \theta_s + \lambda \sum_{s} P_s (e_{1s} + e_{2s}), \tag{39}$$

$$\text{s. t. } \theta_s - \sum_{\mathrm{s}'} P_{s'} \theta_{s'} = e_{1s} - e_{2s}, \forall s \in S. \tag{40}$$

Constraints (2–10), (13), (22), (23), (27-38).

4 Numerical Example

A numerical example is considered to analyze developed models. This example consists of three potential depots, two vehicles for each, and six extremities for arcs. We assume that there is a link between each pair of extremities and between each potential depot and each extremity. Potential depots belong to set $\{1, 2, 3\}$ and extremities are in set $\{4, 5, 6, 7, 8, 9\}$. In this example arcs there are positive demands between extremities $(4, 5)$, $(4, 7)$, $(4, 9)$, $(5, 7)$, $(5, 8)$, $(6, 7)$, $(6, 8)$, $(6, 9)$, and $(8, 9)$. Arcs with positive demands must be served in one direction. For instance, one of arcs 4-5 and 5-4 must be chosen for meeting the demand between extremities 4 and 5. Five parameters of the model are generated with patterns $W \sim \text{Uniform}(100, 200)$, $F \sim \text{Uniform}(400, 800)$, $C_{ij}^{k} \sim \text{Uniform}(50, 100)$, $H_{ij}^{k} \sim \text{Uniform}(10, 50)$, and $D_{ij} \sim \text{Uniform}(100, 1000)$. In addition, parameters of capacities are generated regarding the demands in a way that infeasibility does not occur.

Also, five scenarios are defined. Here, scenario $S1$ has the lowest amount of demands among all scenarios. Then, we assume that this scenario has the lowest amount of capacities and costs. So, scenario $S5$ has the highest amount for each parameter. All parameters of a scenario are generated by above-mentioned patterns through dividing the ranges of each parameter. For example, range (100,200) is assumed for W. This range is divided to five ranges to generate the scenarios. Thus, ranges (100,120), (121,140), (141,160), (161,180), and (181,200) are the ranges of the uniform distribution function of W for scenarios $S1$ to $S5$, respectively. This process is employed for each parameter.

Table 1. Optimal depots and routings for each scenario

Scenarios	Depot	Vehicle	Sequence	Deadheaded
S1	3	1	3-7-6-9-8-3	3-7, 8-3
	3	2	3-5-7-4-5-8-6-4-9-3	3-5, 6-4, 9-3
S2	2	1	2-7-4-9-8-6-2	2-7, 6-2
	3	1	3-8-5-7-6-9-3	3-8, 9-3
	3	2	3-4-5-3	3-4, 5-3
S3	2	1	2-4-9-6-8-5-8-9-2	2-4, 5-8, 9-2
	2	2	2-6-7-4-5-7-2	2-6, 7-2
S4	1	1	1-8-5-7-4-9-6-1	1-8, 4-9, 6-1
	3	1	3-7-6-8-9-4-5-3	3-7, 5-3
S5	3	1	3-6-9-4-5-4-7-5-8-3	3-6, 5-4, 8-3
	3	2	3-9-8-6-7-3	3-9, 7-3

The mathematical models are solved by GAMS optimization software. Table 1 presents the optimum locations of depots and routings for each scenario, separately. Also, Table 2 presents the optimum objective function value (OFV)

Table 2. Values of objective functions

θ^{MD}	1	$\alpha5$	1757.00	2173.00	2531.00	2747.00	3297.00	1054.00	2657.40	2821.16	2984.92
θ^{MD}	1	$\alpha6$	1740.00	2188.00	2542.00	2759.00	3290.00	1046.00	2769.00	2977.40	3185.80

of each scenario. We can find that scenarios do not have same results to each other. It means that the value of parameters affects the optimum decisions even when the arc with positive demands are same. Also it is found that if traversing costs of each tour are dependent to its depot, decision makers cannot simply declare that having multiple tours with one depot is better than having multiple depots. For example, although scenarios $S1$, $S3$, and $S5$ prefer to use two tours for the opened depot and not to open an extra one, $S4$ opens two depots with one tour for each while it can assign another vehicle to each of them and remove the other one. In fact, parameters of the problem indicate the best solution.

SlARP^R and SlARP^{MD} models have been taken into account after obtaining optimal solutions of scenarios. Regarding the objective function of SlARP^{MD}, a value for λ is required. This example assumes three different levels for λ: 0, 0.5, and 1. Also, this model needs to know the probability of each scenario in advance. Considering different conditions, six sets, called P^{set}, are given for the following probabilities of scenarios: $\alpha1 = \{0.2, 0.2, 0.2, 0.2, 0.2\}, \alpha2 = \{0.4, 0.2, 0.2, 0.1, 0.1\}, \alpha3 = \{0.2, 0.4, 0.2, 0.1, 0.1\}$, $\alpha4 = \{0.1, 0.2, 0.4, 0.2, 0.1\}, \alpha5 = \{0.1, 0.1, 0.2, 0.4, 0.2\}$, $\alpha6 = \{0.1, 0.1, 0.2, 0.2, 0.4\}$, where each set is defined as $\{\mathrm{P}_{s1},\mathrm{P}_{s2},\mathrm{P}_{s3},\mathrm{P}_{s4},\mathrm{P}_{s5}\}$. Table 2 indicates the OFV of models under different values for λ and set of probabilities and all equivalent OFVs for scenarios and other models. For instance, the optimum value of θ^R are fixed for scenarios and SlARP^{MD}

Table 3. Optimal depots and routings for the SlARP^R and two cases of the SlARP^{MD}

Model	Depot	Vehicle	Sequence	Deadheaded
SLARP^R	1	1	1-4-9-6-7-5-1	1-4, 5-1
	2	1	2-6-8-9-2	2-6, 9-2
	2	2	2-7-4-5-8-2	2-7, 8-2
SLARP$^{MD}(\lambda = 0, \alpha 1)$	1	1	1-8-5-7-4-5-1	1-8, 5-1
	3	1	3-9-8-6-7-3	3-9, 7-3
	3	2	3-4-9-6-3	3-4, 6-3
SLARP$^{MD}(\lambda = 1, \alpha 6)$	1	1	1-6-9-8-5-4-1	1-6, 4-1
	3	1	3-9-4-7-5-3	3-9, 5-3
	3	2	3-8-6-7-3	3-8, 7-3

model their OFVs are measured. It is worth mentioning that we assume that scenarios have same probabilities when we want to fix the SlARP^R optimum value of decision variables in SlARP^{MD}.

It can be figured out that each OFV is in its lowest level when its respective model is optimized. Obviously, some other problems reached the same value. For example, θ^{R^*} and it equals to the equivalent value for θ^R when SlARP^{MD} model is optimized with $\lambda = 0.5$ and $\alpha 6$. Also, one can find some optimum decisions in Table 3. It shows the effect of parameters and models in optimum solutions. Minimizing the maximum regret of scenarios, depots 1 and 2 are opened while depots 1 and 3 are opened when SlARP^{MD} model is considered. In addition, λ and P^{set} affect the routing of arcs. Minimizing total costs, the models prefer not to deadhead arcs as much as possible. Most deadheading traverses relate to the linking arcs between depots and extremities.

5 Conclusion

This paper aimed at considering uncertainties in a location arc routing problem (LARP). First, a deterministic mathematical model was developed. Then, two scenario-based approaches were employed to deal with the uncertainties of parameters. The bi-objectives were to minimize the maximum regret (SLARP^R) and minimize the mean and deviation of the objective function value (OFV) (SLARP^{MD}). It was required to find the optimal solution of each scenario in both approaches. The SLARP^R measured the distance between the OFV of each scenario to its optimal value (i.e., the regret of each scenario), and minimized the maximum one. On the other hand, the SLARP^{MD} minimizes the mean of OFVs of scenarios and their deviations from their optimum OFVs. A numerical example was generated to demonstrate the performance of models. Further studies may take the other approaches of uncertainty into account in the LARP.

shirleygnd@163.com

Abstract. Taking case of Hebei Province, by building the regression model, this paper estimates and measures the rationalization and high-level of industrial structure effect on economic growth. The results show that the rationalization of industrial structure and advanced industrial structure can bring positive effects on economic growth. The effect of industrial structure rationalization on economic growth is greater than advanced industrial structure. In addition, the relationship between the rationalization of industrial structure and economic growth is basically stable in Hebei, while the relationship between advanced industrial structure and economic growth is instability. Finally, this paper puts forward some suggestions to optimize the industrial structure to promote economic growth.

Keywords: Industrial structure change · Economic growth, Rationalization of industrial structure · Advanced industrial structure

1 Introduction

Industrial structure and regional economic growth are interrelated and promote each other, the upgrading of industrial structure will promote the regional economic growth, regional economic growth process accompany with industrial structure change, reasonable evolution of industrial structure has become important symbol of economic upgrading and modernization, which can promote the potential power of regional economic growth. Domestic and foreign scholars make a lot of research on the industrial structure and economic growth. In the late 1960s, Kuznets explored the process of economic growth in the United States from 1948 to 1966, believing that industrial structural change was an important driving force of economic growth. In the 1980s, Chenery et al. found that economic growth was unbalanced, the production factors would flow from the low-yield sector to the high-yield sector, and the effect of industrial structure can drive economic growth [1]. At the beginning of this century, Peneder argued that the differences in productivity and its changing trends among production sectors would lead to the flow of the production factors in various sectors, the

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_42

resulting structural dividend could cause economic growth [6]. Perez and Freeman indicated the inherent relationship between industrial structure and the whole economic and social development model and the level [2]. Jorgenson discussed the origin of US economic growth and its international comparison, and revealed the role of the evolution of industrial structure [5]. Gan et al. took use of stochastic frontier production function to research and find that industrial structure and institutional factors could directly affect the economic scale, but also through the indirect impact of resource allocation function, and then they acted on the efficiency of output to promote regional economic growth [3].

2 Index Selection

2.1 Measurement of Industrial Structure Rationalization

Rationalization of the structure refers to the coupling relationship of input-output in, reflecting the rational use of resources and the degree of coordination among the various industries. The Theil index was originated from the entropy concept in information theory, which was used by Theil to calculate the degree of income gap in 1967. It is also scientific to use this index to measure the rationalization of the structure. Referring to the relevant research of Chunhui Gan et al. [3], this paper adopts the Theil index, the formula as following:

$$TL = \sum_{i=1}^{n} \left(\frac{Y_i}{Y}\right) \ln\left(\frac{Y_i}{Y} \Big/ \frac{L_I}{L}\right) = \sum_{i=1}^{n} \left(\frac{Y_i}{Y}\right) \ln\left(\frac{Y_i}{L_I} \Big/ \frac{Y}{L}\right),$$

TL is the Theil index, Y is GDP, Y_i is output value of various industries, L is total employment in a region, L_i is number of employment in various Industry. TL is equal to 0, the industrial structure is reasonable, TL is not 0, the economic deviates from the equilibrium state, the industrial structure is unreasonable. The closer the index value is 0, the more reasonable the structure is.

2.2 Measurement of Advanced Industrial Structure

The sophistication is the dynamic process of industrial structure, evolving from low-level to high-level. In this paper, the ratio of third industry and the second industry (TS) is used to measure the high grade, which can not only reflect the service-oriented tendencies of the structure, but also clearly indicate the development direction of industrial structure. Thus, using TS to measure the advanced industrial structure is rationality and scientific. The calculation formula is:

$$TS = \frac{Y_3}{Y_2},$$

where TS is output ratio of the third and second industrial, Y_3 is output value of the third industrial, Y_2 is output value of the second industrial. When TS rises, it shows economic is the evolution of services, industrial structure is in the continuous upgrading.

2.3 Measurement of Economic Growth

This paper chooses the Gross Domestic Product (GDP) as a measure of economic growth. Gross Domestic Product (GDP) refers to the market value of the final products and services which a country or a region uses production factors to produce in a given period. It not only reflects a country's economic performance, but also can reflect national strength and wealth.

3 Model Construction

In order to further explore the impact of industrial Structure rationalization and advanced Industrial Structure on the economic growth of Hebei Province, this paper uses multiple regression model, the model is set to

$$\ln G_i = \beta_1 + \beta_2 \ln TL_i + \beta_3 \ln TS_i + u_i.$$

In the model, G is regional GDP, TL is the Theil index, referring to the rationalization of industrial structure, TS is output ratio of the third and second industrial, to measure advanced industrial structure. In order to eliminate heteroscedasticity, each variable is taken as a natural logarithm, and u is the random error term, β_1, β_2, β_3 is parameter.

4 Empirical Analysis of Industrial Structure Change on Economic Growth in Hebei Province

4.1 The Characteristics of Industrial Structure Change in Hebei Province

This paper selects the relevant data from 1978 to 2012 in Hebei, and applies Eviews7.0 software to process the relevant data. The calculated results of industrial structure rationalization and advanced industrial structure are shown in Table 8.

Table 1 shows: Theil index mean is 0.2324, the standard deviation is 0.0517, the maximum and minimum are 0.3508, 0.1466. In 28 years, degree of industrial structure rationalization kept steady. TS appears overall upward trend, its mean is 0.6596, standard deviation is 0.0709, the maximum and minimum are 0.8160,0.5001, showing volatility rise (Table 2).

Figure 1 shows that from 1985 to 2012, TL changes from initial higher than 0.2 to later less than 0.2, showing that industrial structure is gradual in the reasonable trend. At the same time, TS changes from the initial 0.4 and 0.6 to 0.6 and 0.8 later, industrial structure is a high-level forward in Hebei Province. In addition, it should be emphasized that the correlation of TL and TS is not strong (as shown in Table 1), and the change trend of them is not the same. Thus, the interaction of TL and TS need not to be considered when analyzing the impact industrial structure change on economic growth (Table 3).

Table 1. Indicators values of industrial structure rationalization and advanced measurement in Hebei

Year	TL	TS	Year	TL	TS
1985	0.2252	0.5001	1999	0.2275	0.6943

4.2 Regression Analysis Results

(1) Stationary Test of Time Series
In reality, most of the time series variables are non-stationary, which may lead to pseudo-regression and invalid result in the regression analysis [4,7,8]. Therefore, before testing the co-integration relationship between GDP and industrial structure in Hebei, this paper adopts unit root to test stationary of time series.

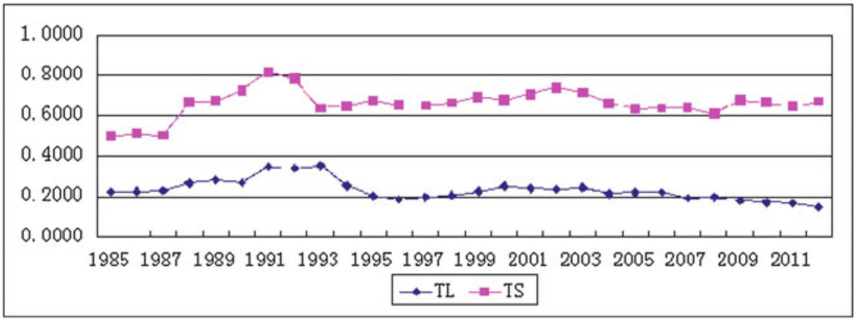

Fig. 1. Change trend of TL and TS

Table 4. Unit root test results

Variable	Stationary difference order	t-Statistic	Test critical values (10%)
lnGDP	level one	−3.316089	−3.233456
lnTL	level one	−4.016404	−3.233456
lnTS	level one	−4.341045	−3.254671

ADF test results show that the t-test values of lnGDP, $\ln TL$, $\ln TS$ are less than the critical value at the significance level of 10%, indicating that the null hypothesis is rejected at least confidence level of 90%, lnGDP and $\ln TL$, $\ln TS$ are integrated of order on. Thus, the long-term relationship between lnGDP and $\ln TL$, $\ln TS$ can be co-integration test.

(2) Co-integration Test
In the co-integration test, the Johansen maximum likelihood method is used to test the co-integration relationship among variables. For a number of non-stationary time series, if one linear combination is stationary, there exists a long-term equilibrium co-integration relationship among these variables. The trace statistic and the maximum eigenvalue statistic can be used to test. The test results are shown in Table 5:

Table 5. Co-integration test results (trace test)

Hypothesized trace = 0.05				
No. of CE(s)	Eigenvalue	Statistic	Critical value	Prob.**
None*	0.860236	68.96358	29.79707	0
At most 1*	0.363917	19.76856	15.49471	0.0107
At most 2*	0.28703	8.457905	3.841466	0.0036

Note: *indicates that the statistical significance is at 5% level, the same below. **indicates that the statistical significance is at 1% level.

Table 6. Co-integration test results

Hypothesized max-eigen = 0.05				
No. of CE(s)	Eigenvalue	Statistic	Critical Value	Prob.**
None*	0.860236	49.19502	21.13162	0
At most 1*	0.363917	11.31066	14.2646	0.0059
At most 2*	0.28703	8.457905	3.841466	0.0036

Note: *indicates that the statistical significance is at 5% level, the same below. **indicates that the statistical significance is at 1% level.

The results of co-integration test in Tables 5 and 6 show that the trace statistic and the largest eigenvalue statistic are larger than the critical value at the significance level of 5%, indicating that the hypothesis can be rejected at the 95% confidence level, indicating that there is co-integration relationship between the variables. Thus, there are more than two co-integration relationships among the three variables (lnGDP, $\ln TL$, $\ln TS$) at the significance level of 5%.

(3) Vector Error Correction Model

The above test shows that there exists co-integration relationship or long-term stability relationship among the variables. On this basis, the VEC model will be established to reflect the long-term static and short-term dynamic relationship. The results are as follows:

Table 7. Vector error correction model

Error correction	D(lnGDP)	D($\ln TL$)	D($\ln TS$)
CointEq1	0.009515	−0.000401	0.011106
	−0.00351	−0.00666	−0.0055
	[2.71014]	[−0.06021]	[2.01862]
D(lnGDP(−1))	0.231887	−0.763078	−0.239289
	−0.18074	−0.34268	−0.28324
	[1.28297]	[−2.22681]	[−0.84484]
D(lnTL(−1))	0.217572	0.041751	−0.072049
	−0.10565	−0.20031	−0.16557
	[2.05929]	[0.20843]	[−0.43517]
D(lnTS(−1))	−0.093157	0.507951	0.146124
	−0.14085	−0.26704	−0.22072
	[−0.66140]	[1.90214]	[0.66204]
C	0.117807	0.099722	0.046109
	−0.0301	−0.05707	−0.04717
	[3.91384]	[1.74742]	[0.97754]

Table 7 shows the estimated values of the parameters of the VEC model, where the value of CointEq1 represent the coefficient estimate of the error correction term. While the error equation can be derived from Table 4:

$$\text{Coint}Eq1 = D(\ln \text{GDP}) + 0.23 \ln \text{GDP}(-1) + 0.22 \ln TL(-1) - 0.09 \ln TS(-1) + 0.12.$$

This equation is deformed to the following equation:

$$D(\ln GDP) = \text{Coint}Eq1 - 0.23 \ln GDP(-1) - 0.22 \ln TL(-1) + 0.09 \ln TS(-1) - 0.12.$$

This error equation shows: when $\ln GDP$ changes each additional unit, the impact of $\ln GDP(-1)$ on it is -0.23 units, the impact of $\ln TL(-1)$ on it is -0.22 units, the impact of $\ln TS(-1)$ on it is 0.09 units. In addition, Theil index and GDP are negative correlation, $lnTL$ rises one unit, D($\ln GDP$) will drop 0.22 units; and TS and GDP show positive correlation, $\ln TS$ rises one unit, D($\ln GDP$) rises 0.09 units. This shows that the economy in Hebei Province will grow with the industrial structure rationalization and the advanced industrial structure, but its influence coefficient shows that the influence of industrial structure rationalization on the economy is higher than that of the advanced industry structure on economy in Hebei.

(4) Granger Causality Test

Table 8 shows: $\ln GDP$ and $\ln TL$ exist causal relationship, there is a mutually reinforcing relationship between industrial structure rationalization and regional economic growth; while advanced industrial structure and economic growth are only a single causal relationship, economic growth can promote advanced industrial structure, and advanced industrial structure can not promote economic growth. GDP in Heibei increased from 39.675 billion RMB in 1985 to 2.65751 trillion RMB in 2012, while the output value of the secondary industry and tertiary industry in Hebei Province has maintained a growing trend, indicating that Hebei's economic growth can promote industrial structure more reasonable. From 1985 to 2012, the second industry in Hebei still dominates in economy. But as time changes, the proportion of the first industry declines, the proportion of tertiary industry continues to rise, the industrial structure is more rationalized. This shows the stability of economic growth is mainly due to the rationalization

Table 8. Granger causality test results

Null hypothesis	Obs	F-Statistic	Prob
InTL is not the Granger cause of lnGDP	25	4.90145	0.0116
Ln GDP is not the Granger cause of lnTL		9.17695	0.0007
lnTS is not the Granger cause of lnGDP	25	0.95535	0.435
Ln GDP is not the Granger cause of lnTS		3.77428	0.0291
LnTS is not the Granger cause of lnTL	25	1.41804	0.2702
lnTL is not the Granger cause of lnTS		0.76488	0.5285

of the structure, but advanced industrial structure is only one aspect of economic growth effect, not to promote sustained economic growth.

5 Conclusion

This paper studies the impact of industrial structure dynamic change on economic growth from the angles of industrial structure rationalization and advanced industrial structure, and draws the conclusion that there is a long-term equilibrium trend between industrial structure change and economic growth, There is a stable relationship between the industrial structure rationalization and economic growth, while the instability of advanced industrial structure is more prominent; the industrial structure is the most important factor for the economic growth in Hebei. Evolution of industrial change in Hebei is in line with the general law, which will gradually move towards higher level.

Disclosure Behavior of Annual Reports of Listed Companies Under Digital Worship

Xiaojing Xu(✉)

Chongqing Technology and Business University,
Chongqing 400067, The People's Republic of China
34144333@qq.com

Abstract. Digital worship is widely used in China. Does this phenomenon also affects the China's stock market? Does Digital Worship influence the choice of disclosure time of listed companies' annual reports? Through the empirical analysis for stock market of China, it founds that the listed companies' behavior of timing of annual reports released is affected by the short-term influence of digital worship, which is a new market phenomenon. The research of this paper has reference significance for investment decision-making, risk management and understanding the behavior of listed companies and investors.

Keywords: Digital worship · Annual report disclosure · Auspicious day

1 Introduction

Digital worship refers to the number of people to avoid or love [2]. The digital worship is widely used in China, such as the choice of telephone numbers, business opening date selection and so on. In this digital influence, people think that figure "8" seems to be "fatten" homophonic, meaning fortune. People think that the number "4" seems to be "dead" homophonic, and quite avoided. Such as the 2008 Beijing Olympic Games elected in August 8th at 8: 8 pm to open, and Alibaba Group was originally scheduled for August 8^{th}, 2014 to be on the United States stock market. Many studies have proved that there is a phenomenon of worshiping number 8 in China's stock market. In this paper the question posed is whether this digital worship exists in the timing of listed company's annual report disclosure? If so, does it have a significant impact on the market? Specifically, on the one hand, if listed companies are affected by the number of worship, whether they will choose date with the lucky number to publish annual report. On the other hand, if the investors' behavior is also affected by the digital worship, whether the listed companies will make good use of selecting the auspicious figures to disclose annual reports to get more investors' attention? If the digital worship has a impact on the disclosure behavior, it will be a new market vision.

The research of this paper has reference significance for investment decision-making, risk management and understanding the behavior of listed companies

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_43

and investors. The article will use the method of empirical analysis, with the date ending in number 8 and number 4 as the starting point to demonstrate whether the listed companies behavior of timing of annual report disclosure is affected by the digital worship. The remainder of the paper is structured as follows: The second part briefly reviews the literature. The third section describes the data and makes assumptions. The fourth part introduces the econometric model and empirical analysis. The fifth part summarizes the full text and makes recommendations.

2 Related Literature

Cao, Li et al. [2] studied China is a very particular about the "homophonic culture" of the country, 8 homonyms are "fatten", meaning fortune. And 4 homophonic is "dead", by a lot of people deliberately avoided. Xu [8] pointed out that the Chinese people believe that the numbers can predict good and bad. With social development, the number will have a new reference meaning and more distinct meaning, the number "8" is repeatedly subject to people's heat Holding. Shen [6] studied the symbolization and illusion of money, and discussed the influence of digital worship on modern wealth. In the stock market, Zhao and Wu [9] selected 569 non-financial stocks in Shanghai stock market as the object of study, and got code ending with 8 stock price high, its price-earnings ratio on IPO day and the following year higher than other mantissa stocks. Philip and Jason [1] found that the stock valuation of Shanghai and Shenzhen stock market there is a number of worship under the cluster effect, the price median with 8 appears twice the frequency of 4, because the Chinese inherent values that the number 8 is auspicious number, 4 is unlucky numbers. The above document proves that the stock code and the price contains the auspicious number will have an impact on the stock price. Liu, Li and Yang [4] found that auspicious number preference will significantly affect the relationship between the systematic risk of stock collapse and the expected rate of return. The above literature proves that there is a phenomenon of digital worship in many areas of Chinese stock market, and it has significant influence on the stock price and the expected return rate. However the number of worship will affect the information disclosure of listed companies and investors decision-making behavior, there is no relevant literature, which is the research direction of this paper.

Human decision-making process is not based on purely rational, but there will be a series of cognitive bias [5]. In a given context, people's decision-making behavior depends not only on the problem itself, but also on the way the problem is expressed. Han and Xu [3] found that listed companies significantly lower or early disclosure of the disclosure of annual reports will receive more attention to investors, which reveals the listed companies through the choice of time to disclose the annual report of an important channel for market value management. Zhou and Huang [10] found that the disclosure of our annual report on the stock market appeared "week preference" and "get together preferences". To disclose the good news on Tuesday, the stock excess return is higher. But the disclosure of bad news on Saturday, the stock is also higher than the excess rate of return. The stock has a positive impact on excess returns which the company chose the time when a number of annual reports published at the same time to disclose the bad news, in order to avoid the attention of investors. Wang and Wang [7] studied the impression management theory of information disclosure strategy of listed companies, and analyzed how listed companies can maximize their own benefits through management information disclosure. Thus, listed companies have strategy in the choice of disclosure of the timing, and they choose to publish are going to catch the chance of timing to attract and distract the attention of investors. This paper attempts to prove whether the listed companies use the digital worship effect and select the mantissa is the auspicious number of dates in order to achieve the effect of investor concern. In short, digital worship and disclosure strategy belong to the category of behavioral finance, and it is also a kind of market vision on the stock market.

3 Data and Assumptions

We collect and analyze the 2011–2015 Shanghai and Shenzhen A-share annual report disclosure date (a total of 12,610 samples) were statistics, the results shown in Fig. 1.

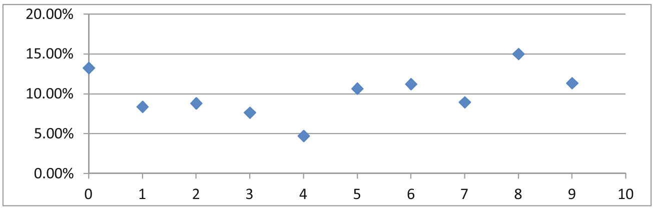

Fig. 1. 2011–2015 Annual report announcement date mantissa chart

As shown in the above figure, the number which listed companies choose to publish the annual report in the date of mantissa 8 is the most, accounting for 15.01%. But the date selected in the mantissa of 4 is the least, accounting for 4.72%. The results shows that the date listed companies choose to publish the annual report is Imbalance. There is a phenomenon of digital worship. However, how much dose this phenomenon impact the stock market? In particular, if the investor has the behavior of digital worship, the listed company chooses the auspicious date to disclose the annual report in order to get more attention from the investors when it chooses the disclosure time of the annual report. How to measure the annual report after the release of more investors are concerned about? This paper selects the 5-day yield index, which reflects the short-term price volatility of the stock market. If the five-day rate of return is greater than zero, then the stock received the attention of investors and investment, so that the stock prices up in the short term. Conversely, the opposite is true.

In order to facilitate the study, this paper chooses the date of the mantissa 8 as the auspicious date and the date of the mantissa 4 as the unlucky date to analyze whether the digital worship on the date will affect the disclosure time of the listed company. So this paper puts forward the hypothesis,

Hypothesis 1 (H1): If it choose the date of the mantissa 8 to publish annual report, the five-day stock returns will have a positive effect.

Hypothesis 2 (H2): If it choose the date of mantissa 4 to publish annual report, the five-day return has a reverse effect.

On the other hand, listed companies are also under the digital worship of praying auspicious, especially the annual report is bad news. They may choose to disclose the annual report in the auspicious date so that corporate earnings have a positive effect. The article sets that when the net profit margin is less than or equal to last year's net profit margin is bad news, when the net profit margin higher than last year's net profit margin is good news. Therefore,

Hypothesis 3 (H3): If the listed company which has good news in annual report select the date of mantissa 8 to disclose annual report, not only have a positive effect on the company's five-day yield, but also have higher five-day yield compared to other days.

Hypothesis 4 (H4): If the listed company which has good news in annual report select the date of mantissa 8 to disclose annual report, not only have a positive effect on the company's five-day yield, but also have higher five-day yield compared to other days.

4 Empirical Analysis

4.1 Data Selection and Data Sources

This data selection follows these principles: (1) As the annual reports always publish in the next year's January to April, so financial data selected from 2010 to 2014 annual report. And the yield selected from 2011 to 2015 annual report after the publication of five-day yield. Since the 2014 annual report is published in 2015, so the annual report data is from 2014, and the yield data is collect in 2015 after the release of annual report. (2) Removing some of the outliers and missing values; (3) The independent variables of the maximum and minimum of 3% flattening treatment. All the data in this article comes from the database of Guotai'an. The empirical analysis is based on Eviews6.0.

4.2 Variable Selection

(1) Dependent Variable

Five-day rate of return $(R_{it}) = \frac{P_1 - P_2}{P_2} \times 100\%$.

P_1 is the annual report after the fifth trading day closing price. P_2 is the annual report published on the day closing price (if the annual report is published after the end of the trading or in the non-trading day, we select the next trading day closing price.

(2) Independent variable
Assets-liability ratio (X_{1it}) = Total liabilities/Total assets × 100%.

Operating profit margin (X_{2it}) = Operating profit/Total business income × 100%.

Total assets growth rate (X_{3it}) = Total assets growth/Total assets at the beginning of the year × 100%.

Net cash flow per share from operating activities (X_{4it}) = Net cash flow from operating activities/Total share capital.

(3) Virtual Variable
This paper sets up the virtual variable to study whether the annual report can attract investors' attention and can cause the significant change of the 5-day rate of return. In order to study the annual report on the end of the mantissa of 8 or 4 on the impact of the five-day rate, we set as following:

Firstly, the annual report published on the end of 8 is 1, not the end of 8 is 0, with DV1 it said. Secondly, Announcement date to 4 at the end is 1, not the end of the 4 is 0, with DV2 it said. Thirdly if the listed company's net profit growth rate is less than or equal to last year is bad news, then the net profit growth rate is greater than last year is good news. The good news is 1, the other is 0, with DV3 it said. Finally, Annual bad news is published 1, the other is 0, with DV4 it said.

4.3 Build Models

This article refers to the requirements of the panel data model, the model is as follows:

Model 1 $R_{it} = X_{1it} + X_{2it} + X_{3it} + X_{4it} + DV_{1it} + \mu_{it}$,
Model 2 $R_{it} = X_{1it} + X_{2it} + X_{3it} + X_{4it} + DV_{1it}DV_{3it} + \mu_{it}$,
Model 3 $R_{it} = X_{1it} + X_{2it} + X_{3it} + X_{4it} + DV_{1it}DV_{4it} + \mu_{it}$,
Model 4 $R_{it} = X_{1it} + X_{2it} + X_{3it} + X_{4it} + DV_{2it} + \mu_{it}$,
Model 5 $R_{it} = X_{1it} + X_{2it} + X_{3it} + X_{4it} + DV_{2it}DV_{3it} + \mu_{it}$,
Model 6 $R_{it} = X_{1it} + X_{2it} + X_{3it} + X_{4it} + DV_{2it}DV_{4it} + \mu_{it}$.

R_{it} is the five-day rate of return, X_{1it} is on behalf of the asset-liability ratio, X_{2it} it represents operating profit margin, X_{3it} represents the total assets growth rate, X_{4it} represents the net cash flow per share of operating activities, $DV_{kit}(k = 1, 2, 3, 4)$ represents the dummy variables, μ_{it} represents the random error term.

4.4 Descriptive Statistics

During the inspection period, the five-day average yield is about 0.2297%, greater than zero. This shows that after the publication of the annual report, the majority of listed companies received the attention and recognition of the market, and stock prices rise. The maximum value is about 48.2540% and the minimum value is −50.2257%. This shows that the annual report after the release of the stock market response is very rapid, and investors can judge the tendency of markets (Table 1).

Table 1. Variable descriptive statistics

	R_{it}	X_{1it}	X_{2it}	X_{3it}	X_{4it}
Average value	0.2297	45.6519	8.564	16.8504	0.3557
Median	0	45.8901	7.064	10.5624	0.2712
The maximum	48.254	92.0426	42.0043	118.4737	2.4154

4.5 Empirical Analysis

In this paper, a hybrid panel data model is used. Using the cross-section weighting method, the empirical results are shown in Table 2.

4.6 Result Analysis

Based on the empirical results in Table 2, the analysis of the various research hypotheses is as follows:

Firstly, the DV1 coefficient of model 1 is 0.9320, which indicates that the listed company has positive effect on its 5-day rate of return on the date of the ending date of 8, and compared to other dates, which can improve the 5-day yield of 0.9320 units. So hypothesis 1 proves.

Secondly, as can be seen from model 2, the good news is better than other dates by 1.0161 units of the five-day rate of return on the date of tail number 8. So the good news announced in the date of tail number 8 can get more investors attention. So *Hypothesis 2* proves.

Thirdly, from Model 3 we can see that listed companies can increase the yield of 0.8512 units by 8 days, which means that bad news can weaken the negative effect of the stock market when the date is 8. So *Hypothesis 4* gives evidence. Finally, in the announcement date mantissa is 4 combinations, the model four DV2 coefficient is -1.6410. It indicated that the listed company in the date with tail number of 4 published annual report will reduce the 1.6410 unit rate of return. So *Hypothesis 2* gives evidence. From Model 5, we can see that the good news is released on the date ending on the 4^{th}, and the yield is reduced by 1.5512 units compared with other dates. From Model 6, we can see that the bad news is released on the date ending on the 4th, which will reduce the 1.8321 unit yield compared with other dates.

5 Conclusion and Suggestion

The influence of digital worship on the stock market belongs to the category of behavioral finance. It is also a kind of market vision and a hot topic in the field of finance research. From the perspective of digital worship, this paper analyzes the motivations of time choice of disclosure of listed companies' annual reports, and draws the following conclusions.

First of all, the annual disclosure of listed companies by the impact of China's digital culture, there is a certain tendency to auspicious. The number of listed companies which select the date with mantissa of 4 to publish annual report is the lowest. But the number of listed companies which select date with mantissa of 8 is the highest.

Second, whether the annual report is bad news or good news of listed companies, choosing the mantissa of the auspicious date to publish the annual report has a positive effect on five-day yield, and the positive effect of the good news is more obvious. Whether the annual report is good news or bad news of the listed companies, choosing the date mantissa of 4 to publish annual report has a reverse effect on five-day rate of return. This fully shows that digital worship behavior exists in the listed companies when they choose the time to announce annual report. While listed companies which has the bad news to use digital worship in the market, and choose a auspicious day to publish annual report in order to dilute the fundamentals of company unfavorable factors. On the other hand, investor behavior is also affected by the number of worship.

Last but not the least, we give the suggestions. The paper chooses the 5-day yield index as an empirical analysis, which is a short-term indicator. Therefore, listed companies in order to continue to receive the attention and recognition of investors should improve the quality of annual reports. Investors should also be aware of the impact on trading behavior which comes from the cultural and psychological factors, and finally make more rational investment decisions.

Abstract. As global climate warming and the continued use of fossil energy are unsustainable, it has become imperative to accelerate the development of renewable energy. As one of the largest developing countries, this is especially true for future sustainable development in China; therefore, focusing on renewable energy can significantly reduce its dependence on imported fossil fuels. With policy support, China's renewable energy industries have had rapid development and are now at the international forefront level in some fields. However, the renewable energy industries are facing challenges, particularly in terms of energy finance. Basically, the renewable energy industry in China is facing a contradictory dilemma because of funding shortages and inefficient investment strategies, due in part to government-centered renewable energy investment and financing. In view of this, the renewable energy financing and the corresponding polices in China are discussed in detail in this paper. Issues of energy finance are also analyzed.

Keywords: Energy finance · Renewable energy · Financing channels · Financing means · Sustainable development

1 Introduction

Renewable energy (RE) has become the fundamental direction and core content of the global energy transformation. As renewable energy is environmentally friendly, low-carbon energy is the main force behind the technological revolution in energy and has become a major emerging industry growth point. China enacted a series of polices to promote sustainable RE development to increase

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_44

investment in RE industries and to gradually eliminate the obstacles to RE sustainable development. These government actions have improved the RE subsidy mechanism and incentives to ensure that renewable energy generation maintains a steady upward development trend. As China is only in the middle stages of industrialization and urbanization, energy demands continue to grow. The average annual RE installed capacity is expected to reach 2600 kilowatts or more every year in the future. There is a need, for example, for new investment in the solar RE industry of around 190 billion CNY to meet the goals of annual new installed capacity of 20 million kilowatts. Wind and solar power development together needs future annual investments of at least 400 billion CNY, with a total RE investment of 2 trillion CNY required for the "13*th* Five-Year" period [10].

International experts have now categorized RE into traditional and new, with the former referring to giant hydropower and directly burnt biomass and the latter referring to small hydropower, solar energy, wind energy, biomass energy, geothermal energy and others [3]. The renewable energies discussed in this article fall into the latter category. There are abundant RE resources in China; therefore, to make good use of these RE resources, China needs to promote the development of large new energy resources. Seeking to increase RE use and deployment to encourage a move towards sustainable development, governments have developed and implemented RE support policies. However, as the renewable energy sector grows, it is facing increasingly more complex investment, financing and policy challenges. Because of the initial high costs of renewable energy projects, market development requires focused policy support. If RE financing mechanisms are incomplete or poorly focused, renewable energy project financing has higher costs and attracts less investment; therefore, innovative investment and financing mechanisms are needed to break through the RE financing bottleneck and the continued reliance on government guidance and incentives and to encourage financial market innovations and policy incentives. Existing studies have found that renewable energy laws and regulations as well as incentive policies are an important driving force in the rapid RE development in China [1,5] such as incentive policies, financial subsidy policies, tax rebates and exemption policies, preferential feed-in tariff policies and technical support policies. China's current renewable energy policies include assistance with development plans, industrial guidance, technical support, legal responsibility and popularization [4,11]. Based on a questionnaire, Lam et al. found that the most important drivers of RE development in China were government financial assistance, technical support, feed-in-tariff policies and tax incentives.

2 The Driving Forces of RE Development

Strategically, it is important for China to develop domestic renewable energy manufacturing and promote RE applications for several reasons. First, the promotion and development of RE can ensure that China achieves its goal of 15% non-fossil energy by 2020 and 20% by 2030. Second, RE gives developing countries an important opportunity to catch up with developed countries in terms of

RE production capacity and to improve their energy structures [9]. Therefore, with these goals in mind, it is important to assess China's renewable energy financing and policies issues to understand how such large scale investments in renewable energies have been achieved, the major renewable power generation investment and financing channels, the types and effectiveness of Chinese government financing incentive mechanisms, the characteristics of China's renewable energy and whether the current policy mechanisms are suitable for the future development of renewable energy. These issues are fully discussed in this paper.

Seeking to satisfy the growing energy needs and to reduce greenhouse gas emissions, it is important that more RE resources be harnessed. However, the wider consumption of RE resources is closely related to financial support. Government financial support mechanisms and appropriate finance policies are important to enhance RE sustainable development. It has been widely recognized that renewable energy policies, such as incentive policies financial subsidy policies, tax rebates and exemption policies, preferential feed-in tariff policies, technical support policies, development plans, industrial guidance and technical support, price incentives, legal responsibility and popularization, are essential for the promotion of renewable energy development. The renewable energy market share has been expanding and in recent years, China's renewable energy has had significant development because of the implementation of the Renewable Energy Law and related policies. Existing studies have shown that incentive policies have been an important driving force behind the rapid RE development in China [8].

3 RE Financing Channels in China

The Energy foundation and the National Development and Reform Commission predicted that from 2005 to 2020, China's needed to invest 18 trillion CNY into the energy sector, with new energy, energy saving and environmental protection measures needing about 7 trillion CNY [6]. Therefore, government subsidies and investment alone is clearly insufficient, so full use needs to be made of market financing using financial channels to resolve the funding shortages. It has been pointed out that the development of appropriate financing channels and instruments for both end users and the industry was one of the drivers for increased investment [2]. This issue is analyzed in this part of the paper.

3.1 Bank Financing

Bank financing, such as policy-related loans and commercial finance, is an important channel for the renewable energy industry. To implement the country's new energy industry policy, the National Development Bank strengthened financial support for the new energy industry. Currently, bank financing plays a significant role in facilitating investment into the renewable energy sector. The World Bank, the Asian Development Bank and other international financial organizations provide low interest concessional loans to support investment into Chinese energy sources, transportation, environmental protection, public utilities and other non-profit projects. Of these, energy saving and emissions reduction have attracted the most finance. The International Bank for Reconstruction and Development also provides market-based (hard) loans and guarantees for Chinese renewable energy projects to increase the share of clean energy.

3.2 International Financing

International financing sources have played a major role as incubator funds for the development of rural renewable energy in China, with many renewable energy projects in China having been financed by multilateral and bilateral organizations. In China the internationally funding projects have included: "Capacity building for the rapid commercialization of renewable energy", a "China renewable energy development project", a "solar village project", a "wind power project in China's Hubei" and a "clean energy research project". International financing channels for China's renewable energy sector include international financial institution loans, inter-government loans, non-government loans and foreign investment, overseas Chinese investment in the territory, the Clean Development Mechanism (CDM) and the Carbon Abatement Fund.

3.3 Public-Private Partnerships

Public-private partnerships involve cooperation between a public sector authority and the private sector for the financing of revitalization, management or infrastructure maintenance projects including renewable energy projects. Private and public capital partnerships are generally joint ventures in which the entrepreneurs and the government work together to provide a faster and more efficient implementation of infrastructure projects. Also, because of the private capital injection, the assets that the public sector would otherwise invest in infrastructure projects in the traditional way can now be redirected towards creating social wealth. Additionally, there is a growing awareness that cooperation with the private sector in such public-private partnership projects has a number of advantages: (1) acceleration, (2) more rapid implementation, (3) reduced whole life infrastructure provision costs, (4) better risk allocation, (5) better incentives to perform, and (6) improved service quality.

3.4 Government Financing

Government financing also plays an important role in financing renewable energy in China, with the government taking a leading position in renewable energy sector financing. Government finance has been the most important channel for the financing of renewable energy projects through the implementation of national programs and the supply of grants to subsidize the capital costs of equipment, loans, loan guarantees and tax incentives. The Chinese government has a played a significant leading role in financing rural renewable energy through national initiatives and the provision of financial incentives. The Chinese Township Electrification Program was the first nationally based implementation of renewable technologies to supply electricity to rural populations and is one of the largest renewable energy-based rural electrification programs in the world. The development of such projects demonstrates the robust and sustainable renewable energy infrastructure in China, especially for solar energy.

3.5 Capital-Market Financing

Capital-market financing is a channel for new energy enterprises to raise funds as it can effectively solve fund shortage problems in a relatively short period of time. However, China's multi-level capital market is still somewhat behind as the capital market, stock market, bond market and investment products are not yet rich enough. China's Shanghai and Shenzhen stock exchange markets are very similar in terms of their organization, listing standards, trading patterns and regulatory bodies. The most direct way to utilize bonds for RE financing would be for RE companies to issue corporate bonds. China has had several successful case-studies for raising investment funds for the RE sector. Green bonds have emerged as a potential financing channel for RE, in which the issuer commits to the use of bond proceeds only for environmentally-friendly products. The key differentiating feature is that a green bond is marketed as green to investors and their proceeds are restricted to green projects. Issuing a green bond also increases the visibility of the bond to conventional investors. The ability to highlight the green attributes of green bonds could also improve overall publicity and improve an organization's image, thereby further broadening their access to capital.

4 RE Financing Means in China

Financing means, such as corporate financing, project financing, Third party financing and financing leases are relatively backward in China compared to developed countries [7].

4.1 Project Financing

Project financing has become one of the most important financing means for Chinese state-owned enterprises. A common project financing method is the Build-operate-transfer (BOT) method, with concessions having been granted to attract foreign and private investment. BOT was introduced as an alternative project financing model to motivate private investment participation. The government and power supplier sign a power purchase agreement, and to ensure that the RE power plant supplies a timely transmission of electricity, the project company receives payment for the power products from the power supplier. The renewable energy project BOT structure is shown in Fig. 1. In addition, the project company can apply for government authorized special renewable energy funds or can apply for financial subsidies. This additional income (including government subsidies) can assist the project company to cover the costs of the renewable energy plants or to repay bank loans or syndicated loan principal and interest.

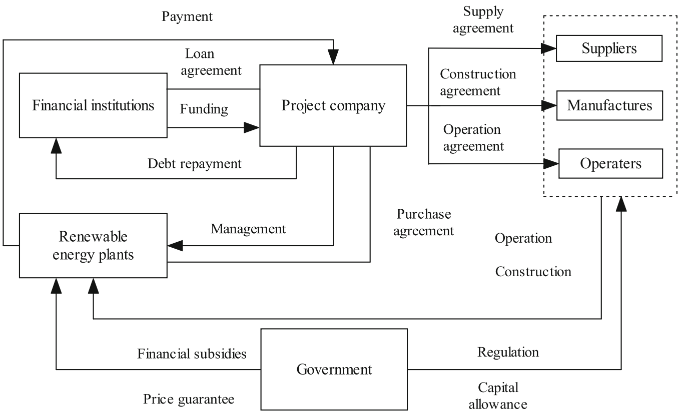

Fig. 1. BOT structure for renewable energy project

4.2 Financing Leases

Financing leases are a significant financing means for the development of China's renewable energy sector. Large scale renewable energy projects are less attractive because of the massive initial investment needed and the uncertainty risks. Lease financing programs refer to the relationship between the enterprises selling the RE equipment and a financial institution, for which the financial institution provides financing for the purchase of the equipment. The typical structure is depicted in Fig. 2. Finance leases for large-scale renewable energy power generation projects are initiated through commercial capital leases for the purchase of power generating equipment and technology, which is then recouped from elec-

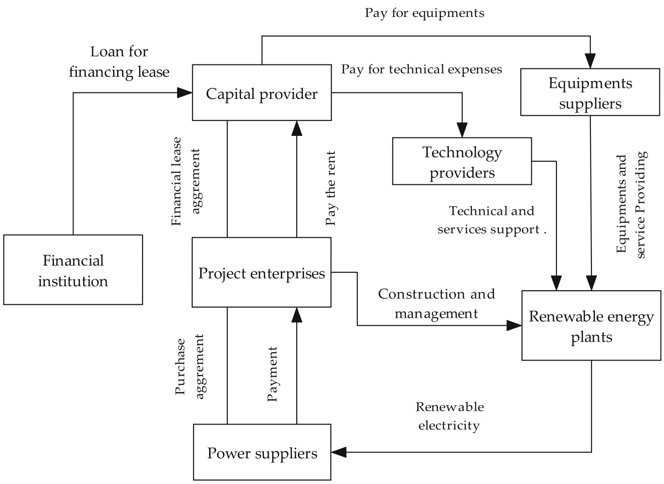

Fig. 2. The FL structure for an RE project

tricity users by the project operators to pay for the lease financing. In this way, a project sponsor can reduce their capital pressure as well as reduce the project's financial risk.

4.3 Third Party Financing

Third party financing (TPF) deals with customer sources, installation, engineering, maintenance and financing services for the RE system on the host customer's properties. The advantages of TPF contracts are that the source of funds is guaranteed and a number of services are provided which minimize commitment risk. TPF can effectively aid in the development of RE technologies in developing countries and rural areas with less investment. The third-party ownership model is shown in Fig. 3.

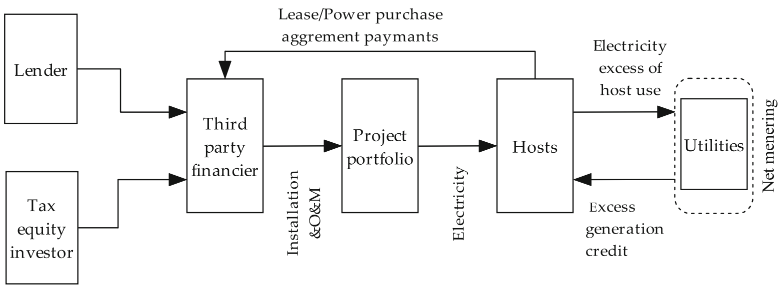

Fig. 3. Third-party ownership model

4.4 Venture Capital

Venture capital or private equity investment facilitates the provision of funding to firms in the industry that may have unproven or high risk technologies. From an investment point of view, almost all new energy projects have a corresponding capital risk, such as solar energy and wind energy related technological research and development projects. Venture capital generally involves a private placement of funds to assist in the establishment of emerging small and medium-sized RE enterprises which tend to have high *risk/high* return characteristics. At present, China's venture capital investment in new energy sectors is still in a trial stage; therefore, the investment is more cautious and the investment funds are often quite limited.

5 Issues of Renewable Energy Finance

This paper has closely examined optimization and innovation in RE finance issues to ensure RE sustainable development in China. From this close examination, there are several outstanding issues that need to be resolved to guarantee the continued long-term sustainable success of RE in China. The main issues are as follows:

(1) Incomplete financing systems for RE projects. Generally, investment options have focused on the industrialization of RE technologies only rather than on innovation. Second, domestic enterprises are not investing enough and have not been sufficiently integrated into RE development chains. However, for the RE true sustainable development, investment chains for renewable industry sectors and investment integration is necessary to ensure that the investments contribute to overall long-term sustainability.
(2) Lack of policy coordination and consistency. As there appear to be differences in the goals of each of the RE sectors, it has been difficult to ensure consistency in policy frameworks making it difficult to develop a long-term and effective policy system to support renewable energy"s sustainable development. Further, as energy issues encompass federal, state and local governments and several different departments such as energy, science and technology and agriculture, there has been inconsistency and a lack of coordination in policy development across these boundaries, ultimately eroding state macro-control and resulting in wasted investments due to duplication.
(3) Weakness Financial subsidies for renewable energy investment projects are much lower than for other sectors and China's support for renewable energy through taxation methods is fairly weak, with the actual taxation benefits for most renewable energy projects being similar to or of less benefit than conventional energy tax benefits.
(4) Inadequate investment in technical R&D and weak independent RE development innovation. At the moment, China lacks a powerful platform to support technological research. What is needed is a clear long-term continuous and rolling R&D development investment plan, with guaranteed funding to support R&D. Most core technologies in most domestic enterprises come from abroad, which will ultimately affect the sustainable development of the RE sector.

6 Conclusion

Investment, financing and corresponding policies have played a significant role in sustainable RE development. Investment, financing, finance means and related laws, regulations and major incentive mechanisms in China have progressed significantly in recent years. Various incentive mechanisms such as the RE preferential fiscal policies and R&D fund support for the commercialization of technologies has gone some way to decreasing the development costs of renewable energy projects. In the future, joint financing and policies and support mechanisms for renewable power generation need to be further strengthened. Fiscal and tax incentives have significantly relieved the financial burdens on renewable energy power generation enterprises and preferential tax policies for VAT, income tax and import duties for the renewable energy power generation industry as well as strong financial subsidies have provided invaluable support for renewable power projects. Tariff incentives, in particular, have ensured reasonable profits for renewable energy power generation enterprises. However, investment and financing renewable energy policies need to be strengthened further as China's RE financing methods and development policies have some inherent disadvantages. For the future, it is necessary to develop a range of coordinated strategies to ensure long-term efficient developments for the RE industry sector. In brief, this paper provides a comprehensive analysis of China's RE sustainable development. The major financing methods and identified incentive strategies and approaches can assist researchers and industry practitioners gain a better understanding of how RE sustainable development can be promoted by the Chinese government. The lessons learned from this China study can also be compared with or used to formulate innovative financing methods and incentive polices for RE sustainable development in other countries.

The Study on Factors Affecting the Attraction of Microblog – An Empirical Study Based on Sina Microblogging Site

Yue He, Yue Zhang(✉), Min Xiao, and Lingxi Song

Business School, Sichuan University, Chengdu 610064,
People's Republic of China
luner.zhang@foxmail.com

Abstract. New media like microblogging site becomes increasingly popular in China nowadays. Microblogging site has become an important social platform for information communication, and also an important marketing channel for enterprises. However, marketing messages are often submerged in a large amount of information on microblogging sites, so how to get more attention for their marketing microblogs becomes a concern of enterprises. Based on the data from Sina Weibo, we put forward "Attraction Index of Microblog" to measure how much attention a microblog has attract. Then we used several quantitative methods like correlation analysis and association rules to find the factors affecting the attraction of microblog, in order to provide some guiding ideas for marketing users to improve the attraction of their microblogs. With empirical studies, we found that microblogs published by authenticated users are more attractive. Whether the microblog has media information does not affect the attraction of microblog. The more fans and microblogs an authenticated user has; the more attractive the user's microblogs are. For a non-authenticated user, the number of fans somehow affects the attraction of their microblogs. The microblogs which are published at 7–10 am or 19–21 pm are more attractive.

Keywords: Microblog marketing · The attraction index of microblog · Influence factor · Association rules

1 Introduction

Sharing and transferring information, from useful knowledge to gossip, is an essential part of social life. In modern society, this needs are met by the social media, which allow people to share information more easily and rapidly. Microblogging site has gained tremendous popularity since their introduction in 2005, with the number of registered users growing exponentially [12]. Twitter, a microblogging service, is one of the most popular social network services [11].

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_45

However, in China, Sina Weibo, similar with Twitter, is currently the most widely used microblogging platform with the most number of users. As of June 2016, the size of micro-blog users was 242 million, and the utilization rate is 34%, which has been gradually recovered compared with the end of 2015 [4]. The widespread use of Sina Weibo has attracted enterprises to pay attention to microblog marketing. Enterprises need to use microblog for branding promotion and products marketing.

With the rapid development of social network based on Web2.0, micro-blog services as an important social platform, which has the advantage of information sharing has attracted the participation of many network users. With the rapid development of Internet and wide application in many fields, most of the enterprises have begun to use the Internet for marketing activities of enterprises, micro-blog can focus on his fans and fans, which can realize real-time information sharing, business information dissemination. As an independent media on social media, the commercial value of micro-blog's business from the micro-blog platform, a large number of users and huge traffic. Enterprises can use micro-blog platform, and according to their own characteristics to implement a variety of marketing activities. Therefore, the paper hopes to find what kind of micro-blog is more likely to get people's attention, and help enterprises to make better social marketing.

2 Related Work

Since Twitter become people's important social networking platform and the important marketing channel of enterprises, there is a growing body of research on Twitter. The characteristics of Twitter and its applications are studied in various fields. Kwak et al. [18] studied the topological features of Twitter, and indicated that Twitter serves more as a news medium than a social network. Fischer and Reuber [5] use an inductive, theory-building methodology to develop propositions regarding how effectuation processes are impacted when entrepreneurs adopt Twitter. Chen [3] studied how active Twitter use gratifies a need to connect with others and the characteristics of user behavior.

There are many scholars have studied the user behavior characteristics on social network like Twitter, and also studied the effect of user behavior on user influence, information spread and information credibility. Cha et al. [1,2] studied the effects of user behavior characteristics such as number of fans and users' authoritativeness on microblog diffusion, and found that microblogs of opinion leaders, celebrities, politicians and entrepreneurs are more widespread. Räbiger and Spiliopoulou [16] proposed a complete framework for supervised separation between influential and non-influential users in a social network, finding that there are predictive properties associated with the activity level of users and their involvement in communities. These studies are focus on the influence of user identity (such as user occupation and user's authoritativeness) and user behavior characteristics (such as number of fans and contact degree between users and fans). They discuss about few influence of contents of tweet. Besides, user influence, information credibility and information spread effect have a certain correlation with popularity or attraction of message, but they are not all the same. Messages of influential users or of credibility may be not attractive. And attractive messages may not have good spread effect (i.e., a tweet receives many comments and likes, but fewer users' retweeting. We may say this tweet is attractive, but with less spread effect).

The largest microblogging website in China, Sina Weibo, born in 2009, also attracts much attention from researchers. In a comparison of Twitter and Sina Weibo, Gao et al. [7] analyzed the textual features, topics and sentiment polarities of posts for two microblogging websites, revealing significant differences between them. Liu et al. [14] analyzed the spatial distribution pattern of Chinese tourism by microblog, and revealed the factors which affect the spatial distribution of tourism. Gao Jie [6] makes some discussion on the celebrity microblog advertisement in Sina micro-blog. Combined with the features of government microblog, Xie et al. [13] constructs a theoretical model, and use structured questionnaire to validate the model. Yu et al. [17] examined the key trending topics on Sina Weibo, compared them with the observations on Twitter. They found that, on Sina Weibo, trends emerge almost completely attributed to reposts of entertainment content such as jokes and images, while on Twitter, the trends are always due to current global events and news stories.

There is also some research about user behavior of popular microblogs on microblogging sites. Qiu [9] qualitatively analyzed the influencing factors on popular microblog from the five aspects of disseminator, dissemination contents, audiences, dissemination channels and dissemination skills. Liu et al. [15] found that source trustworthiness, source expertise, source attractiveness, and the number of multimedia have significant effects on the information retweeting. Guan, Gao and Yang [8] found that male users are more likely to be involved in hot events, and messages that contain pictures and those posted by verified users are more likely to be retweet, while those with URLs are less likely. Lun et al. [10] found that retweeting and commenting are distinct types of microblogging behaviors. Retweeting aims to disseminate information in which the source credibility and posts' in formativeness play important roles, whereas commenting emphasizes social interaction and conversation in which users' experience and posts' topics are more important. Most of them think that a popular microblog is retweeted many times or commented by many people, few of them consider the number of "likes" as the factor to measure the popularities of the microblog.

On the basis of previous studies, this paper combine the forwarding number, the number of comments and points like the number of calculation of "micro-blog attention" score to measure micro-blog attention degree. And through correlation analysis, association analysis to analyze the factors affecting micro-blog attention.

3 Data Collection and Methods

3.1 Data Collection

We randomly extracted 107,328 original microblogs from Sina Weibo with the LocoySpider 8.0. The microblogs were posted from March to April 2015. The data include information about the user (including user's nickname, the number of fans, followers (who the user follows) and microblogs, whether the user is authenticated) and microblog (including microblog content, the number of people who like it, the number of comments, retweeting times, whether with multimedia information, posting time).

Because the data has different dimension or different order of magnitude, which will affect the comparison and analysis of the data, so data standardization is needed first. Data is standardized between the interval [0, 1] with the SoftMax standardization method. The formula to standardize x_i to $x_{i\text{new}}$ is as follows:

$$x_{i\text{new}} = \frac{1}{1 + e^{-x_t}}. \tag{1}$$

The x_t in the formulae (1) is calculated as:

$$x_t = \frac{x_i - \bar{x}}{\sigma}. \tag{2}$$

3.2 MAI ("Attraction Index of Microblog")

Liu et al. [15] measured the attraction of microblog with retweeting times. Lun et al. [8] used number of comments to measure microblog attraction. On Sina Weibo, users can not only "retweet" and "comment" a microblog, but also "like" a microblog. If a user agrees with or appreciates a microblog, he/she may push the button "like". A microblog receives more "like", which means the microblog attracts more attention and love. Therefore, we believe that "like" can also reflect the microblog attention. So the number of "like" should be added into "Attraction Index of Microblog" model.

Compared with "like" and "comment", retweeting is more unique in the three kinds of user behaviors. Retweeting show that a user not only likes this microblog, but is more willing to share with more people. Microblog through retweeting layer upon layer, its mode of transmission is fission, which leads to exponential growth of the number of users it attracts. Therefore, the retweeting times in "Attraction Index of Microblog" model is in the form of exponential function.

According to the characteristics of these three parameters, the number of "like" and comments and the retweeting times should be combined to evaluation microblog attraction. So "Attraction Index of Microblog" was built:

$$\text{MAI} = (\alpha ML_i + \beta MC_i)\, e^{MF_i}. \tag{3}$$

ML_i, MC_i and MF_i respectively represent the number of "likes", comments and retweeting times which are standardized. α, β respectively represent the coefficients of the number of “likes” and comments. In order to determine the coefficient α, β, we used the method of partial correlation analysis. Based on the microblog data, we calculated the partial correlation coefficients of the number of “likes” and comments with retweeting times respectively, which are as the value of α, β.

Partial correlation analysis [10] is used to analyze the partial correlation coefficients of two variables among multiple variables under the control of the effect of other variables, in order to represent the degree of linear relationship.

Suppose there are x_1, x_2, x_3 three variables, it is required to calculate the partial correlation coefficients between the variables x_1 and x_2, with the excluding the impact of variable x_3. The partial correlation coefficient is denoted as r12,3:

$$r_{12,3} = \frac{r_{12} - r_{13}r_{23}}{\sqrt{1 - r_{13}^2\sqrt{1 - r_{23}^2}}}. \tag{4}$$

In formula (4), r_{ij} represents the simple correlation coefficient of variable x_i and x_j, and $i, j = 1, 2, 3$.

The results of partial correlation analysis with SPSS19.0 are shown in Table 2

Table 1. The partial correlation coefficients of the number of “likes” and comments with retweeting times respectively.

	Number of “likes”	Number of comments
Retweeting times	0.457	0.523

Table.1 shows that the coefficients of the number of “likes” $\alpha = 0.457$ and the coefficients of the number of comments $\beta = 0.52$.

Eventually, “Attraction Index of Microblog” formula was:

$$\mathrm{MAI} = (0.457ML_i + 0.523MC_i)\, e^{MF_i}. \tag{5}$$

3.3 Association Rules

Microblog with pictures, video and other multimedia information will bring more visual or auditory stimuli, so these kinds of microblogs more attractive. If the user is authenticated, whose microblog are more reliable and authoritative. So, it is more likely to be commented or retweeted by others, the microblog attraction may also be higher.

We used Apriori model in Clementine 12.0 to analyze the relationship between MAI and microblog multimedia information, users’ authoritativeness respectively. We set the support level with 5%, and the confidence level with 10%.

Association rules is used to find out the relevance hidden in the database, and expressed in the form of rules. It is shaped like an implication "$X \Rightarrow Y$". The associational rule refers to the sets of attribute-values, which frequently appeared in data set recognition, also named as frequent item-sets. Using these frequent sets, association relation rules process is set up. In association rules, count (X) is the number of tuples that object set D contains set X. Support for set X is:

$$\text{Support}\,(X) = \frac{\text{count}\,(X)}{|D|}. \tag{6}$$

Confidence is the proportion of the number of tuples that contains set X and Y and the number of tuples that contains set X:

$$\text{Confidence}\,(X \Rightarrow Y) = \frac{\text{count}\,(X \cap Y)}{\text{count}\,(X)}. \tag{7}$$

Apriori algorithm proposed by Agrawal in 1994 is a relatively simple and general algorithm. The algorithm has two key steps: the first is to find all frequent item sets, and the second is to generate strong association rules.

4 Results

4.1 Descriptive Statistics of MA

For the 107328 microblogs, according to the formula (5) we calculated each microblog's MAI. To limit the value of MAI within [0, 1], we used formula (8) to standardize the value of MAI, then the final MAI of each microblog was got.

$$x_{\text{new}} = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}}. \tag{8}$$

The average of MAI is 6.62×10^{-3}. The minimum value is 0, and the maximum value is 1. The MAI of most microblogs was low. The number of microblogs whose MAI is equal to 0 is 65270, accounting for 60.8% of the total number of microblogs. The number of microblogs whose MAI is greater than the average MAI is 14726, accounting for 13.7% of the total number of microblogs. The MAI distribution is shown in Fig. 1. Due to the small value of MAI, we expanded the value 100 times to display (because the microblogs whose MAI greater than 0.1 is few, Fig. 1 is not in full).

According to the MAI, microblogs were divided into two categories: attractive microblogs and unattractive microblogs. Microblogs whose MAI is greater than the average MAI are attractive microblogs, while Microblogs whose MAI is less than the average MAI are unattractive microblogs. The following analysis is based on this.

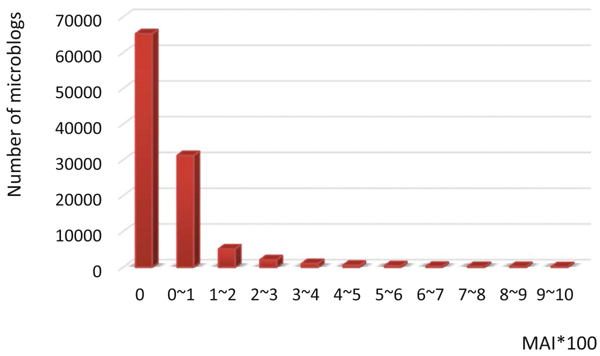

Fig. 1. The MAI distribution situation

4.2 Microblog Multimedia Information and User Authoritativeness

The results of association rules analysis is shown in Table 2:

Table 2 shows:

- Whether the microblog with multimedia information does not affect the microblog attraction.
- Whether the user is authenticated has effect on the microblog attraction. The microblogs posted by authenticated users are more attractive than those posted by non-authenticated users.

Table 2. The extraction results of association rules of MAI

Y	X	support (X)	confidence $(X \Rightarrow Y)$
With multimedia	Attractive	13.72%	72.36%
Attractive	With multimedia	74.52%	13.43%
Authenticated user	Attractive	13.72%	21.49%
Attractive	Authenticated user	8.69%	34.21%

The distribution of MAI of the microblogs respectively post by authenticated users and non-authenticated users is shown in Fig. 2. As we can see, the MAI of microblogs posted by non-authenticated users are lower the authenticated users. It also confirmed whether users' authoritativeness is a key factor affecting the microblog attraction.

4.3 Information of User Behavior

The Spearman correlation coefficients between MAI and the number of user's fans, followees and microblogs respectively are shown in Table 3.

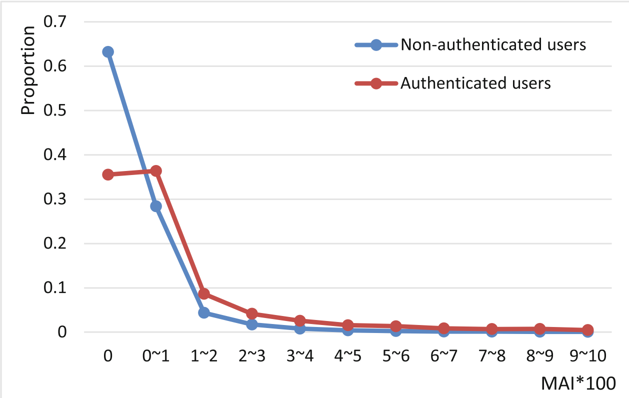

Fig. 2. The distribution of MAI of the microblogs respectively post by authenticated users and non-authenticated users

Table 3. The Spearman correlation coefficients between MAI and the number of user's fans, followers and microblogs respectively

The Spearman correlation coefficient		N_fan[a]	N_fol[b]	N_mcb[c]
MAI	Authenticated user	0.522**	0.113	0.241**
	Non-authenticated user	0.271**	0.074	0.097

[a]: N_fan: The number of fans. [b]: N_fol: The number of followees. [c]: N_mcb: The number of microblogs. **: Correlation is significant at the 0.01 level (2-tailed).

Table 3 shows that for different users, the effect of user behavior on microblog attraction is different. For authenticated users, the number of fans have a great effect on the microblog attraction, with the correlation coefficient reached 0.522, followed by the number of microblogs, and the number of followees has little effect. For non-authenticated users, the number of fans has less effect on the microblog attraction, and the number of followees and microblogs has almost no effect.

4.4 Posting Time

Generally speaking, most people's leisure time is the two period of time at noon and in the evening, so we can guess that microblogs posted in the two period of time are more than other time. So, how about attractive microblogs? Are there also some regularities the posting time of attractive microblogs follow?

In order to study the effects of microblog posting time on microblog attraction, we analyzed the posting time of attractive microblogs. We calculated the number of total microblogs and attractive microblogs per hour, and compared the two distributions of posting time of total microblogs and attractive microblogs.

Due to the large gap of the absolute number of total microblogs and attractive microblogs, it is not suitable to compare the absolute value directly. So, we calculated the proportion of total microblogs and attractive microblogs per hour respectively. For example, the proportion of total microblogs per hour is calculated by dividing the number of total microblogs per hour by the number of all microblogs (107328), so as the proportion of attractive microblogs. The posting time distribution of total microblogs and attractive microblogs is shown in Fig. 3.

As Fig. 3 shows, the posting time distribution of total microblogs conforms to the guess that microblogs posted at noon (11:00–13:00) and in the evening (21:00–23:00) are more than that posted at other time. And there are few microblogs posted between 1:00–7:00 am. We can also find that attractive microblogs posted between 8:00–11:00 and 19:00–21:00 are more than that at other time, and the fluctuation is more obvious.

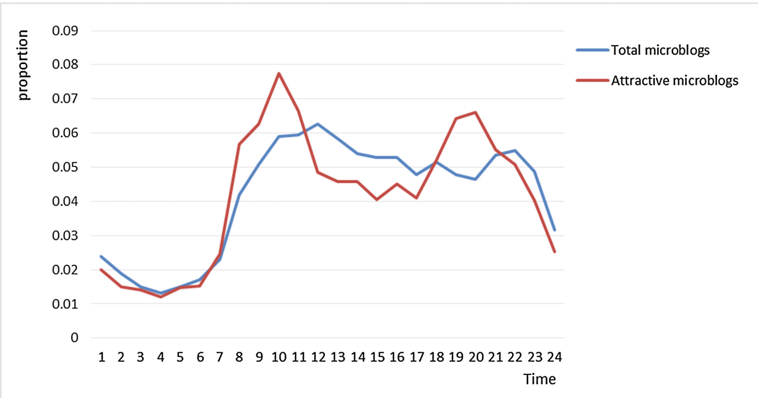

Fig. 3. Posting time distribution of total microblogs and attractive microblogs

In order to observe the posting time distribution of attractive microblogs vividly, the number of attractive microblogs per hour was divided by the number of total microblogs per hour. The proportion of them is shown in Fig. 4, which will eliminate the interference of regularities of the posting time distribution of total microblogs.

From Fig. 4, we can obviously see that the microblogs posted at 8:00–11:00 and 19:00–21:00 are more attractive. Besides, comparing the posting time of total microblogs and attractive microblogs, we can find that attractive microblogs are posted earlier about two hours than total microblogs. According to our real-life, we can explain that most people at the leisure time (11:00–13:00 and 21:00–23:00) are likely to see the microblogs posted 2 or 3 h in advance. So, these microblogs are more likely to be read, increasing the possibility to be retweeted/comment/liked, resulting in becoming attractive microblogs.

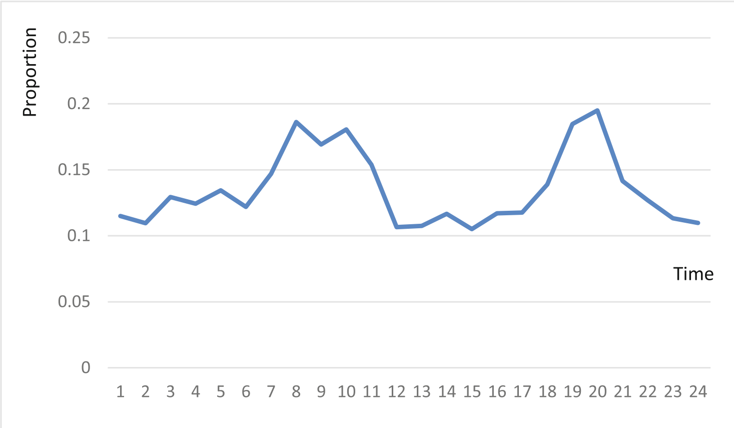

Fig. 4. Proportion of the attractive microblogs within all microblogs per hour

5 Summary and Discussion

Through the empirical research, we found the factors affecting the microblog attraction as follows:

- Users' authoritativeness. If the user is authenticated, he/she is more credible and popular, so his/her microblogs also can obtain others' trust and concern, which makes the microblogs attractive.
- The information of user behavior. For the authenticated users, factors affecting the microblog attraction is the number of fans, followed by the number of microblogs. The more the number of fans or microblogs, the stronger the microblog attraction is. For non-authenticated users, factors affecting the microblog attraction is the number of fans, but it does not affect the microblog attraction as much as the number of authenticated users' fans does.
- Microblog posting time. The study shows that attractive microblogs are mostly posted between 8–11 a.m. and 7–9 p.m., so microblogs posted in these two periods of time would attract more attention.

Our study possesses certain innovation and pertinence. We put forward "Attraction Index of Microblog" to definitely measure how much attention the microblog has attract. And we used several quantitative data analysis methods to analyze how these factors affect the microblog attraction. The findings of our study also have some practical implications. Our study provides some guiding ideas for Weibo users to improve the attraction of their microblogs. Weibo users especially advertisers who aim to market their product and disseminate their corporate culture through microblogging sites, for example, must try to obtain authentication to attract more fans. And they must keep posting microblogs to provide enough messages. It is not necessary to insert media information like pictures or videos into microblogs. It is also important to post microblog in the two period of time, which can make the microblog be seen by more people.

6 Limitations and Directions for Future Studies

This paper has certain innovation, but there are still shortcomings and limitations, which are worthy of exploration and improvement for future research, mainly in the following points:

- We only studied the effects of microblog post form and the user information to the microblog attraction, not considering the influence of microblog content. So in the following research, we can continue to study the effects of microblog content to its attraction, including the microblog sentiment, and topic types etc.
- For the analysis of each factor affecting the microblog attraction, we only used a method. However, different methods as the principle or perspective is different, may lead to different results. Therefore, in the future study, we can analyze the same problem with different methods, and compare the difference of results to choose the more appropriate methods and results.
- The current study examined microblogging behavior using Sina Weibo in the Chinese context. Other social networking sites like Twitter, Facebook have much similarity to microblogging site, but in many ways, they are different, such as different technology, different culture, and different user behaviors between different platforms. Therefore, it would be unacceptably risky to conclude that the findings of this study represent a cross-contextual evaluation of microblogging behavior. Future researchers should make extensive efforts to explore the difference of user behavior between different social networking platforms.

Acknowlegement. A Genetic Algorithm Approach for Loading Cells with Flow Shop Configuration

Patrick Gannon and Gürsel A. Süer(✉)

Department of Industrial and Systems Engineering,
Ohio University, Athens, OH 45701, USA
suer@ohio.edu

Abstract. This paper proposes a three-phase methodology for worker allocation and flowshop scheduling in a multistage manufacturing environment. A case study using a shoe manufacturing plant is examined. The proposed methodology consists of genetic algorithm and mathematical models. Phase 1 allocates workers in between operations in two separate stages in the manufacturing process. Phase 1 evaluates how workers are allocated between and within the manufacturing stages. Phase 2 uses worker allocations from phase 1 to perform cell loading based on machine-level-based similarity using genetic algorithms. Four different Genetic Algorithm approaches are proposed and evaluated. Furthermore, the impact of different manpower levels are also studied. Phase 3 schedules products within cells to optimize makespan, total tardiness, or number of tardy jobs.

Keywords: Genetic algorithms · Cell loading · Flowshop scheduling · Worker allocation

1 Introduction

The goal of this paper is to provide a methodology to most effectively utilize available manpower and optimize the scheduling of products with regards to multiple performance measures. The proper utilization of resources is crucial to success and survivability of any company and the proposed methodology seeks to improve utilization of resources in multi-stage labor-intensive manufacturing environments. Using a shoe manufacturing plant as a case study, this paper addresses the problems of manpower allocation, cell loading, and flowshop scheduling. The shoe manufacturing plant has several cell groups, consisting of a lasting cell (LC), a rotary machine cell (RMC), and a finishing cell (FC) as shown in Fig. 1. The LC and FC are labor intensive manufacturing cells consisting of several sequential operations. A simplified version of the RMC is used in this paper, so the majority of the focus of this paper is on the LC and FC. There are fewer operation types in the LC and FC than there are workers available,

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_46

so several operators can be assigned to each operation. With correct manpower allocation, a balance can be achieved and the cells' output can be maximized. Considering the worker allocation and capacity requirements cell loading can be performed. By carefully assigning products to cells, the benefits of cellular manufacturing, such as reductions in flowtime, setup times, and work-in-progress inventories, can be realized. Once products are assigned to cells, scheduling is performed in each cell group independently. Scheduling is necessary when resources are limited and need to be optimally utilized for several competing tasks.

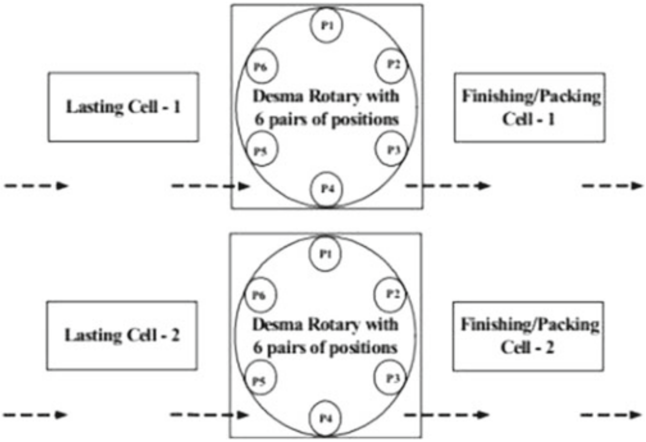

Fig. 1. Shoe manufacturing system

1.1 Products

This plant produces shoes with a variety of designs, colors, and materials. The shoes are available in two sole types, full shot or midsole. Of these two sole types, the shoes can be made using either PVC or TPR and are available in three colors (black, honey, and nicotine). The breakdown of this product structure is shown in Fig. 2.

The demand for shoes is based on their size. The sizes range from size 5 to size 15 and demand is greatest closest to middle of the size range. The demand curve shown in Fig. 3 demonstrates the relationship between size and demand.

1.2 Rotary Machine

The Rotary Machine Cell (RMC) is the bottleneck of the manufacturing cell. The RMC has six available positions, each of which can process a pair of shoes. The Rotary Machine also has a tank to hold the material to be injected. Unprocessed shoes are loaded into the machine and injected with either PVC or TPR in order

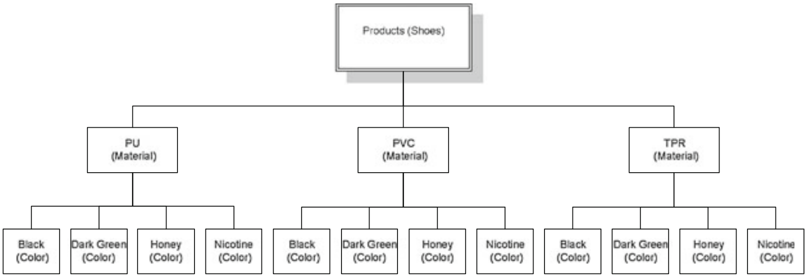

Fig. 2. Product types

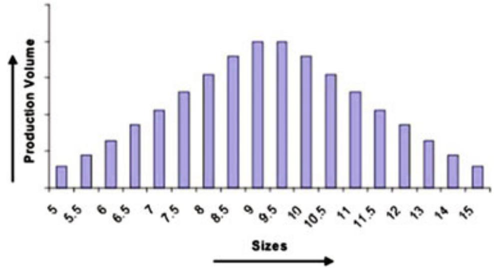

Fig. 3. Typical shoe demand by size

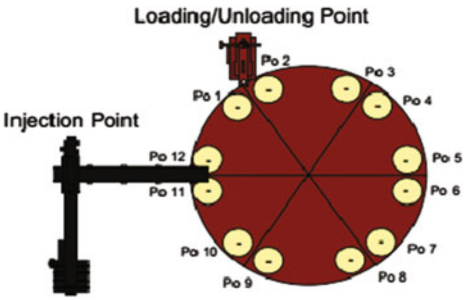

Fig. 4. Rotary injection molding machine

to form the soles of the shoes. A setup period is needed to switch materials or colors to be injected since the machine possesses only one tank to hold the material.

The Rotary Machine consists of a loading/unloading station, an injection station, and four cooling stations. Figure 4 illustrates the setup of the rotary machine. A shoe's processing time on the Rotary Machine is influenced by the mold type (full shot or mid-sole), the size of the shoe, and whether it is designed for males or females. The average injection molding time for full shot shoes is 0.356 min for male shoes and 0.3 min for female shoes. Midsole shoes require less processing, having average injection molding times of .286 min for male shoes and .25 min for female shoes. Table 1 shows injection times for the various designs at the available sizes. Times are classified as Fullshot (FS), Midsole (MS), male (M) and Female (F).

Table 1. Injection Times

FS/MS	M/F	Different sizes								
		1	2	3	4	5	6	7	8	9
		5	5.5	6	6.5	7	7.5	8	8.5	9
FS	M	-	0.224	0.247	0.269	0.281	0.289	0.290	0.301	0.306
FS	F	0.154	0.207	0.216	0.229	0.23	0.237	0.308	0.338	0.356
MS	M	-	-	0.160	0.162	0.203	0.239	0.24	0.242	0.245
MS	F	0.109	0.116	0.183	0.190	0.196	0.260	0.261	0.290	0.305
FS/MS	M/F	Different sizes								
		10	11	12	13	14	15	16	17	18
		9.5	10	10.5	11	11.5	12	13	14	15
FS	M	0.32	0.342	0.372	0.426	0.428	0.448	0.460	0.499	0.556
FS	F	0.368	0.395	-	0.424	-	0.440	-	-	-
MS	M	0.247	0.273	0.293	0.311	0.349	0.398	0.401	0.405	0.415
MS	F	0.31	0.342	-	0.344	-	0.347	-	-	-

Shoes loaded into the rotary machine cannot be unloaded until all shoes in the machine have been processed. This leads to shoes with lower processing times spending more extra time in the machine relative to shoes with higher processing times. This extra time leads to extra material being injected into their molds. Because of this, it is beneficial to minimize variations in the processing times of shoes that are to be loaded together. However, this problem has been addressed in prior works [6,12,16], so for the purpose of this paper, one size will be assigned at a time in the rotary machine.

1.3 Molds

Different molds are needed for processing shoes depending on size and type (Full Shot or Mid Sole). The molds carry a prohibitive cost, limiting their availability. As shoes of varying size and type are processed in the RMC, the molds have to be constantly changed in order to process the corresponding shoe. Also, the molds have to be cleaned when the material or color is changed. The problem considering a limited number of molds for each size has been addressed previously in the literature. For this study, it is assumed that there are no mold availability restrictions.

2 Literature Review

This paragraph will briefly discuss some prior cell loading and manpower decision work done in the literature. Süer, Saiz, Dagli, and Gonzalez [14] expanded research in the cellular control area to multi-cell environment, which necessitates cell loading considerations. Süer [13] developed a two-phase methodology to find optimal manpower allocation and cell loads simultaneously. An extension of this work was done by Süer [13]. This work add lot-splitting considerations to the two phase approach to find optimal manpower allocation and cell loads and found that lot splitting is advantageous when setup times are negligible. Akturk [1] addressed the production planning problem in cellular manufacturing systems. By using capacity constraints to evaluate the impact of cell loading decisions on lower levels, they were able to more accurately portray the cellular manufacturing system and its operation. Saad [9] developed a multi-objective optimization technique to load and schedule cellular manufacturing systems using simulation and a taboo search algorithm. Babayigit [2] analyzed the problems of manpower allocation and cell loading with a mathematical model and genetic algorithm, further extending previous works by Süer [13,14].

Süer [15] proposed a three-phase methodology to address cell loading and product sequencing in labor-intensive cells. Optimal manpower allocation and cell loads are found in the first two stages and the third stage treats product sequencing as a travel salesman problem to minimize intra-cell manpower transfers. Some scheduling work done in the literature is discussed in this paragraph. Nakamura [8] considered group scheduling on a single stage to minimize total tardiness and found that scheduling problems of moderate size can be ordered to reduce the number of schedules to be searched. Sinha [10] found that a desired level of throughput and optimum work-in-progress in a cell can be achieved through sequencing, reduced batch size, and period batch control. Gupta [5] developed an optimization algorithm and heuristic procedures to schedule jobs on two identical machines. The objective was to find a schedule with optimal total flowtime that gives smallest makespan. Kim [3] used a restricted taboo search algorithm to schedule jobs on parallel machines in order to minimize the maximum lateness of jobs. Gupta [4] studied single machine group scheduling with sequence-independent family setup times in order to minimize total tardiness. The heuristics developed were shown to be effective in minimizing total tardiness.

Subramanian [11] focused on cell loading and job scheduling at a shoe manufacturing plant. The objective of this research was to develop heuristics for cell loading and combine these with simple scheduling methodologies to load all jobs without exceeding capacity. This capacity was set using a MaxCap methodology, which is the maximum capacity to be loaded. This methodology is critical in determining the number of cells required and how the load is spread across different cells in the facility. An interesting finding from this research is that the optimal result from the cell loading stage may not remain optimal after the cell scheduling stage. Urs [7] developed three scheduling heuristics using basic machine scheduling methodology. The heuristics aimed to minimize makespan in the rotary machine scheduling. The best performing heuristic was the minimum difference in cycle time heuristic. This research stands out from prior works by assuming a limited number of molds for each size, meaning multiple sizes can be run on the Rotary Molding Machine simultaneously. Mese [7] studied cell loading and family scheduling in a cellular manufacturing environment. This study is distinguished from prior research by giving every job in a family an individual due date. A focus of this study was the tradeoff between meeting due dates of jobs and reducing total setup time. Setup times are reduced if all jobs of a family are scheduled together, but this could cause delays and tardiness in other jobs in other families. A way to offset this is to allow family splitting, but this increases setup times and in return may increase the number of tardy jobs. The author used mathematical modeling and a genetic algorithm to solve this problem. The mathematical model was slow and impractical to use for larger problems. The GA developed was both effective in finding optimal or near optimal solutions and efficient.

Süer [16] developed a three phase methodology to perform cell loading and scheduling in a shoe manufacturing company. This research used three family definitions (sub-families, families, and superfamilies) in the cell loading process. These different family definitions are used at different stages of the planning and scheduling process. Superfamily definition was used to determine the number of cells of each type. Family definitions are used after product-to-cell assignments. These families allow the number of setups to be minimized. Finally, the subfamily definition is used in the implementation of heuristics before cell loading begins. This research also used the MaxCap methodology used by Subramanian [12]. A valuable conclusion from this research is that the best post loading results did not give the best post scheduling results. This demonstrated the need to consider that isolating a single level of a multilevel problem may not result in the best solution for the overall problem. Only the injection molding cell is covered in this research, leaving further research to be done regarding the lasting and finishing cells in the shoe manufacturing company.

3 General Methodology

The three-phase methodology proposed to solve the problem is described in the following sections.

Phase 1 - Manpower Allocation

Thirty-five workers are split between the LC and FC. The six worker splits evaluated are 15/20, 16/19, 17/18, 18/17, 19/16, 20/15, where 15/20 represents 15 workers available for allocation in the LC and 20 available in the FC. The workers allocated to the LC and FC are then allocated among the operations within those cells. A mathematical model is used to optimally allocate manpower in order to maximize production rates. The model is run separately for each product at each worker level in both the LC and FC.

Phase 2 - Cell Loading

Products are assigned to cells in order to maximize the machine-level based similarity among products in the cells and also minimize the number of cells opened. A genetic algorithm is used to assign products to cells.

Phase 3 - Flowshop Scheduling

After jobs have been assigned to cells, flowshop scheduling is performed in each cell to minimize one of three performance measures. The performance measures considered are makespan, total tardiness, and number of tardy jobs. The methodology is summarized in Table 2.

Table 2. Summary of General Methodology

Hase	Method	Objective	Cells	Purpose
1-Worker allocation	Mathematical model	Maximize production rate	LC, FC	Assign workers to stations in LC & FC
2-Cell loading	Genetic algorithm	Maximize machine level similarity between products within cells	LC, FC	Assign products to cells, minimize machines required
3-Flowshop scheduling	Mathematical model	Minimize makespan, number of tardy products, total tardiness, number of machines	LC1-RC1-FC1	Determine sequence of LC2-RC2-FC2 products along with start LCn-RCn-FCn and completion time independently

4 Manpower Allocation Phase

In phase 1, workers are allocated to stations in the LC and FC, considering various worker levels, in order to maximize production rates. The model is solved for each product at each worker level and in both the LC and FC.

The index, parameters and decision variables are defined below:

Index:

j : Operation

Parameters:

R : Production rate for the product;

t_j : Unit operation time for operation j;

u_j : Maximum number of operators for operation j;

W : Total number of workers available

Variable:

m_j : Number of workers assigned to operation j

Objective Function:

$$\max \ Z = R \tag{1}$$

$$\text{s. t. } m_j \left(\frac{1}{t_j}\right) - R \geq 0, j = 1, 2, \cdots, s \tag{2}$$

$$m_j \leq U_j, j = 1, 2, \cdots, s \tag{3}$$

$$\sum_{j=1}^{s} m_j \leq W \tag{4}$$

m_j integer and positive for all j

R positive.

Equation (1) shows the objective function of the mathematical model, which is to maximize the production rate. The relationship between number of workers at a station and the production rate is determined in Eq. (2), ensuring enough workers are assigned to each operation to meet the desired production rate. Eq. (3) establishes an upper limit on the number of workers allowed at an operation. Equation (4) ensures that the total number of workers assigned to the stations does not exceed the total number of workers in the system. An example will be used to explain each phase of the problem. An example featuring 10 products each with five operations in both the LC and FC will be used. Unit processing times are given in Table 3. The mathematical model described earlier in this section was run using these processing times. The optimal worker allocations for product 1 at all worker levels are shown in Table 4. Table 5 shows optimal worker allocations for all 10 products at the 15/20 worker level.

Table 3. Unit processing times (minutes/unit) for the example problem

Product	Lasting cell					Finishing cell				
	Operations					Operations

8	15/20	2	5	4	1	3	3.5211	4	6	2	1	7	2.439
9	15/20	3	2	4	3	3	3.2797	5	6	3	2	4	9.7561
10	15/20	5	2	3	3	2	2.069	5	7	2	2	4	3.1746

The mathematical model was solved using ILOG OPL 6.3. The optimal production rates are determined in both the LC and FC at the given worker level. For example, product 2 at the 15/20 worker level for the Lasting Cell requires three workers at each operation and results in a production rate of 3.52 units/minute.

5 Cell Loading Methodology

Cell loading is performed using a genetic algorithm approach to maximize the similarity among products while minimizing the number cells opened. Similarity between jobs is measured using the machine level-based similarity coefficient between products i and k developed by Süer and Ortega [14]. The coefficient is calculated using Eq. (5). A sample calculation using the worker allocations in the lasting cell for products 1 and 2 is shown in Eq. (5).

$$\mathrm{MLB} - SC_{ik} = \frac{\sum_{j=1}^{s} \min(m_{ij}, m_{kj})}{\sum_{j=1}^{s} \max(m_{ij}, m_{kj})}, \tag{5}$$

$$\mathrm{MLB} - SC_{12} = \frac{\min(4,3) + \min(4,3) + \min(3,3) + \min(2,3) + \min(2,3)}{\max(4,3) + \max(4,3) + \max(3,3) + \max(2,3) + \max(2,3)}$$

$$= \frac{13}{17} = 0.76.$$

This calculation is performed for each pair of jobs to create the similarity matrix used in the genetic algorithm approach. A similarity matrix was generated to evaluate similarity between jobs at each worker level. The matrix generated for the example problem is shown in Table 6.

Table 6. Product similarity coefficients

Products	1	2	3	4	5	6	7	8	9	10
1	-	0.76	0.67	0.5	0.58	0.67	0.76	0.67	0.67	0.76
2	-	-	0.76	0.58	0.76	0.88	0.67	0.67	0.88	0.76
3	-	-	-	0.5	0.58	0.67	0.58	0.58	0.67	0.67
4	-	-	-	-	0.58	0.67	0.58	0.58	0.67	0.5
5	-	-	-	-	-	0.88	0.58	0.58	0.88	0.67
6	-	-	-	-	-	-	0.67	0.67	1.00	0.76
7	-	-	-	-	-	-	-	0.76	0.67	0.58
8	-	-	-	-	-	-	-	-	0.67	0.5
9	-	-	-	-	-	-	-	-	-	0.76
10	-	-	-	-	-	-	-	-	-	-

The capacity requirements are calculated using the production rates found in phase 1 and demand. Each product's demand and capacity requirements are shown in Table 7. Capacity requirements are shown in minutes and as fraction of the total minutes available in each cell. Also, capacity requirements are determined for both the LC and FC and cells are loaded so that neither is over the allowable utilization, 100% for the example problem. An example solution for the problem are shown in Table 8. Cell 1 is assigned products 10, 7, 6, and 2. The utilization in the LC is 0.88 and the utilization for FC is 0.71.

Table 7. Capacity requirements

Product	Demand	Lasting cell			Finishing cell		
		Production rate	Capacity requirement (min)	Capacity requirement (as fraction of 2400 min)	Production rate	Capacity requirement (min)	Capacity requirement (as fraction of 2400 min)
1	1863	2.84	656.70	0.27	4.55	409.86	0.17

Family 1	[10,7,6,2]	0.88	0.71
Family 2	[8,3,1]	0.97	0.77
Family 3	[9,5,4]	0.83	0.4

5.1 Flowshop Scheduling Methodology

The objective of the mathematical model for flowshop scheduling is to sequence the jobs in each part family such that the desired performance measure (makespan, total tardiness, or number of tardy job) is minimized.

Production rates found in phase 1 are used to determine processing times for the LC and FC. The processing times for the RMC are determined by the shoes mold type and size. The indices, parameters and decision variables are described below.

Index:
u : Cell index;
j : Job index

Parameters:
P_{ij} : Processing time of job j in cell i;
d_j : Due date of job j;
r : Small number j;
M : Large number

Decision variable:
y_{ij} : Start time of job j in cell i;
c_{ij} : Completion time of job j in cell i;
t_j : Tardiness of job j;
w_j : 1 if job j is tardy, 0 otherwise;
z_{ji} : 1 if job j is processed before job i in cell 1, 0 otherwise;
b_{ji} : 1 if job j is processed before job i in cell 2, 0 otherwise;
g_{ji} : 1 if job j is processed before job i in cell 3, 0 otherwise;
TT : total tardiness variable;
h : makespan variable
Objective functions:

$$\min\ N_1 = \sum w_j + r \times \sum t_j, j = 1, 2, \cdots, n \tag{6}$$

$$\min\ N_2 = TT \tag{7}$$

$$\min\ N_3 = H. \tag{8}$$

$$\text{s. t.}\ \sum t_j = TT, j = 1, 2, \cdots, n \tag{9}$$

$$c_{ij} \leq h, j = 1, 2, \cdots, n \tag{10}$$

$$y_{i+1,j} - y_{ij} \geq p_{ij}, j = 1, 2, \cdots, n \tag{11}$$

$$c_{ij} - y_{ij} \geq p_{ij}, j = 1, 2, \cdots, n \tag{12}$$

$$c_{ij} - \geq d_j, j = 1, 2, \cdots, n \tag{13}$$

$$M \times w_j \geq t_j, j = 1, 2, \cdots, n \tag{14}$$

$$y_{ij} - y_{ij+1} + M \times z_{ij} \geq p_{ij}, j = 1, 2, \cdots, n \tag{15}$$

$$y_{ij+1} - y_{ij} - M \times z_{ij} \geq -M + p_{ij}, j = 1, 2, \cdots, n \tag{16}$$

$$y_{ij} - y_{ij+1} + M \times b_{ij} \geq p_{ij}, j = 1, 2, \cdots, n \tag{17}$$

$$y_{ij+1} - y_{ij} - M \times b_{ij} \geq -M + p_{ij}, j = 1, 2, \cdots, n \quad (18)$$

$$y_{ij} - y_{ij+1} + M \times g_{ij} \geq p_{ij}, j = 1, 2, \cdots, n \quad (19)$$

$$y_{ij+1} - y_{ij} - M \times g_{ij} \geq -M + p_{ij}, j = 1, 2, \cdots, n. \quad (20)$$

The various objective functions which can be used depending on the desired performance measure are shown in Eqs. (6), (7), (8), which seek to minimize number of tardy jobs, total tardiness, and makespan, respectively. Eq. (9) sums the jobs tardiness to define total tardiness. Eq. (10) establishes the relationship between the jobs' completion time and its makespan, ensuring that makespan is equal to the completion time of the last job. Eq. (11) ensures that a job has to finish processing in its current cell before it can start in the following cell. In a similar manner, Eq. (12) ensures that a job must complete processing in the final cell before it can be labeled complete. The relationship between completion times, due dates, and tardiness is established in Eq. (13). Equation (14) assigns a value of either zero, for on time jobs, or one, for tardy jobs. Equations (15) and (16) perform a pairwise comparison between jobs in cell 1 to determine which job is processed first. This comparison is done between all jobs and Eq. (17) through Eq. (20) show the comparison being performed in the second and third cells.

The schedules for the part families from the example with regards to makespan are shown in Table 9. For example the sequence for part family 1 is 2-7-6-10 and the makespan is 53. A Gantt chart is shown for part family's schedule with regards to makespan in Fig. 5.

Table 9. Example schedules to minimize makespan

	Schedule				Makespan
Part Family 1	2	7	6	10	53
Part Family 2	8	3	1	-	60
Part Family 3	5	4	9	-	50

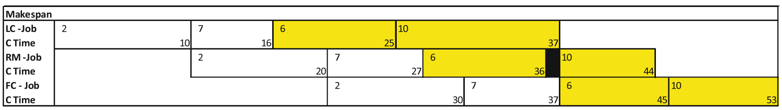

Fig. 5. Gantt chart for family 1

6 Genetic Algorithms Approaches for Cell Loading

A genetic algorithm for cell loading is proposed in this section. Chromosome representation, crossover, and mutation strategies used are discussed. The genetic algorithm has two crossover strategies and the option to perform mutation before crossover. This created four general strategies; (1) order-based crossover before mutation, (2) position-based crossover before mutation, (3) order-based crossover after mutation, and (4) position-based crossover after mutation. Within each of the four general strategies, ten combinations of crossover probability and mutation probability were tested. Five trials were performed for each crossover and mutation probability combination in each of the general strategies.

The chromosome initially is created by randomly ordering the products. The cells are then loaded sequentially from the randomly ordered list. When the utilization in either the lasting cell or finishing exceeds a maximum allowed utilization, that cell is closed and the next cell is opened. This continues until all products are assigned to a cell. An example of the chromosome representation is shown in Table 10. The fitness function is calculated using Eq. (21).

$$\max Z = \sum_{i=1}^{n}\sum_{k=1}^{n} S_{ik}x_{ik} - \sum_{k=1}^{n}(px_{kk}). \tag{21}$$

Table 10. Example chromosome representation

	Product sequence									
	1	2	3	4	5	6	7	8	9	10
Product	2	4	1	5	6	8	3	9	10	7
LC Utilization	0.24	0.3	0.28	0.17	0.22	0.2	0.2	0.15	0.23	0.26
FC Utilization	0.27	0.3	0.17	0.3	0.25	0.22	0.18	0.15	0.23	0.18
Cell	1	1	1	2	2	2	2	3	3	3
Total LC Util	0.24	0.54	0.82	0.17	0.39	0.59	0.79	0.15	0.38	0.64
Total FC Util	0.27	0.57	0.74	0.3	0.55	0.77	0.95	0.15	0.38	0.56

Two crossover strategies are used in the genetic algorithm, order-based crossover and position-based crossover, and these strategies are discussed in the ensuing paragraphs. Position-based crossover is performed by selecting a set of positions at random from one parent chromosome and passing the values at these positions to the child. The missing genes are then selected and filled in the child chromosome in the order they appear in the other parent chromosome. If there are an even number of products, (#Products)/2 is used to determine the number of random positions selected, (#Products-1)/2 is used for an odd number of products. Order-based crossover is performed by selecting a string of genes from one parent and passing the string onto the child chromosome. The remaining genes are then filled in the order they appear in the other parent chromosome. Examples of position-based crossover and order-based crossover are shown in Figs. 6 and 7, respectively. The arrows show how genes are passed from the parent chromosome to the child chromosome.

The mutation strategy used is reciprocal exchange mutation. This is performed by using random numbers to select two positions in the chromosome and swapping the values in these positions. An example of this mutation strategy is shown in Fig. 8.

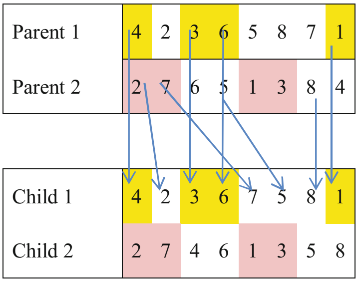

Fig. 6. Position-based Crossover

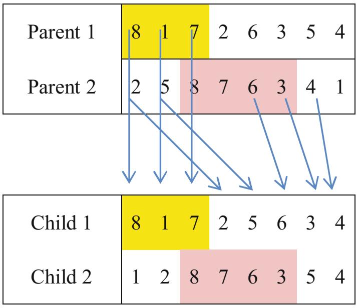

Fig. 7. Order-based Crossover

Chromosome before mutation								
Job	1	2	3	4	5	6	7	8
Chromosome after mutation								
Job	1	7	3	4	5	6	2	8

Fig. 8. Mutation Example

After crossover and mutation have been performed, products are reassigned to cells in the same manner as the original chromosome to ensure the maximum utilizations are not exceeded. Selection is by selecting the top chromosomes among both the parent and child chromosomes to move onto the next generation. This study also investigates the effect of performing mutation before crossover. Classical genetic algorithms flow is crossover before mutation. By reversing the traditional flow, it is possible better parent chromosomes will be created and performing crossover with the better parent chromosomes will result in improved offspring chromosomes. Selection is done in this study by selecting the best ranked chromosomes from all the parent and offspring chromosomes for the next generation.

7 Results and Conclusion

Scheduling is done on the part families found using the four GA strategies. The scheduling results for the worker levels are shown in Tables 11, 12, 13, 14, 15 and 16 below. The bolded and italicized values in the tables below indicate that those are the best result in the particular performance measure in that worker level.

At the 15/20 worker level given in Table 11, GA Strategy 2 either outperformed or tied with respect to MS, TT and number of machines required whereas GA Strategy 4 provided the best result in nT. At the 16/19 worker level shown in Table 12, GA Strategy 4 dominated all other strategies. At the 17/18 worker level presented in Table 13, no strategy dominated others. However, GA Strategy

3 outperformed others with respect to total tardiness and number of machines while GA Strategy 4 outperformed in makespan. At worker level 18/17 given in Table 14, GA Strategy 3 dominated in all scheduling performance measures. However, this strategy requires a significant increase in number of machines relative to the other strategies. This is because an additional part family is opened in this strategy. At worker level 19/16 shown in Table 15, no strategy demonstrated dominance over the rest. GA Strategy 2 and GA Strategy 4 performed equally well. At worker level 20/15 presented in Table 16, GA Strategy 3 dominated in makespan and tied for dominance in nT and number of machines required. Also, GA Strategy 3 provided the lowest makespan among all worker levels in this problem. GA strategy 4 dominated in total tardiness.

The results are summarized in Tables 17 and 18. In terms GA strategies, GA Strategy 3 was the overall best GA Strategy (3 out of 7 times). This was followed by GA Strategies 2 and 4 (2 out of 7 times). GA Strategy 1 never made the list. The variation in MS was 58-61 and nT was 8-9 whereas it was much

MS	58	20/15	GA3
nT	8	20/15, 19/16, 16/19	GA3/GA4, GA2/GA4, GA4
TT	111	19/16	GA1/GA3
# Machines	247	18/17	GA2

higher in terms of TT (111–137) and number of machines (247–279) as shown in Table 17. Finally, the best values of performance measures obtained in this experimentation are summarized in Table 18. We can safely say that unbalanced manpower levels in LC and FC produced better results, in other words, worker levels 20/15, 19/16, and16/19. One can actually say that higher manpower level in LC seemed to work better. One again, GA Strategy 3 produced better results along with GA Strategy 4.

Abstract. In this paper, to take the group buying platform as an example, we use Helloing model to analyze the influence the pricing and profit of the platform enterprises under the different homing behaviors of users. The analysis platform of enterprise competitive strategy from the perspective of pricing and profit, we show that compared with network externalities, the influence of differences is bigger about platform enterprises; changed the competitive strategy to improve customer loyalty can bring more profits; mutual cooperation between the platform of enterprise will increase the enterprise platform competitiveness. We hope to provide references for the competitive strategic choices of the platform enterprises.

Keywords: Group purchase platform enterprise · Hotelling model · Bilateral platform enterprise · Competitive strategy

1 Introduction

In recent years, bilateral market is the industrial organization and the theory of competitive strategy research. Its unique business platform competition strategies have attracted the attention of scholars. The earliest group buying websites appeared in United States (U.S. buy network Groupon). It is mainly the use of consumers to get a larger discount psychology, and take shape an effective network interaction. Then, group buying to earn service fees from businesses. Influenced by this operating mode Chinese group purchase network development rapid after 2010. From the group purchase network to the mobile terminal APP application, Meituan, Public comment network, Juhuasuan, Baidu Nuomi, Wowo Group and other large professional group buying provide abundant products that involved in almost every aspect of people's life such as food, clothing, cosmetics beauty, fitness, hotel, tourism and so on. Then consumers are attracted by lower prices and larger discounts. With the increase of the number of consumers, more and more merchants registered in platform of enterprise. Volume of business brings in profit for the platform enterprise. According to the Chinese group purchase market statistics in June 2015 shows that by the end of June

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_47

2015, Chinese network group purchase transaction volume reached 16.74 billion yuan, compared to the same period the growth of 182.5%, the number of people who participate in the group reached 250 million person-times, compared to the same period the growth of 161.8%. As a typical enterprise platform, group purchase platform competition is increasingly fierce. Everything is not going smoothly. Due to the diversity of businesses and consumers, some businesses and consumers will choose a platform for business, others will be registered in enterprises with different network platform. The choice behavior of different businesses and consumers will influence the pricing direction and profit of enterprise platform. Research the choice behavior of consumers and businesses to develop a reasonable pricing mechanism and competitive strategy for different types of choice is of great significance for the development of the group buying platform.

2 Related Works

Entering twenty-first Century, the bilateral market theory has attracted wide attention with the rapid development of the information economy. As the leading theory of industrial organization, its importance has been increasing. The earliest examples of two-sided markets can be traced back to the "New York sun" led the so-called "penny movement", all the journalists no longer need to pay the cost to buy a newspaper, the newspaper operator is the main profit from advertising revenue [1]. Rochet and Tirole [7] thought bilateral market is described that have two independent edge, and its ultimate benefit from the platform transaction. They established a bilateral market platform model that has become research basis of bilateral market theory. Cheng and Sun [6] put forward that bilateral market is a dumbbell type structure, the participating parties B expressed as consumers, and the participating parties S as businesses, as shown in Fig. 1.

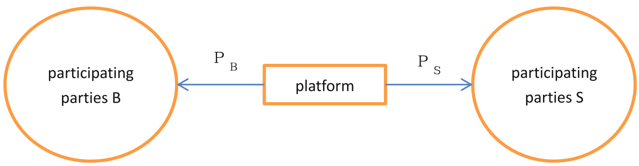

Fig. 1. Two sided market simplified schematic

Chen [4] proposed the network group purchase system, the network group purchase has carried on the more comprehensive description (Fig. 2). As a bilateral platform for enterprises, group buy site is also a two different types of participants through the platform to trade. It is the specific bilateral market dumbbell type structure too.

Through the study a lot of literature, most of scholars think that the bilateral market has the following characteristics. Firstly, the platform has two different types of user (businesses and consumers) at least in the market, and provides

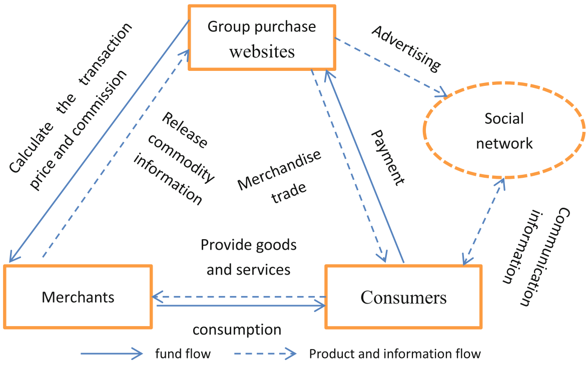

Fig. 2. Network group purchase system

different products or services for different types of user. Or make a deal for different types of user through the platform. Secondly, various types of user interaction platform, they need each other. Platforms help them to complete the transaction and improve the efficiency of transaction. Thirdly, the existence of network externalities between different types of client platform, which increased the number of user on the platform in one side (for example increasing the number of consumers) will increase the value of platform for other types of user [5].

In recent years, with the advent of the era of big data, there has been a new platform of bilateral market enterprise research. Bardey, Helmuth and Lozachmeur [2] studied competition in two-sided markets with a common network externality rather those than with the standard inter-group effects. Behringer and Filistrucchi [3] showed that a two-sided monopolist may find it short-run profit-maximizing to charge a price below marginal cost on one side of the market. Hence showing that the price is below marginal cost on one side of a two-sided market cannot be considered a sign of predation. They then argue for a two-sided Areeda-Turner rule that takes into account price-cost margins on both sides of the market. Roger [8] studies duopoly in which two-sided platforms compete in differentiated products in a two-sided market. Zhu [10] talked about the platforms that is from the one-sided market to the one-sided + two-sided market, as an example of JD.com. Scholars from different angles discussed the bilateral market competition relationship, research more and more comprehensive. This paper will discuss the competitive relationship of bilateral market based on the user ownership relationship.

3 Put Forward Problems

In the bilateral market, users (merchants and consumers) will consider their own interests. Some consumers and businesses only register a group purchase platform, or choose only one platform to make a deal. This user's behavior belongs to the single homing. Other consumers and businesses are registered or select more than one platform to consumption. This user behavior belongs to multi homing. Users behavior present in more than one group purchase platform, because its ownership behavior is not unified. Poolsombat and Vernasca thought in the bilateral market this behavior called partial multi-homing that one part of user belongs to the single homing and other part of user belongs to multi homing. In reality, the users both ends of platform companies such as most of group purchase platform belong to partial multi-homing. Taking into account the factors of customer loyalty, homing behaviors of user are divided into three types: the type of one is the consumers and businesses all belong to single homing behavior; the type of two is the consumers or businesses belonging to partial multi-homing, and other businesses and consumers belong to single homing; types of three consumers and businesses are belonging to partial multi-homing. According to the characteristics of the bilateral market and external factors that influence the bilateral market, this paper studies the following problems.

(1) Owing to the difference between two sides of group platform and impact on network externalities, leading to businesses and consumers have different homing behaviors. The type of users' homing behavior in the difference between the group buying platforms can have an effect on great difference. Whether it can reduce the impact of network externalities, obtain a larger profit for group buying platforms.
(2) Businesses and consumers can freely choose the ownership of the group purchase platform. Belonging to different behavior of businesses and consumers will affect the group purchase platform enterprise pricing. Because of consumers and businesses of different homing types, group purchase platform pricing may be different.
(3) In the two-sided market can choose freely under the condition of different attribution behavior of businesses and consumers. Corporate profits will affect by consumers and businesses of different types of ownership. As a result, group purchase platform gains may be different.
(4) In order to develop itself, group purchase platform may often take different strategy. For example they use market segmentation to attract different consumers and businesses. By taking the difference strategy, ownership behavior of consumer businesses may be changed. Ownership direction guiding of users may bring more profits for the platform of enterprise development.

4 The Model of Competition

Hotelling model is an important analytical model in the theory of industrial organization. Amstrong [9] is an earlier study on the pricing strategy of platform competition in two-sided markets by using the Hotelling analysis framework. In this paper, we also learn from this analysis framework to study competition strategy of the group buying platform.

First of all, we define symbols for the convenience of research and then discuss classification. In this model, service cost of the group buying platform to provide users is ignored.

Notation:

i, j: Two platform enterprises with a competitive relationship;
k, m: Businesses and consumers are located on both sides of the group buying, and obey the uniform distribution on the line k, $m = 1, 2$;
v_k^i, v_k^j: The user register exchange on the group-buying platform i and platform j
p_k^i: Group-buying platform pricing for the users;
t: User to buy platform unit transportation cost (its economic meaning of the difference between the two platforms);
β: Network externalities between the users;
v_0: Users obtain basic utility from platform i or platform j based on the net utility of the platform, if all the users will be registered on the platform to have transaction at least, the v_0 tends to infinity;
n_k^i, n_k^j: The number of single homing user group K on the group buying platform i and platform j;
N_k^i: The number of single homing and the number of multi homing on the group buying platform i of users user group K;
π: The profit of group buying, equal to the number of users of the price multiplied by the price;
ss: Both of two sides are single homing
sm: One side is single homing, another side is partial multi-homing;
mm: Both of two sides are partial multi-homing

4.1 Both of Two Sides are Single Homing

In this model, two group purchase platform enterprise that have competitive relation are supposed, and located at the ends of the line segment [0,1]. Businesses and consumers are users of two sides of group purchase platform enterprise. Through the comparison net income of group buying platform 1 and group buying platform 2, users choose a high net income platform registered and traded. As shown in Fig. 3, making Hotelling model, a user side K to group purchase platform 1 distance is x, and to the group purchase platform 2 distance was $1 - x$. Obviously, the group purchase platform profit equals based utility minus the paid price, minus the cost of transportation, and add users to the group purchase website external effect.

Thus we get v_k^1 and v_k^2:

$$v_k^1 = v_0 - p_k^1 - tx + \beta n_m^1, v_k^2 = v_0 - p_k^2 - t1 - x + \beta n_m^2.$$

A and B is homing zero point on the both of two sides of two group purchase platforms, and in this two points the users obtain same profit. The number of users in the platform $n_k^1 = x$, $n_m^1 + n_m^2 = 1$, so:

$$n_k^1 = 1/2 - 1/2t(p_k^1 - p_k^2) + \beta/2t(2n_m^1 - 1).$$

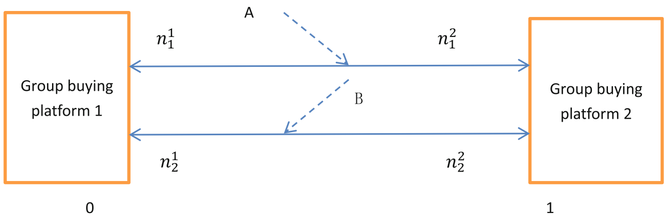

Fig. 3. The user of both of two sides are single homing

Then get the solution:

$$\begin{cases} n_1^1 = \frac{1}{2} - \frac{t(p_1^1 - p_1^2)}{2(t^2-\beta^2)} - \frac{\beta(p_2^1 - p_2^2)}{2(t^2-\beta^2)} \\ n_2^1 = \frac{1}{2} - \frac{t(p_1^1 - p_1^2)}{2(t^2-\beta^2)} - \frac{\beta(p_2^1 - p_2^2)}{2(t^2-\beta^2)}. \end{cases}$$

Because both of two platforms are single homing $n_1^1 + n_2^1 = 1$, $n_1^2 + n_2^2 = 1$, get n_1^2 and n_2^2.

The profit function of the group buying platform is:

$$\begin{cases} \pi_1 = p_1^1 n_1^1 + p_2^1 n_2^1 \\ \pi_2 = p_1^2 n_1^2 + p_2^2 n_2^2. \end{cases}$$

Based on symmetry $p_1^1 = p_1^2 = p_1$, $p_2^1 = p_2^2 = p_2$, p_1, p_2 are got by derivation, as follows, group purchase platform pricing is: $p_1^{ss} = p_2^{ee} = t - \beta$.

Both of sides of the market accounted for 1/2. In the condition of $t > \beta$, profits of the platform 1 and platform 2 have maximum value. So group purchase platform profit is: $\pi^{ss} = t - \beta$

4.2 One Side is Single Homing, Another Side is Partial Multi-homing

Set one side to the side of the single side (Fig. 3 has been described in Fig. 1), part of the multiple homing of 2, the situation as shown in Fig. 4:

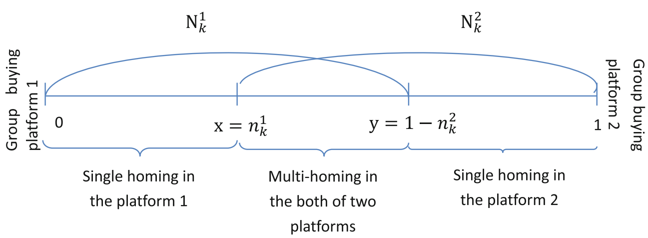

Fig. 4. On both sides of the platform users in the two competing platforms belonging to the range

In the two sides the total number of users is 1. So $N_k^1 + n_k^2 = 1$, $N_k^2 + n_k^1 = 1$. User of single homing on the platform 1 net utility is: $v_k^1 = v_0 - p_k^1 - tx + \beta N_2^1$, K side users of single homing on the platform 2 profit as follows:

$$v_k^1 = v_0 - p_k^1 - tx + \beta N_2^1.$$

The number of users on the platform 1 is: $n_1^1 = \frac{1}{2} - \frac{1}{2t}(p_1^1 - p_1^2) + \frac{\beta}{2t}(N_2^1 - N_2^2)$

Users on the platform 1 of the net utility of n_2^1, which is 2 of the user's distance from the platform 1 of the distance x: $x = n_2^1 = \frac{t-\beta}{t} + (p_2^2)/t + \beta/tn_1^1$.

Users to the platform 2 of the net utility of $1 - n_2^2$, which is 2 of the user's distance from the platform 1 of the distance y: $y = 1 - n_2^2 = \beta/t - (p_2^1)/t - \beta/tn_1^2$.

Simultaneous solution:

$$\begin{cases} n_1^1 = \frac{1}{2} - \frac{t(p_1^1 - p_1^2)}{2(t^2-\beta^2)} - \frac{\beta(p_1^1 - p_1^2)}{2(t^2-\beta^2)} \\ n_2^1 = 1 - \frac{\beta}{2t} - \frac{\beta(p_1^1 - p_1^2)}{2(t^2-\beta^2)} - \frac{\beta^2}{2t(t^2-\beta^2)} p_2^1 - \frac{2t^2-\beta^2}{2t(t^2-\beta^2)} p_2^2 \\ n_2^2 = 1 - \frac{\beta}{2t} - \frac{\beta(p_1^1 - p_1^2)}{2(t^2-\beta^2)} - \frac{\beta^2}{2t(t^2-\beta^2)} p_2^1 - \frac{\beta^2}{2t(t^2-\beta^2)} p_2^2. \end{cases}$$

In the condition of $t > \beta$, the net utility of the group buying platform 1 and group buying platform 2 can get the maximum value, by $p_1^1 = p_1^2 = p_1$, $p_2^1 = p_2^2 = p_2$, group buying platform pricings are: $p_1^{sm} = (t^2 - \beta^2)/t, p_2^{sm} = 0$.

Under the "SM" homing conditions, the numbers of users are:

$$n_1^{1sm} = n_1^{2sm} = \frac{1}{2}, \quad n_2^{1sm} = n_2^{2sm} = 1 - \frac{\beta}{2t}.$$

According to the formula, the profit for the group purchase platform: $\pi^{sm} = \frac{t^2-\beta^2}{2t}$.

4.3 Both of Two Sides are Partial Multi-homing

From the first two sections, we can know the "mm" belonging to the number of users under the conditions of a single:

$$\begin{cases} n_k^1 = 1 + \frac{p_k^2}{t} - \frac{\beta}{t} n_m^2 \\ 1 - n_k^2 = -\frac{p_k^1}{t} + \frac{\beta}{t} n_m^1. \end{cases}$$

Solution to get the user's number of single user on two platforms:

$$\begin{cases} n_1^1 = \frac{t}{t+\beta} - \frac{\beta}{t^2-\beta^2} p_2^1 + \frac{t}{t^2-\beta^2} p_1^2 \\ n_2^1 = \frac{t}{t+\beta} - \frac{\beta}{t^2-\beta^2} p_1^1 + \frac{t}{t^2-\beta^2} p_2^2 \\ n_1^2 = \frac{t}{t+\beta} - \frac{\beta}{t^2-\beta^2} p_1^1 + \frac{\beta}{t^2-\beta^2} p_2^2 \\ n_2^2 = \frac{t}{t+\beta} - \frac{\beta}{t^2-\beta^2} p_2^1 + \frac{\beta}{t^2-\beta^2} p_1^2. \end{cases}$$

Under the circumstances, $p_1^1 = p_1^2 = p_1$, $p_2^1 = p_2^2 = p_2$ we can get the price of the group buying platform:

$$p_1^{mm} = p_2^{mm} = \beta\frac{t-\beta}{2t-\beta}.$$

The number of single belonging to the two group purchase platform is:

$$n_1^{1mm} = n_1^{2mm} = n_2^{1mm} = n_2^{2mm} = \frac{2t^2 - \beta^2}{(t+\beta)(2t-\beta)}.$$

Similarly, in the case of $t > \beta$, the existence of the maximum profit is:

$$\pi^{mm} = \frac{2t\beta^2(t-\beta)}{(t+\beta)(2t-\beta)^2}.$$

5 Analysis of the Model

5.1 The Condition of Maximum Profit

In the condition of $t > \beta$, above of three types of homing are existence of the maximum profit. That is, the difference between the group buying platforms is greater than the network externalities for the maximum value of the platform. These pricings and profits show in Table 1.

Table 1. Three types of users buy site pricing and profits

Type of homing	Pricing	Profits
ss	$p_1^{ss} = p_2^{ss} = t - \beta$	$\pi^{ss} = t - \beta$
sm	$p_1^{sm} = \frac{t^2-\beta^2}{t}$, $p_2^s m = 0$	$\pi^{sm} = \frac{t^2-\beta^2}{2t}$
mm	$p_1^{mm} = p_2^{mm} = \frac{\beta(t-\beta)}{2t-\beta}$	$\pi^{mm} = \frac{2t\beta^2(t-\beta)}{(t+\beta)(2t-\beta)^2}$

The difference of platform enterprises is helpful to eliminate the influence of the uncertainty of network externalities on the profit of the group purchase platform. In other words, if the differences of between the two group buying platforms are enough small, the impact of network externalities may be increased. Then, businesses and consumers are more likely to increase multi-homing behaviors in the platforms, and the uncertainty of platform profit margin is also increased. If there is a big difference between the two platforms of the competition behavior, it can avoid the influence of network externalities on its profitability.

5.2 Different Homing Different Pricing

Compared to the three types of homing structure under the platform pricing: $p_1^{ss} - p_1^{sm} = -\beta\frac{t-\beta}{t}$, due to $t > \beta$, apparently, $p_1^{ss} < p_1^{sm}$. $p_1^{ss} - p_1^{sm} = -\frac{\beta(t-\beta)}{t} < 0$, get $p_1^{mm} < p_1^{ss} < p_1^{sm}$.

$p_1^{mm} < p_1^{ss} < p_1^{sm}$ shows that the bilateral market platform can also by attract consumers by increasing consumer quantity and obtaining consumer loyalty influence of the numbers of registers of businesses at group buying platform. As a result, platform through charge higher fees to businesses to obtain profits.

This conclusion is consistent with the general pricing rules of the group buying platform and the basic characteristics of the bilateral market. There is also difference pricing strategies for the platform enterprises. Adopted differential pricing method is also one of the strategies of competition between enterprises.

5.3 Different Homing Different Profit

Comparison of three types of group purchase websites belonging to profit $\pi^{ss} - \pi^{sm} = \frac{(t-\beta)^2}{2t}$, obviously $\pi^s s > \pi^{sm}$.

$$\pi^{sm} - \pi^{mm} = (t-\beta)\frac{[(t+\beta)(2t-\beta)+2t\beta][(t-\beta)(2t+\beta)]}{2t(t+\beta)(2t-\beta)^2} > 0, \text{ by } \pi^{ss} > \pi^{sm} > \pi^{mm}.$$

Group buying platform can get the highest profit in this condition that users on both of sides belong to single homing. The users on one side belong to single homing, and on another side belong to partial multi-homing take the second place. The behavior of users on both of two sides belong to partial multi-homing is reduced the platform profits. On the one hand, users on the one side belong to single homing and on the another side belong to partial multi-homing can put up the platform enterprise pricing, on the other hand, both sides of the user are single homing can obtain most profitable. This conclusion seems contrary to the conclusion of the 2. In fact, through use of various initiatives to prevent users' multi-homing behaviors, the group purchase platforms enhance loyalty of user for the platform. It is the internal incentive factors for the development of platform enterprises.

5.4 Influence of Difference

Considering the effect of the t for a variety of homing structure and profit pricing platform $\frac{\partial p_1^{sm}}{\partial t} = 1 + \frac{\beta^2}{t^2} > 0 \frac{\partial p_1^{mm}}{\partial t} = \frac{\beta}{(2t-\beta)^2} > 0 \frac{\partial \pi^{sm}}{\partial t} = \frac{1}{2} + \frac{\beta^2}{2t^2} > 0$, $\frac{\partial \pi^{,mm}}{\partial t} = \frac{2\beta^2[t^2(3\beta-2t)+\beta^3]}{(t+\beta)^2(2t-\beta)^3}$, when $t > \beta$, $\frac{\partial \pi^{,mm}}{\partial t}$ number of well over 0, simple that when $\beta \geq \frac{2}{3}t$, $\frac{\partial \pi^{,mm}}{\partial t} > 0$, when $\beta \leq \frac{2}{3}t$, $\frac{\partial \pi^{,mm}}{\partial t}$ well t sign of uncertainty.

From the above of that, users on both of sides belong to single homing and users on one side belong to single homing and another side belongs to partial multi-homing are show that the difference of group buying platform is influence greater than network externalities. In these two cases, pricing and profit of platform will be higher. When users on both of sides belong to partial multi-homing the platform profit is uncertain. This conclusion shows that platform may not be able to get higher profits. If they only consider the unilateral profits and higher prices in the process of competition, they need a reasonable price for platform competition.

6 Conclusion

The users' homing behavior is a complicated economic behavior, which has an important influence on the development of competitive strategy. Based on the group buying platform as an example, from the complexity of social competition in the market, we sum up the characteristic of group purchase platform and discuss the pricing and profit enterprise platform strategy in the different user behavior attribution by making use of the mathematical model. According to the above research conclusions, this paper puts forward some conclusions:

(1) The platform should be based on the needs of users to develop differentiated strategies, personalized competitive strategies to meet the needs of the type of customer needs, and to avoid the impact of network externalities that bring the risk to the platform.
(2) On the online group buying platform Multi homing behavior of users will reduce the fees charged to merchants. Forming malignant price competition and rapid expansion also appeared a lot of homogeneous of group buying platforms such as lashou.com. At last it lost competitiveness. In the course of the operation of the platform, we should pay attention to both businesses and consumers on both sides of the users and try to improve the customers' loyalty for the development of the platform and enterprise profitability.
(3) Users only choose a group buying platform can enhance the competitive advantage of group buying platform. Behaviors of consumers and businesses can get a distinct competitive advantage. Such as the group purchase website, the more good reputations the more consumer users, which can attract more business enterprises to cooperate with the site, forming a virtuous circle and crowding out other competitors.
(4) Effect of multi homing behavior interoperability platform users on the platform can weaken the profit. Cooperation with a number of group purchase website payment platform is not only good for consumer convenience but also attract more business cooperation. Although the consumer is multi homing behavior, in the view of platform, it is a single ownership for the group purchase website. As a whole, the interconnection platform can weaken ownership of consumer behavior, improve the competitiveness of the platform enterprise.

In this paper, we use mathematical model to calculate and compare the competitive price and the profit of the net purchase platform under different ownership types. Because group buying platform is a typical bilateral platform, the study of bilateral platform has a representative significance, to reflect the actual situation of the operation process of the platform. But the deficiency lies in the failure of the general suitability of the model to draw the relevant conclusions. In the future research, we will be in-depth mining related theory, as early as possible to improve the model of universal verification.

Abstract. Chinese excellent traditional culture is an important source of the party in governing the country. Xi Jinping, emphasized the historical influence and significance of Chinese traditional culture several times, and gave it new connotation of the time. Represented by Chengdu Temple Fair in recent years, the traditional culture festival activities were not only for the protection and inheritance of traditional culture, but also became the organic composition part of the local tourism festival activities. In this paper, we stand in the perspective of tourist experience and take Chengdu Temple Fair as the research object. It carried on the questionnaire design and survey to understand of tourists focus and satisfaction. The IPA methods help us to identify the strengths and weaknesses and give improvement suggestions.

Keywords: Tourists experience · Importance-performance analysis (IPA) · Cultural festival activities

1 Introduction

The former researches on traditional culture festival activities mostly focus on culture itself, such as cultural value, cultural inheritance, cultural exchange, and so on. However, in the tourism activities, tourist experience has been considered as one of the most important embodiment of product quality. At the same time, the tourism experience measurement is also the emphasis and difficulty of such research. Therefore, the attention to visitors experience is the crucial factor to make the sustainable development of traditional culture festival activities.

From the perspective of management and marketing, tourist experience is the tourist satisfaction. From the perspective of managers, the tourist experience is formed by a travel destination. At present, tourist satisfaction measurement model in the industry are mainly applied with American consumer

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_48

satisfaction index (ACSI), service quality (SERVQUAL), as well as Importance - performance Analysis method (IPA) [3]. IPA analysis method has been applied to enterprise management and marketing, service quality, competitive analysis, and other fields.

This paper is to study the situation of the festival activities in the tourist experience through the IPA analysis method. It analyses the degree of satisfaction and importance on quadrant distribution. The suggestions for such activities in the future development and quality improvement are also proposed.

Firstly, this paper carries on the literature review of tourism experience and tourist satisfaction, cultural festivals and tourism experience, satisfaction analysis theory to the literature review. It demonstrates the necessity of carry out the research in this field and the feasibility of using the IPA analysis. Then, it focuses in the perspective of tourist experience and takes Chengdu Temple Fair as the research object. It carried on the questionnaire design and survey to understand of tourists focus and satisfaction. Finally, it uses the IPA methods to identify the strengths and weaknesses of traditional culture festival activities and give improvement suggestions.

2 Literature Review

2.1 Tourist Experience and Satisfaction

Research on tourist experience is an important and difficult problem. Tourist experiences have both individual difference and the common performance. The differences mean that the scope, content, depth of each tourists experience are not the same. But if we take the point of tourist groups, their experiences have a certain commonality and show similar regularity.

In theory, the ultimate goal of travel is in order to obtain high quality tourism experience. Therefore, tourism destination and their managers try to achieve the aim through offering high quality tourist experience [2].

From the perspective of management and marketing, tourist experience is the tourist satisfaction. From the perspective of managers, the tourist experience is formed by a travel destination. Thus tourist is the main source of information for destination management. Tourist evaluations of tourism destination constitute the important feedback. Managers take the corresponding management improvement and marketing strategies according to the feedback information [16].

This shows the current research situation for all visitors' experience. Although the ontology of tourists experience has not reached consensus, most scholars formed the understanding of the different Angle of view. They showed their own understandings of tourist experience from different aspects. They also correspondingly gives the measure method and management tools of tourists experience [1,11,15].

2.2 Culture Festival Activities and Tourists Experience

External studies on festival tourism started earlier. Meyer [14] classified tourism festivals according to the festival theme, and made the comparative study of festival tourism between the United States and Canada. Gatz [7], Hoyle [10] studied the problem of festival tourism marketing. Mayfield and Crompton [13] discussed the marketing concept of festival organizers.

It shows that the researches mainly focus on the influence of the large tourism festival, particularly in terms of festival tourism and city relationships [6]. Chinese scholars that studied tourism festival activities focus on the following aspects, including the impact on the destination, the festival tourism operation models, the development present situation and countermeasures, perception of festival tourism for destination residents and tourists, etc.

2.3 IPA Analysis Method

Importance-performance Analysis method, namely IPA method, is widely used for its intuitive, easy to operate and understand. The method is studied out by Martilla and James in 1977 [12].

Since the early 1990s, the IPA analysis began to be widely used in service industry. Its application scope mainly includes service satisfaction, product performance, regional competition (appeal) and macro tourism policy, etc.

On the basis of understanding the multidimensional and multifaceted properties to the satisfaction, IPA analysis method got rapid development in the field of marketing research. It can transmit evaluation message to management through customer evaluation of service product multiple attribute. IPA method asked respondents to evaluate various evaluation factors in all kinds of measures from two aspects of importance and performance.

Fig. 1. IPA matrix

When it is used for satisfaction measurement, performance means the satisfaction evaluation [3]. On the concrete application, first of all, customer understanding the importance of product attributes is to be investigated. Then, we shall understand customer perception of product attribute performance. The overall average of the two will be showed on the two-dimensional coordinate axis [8] (Fig. 1). By the graphic method, managers can accurately grasp the management status, so as to determine the different management area easily.

For the satisfaction evaluation of tourist experience, attribute of tourist products is transmitted into a multilevel index system. The perception of tourism product shows the importance and performance. The status from the survey is put in the I-P model diagram, which can help managers to find the problem and the corresponding management methods to solve the problem. However, the traditional I-P model only presented the direction of management, failure to put forward a measure of the management to improve. Hollenhorst proposed to improvement model-indicator performance estimate (IPE) [9]. IPE model not only to helps managers to understand the importance of each index, but also realize that deviation degree of each index and make its corresponding management action.

3 The Empirical Study

Chengdu Temple Fair is selected as a case for empirical research. Chengdu is the capital of Sichuan province, of Southwest China. It is also one of the most important economic centers, transportation and communication hubs in Western China. Chengdu's earliest temple fair is held before the Qin dynasty period more than two thousand years ago. Since 2005, the Chengdu temple fair festival began to hold in Wuhou Shrine till today. The festival takes public benefit as the core and reveals the local cultural characteristics. Chengdu temple fair festival highlights three kingdoms culture theme, and constantly absorbed all kinds of fresh elements. It gradually formed the culture brand and has a wide influence nowadays. The temple fair was held for years continuously. It has received visitors over tens of millions of people in 11 years.

"The Spring Festival to the Temple fair", it has become a New Year customs of Chengdu area people. Through the successfully held for many years, Chengdu Temple Fair improved year by year. It becomes not only a regional cultural brand, but also one of the most famous Chinese traditional Spring Festival temple fair. Thus, Chengdu temple fair is an appropriate and meaningful case for empirical research. It is both culture and festival tourism activities representative.

3.1 Research Design

The purpose of this study was to apply IPA analysis on festival tourists experience research. Chengdu temple fair festival is selected as empirical research object. The most prominent five factors were extracted in the cultural festivals. Visitors of the target group random questionnaires were distributed during the 2016 Chengdu temple fair. SPASS19.0 software and IPA analysis method was use to analyze tourist experience and satisfaction.

This study used the traditional IPA method to analyze the important factors of tourists' satisfaction at first. Then the importance and satisfaction evaluation correlation detection was carried forward. Thirdly, it made the IPA raw data transformation in the way proposed by Deng [4,5]. Extended importance was calculated by satisfaction evaluation. Each factor was analyzed through transform data. Finally, the two analysis results were compared to get corresponding conclusions and suggestions.

3.2 Survey Design

The questionnaire is made up of three parts. The first part is the survey on tourist satisfaction of cultural festivals elements. On the basis of literature review, the author consulted the expert group of tourism research. According to the specific condition of Chengdu Temple Fair, the tourist experience in cultural festival activities is gained in five elements. They are "The Three Kingdoms culture theme features", "traditional folk performances and activities", "facilities and services", "fashion elements and innovation", and "ticket price setting". Using Likert Scale, we ask the respondents to comment on the five aspects of cognitive performance. In addition, the overall satisfaction perceived evaluation of the elements is added into the survey, so that subsequent calculation and analysis on the importance of extension.

The descriptions of the completely positive statements are made for each element. Respondents are asked to give evaluation ranges from fully agree (5 points) to completely disagree (1 point). So that visitors' satisfaction ranges from fully satisfied (5 points) to completely dissatisfied (1 point). The second part is the survey on the importance of the evaluation factors in cultural festivals activity. In this part, the visitors are asked to the rank the importance by their demands for each element. This design is to reduce the mutual interference of satisfaction and importance evaluation. The third part is the survey of demographic characteristics.

3.3 Data Collection and Analysis

From February to March in 2016, this research made questionnaire investigation at the scene of the Chengdu Temple Fair. A total of five interviewers investigated the visitors in the rest area by random survey. This survey parted out 220 questionnaires, 204 valid questionnaires, and the effective rate of recycling questionnaire was 93%. During the survey, the interviewers required each visitor to score on evaluation factors and overall experience satisfaction. Then, according to the personal value, visitors were asked to make importance ranking for evaluation factors.

After the completion of the questionnaire, the results of the survey were input to SPSS 19.0 database. Data calculation and analysis were done with the help of software. First of all, we made descriptive statistical analysis of the general situation of the respondents. Then, the five key elements of the evaluation of satisfaction and importance of average were calculated. IPA analysis diagram was drawn. The specific steps of research are listed below. The first step, the five elements of satisfaction mean value was determined. Then, according to the importance of evaluation data, we calculated the percentage of the importance, the average value. We made a horizontal axis and vertical axis, the horizontal axis represents the degree of satisfaction axis, the dashed vertical axis represents the importance. The second step, we confirmed the corresponding position location of 5 evaluation factors in four quadrants according to their importance and satisfaction of the actual average. The third step, according to the characteristics of the various factors in different quadrant, we put forward the corresponding countermeasures and suggestions.

In addition, in order to eliminate the correlation between importance and satisfaction factors, many scholars suggested using extended importance to replace self-statement importance. Two kinds of caliber is also analyzed in this paper. Scored for indirect importance, natural logarithmic is computed by partial correlation coefficient of overall satisfaction and satisfaction with all the elements in the way of Wei-jaw Deng, namely extended importance score.

Table 1. Demographic characteristic of tourists

	Item	Number	Percent
Gender	Male	104	51.2
	Female	100	48.8
Age	≤17	6	2.9
	18–30	153	75
	31–45	24	11.8
	46–60	11	5.4
	≥61	10	4.9
Education	Primary school and below	2	2
	Junior high school	14	6.9
	High school	43	21.2
	Undergraduate	138	67.5
	Graduate and above	5	2.5
Monthly income (RMB)	≤3000	21	10.3
	3000–5000	63	30.9
	5000–8000	64	31.4
	8000–10000	24	11.8
	≥10000	29	14.2
Traveler generating region	Chengdu city	83	40.7
	Non - Chengdu city	121	59.3

4 Research Results

4.1 Tourists' Demographic and Tourism Characteristics

Demographic characteristics showed the 204 visitors polled, basically reached the same level of the male to female ratio, which accounted for 51.2% of men, accounted for 48.8% of women. Levels of the age focused on range 18 to 30 years old, accounted for 75%. Level of education was mostly for college/university level, 67.5%. Family income more focused on 3000–8000 interval, accounted for 62.3%. Tourist's origin was in a slightly better non Chengdu city, at 59.3%. Please refer to Table 1 for relevant information.

This study also surveyed the tourists travelling characteristics, including travel patterns, the purpose of the visit, travel expenses, etc. In view of traditional culture festival activities, we also added the play frequency as a survey element. From the statistical results, it can be seen that the first time visitors accounted for 59.6%, but there are still close to half for many times. Chengdu Temple Fair revisit rate is higher, to a certain extent, which also reflects the regional influence of the cultural festival activities. Travel patterns were given priority to with family and friends travel together, accounted for 42.2% and 42.2% respectively. For visit purpose, relax accounted for up to 66.7%, the second is the scenery which is 46.6%. Travel expense (including tickets, transportation, catering and shopping, etc.) average of about 300 Yuan. Relevant information as shown in Table 2.

Table 2. Travel characteristics of tourists

	Item	Number	Percent
Times	1	121	59.6
	2	39	19.2
	3	24	11.8
	>3	20	9.4
Travel patterns	Alone	18	8.8
	With family	86	42.2
	With colleagues or friends	63	30.9
	With lovers	36	17.7
Purpose	Relax	136	66.7
	Family reunion	30	14.7
	Sightseeing	95	46.6
	Photography	9	4.4
	Parents-child campaign	13	6.4
	Friends meeting	23	11.3
	Others	17	8.8
Expense	Average	332.43 (RMB)	

4.2 IPA Analysis of the Importance and Satisfaction

(1) On the basis of tourists' self-statement importance
The results showed that Chengdu temple fair investigated into five elements. Tourists' self-statement importance showed traditional folk performances and activities, Three kingdoms culture theme, fashion elements and innovation, supporting facilities and services, and ticket price setting in turn (See details in Table 3).

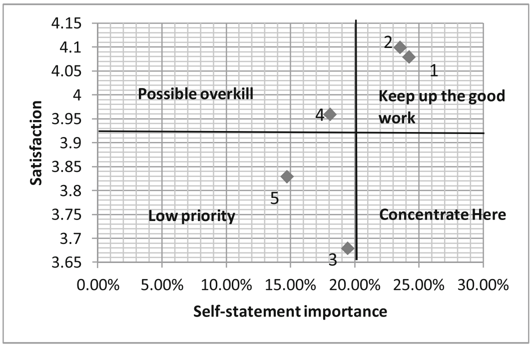

Fig. 2. IPA analysis diagram of self-statement importance and satisfaction

Table 3. Ranking of Tourists' self-statement importance and satisfaction

Ranking of tourists' self-statement importance	Elements (percent)	Importance (5 credits)	Satisfaction	Ranking of satisfaction
1	The Three Kingdoms culture theme features	0.139	4.1	1
2	Traditional folk performances and activities	0.137	4.08	2
3	Fashion elements and innovation	0.115	3.68	5
4	Ticket price setting	0.09	3.83	4
5	Supporting facilities and services	0.087	3.96	3

Thus, we can draw IPA analysis diagram of self-statement importance and satisfaction. It takes tourists self-statement importance as the horizontal axis, satisfaction as the longitudinal axis, and the mean average of each dimension as the midpoint of four quadrants, as shown in Fig. 2. The 2 elements situated in the first quadrant means “Keep up the good work”, namely whose satisfaction and importance are both higher. They are element 1 “Traditional folk performances and activities” and 2 “The Three Kingdoms culture theme features”. The element situated in the second quadrant means “Possible overkill”, namely whose importance is lower but satisfaction is higher. Element The element situated in4 “Supporting facilities and services” is like that. The 2 elements situated in the third quadrant show “Low priority”, namely whose importance and satisfaction are both lower. They are element 3 “Fashion innovation and innovation” and 5 “Ticket price setting”.

(2) On the basis of extended importance
According to the results of the questionnaire, the mean value of overall tourist satisfaction for Chengdu temple fair is 4.00. Then, we calculated extended importance of various factors accordance with the method of Deng [4] (See Table 4).

Table 4. Ranking of extended importance and satisfaction

Ranking of extended importance	Elements	Extended importance (The method of Wei-jaw Deng)	Satisfaction (5 credits)	Ranking of satisfaction
1	The Three Kingdoms culture theme features	0.139	4.1	1
2	Traditional folk performances and activities	0.137	4.08	2
3	Fashion elements and innovation	0.115	3.68	5
4	Ticket price setting	0.09	3.83	4
5	Supporting facilities and services	0.087	3.96	3

As a result, IPA analysis diagram of extended importance and satisfaction was drawn. The basic method is same as the former, but we need to change self-statement importance data into extended importance, as shown in Fig. 3. The 2 elements situated in the first quadrant means “Keep up the good work”, namely still the elements 1 “Traditional folk performances and activities” and 2 “The Three Kingdoms culture theme”. The element situated in the second quadrant is “Possible overkill”, which implied lower importance but higher satisfaction. The elements 5 “Supporting facilities and services” showed that. The element

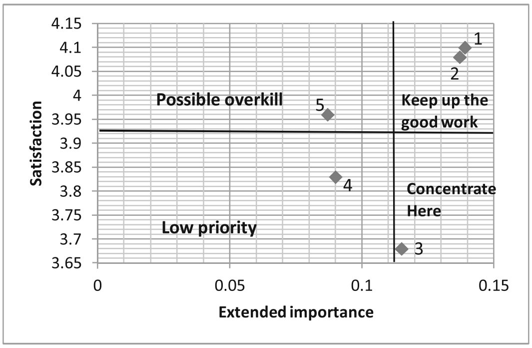

Fig. 3. IPA analysis diagram of extended importance and satisfaction

situated in the third quadrant means "Low priority", which implied extended importance and satisfaction are both lower. It is the elements 5 "Ticket price setting". Element 3 "fashion elements and innovation" is situated in the fourth quadrant, namely lower satisfaction but higher importance, which means "Concentrate Here".

(3) Comparison two kinds of IPA analysis conclusion
The results showed that two kinds of IPA analysis conclusion were basically the same. Slight differences were in two aspects. Firstly, on the ranking of extended importance, "Three kingdoms culture theme" exceed the "Traditional folk performances and activities", in the first place. Extended importance of "Supporting facilities and services" was below "Ticket price setting", which rowed at the bottom. Secondly, by the IPA analysis diagram, we can find that in extended importance analysis, the "Fashion elements and innovation" element was situated in the fourth quadrant, which means "Concentrate Here".

From the two kinds of IPA analysis conclusion, it can be seen that the overall tourist satisfaction of Chengdu temple fair is good. Core competitive elements were traditional folk activities and the Three Kingdoms culture theme features. Tourists' attention and satisfaction on the both elements is high. We need to "Keep up the good work" on the two. And for the evaluation of supporting facilities and services, it was different from traditional scenic spots. Tourists showed lower attention and higher satisfaction. The element was situated in the "Possible overkill" quadrant. The experience length during the festival activities and distance of tourist source region can be related reasons. Ticket price is located in the range of the low awareness and low satisfaction, which embodies the low sensitivity of tickets present price. In addition, the "fashion and innovation elements" is situated in different quadrants of different analysis methods. On the one hand, it reflected the innovation elements had a substantial impact to overall satisfaction. On the other hand, it also indirectly showed the high attention to the traditional culture. Visitors still hope the traditional festival activities can reflect more pure original flavor and essence of traditional culture.

5 Conclusions and Proposal

This study used the IPA analysis to do case investigation and data analysis for tourists experience factors of traditional culture festival activities. We selected Chengdu Temple Fair for empirical research. The self-statement and extended importance were both used to make IPA analysis comparison. Elements need to be focus on and improved were obtained to improve tourist experience evaluation and satisfaction in such cultural festival activities in the future.

First of all, the traditional culture festival activity is a kind of traditional cultural heritage value and means, and also part of the tourism activities. From visitors experience the evaluation results, the majority of visitors still focus on "traditional culture" and "characteristic theme culture" to this kind of festival activities. Chengdu Temple Fair designed a lot of rich and colorful activities, such as opening ceremonies, play god party activities, performing arts activities, theme Lantern Festival, cultural exhibitions, lectures on culture, folk custom activity, interactive games, traditional arts and crafts exhibition, snack sales and other major sections. Visible, the key factor to improve the satisfaction degree of the tourists is to find the core of culture and enhances the core resources of the "traditional culture" in such festival activities.

Secondly, if we take Chengdu Temple Fair as an example, they paid attention to not only the Spring Festival traditional culture in local region, but also its own characteristics and advantages, namely the Three Kingdoms theme culture. In the temple fair, Three kingdoms culture penetrated into all aspects of the festival, from activity forms to content. It has been on full display and extension. Chengdu Temple Fair is different from other temple fairs of the nation's by conducting a lot of activities, such as the Three Kingdoms hero theme day, Three kingdoms culture lamp exhibition, Three kingdoms culture exhibition, the Three kingdoms interactive games, the Three kingdoms cartoon show, the Three kingdoms characters in theme and ambience and so on. The Three kingdoms theme features have been the most prominent, attractive features and core competitiveness of Chengdu temple fair. From the research results, the attention and satisfaction of visitors to the Three Kingdoms culture theme are also one of the best.

Thirdly, the IPA analysis tends to a wide range of applications in the industry due to its simple and easy to interpret. The premise of the analysis request variables on the two dimensions of importance and satisfaction evaluation are independent of each other, and each variable is linear correlation between satisfaction and overall satisfaction. However, in reality survey, the two assumptions are impossible to meet. The main reason is that, on the one hand, the self-statement importance will be inevitably affected by the respondents' satisfaction perception. On the other hand, a certain degree change of satisfaction will not bring the change of overall satisfaction [3]. As a result, this research used two caliber of the self-statement satisfaction and extended satisfaction to do IPA analysis. Managers can make countermeasures for selective in the premise of contrast both the analysis results.

The main limitations of this study is because of selecting importance sorting method for evaluation, we selected limited number of elements from several big aspects. More comprehensive and detailed evaluation and analysis of cultural festivals can be made by kinds of tourist experience factors. These can also become the content of the related research in the future.

Abstract. With the wave of overseas-listed companies returning to A-share market, this paper, taking the perspective of corporate governance, uses Propensity Score Matching (PSM) to measure the difference of operating performance between cross-listed companies and non-cross-listed companies, and uses Structural Equation Model and path analysis to examine the impact mechanism and specific effect of cross listing on operating performance. The results show: (1) Compared with non-cross-listed companies, those companies cross-listed in both A and H-share market, have witnessed a worsening of operating performance, a significant increase of ownership concentration and liabilities to assets (L/A) ratio, and a significant decrease of asset liquidity. (2) Cross listing has affected operating performance mainly through debt structure, asset liquidity, less through ownership structure. The results of this paper can provide the theoretic and empirical basis for future cross listing of companies in China.

Keywords: Cross listing · Propensity Score Matching (PSM) · Structural equation model · Corporate governance · Operating performance

1 Introduction

As the economic globalization accelerates and international capital market becomes more and more integrated, many Chinese companies listed overseas have returned to the domestic A-share market, and got cross-listed. Meanwhile in recent years, domestic and foreign scholars have paid more attention to the change of corporate performance after cross listing. However, empirical results proved cross listing cannot improve corporate performance. Instead, foreign researches showed that after cross listing, corporate internal and external performance had gone down [8,15,26]. Researches on the change of corporate internal

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_49

environment after cross listing, showed cross listing can improve the stock liquidity, reduce the agency cost [6,7], relax financing constraints and reduce the cost of financing constraints [22]. In the past, researches on cross listing often focused on the effect of cross listing on corporate performance, then according to whether the company had been cross listed, set dummy variables for *OLS* regression, ignoring the systematic bias; simultaneously, there was selective bias in samples of cross-listed companies and non-cross-listed companies. No relevant research on impact mechanism of cross listing has been found.

This paper, based on mass samples of China's A-share market, uses Propensity Score Matching (PSM) to examine the difference of operating performance between cross-listed and non-cross-listed companies, and effectively avoid systematic bias in the study of cross listing. And then, this paper uses Structural Equation Model to explore the impact mechanism of cross listing on operating performance.

The structure of this paper is as follows: the first section is an introduction; the second section will be literature review; the third section will be research design; the fourth section will be empirical results; the last section will be conclusion and suggestions.

2 Literature Review

Jaffee and Russell [12] and Stiglitz and Weiss [27] pointed out that there was information asymmetry in credit market, companies were able to complete projects, but banks did not know about this. Most Chinese listed companies get external financing from the credit market, where they encounter serious financing constraints. Therefore, cross listing has always been regarded as an important signal that a company focuses on protecting investors, strictly discloses information and standardizes corporate governance, which can improve public awareness and information environment of the company [2], increase the level of information disclosure in the market, and strengthen investor protection [3,28], thereby reducing the degree of information asymmetry, and relaxing financing constraints. Researches of Lins et al. [18] showed that cross listing can loosen corporate financing constraints, reduce financing costs, and reduce the dependence on internal cash; Doidge et al. [7] thought that compared with non-cross-listed companies, cross-listed companies can expand their financing channels, and prevent management from appropriation of corporate resources; in China, empirical results of Pan and Dai [23] also showed that after cross listing, corporate investments can be much less sensitive to cash flow, so financing constraints can be effectively loosened. Empirical studies of Liu [19] showed that returning to A-share market can ease corporate financing constraints to a certain extent.

With less financing constraints, companies would reduce cash holdings. Gu and Sun [10] pointed out that companies with serious financing constraints had reserve cash to prevent financial risks; Myers [21] pointed out that enterprises holding with a certain amount of cash holdings can seize every investment opportunities, and also can avoid information asymmetry caused by financing constraints. Zhang et al. [30] found that cross listing can enhance the awareness of investor protection, and then reduce the company's cash holdings. However, according to Agency Theory and Free Cash Flow Theory, too much cash holdings can facilitate management to seek personal gain, and increase haphazard investments. La Porta [24] found that with too much cash holdings, management is prone to damage investors' interests by transfer prices, overinvestment, and high salaries. Kalcheva [14] pointed out that too much cash holdings can harm corporate performance and market value.

On the other hand, the mitigation of financing constraints will inevitably lead to the expansion of credit financing. The Pecking Order Theory argues that corporate debt financing outperforms equity financing. Jensen [13] pointed out that debt, as a governance mechanism, can constrain behaviors of major shareholders and management. Berger [4] argued that higher debt ratio can reduce agency costs associated with external equity. However, there are many other factors affecting corporate performance. Aslan and Kumar et al. [1] found that debt financing did not restrain internal agency, but facilitated major shareholders to appropriate corporate resources. The Margaritis and Psillaki [20] pointed out that the relationship of L/A ratio and operating performance presented an inverted U curve, while the ownership concentration was positively correlated to operating performance. Korajczyk and Levy [16] pointed out that without financing constraints, companies would prefer equity financing during periods of economic expansion, and debt financing during periods of economic contraction, and vice versa.

Busaba et al. [5] found when overseas-listed companies return to A-share market in China, they experience poorer post-issuance stock and operating performance in comparison to companies purely listed in China. Meanwhile, companies from less-developed markets would take advantage of the enhanced visibility and prestige associated with their foreign listing to issue shares domestically at inflated prices and favorable terms, and to raise greater proceeds than they can efficiently use. On the basis of Busaba's studies, Kot and Tam [16] pointed out that companies returning to A-share market should be regarded as the valuation and timing of the whole A-share market. Fernandes and Giannetti [9] made sample survey on cross-listed companies worldwide, and drew the same conclusion.

In summary, most scholars held the view about cross listing that after cross listing, operating performance would be damaged, while due to information disclosure, regulatory management and the expansion of financing environment, corporate financing constraints can be mitigated, and corporate governance level can be improved.

3 Research Design

3.1 Research Methodology and Procedures

In order to examine the effect of A+H cross listing, it is necessary to further consider the endogeneity of cross listing. Traditional multiple regression analysis might get biased and inconsistent results; and ordinary matching method cannot solve the problem of endogeneity. This paper uses PSM proposed by Rosenbaum and Rubin [25] to examine the effect of A+H cross listing. With PSM, propensity score of each company is calculated, and the most comparable control samples are matched with samples of A+H cross-listed companies in multiple dimensions; and then the difference between the two groups can show the net effect of A+H cross listing. Therefore, PSM can effectively reduce the selective bias. The specific steps are as follows:

(1) Get propensity scores

Propensity score refers to the conditional probability of a company to get A+H cross-listed.

$$P\left(X\right) = \Pr\left[D = 1\left|X\right.\right] = E\left[D\left|X\right.\right]. \tag{1}$$

D is the research variable, standard samples are divided into AH group and control group, if a company is cross-listed, $D = 1$, otherwise $D = 0$; P is probability of a company to get A+H cross-listed, that is, the propensity score; X is the influencing factor of cross listing, that is, the matching variable.

Then, as what Dehejia did, this paper uses Logit binary regression model to estimate:

$$PS\left(X_i\right) = P\left(X_i\right) = \Pr\left[D_i = 1\left|X_i\right.\right] = \exp\left(\beta X_i\right) / \left(1 + \exp\left(\beta X_i\right)\right). \tag{2}$$

PS is the propensity score of Company i to get cross-listed; D is the research variable, if cross-listed, $D = 1$, otherwise $D = 0$; is the cumulative distribution function of logical distribution; X is the matching variable, which affects cross listing of a company, β is the parametric variable.

(2) Choose the matching method

After getting propensity scores, sample matching is conducted between AH group and control group. Because of the consistency of propensity score, it is difficult to find samples with the same propensity score. Therefore, this paper examines the effect of A+H cross listing by k-nearest neighbors matching.

(3) Conduct balance test

Before getting matching results, it is necessary to test its effectiveness by "hypothesis of commonality" and "hypothesis of independence". "Hypothesis of commonality" requires that control samples should be matched with samples of cross-listed companies by propensity scores. "Hypothesis of independence" requires that there should be no significant difference in the matching variable between AH group and control group.

(4) Calculate the average treatment effect

The average treatment effect (ATT) of AH group and control group, that is, the net effect of A+H cross listing on the research variable, is calculated with the formula Eq. (3). If ATT is statistically significant, then cross listing does have effect on the research variable.

$$\begin{aligned} ATT = & E\left[Y_{1i} - Y_{0i} \left| D_i = 1\right.\right] = E\left\{E\left[Y_{1i} - Y_{0i} \left| D_i = 1, P\left(X_i\right)\right.\right]\right\} \\ & = E\left\{E\left[Y_{1i} \left| D_i = 1, P\left(X_i\right)\right.\right] - E\left[Y_{0i} \left| D_i = 0, P\left(X_i\right) \right| D_i = 1\right]\right\}. \end{aligned} \tag{3}$$

Y is the outcome variable, which is the relevant indicator measuring the effect of A+H cross listing; Y_{1i} and Y_{0i} represent the outcome variable when a company is cross-listed and not cross-listed respectively.

3.2 The Design and Definition of Variables

In case of the measurement bias caused by single indicator, this paper chooses return on total assets (ROA) and Tobin's Q ratio (TBQ) as proxy variables of a company's operating performance, chooses total profitability and market value to measure its operating performance, and ownership concentration (GQJZD), L/A ratio (DEBT) and asset liquidity (XJZCB) to measure corporate governance. Drawing on previous researches, this paper chooses size of asset (SIZE), L/A ratio (DEBT), Tobin's Q ratio (TBQ), fixed asset ratio (GDZCB), debt per share (MGFZ), ownership concentration (GQJZD) and types of enterprises (QYXZ) as matching variables of logistic regression (Logit) (Table 1).

Table 1. The design and calculation of variables

Names of variables	Symbols of variables	Calculation of variables
Return on total assets	ROA	Net return/Average total assets
Tobin's Q ratio	TBQ	Company's market value/Replacement cost of assets
Liquidity ratio	XJZCB	Cash assets at the end of the period/Owner's equity at the end of the period
Size of assets	SIZE	Natural logarithm of total assets
L/A ratio	DEBT	Total debt/Total assets
Fixed asset ratio	GDZCB	Fix assets/Total assets
Debt per share	MGFZ	Total debt at the end of the period/Paid-in capital at the end of the period
Ownership concentration	GQJZD	Sum of squares of the biggest three shareholders' shareholding ratios
Types of enterprises	QYXZ	State-owned enterprises is represented by 1; otherwise, 0

3.3 The Screening of Samples

This paper chooses 58 companies cross-listed in both A and H share market before 2008 as samples of treatment group, and all companies listed in A share market between 2006 and 2014 as initial samples of control group; all samples are screened following three principles: (1) listed financial companies are excluded; (2) companies specially treated and particularly transferred are excluded; (3) companies whose data is missing or abnormal are excluded. Most data of this paper comes from CSMAR Solution, some data comes from corporate annual reports, and the sample size of this research is 14448 companies. All the data is processed with Stata11.2.

4 Empirical Results

4.1 The Screening of Matching Models

In order to make effective matching, regression results of five Logit models are listed in Table 2. Regression results show that the larger size is, and the higher Tobin's Q ratio or the market value is, the more a company is willing to be cross-listed; the higher fixed asset ratio is, the less current asset holdings a company has, then the higher demand for external financing is, therefore, the higher fixed asset ratio is, the more a company is willing to be cross-listed; the higher ownership concentration is, the more a company is willing to be cross-listed, but after cross-listing, the power of controlling shareholders will undoubtedly be diluted, therefore, considering the change of balance of shareholder power after cross listing, we find that cross listing can reduce the power of controlling shareholders, but nearly double the shareholding ratio of the second and third largest shareholders, as a result, ownership concentration index is significantly positive, indicating that major shareholders other than controlling shareholders have great power to decide whether to be cross-listed or not; L/A ratio and debt per share have negative effect on the tendency for cross listing; at the same time, state-owned enterprises (SOEs) are more likely to choose cross listing, as Huang [11] found that, because of China's special capital market environment, leaders of SOEs try to promote their own reputation and benefit their political career through overseas listing; meanwhile, the total asset growth rate has a negative effect on the tendency for cross listing, because controlling shareholders with strong growth ability reject cross listing for fear of the dilution of their power [5].

As what Lian [17] did, this paper, considering the significance of variables in Logit regression, uses Psedo-R2 value and AUC value, the area under the ROC curve, to measure the effect of Logit regression model [29], and all Psedo-R2 values of 5 Logit regression models are more than 0.38, AUC values more than 0.9. When conducting PSM with Logit regression, if AUC value is more than 0.8, then indicators of the regression model are suitable. In this paper, all AUC values are more than 0.9, so indicators are suitable. Considering Psedo-R2 values and the significance of variables, Model 4 is chosen as the matching model.

Table 2. The design and calculation of variables

Variables	Model1	Model2	Model3	Model4	Model5
SIZE	1.2905***	1.3790***	1.2828***	1.3503***	1.3604***
	−26.65	−28.74	−26.57	−26.55	−26.83
DEBT	−1.8016***	−1.4628***	−1.7414***	−1.3864***	−1.4171***

4.2 Matching Effect Test

Before getting matching results, balance test was conducted by "hypothesis of commonality" and "hypothesis of independence". Figure 1 is the probability distribution of propensity scores of AH group and control group before and after matching. It shows that before matching, there is a significant difference in the probability distribution of propensity scores between the two groups, and the distribution center of control group is significantly higher than that of AH group. If the difference between the two groups is directly compared, there must be large deviation in the results. However after matching, the probability distribution curve of propensity scores of control group shifts significantly to the right, and the difference of the probability distribution of propensity scores between the two groups significantly decreases, indicating that the matching significantly amends the deviation of the probability distribution of propensity scores, the matching is effective, and hypothesis of commonality is verified.

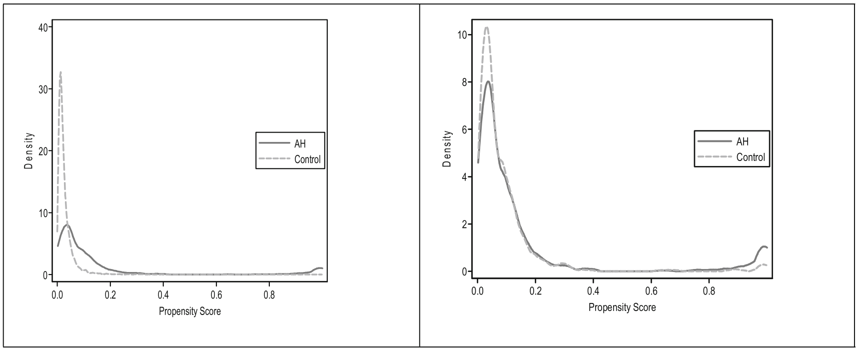

Fig. 1. Probability distribution of propensity scores of *AH* group and control group before and after matching

Hypothesis of independence requires that after matching, there is no significant difference in variables between *AH* group and control group. As shown in Table 3, after matching, all standard deviations sharply decrease, and all absolute standard deviations are less than 10%, indicating that the matching achieves good results. After matching, t-test results show that there is no significant difference between AH group and control group. Above all, hypothesis of balance is verified.

4.3 Univariate Test

After the first phase of PSM, we match cross-listed companies with non-cross-listed companies, and use univariate test to examine their operating performance and corporate governance. In Panel A, all samples in treatment group and control group are compared, and results are as follows: after cross listing in both A and $H - share$ market, the company's cash asset ratio significantly decreases by 0.0406, and ownership concentration significantly increases, indicating that after cross listing, major shareholders increase their stakes in case of the dilution of their power. L/A ratio increases by 0.0398, indicating that after cross listing, it is easier to get external debt financing. Meanwhile, this paper chooses ROA and TBQ as proxy variables of corporate value, which decrease by different degrees after cross listing. In Panel B, samples of state-owned enterprises in treatment group and control group are compared, and results show that cash asset ratio slightly decreases in the significance level of 10%, while none of TBQ,

Table 3. Matching variables and balance test

Names of variables		Mean		Standard deviation (%)	Decrease of standard deviation (%)	*t*-test	
		Treatment group	Control group			*t*	*p*-value

Note: *, **, *** represent significance at the level of 10%, 5% and 1% respectively.

Table 4. The effect of cross listing in *A* and H-share market

Variables	ROA	TBQ	XJZCB	GQJZD	LEV
Panel A Treatment group VS Control group					
Treatment group (AH = 1)	0.0371	1.0988	0.1098	0.2894	0.5854
Control group (AH = 0)	0.0492	1.3462	0.1504	0.254	0.5456
Treatment group-control group	0.0121	0.2474	0.0406	−0.0354	−0.0398
T-value	3.0436***	2.2772**	5.2667***	−3.2978***	−2.6576***
Panel B state-owned enterprises: treatment group vs control group					
Treatment group (AH = 1)	0.0407	1.22	0.1132	0.2972	0.5922
Control group (AH = 0)	0.0446	1.3158	0.1348	0.3106	0.5729
Treatment group-control group	0.0039	0.0958	0.0216	0.0134	−0.0193
T-value	0.6567	0.4833	1.8230*	0.8631	−0.8669
Panel B Private Enterprises: Treatment group VS Control group					
Treatment group (AH = 1)	0.0346	1.0151	0.1074	0.2841	0.5807
Control group (AH = 0)	0.0526	1.3692	0.1622	0.2112	0.525
Treatment group-control group	0.018	0.3541	0.0548	−0.0729	−0.0557
T-value	3.4034***	2.9402***	5.4136***	−5.1239**	− 2.7719***

Note: *, **, *** represent significance at the level of 10%, 5% and 1% respectively, and T-value represents the statistics of *t* in the univariate test.

ROA, ownership concentration and L/A ratio passes the significance test. In Panel C, samples of private enterprises in treatment group and control group are compared, the change trend of each indicator is in accordance with that in Panel A, and all indicators are significant at the level of 1%. However, after cross listing, ownership concentration and L/A ratio of private enterprises are apparently higher than that in Panel A, cash asset ratio decreases more than that in Panel A, ROA and TBQ also decrease more than that in Panel A, indicating that after cross listing, major shareholders of private enterprises have stronger awareness of the risk of ownership dispersion, are more willing to increase their stakes, and are more prone to expand the ratio of debt financing, and to use financial leverage to gain profits (Table 4).

4.4 Descriptive Statistics

Table 5 is the descriptive statistical analysis of samples after matching. The mean of market values is 39 billion yuan ($e^{2}4.3864$), indicating that these companies are big in size, which reflects the choice of overseas-listed companies; their L/A ratios are relatively higher, and the mean of L/A ratio is 56.94%; the mean of return on total assets is 0.0419, and TBQ, 1.1603, which reflect corporate operating performance; the mean of sum of squares of the biggest three shareholders' shareholding ratios is 0.2752, indicating that the ownership concentration of China's listed companies is relatively higher, which reflects the possibility of the practice of what one person says counts. Relevant variables are winsorized.

Table 5. Descriptive statistics

Variables	Mean	Standard deviation	Minimum	P25	P50	P75	Maximum
ROA	0.0419	0.0542	−0.2969	0.0126	0.0331	0.067	0.3113

4.5 Path Analysis of Operating Performance

(1) The establishment of conceptual model of cross listing's effect on operating performance

Above all, cross listing will worsen operating performance. This paper will explore the impact mechanism of crossing listing on operating performance from debt structure, asset liquidity and ownership structure.

- Debt Structure. It is certain that changes of financing environment can affect a company's asset structure, and then operating performance.
- Asset Liquidity. The mitigation of financing constraints after cross listing can improve the company's cash holdings, and then affect operating performance.
- Ownership Structure. After cross listing, financing market is larger, ownership structure changes, and corporate governance is improved, and then operating performance is affected.

(2) Path effect analysis

Using Structural Equation Model to perform an iterative scheme for maximum likelihood with the conceptual model of Fig. 2, and path analysis results are shown in Fig. 3. The probability of the whole model in adaptability test, is $P = 0.902 > 0.1$, which does not pass the significance test and accept the null hypothesis, indicating that the theoretical model and sample data are adaptable. Other adaptability indicators are RMSEA $= 0.000 < 0.05$, CFI $= 1.000$, TLI $= 1.025$, IFI $= 1.002$, RFI $= 1.000$, NFI $= 1.000$, indicating that adaptability of the model is great.

① The Effect of Cross Listing on Operating Performance

As shown in Fig. 3, cross listing has no significant direct effect on proxy variables of operating performance ROA and TBQ. Results of significant path effect are listed in Table 6.

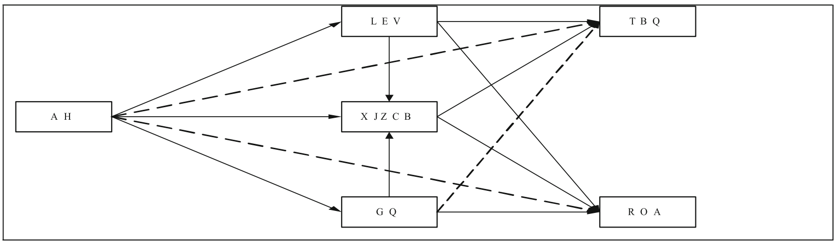

Fig. 2. Conceptual model of cross listing's effect on operating performance

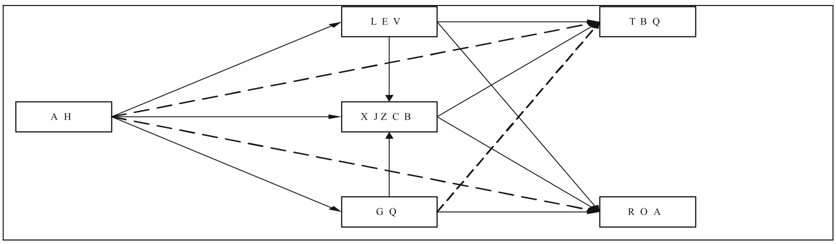

Fig. 3. Coefficient map of path analysis

Table 6. The effect of cross listing on corporate value

Types of path	Paths	Results
Path of ROA	ah-lev-roa	$0.040 \times (-0.111) = -0.0044$
	ah-xjzcb-roa	$-0.031 \times 0.108 = -0.0033$
	ah-gq-roa	$0.035 \times 0.026 = 0.0009$
	ah-lev-xjzcb-roa	$0.040 \times (-0.120) \times 0.108 = -0.0005$
	ah-gq-xjzcb-roa	$0.035 \times (-0.128) \times 0.108 = -0.0005$
	Total effect	-0.0078
	ah-lev-tbq	$0.040 \times (-3.122) = -0.1249$
	ah-xjzcb-tbq	$-0.031 \times 2.308 = -0.0632$
Path of TBQ	ah-lev-xjzcb-tbq	$0.040 \times (-0.120) \times 2.038 = -0.0098$
	ah-gq-xjzcb-tbq	$0.035 \times (-0.128) \times 2.038 = -0.0091$
	Total effect	-0.207

As shown in Table 6, the total effect of path of ROA is -0.0078, indicating that after cross listing in both A and H-share market, corporate operating performance turns down, specifically, after cross listing, debt structure and asset liquidity change in different degrees, affecting operating performance. The total effect of path of TBQ is -0.2070, indicating that after cross listing, corporate market value is negatively affected, and decreases sharply. The coefficient of ah-lev is 0.040, indicating after cross listing, because of the relaxation of financing environment, companies are more inclined to increase debt financing to get rapid expansion; the coefficient of ah-xjzcb is negative, indicating after cross listing, companies reduce their cash holdings to lower the agent cost; the coefficient of ah-gq is significantly positive, indicating after cross listing, ownership concentration increases, as market environment is more complex, and major shareholders are more willing to increase their stakes to further consolidate their power.

As shown in ah-lev-roa and ah-lev-tbq, cross listing can significantly improve debt capacity, indicating cross listing can enhance companies' ability to obtain external financing, however, the increase of L/A ratio cannot bring about growth, but become an obstacle to the development. As shown in ah-gq-roa, after cross listing ownership concentration increases, which improves corporate value, but with limited effect. As shown in ah-xjzcb-roa and ah-xjzcb-tbq, after cross listing, cash asset ratio sharply decreases, and low cash asset ratio has negative effect on corporate value. Simultaneously, as shown in indirect path, after cross listing, ownership concentration and L/A ratio also lead to the significant decrease of cash holdings, and then the decrease of corporate value.

② Path Decomposition of the Effect of Cross Listing on Corporate Value

Empirical researches on A+H cross-listed companies in China, choosing ROA and TBQ as proxy variables of corporate value, show that after cross listing, internal assets structure is not improved. Specifically, when ROA is the proxy variable of corporate value, path of debt contributes 51.6% to the decrease of corporate value after cross listing, path of cash flow, 34.0%, and path of ownership, 14.4%. When TBQ is the proxy variable of corporate value, path of debt structure contributes 65% to the decrease of corporate value, path of cash flow, 30.5%, and path of ownership, 4.5%, which is relatively lower (Table 7).

Table 7. Path decomposition of the effect of cross listing on corporate value

Proxy variables	Types of path	Paths	Effect	Contribution degree	Ratio of contribution degree
Path of ROA	Path of debt	ah-lev-roa	−0.0044	0.0045	46.40%
		ah-lev-xjzcb-roa	−0.0005	0.0005	5.20%
		Total	−0.0049	0.005	51.60%
		ah-gq-roa	0.0009	0.0009	9.20%
	Path of ownership	ah-gq-xjzcb-roa	−0.0005	0.0005	5.20%
		Total	0.0004	0.0014	14.40%
	Path of cash flow	ah-xjzcb-roa	−0.0033	0.0033	34.00%
	Total effect		−0.0078	0.0097	100%
Path of TBQ	Path of debt	ah-lev-tbq	−0.1249	0.1249	60.30%
		ah-lev-xjzcb-tbq	−0.0098	0.0098	4.70%
		Total	−0.1349	0.1349	65%
	Path of ownership	ah-gq-xjzcb-tbq	−0.0091	0.0091	4.50%
	Path of cash flow	ah-xjzcb-tbq	−0.0632	0.0632	30.50%
	Total effect		−0.207	0.207	100%

Note: Contribution degree is indicated by absolute effect, without differentiating positive effect and negative effect.

5 Conclusion

This paper discusses the development status of companies cross-listed in both A and H-share market in China, and examines the effect of cross listing on operating performance by using Propensity Score Matching (PSM), and then uses Structural Equation Model and path analysis to explore the impact mechanism and specific effect of cross listing on operating performance from paths including debt structure, asset liquidity and ownership structure. The results show: (1) Compared with non-cross-listed companies, those companies cross-listed in both *A* and H-share market, have witnessed a worsening of operating performance, a significant increase of ownership concentration and liabilities to assets (L/A) ratio, and a significant decrease of asset liquidity. (2) Cross listing has affected operating performance mainly through debt structure, asset liquidity, less through ownership structure. Main contributions of this paper are as follows: (1) using Propensity Score Matching (PSM) to solve the problem of endogeneity in the research of cross listing; (2) further analyzing the impact mechanism and specific effect of cross listing on corporate performance.

Suggestions are as follows: Firstly, A+H cross listing cannot improve operating performance of Chinese companies, because most A+H cross-listed companies choose to be listed in H-share market first, and then in A-share market, however, compared with the capital market in Hong Kong, the capital market in the mainland of China is not completed enough, thus after A+H cross listing, companies' governance environment has not been improved. Therefore, the top priority is to improve the capital market system. Secondly, domestic listed companies should be encouraged to go out into the developed capital market for financing, utilizing good markets in developed countries, so as to improve the domestic market in an indirect way; after cross listing, companies' ownership concentration and ratio of debt financing significantly increase, indicating debt financing becomes more important, and then companies face greater investment risk. As path of debt is the main factor worsening operating performance, so companies should adjust their ratio of debt financing to a reasonable range, in order to avoid excessive leverage risk; after cross listing, with less financial constraints, companies tend to reduce their cash holdings, and then to make blind investments. As decrease of asset liquidity is also a main factor reducing corporate profitability, companies should properly hold liquidity assets in case of need.

Abstract. The study provides the cognitive support for developing employee's motivation level at optimized level through consciousness towards applied approach and unrealistic ideas. The diligence of the research is to present the factors that help to motivate the employees to perform their job well. Whereas, the study restrains empirical and descriptive analysis of variables which comprehensibly highlight the significant relationship among the independent variable and dependent variable; the close-ended questionnaire is constructed to compute the statistical data. The study identifies the strong relationship among the defined factors that enhance the employee's motivation level in banking sector. Although the research is also aware the management and the managers of banks about the most preference factors that improves the employee motivation in the banks. This study valued the integrating knowledge, experience, action to groom skilled employees in the banks. Moreover, the main contribution of the research evaluating the role of the motivational factors in banking industry.

Keywords: Motivation · Empowerment · Job environment · Banking · Employee performance algorithm

1 Introduction

In the most current scenario employees have became the primary strength of any business where the employees deliver their continuous effort to drive organizations' decisions into action to accomplish its objectives. Whereas, the motivational factor regarding the employees is becoming a part of organizational strategy. However, motivation is an aspect that helps an individual to select or deselect the job, to continue and work proficiently during his/her job [16].

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_50

Further, the motivational research proposes to facilitate the individuals to get motivated through the target to satisfy their unconvinced desires; consequently they apply their endeavor hoping to be satisfied with their needs. Conversely, modern studies' regarding the motivation doesn't highlight the Basel desire conception, but in addition they highlight the objective, equality, and values [24]. However, the after effect from the motivated workforce provides the less employees, turnover, retention and high productivity rate, which leads the organization towards growth and development [13].

Further, the motivation explains as a dynamic strength among individual which inspire the employees to do the incredible work to achieve the goal that regulates to accomplish want or anticipation [19]. It is a complex subject of human behavior which differs from person to person; therefore, varied individuals will be stimulated in unique ways [12]. Individual's behavior will state that what encourages them to implement the effect of both capacity and inspiration [19]. Spiral inspiration can be characteristic and inappropriate [9]. A few theories of inspiration were created to recognize the variables of inspiration that impact human conduct in distinctive ways.

While in conventional management approach the idea is that "Manager recognize the job optimum" is prevailing in current management. In modern conception the representative's inspiration will be extremely enormous particularly for service businesses. While, the resource provokes the representatives, that analyst separated them into two gatherings; outside and inside components [10]. However, external elements, there will be inspiration implies such as meeting expectations condition, pursuing, organization's picture, work assurance, advancement, social environment, and position. In terms of learning organizations, when seeing outer ecological components quick alteration and difficulty to be measured in a firm national and global struggle, these organizations taking choices to profound impact in organizations' by keeping up its presence.

The method individual responds towards organizational working condition depends over job reliability, job stress, working hours. Thus interpersonal associations imitate satisfaction in correspondence with a subordinate. Job satisfaction is completely prejudiced by range of professional characteristic such as organizational ethnicity, interpersonal affairs, worker empowerment, cooperation, and self-apparent accountability [11]. Further, employees assess their working ability by receiving rewards furthermore identify additional fulfillment by getting fair pay in exchange of their efforts within the organization [8]. Fair payment for their efforts can effect in motivation and fulfillment for invulnerable workforce. An individual value system is being studied while creating the awareness of rewards and compensation, whereas individual's values of receiving pride for their efforts to support and increase their work level while it's related to their educational period or from salaried time line [7]. Individual at its initial level of its career pays high values to intrinsic and extrinsic feature related to their job. Moreover, individuals with the startup of their careers valued the rewarding towards their work assessment and environment further the expert and experienced individuals with high potential and opportunities also provide values. As the different researcher consider the motivation as the function of compensation and belief towards their jobs; because of which the high rewarding employees having the high satisfaction in respect to their job [11].

2 Literature Review

2.1 Motivation

Motivation is mostly differentiate as one of the most influential predictors of individual behavior and a key analyst of performance for essential aspect of behavior [22]. Hence, it is not shocking that motivation show in a range of regulation paper [15], scholars and executives have vast attention in accepting person motivation to use communal medium and tools on behalf of companies [14]. Motivational aspect (such as success, appreciation, accountability, effort, progression, individual development) are associated to the application contented though hygiene aspects (such as corporation strategy and management, interpersonal relatives, working environment, pay, job safety, position, reimbursement) are associated to the employment background [6]. Herzberg measured hygiene aspects as extrinsic features, which have an unsettling outcome on the staff job approach and create them eventually displeased in their profession when the needs aren't sufficiently meet. Further, motivational aspects are recognized as intrinsic feature, which make staff fulfilled when needs are meet, conversely, do not formulate them disgruntled in the deficiency of these [21]. Further the study affirms that motivation exists merely when individual appreciates an optimistic correlation that endeavor direct to work performance and work performance directs to incentives [6]. Moreover, the objective locale theory of motivation, where the theory emerge from the proposal of anticipation theory as a target locale is an essential instrument, which work as an "instant valve of individual act" [17] that direct the individuals towards attaining the objective. The objective influences the performance by straight concentration, organizing endeavor, rising determination and inspiring plan. Further the earlier research [3] offer a perceptive of an individual attitude, prospect, plan and aims in life. Moreover, this research helps business to considerate their employees' objective in both their qualified and private life, whilst identifying the need to stimulate them. At the Similar time, they seem to improve the participation, reliability, and assurance of the staff to their businesses. Positively, accepting the features that influence the motivation of staff is an huge dispute for business, leaders and executives [23]. Especially the people worth different aims in life. People might have diverse needs and wants, ethics, ambition, objective, and prospect in life [1]. A motivational presumption effort to clarify the aspect that have straight or circuitous pressure on motivation and business performance, such as worker stimulus and other motivational factors [23].

2.2 Job Environment

The environment where the job performs in their work surroundings can be diverse from those fully contented challenging and unsafe for the life and health of employees. Whereas, the complex operational surroundings can be prejudiced by:

- Peripheral aspect that comprises environment, meteorological condition, temperature, clamminess, breeze, illumination in the office and intrusion, gases and other harmful factors.
- Individual aspect that contain sexual characteristics and maturity of the employee, exhaustion, repetitiveness, adverse stance throughout exertion.
- Another aspect associated with the business of production towards the period of the working hour, working plan, working occasion, work speed, extreme injure, etc. further, the work with complicated operational circumstances may achieve only the workforce who convene precise requirements in stipulations of maturity, gender, education, strength, corporeal and psychological circumstances and psycho-physiological and emotional capacity. Complex operational environment manipulates employees' work performance.

Further, it is significant that staffs are qualified and knows how to perform job related duties with the help of paraphernalia as insufficient utensil usage can affect in mishap or divergences in recital no issue that how a lot and utensil was appropriate. Learning of the individual must also be provided oriented to the good use of defensive tools and individual safety [4].

2.3 Benefits

Benefits can affect the Employee performance in many ways. The benefits are not frequently issued towards assessment and are consequently cheaper to achieve during an employer throughout the market [2]. Therefore, cheaper the benefits ought to amplify employee performance. Further the benefits can proceed as an alternate for salary. To inspect the employer investigation facts and establish the employee's reduced the salary; once numerous benefits had obtained to the individual after a few years [2]. Moreover, the employees sight the benefits and salary as alternatives, disposed to provide salary in trade for extra benefits. While the benefits set as a significant part of employee compensation correspondence and simply acted as organize in different researches, but not as the key issues of analysis.

Furthermore, in the literature the reward shape towards the benefits that individual obtain from their work [11], and the important part of a worker job approach such as business assurance, incentive and employee performance [12]. Thus, in any business rewards in cooperate as a significant role in structuring and supporting the obligation between the workers that guarantee an average job performance and employee loyalty. As, the business entity substitute premise, employee penetrates corporate with the exact set of proficiency towards requiring goals, and anticipate in revisit a respectable working conditions where the employees assist to use their skills and satisfy and attain the desired goals [18]. The rewards enhance the height of effectiveness and efficiency of the individual towards their jobs and in place of outcome there is an improvement of organizational performance [18].

2.4 Empowerment Concept

Empowerment as initially is an important and vital concept by which personnel are capable to effect and have regulator over judgments that influence over their productivity in their job. Moreover, this perception support workers to workout determined regulator or consultant of their effort situation tangibly, communally, ethnically and spiritually over the assets owed to them [5]. Partaking egalitarianism is extra essential idea or belief that qualities enlarging on. Rendering to [25] sharing was careful to be an inherent quality of equality and thus a clarification to suppression. This idea contains the methods and conclusions to inspire development and autonomy.

2.5 Recognition

"Recognition explains as the appreciation to the employees for the level of performance, and success or an influence to achieve goal. It can be intimate or community, fundamental or official. It is continuously in tally to pay." [20]. However the employees also need recognition. Persons like to distribute the celebration of their success with others and have to be recognized in the organization. Whereas the needed is satisfied it works to be an excellent motivator. Further, if employers depend on reward only to recognize influence and success it is most probable that the employee's goals will become altered to protect the pay and nothing more while this will lead to a besmirched culture of the organization. Thus using recognition correctly it will be cost-effective way of increasing success and allow employees to feel intricate in the corporation culture [20].

3 Problem Statement

Today the banks are facing the problem of low productive employees in all the sectors. However, in banking industry the lower level of motivating employees are in number due to the nature of their work. However, this study assist to find out the relationship among the following factors Benefits, Job environment, Empowerment, Recognition, to extract the best known factor among the employees to enhance their motivational level. The study will investigate the impact level for the above mentioned aspects on employee motivation of their job and their after cause on their moral satisfaction and their individual performance in banks.

3.1 Research Question/Objective

The following are the objectives of the research:

- To extract the best known motivational factors that supports the moral intention of individual to perform.
- Which factor is highly motivates employees in the banking industry?
- Do the motivational aspects enhance the individual performance?

4 Hypothesis

4.1 Motivational Factors

$Hypothesis_{a1}(H_{a1})$: There is a significant impact of Benefits over employee Motivation in the Pakistani Banks.
$Hypothesis_{a2}(H_{a2})$: There is a significant impact of Job environment over employee Motivation in the Pakistani Banks.
$Hypothesis_{a3}(H_{a3})$: There is a significant impact of Empowerment over employee Motivation in the Pakistani Banks.
$Hypothesis_{a4}(H_{a4})$: There is a significant impact of Recognition over employee Motivation in the Pakistani Banks.

4.2 Motivation and Individual Performance

$Hypothesis_{a5}(H_{a5})$: There is a significant relationship among motivation and individual performance in the Pakistani Banks.
$Hypothesis_{05}(H_{05})$: There isn't a significant relationship among motivation and individual performance in the Pakistani Banks.

5 Methodology

The research focuses on descriptive research design. Whereas, the precarious connection among the answers about discovering out the connection of Benefits, Job environment, Empowerment, Recognition, that help to enhance the motivational level of individual also to optimize their work performance and as well as its effect on organization. Furthermore explanatory study helps us to explain the relationship among Dependent and independent variables. The descriptive study helps to find out the line of intervention on the factors affecting the individual motivation. However, the job satisfied employee's leads the organization towards the improvement in employee performance and customer satisfaction. This study disquiet with discover how, when, what, why questions concerning about the factors of motivation and clarification of distinct variables may lie in the study which also ornate the modern association among variables that how the delimit factors have their impact over the employee performance.

However, the research depends upon two areas, i.e. the base use which is used for the tactical attitude which trusts over secondary data, comprising seminar proceedings, books, intellectual journals, webinars and articles. Moreover, the research sturdily depends over primary data source by accompanying the survey on employee motivation to collect material about diverse aspects which expressively influence over the employee job performance in banking industry. The banks included in this study are Meezan Bank, Bank Al-Habib, Albaraka, and Faysal Bank. The demographic aspect included age, gender, salary range, job position, service period, and last promotion that received in their organization cover in the questionnaire. Structured Close ended questionnaire is being a part of my study. The questionnaire is the primary tools to gather data for my dissertation. Further human comportment is coherent which rely upon reasons, however all individuals has their own explanation for precise concern they are attaining from convinced area and services even by exploiting certain individual skills, this is the key reason for picking questionnaire as the primary to of data collection.

5.1 Research Model

The motivated employees are the most important assets for the organization. Although it is the considerate perceptional preference of employees being rightly treatment, the functional loom is being centered towards the inference of an employee's motivation on executive success (Fig. 1).

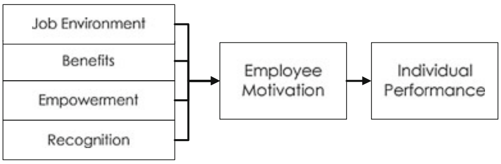

Fig. 1. Conceptual model

Moreover, the employee motivation is in the interest to the executives since it has a reciprocal outcome for every individual and every other thing in organization. Further, in banks employee's motivation is the main factor due to the nature of job and higher employee turnover rate and stress. Further testing will I identify the effect of factors on employee motivation.

6 Results and Discussions

6.1 Employee Preference over the Factors Affects Employee Motivation

The Analysis of the motivational factors that is most preferable by the employees working in the banking sector industry. However, the factor state below indicates that the maximum preferable factor is used to increase the level of individual motivational (Table 1). Further the bar-chart indicate that Benefits share the ratio of 18% to enhance employee motivational level as well as the interpersonal skills of an individual has 13% of its contribution (Fig. 2).

Although the most affective factors that helps to improve the employee inner motivational level is the individual empowerment the employee decision making authority and its contribution among the other factors is almost 22%. However, job environment, recognition and employee growth also have their impact on employee motivational level over their job.

Table 1. Preferable factors that improves employees motivation

Motivational factor	Frequency	Percentage
Benefits	79	26.1589404
Job environment	51	16.88741722
Empowerment	95	31.45695364
Recognition	77	25.49668874
Total	302	100

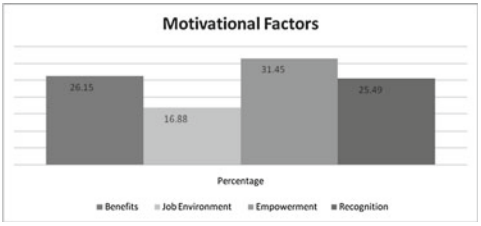

Fig. 2. Preferable factors that improves employees motivation

6.2 Multi Regression Empowerment, Benefits, Job Environment, Recognition and Motivation

The regression equation between empowerment, recognition, growth & development with motivation:

$$\text{Motivation}(y) = f(\text{empowerment, recognition, benefits, job environment}),$$
$$y = b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4 + \text{Error},$$

where b_1x_1 signifies the intercept of empowerment x, b_2x_2 signifies the intercept of recognition x, b_3x_3 signifies the intercept of benefits b_4x_4 signifies the intercept of job environment (Table 2).

Although the table of regression shows the value of R about 0.942 which identifies the strong relationship among independent variable (empowerment, recognition, benefits and job environment) and dependent variable Employee motivation. Whereas, R square shows co-efficient of simple determination which is 88% variance in empowerment, recognition, benefits and job environment explained by motivation. The F-test identifies the rationality of the research model and the model fitness. The significance of F-test is computed where the F calculated is greater than F tabulated which is 0.05. Thus, the null hypothesis H_{01}, H_{02}, H_{03} and H_{04} has been rejected followed by the results and the results also identifies the significant connection between empowerment, recognition, job environment, benefits and employee motivation.

Table 2. Please write your table caption here

Regression Statistics					
Multiple R					0.942
R Square					0.888
Adjusted R Square					0.884
Standard Error					0.1704
Observations					126
ANOVA					
	df	SS	MS	F	Significance
Regression	4	27.92	6.98	240.18	0.000
Residual	121	3.516	0.029		
Total	125	31.437			

6.3 Regression Analysis Between Employee Motivation and Employee Performance

The regression equation between motivation and employee performance:

$$\text{Employee performance}(y) = f(\text{motivation}).$$

The regression outcome identifies the relation among employee motivation and performance which is being further specifies in the below mention table (Table 3).

Table 3. Regression analysis between employee motivation and performance

Regression Statistics					
Multiple R					0.722
R Square					0.522
Adjusted R Square					0.518
Standard Error					0.32622
Observations					126
ANOVA					
	df	SS	MS	F	Significance
Regression	1	14.386	14.386	135.184	0.000
Residual	124	13.196	0.106		
Total	125	27.583			

In Table 3, the outcomes indicates the positive connection among motivation and employee performance is and identify that motivation is also a factor to enhance the employee work performance. However the result shows the regression R 0.722 and adjusted Rsquare is 0.522 which shows the significant relationship. $F_{calculated}$ is greater than $F_{tabulated}$ which is 0.05. Furthermore the result rejects the null hypothesis H_{05}.

6.4 Conclusion and Managerial Implication

The study specifically identifies the importance of motivation in the environment of the banking industries and specifies the factors that improve the employee motivation leveling banks. Whereas, the people spent their life working in the banks, which highlighted the point to improve the motivation level of employees towards their job. This research conducted to keep the motivation level high in banks. Further, the results identify the factors (benefits, recognition, empowerment, and job environment) helps to improve the employee motivation level. Further, each factor shows its level of importance. Moreover the study also explains the satisfactory results from the banks employees about the define factors can enhance employee motivation towards their jobs. The study illustrates that motivated employees satisfied with their job more delicately and serve the organization and customer, especially in the banks where the employees is directly linked with the customer. Whereas the results shows that the factors not only enhance the employee motivation as well as the factors also enhances their moral and social behavior that tends to improve their work performance.

How Content Marketing Can Help the Bank Industrial: Experience from Iran

Sima Zomorodian and Yi Lu(✉)

Business School, Sichuan University, Chengdu 610065, People's Republic of China
luyiscu@163.com

Abstract. In today's market, Content marketing is one of the most efficient and successful ways you can do that, but only if you know how to use it correctly. We tried in this article to find, are there any relationship between sensitive content, quality content, new content and content marketing? The study had been designing a questionnaire consists of 37 questions in Likert scale to help us finding our hypotheses clearly, after analyzed the data of questionnaires with SPSS software we fund our three hypotheses and for accept or reject them we use another questionnaires with 40 questions in Likert scale and among 550 randomly selected regular customers of Bank Mellat in Tehran (the capital of Iran) and 400 roperly filled questionnaires were collecting. Then analyzed all the questionnaire with Amos software. The result show all of those items(sensitive content, quality content, new content) can have effect on the customer. So an empirical investigation to determine factors influencing on content marketing in banking industry because in this area there are a lots of brands and customers that can use all of them very easy so they should find different way for attract customers. The result can help the bank industrial to improve their content marketing and increase their customer.

Keywords: Marketing · Content marketing · Export company · Customer

1 Introduction

Content marketing is the process of creating high-quality, valuable content to attract, inform, and engage an audience, while also promoting the brand itself. Content marketing is a kind of Marketing that use words, sounds and photos to improve the knowledge of customer, introduce their brands and new products. Content marketing is about giving away information to build relationships and earn trust, but gating some of your best content is an acceptable and valuable practice. In fact, this is not the only benefit of content marketing, another utility of this kind of marketing is costs less than other types of marketing. Content marketing is a new topic in Iran. Perviously, in bank industrial, they just tried to give better services to customers and hope they introduction their brands. We

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_51

are trying to help the bank industrial for using content marketing to increase their customer. Content marketing is comparable to what media companies do as their core business, except that in place of paid content or sponsorship as a measure of success, brands define success by ultimately selling more products or services [13]. Content marketing is the marketing and Business Process for creating and distributing relevant and valuable content to attract, acquire, and engage a clearly defined and understood target audience - with the objective of driving profitable customer action [10]. "Strong brands are based on a story that communicates who is the company, is to communicate what you really are" [2]. Therefore, the content marketing should be based on the company's values. Also, without considering the quality of the content, which is the most important part of digital marketing, the choice of the frequency of promotion and of the right social media plays a significant role in the success of the content marketing campaign. When building such a strategy, it is important to always have in mind all the social business strategy factors. All content has to work together; all the groups need to work together. There are 6 essential components of content marketing strategy: creation - curation - optimization - social media - amplification - analysis [1]. Content marketing aids in brand recognition, trust, authority, credibility, loyalty and authenticity. Content marketing can help accomplish these tasks for a variety of constituencies, and on several levels: for the organization it represents, for a company's products and services, and for the employee who represent the business or service [8]. In the development of a content marketing, there are numerous opportunities to be more relevant and effective. Planning content that's meaningful to the customers you're trying to engage according of content [9]. Content marketing is anything an individual or an organization creates and/or shares to tell their story. What it isn't: A warmed-over press release served as a blog post. It is conversational, human and doesn't try to constantly sell to you. It also isn't a tactic that you can just turn on and off and hope that will be successful. It has to be a mindset that is embraced and encouraged. You've got to start thinking like a publisher and use that to plan and execute your entire marketing plan which content of any variety should be a part [3]. Making professionally produced creative content available online is proving to be a high-risk business, because of market fragmentation, high development and production costs and the need to fund as yet unprofitable new services from the declining revenue streams of "traditional" analogue and physical distribution [12]. The marketing management philosophy which holds that achieving organizational goals depends on determining the needs and wants of target markets and delivering the desired level of satisfaction more effectively and efficiently than competitors [7]. The forms of content marketing are constantly changing as new tools to create, publish and share that content are launched and others are shut down. Enhancements and new functionality are added to content publishing tools every day, which means the tools you are using to create, publish and share content today might not be the tools you are using tomorrow [5]. The paper has two main research objectives: (1) Study the influential factors on content marketing (2) Study the influential factors on content marketing in Bank Mellat.

The paper is structured as follows: literature review that show our hypothesis come from previous study. Research methodology that show our method for survey the elements. Result that show why we accept hypothesis. Discussion that show the final result and give some suggestion for future research.

2 Literature Review

In today's market, content marketing can solve some problems for company. Actually in Iran this kind of marketing is new and we try in this article to show how this kind of marketing can help to the bank industrial for attract more customers. So we focus on previous studies to find some elements related to content marketing and then use questionnaire to collected data from customers, after that we analyze the data and make the hypothesis. Again we use questionnaire to collected data to accept or reject the hypothesis. Content marketing is defined as a marketing process of creating and properly distributing the content in order to attract, make communication with, and understand other people so that they can be motivated to do beneficial activities [4]. More specific solutions are outlined in content marketing strategies 'where I focus on quality of the content, its creation, distribution and evaluation' [1]. In addition to monitoring mentions and share, engaging with people who responded to the content can be a very powerful way to spread your reach and to connect with potential prospects or industry stakeholders [10]. The explanation is that "When a brand uses specific words or stories that resonate with a consumer, they can dig deeper into who they are as a consumer. By utilizing content marketing, brands can cater campaigns and stories around buying patterns and personalities" [2]. Base on those researches we make this hypothesis: Quality of content has effect on export companies customers. To be relevant to your audience and create a powerful brand you must win their trust and admiration. With the creation of valuable content you build interest that transforms into lasting relationships [11]. Due to the characteristics of these emerging technologies, the digital content market is growing rapidly and traditional content providers face service transformation decisions. While a majority of the previous technology adoption studies have focused on the viewpoints of users and customers, cost reduction, or electronic channel related technologies, in this research we analyze the emerging technology adoption decisions of competing firms for providing new content services from a strategic perspective. Utilizing game theoretical models, we examine the effects of market environments (technology cost, channel cannibalization, brand power, brand extension, information asymmetry and market uncertainty) on firms' adoption decisions [6]. Base on those researches we make this hypothesis: Sensitive of content has effect on export companies customers. However, by implicitly restricting it's focus to a buyer's perspective, the resource-based and relational views also leave the question of which resources and competencies add greater value-for-customer largely unanswered [14]. According to some authors, the contribution of different benefits to a relationship's value will vary along the relationship life-cycle. Specifically, the supplier's know-how of the supply market, the adaptation and improvement of extant products and the development of new products become increasingly relevant in explaining the value of a relationship from the customer's perspective as the life-cycle advances [14]. Base on those researches we make this hypothesis: New of content has effect on export companies customers.

3 Research Methodology

For finding the elements related to content marketing in the bank industrial, we find some elements from previous studies use questionnaire in the different branch of Mellat bank and the customer answer them after that we analyze the data. The questionnaire consists of 40 questions divided into two sections: the first, consisting of 4 multiple choice questions, allow us to obtain general information about the sample (gender, age, years of service and Education level). The second, measured by a Cronbach's Alpha analyze:

- Has quality of content effect on bank industrial customers?
- Has sensitive content effect on bank industrial customers?
- Has new content effect on bank industrial customers?

The area of this research is Tehran. The capital of Iran. Statistical Society of this research is the customers of Mellat bank in 2016. Scale of five options to describe the items listed in the questionnaire of "very large impact" to "very little impact" is used. A total of 370 questionnaires were collected at the end of the questionnaire, as shown in Table 1.

Table 1. The elements

Element	Questionnaires	The percentage	
New content sharing	0.623	Less than 0.001	Accept
Brand	0.742	Less than 0.001	Accept
Content creation	0.701	Less than 0.001	Accept

4 Result

In the first analysis, factor analysis was exploratory and in the second one confirmatory. There are plans to test certain hidden factors beyond the variables. In this case, orders are expected variables. In the researchers to test hypotheses related to a particular factor structure of the action. In this analysis, the researchers tried to obtain empirical data based on a model that assumes a relatively small number of parameters, describing explain or justify. Reliability Statistics: as shown in Table 2.

KMO and Bartlett's Test: as shown in Table 3.

The SPSS software for data Factor and AMOS software for factor analysis was used, the result is as shown in Fig. 1.

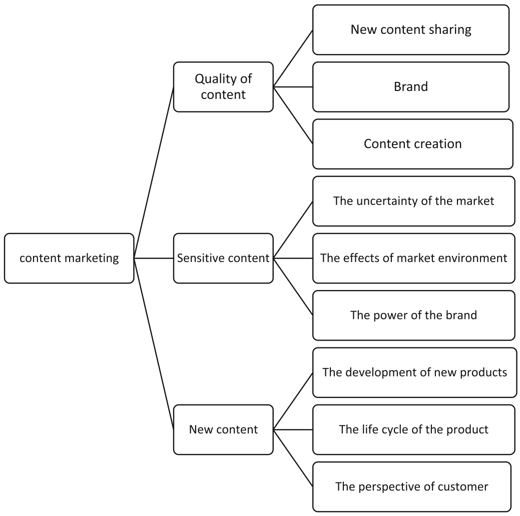

Fig. 1. Factor analysis result

(1) Quality of Content
Exploratory factor analysis in the first order for quality of content, and finally, the three most important variable component factors identified in accordance with the following table can be significant.as shown in Table 4.

(2) Sensitive Content
Exploratory factor analysis in the first order for sensitive content, and finally, the three most important variable component factors identified in accordance with the following table can be significant, as shown in Table 5.

(3) New Content
Exploratory factor analysis in the first order for new content, and finally, the three most important variable component factors identified in accordance with the following table can be significant, as shown in Table 6.

Table 4. Quality of content

The index	Standard coefficient	Significant level	Acceptance or rejection situation
New content sharing	0.623	Less than 0.001	Accept
Brand	0.742	Less than 0.001	Accept
Content creation	0.701	Less than 0.001	Accept

Table 5. Sensitive content

The index	Standard coefficient	Significant level	Acceptance or rejection situation
The uncertainty of the market	0.586	Less than 0.001	Accept
The effects of market environment	0.492	Less than 0.001	Accept
The power of the brand	0.606	Less than 0.001	Accept

5 Discussion

In content marketing the customers are not presented with a direct suggestion, instead they take another issue and information that is useful for them. At the end they trust the content provider. Content marketing also can use with another kinds of marketing.

In this paper, we examine customer opinion to analyze some elements that can be effective on content marketing. In Iran this kind of marketing is new so we try to show the bank industrial that they can use it to improve their business.

Our results show that there are elements related to content marketing. However, they are sensitive content, quality of content and new content. In conclusion, In today's marketing, content marketing due to lower fee than other marketing methods can be very effective. In the banking industry in Iran due to the existence of different banks and brand diversity is very high, customers in the choice of the Bank are having doubts.

The most simple and low-cost way to attract customers in order to help create content provides the services of the Bank and the Bank's competitive advantages compared to other banks to inform customers. In this context must be carefully that creating content is purely informational aspect and do not have directly tried to attract customers, because it may have a reverse and does not help to attract customers.

Table 6. New content

The index	Standard coefficient	Significant level	Acceptance or rejection situation
The development of new products	0.545	Less than 0.001	Accept
The life cycle of the product	0.714	Less than 0.001	Accept
The perspective of customer	0.810	Less than 0.001	Accept

After content attract trust of a group of customers, this group begin to do mouth to mouth advertising, this action does not have charge for Bank. According to the result of the study, New content can improve the knowledge of customer and can help them to make a good decision. Must be careful in creating content do not use imitation method because the duplicate content to help not only our business, but does not cause a lack of quality in the customer's mentality.

To create the content need a team to be active and knowledgeable in this field, that continuously target market observation and based on customer needs to start creating content.

Content marketing is the present and especially the future of marketing and inherently to marketing in general. Therefore, a content marketing strategy cannot be successful without having a quality of content. Higher quality of content created as compared to other competitors is the number of people who can trust our business will increase. In today's world most people unwilling to spend time for unnecessary information. So the creation of quality content is one of the critical components in creating the content. Also when we improve the quality of content we can make a competitive advantage and this is improve our chance to have more customer. In the uncertainty market we should be careful about which kind of content is necessary for customer.

In creating the content should be think about specific time like New year. Create the appropriate content at any time, can be very useful in the success of the business. So teams that create content need to be aware of the point and make a suitable content for customers.

Content marketing is still in developmental stage. There is a need to consider content for bank's industrial. There is an opportunity for banks to use content marketing more and more for finding new customer.

For future research there are some suggestions. We can do this research on another industrial. Also evaluation of the factors influencing the content marketing customer in a bank-centered and compare it to other banks. Factors influencing the relation between detection of content-driven marketing and customer satisfaction.

Abstract. It is even the most difficult and critical step in starting a business. Unfortunately, prior entrepreneurial project selection (EPS) methods are barely satisfactory. In this paper, we constructed AHP-BP neural network mode based on the traditional BP neural network. It effectively reduces the input dimensions of traditional BP neural network, significantly raises its learning speed, and improves the prediction accuracy. In the end, empirical study shows that this model is able to fully absorb the tacit knowledge of expert assessment, reduce subjective randomness, which provides important references to entrepreneurs in starting a business, thus it is worthy being popularized and applied.

Keywords: Entrepreneurial project · Analytic hierarchy process · BP neural network · Risk decision

1 Introduction

Entrepreneurial activities have shown increasingly close relationship with job creation in both developed and developing countries, and have become a strong driving force to world's economic development. Meanwhile, entrepreneurship has occupied a prominent position on the agendas of policymakers and researchers [14]. In complex environments, Triple Helix has been operationalized in different ways, spaces, and contexts where those agents are transforming their roles in the development and strengthening of national innovation and entrepreneurial ecosystems [3]. Unfortunately, at early start, failure is always going along with those entrepreneurial projects. According to 2015 Annual Report of GEM (Global Entrepreneurship Watch), the huge success made by 20%–30% startups in China is at the cost of 70–80% failures. Even in developed countries, 35% startups failed in the first year, almost half of them disappeared in five years [15]. Numerous reasons exist but mainly because entrepreneur started with an inappropriate project. For instance, Nabil provided a starting point for a stronger

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_52

theoretical grounding of research that goes beyond the traditional interpretation of entrepreneurial failure and opens new avenues of research opportunities to explore and compare the different configurations that have emerged and identify the possible dynamism and trajectories among these configurations [7]. However, how to use scientific methods to select appropriate projects is particularly important for entrepreneurs [11].

Currently, scholars are dedicated to studying the theory and method of EPS, and made some achievements [4,6,8,12,19,21]. These studies could be divided into two categories: first, qualitative analyses based on theories, including SWOT analysis, brainstorming and vision method. These studies has certain feasibility but underper forms in practice. Secondly, quantitative analyses using mathematical models, including income constraint method, utility function method, risk ranking method and fuzzy evaluation method. These methods are barely satisfactory in practice because of subjective factors. Therefore, how to choose a right entrepreneurial project has become a difficult problem in management.

This paper is organized as follows. In Sect. 2, the evaluation index system of EPS is built. In Sect. 3, the traditional BP artificial neural network is introduced. In Sect. 4, we combined AHP and BP neural network to construct the AHP-BP neural network model of EPS. In Sect. 5, the empirical research based on 21 entrepreneurial projects shows that the model is scientific and practical.

2 Evaluation Index System

Entrepreneurial Project Selection (EPS) means choosing the right entrepreneurial projects at the beginning of business. There are a lot of factors influencing EPS, subjectively and objectively. Thus, we need to follow certain principles and methods when establishing scientific index system of EPS. The principles are as follows:

(1) Goal oriented principles. The index system should be designed according to the needs of entrepreneurs, and keep in line with policy guidance, and it should be able to evaluate the market prospects of the entrepreneurial project.
(2) Scientific principle. Evaluation indicators must be able to reflect and evaluate the entrepreneurial projects correctly.
(3) Systematic principle. The indicators should be able to reflect the horizontal and vertical relationship between different levels.
(4) Operational principles. The selected indexes should be easy to practice. The index system should be simplified, be able to provide qualitative and quantitative evaluation to projects.

According to the principles above, the factors that influence the normal operation of the enterprise are classified into several parts. By sending questionnaires, interviewing experts and referring to literature at home and abroad [2,17,20,22], the frame is subdivided, supplemented and deleted in detail. Finally, the index system is built, as is shown in Table 1.

Table 1. The evaluation index system of entrepreneurial project

Target layer A	Criterion layer (weight)	Index layer	Weight of Index	Comprehensive weight
The evaluation index system of entrepreneurial project	Environmental competitiveness (0.066)	Industry environment	0.3946	0.026

3 BP Neural Network Architecture and Algorithm

3.1 Overview of AHP Methods

The analytic hierarchy process (AHP), is formally proposed by operational research experts Thomas L. Satty (T.L. Satty) in the middle of 1970s [9]. AHP decomposes a complex problem into various components, and group these factors into an orderly hierarchical structure. The relative importance of the factors is determined by pair wise comparison, and the overall order of the relative importance is determined by the comprehensive human judgment. The appearance of AHP brings great convenience to the decision makers in solving the decision problem which is difficult to be quantitatively described, it can be used in almost any scientific field. The detailed calculation steps of AHP method can be found in literature [1]. But Analytic Hierarchy Process, which analyzes complex decisions by organizing the problems into a multilayer hierarchic structure, is a simple yet popular decision technique used extensively in every decision field and is inadequate to handle the uncertain decision making problems [13].

3.2 Algorithm of Traditional BP Neural Network

BP (Back Propagation) neural network is a kind of error back propagation training algorithm for the multilayer feed forward network, it is one of the most widely used neural network model [10], proposed by a group of scientists led by Rumelhart and McCelland in 1986. BP neural network reflects many basic features of human brain. It is a highly complex nonlinear dynamic learning system, especially suitable for processing imprecise and fuzzy information.

Traditional BP neural network is a kind of non feedback feed forward network [18]. It is composed of input layer, hidden layer and output layer. A typical topology of three layer forward BP network is shown in Fig. 1. The first layer consists of n input nodes. Each of the n input nodes is connect to each of the r nodes in the hidden layer. The r output nodes of the hidden layer are all connected to each of the m node in the output layer.

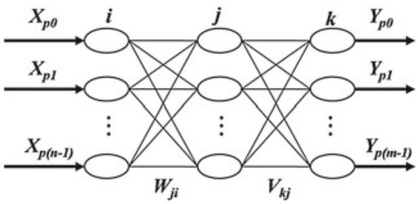

Fig. 1. Typical three layers BP network structure

The connection weights of input nodes i and hidden nodes j is w_{ij}, the connection weights of hidden node j and the output node k is v_{kj}, the threshold of the hidden layer node is, the threshold of the output layer node is θ_j. The model is $\theta_k^{'}$ provided with N learning samples $(X_P, Y_P)(p = 1, 2, \cdots, N)$. $X_P = (x_{p0}, x_{p1}, \cdots, x_{p(n-1)})^T$ is the input vectors for learning sample P, $Y_P = (y_{p0}, y_{p1}, \cdots, y_{p(n-1)})^T$ is the ideal output vector for learning sample P.

In input layer, let the input equals output, that is:

$$O_{pi} = x_{pi}(i = 0, 1, \cdots, n-1). \tag{1}$$

The operating characteristic of the middle hidden layer node is:

$$\mathrm{net}_{pj} = \sum_{i-0}^{n-1} w_{ji} O_{pi} - \theta_j, \tag{2}$$

$$O_{pj} = f(\mathrm{net}_{Rj})(j = 0, 1, \cdots, r-1). \tag{3}$$

The operating characteristic of the output layer node is:

$$net_{pk} = \sum_{j-0}^{r-1} v_{kj} O_{pj} - \theta_k^{'}, \tag{4}$$

$$O_{pk} = f(\mathrm{net}_{pk})(k = 0, 1, \cdots, m-1). \tag{5}$$

O_{pi}, O_{pj}, O_{pk} are the output of input layer node, hidden layer node and output layer node separately. net_{pj}, net_{pk} are the input of hidden layer and output layer separately. Sigmoid function is used as transfer function $f(\cdot)$: $f(x) = 1/(1+e^{-x})$.

For convenience, in the Eqs. (2), (4), let:

$$w_{jn} = -\theta_j, O_{pn} = 1, v_{kr} = -\theta_k^{'}, O_{pr} = 1.$$

Equations (2) and (4) become:

$$\text{net}_{pj} = \sum_{i-0}^{n} w_{ji} O_{pi} \quad O_{pj} = f(\text{net}_{pj}) = \frac{1}{1+e^{-\text{net}_{pj}}}, \tag{6}$$

$$\text{net}_{pk} = \sum_{j-0}^{r} v_{kj} O_{pj} \quad O_{pk} = f(\text{net}_{pk}) = \frac{1}{1+e^{-\text{net}_{pk}}}. \tag{7}$$

The learning process of the input and output samples of the traditional BP network is the adjustment of error between the actual output and sample output of network weights, it is actually a nonlinear optimization problem uses the most common gradient descent method in mathematical programming:

$$w(n+1) = w(n) - b \cdot \frac{\partial E}{\partial w} \quad v(n+1) = v(n) - b \cdot \frac{\partial E}{\partial v}.$$

In the above equity, b refers to learning rate. In the traditional BP algorithm, b is constant. The value of b directly affects the convergence and convergence rate of the algorithm.

3.3 Improvement of Traditional BP Neural Network Algorithm

Traditional BP neural network has many disadvantages. The steps of the traditional BP neural network which was improved by HE Chang-zheng etc. [5] are as follows:

Step 1. Based on actual problem, set the number of input and output layer nodes, and initialize the parameters, including the learning accuracy ε, the prescribed number of iterative steps M_0, he upper limit of hidden layer nodes R, learning parameters b, momentum coefficient a, the initial number of R is 1. The admissible region of the initial weight H is divided into N equal parts $\beta_1 \beta_2 \cdots \beta_N$.

Step 2. Input the learning samples and make the values of sample parameters [0, 1].

Step 3. Give random numbers between −1 and 1 to the initial weighting matrix $\beta_i(\beta_i \subset H)(i = 1, 2, \cdots, N)$.

Step 4. Train the network with the traditional BP method.

Step 5. Judge whether or not the number of iterative steps is exceeding M_0. If yes, continue. If no, turn to Step 7.

Step 6. If $r+1$ exceed the upper limit of R, if yes, end, no, turn to Step 3.
Step 7. Determine whether the accuracy of learning meets the requirements, if yes, continue, if no, turn to Step 4.
Step 8. Call the deletion and merge algorithm of hidden nodes, if there is a deletion or merger, turn to Step 4, otherwise, algorithm completes.

4 BP-AHP Model Construction

Table 1 indicates that 24 factors affect the choice of entrepreneurial projects. By using all of them as the input variables, the complexity will obviously increase and we may lose the calculation precision. Fortunately, AHP could address this issue. Firstly, acquire the important evaluation indicators by AHP, and use them as input variables of the BP network. Secondly, train the improved BP algorithm. When fitting with other conventional methods, the accuracy of AHP is often not as good as the BP algorithm. Therefore, we combine these two methods organically, so as to enhance the problem solving ability of artificial neural network in the complex nonlinear problem.

4.1 Determine the Input Variables of BP Network Using AHP

Based on the analysis of the factors influencing EPS, a multi-level hierarchical structure can be established (see Table 1). Then, construct the judgment matrix and determine the weight of the index. Invite experts to conduct in-depth analysis and reach a consensus on the importance of each index, use the $9-1$ scale methods to establish the various layers of λ_{max} of each judgment matrix and its corresponding characteristic vector are obtained respectively. Finally, the feature vectors are normalized to get the comprehensive weight of each evaluation index, see Table 1, $CR = 0.016 < 0.10$, consistency test passed.

The results show that important indicators affect the choice of entrepreneurial projects are: Industry Environment (x_1), Advanced Technology (x_2), Technical Complexity (x_3), Leadership Ability (x_4), Technology Substitutability (x_5), Entrepreneurial Skills (x_6), Technical Reliability (x_7), Social Resources (x_8), Entrepreneurial Knowledge (x_9), Practical Experience (x_{10}), Market Demand (x_{11}), Market Entry Barriers (x_{12}), Fund-Raising Ability (x_{13}), Competitor Capability (x_{14}), Capital Requirement (x_{15}). The above 15 indicators have 90% or more impact on EPS; they are input variables of the BP network. Other indicators are less influential, can be deleted.

Denote $V_j (j = 1, 2, \cdots, n)$, $V = \{V_1, V_2, \cdots, V_n\}$ represents the comment set of entrepreneurial projects. V = excellent, fine, ordinary, bad $=$ $A1, A2, A3, A4 = 1, 2, 3, 4$.

In order to evaluate the entrepreneurial projects objectively, we set up a team to select evaluation indicators of entrepreneurial projects. The team members include 3 entrepreneurs, 3 venture capitalists, 3 business management experts. The experts involved in the evaluation are required to grade the indexes. Then, denote $v_k = \frac{1}{9}\sum_{i-1}^{9} vu_i$, v_k stands for the evaluation value of index, x_k,

$i (i = 1, 2, \cdots, 9)$ stands for the 9 experts. vu_1 stands for the grade given by experts, $u_1 \in [0, 1]$ stands for "poor", $u_2 \in (1, 2]$ stands for "bad", by analogy, $u_5 \in (4, 5]$ stands for "excellent".

4.2 Construction of BP-AHP Model

According to the structure of BP neural network, the BP-AHP model includes three layers:

(1) Input Layer. First of all, assign the evaluation of the index selected by the AHP method; and they are used as the input layer of the neural network variables. From what has been stated above, 15 input layer variables belong in the neural network.
(2) Hidden Layer. According to the improved learning algorithm of BP neural network proposed by TIAN Jing-wen etc. [16], set the number of hidden layer nodes as 1, then, the network will learn by itself until we get the appropriate number of nodes.
(3) Output Layer. The comments of entrepreneurial project evaluation are defined as two categories: "choose it" and "give it up", these can be represented by the output vectors $(1, 0)$, $(0, 1)$. So, the number of output layer nodes is 2.

AHP and BP neural network methods are combined to create the BP-AHP model of EPS, and the basic steps of the algorithm are as follows:

Step 1. Simplify the evaluation index of EPS, and the important index is selected as the input layer of neural network.
Step 2. Set the number of neural network output layer nodes, and initialize the network parameters (including the given learning accuracy ε, provisions iteration number M0, the limit of hidden nodes r, learning parameter η. The initial hidden node number is set to 1.)
Step 3. Input the learning samples and make the values of sample parameters $[0, 1]$.
Step 4. Give random numbers between -1 and 1 to the initial weighting matrix.
Step 5. Train the network with the modified BP method, and determine the weight matrix between each layer.
Step 6. Judge whether or not the number of iterative steps is exceeding the prescribed. If yes, end; If no, go back to step 5 and continue learning.
Step 7. Collect values of the indexes and process these data to make them $[0, 1]$.
Step 8. Input the processed data to the trained BP neural network and get the output.
Step 9. According to the output results, combined with the entrepreneurial project index reviews set, choose the right entrepreneurial projects.

5 Empirical Research

We choose 21 entrepreneurial cases from Sichuan University in the past 3 years, of which 10 projects have been successful, 11 entrepreneurial projects ended in failure. Use the BP-AHP model to evaluate entrepreneurial projects selected. The cases are: computer training (Q_1), online digital products (Q_2), development and production of management software (Q_3), computer DIY and maintenance (Q_4), website construction and service (Q_5), computer cleaning services (Q_6), water saving car washing (Q_7), reward supervision social software (Q_8), online customized travel (Q_9), advertisement designing (Q_{10}), anime 3D printing (Q_{11}), a beverage shop (Q_{12}), fruit fast delivery (Q_{13}), creative souvenirs design (Q_{14}), fast dry cleaning service (Q_{15}), household service (Q_{16}), cozy cafe (Q_{17}), creative home decoration (Q_{18}), children's art training (Q_{19}), architectural design (Q_{20}), online second hand market (Q_{21}). Q_1, Q_2, Q_3, Q_5, Q_6, Q_{10}, Q_{12}, Q_{16}, Q_{17}, Q_{19}, Q_{21} failed in the first half year; others operate smoothly. We used the first 16 entrepreneurial projects as training samples of the BP - AHP model, the last 5 items as prediction evaluation samples.

5.1 BP-AHP Neural Network Training

In the process of quantitative evaluation of the selection of venture capital projects, 9 experts were invited to set up the quantitative evaluation group of the index system. According to the evaluation index of the evaluation team, the evaluation team can be used to evaluate the evaluation index of the entrepreneurial project 1 to the venture capital project (x_k), and the evaluation value of the evaluation index x_k is obtained

$$v_k = \frac{1}{9}\sum_{i-1}^{9} vu_i.$$

The output of successful projects are $(1, 0)$, the output of failed projects are $(0, 1)$. The BP neural network architecture is built by 15-1-2 (The number of input layer nodes is 15, the number of hidden layer nodes is 1, the number of output layer nodes is 2). We initialize the network (the upper limit $\varepsilon = 0.0002$, learning rate $\eta = 0.5$, Inertia Parameter $a = 0.1$), Make $x_k(k = 1, 2, \cdots, 15) \in [0, 1]$ by dividing them with 10, and input the processed data to the BP network model. Then the network is trained by the modified BP learning algorithm and the network architecture becomes 15-9-2. At the same time, we get the optimized network weight matrix.

5.2 Entrepreneurial Project Selection

Now, it is time to evaluate Q_{17}, Q_{18}, Q_{19}, Q_{20}, and Q_{21} with the trained neural network. Give values to the indexes x_k of the 5 entrepreneurial projects, Make $x_k \in [0, 1]$ by dividing them with 10. Input the processed data to the trained

BP neural network and get the outputs as shown in the second row of Table 2. According to the principle of maximum membership degree, we can determine the evaluation results of each project; see the third row of Table 2.

Table 2. BP neural network output

Entrepreneurial projects	BP neural network output	Evaluation result	The actual operation of the business project
Q17	(0.0129, 0.9965)	Give it up	Failed
Q18	(0.9847, 0.0355)	Choose it	Succeed
Q19	(0.0287, 1.0002)	Give it up	Failed
Q20	(0.9798, 0.0032)	Choose it	Succeed
Q21	(0.0195, 0.9921)	Give it up	Failed

It can be seen from Table 2, the projects which evaluation is "Give it up" failed in actual operation; the "Choose it" ones succeed. The predictions of BP neural network completely accord with the practical ones, which indicate that, this risk early warning model feasible and effective.

6 Conclusions

EPS is a comprehensive prediction problem affected by many factors, so it is important to choose appropriate evaluation method. According to the characteristics of entrepreneurial projects, this paper analyzes the factors that affect EPS, and constructs the evaluation model of EPS based on AHP and BP neural network subjectively and objectively. This model can not only extract the main attributes of entrepreneurial projects, reduce the input variables of the neural network, but also reduce the complexity of the neural network and the training time, improve the generalization ability, reasoning ability and classification ability. Therefore, the model is feasible and effective, and it has important reference value in guiding the entrepreneur to choose the right project.

Abstract. The percentage of people using social network services (SNSs) exceeds 60% in Japan; SNSs are being used by people of various age groups. Recently, the number of companies that use Facebook Pages to advertise their activities and the number of organizations that use them to disseminate information have been increasing. In tourism, disseminating local information on Facebook Pages and increasing the attractiveness of the pages are expected to lead to the promotion of regional tourism industries. In this study, the current state of the use of tourism-related Facebook Pages was examined. The engagement rate and the number of fans were used as an indicator of the attractiveness of Facebook Pages. An increasing the attractiveness of Facebook Pages was examined through emotion analysis of user comments.

Keywords: Facebook page · Regional development · User comments · Emotion analysis

1 Introduction

Along with the spread of smartphones, the number of people using social network services (SNSs) has been increasing. The number of monthly active users of Facebook worldwide (those who use Facebook one or more times per month) reached 1.79 billion as of 30 September 2016 [1]. In addition, it is reported that the number of monthly active users of Instagram is 0.6 billion (as of 15 December 2016) [4], that of Twitter is 0.313 billion (as of 30 June 2016) [12], and that of Line is 0.2184 billion (as of 31 March 2016) [6]. According to the 2015 White Paper on Information and Communications in Japan published by the Ministry of Internal Affairs and Communications [5], the SNSs used in Japan over the last one year include Line (37.5%), Facebook (35.3%), and Twitter (31.0%). The number of people using SNSs generally tends to decrease with increasing age: approximately 50% of people aged 20 or younger, less than 40% of people in their 30's and 40's, and more than 20% of people aged 60 or older use Facebook. It is reported that Facebook is being used by people of various age groups. With this background, a variety of research projects on Facebook have been

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_53

carried out. Wilson et al. classified 412 sociology papers on Facebook into five categories: descriptive analysis of users, motivations for using Facebook, identity presentation, the role of Facebook in social interaction, and private information disclosure [13].

Recently, both the number of companies that use Facebook Pages to advertise their activities and the number of organizations that use them to disseminate information have increased. Ohara et al. clarified the characteristics of photos that increase the responses of users of Facebook Pages of fast-food companies by principal component analysis [8]. In tourism, disseminating local information on Facebook Pages and increasing the attractiveness of pages are expected to lead to the promotion of regional tourism industries. By multiple regression analysis, Sabate et al. investigated the factors that increase the attractiveness of Facebook Fan Pages (currently, Facebook Pages) of five travel agencies in Spain using the numbers of "Likes" and comments regarding each post as indices of attractiveness [9]. The results indicate that the number of "Likes" is affected by the presence of video images and photos in the post and that the number of comments is affected by the presence of photos and the time period of posting. However, the methods of using Facebook are rapidly advancing and most recent posts almost always include photos or video images.

Research on Facebook and its usefulness for those involved in the promotion of regional tourism industries is limited, although how-to books on posting on Facebook Pages [3] and marketing strategies using Facebook [10] have been published. Consequently, Sawada et al. [11] analyzed the content of tourism-related posts on Facebook Pages with high attractiveness and clarified the following. The responses of users of Facebook Pages offering information related to Christmas, flowers, and foods were high, whereas those for pages offering information on cultural events tended to be low. The responses of users of Facebook Pages offering real-time information, such as information on the start of the blooming of cherry blossoms, tended to be high. In addition, it was found that the responses of users were affected by the type of photos posted.

To increase the attractiveness of Facebook Pages, the analysis of not only the posts of organizations but also the feelings of users that cause them to post comments need to be clarified. The purpose of this study is to analyze the current state of the use of Facebook Pages in tourism in Japan and the sentiments behind the comments on Facebook Pages with high attractiveness, and to clarify the feelings of the users who posted comments and the factors behind the increase in the attractiveness of these pages.

In Sect. 2, the current state of the use of Facebook Pages offering regional tourism information is analyzed in terms of the number of fans, management, and the responses of users to find the characteristics of Facebook Pages with high attractiveness. In Sect. 3, user comments on these Facebook Pages are analyzed. In Sect. 4, the factors behind the increase in the attractiveness of pages are discussed on the basis of the results of analyzing user comments. Section 5 is the conclusion.

2 Facebook Pages in Tourism

Facebook navi (http://f-navigation.jp/) is the only navigation site in Japan recognized by Facebook, Inc. In this study, 842 Facebook Pages registered in the Facebook Page ranking in the travel category of Facebook navi were examined. The data were collected on 10 January 2016. In this section, Facebook Pages offering regional tourism information were selected and the relationship between the number of fans and organization managing the site was clarified. Then, Facebook Pages with high attractiveness were determined on the basis of the responses of users and the number of fans.

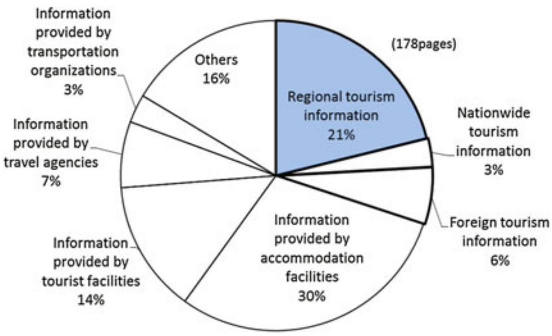

Fig. 1. Content of Facebook Pages in the travel category

2.1 Contents of Facebook Pages

The authors browsed the 842 target pages in the travel category and classified them depending on their contents. Figure 1 shows the results. Among the 842 pages, 30% of the pages are managed by accommodation facilities, 14% by tourist facilities such as aquariums and museums, 7% by travel agencies, and 3% by transportation organizations. Some of these pages offer regional tourism information such as festivals, events, and the start of the autumn foliage season. However, these pages are basically used as a public relations tool of these facilities and organizations. Other pages disseminate regional tourism information rather than advertising the activities of organizations. The management of these pages varies from companies and individuals to volunteer groups. Twenty-one percent of the pages (178 pages) focus on information about particular regions; 3% focus on information about specific topics such as one-day hot spring trips, famous places for flowers, and Buddhist statues; and 6% focus on information about foreign countries. In this study, we targeted the 178 pages focusing on information about particular regions.

2.2 Pages Offering Regional Tourism Information

(1) Number of Fans
The users clicking the "Like" button of a Facebook Page are registered as fans of the page. The postings on the page appear in the News Feed of the user, and the user can browse the various types of information on a Facebook Page on which they are registered as fans. The number of users who have clicked the "Like" button is "the number of fans". Figure 2 shows the number of fans of the 178 Facebook Pages offering regional tourism information. The number of fans of the top-ranking page exceeds 70,000. There are 19 pages with more than 10,000 fans. There are 143 pages with less than 5,000 fans, and 72 of the 143 pages with less than 1,000 fans. For most of the pages, the number of fans is limited and the number of users browsing the pages offering regional tourism information is low, suggesting that the effect of these pages on the promotion of regional tourism industries is limited.

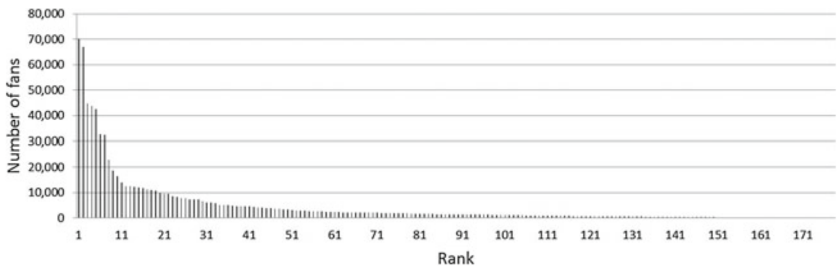

Fig. 2. Number of fans of the 178 Facebook Pages offering regional tourism information

(2) Management
Figure 3 shows the classification of the management of the 178 pages offering regional tourism information. Among the pages, 36, 24, and 9% of the Facebook Pages are managed by individuals, private companies, and local governments, respectively. Others include regional tourist associations in the form of general incorporated associations, incorporated nonprofit organizations (NPOs), and volunteer groups.

Figure 4 shows the classification of the management of Facebook Pages with more than 10,000 fans among the 178 pages. Considering all the Facebook Pages offering regional tourism information, more than 30% of the pages are managed by individuals, as shown in Fig. 3; however, only 11% (2 pages) of Facebook Pages with more than 10,000 fans are managed by individuals, as shown in Fig. 4.

An organization that manages one of the Facebook Pages with more than 40,000 fans was interviewed on 30 October 2015. The management consisted of a total of nine members including one young staff member and eight people who provide regional information. They have adopted the management rule that the frequency of posting is one or two posts per day. The interviewee said that finding

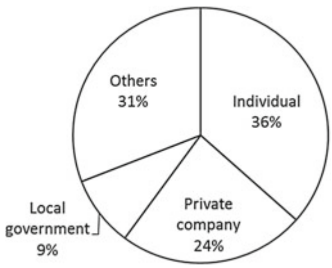

Fig. 3. Management of Facebook Pages offering regional tourism information

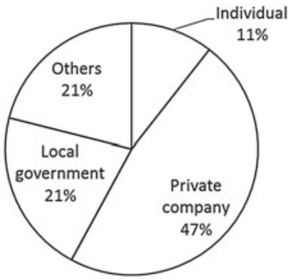

Fig. 4. Management of Facebook Pages with more than 10,000 fans

new material every day is troublesome work even though there are nine members. When a Facebook Page is managed by individuals, finding raw material and collecting information require much time and expense, leading to difficulty in posting at a high frequency.

(3) Facebook Pages with High Attractiveness
Table 1 shows a summary of 19 Facebook Pages with more than 10,000 fans. Facebook Pages for various areas from Hokkaido to Okinawa attract many fans, although 2 pages on Yokohama are also included in the list. For these 19 Facebook Pages, posts, the presence or absence of photo and video images, the presence or absence of links to other homepages, the number of "Likes" for each post, the number of "Shares" of each post, and the number of user comments were obtained between January 1 and December 31, 2015, by Graph API.

Engagement rate is an index for evaluating the attractiveness of pages on SNSs. The conventional engagement rate of Facebook Pages is given by

$$\text{Conventional engagement rate} = \begin{aligned}&(\text{Number of “Likes”} + \text{Number of}\\ &\text{comments} + \text{Number of “Shares” of}\\ &\text{the post})/\text{Number of fans.}\end{aligned} \tag{1}$$

However, conventional engagement rate defined in this way decreases as the number of fans increases [2]. Therefore, Facebook, Inc. defined a new engagement rate as

$$\text{New engagement rate} = \begin{aligned}&(\text{Number of “Likes”} + \text{Number of comments}\\ &+ \text{Number of “Shares”} + \text{Number of people who}\\ &\text{have clicked on the post})/\text{Number of reaches.}\end{aligned} \tag{2}$$

This was released in January 2015 or later but the exact date of introduction was not publicized. The new engagement rate cannot be calculated by third parties, other than the management, because the reach count and click count of the page are used in the calculation. Therefore, in this study, the conventional engagement rate calculated using Eq. (1) was used to determine the engagement rate per fan in Table 1. According to the Facebook Engagement Survey 2014 [2], the mean engagement rate of Facebook Pages with $\leq 10,000$ and $< 50,000$ fans is 1.996% and that of Facebook Pages with $\leq 50,000$ and $< 100,000$ fans is 1.499%. The mean engagement rate of Facebook Pages in the travel/leisure category is 1.56% (mean number of fans: 30,642).

The number of Facebook Pages with engagement rates of $< 1\%$, ≥ 1 and $< 2\%$, ≥ 2 and $< 3\%$, ≥ 3 and $< 4\%$, and ≥ 8 and $< 9\%$ per fan is 5, 2, 4, 7, and 1, respectively. The Facebook Page on Shirakawa-go accepts posts from users, and the number of posts is extremely high. The engagement rate per post is small, as is the engagement rate per fan.

In this study, both the engagement rate per fan and the number of fans are used as indices of attractiveness. Three Facebook Pages with an engagement rate of $\geq 3\%$ and a large number of fans, namely, the Facebook Pages of "Kyushu Tourism Information", "Akita Vision", and "Yokohama Tourism Information", were selected from Table 1 as Facebook Pages with high attractiveness to be analyzed.

3 Analysis of User Comments

In this section, the user comments on the pages with high attractiveness were classified into ten types to clarify the feelings that cause users to post comments.

3.1 Analysis Method

For the Facebook Pages of "Kyushu Tourism Information", "Akita Vision", and "Yokohama Tourism Information", user comments collected over a period of one year (2015) were analyzed to avoid seasonal bias.

First, engagement rates of all the posts for the three pages in 2015 were calculated. We read all the user comments for the posts with the top 100 engagement rates (hereafter, user comments for the top 100 posts) and the user comments for the posts with the lowest 100 engagement rates (hereafter, user comments for the lowest 100 posts) and classified the user comments in accordance with the feelings that caused users to post comments. For this classification, ten feelings in the *Dictionaryon Expression of Feeling* [7]; namely, "joy (pleasure)", "anger (unpleasantness)", "sadness (crying)", "fear (apprehension)", "shame (humiliation)", "liking (longing, nostalgia)", "disgust (loathing, regret)", "sensation (inspiring, excitement)", "ease (calm)", and "surprise (amazement)". Table 2 shows examples of user comments classified into these ten feelings. Examples 1–9 are classified as one of the ten feelings. When multiple feelings are included in one comment, as in example 10, the user comment is classified as multiple feelings. Comments including the intension of "share" in the sentence are classified as "share". The comments that do not belong to any of the ten feelings are classified as "others". Stamps without any comments are classified as "stamp".

Table 1. Facebook Pages with more than 10,000 fans

Rank	Facebook page name	Management	Number of fans	Engagements number			Engagement rate		Number of posts between Jan. 1-Dec. 31 2015
				"Likes"	"Shares"	Comments	Per post	Per fan	
1	Kyushu Tourism Information	General incorporated association	70,105	856,559	38,515	5,493	2,427	3.5%	371
2	Shirakawa-go	Private company	67,049	1,125,034	44,538	6,147	450	0.7%	2,612
3	Akita Vision	Local government	44,780	621,495	26,001	4,637	1,513	3.4%	431
4	The Heart of Osaka-Visit Osaka Japan	Local government	43,673	27,622	553	151	44	0.1%	651
5	Yokohama Tourism Information	Public interest incorporated foundation	42,655	651,163	23,136	3,370	1,433	3.4%	473
6	Yokohama China Town	Cooperative association	32,748	149,274	4,468	1,054	499	1.5%	310
7	Gooood Place!! in Shiga	Private company	32,566	236,962	7,080	1,297	1,141	3.5%	215
8	Otaru Fan	Private company	22,830	31,289	27	9	870	3.8%	36
9	Exchange of Kyoto Information -Kyoto Now-	Private company	18,592	99,287	5,473	436	408	2.2%	258
10	Hyogo Tourism Guide	Local government	16,470	18,832	529	115	81	0.5%	239
11	Okinawa Diving	Private company	13,870	1,520	18	13	111	0.8%	14
12	Okayama Great Spot Net	Public interest incorporated association	12,547	76,720	3,081	721	323	2.6%	249
13	Fukuoka No Machi	Individual	12,472	4,241	51	28	103	0.8%	42
14	I LOVE TOKUSHIMA	Individual	12,267	62,946	3,432	797	1,050	8.6%	64
15	Hokkaido Fan Magazine	Private company	12,053	179,615	10,050	1,129	305	2.5%	625
16	Let's Visit Nara	Private company	11,857	40,560	1,590	157	188	1.6%	225
17	Kamakura Block	Private company	11,275	58,557	1,301	671	348	3.1%	174
18	Web magazine [Shikoku Tairiku]	Private company	11,026	58,428	2,468	362	286	2.6%	214
19	Nagasaki Tourism Promotion Section	Local government	10,657	58,284	2,647	384	383	3.6%	160

3.2 Analysis Results

Figures 5 and 6 show the classifications of feelings underlying the user comments for the top 100 posts and those underlying the user comments for the lowest 100 posts, respectively. The total number of user comments for the top 100 posts classified as one of the feelings, "share", "stamp", or "others" is 6,924. The percentage of "liking (longing, nostalgia)" was the highest (25.9%), followed by "sensation (inspiring, excitement)" (17.9%). The total number of user comments for the lowest 100 posts classified as one of the feelings, "share", "stamp", or

Table 2. Examples of classifications of feeling of user comments

	User comment	Classification
Example 1	I will go there next week (^^). I can't wait	Joy
Example 2	It's a waste of electricity	Anger
Example 3	I can't visit to take photos because of work this year (T_T)	Sadness
Example 4	I'm worried about fainting because of the high temperature	Fear
Example 5	I love Yokohama!	Liking
Example 6	Oh, my god. I can't take holidays during silver week because of work	Disgust
Example 7	It's a beautiful night scene!!!	Sensation
Example 8	I feel relaxed. I'll enjoy the night scene when I go back to my hometown	Ease
Example 9	5000, wonderful!	Surprise
Example 10	It's really beautiful!! I'd like to visit there and ride it!	Sensation, Liking
Example 11	I will share the page	"Share"
Example 12	Can I get it in Tokyo?	"Others"

"others" is 1,200. The percentage of "liking (longing, nostalgia)" was the highest (29.8%), followed by "share" (11.3%) and "sensation" (8.2%). There are no user comments for either the top or the lowest 100 posts classified as "shame".

The numbers of the user comments for the top and lowest 100 posts in each feeling classification were compared. As shown in Table 3, we developed a 2×2 contingency table to summarize the number of user comments classified as one of the feelings and the total number of user comments classified as other feelings, "share", "stamp", and "others", to carry out Fisher's exact test. A contingency table was developed for each feeling in the test. Table 4 shows the summary of the data and results. A significant difference was observed between the user comments for the top and lowest 100 posts for six feelings, "share", "stamp", and "others". The underlines in Table 4 indicate which of the top or lowest 100 posts has a higher number of user comments than the expected value for the classification with significant difference.

3.3 Tendency of User Comments Classified as Each Feeling

The number of user comments for the top and lowest 100 posts classified as "joy" is small. Although a significant difference was observed between the two, the content of comments is an expression of gratitude, such as "thank you for the information on xxx", "I'm looking forward to attending xxx" for the announcement of an event, and "I'm looking forward to eating xxx" for seasonal food.

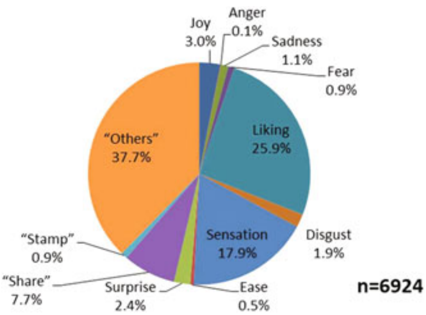

Fig. 5. Classification of feelings of user comments for the top 100 posts.

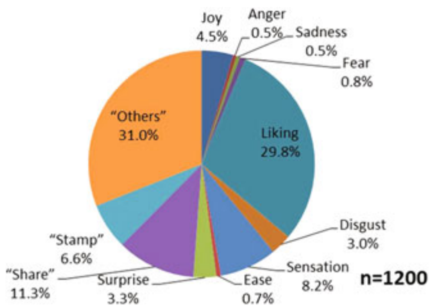

Fig. 6. Classification of feelings of user comments for the lowest 100 posts.

Table 3. Contingency table summarizing the number of particular feelings for the user comments for the top and lowest 100 posts.

	Top	Lowest
Feeling X	a	b
Feelings other than feeling X	c	d

a: The number of user comments for the top 100 posts classified as feeling X
b: The number of user comments for the lowest 100 posts classified as feeling X
c: The number of user comments for the top 100 posts classified as feeling other than X
d: The number of user comments for the lowest 100 posts classified as feeling other than X

The number of user comments for the top and lowest 100 posts classified as "anger" is small. Although a significant difference was observed between the two, there are few user comments expressing anger and unpleasantness.

The number of user comments for the lowest 100 post classified as "sadness" is small. For the top 100 posts, most of the user comments classified as "sadness" express sadness that they cannot visit a place because of work despite a desire to do so or that photos of their hometown cause a longing to return.

The number of user comments for the lowest 100 posts classified as "fear" is small. Examples of the user comments for the top 100 posts include concern regarding going to a place introduced in the post and the fear of unconventional designs and ideas in the post.

There are no user comments classified as "shame" for either the top or the lowest 100 posts.

The number of user comments classified as "liking" is the largest among the user comments for both the top and lowest 100 posts. Although a significant difference was observed between the two, the content of comments is an expression of liking, such as "I like xxx hot spring" and "I love xxx!", the expression

Table 4. Number of comments for the top and lowest 100 posts classified into each feeling category and the results of Fisher's exact test

Feeling	Top	Lowest	p value of Fisher's exact test
Joy	211	54	0.013*
Anger	5	6	0.002*
Sadness	78	6	0.045*
Fear	59	10	1.000
Liking	1793	357	0.006*
Disgust	133	36	0.021*
Sensation	1237	98	0.000*
Ease	35	8	0.515
Surprise	165	39	0.088
"Share"	533	135	0.000*
"Stamp"	62	79	0.000*
"Others"	2613	372	0.000*

Fisher's exact test: * $p < 0.05$.
The underlines indicate which of the top or lowest 100 posts has a greater number of user comments than the expected value. Also, a significant difference was observed between the user comments for the top and lowest 100 posts.

of longing, such as "I would like to visit xxx once in the future", and the feeling of nostalgia because of overlapping old memories with the post. People often express liking when they read posts related to their past experience and knowledge, such as a previously eaten food, a place they would like to visit in the future, and memories of childhood.

The user comments for the top and lowest 100 post classified as "disgust" mostly express feelings of regret, such as "I would like to go but I cannot". Only a few user comments express undesirable and unfavorable feelings.

The number of user comments for the top 100 posts classified as "sensation" tended to be large, and a significant difference was observed between users comments for the top and lowest 100 posts. Among the user comments for the top 100 posts, the number of user comments classified as "sensation" is the second most numerous after those classified as "liking". Users are moved by photos of beautiful scenes and excited by photos of delicious-looking food for both categories of posts.

The number of user comments for the top and lowest 100 posts classified as "ease" is small. Users feel relief or healed upon viewing the photos posted.

Regarding "surprise", for user comments on the top 100 posts, users are surprised at the scale and impact of photos or amazed by the beauty of photos. User comments for the lowest 100 posts express surprise because they found unexpected content in the post, such as "I never imagined that such a place existed there".

Some users making comments classified as "share" feel empathy with the post and express their intent to share the post. However, users simply click the share button (a simple comment expressing the intension as is often the case). A significant difference was observed between the user comments for the top and lowest 100 posts. The number of user comments classified as "share" is greater for the lowest 100 posts. We request that users related to the management and the fans of the Facebook Page share posts regardless of their feelings toward the contents of posts.

The number of user comments for the top and lowest 100 posts classified as "stamp" is small. A significant difference was observed between the two, and the number of user comments for the lowest 100 posts classified as "stamp" tended to be larger.

The number of user comments classified as "others" is largest for both the top and lowest 100 posts. Examples of user comments include questions, such as example 12 in Table 2, reports of past experience, such as "I have visited there" and "I ate it yesterday", and expressions of intent and plans, such as "I will visit there next" and "I will go to eat there again this year". We suggest that the comments reporting past experiences are triggered by the feeling of liking the post. The comments expressing intent and plans are possibly triggered by the feeling of sensation (users are moved or excited about the post) and the feeling of joy. However, we cannot detect the true feeling of users, and we classified user comments that do not include the direct expression of feelings as "others" in this study.

4 Discussion

In this section, directions for increasing the attractiveness of Facebook Pages for those involved in the promotion of regional tourism industries are discussed by referring to actual examples of user comments for which a large number of user comments expressed the feelings of users.

4.1 User Comments for the Top 100 Posts Classified as Liking

Example 1 is a post related to seasonal fish. Users report that the fish is delicious and describe the characteristic taste of the fish during breeding season. Example 2 is a post reporting the arrival of the season for tourist boats with kotatsu, a small table having an electric heater underneath and covered by a quilt. Comments 2-1 and 2-2 indicate that users have enjoyed this type of boat before, recommend it to others, and express their intent to experience it again. The user of comment 2-3 had experienced the boat without kotatsu and expresses a willingness to experience the boat with kotatsu this season.

Among the user comments for the top 100 posts, those classified as "liking" are the most numerous. To increase the attractiveness of Facebook Pages for tourist spots and food, it is indispensable to offer posts of famous tourist spots and food that many users like, want to visit, and experience. For well-known information (tourism resources), timely posts considering the best season to enjoy the resources will contribute to the improvement of the engagement rate through links between the information and the lifestyle and memories of users.

Example 1. Seasonal fish

- Comment 1-1 ("liking") I ate that fish. It was delicious!
- Comment 1-2 ("liking") I've eaten this fish! It had many eggs and was delicious.

Example 2. Cruise on a boat with kotatsu

- Comment 2-1 ("liking") The boat with kotatsu is only in winter and was quaint. It was really nice (^_^)/!
- Comment 2-2 ("liking") We ate steamed eel after enjoying a boat with kotatsu!! I'd like to visit again.
- Comment 2-3 ("liking") I visited there about 5 years ago because it's my husband's hometown(^o^)/. It was December, but the boat didn't have a kotatsu. I'd like to try it when I visit again(o^^o).

4.2 User Comments for the Top 100 Posts Classified as Sensation

Example 3 is a post related to the illumination of the buildings and gardens of temples and shrines of a certain region. Users posted comments 3-1 and 3-2 because they were moved by the beautiful photos, although it is not clear whether the users actually had visited the place or not. The user posting comment 3-3 was moved by the beautiful photos and posted a comment although the user had not visited the place.

The user comments classified as "liking" were mostly posted in response to objects that users already knew, whereas the user comments classified as "sensation" were posted by users who were moved or excited by the photos regardless of their previous knowledge. This finding suggests that the content and quality of the attached photos are important and that posting of photos that may induce sensation and excitement in users is effective when posting information (tourism resources) on sites that people may not be aware of.

Example 3. Illumination of buildings and gardens of temples and shrines

- Comment 3-1 ("sensation") It's really beautiful!
- Comment 3-2 ("sensation") The illumination of a temple in Fukuoka prefecture is beautiful.
- Comment 3-3 ("sensation") It's wonderful. I've been there once before, but I didn't know that it was such a beautiful and wonderful place.

4.3 User Comments for the Lowest 100 Posts Classified as Liking

Example 4 is a post related to local sweets. From comments 4-1 and 4-2, we can see that users feel nostalgia for their favorite sweets. In contrast, comments 4-3 and 4-4 indicate that the sweets are not famous; only a small number of people know about the sweets. Example 5 is a post related to a local restaurant. From the post and comments 5-1 and 5-2, it is clear that the users know the restaurant introduced in the post and agree on its attractiveness. From comments 5-3 and 5-4, it is clear that the users would like to visit the restaurant and eat the dishes described in the post.

Among the user comments for the lowest 100 posts, the number of comments classified as "liking" was the largest (357). The users who have eaten the sweets or visited the restaurant before, as shown in Examples 4 and 5, are thought to feel empathy for the posts and make comments because of a feeling of nostalgia and the memory of the food and service, although users who did not know the contents of the posts showed no interest in and did not respond to the posts. In addition, users related to the region are interested in the posts because information new to them is provided in the posts. This finding suggests that the posts about places and foods familiar to those from the region or to the local people, even though not famous, can attract a certain amount of responses from users, leading to an increase in the attractiveness of Facebook Pages.

Example 4. Local sweets

- Comment 4-1 ("liking") I love the sweets! This reminds me of the sweets made by my mother.
- Comment 4-2 ("liking") It brings back old memories(*^ ^*). I want to eat it again!
- Comment 4-3 ("others") I grew up in Akita, but don't know these sweets.
- Comment 4-4 ("others") I don't know them, either.

Example 5. Local restaurant

- Comment 5-1 ("liking") I've frequently visited this restaurant! The hamburger, rice omelet, and demiglace sauce there are delicious!
- Comment 5-2 ("liking") I loved the dishes (≥∇≤)
- Comment 5-3 ("liking") They look delicious. I want to eat them.
- Comment 5-4 ("liking") I'd like to visit this restaurant!

5 Conclusion

In this study, we carried out an analysis of the feelings expressed in user comments on Facebook Pages with many fans offering regional tourism information, and clarified the feelings of the users who posted the comments and the factors behind the increase in the attractiveness of these Facebook Pages.

Compared with websites, Facebook Pages can be easily started and have no startup costs. Therefore, the number of pages managed by individuals is large. When focusing on Facebook Pages with many fans, the percentage of Facebook Pages managed by individuals is small; the Facebook Pages managed by organizations such as regional tourist associations and companies offering regional tourism information are the mainstream. However, such pages are not always actively accessed by many visitors. The information explained in this paper may be useful for increasing the attractiveness of Facebook Pages.

The engagement rate of the Facebook Page "I Love Tokushima" (Table 1) is extremely high (8.6%). The number of posts per year is 64, which means an annual posting frequency of 1.2. According to Locowise Ltd. (the UK), the engagement rate of Facebook Pages with 1-4 posts per week is the highest. The survey by Locowise Ltd. targeted all Facebook Pages, not limited to those of the tourism industry. In future studies, we will investigate the relationship between the frequency of posting and the engagement rate of Facebook Pages on tourism to determine the optimal frequency of posting.

Acknowledgments. This study was supported by Japan Society for the Promotion of Science (JSPS) KAKENHI (Grant Number 15K00476).

Abstract. Innovation has become a popular topic in society. The creative performance fluctuates with the employees' mood caused by the working environment. Many factors have been suggested to be affecting the employees' creative performance. The paper answered the questions as "What are the factors that affect the employees' creative performance through employee behavior? What is the proportion (weight) of each of these determinants?" Furthermore, this study resolves this problem via the meta-analysis, which refers to do systematic quantitative analysis by former studies to summarize the research results of creative performance over the last ten years, and to ascertain the factors influencing the creative performance as well as to determine the correlation between them. Suggestion having been proposed including the further investigation of the interaction between the factors impacting the employees' creative performance as well as explore the corresponding effects. And it is necessary to note that changing one factor may eliminate the effect of several factors, which may cause negative change in the staff creative performance and there is joint efforts needed in terms of enhancing the employees' creative performance.

Keywords: Factors · Creative performance · Meta-analysis

1 Introduction

Creative performance refers to the products, processes, methods, and ideas created by the employees, which are novel, practical, and valuable to an organization. Although creativity varying from person to person cannot be generalized, it is not fixed. In other words, creativity is constantly fluctuating. Likewise, the creative performance fluctuates with the employees' mood caused by the working environment. What are the factors affecting the employees' creative performance? Do they have positive or negative impacts on the staff? Which of these factors has more profound influence and which has less? These issues are

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_54

considered by both business managers and numerous scholars. By surveying past scholarship on creative performance, the paper finds that there are similarities and differences between the researches. Specifically, some examine the impact of internal factors on the employees' creative performance; some explore the external factors; some investigate the employees' creative performance affected by both internal and external determinants, while others study several other influencing factors. All these researches, however, are not comprehensive. What are the factors that affect the employees' creative performance through employee behavior? What is the proportion (weight) of each of these determinants? The paper resolves this problem via the meta-analysis, hoping to summarize the research results of creative performance over the last ten years, and to ascertain the factors influencing the creative performance as well as to determine the correlation between them.

1.1 Related Concepts

Creative performance refers to the products, processes, methods and ideas created by the employees, which are novel, practical, and valuable to an organization. Work passion, a core characteristic of self-identification, refers an employee's strong love for a certain occupation, which he or she considers vital and into which this individual tends to invest time and effort.

Autonomous orientation refers to an individual's desire to act, based on his or her interests and self-values. More precisely, this individual considers incidents as opportunities and challenges, and he or she will take active actions to seize these opportunities and to shoulder the responsibilities, showing strong internal and extrinsic motivations.

Control orientation refers to an individual's desire to act, based on other individuals' attitudes rather than his or her own ideas, because he or she is vulnerable to the external environment.

Mastery approach goal orientation refers to the development process in which an individual tends to concentrate on the abilities, learning, and tasks. Performance approach goal orientation refers to an individual's emphasis of the performance-related matters.

Performance avoidance goal orientation refers to an individual's avoidance of the performance-related matters.

Cognitive re-evaluation refers to an individual's control of the emotional response through changing the impact of events on personal awareness.

Inhibition of expression refers to an individual's control of the emotional response by suppressing the emotional expression.

Feedback consistency refers to the consistency between an employee's expectation of the boss's feedback on his or her work performance and the actual feedback this individual receives.

1.2 Literature Review

(1) Overview of Foreign Researches

As early as the 20th century, the academic circle started researching on the creativity and creative performance. Analyzing the impact of leadership style and support on the employees' creative performance through empirical studies, Huang et al. [4], argued that charismatic and supportive leaders will facilitate the creative performance. Based on the investigation of the relationship between the employers and the employees, their research results provide references for the managers. The above researchers, however, do not consider the impacts of the employees' personal factors on the creative performance. Ulger [7] examined the impact of employees' participation in the creative processes and the pleasure and challenge of creative tasks on their creative performance through empirical researches. They claim that the more staff participation and the more intriguing and challenging the task, the better the creative performance will be. Moreover, the time of the staff participation process, during which multiple factors may contribute to the change of staff creativity, will determine the level of the final creative performance. Nevertheless, these scholars leave the second point for future research. Chong and Ma [1] explored the influence of the personal factors of employees, such as motivation, mood and demand, on the creative performance via empirical researches, he suggest that the motivations and demands of employees generally have positive impacts on their creative performance. Furthermore, in terms of mood, the negative emotions have an adverse effect on their creative performance and vice versa. Their researches assist readers to understand what affects the employees' creative performance from the internal perspective, but they fail to consider the external factor.

(2) Overview of Domestic Researches

Likewise, being interested in this topic, Chinese researchers conduct a host of studies. Using the empirical research, Zhang [8], Zhang et al. [9], Zhang et al. [10], Tang et al. [6], examine the impacts of organizational environment (for instance, working time and pressure, organizational situation, and leadership) on the employees' creative performance. They conclude that the staff creativity is positively correlated with the working time and pressure as well as leadership styles; the influence of organizational situations varies from person to person. Song [5], Zhang et al. [9], Dong et al. [2], analyzing the impacts of the employees' emotions on their creative performance, concur that the negative emotions have adverse impacts on creative performance, and vice versa. Due to other factors in these studies, their research data differ moderately. Similar to foreign scholars, the above researchers only investigate one aspect that affects the staff creativity. Gong et al. [3], exploring the influence of employees' motivations on their creative performance via the empirical research and scenario analysis, ascertain that the creative performance is inhibited by the workers' extrinsic motivations and control motivations but promoted by the employees' other motives. Their final results differ because of various classifications of the motivations.

Overall, Chinese and foreign scholars have investigated numerous factors affecting the creative performance, and their conclusions, which differ slightly in each essay, are roughly the same. In terms of research methods, these papers, however, principally adopt empirical research and scenario simulation. As for the investigations of the influencing factors, they largely highlight one of them. Based on the literature above, this paper utilizes a different approach– the meta-analysis, seeking to examine the factors that impact the employees' creative performance holistically.

1.3 Introduction to the Meta-analysis

(1) Definition and Characteristics of the Meta-analysis

The Meta-analysis is widely used in disciplines, such as medicine, psychology, economics, and management. In these fields, numerous scholars, for the most part, study the same problem, but the final results may be different due to the process control, error, and sample selections. Therefore, they fail to reach a clear conclusion. It is of necessity and significance to analyze the results achieved by other scholars through the Meta-analysis.

Meta-analysis was first proposed by American scholar Glass when he gave a speech at the American Educational Research Association in 1976. According to Glass, meta-analysis refers to a statistical analysis that combines the results of multiple individual studied to resolve uncertainty when reports disagree.

Nonetheless, there is no unified definition of the Meta-analysis. This paper adopts the definition from the book titled Conducting Meta-Analysis through Stata: Meta-analysis is a statistical approach that examines the results of the individual studies of the same topic, analyzing the similarities and the sources of difference between these research outcomes. Meta-analysis and systematic evaluation are different concepts, even though there are similarities between them. Systematic evaluation refers to a rigorous evaluation and review of an issue via a certain search strategy, in the process of which the Meta-analysis may or may not be used.

There are some salient features (advantages) of the Meta-analysis, compared with the individual study: (i) to improve the statistical efficacy; (ii) to evaluate the results quantitatively and comprehensively, resolving uncertainty when reports disagree; (iii) to evaluate the hypothesis, discovering the deficiencies of the previous researches; (iv) to analyze numerous literature data simultaneously, without being affected by the number of references; (v) Using the individual research results as the original data, Meta-analysis is a higher level of logical analysis.

(2) Advantages and Disadvantages of the Meta-analysis

Each research method has its advantages and limitations, and the paper presents a brief introduction to the merits and demerits of the Meta-analysis.

The Meta-analysis is used extensively because of four advantages. First, the Meta-analysis is more accurate than the significance test in terms of the estimation and reliability analysis of the effect values. Second, the scholars may discover the shortcomings of the individual researches via the Meta-analysis, thereby avoiding the flaws. Third, the results of individual studies are aggregated through the Meta-analysis; hence, more objective explanations are conducted, and more reliable and accurate conclusions are researched. Fourth, new research directions and suggestions will be put forward after the Meta-analysis, which will provide references for further researches.

Nevertheless, like other methods, there are some flaws in the Meta-analysis. First, it takes a long period of time to conduct the Meta-analysis, due to its requirement for a large amount of literature. Thus, the workload is heavy. Second, it is difficult to find all the literature on a particular issue; hence, researchers cannot conduct a comprehensive statistical analysis. Last, it is difficult to ensure that the thinking and structure of the existing studies are consistent, that the qualities of these essays are high, and that the data is complete. Therefore, not all the documents are useful, and the amount of the literature may vary significantly among different research groups.

2 Research Method

2.1 Literature Retrieval

Although creative performance is a relatively new topic, scholars at home and around the world have conducted numerous researches. The paper firstly utilizes the keyword retrieval, the main method of literature retrieval, to search articles on the creative performance, employee behavior, and the factors affecting the employees' creative performance. Secondly, according to the references of the retrieved essays, the paper searches the related documents in each database, including the doctoral dissertations and journal articles published after 2010. The literature retrieval is conducted at the library of Sichuan University. Both Chinese databases (such as the CNKI, Wan) and foreign databases (for instance, Science-Direct, and Springer Link) are used in this research paper. Manual search is not required, since electronic magazines are available in the information age, and the databases above provide all the materials needed in this study.

2.2 Inclusion and Exclusion Criteria for Literature

(1) Literature Inclusion Criteria

First, the literature should be published or unpublished between 2000 to 2015.

Second, the literature should be associated with creative performance.

Third, the data should be relatively complete, including the values of correlation coefficients, such as T, F, and P. The articles may not contain all these data, but they should provide sufficient figures that are needed in this research.

Fourth, the research object should be explicit, describing the sample size, age, and gender.

Fifth, the factors for creative performance should be quantitatively determined.

Sixth, the questions listed in the scales should be expressed clearly.

Table 1. An overview of the selected literature

Number	Author	Year	Influencing factor	Research object	Effective sample size
1	Zhang Jian et al.	2013	The employees' emotions, orientations, etc.	Employees	222
2	Zhang Jian et al.	2013	Time pressure, creative personality, etc.	Freshmen	60
3	Dong Li et al.	2012	The employees' emotions, orientations, etc.	Freshmen	273
4	Zhang Jian et al.	2010	Independent motivation, control motivation, etc.	Employees	150
5	Tang ChaoYing et al.	2012	Leadership style, team recognition, etc.	Researchers	209
6	Song Yahui et al.	2015	Passion for work	Employees	162
7	Gong Zhenxing et al.	2015	Feedback, goal and personality, etc.	Employees	159
8	Wang Haocheng et al.	2013	Time pressure	College students	300
9	Li Xiulin et al.	2012	The employees' emotions	College students	91
10	Zhang Jian	2003	Working environment, motivation, needs, etc.	Employees, graduates	459
11	Gu Rui et al.	2015	Leadership style, etc.	Health care workers	101
12	Pamela Tierney	2004	The employees' creativity, leadership support, working experience, job complexity, etc.	Managers	12
13	Bartol Kathryn	2010	Participation in the creative process, etc.	Employees	86
14	Kwok Leung	2014	Work motivation, etc.	Employees	112
15	Yu-Shan Chan	2015	Environmental factors	College students	160
16	Kani Ulge	2016	Creative thinking, etc.	College students	216
17	Dong gun An	2016	The employees' motivations and personality, etc.	College students	143
18	Jin Nam Choi	2004	Personal factors, organizational environment, etc.	College students	430
19	Jan Kratzer	2004	Team communication, team recognition, etc.	Employees	243
20	Eric Chong	2010	Individual factors, supervision, and working environment, etc.	Employees	350
21	Wasilu Suleiman	2013	Working attitude, etc.	Employees	70
22	L. Olsson, S	2012	The quantity of managers, leadership style, etc.	Managers, employees	137

(2) Literature Exclusion Criteria

First, the articles largely about the literature review of this topic should be excluded.

Second, repeated reports should be excluded.

Third, the literature without relevant correlation coefficients or data should be excluded.

Fourth, the literature without explicit scale measurement questions should be excluded, since these articles cannot appropriately describe the research objects.

(3) An Overview of the Selected Literature

In the initial screening process of the Meta-analysis by using Stata, all literature adopts an empirical research with available data. According to different dependent variables, the selected articles are grouped into six categories: the employees' emotions (3 articles), time pressure (2 articles), creative personality (4 articles), work motivation (6 articles), leadership and teamwork (6 articles), and feedback consistency (2 articles). This paper examines which factor affects the employees' creative performance; hence, there is no causal relationship between these documents. In other words, the data in each article should be considered separately. After the searching and screening process, the selected articles are shown in Table 1: Considering the large data used in the Meta analysis via Stata (a software), it is inconvenient to list all of them in the table above. In the calculation process, however, the paper, according to a calculation method named the overall effect size, will select the complete and appropriate data from these research articles as the study data.

3 Research Results

3.1 Description of the Research Data

(1) Overall Effect Value

First of all, according to the above-mentioned method, the paper calculates and sorts the data extracted from the selected research articles. This study contains a total of nine research articles, each of which contain multiple influencing factors. Hence, a total of 25 effect values are obtained. Next, the paper presents a description of the selected research articles and effect values.

The selected articles with various effect values are divided into different types according to the reference sources. Table 2 illustrates the type and quantity of the research articles containing different effect values.

In Table 2, the "Journal" shows the effect value extracted from the journal articles, the largest proportion of which is 80%. "Thesis" indicates the effect value extracted from the doctoral dissertations and master's theses, which is 8%. The effect value extracted from the research reports is 12%. Figure 1 clearly illustrates these data.

Second, the paper calculates all effect values listed in the literature. This study mainly considers the factors that affect the creative performance of employees; therefore, all the determinants with data integrity mentioned in the

Table 2. The quantity of effect values from different article types

	Frequency	Percentage	Effective percentage
Journal	20	80%	80%
Thesis	2	8%	8%
Research report	3	12%	12%
Total	25	100%	100%

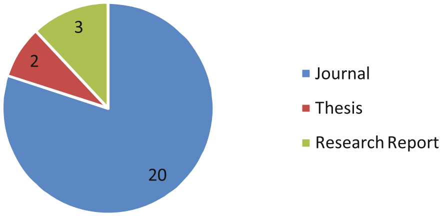

Fig. 1. Distribution of the quantity of effect values from different article types

selected documents are included in the table, even though they may influence each other. The specific data are shown in Table 3.

The distribution of the value of R and Z is clearly illustrated in Fig. 2, a line graph. In terms of the value of R, the average is 0.35; the standard deviation is 0.201; the maximum value is 0.71; the minimum value is -0.058; and the skewness is -0.219, which demonstrates negative skewness. As for the value of Z, the average is 0.62; the standard deviation is 0.410; the maximum value is 1.506; the minimum value is -0.086; and the skewness is 0.421, indicating positive skewness (See Table 4). Eventually, the paper, calculates the overall effect value of all literature, which is 0.551, generally indicating the positive correlation between the variables of the selected research articles and the employees' creative performance.

3.2 Homogeneity Test

The methods for homogeneity test include Q test, H test, chi-square test, forest plot. Using the Q test, the paper first calculates the Q value through the following equations:

$$Q = \sum\nolimits_{i=0}^{k} wi(ri - R)^2, \tag{1}$$

$$R = \sum wiri / \sum wi, \tag{2}$$

where k represents the number of the effect values of the selected literature; r is the effect value; and w denotes the proportion of the effect value. The calculated values of R and Q are 0.313575684 and 0.040220883, respectively.

Table 3. Related data for the selected literature

Number	Factor	R value	Z value	Sample size
1	Positive mood	0.228	0.301	495
2	Negative mood	0.054	0.082	495
3	Autonomous orientation	0.182	0.284	495
4	Control orientation	0.193	0.303	222
5	Features of time and pressure	0.33	0.543	60
6	Psychological satisfaction	0.419	0.718	60
7	Executive support	0.266	0.427	150
8	Need for autonomy	0.172	0.268	150
9	Capability requirement	0.243	0.387	150
10	Relationship requirement	0.277	0.447	150
11	Internal motivation	0.477	0.843	150
12	Motivation for identification	0.442	0.766	150
13	External motivation	−0.058	−0.086	150
14	Control motivation	−0.04	−0.06	150
15	Working motivation	0.395	0.669	150
16	Team performance	0.71	1.506	209
17	Team identity	0.509	0.917	209
18	Charismatic leadership	0.449	0.781	209
19	Concentration	0.585	1.11	162
20	Mastery approach goal orientation	0.485	0.861	162
21	Performance approach goal orientation	0.548	1.013	162
22	Performance avoidance goal orientation	0.348	0.577	162
23	Cognitive reevaluation	0.707	1.495	162
24	Inhibition of expression	0.431	0.743	162
25	Feedback consistency	0.33	0.543	159

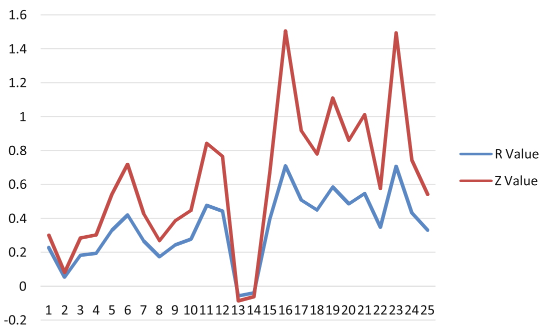

Fig. 2. Distribution of related data for the selected literature

Table 4. Description of statistical data of the selected literature

	N	Min	Max	Mean	Standard deviation	Skewness		Kurtosis	
							Standard error		Standard error
R value	25	0	1	0.35	0.201	−0.219	0.464	−0.158	0.902
Z value	25	0	2	0.62	0.41	0.421	0.464	0.184	0.902
Valid N (list state)	25								

The Meta results in Table 3 show that the 25 effect values are homogeneous. The Q test follows the chi-square distribution with a degree of freedom $K - 1$; hence, when the value of K is 25, the chi-squared value is 28.241 at a significance level of 0.05. In other words, if $Q = 0.040220883 < X^2_{0.02524} = 28.241$, then the selected research articles are homogeneous.

3.3 Bias Test

Bias test is considered essential in the meta-analysis. The publication bias refers to the different opportunities for publication and corresponding impacts on the results caused by the researchers, evaluators, editors' preferences of the direction and intensity of the research in the submission, acceptance, and publication process of an article. According to the book Conducting Meta-Analysis through Stata, there are multiple approaches to testing the publication bias, such as the funnel plot, Egger linear regression method, and Begg rank correlation method.

This paper uses the funnel plot, which is the most commonly used visualized method for a qualitative measurement of publication bias, first proposed by Light et al., in 1984. Figure 3 shows the funnel plot derived from the Meta-analysis of Table 3.

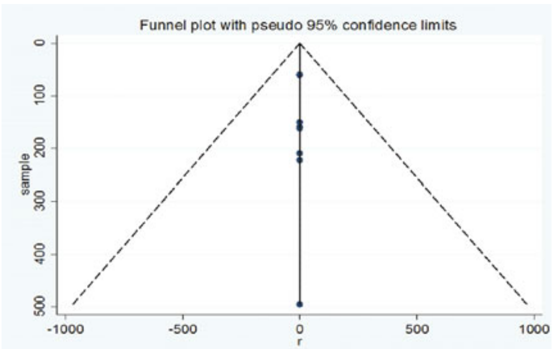

Fig. 3. The effect value of the selected literature

According to Fig. 3, there is no publication bias among the articles and theses used in this study, since the funnel plot is relatively symmetric.

4 Conclusions and Suggestions

It can be seen from overall effect values in Table 3 that when wholly considering the influencing factors (positive mood, negative mood, autonomous orientation, control orientation, time pressure, psychological satisfaction, supervisor support, autonomous need, relationship motive, internal motivation, external motivation, control motivation, working motivation, team performance, team identity, charismatic leadership, concentration, mastery approach goal orientation, performance approach goal orientation, performance avoidance goal orientation, cognitive reevaluation, inhibition of expression, feedback consistency), they are positively correlated to the employees' creative performance ($R = 0.551$). To enhance the creative performance, the managers may improve the employees' intrinsic motivation through incentive policies or through the executives' encouragement and support. Every employee, for the most part, will be affected by these factors; hence, this study, to some extent, may serve as a reference for the scholars or managers. Nevertheless, due to the possible interaction between these factors, their relationship with the employees' creative performance may be weak and accurate, which is the limitation of this paper. The author hopes that the future scholars of this field may clearly analyze this interaction.

We proposed suggestion as following: First, the future researchers may investigate the interaction between the factors impacting the employees' creative performance as well as explore the corresponding effects. The reason is because adjusting or changing one of the factors may indirectly influence other determinants, which contributes to a great change in the creative performance of the employees. Meanwhile, changing one factor may eliminate the effect of several factors, which may cause negative change in the staff creative performance. Second, the future researchers may examine the proportion of the effect of the individual factor on the creative performance. It assists managers to prioritize incentives so that the enterprise may maximize the profits at the lowest cost. Overall, joint efforts are needed in terms of enhancing the employees' creative performance.

The Impact of Mixed Ownership Reform on Enterprise Performance–An Empirical Study Based on A-Share Listing Corporation in China

Sheng Ma(✉), Wenjie Li, and Sicheng Yan

Institute of Economics and Management,
Chengdu College, Chengdu, People's Republic of China
478767236@qq.com

Abstract. This paper, with data of 486 listed companies from 2003 to 2014 over the time span of 12 years, finds that the proportion of non state-owned shares in the Fixed-Effect Model is negatively correlated with the profitability of the company, and it is positively correlated with the company's development capacity; The proportion of circulating stocks has a significant positive impact on the corporate debt solvency and development ability; The proportion of the largest shareholder's shareholding and the proportion of the top ten shareholders are significantly correlated with the total asset growth rate, while separation rate of two rights and total asset growth rate are negatively correlated. Moreover, by using the Difference-in-Difference Model to test the reform policies, the regression results find that the restructuring has a significantly positive impact on corporate profitability and development capacity. The consistency of two methods confirms that the mixed ownership reform policy has a positive role in promoting the profitability, debt solvency and development capability of state-owned listed companies.

Keywords: Mixed ownership reform · Non state-owned shares · Enterprise performance

1 Introduction

The core reforms of state-owned enterprise (SOE) on the three levels are mainly: state-owned assets supervision, state-owned enterprise equity, state-owned enterprise operation. Among the three, SOE equity is the core of state-owned enterprise restructuring. The main core of SOE equity is to actively develop a mixed ownership economy, allowing more state-owned economy and other ownership economy to develop a mixed ownership economy, allowing mixed ownership economy to implement employee holdings, and finally the formation of co-ownership of capital and labor Therefore, the exploration of the relationship between the different ownership structure of various property nature and the performance of enterprises in the first restructuring process and the "second revision" is a

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_55

great guidance for the reform of SOE, and is conducive to a comprehensive understanding of the impact of restructuring on corporate performance.

In theory, the restructuring of SOE will improve the ownership structure of listed companies, improve the governance structure of listed companies, and then is conducive to improving the performance of SOE. This paper attempts to explore the impact of mixed ownership reform on corporate performance and analyze the policy implications of restructuring policy-making in the state-owned enterprises and non-state-owned enterprises, and, through theoretical and empirical analysis, tries to have some reference value to the participants and researchers of SOE reform.

2 Literature Review

2.1 Summary of Relevant Literature Abroad

Researches of foreign scholars on corporate restructuring in the background of the privatization began in the 1980s, and later expanded to a number of countries, including the restructuring of China's SOE [3,5,6]. Djankov and Murrell use the regression method of econometrics to make an empirical research on the enterprises in the transition economy and carry on the detailed model analysis [2]. Megginson and Nash studied the political, public institutions and economic factors in the state-owned enterprises privatization by shares issuance and sale on the public capital markets, conducted a comprehensive discussion of private ownership and supported the view that national policy and legal environment impact financial decisions [9]. Many foreign scholars have make related researches on the economic policy of corporate governance, such as Pagano and Volpin [10].

2.2 Summary of Relevant Literature in China

Since reform and opening up, China has been experiencing a slow process of economic transition. From the mid and late 1990s, due to the establishment of the modern enterprise system emphasized by the Third Plenary Session of the 14th CPC, the inefficiency of SOE drew the attention of the majority of Chinese scholars to the researches on the efficiency of SOE. Yao [15] based on the data analysis of the third industrial census, concluded that the rise of non-state economic components may promote the overall level of China's industrial improvement. Liu using the 1995 national industrial census data, found that among the variety of ownership enterprises, SOE has the lowest efficiency [7]. Liu and Li used [8] the data from 451 competitive enterprises (1994–1999) to make an empirical research and obtain the negative impact of state ownership on corporate performance, and conclude that non-state capital is positively correlated with firm performance. During this period, many scholars have studied the impact of ownership changes on corporate performance [4,13]. Song Ligang, Yao [12] also found a clear time trend, the effect of restructuring is most stable for those enterprises with a moderate length of restructuring history and for the enterprises that implemented restructuring between 1997 and 1999. Bai and Tao [1] used the panel data of the national industrial enterprises from 1998 to 2003 to analyze the economic and social benefits of the SOE restructuring, and concluded that the economic benefits of the state-controlled enterprises are better while the social benefits of the non-state-owned enterprises are better, and that the restructuring effect will continue for some time. Yang et al. [14] found that although the number of employees decreased after the restructuring of collective enterprises, the wage benefits per capita and taxation increased significantly, indicating that in general the restructuring of collective enterprises had a positive effect on social welfare. Sheng [11] used the multiplier method based on the tendency scoring matching to analyze the micro-data of Chinese industrial enterprises from 1999 to 2007, and concludes that the marketization and the introduction of competition mechanism makes the reform of SOE play a role in promoting social welfare. In the ongoing process of enterprise restructuring, some scholars use the Double-differential Model to compare the effects of the restructuring policy. Li and Qiao adopted the Double-differential Model for China's industrial data from 1999 to 2006, and found that the economic performance of state-owned enterprises improved significantly in 2003, and that the overall economic performance of SOE improved. Chen and Tang based on the national industrial data from 1999 to 2007, study the social burden and the policy burden on the enterprises with the Double-differential Model, and find that the mixed ownership reform can reduce the policy burden of SOR, and that the reform efficiency of monopoly mixed ownership is higher than that of the competitive industry.

3 An Empirical Study on Enterprise Performance by Mixed Ownership Reform

3.1 Data Sources

This paper uses the 486 listed companies listed in China's A-share market from 2003 to 2014, including all the industry classification of the SFC in 2014, with a total of 5832 effective observations, and set the dummy variable for the industry and the three economic zones. According to the "State Council's work report on the state-owned enterprise reform and development" published in 2012, more than 90% of the state-owned enterprises have completed the shareholding reform.

3.2 Definitions of Variables

(1) Corporate Performance Indicators

We use the company's financial indicators to measure the corporate performance indicators. ① Profitability is replaced by ROA of total assets. The return of the total assets(ROA) is the ratio of the net profit to the total assets of the enterprise over a certain period of time. The higher the value of ROA, the higher the profitability of the enterprise. ② Debt solvency is measured by the

Debt Asset ratio (DAR), which is the percentage of total liabilities at the end of the period divided by the total amount of assets. It is an important measure of the level of corporate liabilities and the degree of risk. ③ The growth capacity is measured by the sustainable growth rate (SGR) and the total asset growth rate (TAGR). The SGR is the highest growth rate that can be achieved by the non-issuance of new shares and maintaining the current operating efficiency and financial policy. So, this indicator represents a suitable pace of development The growth rate of the total assets is the ratio of the total assets increase of the year to its total assets at the beginning of the year, so it reflects the growth of the assets. The growth of the assets is an important aspect of the development of the enterprises. Enterprises of high growth rate can maintain the steady growth of assets.

(2) Explain the Variables

① Mixed ownership restructuring index: the proportion of non-state-owned shares (nonNSOS). Because the GTA CSMAR database contain the capital structure of all the listed companies including the total number of shares and the number of state-owned shares, so the proportion of non-state shares can be calculated.

② The proportion of circulating capital shares (LTBL): the ratio of the circulating shares to the total shares of the company. The greater the proportion of circulating shares, the more the stock reflects the true value of the company.

③ Proportion of sponsor shares (POP) is the ratio of the total number of sponsor shares to the total capital shares of the company. The sponsor shares refer to the special shares offered by the listed company to the founder(s) of the company.

④ The proportion of the largest shareholder holdings (POFLS): the ratio of the number of shares held by the largest shareholder to the total number of shares.

⑤ The proportion of the top ten shareholders holding (POTTS): the ratio of the number of shares held by the top ten shareholders to the total number of shares.

⑥ The separation rate of two rights (SRTR): the difference between the control of the actual controller of the listed company and his or her ownership.

We use the Herfindahl index to measure the concentration of the industrial market. The higher the Herfindahl index, the higher the degree of market concentration, and the higher the degree of monopoly. Other explanatory variables include total assets, total liabilities, paid-in capital, gross operating income, total operating costs, equity multiplier, equity ratio, flow ratio, quick ratio, total number of shareholders, and income tax.

As the listed companies that we have selected basically involve in the SFC industry classification of 2014, and these listed companies registered in the three major economic zones of the eastern and central regions. Therefore, for the study of the industry, several major industry categories are focused on, such as (1) electricity, heat, gas and water production and supply, (2) manufacturing, (3) real estate and (4) wholesale and retail. For the study of the regions, the three major economic zones in the eastern, central and western regions, two dummy variables are set as (East) for the East region and (West) for the West region. Of the 486 listed companies selected, 268 are located in the eastern region, 114 are in the central region and 106 are in the western region.

3.3 Design of the Measurement Model and Empirical Results

(1) The Impact of Restructuring on Corporate Performance of Listed Companies C An Analysis of Fixed-effect Model.

First of all, in order to study the impact of restructuring on the performance of listed companies, that is, the changes of the proportion of non-state equity in the overall equity changes, we need to control other factors that affect the performance. Both observable and unobservable factors can affect the corporate performance, so the observable factors are added to the regression model; for the unobservable factors that are not observable but will not vary over time, we can use the Fixed-Effect Model for their estimation, so the Fixed-effect Model is constructed as follows:

$$Y_{it} = \alpha + \beta_1 \text{nonNSOS}_{it} + \beta_i i = 26 X_{it} + \gamma_{it} \text{control}_{it} + \varepsilon_{it}. \tag{1}$$

Y_{it} is the performance index of the listed company i in the year t, LTBL_{it} is the proportion of circulating capital shares of the company i in the year t, and $\sum_{i=2}^{6} X_{it}$ are other important explanatory variables. The five explanatory variables are explained as follow: LTBL_{it} is the proportion of circulating capital shares of the company i in the year t, POP_{it} is the ratio of the total number of sponsor shares to the total capital shares of the company i in the year t, POFLS_{it} is the ratio of the number of shares held by the largest shareholder to the total number of shares of the company i in the year t, POTTS_{it} is the ratio of the number of shares held by the top ten shareholders to the total number of shares of the company i in the year t, and SRTR_{it} is the separation rate of two rights the company i in the year t. $\sum \text{control}_{it}$ is the other control variables used to improve the accuracy of the study. ε it is a random perturbation term and α, β_1, β_2, β_3, β_4, β_5, β_6 are the coefficients to be estimated. The results of model 1 are listed in Table 1.

From Table 1 on the results of restructuring effects, we find that: with the non-state-owned shares increasing, the profitability declines, sustainable growth rate decreases, but the total asset growth rate increases significantly. The proportion of circulating shares has a positive impact on the total assets growth rate and Debt Asset ratio. The proportion of circulating shares is correlated to the total asset growth rate at the significance level of 1%, and the proportion of circulating shares is correlated to Debt Asset ratio at the significance level of 5%.

(2) An Analysis of the Effectiveness of Mixed Ownership Reform Policy on Corporate Performance of Listed Companies C a Difference-In-Difference Model Analysis.

In order to further effectively separate the impact of mixed ownership reform on the performance of listed companies, the Difference-In-Difference can effectively overcome the selective deviation of the sample in the regression process.

Table 1. Impact of restructuring on corporate performance of listed companies (Fixed-effect Regression).

	Profitability Return of the total assets (ROA)	Debt solvency debt asset ratio (DAR)	Development capacity Sustainable growth rate (SGR)	Total asset growth rate (TAGR)

Note: The values in parentheses are the standard deviation. The superscripts ***, ** and * indicate that the estimated coefficients are significant at the 1%, 5% and 10% levels respectively.

Measuring and comparing the impact of restructuring policies on listed companies requires a more definite restructuring time point. From the micro level, we, in the process of handling the enterprise sample data, have recognized that China's restructuring process is a gradual reform, will always go through a number of steps or stages in order to achieve the final restructuring goals So the restructuring time point remains difficult to define from the micro level. At the macro level, the reform of state-owned enterprises has gone through five stages The emphasis on deepening the reform and on the development of mixed ownership economy began in the fourth stage with the "Decisions of the CPC Central Committee on Several Issues Concerning the Improvement of the Socialist Market Economic System" reviewed and approved by the Third Plenary Session of the 16th CPC Central Committee. Then the State Council SASAC has put forward two notices: "General Office of the State Council forwarded the SASAC Notice on Regulating the Reform of State-owned Enterprises" and "Opinions on Further Standardizing the Reform of State-owned Enterprises". Most of the equity nature changes of the listed companies from the CSMAR database occurred around 2006, and the number of publications on the restructuring of China's state-owned enterprises at the China National Knowledge Infrastructure (CNKI) reached its peak point in 2006. So in our literature the restructuring time point is roughly determined on this basis. Since the targets of SOE reform process are state-owned enterprises, and non-state enterprises are not involved in, so Difference-In-Difference model can be built. The specific procedures are as follow:

The data sample is divided into two groups: one is the state-owned enterprises labeled as $D1_i = 1$ (known as the test group, i.e., enterprise i is a state-owned enterprise), and the other group is non-state-owned enterprises (including private and foreign capital) labeled as $D1_i = 0$ (Known as the control group, i.e., enterprise i is a non-state-owned enterprise). Therefore, in the implementation of SOE restructuring policy, it is clear that only the SOE as the test group are affected, so the impact of restructuring policy on SOE can be expressed as E $(Y|D1_i = 1)$, and the impact of restructuring policy on non-state-owned enterprises can be expressed as $\mathrm{E}(Y|D1_i = 0)$. So we can express the net effect of restructuring policy on the performance of SOE as:

$$E(Y|D1_i = 1) - E(Y|D1_i = 0). \tag{2}$$

In order to explore the dynamic impact of the restructuring process, we carry out the time difference on this basis. Because the restructuring policy at different times will have differences, the test group and the control group will change with the policy time. One period labeled as $D2_i = 1$ is after the implementation of the restructuring policy, the other period labeled as $D2_i = 0$ is before the implementation of the restructuring policy. Therefore, we must also compare the performance changes before and after the restructuring policy, in which the performance impact after the implementation of restructuring policy can be expressed as $E(Y|D2_i = 1)$, and the performance impact before the implementation of restructuring policy can be expressed as $E(Y|D2_i = 0)$, so we can get the impact of restructuring policy at the time level:

$$E(Y|D2_i = 1) - E(Y|D2_i = 0). \tag{3}$$

So in order to measure the policy impact changes of the test group and the control group at the same time level, we can make the following adjustment to get the difference caused by restructuring policies:

Table 2. An analysis of the effect of mixed ownership reform policy on the performance of listed companies (difference-in-difference model regression).

	Profitability	Debt solvency	Development capacity	Total asset growth rate (TAGR)
	Return of the total assets (ROA)	Debt Asset ratio (DAR)	Sustainable growth rate (SGR)

POFLS	−0.00029	0.000958	0.00697	0.00337***
Proportion of largest shareholder holdings	(0.000513)	(0.00113)	(0.00889)	(0.00119)
POTTS	0.000712	0.00313**	0.00499	0.00395***
Proportion of top ten shareholders holding	(0.000572)	(0.00127)	(0.00992)	(0.00133)
SRTR	−0.000392	−0.00223	−0.0056	−0.0043***
The separation rate of two rights	(0.000681)	(0.00151)	(0.0118)	(0.00158)
h	−0.0281	−0.295**	−0.5	−0.286*
The Herfindahl index	(0.0656)	(0.145)	(1.139)	(0.153)
Constant	−0.0407	0.727**	−0.864	−1.215***
	(0.167)	(0.369)	(2.889)	(0.388)
Observations	4,111	4,111	4,110	4,107
R-squared goodness of fit	0.7013	0.3809	0.0339	0.1518

Note: The values in parentheses are the standard deviation. The superscripts ***, ** and * indicate that the estimated coefficients are significant at the 1%, 5% and 10% levels respectively.

$$\{E(Y|D1_i = 1) - E(Y|D1_i = 0)\} - \{E(Y|D2_i = 1) - E(Y|D2_i = 0)\}. \quad (4)$$

The net effect of this restructuring policy not only measures the impact of the policy before and after its implementation, but also measures the policy differences between the test group and control group. So we have this regression model of Difference-In-Difference (Model 2):

$$Y_{it} = \alpha + \beta_1 D1_i + \beta_2 D2_i + \beta_3 D3_i + \beta_i i = 49X_{it} + \gamma_{it}\text{control}_{it} + \varepsilon_{it}. \quad (5)$$

Y_{it} is the performance index of the listed company i in the year t, and $D1_i$ is the dummy variable between groups, where $D1_i = 1$ is the test group, $D2_i$ is the time dummy variable; and $D3_i$ is the interactive item. $D3_i = D1_i \times D2_i$; β_3 is the Difference-in-Difference statistics, that is, the differences brought about by policy. Since other variables in Model Two are derived from the Model One, so the definition and interpretation of these variables in Model Two are not repeated here. For brevity we only list the regression results of several variables that related to the proportion of non-state equity, and the results and discussion of other variables are omitted. The results of Model (2) are shown in Table 2:

Table 2 shows the regression results for Model (2). The regression results between the companies that implement mixed ownership reforms and those that do not implement mixed ownership reforms show that difference-in-difference statistics for the Interactive item D3 is very significant for the total net profit margin, and is relatively significant for the total assets growth rate. In addition, the difference-in-difference statistics β_3 coefficient is significantly positive, indicating that compared to the enterprise without reform, the enterprise with reforms have greatly improved their profitability and development capability. The effect of the mixed ownership restructuring policy is not significant to the difference-in-difference statistics β_3 coefficient in the regression of the debt solvency, which indicates that the effect of the mixed ownership reform policy is not reflected. From Table 2, we can also see that with the increase in the proportion of non-state-owned shares, the decline in profitability and sustainable growth rate is relatively alleviated compared with the results in Table 1, indicating that the restructuring policy has played a role in improving the profitability of enterprises.

4 Conclusions and Suggestions

The empirical conclusion is as follows:

(1) With the increase in the proportion of non-state-owned shares, the total asset net profit margin decreases, and the sustainable growth rate decreases, but the total assets growth rate increases significantly; the proportion of circulating shares has a positive impact on the total assets growth rate and Debt Asset ratio; Both the proportion of the largest shareholders holding and the proportion of the top ten shareholders holding are positively correlated with the total asset growth rate, while the separation rate of two rights is negatively correlated with the total assets growth rate. The vertical comparison indicates that the increase

in the proportion of non-state equity can improve the development capacity of enterprises, increase its debt solvency and reduce its profitability.

(2) The policy effect of Mixed ownership reform: Compared with enterprises that have not been reformed, the enterprises that are reformed have a greater improvement in profitability and development capability. The policy effect of mixed ownership reform is not reflected in the debt solvency the results of other explanatory variables in the Difference-in-difference Model are in good agreement with the regression results of the Fixed-effect Model, which indirectly confirm that the mixed ownership reform policy has a positive role in promoting these financial measure of state-owned listed companies such as profitability, debt solvency and development capability.

Abstract. "Double Eleven" online shopping festival has become the most celebrated and largest online shopping event in China. This phenomenon originates the need to explore impulse buying behavior in relationship of double eleven festival. This study aims to investigate the structural relationship between hedonic, utilitarian web browsing and online impulse buying behavior on "Double Eleven" shopping festival. Data was collected from 426 online shoppers in six different districts of Beijing. In order to assess the measurement model and to test the hypothesis structural equation modeling was utilized by using AMOS 21. Additionally, Reliability, Discriminant and convergent validity was used for the results of proposed model. The results of this study found that utilitarian and hedonic web browsing positively influence on online impulse shoppers with regard to "Double Eleven" shopping festival in China. To the best of our knowledge, this study is pioneer, aiming at exploring the dynamics of online impulse buying behavior with utilitarian and hedonic predictors with regard to biggest online shopping festival in China. This study provides a deep understanding of e-shoppers toward online impulse behavior in the field of Chinese e-commerce industry that can be generalized to other countries also. Implications for scholars and e-tail managers of our study are discussed.

Keywords: E-commerce · "Double Eleven" shopping festival · Online impulse buying · Utilitarian web browsing · Hedonic web browsing

1 Introduction

With the growing field of e-commerce, online shopping trend is becoming popular across the world. China has become largest e-commerce economy in the world. Consumers always prefer to buy goods online especially on occasions. Most of

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_56

the time when they make decision about online shopping they act impulsively. One click ordering, easy access to products, absence of delivery, rich information about product and time saving these all factors leads to buy impulsively online. There are many factors that influence on impulse buying behavior. Impulse purchase, is explained as compelling, hedonically complex and unplanned buying behavior [35]. With the tremendous growth of e-commerce and rapid development of information technology, online impulse purchasing has become an epidemic. It is also noteworthy that about 40% of all online shoppers spending is attributable to online impulse purchasing [24,36]. Online shopping setting is more encouraging to impulse buying behavior than its offline complement. Online shopping environment liberates consumers from the constraints (e.g., social pressure from the staff, inconvenient store locations, limited operating hours, and it need much time) that they might experience during physical shopping events [13].

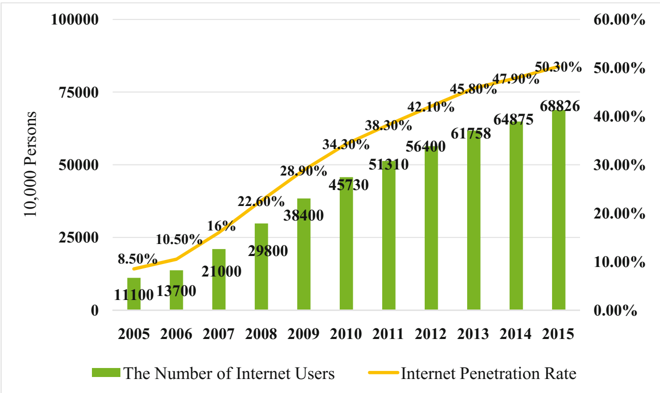

Fig. 1. The size of Chinese internet users and penetration rate

According to the CNNIC report in December 2015 China had 688 million netizens, up 39.51 million over the previous year. The internet penetration rate reached 50.3%, up 2.4% points from the end of 2014 (see Fig. 1) [8]. The survey result shows that in 2015, the mobile phone was the most popular device used for internet access by new internet users, by 71.5% of them, up by 7.4% points from the end to 2014. Among the new internet users in 2015, 46.1% were under 19, and 46.4% were students, and entertainment and communication were their two biggest reasons to access the internet. Online impulse purchase is defined as an immediate and sudden online buying with no preshopping intentions [31]. Previous studies reported that unplanned buying account for up to 60% of all purchases [19,27] and according to [18,21] 40% to 60% of impulse purchases depending on product category. A number of studies have been done in offline setting with impulse buying while a little attention focused on online impulse buying. Recently in an online buying setting, scholars have studied how to better appeal to impulse shoppers to take benefit of the behavior which has helped brick and mortar retailers flourish for decades [9,23,36,37]. Irrespective of context, a main purpose in retailing is to increase the attraction to improve sales [6,21]. Due to the pervasiveness and practical implications of impulse purchase, retailers have focused significant efforts on facilitating the behavior [9,23]. This study is not only beneficial for online retailers, but it also has future directions and guidelines for scholars who are having been studied on impulse buying behavior and produced number of studies in last decade.

In this regards, it is important to understand the comparative benefits of buying online over offline shopping. Therefore, retailers should be aware of the motivations behind the consumers' online buying process. Motivations are an essential factor to define the individual's behavior. They stem unmet needs and represent, through concrete actions, the benefits which people hope to achieve [33]. Two types of motivational factors influence on online shopping i.e., Utilitarian and Hedonic motivations [26]. While making essential consumption decisions, it is reasonable to create a difference between utilitarian and hedonic motives. These motives construct two aspects of attitudes with respect to behavioral acts. Hedonic motivations are related with experiential or emotional aspects which make the pleasured shopping experience while utilitarian motivation aspects associated with rational, functional, practical, economic or extrinsic benefits. In this research, we focus on how these two motivations influence on online impulse shopping.

Table 1. 2009–2016 Alipay "Double Eleven" day trading volume (unit: 100 million yuan)

Year	2009	2010	2011	2012	2013	2014	2015
Turnover	0.5	2.5	53	181	350.19	571.12	912.17

Source: Taobao official website.

In China, online shopping market has shown great potential due to rapid growth of Chinese netizens and online consumers (see Fig. 1). In order to achieve the competitive advantages a number of businesses joining the e-commerce industry. They must understand consumer needs and try to meet their demands, they should make a marketing strategies (e.g., low price product, augmented services, speedy transaction process, quality of products) to earn profit and attract netizens. In this regards, the "Double Eleven" online shopping festival has an emerging trend. Taobao introduced "Double Eleven" shopping festival on November 11, 2009 on "singles' Day". "Double Eleven" online shopping festival is most popular among Chinese netizens/e-commerce industry and it is largest commercial activity. Early 2016, the festival has been successfully held for seven times. This event has carried out vast economic benefits, which have increased year by year, and every year revive the record single-day net buying business amount (see Table 1). Aforesaid studies about online impulse buying behavior have shown that there is a great opportunity to identify how online impulse purchase effected due to this event i.e. "Double Eleven" because authors best knowledge no study has been conducted in this context. Only a few researchers have studied to examine the "Double Eleven" model successful factors from different perspectives. Liu [24] reported that this setting can effectively motivate to online shoppers to create impulse buying behavior (buying behavior that goes beyond what has been planned).

This study provides a better understanding about motivational factors that influence on online impulse buying adoption in China with the perspective of "Double Eleven" shopping festival. A little work has been investigated on relationship between motivational factors and online impulse buying, but no single study has yet investigated these factors in the context of "Double Eleven" shopping event. The Current study fill this gap by incorporated the conception of motivational factors i.e. Utilitarian and Hedonic on online impulse buying behavior in the context of "Double Eleven" shopping activity. Aforementioned discussions, the purpose of this manuscript is threefold: (1) to highlights the major findings in study regarding "Double Eleven" shopping festival, (2) to investigate the relationship between online impulse buying and utilitarian motivations with the regard of Double Eleven shopping activity (3) to explore the relationship between hedonic motivations and online impulse buying with the regard to "Double Eleven" shopping activity. The rest of the manuscript is organized as follows. First we discuss core concepts of online impulse buying and motivational factors i.e., utilitarian and hedonic and their relationship, based on their connection we develop the hypotheses and draw research model. The next section, we test the hypotheses based on data collection and data analysis. Finally, last section presents the research outcomes, managerial implications and future direction.

2 Online Impulse Buying

Online impulse purchasing is an immediate, unplanned, compelling and sudden purchase behavior while shopping experience [1,2]. Consumers usually tend to make immediate and unintended purchases while making online buying [20] their intention about online buying might be related to website complicity and simplicity [38]. In this context, Sharma [34] demonstrated that online buying is driven by low cognitive control or spontaneous behavior and consumers' emotions. They argued that consumer's impulse buying behavior is driven by appealing objects, which influence them to make purchase without considering financial and other factors of the online buying. Verhagen et al. [36] and Dholakia [9] mentioned that online consumers are more likely to buy impulsive as compared to offline. Many consumers to overspend due to online transactions because the virtual procedure does not feel like spending money [11]. Online marketing stimuli make buying spontaneously and allow online buyers to be less risk-averse [25]. E-impulse influenced by many motivational factors i.e. utilitarian and hedonic web browsing and other factors such as web site quality, sales promotion, ease of payment.

3 Utilitarian and Hedonic Motivations

According to the scholars [25,28] Utilitarian and hedonic factor both influence on impulse purchase. Impulse purchasing and different kind of browsing are effortless feelings [34]. Online shoppers motivate by searching due to the benefits such as entertainment, uniqueness and fun [15]. For specific products, online impulse buying occurs due to emotional and hedonic browsing [30]. Internet facilitates browsing the online merchandise for informational purpose (i.e., utilitarian) and recreational i.e., hedonic browsing [25]. Consumers usually act as impulsively when they are taking online decisions due to easy buying e.g., one click order, absence of delivery efforts and easy access to product [36]. Park [9] confirmed that utilitarian and hedonic browsing has a relationship with impulsiveness in the context of online buying of apparel products. Additionally, Gohary [14] demonstrated that effect of hedonic and utilitarian browsing on impulse behavior which points towards the importance of hedonic and utilitarian browsing for impulse purchasing over the internet [12,36]. Finally, Rezaei [32] confirmed that utilitarian and hedonic browsing positively influence on online impulse buying. Based on above studies the following hypotheses regarding the relationship between motivational factors and online impulse buying is derived:

H1 (HWB → OIB): Hedonic web browsing positively relate with online impulse buying in the context of "Double Eleven" shopping events.
H2 (UWB → OIB): Utilitarian web browsing positively relate with online impulse buying in the context of "Double Eleven" shopping events.

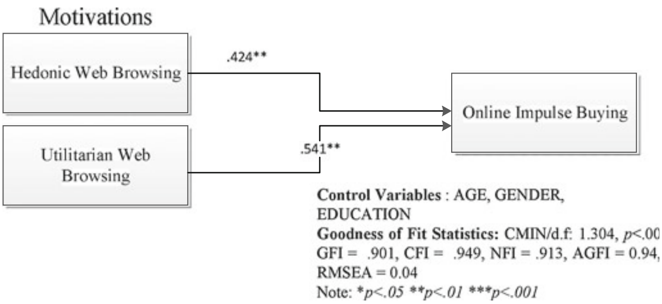

Fig. 2. A structure model for Hedonic web browsing, Utilitarian Web browsing and Online impulse buying

Mathematical Model

$$\text{OIB} = \beta_0 + \beta_1\,(\text{HWB}) + \beta_2\,(\text{UWB}) + \varepsilon.$$

4 Research Methodology

The aim of this study is to find the motivational factors effect on OIB on "Double Eleven" shopping festival. Data was collected from six different districts i.e. Haidian, Chaoyang, Fengtai, Changping, Tongzhou, and Dongcheng of Beijing. The survey was conducted on the Double Eleven shopping festival date on 11th November 2016. Convenience sampling method was utilized to collect the large data.

4.1 Questionnaire

Paper questionnaire and online survey techniques was used for data collection. Initially, questionnaire was developed/adapt in English and subsequently translated into Chinese and back translation into English for accuracy. Services of Chinese language experts and translators were employed to translate the questionnaire into Chinese and then it was also translated back into English to check accuracy. Translation and back translation was validated by International Chinese Training Center, Beijing. The first part of questionnaire was designed to ensure the respondents have online buying experience on "Double Eleven" shopping festival and in order to get information related with respondents' characteristics. The second section was designed to examine the relationship among online impulse buying behavior, hedonic and utilitarian motivations. Pilot testing were utilized ($n = 65$). Additionally, total 470 questionnaires were distributed among online shoppers and ($n = 426$) was valid for the data analysis with response rate 90.63%. Note books were provided to the respondents in order to motivate and seduce their patience, which cost about 5 RMB (.7 $).

4.2 Instrumentations

Five items were adapted from [36] to measure the online impulse buying behavior e.g., My purchases were spontaneous. In order to measure the utilitarian web browsing five items were adopted from [9] e.g., I browse to buy better items in price and quality and to measure the hedonic web browsing four items were adopted from [9] e.g., while web browsing, I am able to forget my problems and to feel relaxed. Rezaei [32] also used these three instruments in his study.

5 Results and Hypothesis Testing

Table 2 reports the demographic characteristics of the respondents. Total 470 questionnaires were floated, out of 470, 426 respondents were found who had online shopping experience. Demographics show that there are higher number of female respondents as compared to males i.e. 63% are females and 37% males. Maximum respondents were belonging to 25–31 years of age (i.e. 38.6% of total respondents). Final collected respondents came out to be 51.8% students, 20.6% employed, 11.2% individuals having managerial job and 9.8% having their own business.

Table 2. Respondents Demographic Information ($n = 426$)

Age		Gender		Education	
18–24	32.1%	Male	37%	Doctorate	11.5%
25–31	38.6%	Female	63%	Master	23.2%
32–40	25.3%			Bachelor	35.3%
above 40	4.0%			Diploma	25.0%
				Other	5.0%
Occupation		**Years using the internet**		**Online Impulse Experience**	
Business Owner	9.8%	1–4	7.5%	Yes	426
Managerial level	11.2%	4–9	53.1%	No	470
Employee level	20.6%	10–14	35.6%		
Student	51.8%	More than 14	3.8%		
Other	6.6%				

Kaiser-Meyer-Olkin (KMO) test formula

$$\mathrm{KMO}_j = \frac{\sum_{i\neq j} r_{ij}^2}{\sum_{i\neq j} r_{ij}^2 + \sum_{i\neq j} u_{ij}^2},$$

$$\mathrm{AVE} = \left(\sum_{i=1}^{k} \lambda_i\right)^2 \Bigg/ \left[\left(\sum_{i=1}^{k} \lambda_i\right)^2 + \sum_{i=1}^{k} (1-\lambda_i^2)\right].$$

Measured with the Joreskog Rho $= \sum_{i=1}^{k} \lambda_i^2 \Big/ \left[\sum_{i=1}^{k} \lambda_i^2 + \sum_{i=1}^{k} (1-\lambda_i^2)\right]$.

Before examining the structure model, multi-collinearity issue was assessed through variance inflation factor (VIF) produced by SPSS 21 version. The results of VIFs indicated the value of 1.34 for online impulse buying, 2.70 for utilitarian web browsing and 1.76 for hedonic web browsing variable, all stated values are lower than the threshold value 10 [10]. Therefore, the results show that no serious problem of multicollinearity in our study. Missing values in data set is a big challenge for social science scholars like information system, Human resource management and marketing areas. Many techniques can be performed for the treatment of missing values but multiple imputation considered effectively [32]. In this study, to handle missing values and impute missing values effectively by using SPSS, expectation maximization algorithm (EMA) was utilized. For the missing value treatment, little's missing completely at random MCAR which is chi-square χ^2 test for missing completely at random Little's MCAR test: $\chi^2 = 334.270$, $df = 332$, significance level = .444. Furthermore, before factor analysis Kaiser-Meyer-Olkin (KMO) test was assessed for the sampling adequacy which shows KMO value .867. KMO value .867 is less then benchmark value .10 [16].

To examine the structure model confirmatory factor analysis (CFA) was used to test the hypothesis and measurement model by using AMOS 21 version. After removing problematic items, we reran the CFA analysis, the results indicated that satisfactory fit (CMIN/DF: 1.82; $p < .000$; NFI = .98; IFI = 0.96;

Table 3. Convergent Validity and Reliability

Construct	Item	Loadings	Cronbach's alpha	Composite reliability[a]	AVE[b]
Online Impulse Buying (OIB)	OIB1	0.875	0.894	0.98	0.81
	OIB2	0.863			
	OIB3	0.924			
	OIB4	0.911			
	OIB5	0.889			
Utilitarian web browsing	UWB1	0.945	0.877	0.912	0.9
	UWB2	0.865			
	UWB3	0.876			
	UWB4	0.878			
Hedonic web browsing	HWB1	0.888	0.845	0.92	0.79
	HWB2	0.899			
	HWB3	0.924			
	HWB4	0.789			

Notes: [a]Composite reliability (CR) = (Square of the summation of the factor loading)/(square of the summation of the factor loadings) + (square of the summation of the error variance); [b]Average variance extracted (AVE) = (summation of the square of the factor loadings)/(summation of the square of the factor loadings) + (summation of the error variances).

Table 4. Results of structural relationships and hypothesis testing

Construct	Mean	Std. Deviation	OIB	UWB	HWB
OIB	4.03	1.56	0.81	-	-
UWB	3.98	1.77	0.54	0.9	-
HWB	4.16	1.55	0.452	0.64	0.79

Note: Acronyms: Online impulse buying (OIB); Utilitarian web browsing and hedonic web browsing; Diagonal bold values represent AVEs and off-diagonal denotes square correlation among constructs. [$*p < 0.05$, $**p < 0.01$, $***p < 0.001$].

GFI = .887; CFI = .91; RMSEA = 0.05). All values of CFA analysis were satisfactory and meet the threshold value. Reliability and Validity test performed in the model. Convergent validity was examined by using three parameters i.e., (1) factor loading grater then .70 with statistical significance (2) composite reliability (CR) larger then .80. (3) Average variance extraction (AVE) higher then .50 [16]. Table 3 indicated that all values of factor loading is greater than .70, in addition, all constructs show the high level of reliability internal consistency CR and Cronbach's alpha values ranges from .84 to .98. The value of AVE is greater then the benchmark value .50. Thus, we attained the good level of convergent validity and reliability. Table 3 reports all statistical values of mean, standard deviation and discriminant validity. We used Hair's criterion to evaluate the discriminant validity which directs square root to average variance extraction AVE for all constructs should be higher then it correlations [16]. Discriminant validity among all variables were confirmed based upon Hair's criterion (see Table 4).

Table 5. Results of structural relationships and hypothesis testing

Hypotheses	Path	R^2	Path Coefficient	Standard error	t-statistics	Decision
H1	HWB → OIB	0.424	0.823	0.067	21.4***	Supported
H2	HWB → OIB	0.541	0.764	0.089	32.1***	Supported

Notes: t-values for two tailed test: ***2.58 (significance level = 1%); **1.96 (significance level = 5%); and *t-value 1.56 (significance level 10%) [17]; Acronyms: online impulse buying (OIB); Hedonic web browsing (HWB) and utilitarian web browsing (UWB).

Table 5 depicts the results of path coefficients (β) which indicates the hypothesized association among the constructs. Figure 2 represents the results of structure model. *H1* that proposes there is a positive relationship between hedonic web browsing and online impulse buying was approved with path coefficient (β) 0.823, t-statistics 21.4 and standard error 0.067. Results demonstrated that hedonic web browsing positive and significantly influences on online impulse buying on "Double Eleven" shopping festival. *H2* proposed that utilitarian web browsing positively influence on online impulse buying (utilitarian web browsing → online impulse buying) with coefficient (β) of 0.764, standard error of 0.089 and the value of t-statistics 32.1. *H2* was also supported. Furthermore, Table 4 shows the values of R^2 for the relationships of constructs. The R^2 value for (UWB → OIB) .541 and for (HWB → OIB) .424, which means 54.1% change in online impulse buying due to utilitarian web browsing while 42.4% change in online impulse buying due to hedonic web browsing. Hedonic web browsing strongly influences on online impulse buying than utilitarian web browsing. The findings confirm that UWB and HWB strongly influenced on online impulse buying.

6 Discussions and Conclusion

With a remarkable growth of Chinese internet users and tremendous penetration rate of internet (see Fig. 1), web browsing motivation is considered as an essential part of online shoppers' experience. The current study provides important insights of online impulse behavior based on web browsing motivation i.e., Hedonic and Utilitarian for e-tailers to develop their e-business strategies specially on big event like "Double Eleven". This study investigates online impulse buying shoppers towards "Double Eleven" e-shopping festival and examines whether hedonic and utilitarian web browsing have any impact on it. This manuscript contributes to existing studies regarding online impulse buying behavior by using exogenous constructs i.e., hedonic and utilitarian web browsing. With the remarkable growth of online business, "Double Eleven" has turned out not only a festival to celebrate, but also most popular and highest sales volume festival in online shopping. This study provides a significant insight of utilitarian and hedonic web browsing behavior which influence on online impulse buying behavior. In China, e-commerce companies are facing high rivalry environment and they need to make innovative e-business strategies in order to increase online impulse buying, that makes the results of this paper useful.

The results of this study demonstrated that Hedonic and utilitarian web browsing both influenced on online impulse buying behavior on “Double Eleven” shopping festival. The findings also support broadened theory of impulse purchase behavior [5], which recommends that web browsing motivation is a key to enhance online impulse purchase for apparel purchase from both hedonic and utilitarian perspective. Inclination with the findings of this study Kim and Eastim argued that there is a huge difference between hedonic and web browsing behavior in online shopping. With the perspective of utilitarian value, consumers are focused towards completing consumption goals [3,4,7,29], while hedonic value, consumers are more attentive on entertainment, emotional and fun when dealing with online browsing [7,22]. Park [9] found that hedonic web browsing positively influences on OIB whereas utilitarian web browsing negatively influenced on online impulse buying. In an online shopping context, this evidence supports the hedonic nature of online impulse behavior [6,30].

E-tailer should make successful strategies by focusing on hedonic and utilitarian web browsing motives for e-shoppers by ensuring in professional manner, for instance; easy purchase process, good selection of variety, elegance and security of the web site. These all factors lead to online impulse shopper. This manuscript has some important practical implication towards OIB on “Double Eleven” shopping activity. This study’s finding will help the e-tail managers and web hosts associated with online selling to exploit exogenous factors HEB and UWB to enhance their impulse sales through web traffic. Utilitarian and hedonic web browsing plays a significant role to motivate e-shoppers to buy impulsively specially on “Double Eleven” event. In China, there is rapid growth towards netizens and penetration rate of internet users, now every individual prefer buying online. The outcomes of this study will useful for two e-tail big players in China (i.e., www.jd.com and www.taobao.com) as well as small e-tail businesses. Therefore, marketers should focus on these strategies in order to increase the impulse buying behavior which is major contribution in the field of e-commerce retailing and marketing (Table 6).

Despite all the strengths and potential contributions of the study, to generalize the findings, future research should consider the limitation of study. First, in this study we collect data from Beijing and just focus on “Double Eleven” shopping festival. Results can be enhanced by expanding the study sample and incorporating more festivals that are found to increase online sales. Moreover, this manuscript has considered only two motivational factors i.e., UWB and HWB, future scholars may use other factors related to web site personality, emotional factors such as perceived usefulness and perceived ease of use and outcomes could be used to improve other type of e-commerce web site. This study is based on quantitative data analysis and cross sectional in nature. For online shopping characteristic of Double Eleven festival longitudinal and qualitative method (i.e., interviews and focus group) may also be used for deep understanding of online shopping environment. Pre-and post-purchase behavior with regard to “Double Eleven” shopping festival may also be analyzed by future researchers. Lastly, future studies are recommended to analyze the proposed model in different e-tail cultural environment.

Acknowledgements. The authors want to extend their gratitude towards the Editor (Jiuping, Xu) and the anonymous Reviewers for their indispensable and valuable suggestions and comments that improved the quality of the paper significantly. Furthermore, they thank Prof. Peng Hui, Professor of finance, School of economics and management, Beijing University of Posts and Telecommunications for valuable suggestions.

Appendix

Table 6. Measurement items

No	Construct	Scale	Source
1	Utilitarian web browsing	UWB1 I browse to buy better items in price or quality	[30]
		UWB2 I browse the shopping web sites to gather information about products	
		UWB3 I look around the shopping web sites to comparison shop	
		UWB4 I browse the shopping web sites to get additional value as much as possible	
		UWB5 I browse for efficient shopping online	
2	Hedonic web browsing	HWB1 While web browsing, I am able to forget my problems and to feel relaxed	[30]
		HWB2 During web browsing, I am very excited, like playing	
		HWB3 I enjoy web browsing enough to forget a time out	
		HWB4 I look around at items on the internet just for fun	
3	Online impulse buying	OIB1 My purchase was spontaneous	[36]
		OIB2 My purchase was unplanned	
		OIB3 I did not intend to do this purchase before this shopping trip	
		OIB4 Before visiting the site, I did not have the intention to do this purchase	
		OIB5 I could not resist doing this purchase at the site

Fuzzy Multi-attribute Grey Relational Analysis Using DEA and AHP

Mohammad Sadegh Pakkar(✉)

Faculty of Management, Laurentian University, Sudbury, ON P3E 2C6, Canada
ms_pakkar@laurentian.ca

Abstract. This research applies the method of grey relational analysis (GRA) for multiple attribute decision making (MADM) problems in which the attribute weights are completely unknown and attribute values take the form of fuzzy numbers. In order to obtain the attribute weights, this research proposes an integrated data envelopment analysis (DEA) and analytic hierarchy process (AHP) approach. According to this, we define two sets of weights in a domain of grey relational loss, i.e., a reduction in grey relational grade, between each alternative and the ideal alternative. The first set represents the weights of attributes with the minimal grey relational loss in DEA. The second set represents the priority weights of attributes, bounded by AHP, with the maximal grey relational loss. Using a parametric goal programming model, we explore the various sets of weights in a defined domain of grey relational loss. This may result in various ranking positions for each alternative in comparison to the other alternatives. An illustrated example of a nuclear waste dump site selection is used to highlight the usefulness of the proposed approach.

Keywords: Grey relational analysis · Data envelopment analysis · Analytic hierarchy process · Multiple attribute decision making · Goal programming · Fuzzy numbers

1 Introduction

Multiple attribute decision making (MADM) aims to find the ranking position of alternatives in the presence of multiple incommensurate attributes. Many MADM problems take place in an environment in which the information about attribute weights are incompletely known and attribute values take the form of intervals and fuzzy numbers [16,24,29].

Grey relational analysis (GRA) is part of grey system theory [3], which is suitable for solving a variety of MADM problems with both crisp and fuzzy data. The application of GRA with fuzzy data has recently attracted the attention of many scholars [5,8,25].

GRA solves MADM problems by aggregating incommensurate attributes for each alternative into a single composite value while the weight of each attribute is

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_57

subject to the decision maker's judgment. When such information is unavailable equal weights seem to be a norm. However, this is often the source of controversies for the final ranking results. Therefore, how to properly select the attribute weights is a main source of difficulty in the application of this technique. Fortunately, the development of modern operational research has provided us two excellent tools called data envelopment analysis (DEA) and analytic hierarchy process (AHP), which can be used to derive attribute weights in GRA.

DEA is an objective data-oriented approach to assess the relative performance of a group of decision making units (DMUs) with multiple inputs and outputs [2]. Traditional DEA models require crisp input and output data. However, in recent years, fuzzy set theory has been proposed as a way to quantify imprecise and vague data in DEA models [7,14,26]. In the field of GRA, DEA models without explicit inputs are applied, i.e., the models in which only pure outputs or index data are taken into account [11,27,28]. In these models, each DMU or alternative can freely choose its own favorable system of weights to maximize its performance. However, this freedom of choosing weights is equivalent to keeping the preferences of a decision maker out of the decision process.

Alternatively, AHP is a subjective data-oriented procedure which can reflect the relative importance of a set of attributes and alternatives based on the formal expression of the decision maker's preferences. AHP usually involves three basic functions: structuring complexities, measuring on a ratio-scale and synthesizing [23]. Some researchers incorporate fuzzy set theory in the conventional AHP to express the uncertain comparison judgments as fuzzy numbers [9,12,17].

However, AHP has been a target of criticism because of the subjective nature of the ranking process [4]. The application of AHP with GRA can be seen in [1,10,30].

In order to overcome the problematic issue of confronting the contradiction between the objective weights in DEA and subjective weights in AHP, this research proposes an integrated DEA and AHP approach in deriving the attribute weights in a fuzzy GRA methodology. This can be implemented by incorporating weight bounds using AHP in DEA-based GRA models. It is worth pointing out that the models proposed in this article are not brand-new models in the DEA-AHP literature. Conceptually, they are parallel to the application of DEA and AHP in GRA using crisp data as discussed in [20]. Nevertheless, it is the first time that these models are applied to a fuzzy GRA methodology. Further research on the integration of DEA and AHP approach in deriving the attribute weights with fuzzy data can be seen in [19].

2 Methodology

2.1 Fuzzy Multiple Attribute Grey Relational Analysis

Let $A = \{A_1, A_2, \cdots, A_m\}$ be a discrete set of alternatives and $C = \{C_1, C_2, \cdots, C_n\}$ be a set of attributes. Let $\tilde{y}_{ij} = (y_{1ij}, y_{2ij}, y_{3ij}, y_{4ij})$ be a trapezoidal fuzzy number representing the value of attribute $C_j (j = 1, 2, \cdots, n)$ for alternative $A_i (i = 1, 2, \cdots, m)$. Using α-cut technique, a trapezoidal fuzzy number can be transformed into an interval number as follows:

$$y_{ij} = [y_{ij}^-, y_{ij}^+] = [\alpha y_{2ij} + (1 - \alpha) y_{1ij}, \alpha y_{3ij} + (1 - \alpha) y_{4ij})], \tag{1}$$

where $y_{ij} = [y_{ij}^-, y_{ij}^+], y_{ij}^- \leq y_{ij}^+$, is an interval number representing the value of attribute $C_j (j = 1, 2, \cdots, n)$ for alternative $A_i (i = 1, 2, \cdots, m)$. Then alternative A_i is characterized by a vector $Y_i = \left([y_{i1}^-, y_{i1}^+], [y_{i2}^-, y_{i2}^+], \cdots, [y_{in}^-, y_{in}^+]\right)$ of attribute values. The term Y_i can be translated into the comparability sequence $R_i = ([r_{i1}^-, r_{i1}^+], [r_{i2}^-, r_{i2}^+], \cdots, [r_{in}^-, r_{in}^+])$ by using the following equations [31]:

$$[r_{ij}^-, r_{ij}^+] = \left[\frac{y_{ij}^-}{y_{j(\max)}^+}, \frac{y_{ij}^+}{y_{j(\max)}^+}\right] \quad \forall j, \quad y_{j(\max)}^+ = \max\{y_{1j}^+, y_{2j}^+, \cdots, y_{mj}^+\} \tag{2}$$

for desirable attributes,

$$[r_{ij}^-, r_{ij}^+] = \left[\frac{y_{i(\min)}^-}{y_{ij}^-}, \frac{y_{i(\min)}^-}{y_{ij}^+}\right] \quad \forall j, \quad y_{j(\min)}^- = \min\{y_{1j}^-, y_{2j}^-, \cdots, y_{mj}^-\} \tag{3}$$

for undesirable attributes.

Now, let A_0 be a virtual ideal alternative which is characterized by a reference sequence $U_0 = \left([u_{01}^-, u_{01}^+], [u_{02}^-, u_{02}^+], \cdots, [u_{0n}^-, u_{0n}^+]\right)$ of the maximum attribute values as follows:

$$u_{0j}^- = \max\{r_{1j}^-, r_{2j}^-, \cdots, r_{mj}^-\} \ \ \forall j, \tag{4}$$
$$u_{0j}^+ = \max\{r_{1j}^+, r_{2j}^+, \cdots, r_{mj}^+\} \ \ \forall j. \tag{5}$$

To measure the degree of similarity between $r_{ij} = [r_{ij}^-, r_{ij}^+]$ and $u_{0j} = [u_{0j}^-, u_{0j}^+]$ for each attribute, the grey relational coefficient, ξ_{ij}, can be calculated as follows:

$$\xi_{ij} = \frac{\min_i \min_j \left|[u_{0j}^-, u_{0j}^+] - [r_{ij}^-, r_{ij}^+]\right| + \rho \max_i \max_j \left|[u_{0j}^-, u_{0j}^+] - [r_{ij}^-, r_{ij}^+]\right|}{\left|[u_{0j}^-, u_{0j}^+] - [r_{ij}^-, r_{ij}^+]\right| + \rho \max_i \max_j \left|[u_{0j}^-, u_{0j}^+] - [r_{ij}^-, r_{ij}^+]\right|}, \tag{6}$$

while the distance between $u_{0j} = [u_{0j}^-, u_{0j}^+]$ and $r_{ij} = [r_{ij}^-, r_{ij}^+]$ is measured by $|u_{0j} - r_{ij}| = \max\left(\left|u_{0j}^- - r_{ij}^-\right|, \left|u_{0j}^+ - r_{ij}^+\right|\right)$. $\rho \in [0, 1]$ is the distinguishing coefficient, generally $\rho = 0.5$. It should be noted that the final results of GRA for MADM problems are very robust to changes in the values of ρ. Therefore, selecting the different values of ρ would only slightly change the rank order of attributes [13]. To find an aggregated measure of similarity between alternative A_i, characterized by the comparability sequence R_i, and the ideal alternative A_0, characterized by the reference sequence U_0, over all the attributes, the grey relational grade, Γ_i, can be computed as follows:

$$\Gamma_i = \sum_{j=1}^{n} w_j \xi_{ij}, \tag{7}$$

where w_j is the weight of attribute C_j and $\sum_{j=1}^{n} w_j = 1$. In practice, expert judgments are often used to obtain the weights of attributes. When such information is unavailable equal weights seem to be a norm. Nonetheless, the use of equal weights does not place an alternative in the best ranking position in comparison to the other alternatives. In the next section, we show how DEA can be used to obtain the optimal weights of attributes for each alternative in GRA.

2.2 DEA-Based GRA Models

Since all the grey relational coefficients are benefit (output) data, a DEA-based GRA model can be formulated similar to a classical DEA model without explicit inputs [15]:

$$\Gamma_k = \max \sum_{j=1}^{n} w_j \xi_{kj}, \tag{8}$$

$$\sum_{j=1}^{n} w_j \xi_{ij} \leq 1 \quad \forall i, \tag{9}$$

$$w_j > 0 \quad \forall j, \tag{10}$$

where Γ_k is the grey relational grade for alternative under assessment A_k (known as a decision making unit in the DEA terminology). k is the index for the alternative under assessment where k ranges over $1, 2, \cdots, m$. w_j is the weight of attribute C_j. The first set of constraints (9) assures that if the computed weights are applied to a group of m alternatives, $(i = 1, 2, \cdots, m)$, they do not attain a grade of larger than 1. The process of solving the model is repeated to obtain the optimal grey relational grade and the optimal weights required to attain such a grade for each alternative. The objective function (8) in this model maximizes the ratio of the grey relational grade of alternative A_k to the maximum grey relational grade across all alternatives for the same set of weights $(\max \Gamma_k / \max_{i=1,\cdots,m} \Gamma_i)$. Hence, an optimal set of weights in the DEA based-GRA model represents A_k in the best light in comparison to all the other alternatives. It should be noted that the grey relational coefficients are normalized data. Consequently, the weights attached to them are also normalized. In addition, adding the constraint $\sum_{j=1}^{n} w_j = 1$ to the DEA-based GRA model is not recommended here. In fact, the sum-to-one constraint is a non-homogeneous constraint (i.e., its right-hand side is a non-zero free constant) which can lead to underestimation of the grey relational grades of alternatives or infeasibility in the DEA-based GRA model (see [22])

2.3 Minimax DEA-Based GRA Model Using AHP

We develop our formulation based on a simplified version of the generalized distance model (see for example [6]). Let $\Gamma_k^* (k = 1, 2, \cdots, m)$ be the best attainable grey relational grade for the alternative under assessment, calculated from the

DEA-based GRA model. We want the grey relational grade, $\Gamma_k(w)$, calculated from the vector of weights $w = (w_1, \cdots, w_n)$ to be closest to Γ_k^*. Our definition of "*closest*" is that the largest distance is at its minimum. Hence we choose the form of the minimax model: $\min_w \max_k \{\Gamma_k^* - \Gamma_k(w)\}$ to minimize a single deviation which is equivalent to the following linear model:

$$\min \ \theta \tag{11}$$

$$\text{s. t. } \Gamma_k^* - \sum_{j=1}^{n} w_j \xi_{kj} \le \theta, \tag{12}$$

$$\sum_{j=1}^{n} w_j \xi_{ij} \le \Gamma_i^* \quad \forall i, \tag{13}$$

$$\theta \le 1, \tag{14}$$

$$\theta, w_j \ge 0 \quad \forall j. \tag{15}$$

The combination of (11)–(15) forms a minimax DEA based-GRA model that identifies the minimum grey relational loss $\theta_{\min}$ needed to arrive at an optimal set of weights. The first constraint ensures that each alternative loses no more than θ of its best attainable relational grade, Γ_k^*. The second set of constraints satisfies that the relational grades of all alternatives are less than or equal to their upper bound of Γ_k^*. It should be noted that for each alternative, the minimum grey relational loss $\theta = 0$. Therefore, the optimal set of weights obtained from the minimax DEA based-GRA model is exactly similar to that obtained from the DEA-based GRA model.

On the other hand, the priority weights of attributes are defined out of the internal mechanism of DEA by AHP. In order to more clearly demonstrate how AHP is integrated into the newly proposed minimax DEA-based GRA model, this research presents an analytical process in which attributes' weights are bounded by the AHP method. The AHP procedure for imposing weight bounds may be broken down into the following steps:

Step 1. A decision maker makes a pairwise comparison matrix of different attributes, denoted by B with the entries of $b_{hq} (h = q = 1, 2, \cdots, n)$. The comparative importance of attributes is provided by the decision maker using a rating scale. Saaty [23] recommends using a 1–9 scale.

Step 2. The AHP method obtains the priority weights of attributes by computing the eigenvector of matrix B (Eq. (16)), $e = (e_1, e_2, \cdots, e_j)^T$, which is related to the largest eigenvalue, $\lambda_{\max}$.

$$Be = \lambda_{\max} e. \tag{16}$$

To determine whether or not the inconsistency in a comparison matrix is reasonable the random consistency ratio, $C.R.$ can be computed by the following equation:

$$C.R. = \frac{\lambda_{\max} - N}{(N-1)R.I.}, \tag{17}$$

where $R.I.$ is the average random consistency index and N is the size of a comparison matrix.

In order to estimate the maximum relational loss $\theta_{\max}$ necessary to achieve the priority weights of attributes for each alternative, the following set of constraints is added to the minimax DEA-based GRA model:

$$w_j = \alpha e_j \quad \forall j. \tag{18}$$

The set of constraints (18) changes the priority weights of attributes to weights for the new system by means of a scaling factor α. The scaling factor α is added to avoid the possibility of contradicting constraints leading to infeasibility or underestimating the grey relational grade of alternatives (see [22]).

2.4 A Parametric Goal Programming Model

In this stage we develop a parametric goal programming model that can be solved repeatedly to generate the various sets of weights for the discrete values of the parameter θ, such that $0 \le \theta \le \theta_{\max}$. Let $w(\theta)$ be a vector of attribute weights for a given value of parameter θ. Let $w^*(\theta_{\max})$ be the vector of priority weights of attributes obtained from the minimax DEA-based GRA model after adding the set of constraints (18). Our objective is to minimize the total deviations between $w(\theta)$ and $w^*(\theta_{\max})$ with a city block distance measure. Choosing such a distance measure, each deviation is being equally weighted subject to the following constraints:

$$\min \ Z_k(\theta) = \sum_{j=1}^{n} (d_j^+ + d_j^-) \tag{19}$$

$$\text{s. t. } w_j - d_j^+ + d_j^- = \alpha e_j \quad \forall j, \tag{20}$$

$$d_j^+, d_j^- \ge 0. \tag{21}$$

and constraints (12)–(15), where d_j^+ and d_j^- are the positive and negative deviations from the priority weight of attribute $C_j (j = 1, 2, \cdots, n)$ for alternative $A_k (k = 1, 2, \cdots, m)$. The set of Eq. (20) indicates the goal equations whose right-hand sides are the priority weights of attributes adjusted by a scaling variable.

Because the range of deviations computed by the objective function is different for each alternative, it is necessary to normalize it by using relative deviations rather than absolute ones. Hence, the normalized deviations can be computed by:

$$\Delta_k(\theta) = \frac{Z_k^*(0) - Z_k^*(\theta)}{Z_k^*(0)}, \tag{22}$$

where $Z_k^*(\theta)$ is the optimal value of the objective function for $0 \le \theta \le \theta_{\max}$. We define $\Delta_k(\theta)$ as a *measure of closeness* which represents the relative closeness of each alternative to the weights obtained from the minimax DEA-based GRA model in the range [0, 1] after adding the set of constraint (18) to it. Increasing the parameter (θ), we improve the deviations between the two systems of weights obtained from the minimax DEA-based GRA model before and after adding the set of constraints (18). This may lead to different ranking positions for each alternative in comparison to the other alternatives. It should be noted that in a special case where the parameter $\theta = \theta_{\max} = 0$, we assume $\Delta_k(\theta) = 1$.

3 Numerical Example: Nuclear Waste Dump Site Selection

In this section we present the application of the proposed approach for nuclear waste dump site selection. The multiple attribute data, adopted from Wu and Olson [27], are presented in Table 1. There are twelve alternative sites and 4 performance attributes. *Cost*, *Lives lost*, and *Risk* are undesirable attributes and *Civic improvement* is a desirable attribute. *Cost* is in billions of dollars. *Lives lost* reflects expected lives lost from all exposures. *Risk* shows the risk of catastrophe (earthquake, flood, etc.) and *Civic improvement* is the improvement of the local community due to the construction and operation of each site. *Cost* and *Lives lost* are crisp values as outlined in Table 1, but *Risk* and *Civic improvement* have fuzzy data for each nuclear dump site.

We use the processed data as reported in [27]. First the trapezoidal fuzzy data are used to express linguistic data in Table 1. Using the α-cut technique, the raw data are expressed in fuzzy intervals as shown in Table 2. These data are turned into the comparability sequence by using the Eqs. (2) and (3). Each attribute is now on a common 0–1 scale where 0 represents the worst imaginable attainment on an attribute, and 1.00 the best possible attainment.

Table 3 shows the results of a pairwise comparison matrix in the AHP model as constructed by the author in Expert Choice software. The priority weight for each attribute would be the average of the elements in the corresponding row of the normalized matrix of pairwise comparison, shown in the last column of Table 3. One can argue that the priority weights of attributes must be judged by nuclear safety experts. However, since the aim of this section is just to show the application of the proposed approach on numerical data, we see no problem to use our judgment alone.

Using Eq. (6), all grey relational coefficients are computed to provide the required (output) data for the DEA-based GRA model as shown in Table 4. Note that grey relational coefficients depend on the distinguishing coefficient ρ, which here is 0.80.

Solving the minimax DEA-based GRA model for the site under assessment, we obtain an optimal set of weights with minimum grey relational loss ($\theta_{\min}$). It should be noted that the value of the grey relational grade of all waste dump sites calculated from the minimax DEA-based GRA model is identical to that calculated from the DEA-based GRA model. Therefore, the minimum grey relational loss for the site under assessment is $\theta_{\min} = 0$ (Table 5). This implies that

the measure of relative closeness to the AHP weights for the site under assessment is $\varDelta_k(\theta_{\min}) = 0$. On the other hand, solving the minimax DEA-based GRA model for the site under assessment after adding the set of constraints (18), we adjust the priority weights of attributes (outputs) obtained from AHP in such a way that they become compatible with the weights' structure in the minimax DEA-based GRA model. This results in the maximum grey relational loss, $\theta_{\max}$, for the site under assessment (Table 5). In addition, this implies that the measure of relative closeness to the AHP weights for the site under assessment is $\varDelta_k(\theta_{\max}) = 1$.

Table 6 presents the optimal weights of attributes as well as its scaling factor for all nuclear waste dump sites. It should be noted that the priority weights of AHP (Table 3) used for incorporating weight bounds on the attribute weights are obtained as $e_j = \frac{w_j}{\alpha}$.

Going one step further to the solution process of the parametric goal programming model, we proceed to the estimation of total deviations from the AHP weights for each site while the parameter θ is $0 \leq \theta \leq \theta_{\max}$. Table 7 represents the ranking position of each site based on the minimum deviation from the priority weights of attributes for $\theta = 0$. It should be noted that in a special case where the parameter $\theta = \theta_{\max} = 0$, we assume $\varDelta_k(\theta) = 0$. Table 7 shows that Wells is the best alternative in terms of the grey relational grade and its relative closeness to the priority weights of attributes.

Nevertheless, increasing the value of θ from 0 to $\theta_{\max}$ has two main effects on the performance of the other sites: improving the degree of deviations and reducing the value of the grey relational grade. This, of course, is a phenomenon, one expects to observe frequently. The graph of $\varDelta(\theta)$ versus θ, as shown in Fig. 1, is used to describe the relation between the relative closeness to the priority weights of attributes, versus the grey relational loss for each site. This

may result in different ranking positions for each site in comparison to the other sites. In order to clearly discover the effect of grey relational loss on the ranking position of each nuclear dump site, as shown in Table 8 in Appendix, we performed a Kruskal-Wallis test. The Kruskal-Wallis test compares the medians of rankings to determine whether there is a significant difference between them. The result of the test reveals that its p-value is quite smaller than 0.01. Therefore, we conclude that increasing grey relational loss in the whole range [0.0, 0.33] changes the ranking position of each site significantly. Note that at

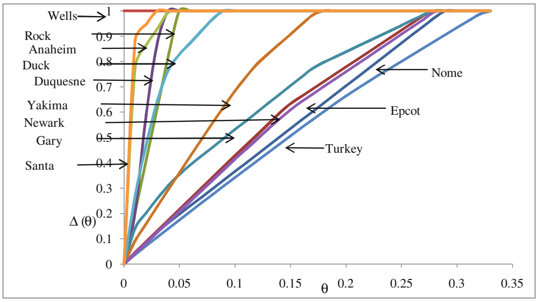

Fig. 1. The relative closeness to the priority weights of attributes [$\Delta(\theta)$], versus grey relational loss (θ) for each site

$\theta = 0$ sites can be ranked based on $Z_k^*(0)$ from the closest to the furthest from the priority weights of attributes. For instance, at $\theta = 0$, Nome, Newark and Rock Sprgs with grey relational grades of one, are ranked in 12^{th}, 4^{th} and 2^{nd} places, respectively (Tables 5 and 7). However, with a small grey relational loss at $\theta = 0.01$, Nome, Newark and Rock Sprgs take 9^{th}, 10^{th} and 5^{th} places in the rankings, respectively. Using this example, as a guideline, it is relatively easy to rank the sites in terms of distance to the priority weights of attributes. At $\theta = 0.02$, Newark moves up into 9^{th} place while Nome and Rock Sprgs drop in 10^{th} and 6^{th} places, respectively. It is clear that both measures, $Z_k^*(0)$ and $\Delta_k(\theta)$, are necessary to explain the ranking position of each nuclear dump site.

4 Conclusion

We develop an integrated approach based on DEA and AHP methodologies for deriving the attribute weights in GRA with fuzzy data. We define two sets of attribute weights in a minimax DEA-based GRA framework. The first set represents the weights of attributes with minimum grey relational loss. The second set represents the corresponding priority weights of attributes, using AHP, with maximum grey relational loss. We assess the performance of each alternative (or DMU) in comparison to the other alternatives based on the relative closeness of the first set of weights to the second set of weights. Improving the measure of relative closeness in a defined range of grey relational loss, we explore the various ranking positions for the alternative under assessment in comparison to the other alternatives. To demonstrate the effectiveness of the proposed approach, an illustrative example of a nuclear waste dump site using twelve alternative sites and 4 attributes is carried out. Further studies can apply the simultaneous application of DEA and AHP to the field of GRA by considering the hierarchical structures of attributes in the ranking positions of alternatives [18, 21].

Abstract. Supplier selection is crucial and multi-criteria decision making problem in supply chain. Nowadays in competitive business environment, supplier selection is a critical task for purchasing department in every organization. Appropriate supplier helps manufacturer to reduce cost, consistent quality product, and enhance competitiveness in market. In order to select potential supplier, it is essential to tradeoff between tangible and intangible factors. Uncertainty and vagueness of decision makers opinion is an important characteristic of this problem. Fuzzy analytical hierarchical process (AHP) and extent analysis method is used to choose appropriate supplier under fuzzy environment. The application procedure of FAHP and extent analysis method is elaborated through numerical example.

Keywords: Supplier selection · Multi-criteria decision making · Fuzzy set theory · Fuzzy AHP · Extent analysis

1 Introduction

Supplier selection is the most challenging issue in supply chain. In order to develop sustainable supply chain companies need to select right supplier. Appropriate selection of supplier helps companies to provide high quality product at right price and at right time. The term "Supply chain management" (SCM) can be defined as it is a process that includes: sourcing raw material, convert raw material to finish goods, and delivers product to final customer. The purpose of SCM is to reduce inventory and production cycle time, to increase production as well as achieve long terms goal of firms with respect to customer stratifications. Appropriate selection of supplier is important task of purchasing department in

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_58

any organization. In order to select supplier, it is necessary to evaluate supplier based on different criteria. The supplier selection problem is considered as a multi-criteria decision making problem. The process of supplier evaluation and selection consists both quantitative and qualitative criteria [3]. Selection of supplier against single factor is not sufficient. Supplier should be evaluated against multi-criterion [11]. In supplier selection problem, it is necessary to be tradeoff between tangible and intangible factors which may conflict each other. Optimal selection of supplier can enable companies to manufacture innovative quality product and gain competitive advantage in market. An effective supplier selection process plays important role to success of any organization. Whether right or wrong selection of supplier directly effect on price, quality, and delivery time. The purpose of supplier selection is to minimize purchase risk and build strong relationship between supplier and buyer in competitive scenario [17]. Selection of potential supplier is strategic decision that helps firms to achieve goal for a longer period of time. Nowadays companies are changing reactive buying to proactive buying to select wealthy supplier [12].

Supplier selection problem can be categorized into two types. Single sourcing and multiple sourcing. Single sourcing means one supplier can provide all required material to the buyer. In multiple sourcing, single supplier unable to satisfy all needs of manufacturer. Hence companies need to split their required material among various supplier [7]. Dickson [8] ranked 23 different criteria includes quality, delivery, warranties, performance history, price, supplier profile, financial position, and technical capability for the purpose of supplier evaluation and selection. The author mentioned that the most important criteria for supplier selection is quality. Weber, et al. [26] reviewed 74 articles from the period 1966 to 1991 about supplier selection criteria and techniques. The author classified supplier selection approaches into three different types; linear weighting methods, mathematical programming models, and statistical techniques. De Boer, et al. [4] defined various phases of supplier selection process. In the initial phase, define problem, formulation of criteria, qualification of supplier, and selection of potential supplier among suppliers.

The process of supplier selection can be simple if one criteria is used in the process of decision making. However, in case of more than one criteria, buyers need to consider a range of different criteria in decision making process. If manufactures are used multiple criteria in supplier selection process, manufacture needs to consider influence of each criteria in decision making process, whether weights are equally given to each criteria or according to type and importance of different criteria [28]. In supplier selection process, two issues are very significant. Formulation of criteria that affect performance of supplier and determine methodology that can be used to select the best supplier. Therefore, selection of appropriate supplier is a critical task for any organization that affects organization efficiency and profitability. Every supplier has a number of strengths and weakness that should be assessed by buyer before ranking them.

2 Literature Review

Recently, supply chain management and supplier selection process have gained great attention in the literature. Appropriate supplier selection is a multi-criteria problem but traditionally supplier selection based on only one criteria price. The supplier selection process is one of the most important task for every firm to establish effective supply chain. In competitive environment, it is critical task for firms to select right supplier because potential supplier helps organizations to produce high quality product at reasonable price. In past, various methodologies have been used to select supplier [1]. Proposed integrated methodology data envelopment analysis (DEA) and group analytical hierarchy process (GAHP) to evaluate and select most efficient supplier. Chatterjee, et al. [12] proposed case based reasoning and decision support system including multi-attribute analysis to measure supplier management performance. Usually, supplier evaluation consists price, quality, flexibility, but in this paper some environment factors were considered in supplier selection process using knowledge-based system. Humphreys et al. [18] presented two methodologies for supplier selection problem and compare relatives performance of organization. Vikor and outranking methods were used to select supplier and compare the relative performance of supplier. Multi-criteria decision making model was applied in a construction industry for supplier evaluation and selection [21]. Multi-criteria decision making enabled construction industry to build good relationships among its supplier, managers, and partners.

The balance and ranking method were used to select supplier based on multi-criteria; profitability of supplier, technological capability, conformance quality, and relationship closeness. The application of model consists three steps; construction of out-ranking matrix, determine relative frequency of each supplier, then triangularised out-ranking matrix to obtain implicit order of each supplier with the help of balancing method [24]. The activity based costing (ABC) technique was proposed for evaluation and selection of vendor. The ABC technique helped to calculate total cost caused by vendor in a company's production process, to judge performance of supplier [19]. The multi-criteria group decision model for supplier selection was applied. This model based on ELECTRE IV and VIP analysis approach. The proposed model consists two stages. In first stage, ELECTRE IV utilized to determine ranking of different criteria. In second stage, VIP analysis method was used to select alternatives [2]. Dimensional analysis technique proposed to measure performance of supplier and to get index called vendor performance index (VPI). In the process of supplier performance evaluation both qualitative and quantitative criterion were used. To overcome blindness of human and vagueness fuzzy approach applied [16]. Supplier selection is crucial task for every organization. The analytical network process (ANP) method was proposed to select the best supplier based on three criteria, business structure of supplier, manufacture capability of supplier, and quality system of supplier. These main three criteria further classified to 45 sub-criteria [10,27]. Neural network (NN) approach used to select potential supplier. The determinant factors quality, performance history, geographical and price were selected in the process of supplier selection.

In Telecommunications Company AHP model was proposed for selection of vendor. Vendor selection is a complex and multi-criteria decision making problem. In application process of AHP, two strategic factors (criteria) cost and quality selected for evaluation of vendor, further both criteria categorized into 26 sub-criteria [23]. Shyura & Hsu-Shih [22] developed integrated model for vendor selection. The hybrid model was included analytical network process (ANP), TOPSIS, and nominal group.

A fuzzy multi-objective integer programming method was developed for supplier selection problem which incorporate three objectives cost minimization, maximize on-time delivery, and quality maximization [14]. Proposed strategy-aligned fuzzy simple multi-attribute rating technique (SMART) to solve supplier selection problem in supply chain. Strategy-aligned fuzzy SMART technique involves three stages. In first stage, define objective and strategy, second step, develop supply chain strategy, third stage recognize criteria for supplier selection [6, 15]. In this study, fuzzy analytical hierarchy process method was proposed with the concept of benefits, opportunities, cost, and risks (BOCR). With the application of this approach supplier can be evaluated various aspects based on quantitative and qualitative criteria. Fuzzy set theory was applied to overcome human ambiguity in decision making process.

In this paper, fuzzy AHP method is applied to select best supplier. In fuzzy AHP method, linguistic variables and triangular fuzzy numbers are used as a pairwise comparison scale to determine priority of main criteria and sub-criteria. After that, extent analysis method is applied to calculate final weight priority of main decision criteria, sub-criteria and alternatives.

3 Fuzzy AHP

The analytical hierarchical process (AHP) introduced by [20]. AHP is very useful method to solve multi-criteria decision making problem. It offers hierarchical procedure to solve problem using both subjective and objective measures. The hierarchical model of supplier selection problem consists four stages; objective, criteria, sub-criteria, and last stage is decision of alternatives.

The advantage of AHP is simple and ease of use but the most important disadvantage of this approach is that it uses nine-point scale which is unable to handle uncertainty in the process of comparisons of decision variables. Tradition AHP is unable to solve uncertain decision making problem, to overcome this problem, linguistic variables and triangular fuzzy numbers are used to decide priority of different decision variables. The extent analysis method is applied to calculate priority of weight using triangular fuzzy numbers. The fuzzy analytical hierarchical process is an extension of AHP which is used to handle fuzziness in supplier selection process based on both quantitative and qualitative criteria.

Fuzzy set theory and fuzzy number

Fuzzy set theory proposed by [29]. Fuzzy set theory helps to overcome vagueness of human, imprecise data, and uncertainty in decision making. Fuzzy set theory is used to represent mathematically human vagueness and uncertainty in decision making problem. A fuzzy set is a class of elements with continuum grades of membership. The membership value of each object lies between 0 and 1. Triangular fuzzy number is a part of fuzzy number whose membership functions are defined by three numbers [9]. Where parameter m donates the most promising value, l and u indicates lower and upper bond of fuzzy event.

The membership function $\mu_{\tilde{A}}$ is defined as

$$\mu_{\tilde{A}} = \left\{ \begin{array}{ll} 0, & x < 1 \\ (x - l/m - l)\,, & l \leq x \leq m, \\ (u - x/u - m)\,, & m \leq x \leq u \\ 0, & x > u \end{array} \right\}. \tag{1}$$

3.1 Extent Analysis for Fuzzy AHP

The extent analysis method introduced by [25]. In this paper extent analysis method is applied for supplier selection problem. In traditional AHP, nine point scale was used to determine priority of one criteria over another. In fuzzy AHP, linguistics variables and triangular fuzzy numbers are used. The fuzzy AHP based on extent analysis is applied for supplier selection problem. Let $X = \{x_1, x_2, \cdots, x_n\}$ represent object set of alternatives and $P = \{p_1, p_2, p_3, \cdots, p_n\}$ represent goal set of supplier selection. Each object is taken and extent analysis for each goal, p_1 is performed respectively [5]. Then m extent analysis value of each object can be obtained, using following signs:

$$M_{gi}^1, M_{gi}^2, \cdots, M_{gi}^m, i = 1, 2, \cdots, n, \tag{2}$$

where M_{gi}^j $(j = 1, 2, 3, \cdots, m)$ are Triangular fuzzy numbers. The steps of extent analysis method proposed by [25];

Step 1. The value of synthetic extent analysis with respect to i^{th} object is defined as

$$S_i = \sum_{j=1}^{m} M_{gi}^j \otimes \left[\sum_{i=1}^{n} \sum_{j=1}^{m} M_{gi}^j \right]^{-1}. \tag{3}$$

To obtain $\sum_{j=i}^{m} M_{gi}^j$, perform the fuzzy addition operation of m extent analysis values for a particular matrix such that,

$$\sum_{j=i}^{m} M_{gi}^j = \left(\sum_{j=1}^{m} l_j, \sum_{j=1}^{m} m_j, \sum_{j=1}^{m} u_j \right), \tag{4}$$

and to obtain $\left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{gi}^{j}\right]^{-1}$, perform the fuzzy addition operation of $M_{gi}^{j}\,(j = 1, 2, \cdots, m)$ values such that,

$$\sum_{i=1}^{n}\sum_{j=1}^{m} M_{gi}^{j} = \left(\sum_{i=1}^{n} l_i, \sum_{i=1}^{n} m_i, \sum_{i=1}^{n} u_i\right), \tag{5}$$

and then the inverse of the vector Eq. (5) is calculated such that,

$$\left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{gi}^{j}\right]^{-1} = \left(\frac{1}{\sum_{i=1}^{n} u_i}, \frac{1}{\sum_{i=1}^{n} m_i}, \frac{1}{\sum_{i=1}^{n} l_i}\right). \tag{6}$$

Step 2. The degree of possibility of $M_2 = (l_2, m_2, u_2) \geq M_1 = (l_1, m_1, u_1)$ is defined as

$$V\left(M_2 \geq M_1\right) = \sup_{y \geq x} \left\lfloor \min\left(\mu_{M_1}(x), \mu_{M_2}(y)\right)\right\rfloor \tag{7}$$

and can be equivalently expressed as follows;

$$V\left(M_2 \geq M_1\right) = hgt\left(M_1 \cap M_2\right) = \mu_{M_2}(d) = \left\{\begin{array}{ll} 1, & \text{if } m_2 \geq m_1 \\ 0, & \text{if } l_1 \geq u_2 \\ \frac{l_1 - u_2}{(m_2 - u_2) - (m_1 - l_1)}, & \text{otherwise} \end{array}\right\}, \tag{8}$$

where d is the ordinate of the highest intersection point D between μ_{M_1} and μ_{M_2}. In Fig. 1, the intersection between M_1 and M_2 has been shown.
To compare M_1 and M_2, we need both the values of $V\left(M_1 \geq M_2\right)$ and $V\left(M_2 \geq M_1\right)$.

Step 3. The degree of possibility for a convex fuzzy number to be greater than k convex fuzzy numbers $M_i\,(1, 2, \cdots, k)$ can be defined by

$$\begin{aligned} V\left(M \geq M_1, M_2, \cdots, M_k\right) &= V\left[\left(M \geq M_1\right) \text{ and } \left(M \geq M_2\right) \text{ and } \cdots \text{ and } \left(M \geq M_k\right)\right] \\ &= \min \mathrm{V}\left(M \geq M_i\right), \end{aligned} \tag{9}$$

Assume that

$$d'\left(A_i\right) = \min V\left(S_i \geq S_k\right). \tag{10}$$

For $k = 1, 2, \cdots, n;\ k \neq 1$.

$$W' = \left(d'\left(A_1\right), d'\left(A_2\right), \cdots, d'\left(A_n\right)\right)^T, \tag{11}$$

where $A_i\,(i = 1, 2, \cdots, n)$ are n elements.

Step 4. Via normalization, the normalized weight vectors are

$$W = \left(d\left(A_1\right), d\left(A_2\right), \cdots, d\left(A_n\right)\right)^T, \tag{12}$$

where W is a non-fuzzy numbers [25]. It gives the weight priority one alternative to another.

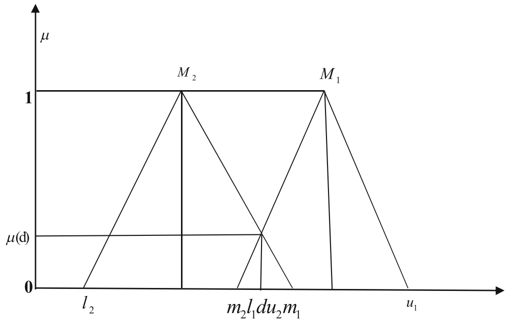

Fig. 1. The intersection between M2 and M1

4 Numerical Example

Suppose a manufacturing company wants to select supplier. Supplier selection is critical task for every company. The fuzzy AHP method is applied to select potential supplier. In supplier selection process, three suppliers have been selected for evaluation against three decision criteria. In evaluation process of supplier, each criteria is defined using linguistic judgments provided by decision makers (Table 1). The criteria is given below:

- Price: relates to product price and logistics management cost.
- Quality: relates to product durability and supporting service of quality.
- Flexibility: relates to production capacity flexibility and customization capability.

In Table 2, fuzzy pairwise comparison matrix of main decision criteria is made with respect to triangular fuzzy numbers. Fuzzy synthetic extent values Eq. (3) is used to calculate priority weight of main criteria (Fig. 2).

Table 1. Linguistic scale for supplier evaluation [13]

Linguistic variable	Fuzzy triangular number
Just equal	(1,1,1)
Equally preferred	(1/2,1,3/2)
Weakly more preferred	(1,3/2,2)
Strongly preferred	(3/2,2,5/2)
Very strongly preferred	(2,5/2,3)
Absolutely preferred	(5/2,3,7/2)

Table 2. Fuzzy pairwise comparison matrix of main attribute

	Price	Quality	Flexibility
Price	(1,1,1)	(1/2,1,3/2)	(1,3/2,2)
Quality	(2/3,1,2)	(1,1,1)	(3/2,2,5/2)
Flexibility	(1/2,2/3,1)	(2/5,1/2,2/3)	(1,1,1)

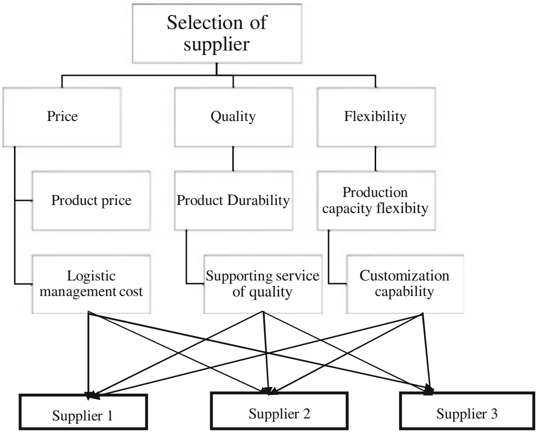

Fig. 2. Hierarchical structure of supplier selection problem

$$\text{Price} = (2.5, 3.5, 4.5) \otimes \left(\frac{1}{12.67}, \frac{1}{9.67}, \frac{1}{6.86}\right) = (0.20, 0.36, 0.66), \tag{13}$$

$$\text{Quality} = (3.17, 4, 5.5) \otimes \left(\frac{1}{12.67}, \frac{1}{9.67}, \frac{1}{6.86}\right) = (0.25, 0.41, 0.80), \tag{14}$$

$$\text{Flexibility} = (1.9, 2.17, 2.67) \otimes \left(\frac{1}{12.67}, \frac{1}{9.67}, \frac{1}{6.86}\right) = (0.15, 0.22, 0.39). \tag{15}$$

Next step is to calculate degree of possibility using Eqs. (7) and (8).

$$V(\text{Price} \geq \text{Quality}) = \frac{(0.25 - 0.66)}{(0.36 - 0.66) - (0.41 - 0.25)} = 0.89, \tag{16}$$

$$V(\text{Price} \geq \text{Flexibility}) = 1, \tag{17}$$

$$V(\text{Quality} \geq \text{Flexibility}) = 1, \tag{18}$$

$$V(\text{Quality} \geq \text{Price}) = 1, \tag{19}$$

$$V(\text{Flexibility} \geq \text{Price}) = \frac{(0.20 - 0.39)}{(0.22 - 0.39) - (0.36 - 0.20)} = 0.57, \tag{20}$$

$$V(\text{Flexibility} \geq \text{Quality}) = \frac{(0.25 - 0.39)}{(0.22 - 0.39) - (0.41 - 0.25)} = 0.42. \tag{21}$$

Table 3. Fuzzy pairwise comparison matrix with respect to price

	Product price	Logistics management cost
Product price	(1,1,1)	(3/2,2,5/2)
Logistics management cost	(2/5,1/2,2/3)	(1,1,1)

Normalized weight vector is $W_P = (1, 0)$.

Table 4. Fuzzy pairwise comparison matrix with respect to quality

	Product durability	Supporting service quality
Product durability	(1,1,1)	(1,3/2,2)
Supporting service quality	(1/2,2/3,1)	(1,1,1)

Normalized weight vector is $W_Q = (0.68, 0.32)$.

Table 5. Fuzzy pairwise comparison matrix with respect to flexibility

	Production capacity flexibility	Customization flexibility
Production capacity flexibility	(1,1,1)	(2,5/2,3)
Customization flexibility	(1/3,2/5,1/2)	(1,1,1)

Normalized weight vector is $W_F = (1, 0)$.

Table 6. Fuzzy pairwise comparison matrix of alternative with respect to product price

	Supplier 1	Supplier 2	Supplier 3
Supplier 1	(1,1,1)	(3/2,2,5/2)	(1,3/2,2)
Suupplier 2	(2/5,1/2,2/3)	(1,1,1)	(1/2,1,3/2)
Supplier 3	(1/2,2/3,1)	(2/3,1,2)	(1,1,1)

Normalized weight vector is $W_{PP} = (0.51, 0.20, 0.29)$.

Table 7. Fuzzy pairwise comparison matrix of alternative with respect to logistics management cost

	Supplier 1	Supplier 2	Supplier 3
Supplier 1	(1,1,1)	(2/3,1,2)	(1,3/2,2)
Supplier 2	(1/2,1,3/2)	(1,1,1)	(3/2,2,5/2)
Supplier 3	(1/2,2/3,1)	(2/5,1/2,2/3)	(1,1,1)

Normalized weight vector is $W_{LMC} = (0.39, 0.44, 0.16)$.

Applying Eq. (10) to calculate minimum degree of possibility:

$$d'(\text{Price}) = \min(0.89, 1) = 0.89, \tag{22}$$
$$d'(\text{Quality}) = \min(1, 1) = 1, \tag{23}$$
$$d'(\text{Flexibility}) = \min(0.57, 0.42) = 0.42. \tag{24}$$

Table 8. Fuzzy pairwise comparison matrix of alternatives with respect to product durability

	Supplier 1	Supplier 2	Supplier 3
Supplier 1	(1,1,1)	(1/2,1,3/2)	(2/7,1/3,2/5)
Supplier 2	(2/3,1,2)	(1,1,1)	(1,3/2,2)
Supplier 3	(5/2,3,7/2)	(1/2,2/3,1)	(1,1,1)

Normalized weight vector is $W_{PD} = (0.08, 0.39, 0.53)$.

Table 9. Fuzzy pairwise comparison matrix of alternatives with respect to supporting service quality

	Supplier 1	Supplier 2	Supplier 3
Supplier 1	(1,1,1)	(1,3/2,2)	(5/2,3,7/2)
Supplier 2	(1/2,2/3,1)	(1,1,1)	(2,5/2,3)
Supplier 3	(2/7,1/3,2/5)	(1/3,2/5,1/2)	(1,1,1)

Normalized weight vector is $W_{SSQ} = (0.62, 0.38, 0.00)$.

Table 10. Fuzzy pairwise comparison matrix of alternatives with respect to production capacity flexibility

	Supplier 1	Supplier 2	Supplier 3
Supplier 1	(1,1,1)	(1/2,2/3,1)	(2,5/2,3)
Supplier 2	(1,3/2,2)	(1,1,1)	(2/7,1/3,2/5)
Supplier 3	(1/3,2/5,1/2)	(5/2,3,7/2)	(1,1,1)

Normalized weight vector is $W_{PCF} = (0.41, 0.14, 0.45)$.

Table 11. Fuzzy pairwise comparison matrix of alternatives with respect to customization flexibility

	Supplier 1	Supplier 2	Supplier 3
Supplier 1	(1,1,1)	(2,5/2,3)	(1/2,1,3/2)
Supplier 2	(1/3,2/5,1/2)	(1,1,1)	(5/2,3,7/2)
Supplier 3	(2/3,1,2)	(2/7,1/3,2/5)	(1,1,1)

Normalized weight vector is $W_{CC} = (0.43, 0.42, 0.15)$.

The weight vector calculated as $W' = (0.89, 1, 0.42)$. After the normalization process, weight vector of main criteria price, quality, and flexibility was calculated $W_G = (0.39, 0.43, 0.18)$. The same procedure of calculation is used to determine priority weight of other pairwise comparison matrices (Tables 3, 4 and 5).

Therefore, supplier 1 is the best supplier for company among them because of high priority weight. The second best supplier for company is supplier 3 (Tables 6, 7, 8, 9, 10, 11 and 12).

Table 12. Summary of combined priority weights

Sub-criteria of price

Product price	Logistics management cost	Priority	Weight of alternatives
Weight	1	0	
Alternatives			
Supplier 1	0.51	0.39	0.51
Supplier 2	0.20	0.44	0.20
Supplier 3	0.29	0.16	0.29

Sub-criteria of quality

Product durability	Supporting service quality	Priority	Weight of alternatives
Weight	0.68	0.32	
Alternatives			
Supplier 1	0.08	0.62	0.25
Supplier 2	0.39	0.38	0.39
Supplier 3	0.53	0.00	0.36

Sub-criteria of flexibility

Production capacity flexibility	Customization flexibility	Priority	Weight of alternatives
Weight	1	0	
Alternatives			
Supplier 1	0.41	0.43	0.41
Supplier 2	0.14	0.42	0.14
Supplier 3	0.45	0.15	0.45

Goal of main criteria

Price	Quality	Flexibility	Priority	Weight of alternatives
Weight	0.39	0.43	0.18	
Alternatives				
Supplier 1	0.51	0.25	0.41	0.38
Supplier 2	0.20	0.39	0.14	0.28
Supplier 3	0.29	0.36	0.45	0.34

5 Conclusion

Suppler selection process is a broad and complex task for firms. In this paper, multi-criteria decision making approach fuzzy AHP has been used which includes both quantitative and qualitative criteria, to measure supplier performance. In this model, linguistic variables and triangular fuzzy numbers are used to overcome vagueness and uncertainty of decision makers. Multiple criteria helps decision makers to measure overall performance of supplier more efficiently. The advantage of this approach is that it takes less time and more accurate to solve supplier selection problem. Furthermore, fuzzy AHP model can be applied to any manufacturing company to choose best supplier. The application of this model is significantly effective and easily implement to choose best supplier.

Abstract. Location problem is a fundamental task for the cement plant enterprises. This paper mainly investigates this problem with carbon emission trading mechanism. In practice, most of cement plant location problems are multi-objective and uncertain in nature. To enhance the general practice of cement plant location problem, this paper proposes a fuzzy random bi-level multi-objective model with carbon emission trading mechanism. Genetic algorithm is used to seek the approximate best solution of the model. A numerical example is also given to show the effectiveness of the proposed model.

Keywords: Cement plant location problem · Carbon emission trading mechanism · Genetic algorithm

1 Introduction

Cement is the most widely used essential construction material which is the main component of concrete, in addition, the cement industry is one of the most intensive energy consumptions [4,5]. Cement industry has been always among the largest CO_2 emission sources. Almost 5–7% of global CO_2 emissions are caused by cement plants, while 900 kg CO_2 is emitted to the atmosphere for producing one ton of cement [3].

Along with the phenomenon that carbon emission trading is accepted by many countries, the cement industry how to make product plan and select site to get the maximum profit and customer satisfaction under carbon dioxide trading mechanism, which are one of the most significant decision-making challenges and practical significance problem. As a consequence, the cement industry worldwide is facing growing challenges in conserving material and energy resources, as well as reducing its CO_2 emissions [7]. Because of the high carbon emission by cement industry, a series of researches have been constructed to attempt to reduce carbon emissions. Benhelal [2] presented new design of pyro-processing unit in a cement

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_59

factory and proved such novelties new process can significantly reduce 66% of CO_2 emission compared to the existing process. Madlool [6] found that carbon emission reduced by using energy efficiency measures in the cement industry.

However, there are few researches about cement plant site selection problem in the traditional article. Ataei [1] used a multi criteria decision-making method to rank alternative plant locations and found the best site. The problem of location of cement plant mainly has considered the cement industry. In fact, the customers purchase-choosing behavior should been taken into account in the cement plant location problem. It is often difficult to estimate cement sale revenues because these are decided by the customers. In turn, cement industry can also have an impact on the customers purchase-choosing behavior. Therefore, the cement plant location problem is formulated as a bi-level model with two decision-makers: cement industry and customers. Because the purchase-choosing behavior among the customers is uncertain, it is more reasonable to regard the customer's demands as a fuzzy-random variable. Therefore, the objective of this study aims to develop a fuzzy-random bi-level model for cement plant location problem with carbon emission trading mechanism.

The structure of the paper is as follows. Section 2 is the problem statement part. A fuzzy-random bi-level multi-objective model for location of cement plant with carbon emission trading mechanism is introduced in Sect. 3. And then a solution algorithm for the problem based on the KKT condition and GA (Genetic Algorithm) in Sect. 4. Section 5 gives a numerical example to illustrate the application of the model. Finally, some conclusions are presented in Sect. 6.

2 Problem Statement

The problem considered in this paper is a decision making problem between the cement industry and its consumers with carbon emission trading mechanism. For cement plant location problem, because each consumer is independent individual, cement plant site selection plan is not only determined by the cement industry, but also influenced by consumers. The cement industry choose some points to establish cement plants, decide the output and sale price, and after obtaining the cement price, the consumers make their decision in an consumer optimal manner to meet their demand and achieve the goal of minimal each cost at the same time. Therefore, the cement industry influences the consumers' purchase choosing behavior by adjusting the production plan and cement sale price, whereas each consumer tries to meet their demand to make the minimal cost based on decision made by the cement industry.

This paper considers the cement plant site selection problem as a leader-follower game where the cement industry is leader and the consumers who can freely chose the cement plant to purchase cement are the followers. In this situation, the cement plant site selection problem can be represented as a bi-level problem where the cement industry is the upper-level and the consumer is the lower-level (see Fig. 1).

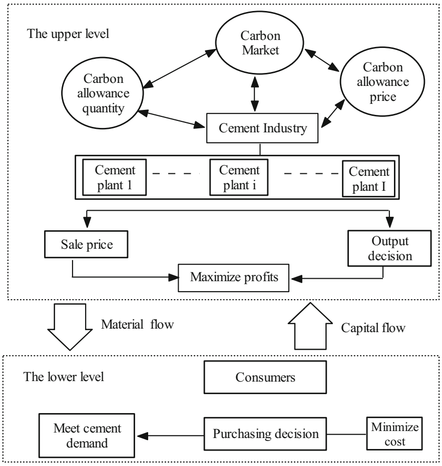

Fig. 1. The bi-level relationship between the cement plant and customers

3 Modeling Formulation

In this section, the relevant assumptions are first outlined, and then the bi-level model for the cement plant site selection problem under the carbon emission trading mechanism and considering fuzzy random is constructed. The mathematical description of the problem is given as follows.

3.1 Assumptions

To construct a model for the location problem of cement plant, the following assumptions are adopted:

(1) If customers buy cement, the cement plant must help the customer transport the cement without fee.
(2) The total alternative points is fixed.
(3) There are not any old cement plants before the new ones to be built.

3.2 Notations

The following mathematical notations are used to describe the cement plant location problem.

Index:

i: index of cement plants, where $i = 1, 2, \cdots, I$;
j: index of demand nodes, where $j = 1, 2, \cdots, J$;
n: index of cement species, where $k = 1, 2, \cdots, N$;

Certain parameters:

I: number of cement plants;
J: number of demand nodes;
N: number of cement species;
$t_j^{\max}$: the maximum tolerant transportation time of demand node j;
$t_j^{\min}$: the minimum transportation time of demand node j;
β_{n1}: the percentage of Ca in the cement n;
β_{n2}: the percentage of Mg in the cement n;
α_{i1}: the emission coefficient in product process at cement plant i;
α_{i2}: the emission coefficient in transportation process at cement plant i;
R: the initial allocated carbon allowance for cement company

Uncertain parameters:

$\tilde{\tilde{f}}_i$: the annual fixed costs for cement plant i;
$\tilde{\tilde{v}}_{i1}$: the unit variable costs for cement plant i in product process;
$\tilde{\tilde{v}}_{i2}$: the unit variable costs for cement plant i in transportation process;
$\tilde{\tilde{\eta}}$: the carbon emission quota price;
$\tilde{\tilde{a}}_{ijn}$: the unit transportation time of cement n between cement plant i and demand node j;
$\tilde{\tilde{D}}_{jn}$: the consumer j demand of cement n

Decision variables:

O_{in}: output decision of cement plant i about cement n;
u_i: the binary variable, if $O_{in} > 0$, $u_i = 1$, otherwise $u_i = 0$;
P_n: the sale price of cement n;
x_{ijn}: purchasing decision of demand node j

3.3 Upper-Level Model for Cement Plant Location Problem

It is not easy for the cement industry to make decision to get maximize profits and service satisfaction at the same time. Moreover, cement plant which is one of the major contributors to carbon emission, location problem is more meaningful to study with carbon emission mechanism.

(1) Objective Functions

In this paper, we consider cement plant which own two objectives, as the upper-level. In order to maximize economic profit, taking into account both improving the sales and saving the cost.

① Sale revenues

Cement industry revenues come from cement sales which related to the sale quantity and cement price. So the expected value of economic benefits is $\sum_{n=1}^{N} P_n \sum_{i=1}^{I} \sum_{j=1}^{J} x_{ijn}$.

② Carbon emission cost

The cement industry carbon emission comes from energy consumption for complete process and the raw material calcination process. The carbon emission by calcination process mainly from the reaction [3,8–10]:

$$CaCO_3 \rightarrow CaO + CO_2, \tag{1}$$

$$MgCO_3 \rightarrow MgO + CO_2. \tag{2}$$

From the reaction, we can calculate the carbon emission from the calcination process is: $\frac{11}{10}\sum_{n=1}^{N} O_{in}\beta_{n1} + \frac{11}{6}\sum_{n=1}^{N} O_{in}\beta_{n2}$. Approximately 50% of the total CO_2 emissions from the cement manufacturing process are released by the chemical processes and approximately 40% are released from burning fuel [10]. A minor contribution, 10%, is derived from electricity use or transport processes [11]. So the carbon emission from energy consumption includes produce processes and transport processes, i.e. $\alpha_{i1}\sum_{n=1}^{N} O_{in} + \alpha_{i2}\sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn}$. The carbon emission is limited by the government, the amount of cement industry's carbon emission would better not more than the limited standard. If initial carbon allowances allocated are sufficient, the carbon related cost is negative value, otherwise it indicates needing to buy carbon allowances. The carbon emission cost is as follows:

$$\left[\sum_{i=1}^{I}\left(\left(\frac{11}{10}\sum_{n=1}^{N} O_{ik}\beta_{n1} + \frac{11}{6}\sum_{n=1}^{N} O_{in}\beta_{n2}\right) + \alpha_{i1}\sum_{n=1}^{N} O_{in} + \alpha_{i2}\sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn}\right) - R\right] E_d(\tilde{\tilde{\eta}}). \tag{3}$$

③ Construction cost

The construction costs take into account fixed cost $E_d(\tilde{\tilde{f}}_i)$ and variable costs which are related to the cement quantity, $\sum_{n=1}^{N} O_{in}E_d(\tilde{\tilde{v}}_{i1}) + \sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn}E_d(\tilde{\tilde{v}}_{i2})$.

According to the aforementioned information, the equivalent for the total economic profits of cement industry is established as:

$$\begin{aligned} \max F = & \sum_{n=1}^{N} P_n \sum_{i=1}^{I}\sum_{j=1}^{J} u_i - E_d(\tilde{\tilde{\eta}}) \left[\sum_{i=1}^{I}\left(\left(\frac{11}{10}\sum_{n=1}^{N} O_{in}\beta_{n1} + \frac{11}{6}\sum_{n=1}^{N} O_{in}\beta_{n2}\right)\right.\right. \\ & \left.\left. + \alpha_{i1}\sum_{n=1}^{N} O_{in} + \alpha_{i2}\sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn}\right) - R\right] \\ & - \sum_{i=1}^{I} E_d(\tilde{\tilde{f}}_i) - \sum_{i=1}^{I}\left(\sum_{n=1}^{N} O_{in}E_d(\tilde{\tilde{v}}_{i1}) \sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn}E_d(\tilde{\tilde{v}}_{i2})\right). \end{aligned}$$

(2) Constraints

The cement industry will choose no more than M points from the total alternative points to built cement plant, so we have:

$$\sum_{i=1}^{I} u_i \leq M, \tag{4}$$

where u_i is decided by the cement plant output x_{ijn},

$$u_i = \begin{cases} 1, & x_{ijn} > 0 \\ 0, & x_{ijn} = 0. \end{cases} \tag{5}$$

It acquire the variable costs and fixed costs which will quickly be sank cost not more than G,

$$\sum_{i=1}^{I} \left(\sum_{n=1}^{N} O_{in} E_d(\tilde{\tilde{v}}_{i1}) + \sum_{n=1}^{N} \sum_{j=1}^{J} x_{ijn} E_d(\tilde{\tilde{v}}_{i2}) \right) + \sum_{i=1}^{I} E_d(\tilde{\tilde{f}}_i) \leq G. \tag{6}$$

3.4 Lower-Level Model for Cement Plant Location Problem

The lower-level problem represents the customers' choice behaviors and the demand of distributed among cement plants, that is to say each customer assigns his demand among the cement plants to minimize the total cost.

(1) Minimum Cost Objective

The lower-level objective is the minimum cost, it is decided by the cement price and purchase quantity, the customer's total cost is as follows:

$$\min L = \sum_{j=1}^{J} \sum_{n=1}^{N} P_n \sum_{i=1}^{I} x_{ijn}. \tag{7}$$

(2) Constraints

The purchase plan must satisfy the cement demand:

$$\sum_{i=1}^{I} x_{ijn} \geq E_d(\tilde{\tilde{D}}_{jn}). \tag{8}$$

The total purchase quantity of cement plant i is not more than the capacity of it:

$$\sum_{j=1}^{J} x_{ijn} \leq O_{in}. \tag{9}$$

3.5 Global Model

The lower-level customer choose cement plant and the amount of cement buying from it. The up-level cement industry choose some points from the fixed points to get the maximum profit and improve the service satisfactory; The customer try to influence the cement industry's decision to make their cost minimum. On the one hand, the lower cement price, the lower cost to the customer; On the other hand, the higher cement price, the higher profit to the cement industry. The location of cement plant can be represented as an game, they both can influence but can not control the other part.

The complete location problem involves the cement industry output decisions and sale price and the consumers purchase decision. Therefore, the global model includes bi-level objectives and constraints. In Noncooperative environments, we consider bi-level programming problems and it can be expressed as:

$$\begin{cases} \max\limits_{O_{in},P_n} F = \sum\limits_{n=1}^{N} P_n \sum\limits_{i=1}^{I}\sum\limits_{j=1}^{J} x_{ijn} - E_d(\tilde{\bar{\eta}}) \left[\sum\limits_{i=1}^{I} \left(\left(\frac{11}{10} \sum\limits_{n=1}^{N} O_{in}\beta_{n1} + \frac{11}{6} \sum\limits_{n=1}^{N} O_{in}\beta_{n2} \right) \right.\right. \\ \qquad \left.\left. + \alpha_{i1} \sum\limits_{n=1}^{N} O_{in} + \alpha_{i2} \sum\limits_{n=1}^{N}\sum\limits_{j=1}^{J} x_{ijn} \right) - R \right] - \sum\limits_{i=1}^{I} u_i E_d(\tilde{\bar{f}}_i) \\ \qquad - \sum\limits_{i=1}^{I} \left(\sum\limits_{n=1}^{N} O_{in} E_d(\tilde{\bar{v}}_{i1}) + \sum\limits_{n=1}^{N}\sum\limits_{j=1}^{J} x_{ijn} E_d(\tilde{\bar{v}}_{i2}) \right) \\ \text{s.t.} \begin{cases} \sum\limits_{i=1}^{I} u_i \le M \qquad i = 1, 2, \cdots, I \\ u_i = 0 \text{ or } 1, \qquad i = 1, 2, \cdots, I \\ \sum\limits_{i=1}^{I} \left(\sum\limits_{n=1}^{N} O_{in} E_d(\tilde{\bar{v}}_{i1}) + \sum\limits_{n=1}^{N}\sum\limits_{j=1}^{J} x_{ijn} E_d(\tilde{\bar{v}}_{i2}) \right) + \sum\limits_{i=1}^{I} E_d(\tilde{\bar{f}}_i) \le G \\ \text{where } x_{ijn} \text{ solve} \\ \min\limits_{x_{ijn}} L = \sum\limits_{j=1}^{J}\sum\limits_{n=1}^{N} P_n \sum\limits_{i=1}^{I} x_{ijn} \\ \text{s.t.} \begin{cases} \sum\limits_{i=1}^{I} x_{ijn} \ge E_d(\tilde{\bar{D}}_{jn}) \quad j = 1, 2, \cdots, J, \quad n = 1, 2, \cdots, N \\ \sum\limits_{j=1}^{J} x_{ijn} \le O_{in} \quad i = 1, 2, \cdots, I, \quad n = 1, 2, \cdots, N \\ x_{ijn} \ge 0 \quad i = 1, 2, \cdots, I, j = 1, 2, \cdots, J, \quad n = 1, 2, \cdots, N \end{cases} \end{cases} \end{cases} \tag{10}$$

4 Solution Approach

The proposed model (9) is a bi-level decision making problem, which reflects the interactive relationship between the cement industry and consumers. There are many algorithms available to solve bi-level programming. Therefore, the bi-level model (9) can be converted into a single level model with additional constrains by using KKT optimal conditions. So, the single level transformed from (10) by

KKT conditions is as follows:

$$
\left\{
\begin{aligned}
&\max_{O_{in},P_n} F = \sum_{n=1}^{N} P_n \sum_{i=1}^{I}\sum_{j=1}^{J} x_{ijn} - E_d(\tilde{\eta})\left[\sum_{i=1}^{I}\left(\left(\tfrac{11}{10}\sum_{n=1}^{N} O_{in}\beta_{n1} + \tfrac{11}{6}\sum_{n=1}^{N} O_{in}\beta_{n2}\right)\right.\right. \\
&\qquad \left.\left. +\alpha_{i1}\sum_{n=1}^{N} O_{in} + \alpha_{i2}\sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn}\right) - R\right] - \sum_{i=1}^{I} u_i E_d(\tilde{\tilde{f}}_i) \\
&\qquad -\sum_{i=1}^{I}\left(\sum_{n=1}^{N} O_{in} E_d(\tilde{\tilde{v}}_{i1}) + \sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn} E_d(\tilde{\tilde{v}}_{i2})\right) \\
&s.t. \begin{cases}
\sum_{i=1}^{I} u_i \le M \quad i = 1,2,\cdots,I \\
u_i = 0 \text{ or } 1, \quad i = 1,2,\cdots,I \\
\sum_{i=1}^{I}\left(\sum_{n=1}^{N} O_{in} E_d(\tilde{\tilde{v}}_{i1}) + \sum_{n=1}^{N}\sum_{j=1}^{J} x_{ijn} E_d(\tilde{\tilde{v}}_{i2})\right) + \sum_{i=1}^{I} E_d(\tilde{\tilde{f}}_i) \le G \\
\sum_{n=1}^{N} p_n - \lambda_{jn} - \varphi_{in} + \delta_{ijn} = 0, \quad i = 1,2,\cdots,I, \quad j = 1,2,\cdots,J \\
\lambda_{jn}\left(E_d(\tilde{\tilde{D}}_{jn}) - \sum_{i=1}^{I} x_{ijn}\right) = 0, \quad j = 1,2,\cdots,J, \quad n = 1,2,\cdots,N \\
\varphi_{in}\left(\sum_{j=1}^{J} x_{ijn} - O_{in}\right) = 0, \quad i = 1,2,\cdots,I, \quad n = 1,2,\cdots,N \\
\delta_{ijn}(x_{ijn}) = 0, \quad i = 1,2,\cdots,I, \quad j = 1,2,\cdots,J, n = 1,2,\cdots,N \\
\sum_{i=1}^{I}\sum_{n=1}^{N} x_{ijn} \ge E_d(\tilde{\tilde{D}}_{jn}), \quad j = 1,2,\cdots,J \\

$$

The KKT conditions switched the cement sales from a game between cement industry and consumers to single decision making problem only by cement industry. The cement industry must try to control the sale price to get more market share. The consumers make purchase decisions by the cement price that reflects the competition.

5 Practical Application and Results

In this section, a case study of a practical cement plant selection problem in Conch cement company in China is introduced to demonstrate the effectiveness of the proposed model and optimization method.

5.1 Description of Case Problem

In this part, Conch cement company is taken as an application to explore the problem. Conch cement is a listed company with more than 80 subsidiaries in 17 province in China, and the parent company is located at Anhui province.

The average sales increased rate of Conch cement is 31.01% in last three years, ranking at 471 in total 1710 listed company and ranking at (9/29) in the construction industry. At the Copenhagen climate conference in 2009, the Chinese government pledged that China would reduce carbon emissions intensity (i.e. carbon emissions per unit GDP) by 40% $\sim$ 45% based on 2005 levels by 2020. In order to achieve this target, the government has proposed policy to control carbon emission. As one of the largest company in the construction industry, Conch cement must be more cautious when deals with decision problem like cement plant selection problem with limited carbon emission allowance.

5.2 Data Collection

Conch cement industry choose some points to build new cement plants which not more than 4 points in the possible 6 points. Every cement plants produce 2 different type cement. The Ca and Mg's percentage are different in the different cement which will influence the carbon emission from natural release, is shown in Table 1. The basic information for theses possible points, such as unit variable cost in production and transportation process, maximum output, emission coefficients in the production and transportation process are show in Tables 2 and 3. There are 3 different companies need buy some cements to build road,

Table 1. The percentage of Ca and Mg in the cement n

Cement n	Ca	Mg
$n = 1$	$\beta_{11} = 12.19\%$	$\beta_{12} = 20.31\%$
$n = 2$	$\beta_{21} = 23.16\%$	$\beta_{22} = 38.59\%$

Table 2. The basic information of the cement plants

Cement plant index i	Unit variable cost in produce process $\tilde{\tilde{v}}_{i1}$ (RMB/Tone)	Unit variable cost in transportation process $\tilde{\tilde{v}}_{i2}$ (RMB/Tone)	Maximum output l_i (10^4 Tone)
$i = 1$	(165, ξ_1, 179) $\xi_1 \sim N(172, 0.0258)$	(55, θ_1, 72) $\theta_1 \sim N(57.28, 0.0127)$	195
$i = 2$	(190, ξ_2 203) $\xi_2 \sim N(195, 0.0081)$	(69, θ_2, 81) $\theta_2 \sim N(70.34, 0.0215)$	168
$i = 3$	(230, ξ_3, 258) $\xi_3 \sim N(242, 0.0195)$	(96.2, θ_3, 101.7) $\theta_3 \sim N(98.5, 0.0097)$	175
$i = 4$	(262, ξ_4, 288.75) $\xi_4 \sim N(273, 0.0347)$	(79, θ_4, 105.2) $\theta_4 \sim N(83.2, 0.0438)$	210

$i = 6$	(176, ξ_6, 227.6) $\xi_6 \sim N(187, 0.0392)$	(82.05, θ_6, 97.63) $\theta_6 \sim N(86.42, 0.0365)$	220

Table 3. The basic information of the cement plants

Cement plant index i	Emission coefficient in produce process α_{i1} (kg/Tone)	Emission coefficient in transportation process α_{i2} (kg/Tone)	Annual fixed cost $\tilde{\tilde{u}}_i$ (10^8 RBM)
$i = 1$	302.12	90.24	$(1.0542,\ \varrho_1,\ 1.4518)$ $\varrho_1 \sim N(1.0589, 0.0653)$
$i = 2$	247.95	68.98	$(2.0786,\ \varrho_2,\ 2.4776)$ $\varrho_2 \sim N(2.2318, 0.1142)$
$i = 3$	444.44	103.65	$(0.8269,\ \varrho_3,\ 0.9287)$ $\varrho_3 \sim N(0.8675, 0.0625)$
$i = 4$	362.58	78.29	$(1.8841,\ \varrho_4,\ 2.0012)$ $\varrho_4 \sim N(1.9857, 0.0929)$
$i = 5$	233.92	57.48	$(2.5987,\ \varrho_5,\ 2.7014)$ $\varrho_5 \sim N(2.6013, 0.0471)$
$i = 6$	471.12	114.78	$(1.6638,\ \varrho_6,\ 1.8247)$ $\varrho_6 \sim N(1.6959, 0.0516)$

Table 4. The information of the consumers

Consumer index$j$	The consumers' demand of cement 1 $\tilde{\tilde{D}}_{1j}$ (Tone)	The consumers' demand of cement 2 $\tilde{\tilde{D}}_{2j}$ (Tone)
$j = 1$	$(48.4,\ \zeta_{11},\ 75.12)$ $\zeta_{11} \sim N(50.6, 0.0621)$	$(11.7,\ \zeta_{21},\ 24)$ $\zeta_{21} \sim N(12.4, 0.0315)$
$j = 2$	$(95.8,\ \zeta_{21},\ 119.9)$ $\zeta_{21} \sim N(105.37, 0.0323)$	$(26.6,\ \zeta_{22},\ 42.1)$ $\zeta_{22} \sim N(31.2, 0.0519)$
$j = 3$	$(146,\ \zeta_{31},\ 170.05)$ $\zeta_{31} \sim N(156, 0.0282)$	$(54.3,\ \zeta_{32},\ 89.7)$ $\zeta_{32} \sim N(76.7, 0.0724)$

airport, house, the relative information for these consumers, such as demand for the cement are show in Table 4. The data about *ca* and *mg* percentage in Table 1 are from the Conch cement industry. Most data in the Tables 2 and 3 were estimated based on expert consultations as well as the data in Table 4. The "allocation cap" was calculated to be 849.6×10^4 Tonnes, according to the total maximum output 944×10^4 Tonnes. The allowance price is $(20, \gamma, 60)$, where $\gamma \sim N(27.5, 10.36)$.

5.3 Results and Analysis

Almost 5–7% of global CO_2 emissions are caused by cement plants, therefore, the government allocated the allowance to the cement industry by the proportion. But to ensure the efficiency of the proved model, the carbon emission allowance R considering the following 3 scenarios.

Table 5. The purchase decision of the consumers

Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)	Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)	Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)
$j = 1$	$n = 1$	$x_{111} = 0$	$j = 2$	$n = 1$	$x_{211} = 9$	$j = 3$	$n = 1$	$x_{311} = 156$

		$x_{142} = 0$			$x_{242} = 0$			$x_{342} = 0$
		$x_{152} = 0$			$x_{252} = 0$			$x_{352} = 0$
		$x_{162} = 12.4$			$x_{262} = 0.6$			$x_{362} = 0$

Table 6. The purchase decision of the consumers

Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)	Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)	Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)
$j = 1$	$n = 1$	$x_{111} = 53$	$j = 2$	$n = 1$	$x_{211} = 0$	$j = 3$	$n = 1$	$x_{311} = 25$
		$x_{121} = 0$			$x_{221} = 0$			$x_{321} = 0$
		$x_{131} = 0$			$x_{231} = 0$			$x_{331} = 0$
		$x_{141} = 0$			$x_{241} = 110$			$x_{341} = 0$
		$x_{151} = 0$			$x_{251} = 0$			$x_{351} = 0$
		$x_{161} = 0$			$x_{261} = 0$			$x_{361} = 130$
	$n = 2$	$x_{112} = 14$		$n = 2$	$x_{212} = 0$		$n = 2$	$x_{312} = 22$
		$x_{122} = 0$			$x_{222} = 0$			$x_{322} = 0$
		$x_{132} = 0$			$x_{232} = 0$			$x_{332} = 0$
		$x_{142} = 0$			$x_{242} = 33$			$x_{342} = 0$
		$x_{152} = 0$			$x_{252} = 0$			$x_{352} = 0$
		$x_{162} = 0$			$x_{262} = 0$			$x_{362} = 57$

(1) Scenario1: $R = 1 \times 10^6$ Tones

In this scenario, the allowance is controlled by the government very strict. Conch cement company should take action to decrease the carbon emission. The optimal cement price are 507.2 RBM/Tone and 700 RBM/Tone, and other optimal results are in Tables 5 and 7.

(2) Scenario2: $R = 4 \times 10^6$ Tones

In this scenario, the government allocated enough allowance to the cement company. Conch cement company can make full use of the resource. The optimal cement price are 447.29 RBM/Tone and 580.21 RBM/Tone, and other optimal results are in Tables 6 and 7.

(3) Scenario3: $R = 8 \times 10^6$ Tones

In this scenario, the government allocated more allowance to the cement company. Conch cement company can make full use of the resource and improve the cement production at the same time. The optimal cement price are 370.9 RBM/Tone and 550.21 RBM/Tone, and other optimal results are in Tables 7 and 8.

6 Policy Implications

The above results indicates that carbon emission allowance paly a important role in the cement site selection problem. When the government allocated low level allowance (i,e. 1×10^6 Tones) to cement company, it will control the output which just meet the consumers' demand, decrease the cost by limit the carbon emissions and make higher sale price; When the cement company gets medium level (i,e. 4×10^6 Tones), it will expand the scale suitably, increase the output and take lower sale price policy to improve the sale quantity; When the government allocated high level allowance (i,e. 8×10^6 Tones) to cement company, it will built more cement plants, take low price policy to arouse consumers extra demand to sale more cement.

As one of the most contributor to the carbon emission, the cement industry has different decisions with different allowance. On the one hand, building new cement plants and exploiting new market with high level allowance. The demand

Table 8. The purchase decision of the consumers

Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)	Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)	Consumer j	Cement n	Purchase decision x_{ijn} (10^4 Tones)
$j=1$	$n=1$	$x_{111}=100$	$j=2$	$n=1$	$x_{211}=0$	$j=3$	$n=1$	$x_{311}=45$
		$x_{121}=0$			$x_{221}=123$			$x_{321}=0$
		$x_{131}=0$			$x_{231}=0$			$x_{331}=118$
		$x_{141}=0$			$x_{241}=0$			$x_{341}=0$
		$x_{151}=0$			$x_{251}=0$			$x_{351}=0$
		$x_{161}=0$			$x_{261}=0$			$x_{361}=50$
	$n=2$	$x_{112}=20$		$n=2$	$x_{212}=0$		$n=2$	$x_{312}=0$
		$x_{122}=0$			$x_{222}=28$			$x_{322}=0$
		$x_{132}=0$			$x_{232}=20$			$x_{332}=30$
		$x_{142}=0$			$x_{242}=0$			$x_{342}=0$
		$x_{152}=0$			$x_{252}=0$			$x_{352}=0$
		$x_{162}=0$			$x_{262}=0$			$x_{362}=80$

of cement will increased rapidly with the expanded of population scale, the cement company need to produce more cement to meet consumers' demand; On the other hand, the cement industry will control the output or do more research to exploit new technology to decrease carbon emission in the cement produce and transportation processes. Otherwise, if the cement company increase the output without new technology, it will face huge emission cost.

7 Conclusion

In this paper, a bi-level programming model with fuzzy random variables is proposed to deal with the cement plants site selection problem with carbon emission trading mechanism. Getting total profits maximum and making the total cost minimum are the cement company (i.e. the upper) and the consumers (i.e. the lower) targets, respectively. In contrast to the previous studies, the research takes the natural release and energy consumption which includes produce and transportation process as the total carbon emissions from the cement company. To solve the complex programming model, a KKT convert technique and a multi-cut points-based genetic algorithm are taken as a solution method. Finally, the results of the case study in Conch cement plants site selection problem are proved the efficiency of the optimization model and method.

Abstract. The paper considers questions related to the formal description of concepts used in the multivariate analysis of data, as well as to the set of operations on multidimensional cubes structuring the data. Discussed are questions in regard of the effectiveness of a class of multidimensional data models, and searching ways to solve the problem of "explosive" growth in the volume of data in a multidimensional OLAP-analysis.

Keywords: Data aggregation · Data hypercube · Data mining · Data selection · Data warehouse · Multidimensional representation of data · OLAP (On-Line Analytical Processing) · Operations in data manipulation

1 Introduction

An effective control of any production process, technical maintenance, or social configuration is not possible without taking timely, well-weighted adequate decisions. The complete work on such decisions requires the responsible teams and leaders to analysis large volumes of information, and as a rule, in conditions of rush and time limitations.

In the data analysis and decision support three basic concepts are used:

- The coding and structure of data base to ensure flexible navigation through the database, targeting generation of ad hoc queries and presentation of the results in the form of various reports. Their display should be based on the topological realization of algorithms for spatial analysis;
- The multi dimensional data manipulations to allow an easy organization of aggregated information from the storage in the self-saved form of a hypercubic model. This model would provide comfortable visualization and analysis

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_60

of data. Simultaneously, in the cells of a hypercube where numeric values are stored as aggregated indicators, the measurements to allow the organization of data in accordance to its chronology, geography and to other classifications, based on the reference storage;
- The search of dependences within the accumulated information to allow the use of algorithms for intellectual data analysis.

The concept of interactive multidimensional data analysis OLAP (On-Line Analytical Processing) was proposed in 1993, by Codd et al. [2], one of the ideologists of the relational databases. It was in the form of 12 basic rules that must be satisfied by the OLAP-systems, as well as the products providing the ability to perform online analytical processing. These rules can be considered as a theoretical basis for online analytical processing. In 1995, based on the Codd's et al. set of requirements, Nigel Pendse formulated the so-called Fast Analysis of Shared Multidimensional Information (FASMI) test, defining requirements for the applications of multidimensional data analysis.

OLAP-technology is an actual and essential topic of research. Its practical results are widely applicable. In this regard, the research analysis and presentation of multidimensional data have lately become a priority in the development of methods for designing information systems and systems for information analysis. The relevance of operational support systems for multidimensional data analysis has been around, and there are already many publications in this field. Despite a long history of research, materials on the formalized description of OLAP-systems are very few. In general, the available literature concerning this subject is devoted to the concepts, technology of OLAP-system, as well as to some practical issues. There can be found a lot of information on OLAP-systems, but virtually nowhere is written and said about how it works internally. Due to this reason, the solution of most problems in the construction of OLAP-systems is mainly carried out by the method of trials and errors. Currently, there is virtually no rigorous, unified mathematical foundation for systems of multidimensional data storage and analysis, such as that which exists for relational database management systems (DBMS). Little work is available on the formal description of the mechanism of aggregation in OLAP-cubes. Until now, there is no single terminology standard about data transmission, data query language, and about the formation of OLAP-cubes. In the existing publications it is mostly proposed multi-dimensional models describing the subject studied domains. Typically, these models were built for specific tasks. Moreover, their authors are using different terminology in description of various aspects of the subject area at different stages of design and data analysis. In order to be able to compare and analyze these works, we must have a unified system for classification of multidimensional models.

A rigorous mathematical description of the concept of multidimensional data and methods for constructing multivariate models provide several advantages. First and foremost, is to simplify the design process of multidimensional models, just as the normal form simplifies the design of relational models. Mathematical description of multidimensional operations can help to build simple and clear requests at the data analysis phase. Therefore, the development of a mathematical model for multi-dimensional representation of data and methods of analysis, is currently very topical problem. This article attempts to fill this gap.

Proceeding from the aforesaid, the purpose of this paper is: Firstly, to provide a formal description of concepts used in the multivariate analysis of data, as well as many operations on the multidimensional cube, by structuring the data; Secondary, to offer a study of the efficacy of a class of multidimensional data models, and to help in finding ways to solve the problem of "explosive" growth in the volume of data in multidimensional OLAP-analysis [1,2].

2 Basic Concepts of Multidimensional Data Model

Before proceeding to a formal description of a multidimensional data model, we adopt the basic concepts of multidimensional data model. Until now, there is no generally accepted point of view for the multidimensional models of data. Despite the absence of fundamental differences in existing views, however, there are some differences in terminology. We follow the terminology described in [1,3,5–7].

Basic concepts of multidimensional data models are:

- Data Hypercube is the entity of stored information;
- Dimension: a set of objects of one or several types organized in a hierarchical structure, which provides information context for a numeric indicator. Dimensions are usually visualized as the edges of a multidimensional cube;
- Facts: components of the measurements, tags (sequence of characteristics). These are objects, the totality of which forms the measurement. Facts are visualized as points or areas, located on the axes of the hypercube. These objects should be organized in a hierarchical structure so that the objects of the same type belong to only one level of hierarchy;
- Cells: atomic structures of the cube corresponding to particular values of some indicators. Cells in the visualization are inside the cube and are used to display the corresponding values of the indices;
- Indicator (Measure): a characteristic (usually numeric), which itself can be subject of analysis. An OLAP cube can have one or more indicators.

Data hypercube may contain one or more dimensions and is an ordered set of cells. Each cell is determined by the one and only one set of values of measurement–the facts. A cell can contain data - some measure or can be empty (Fig. 1).

In typical applications of OLAP-systems, it is usually used a "basic" attitude, which is called as the table of actual values (in short a fact table). Attributes of this attitude can be perceived as separate measurements of the multidimensional space in the form of a measurements table, or cube the original data (further called the hypercube), and each train - as a point in this space. At the intersection of the axes of measurement are located the data, quantitatively characterizing the analyzed facts C the measures. Data cube (or OLAP-cube) is different from the original data cube in the following aspects:

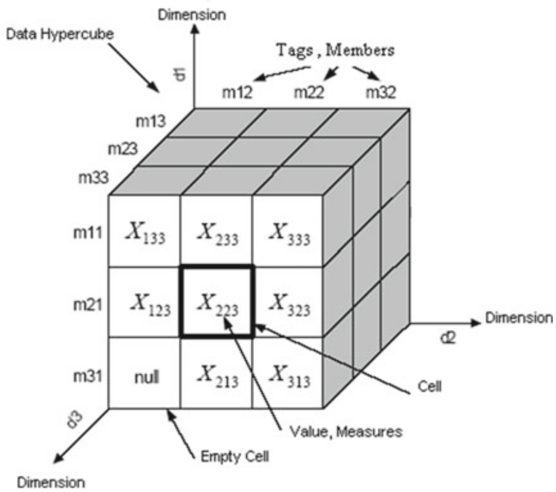

Fig. 1. An example of a data hypercube

- Along with the original data it contains information, aggregated over all subsets of measurements;
- Points in the data cube can be aggregated versions of the starting points of the original data. For example, the dimension of a "quarter" of the cube of initial data that determines the information about the progress for each quarter of a year may be reduced to the dimension of "half of a year".

3 A Mathematical Model of Multi-dimensional Representation and Data Analysis

OLAP systems represent software whose construction ideology is open towards analysis of large volume of structured information. Technology and application of class OLAP is focused on online analytical processing of multidimensional data sets, used to analyze the current and predict future activities of object management to managerial decision-making. OLAP technology simplifies the work with multi-purpose accumulated data, on the activities in decision making from the past with their extremely high volume. It also transfers sets of quantitative indicators into qualitative ones which are easy to understand. The system allows analysts, managers, and responsible personnel to form their own view on the data, using a fast, consistent, rapid access to diverse forms of information. These forms, based on primary data, allow the user to get a full picture of the activities which are subject of the control.

OLAP technology is an alternative to traditional methods of data analysis based on various systems implementation of SQL-queries to a relational database. OLAP systems play a crucial role in analysis and planning activities in the subjects of control. The analysis of data is mainly based on the requirements of decision makers to the information provided, traditionally existing individual characteristics of doing business in the objects of control, and decision-making mechanisms. From a user perspective the main difference between the OLAP systems and the Data Warehouse (DWH) systems is not technical, but in the subjected structure of the information.

The hallmark of OLAP systems is the representation of data in the form of multidimensional cubes (see e.g. [1,4]. All information about the business process is systematized, divided into categories, which, in turn, are converted to axes (measurements) of the cubes. Such an approach allows us to provide all the data in the form of two, three, or more dimensional sections of these cubes. The user can choose the sections on those or other categories, which allow combining, comparing and analyzing information in many possible directions. Moreover, each marginal direction can in turn be divided into sub-directions depending on the type of information.

Cube, this is a multidimensional database that stores two kinds of fields: measurement and evidence. Cube has a hierarchical structure which is optimized to be instantly used for immediate excerption of aggregated facts at the intersection of values (or components) of the measurements. The cube can contain pre-computed aggregates or provide special sampling data to calculate desirable units in real time. Its design provides instant performance and manipulations: data filtering, searching, changing the rules of aggregation, and more. In the sequel we consider OLAP features in detail.

Formal descriptions of terms used in the multivariate analysis of data, as well as many operations on multidimensional cubes structuring the data, we consider on the example of the data hyper-cube shown in Fig. 1.

Let consider first the algorithms for constructing a multidimensional data model to create a multidimensional database and data analysis using the mechanisms described in [1,3,5–7].

On Fig. 1 are depicted: $H(D, M)$ is the hypercube itself, i.e. plurality of cells; $V(H)$ is the set of measures; $D = \{d_{1,}d_{2,} \cdots, d_n\}$ is the set of measures; $M_{d_i} = \{m_{1_i}, m_{2_i}, \cdots, m_{k_i}\}$ is the set of measurements; - the set of labels pertinent to measurement d_i; $M = M_{d_1} \cup M_{d_1} \cup \cdots \cup M_{d_n}$ is the whole set of labels; $D' \subseteq D$ is a set of selected fixed dimensions; $M' \subseteq M$ is a set of selected fixed labels; $H'(D', M')|H' \subseteq H$ is a slice selected from the hypercube by the use of the sets D' and M'.

In order to gain access to the data, the user must specify one or more cells by selecting the measurement values (indicators), which correspond to the desired cells (the labels). This process of choosing some wished values of measurement is called fixing the facts, and the set of selected values of measurements - a set of fixed facts. The set of cells corresponding to the fixed labels and measurements is denoted as slice of the hypercube.

Hence, let $D = \{d_{1,}d_{2,} \cdots, d_n\}$ be the set of dimensions of the hypercube;

$M_{d_i} = \{m_{1_i}, m_{2_i}, \cdots, m_{k_i}\}$ is the set of labels for the measurement;
$M = M_{d_1} \cup M_{d_1} \cup \cdots \cup M_{d_n}$ is the set of facts contained in the hypercube;
$D' \subseteq D$ is a set of fixed dimensions;
$M' \subseteq M$ is a fixed array of facts.

The data hypercube consists of the array of all cells $H(D, M)$, corresponding to the sets D and M.

A subset of $H(D, M)$, corresponding to some subsets of fixed values D', M'. We denote as $H'(D', M')$.

Each cell h of the data hypercube $H(D, M)$ corresponds to only one possible set of facts measurement $M_h \subset M$. The cell can be empty (contains no data), or contains a value index - a measure.

The set of all measures included in the hypercube $H(D, M)$ is denoted by $V(H)$.

In a data hypercube one can perform either of the following operations (or manipulations) with data:

- operation "slicing";
- operation "rotation";
- operation "convolution and detail";
- operation "Data Aggregation";
- operation "sampling".

Consider these operations.

(1) The operation "slicing"
Any subset $H'(D', M')$ of the hypercube, obtained by fixing the labels from one or more dimensions, is called a slice. The operation of constructing the slice is carried out to obtain the desired subset of cells $H' \subset H$, and cutting the "unnecessary" values by successively fixing the needed tags. The slice can be interpreted as a two-dimensional array (a two-way table).

The label $m_{j_i} \in M$ specifies the hyper-plane section of a data hypercube, corresponding to an appropriate measurement $d_i \in D$. The set of fixed labels $M' \subseteq M$, thus defines a set of hyperplane intercepts (dissections) of the data hypercube corresponding to the set of fixed dimensions $D' \subseteq D$. The common intersection of these hyper-planes defines a set of cells $H'(D', M')$ is the slice of the data hypercube which is of interest to the user. The essence of the process of retrieving data from a data hypercube, thus consists in constructing a slice-a sub-hypercube of data $H'(D', M')$, by specifying the sets D', M'. Sometime, the result of this operation is called dice, and the operation itself is called dicing.

(2) The operation "rotation"
Any change in the order of presentation (imaging and visualization) of the measurements is called rotation. The rotations allow visualization of the data in forms, most comfortable for their perception.

(3) The operation "Data Aggregation" (Drill Up, consolidation, roll-up)
Data hypercube generally has hierarchies or formula-based relationships of data within each dimension. Aggregation involves computing all of these data relationships for one or more dimensions. While such relationships are normally summations, any type of computational relationship or formula might be defined. This means to get the values corresponding to the labels from a certain higher level $l, l1$ of the hierarchical dimension D based on the values from the previous lower hierarchical level $l - 1$.

Consider the hierarchical dimension D with L levels (Fig. 2). The primary data (events, facts) correspond to the lower level of the hierarchy ($l = 0$). Computation of aggregates is made in accordance with the applicable method of aggregation. In the case of summation, the values X_j^1 of the units at the level of the hierarchy $l = 1$ can be calculated by the formula $X_j^1 = \sum_{i=1}^{M_j} x_i^0$, where M_j is the number of values corresponding to the facts appearing subsidiaries to the label j.

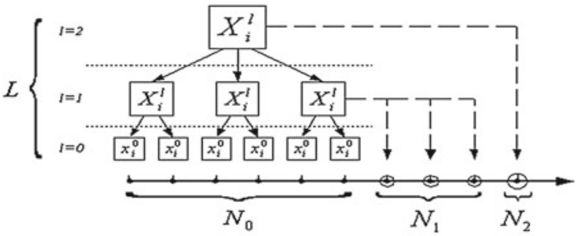

Fig. 2. Aggregation of data hypercube. One-dimensional representation

Summarizing, we obtain formulas for calculating the aggregated units according to the method of summation at other levels of hierarchy

$$X_j^l = \sum_{i=1}^{M_j} x_i^{l-1}, \quad l = 1, \cdots, L, \quad j = 1, \cdots, N_l.$$

The number of aggregated units in a data hypercube for a single measurement is $N_A = \sum_{i=1}^{L} N_i$.

Generalizing, for the case of an arbitrary number of dimensions D, for the number of aggregated units we obtain

$$N_A = \prod_{j=1}^{D} \prod_{i=1}^{L_j} N_i^j - \prod_{j=1}^{D} N_0^j,$$

where N_i^j is number of labels the i^{th} level of the hierarchy of measurements j, $l = 1, \cdots, D$, and L_j is the number of hierarchical levels of measurement j.

(4) The operation "convolution and detail" (Drill Down)
Drilling down is a specific analytical technique, where the user navigates among levels of data ranging from summarized data at higher level to more detailed data, located at lower level. This operation is carried out thanks to the hierarchical structure of the measurements. Readings (events, measurements) may be combined in a hierarchy, consisting of one or more levels. For example:

Day ⇒ Month ⇒ Quarter ⇒ Year;

Manager ⇒ unit ⇒ Region ⇒ Company ⇒ Country;

Model Car ⇒ The manufacturing plant ⇒ Country.

When going down to more and more detailed information the user is actually doing drill down.

(5) The operation "sampling"
This is a process of constructing a query to retrieve data from a data hypercube. It can be presented as a model of the network graph.

Consider the network graph $G(S, V)$ on Fig. 3, whose vertices correspond to the facts in the data hypercube $H(D, M)$. The set S of vertices consists of n subsets, or layers $S_i \subset S$. Among these are the "steps" of the user (a pattern) with which will be restricted the facts needed for the sample. The layer $S_i, i = 1, \cdots, n$ consists of specific vertices S_{j_i}, $j_i \in \{1, \cdots, |M|\}$, corresponding to facts that will be selected by the user on the i^{th} step.

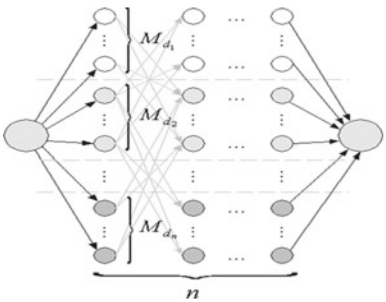

Fig. 3. Query construction

The set of edges of the graph, V, is a set of pairs of vertices $v^i_{jk} = \{s_{j_i}, s_{k_{i+1}}\}$. The edge $v^i_{jk} \in V$ of the graph, thus connecting the $j-th$ vertex S_{j_i} from the layer S_i with the $k-th$ vertex $S_{k_{i+1}}$ from the layer S_{i+1}.

The procedure for constructing a user request to retrieve data from a data hypercube $H(D, M)$ can be represented as a sequence of steps, at each of which the user captures a fact $m_{d_i} \in M$ from the measurement $\mathrm{d}_i \in D$. By fixing facts in desired dimensions, the user gets access to the cell corresponding to recorded and requested facts. The sequence of fixing a series of facts can be presented on the network graph $G(S, V)$ as a sequence of edges (paths) $w = \{v^0_{jk}; v^1_{jk}, \cdots, v^n_{jk}\}$, reflecting the process of formation of the user's query.

The initial vertex on the graph S_{0_0} corresponds to the beginning of the procedure of forming a user's query and to the absence of any fixed facts. In the first step ($n = 1$), the user fixes a fact $m_{d_i} \in M$ from the measurement $\mathrm{d}_i \in D$ of the data hypercube $H(D, M)$, and this corresponds to the vertex v_{j_i} on the layer S_1 of the graph $G(S, V)$. In the second step, the user captures a fact $m_{d_i} \in M \backslash M_{d_i}$ from the measurement $d_j \in D \backslash d_i$, since the measurement d_i has already been fixed. This procedure is performed consecutively n times, where n is the number of measurements needed to be fixed to obtain the required data slice (in general $n = |D|$).

The final vertex $S_{0_{n+1}}$ corresponds to the end of the procedure of forming a request and obtain access to the cell $h(w)$ of the data hypercube. Here w is the path selected by user's query on the graph $G(S, V)$.

In a diluted (scarce) data hypercube the requested cell $h(w)$, generally speaking, may be empty. Thus, time spent on the formation of a user query will be "wasted", because this particular query result is empty. The problem of optimizing the formation of user's queries by using step-by-step fixing facts measurement of the hypercube $H(D, M)$, is thus reduced to finding the set of paths W_{true} on a network graph $G(S, V)$, leading mainly to non-empty cells [7].

Unfortunately, the use of the described multidimensional data models and operations in the hypercube has shown poor performance on large volumes of data. For example, if the hypercube contains information about the sales in one year, and if it has only 3 measurements–Customers (250) Products (500) and Dates (365), we obtain a matrix of facts of the size $250 \times 500 \times 365 = 45625000$.

The total number of non-empty cells in the matrix can be practically only a few thousand. Moreover, the more the number of dimensions, the more tenuous will be the matrix. Therefore, to work with such matrix it is preferable to create and use special methods of processing data in sparse matrices. To solve this problem, it is possible by preliminary "cleaning" the data before to use them to build the cubes. But this approach is not always applicable. Another drawback is that the choice of a higher level of minuteness in the creation of a hypercube can greatly increase the size of the multidimensional database. Because of these, and some other additional reasons, commercially available multidimensional database management systems are not able to handle large amounts of data. It is advisable to use this multivariate model, when the size of the database is small and has a homogeneous in time set of measurements.

In contrast to the multidimensional databases, the relational management systems of databases are capable to store huge amounts of data. But they lose their advantages when compared in the speed of execution of analytical queries. When using relational database management systems, the principles for data storage are organized in a special way. The most commonly used so-called radial (or "star") pattern. In this scheme, two types of tables are used: (1) Fact table and (2) Several reference tables (dimension tables). The fact table usually contains data, the most intensively used for analysis of data in the cube. If we draw an analogy with the multivariate model, a record in the factual table corresponds to a cell in the hypercube. In the reference tables are listed all the possible values of each one dimension of the hypercube. Each dimension is described by its own lookup table. Fact table is indexed on a complex key that is built from individual keys help reference tables. It provides a link-up table with the factual by suitable sets of key attributes.

To shorten the response time in an analytical system one can use some special tools. In the composition of powerful relational database management systems there are typically included query optimizers. When creating a data warehouse based on relational database management systems, their presence is of particular importance. Optimizers analyze the request and determine the best position, in regard to some criterion, of the sequence of operations to access the database for this specific request implementation. For example, in this way one can minimize the number of physical disk accesses for the query. The query optimizers use sophisticated algorithms for statistical processing, which operate on the number of entries in the tables, ranges of keys, etc.

Each of the models described above has both, advantages and disadvantages. Multivariate model allows implementation of fast analysis of data, but cannot store large amounts of information. Relational model, by contrast, has virtually no limit on the amount of accumulated data, but such database does not provide the desirable speed in the run of analytical queries, as the multidimensional database.

4 Ways to Solve the "Explosive Volume Growth" Problem in Multidimensional OLAP

Data warehouses and OLAP analytical system are designed for analysis and synthesis of detailed data. So, they can include a full range of detailed data contained in database sources, and may increase the amount of data as a result of denormalization and duplication of detailed data. In addition, the amount of data can grow when aggregated information is added to the detailed data. This explains the rapid growth of data in the OLAP structures, as compared with the rate of increase of the volume in source databases. Often to describe this phenomenon, the experts are using the term "explosive" nature of increase of data in hypercube.

Accelerated growth of data volumes dramatically reduces the performance of multivariate analysis and limits its scalability. We have investigated various strategies to improve query performance in relational data warehouses and analytical OLAP-systems. We tried to achieve the rapid growth of the processed data and typical compact solutions without built-in mechanisms to improve system's performance and scalability. Considered were the following strategies:

- Distributing the data according to its relevance of use;
- Partitioning the storage fact table and the hypercube structure into sections and into sub-cubes of smaller size;
- Organization of parallel query processing.

The results show that the largest integrated effect on improved performance and scalability provides a combined strategy. It combines the strategies of partitioning and parallel processing of sections. While the available storage capacity increases in proportion to the number of sections in the fact table, the query performance increases by several times. It was found that the specificity of the multivariate analysis cannot directly transfer the methods for partitioning fact tables on the hypercube. This is due to the difference in the processes of indexing data in hypercube, and these in relational tables.

As noted above, OLAP-technology has emerged as an alternative to the traditional methods of data analysis based on limited and SQL-queries to a relational database. The main advantage of OLAP lies in the wide possibility of forming ad-hoc queries for analytical databases. However, our studies show that from a theoretical point of view, unlimited opportunity to form ad hoc queries to OLAP hypercube when working with the above model, under certain conditions can lead to complex problems, associated with ensuring the integrity of the multidimensional data. A similar problem arises, for example, when using the methods of the additive decomposition of a hyper-cube's structure into sub-cubes of smaller size. In such cases an ad hoc query, being addressed to the complete hypercube (as a whole), first processes the sub-cube, and the results are then consolidated into the overall result. With ad-hoc queries indexing hypercube becomes arbitrary, varies from request to request, and may contribute to errors in the procedure of consolidation in the settlement of the results from sub-cubes. We have investigated the issue and presented a new method for its solution. It eliminates data corruption, despite the non-additive indexing of additively decomposed hypercubes. The conditions for indexing data in sub-cubes were analyzed. An assertion was stated, that allows to identify any subset of undistorted data sub-set X_{sec} and the potentially faulty data subsets X'sec at the intersections of indices in the following form

$$X_{\text{sec}} \equiv X \backslash X'_{\text{sec}} = X \backslash \overset{n-1}{\underset{i=1}{U}} \big(\underset{i<j\leq n}{U} (X_i I X_j) \big),$$

here n is the number of decomposed sub-cubes, and X is a notation for the original hypercube:

$$X = X_{\text{sec}} \cup X'_{\text{sec}};\ (X_{\text{sec}} | X'_{\text{sec}} = \emptyset).$$

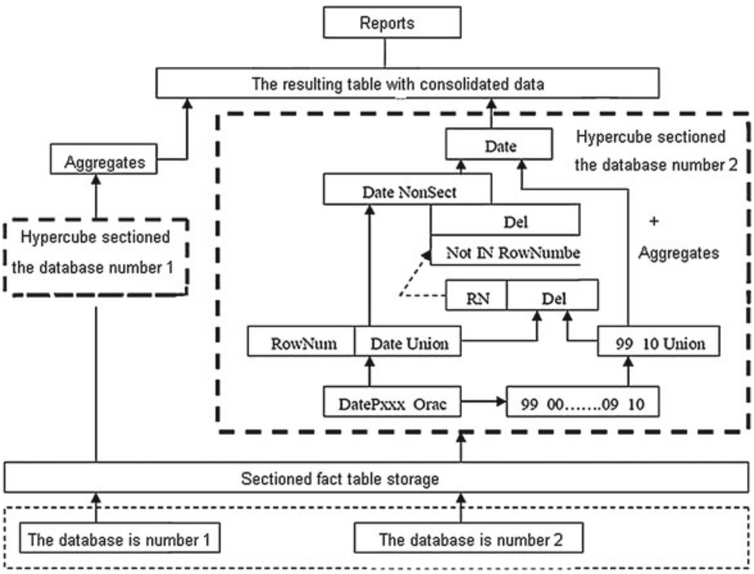

Fig. 4. The structure of the algorithm of multidimensional data aggregation

In accordance with the obtained by us conditions for the algorithm of multi-dimensional data aggregation, the overall structure is shown in Fig. 4.

The developed algorithm is tested in the solution of specific applications. It allows the use of a convenient way for additive decomposition of hyper-cube's structure in cases of ad hoc requests from users, resulting in non-additive indexing of the data in the hypercube.

5 Example

As an example, consider the formation of OLAP-cube based on existing relational fact table sales from managers, M1, M2 and M3 cars Nexia, Tico and Damas in the years of 2007, 2008 *and* 2009. To do this, it is needed to select the values of all measures and carry out the aggregation of all the obtained values, and record it in the cube. Consider the application of the obtained models on the example of a cube with 3 dimensions (Fig. 5).

Here measurements are: the model made of cars (products, a categorical variable), the sale person (manager, another structural attribute), and the year of production (time dimension), i.e. this is the triplet C, M, T;

Facts are: Model car (Nexia, Tico, Damas), labeled as (N, T, D); Managers (Manager 1, Manager 2, Manager 3) labeled as $(M1, M2, M3)$; The time (year) recorded $(2007, 2008, 2009)$ labeled as $(Y4, Y5, Y6)$;

Measures are: the volume of sales $(7, 7, 4, etc.)$.

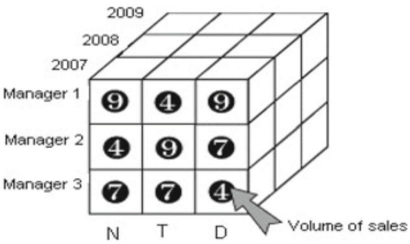

Fig. 5. A cube with three dimensions

In our example we have:

The set of dimensions of the hypercube is $D = C, M, T$;

The set of labels for the measurement d_i: $M_C = \{N, T, D\}$, $M_M = \{M1, M2, M3\}$ and $M_T = \{Y4, Y5, Y6\}$.

In this example each value in the field of sales is uniquely determined by a combination of fields: Model car, Manager, Year of sale. The indicator is the sales volume, located in the cell of the intersection of specified dimension of each kind.

Consider the application of operations to manipulate dimensions:

(1) Formation of a "Slice"
If we limit the value "dimensions of a model car" = "Nexia GL", then we obtain a subset of the hypercube (in our case - two-dimensional table) containing information about the history of sales of this model by different managers in different years. This is the content on the left wall of the cube on Fig. 5.

(2) Operation "Rotation"
This operation provides the ability to visualize data in a manner most comfortable for its perception. Rotating consists of swapping the rows and columns. For example, by changing the Measures of Products down on front X-axis by the Time measure across the side Y-axis into a report, an entirely new vision of the data hypercube on Fig. 4 will be obtained. This will be equivalent to a rotation in 90° counter clock wise along the Z-axis (the managers).

(3) Operation "Aggregation"
To get the sales for each car model and for each year, we need to accumulate the numbers in the cell of each column for all the managers. To get the total sales of each manager throughout the years we need to add his/her results for each car model for all years. This is aggregation.

From user's perspective, in a larger dimension hierarchical model Division, Region, Company, Country is exactly the same kind of measurements as the manager is. But each of these added dimensions would correspond to a new, higher level of aggregated values of the index "volume of sales". In the process of analysis the user works not only with a variety of data slices and performs their rotation, but also moves from detailed data to aggregated, i.e. applies the operation Aggregation. For example, after noticing how successfully Manager 1 sold the models of "Nexia" and "Tico" in 2007, his supervisor may want to see how looks its relationship with the sales of these models at the unit level, where Manager 1 works. And after that the supervisor may want to obtain a similar certificate for the Region or firm.

(4) Operation "Detailization"
The transition from aggregated to more detailed data is the operation "Detailization". For example, beginning the analysis at the level of total sales through all the years, the supervisor may wish to obtain more precise information about specific local sale in a year and by a $Manager$.

(5) The "Sampling"
To construct a query to retrieve data from the data hypercube presented on Fig. 4 a user need to select a sequence of addresses (vertices of an associated graph) of cells whose content are required in the sample. For instance, the choice $(N, M2, Y5) \Rightarrow$ (T, M3, Y4) $\Rightarrow (T, M1, Y6)$ will retrieve the content of the corresponding cells on the display in this order.

6 Conclusions

It is shown that the use of the conventional multidimensional data models and operations in the hypercube does not provide the desired speed performance on large volumes of data. This problem can be solved by pre-treatment of data before to use them to build the data cubes. Another drawback is that the choice of a high level of detail in the creation of a hypercube can significantly increase the size of a multidimensional database. Because of these and some other reasons, commercially available multidimensional database management systems are not able to handle large amounts of data. It is advisable to use a standard (conventional) multivariate model, if the size of the database is small and has a homogeneous set of measurements. Largest integrated effect of improved performance and scalability provides a combined strategy that combines partitioning and parallel processing sections. Then the available storage capacity increases in proportion to the number of sections in the fact table, and query performance increases by several times.

It was found that the specificity of the multivariate analysis cannot immediately transfer the methods for partitioning the fact table on the hypercube. This is due to the difference in the processes of indexing data for hyper-cubes, and for relational tables.

Abstract. This article focuses on the monitoring of a wind farm in real time based on big data collected by Supervisory Control and Data Acquisition (SCADA) system. The decision-making of the type of maintenance to be applied can be insured by SCADA system. This system generates alarms based on the collected data. False alarms cause false interventions by the maintenance team resulting in loss of production and costs. The reduction of these false alarms makes it possible to contribute better to the management of the maintenance of the wind farm. In this paper, we propose a new approach for the identification of alarms by Fuzzy Logic based on the data collected by the SCADA system. The alarms generated in this case can be divided into two categories: orange alarms corresponding to faults requiring the intervention of preventive maintenance and red alarms corresponding to critical states that can cause system failures.

Keywords: Wind farm · Monitoring · SCADA · Alarms · Fuzzy logic approach

1 Introduction

The generation of electricity through wind energy systems is demanded by the industry in order to increase the competitiveness of the business. The maintenance of these systems becomes very complex because the stochastic city of the random loads can cause catastrophic failures [3,12]. The optimization of the maintenance planning is a crucial factor for the efficiency of the wind farms [15]. With this purpose, wind turbines (WT) can be monitored by SCADA or condition monitoring systems to detect failures [13,14], risks and to take necessary actions online [8]. Several studies have proved the efficiency of this systems in the WTs [9] and other types of industries [7,13,19].

False alarms generated by SCADA system are a important problem because they cause unnecessary stops, false interventions by the maintenance team, loss of production and, consequently, extra costs [11,17,18]. Some studies aim to

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_61

eliminate false alarms of WTs [5]. Chen et al. [5] present a study on the treatment of SCADA using an artificial neural network 'ANN'. Qiu et al. proposes two methods (sequential and probabilistic) for the analysis of alarms for two large onshore wind farms considering the defects of pitch and converter systems [20].

This paper proposes a new approach based on fuzzy logic for controlling wind farms considering the big data collected by SCADA system, and give a complementary response to strengthen the response of the SCADA. Figure 1 shows the general structure of a fuzzy system [1].

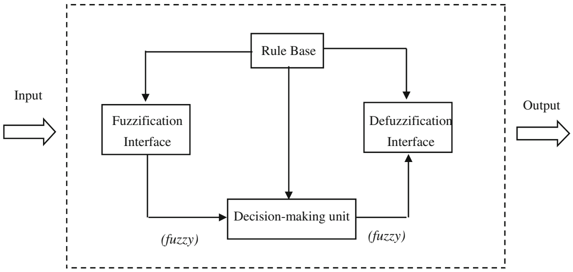

Fig. 1. Basic configuration of a fuzzy logic system

In the fuzzification part, any numeric value of the input data is converted into a linguistic value between 0 and 1. The fuzzy system requires functions for each input data:

- Input (1): Variable (1). Subsets: low, average and maximum.
- Input (2): Variable (2). Subsets: low, average and maximum.
- Input (3): Variable (3). Subsets: low, average and maximum.
- Input (n): Variable (n). Subsets: low, average and maximum.

Fuzzy inference is a method that interprets the values in the input vector and, based on fuzzy rules, assigns values to the output vector [16]. With this purpose, it is necessary to stablish the rules that will perform the defuzzification process to provide the output. The Fuzzy rules (IF antecedent THEN consequent) in expert system are usually is following [10]:

IF Var(1) is $A11$ and/or Var(2) is $A21, \cdots$ THEN y is $B1$
else
IF Var(1) is $A12$ and/or Var(2) is $A22, \cdots$ THEN y is $B2$
else

IF Var(1) is $A1n$ and/or Var(2) is $A2n, \cdots$ THEN y is Bn
where $\mathrm{Var}(1), \mathrm{Var}(2), \cdots, \mathrm{Var}(n)$ are the fuzzy input (antecedent) variables, y is a single output (consequent) variable, and $A11, \cdots, A1n$ are the fuzzy sets [5]. Generally, there are n input variables consisting of 3 fuzzy linguistic variables. Therefore, a total of 3^n rules will provide all possible combinations of the input variables.

Defuzzification is the process of producing a quantifiable result given fuzzy sets and corresponding membership degrees. There are many types of defuzzification methods, usually maximum membership and centroid techniques are used [22].

2 Methodology Proposed

In this paper, a novel methodology is presented to make an original treatment of the SCADA dataset. The flowchart of the methodology proposed is shown by Fig. 2.

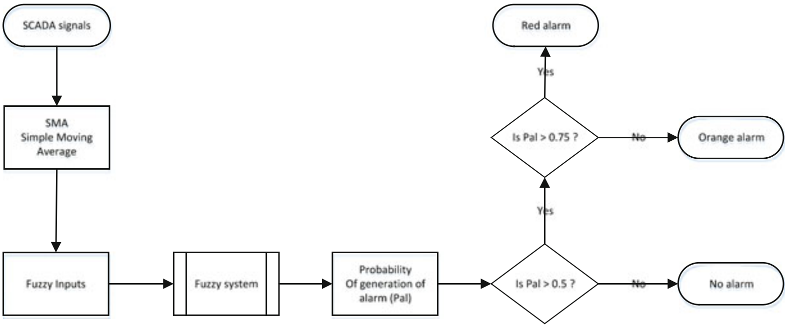

Fig. 2. Alarm identification flowchart

In the diagram adopted for the identification of alarms, it is integrated the real data collected by SCADA system with the fuzzy system. With this purpose, the SCADA data will be preprocessed before of being inputted in the fuzzy system. This preprocess starts with the evaluation of the simple moving average (SMA) of the SCADA signals. Then, the difference between the signals and the SMA is calculated. These differences will be used as input vectors for the fuzzy system.

Once the new variables have been obtained, the next step is to establish some control laws for them. The new variables will be analyzed statistically to obtain two thresholds. These thresholds will separate the graph into three different regions. Figure 3 shows the definition of the thresholds and the regions (good, acceptable, unacceptable) considered

This classification allows for determining the member functions of the inputs of the fuzzy system and generate the fuzzy system. The control of each physical parameter collected by SCADA can be represented by the difference between the values of all the peaks and the mean value. The fuzzy inference system is based on different rules to generate the occurrence probabilities of the alarms in the output.

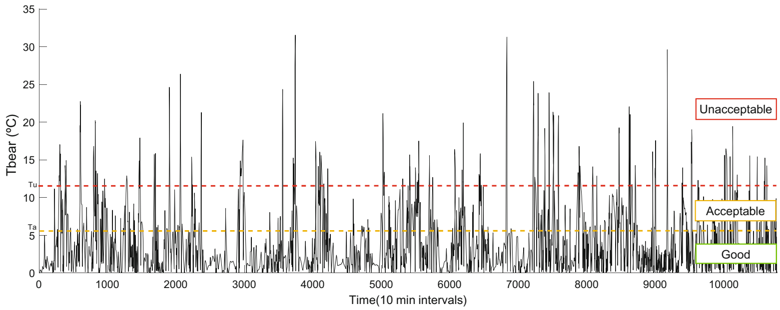

Fig. 3. Classification for member functions

3 Real Case Study

The data considered for this real case study is obtained from the European Project entitled OPTIMUS [4]. The database used in this paper come from a SCADA system that provides different measures every 10 min in the period from 01/01/2015 to 28/03/2015. The system measure 37 physical variables, but in this paper only 4 parameters have been considered to simplify the example. These parameters correspond to the speed of main shaft (Vel), vibration at the main shaft (Vibr), oil temperature (Toil) and bearing temperature (Tbear). Figure 4 shows these parameters.

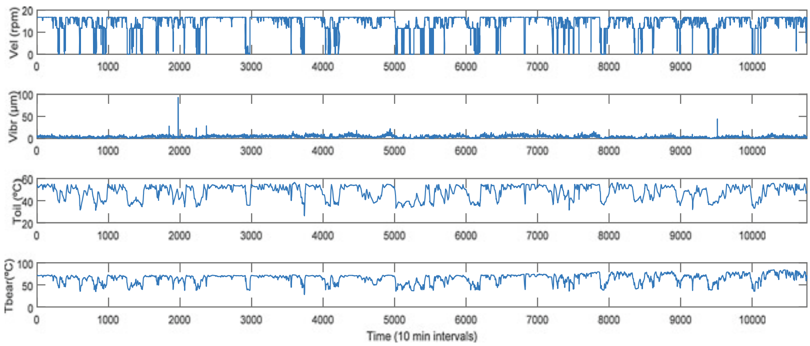

Fig. 4. Evolution of real data in time

Figure 5 shows the preprocessing of the variable Tbear before of being inputed in the fuzzy system. The blue line corresponds to the “Temperature of bearing (Tbear)”. The red line evaluates the moving average (MA) calculated for a period of 2 h. The black line represents the absolute value of the difference blue and the red line. This new variable will be named “Difference of Tbear” and noted (DTbear).

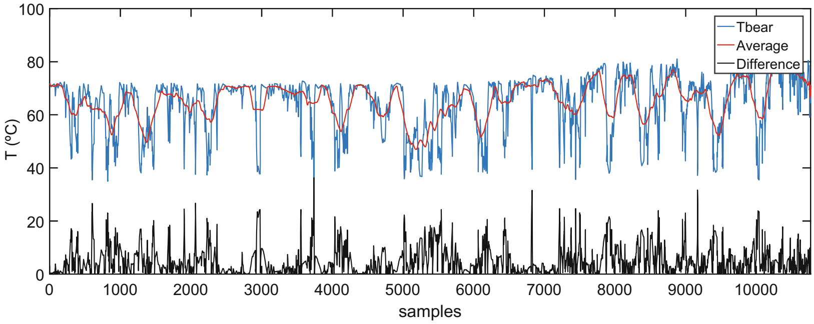

Fig. 5. Preprocessing of SCADA signals

The same procedure will be applied to the rest of variables. The new variables will be obtained by the following equations:

$$\begin{aligned}
\mathrm{Dvel} &= \mid \mathrm{Vel} - \mathrm{SMA}(\mathrm{Vel}) \mid, \\
\mathrm{DVibr} &= \mid \mathrm{Vibr} - \mathrm{SMA}(\mathrm{Vibr}) \mid, \\
\mathrm{DToil} &= \mid \mathrm{Toil} - \mathrm{SMA}(\mathrm{Toil}) \mid, \\
\mathrm{DTbear} &= \mid \mathrm{Tbear} - \mathrm{SMA}(\mathrm{Tbear}) \mid .
\end{aligned}$$

Consequently, Fig. 4 will be transformed to Fig. 6, considering the new variables.

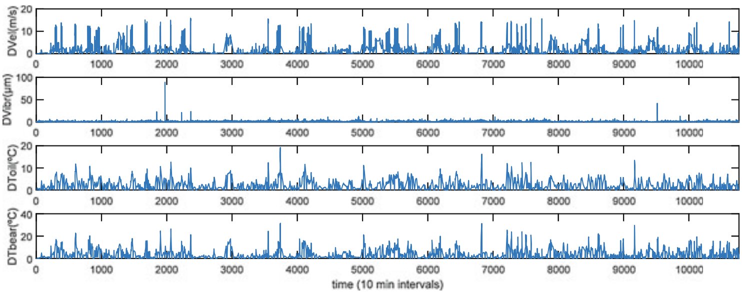

Fig. 6. Evolution of real data in time

For stablishing the different thresholds pointed in Fig. 3, a maximum value have been assigned to each input considering several norms and standards [2,6,12,21]. These values correspond to:

- max(Rotor velocity) = 20.2 rpm.
- max(Vibration) = 115 μm, max(Temperature of oil) = 95 °C.
- max(Temperature of bearing) = 110 °C.

Thus, some of the rules defined in this example are:

- IF DVel is good and DVibr is good and DToil is good and DBear is good THEN the output is green.
- IF DVel is good and DVibr is acceptable and DToil is unacceptable and DBear is Good THEN the output is red.
- IF DVel is unacceptable and DVibr is good and DToil is unacceptable and DBear is unacceptable THEN the output is red.
- If DVel or DVibr or DToil or DBear is unacceptable then the output is red.

More rules of the Fuzzy system are presented graphically in the Fig. 7:

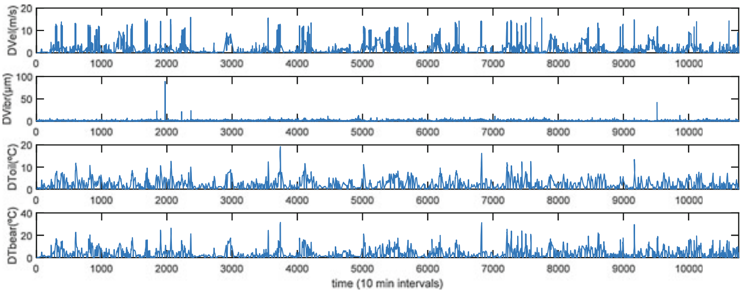

Fig. 7. Rule based Fuzzy Inference System for generation of probabilistic alarms

The red line of each variable shows the value of the variable. The displacements to the left or the right of these lines generates a new position of the output, and therefore, a new probability of alarm. Once, the fuzzy system is defined, it is possible to represent surfaces that explain the behavior of the system under different conditions. For example, Fig. 8 represents the probability of alarm depending on DTbear and DVibr.

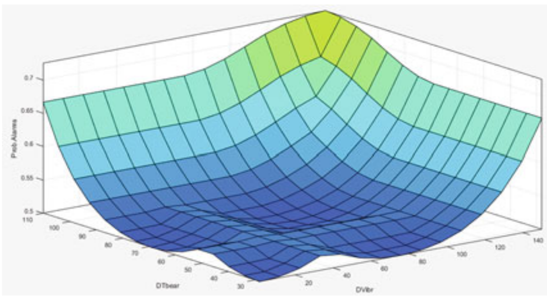

Fig. 8. Surface view of alarms probability with respect to DTbear and DVibr

It is noted that the probability varies proportionally with the temperature of the bearings and the vibration. For values of DTbear and DVibr respectively less than certain value, the probability has very minimal values, in opposite, the probability of alarm increase exponentially when these values are exceeded.

The system built has been proved by performing a simulation with the SCADA data. The results of the simulations are shown in Fig. 9. The system provides a certain probability of alarm regarding to the inputs.

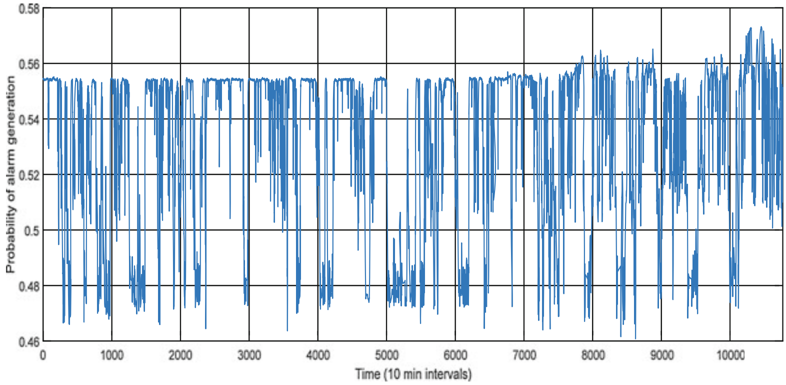

Fig. 9. Probability of alarms generation

A total of 10768 inputs have been analyzed through the created fuzzy system. The outcomes are:

- 10407 normal measures. This represent the 96.7% of the total data.
- 361 orange alarms. This represent a 3.3% of the total data.
- No red alarms. In the period studied there is not any value exceeding the limits of critical alarm.

This method allows to transform the data collected by the SCADA system into probability of alarms. It can be a useful information for complementing the decision making. The methodology can aid to reduce false alarms because when a critical alarm arises from the SCADA system, the response of the fuzzy system can reinforce that alarm.

4 Conclusions

In this paper, a new methodology based on fuzzy logic is proposed in order to analyze the SCADA data and provide an alternative decision support. The main purpose is to process the signals collected by the SCADA system from a different perspective. These signals are converted into new variables to be inputted in the fuzzy system. A fuzzy system has been created using several standards and considering the signals of the SCADA system from a statistical point of view. The creation of the fuzzy systems implies the definition of a set of fuzzy rules.

In this case, the variables considered correspond to the distance of the value measured by the SCADA to the simple moving average. The more distance to the average, the more probability of being an abnormal measure, and therefore, the more probability to generate an alarm.

Three different outcomes of the fuzzy system have been considered. Firstly, the values are in range of normal behavior and no actions are required. Secondly, orange alarms where the probability of alarm reaches exceeds a defined threshold but it is not a critical point. Finally, red alarm when the probability is unacceptable and the system need an urgent action.

The results of this methodology can become a statistical support for the generation of alarms. The methodology can be also used as a complementary information for evaluate the priority of each alarm.

On Causal Analysis of Accident and Design of Risk-Proof Procedure for Nuclear Materials Operation: The Case of JCO Accident

Sachiko Oshima(✉)

Faculty of Science and Engineering, Waseda University, Tokyo, Japan
oshima.sachiko@aoni.waseda.jp

Abstract. This paper aims to examine a risk-proof procedure for nuclear materials operation through the causal analysis of JCO accident in 1999. Nuclear chain reactions are, by now, commonly used in the nuclear reactors, and thus it seems that there is no basic problem in fission processes from the scientific point of view. However, the criticality accident that occurred in JCO suggests that one should carefully examine this accident from the nuclear physics point of view. Indeed the nuclear chain reactions should have taken place in the small area of sedimentation tank. In fact, when people carry the uranium nitrate solution into the tank, then this solution with uranium should get into the critical state at given uranium nitrate solution. The root cause of the accident should not be very simple from the nuclear physics point of view, and it should be quite important to examine why the uranium nitrate solution could have become critical. Based on the analysis result, this paper also proposes the conditions for the operation without criticality accident which leads to serious damage of workers' life.

Keywords: Risk management · Operation system design · Nuclear fission · Criticality accidents

1 Introduction

In this paper the contents and/or expressions of the previous paper published by the first author [8] is reused for readers' convenience and understanding. The criticality accident that occurred in JCO company in 1999 (called Tokai-mura JCO-rinkai-jiko) in Japanses must be most serious, and it should not be very easy to understand why the nuclear chain reactions could proceed in a small area of sedimentation tank for a finite period of time. In this sense, it should be quite important to carry out the careful examination of criticality accidents from the nuclear physics point of view. It should be, of course, difficult to claim that the JCO accident can be a target of the scientific study as it is impossible to make the experimental study of the JCO type accidents. However, we believe

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_62

that the basic mechanism of the criticality accident should be clarified why it could naturally occur in the small area.

Here, we explain briefly the theoretical examination of the criticality accident, which are carried out in terms of the multiple scattering theory, and we show why the nuclear chain reactions can proceed in the small area [8]. In particular, the nuclear fission reactions (nucleon-nucleon collision together with nuclear fission) is traced each by each, and the microscopic processes why and how the criticality accident occurred is clarified. As a result, this paper provides some specific reasons why the chain reactions can proceed, and this can be done by making use of the mean free path which is the result of the nuclear multiple scattering theory.

When the causal event of this criticality accident is identified, another question as to why the criticality stop must be analyzed. This study tries to find an answer for this question, though not necessarily sufficient. This mechanism of stopping criticality may be related to the quick settle of the uranium compound. The calculation of this paper tells a possible dangerous situation which was thought to be due to the eighth batch, if it were carried into the sedimentation tank. The estimated energy release after the virtual eighth batch should become the same order of magnitude as the Chernobyl nuclear accident.

Finally, a procedure is designed to prevent in advance criticality accidents from the standpoint of three manufacturing resources that is Human, Machine and Material [11], grounded in the above physical theoretical discussion.

2 Research Background

2.1 Nuclear Chain Reactions

Nuclear fission reaction by incident neutrons can be written as Bohr et al. [1].

$$n + {}^{235}U \rightarrow A_1 + A_2 + (2 \sim 3)n, \tag{1}$$

where A_1, A_2 are new nuclei which are produced in the reactions. In this reaction, there are two important points. The first one is concerned with two or three neutrons which are produced in the reactions. The second point is that the probability of this nuclear reactions is strongly based on the incident neutron energy, and the biggest cross section is for the incident neutron with almost zero energy (thermal energy).

The chain reactions indicate that the produced neutrons should be absorbed by another ${}^{235}U$ such that the nuclear fission can proceed further on. In addition, if the chain reactions continue to proceed without the aid of other external neutron sources, then this situation is called a criticality stage. In reactors, this criticality must be kept by controlling the number of neutrons involved in the chain reactions.

In normal reactors, a few percent enriched uranium (${}^{235}U$ exists a few percent of total amount) should be commonly used, but in this JCO accident, 18.8% enriched uranium were used, and this high enrichment should be one of the strong reasons why the nuclear reactions run wild.

2.2 JCO Criticality Accident

This criticality accident occurred when workers in JCO were carrying the uranium nitrate solution (18.8% enriched uranium) into sedimentation tank [5,9,10]. They executed the following procedure. First, they made the uranium nitrate solution which was composed of 2.4 kg U_3O_8 with the nitric acid of 1.7ℓ in the stainless vessel. In addition, they add water to the uranium nitrate solution until the total volume became 6.5ℓ. Then, they carries the 6.5ℓ solution into the sedimentation tank, and this working procedure was called one batch. The criticality accident should have occurred in the middle of the seventh batch since the workers noticed blue lights that should be due to the Cherenkov radiation. In fact, two of the workers suffered from the neutron radiation.

A question should arise as to how the nuclear chain reactions could proceed within the small sedimentation tank (45 cm diameter, 60 cm high). There are, of course, some analyses of this criticality accident [10]. However, these studies are mainly carried out by the computer simulation such that the total energy emitted via radiations can be reproduced in some way or the other. These investigations are, of course, very important in order to understand the accident cause. However, it is also important to carry out the study of the criticality accident from the nuclear physics point of view.

3 Causal Analysis of JCO Case

3.1 Why Criticality?

Now, a question is as to why the criticality is realized in the small area of the sedimentation tank with 50ℓ of the uranium nitrate solution. That is, why nuclear chain reactions continue to occur in this small area. Here this section clarifies the basic mechanism of the criticality accident.

(1) Neutron source

The nuclear chain reactions should require thermal neutrons to start for the initial fission reactions. Since neutrons should decay within 15 min, they do not exist as a natural source. Neutrons should be produced in some way or the other. Here in this accident, the neutron source should be the decay of ${}^{238}U$ spontaneous fissions. The life time of ${}^{238}U$ is about 4.5 billion years and, in addition, the rate of the spontaneous fission to the total width is around 5.45×10^{-7}. Therefore, 1 gram weight of ${}^{238}U$ make the spontaneous fission of 0.01 times per second. Since one batch contains 1.6 kg of ${}^{238}U$, we should find about 20 neutrons per second in the one batch solution.

(2) Mean free path of $n - {}^{235}U$ fission (fast neutrons)

The probability of nuclear fission of ${}^{235}U$ induced by neutrons should be evaluated in terms of mean free path of λ inside the uranium nitrate solution. This mean free path of nuclear reactions can be obtained from the multiple scattering theory as

$$\lambda_f = \frac{1}{\rho \sigma_f}. \tag{2}$$

This derivation of the mean free path (2) is based on the Glauber theory [4], and this theoretical frame work is well examined in atomic and nuclear reactions [2,3]. Here, ρ denotes the number density of ^{235}U in solution and σ_{f} corresponds to the nuclear fission cross section of ^{235}U induced by neutrons. In fact, the number density of ^{235}U in one batch solution is $\rho \approx 1.5 \times 10^{20}$ numbers/cm^3 which is a constant. On the other hand, the nuclear fission cross section σ_{f} of ^{235}U induced by neutrons crucially depends on the incident energy of neutrons. The incident energy dependence of the observed cross sections σ_{f} can be written as [7].

$$\sigma_f \approx \begin{cases} 585\mathrm{b}: & E_n \approx 0.025\mathrm{eV} \\ 1\mathrm{b}: & E_n \approx 1\mathrm{MeV}, \end{cases} \tag{3}$$

where $1\mathrm{b} = 10^{-24}$ cm^2.

(3) Mean free path of prompt neutrons in nuclear fission

In fission process, the average energy of prompt neutrons is around 1 MeV, and therefore the average mean free path of the prompt neutrons after fissions becomes

$$\lambda_f = \frac{1}{\rho\sigma_f} \approx 67 \text{ m}. \tag{4}$$

This is quite long in comparison with the scale of the tank, and therefore this prompt neutrons by themselves cannot induce subsequent fissions in corresponding solution in the tank. In this respect, we ask a question as to why the criticality should take place within the small sedimentation tank.

3.2 Collision Between Neutrons and Water Molecule

In reality, the prompt neutrons may collide with protons in water molecule, and they should lose their energy by nucleon-nucleon collisions. Since the nuclear fission cross sections become largest for the thermal neutrons, the fission processes should start in case the prompt neutrons lose most of their energy inside the uranium nitrate solution.

(1) Energy Loss after the Collision of Prompt Neutrons with Protons in Water

When the prompt neutron scatters with protons in water, this neutron should lose a half of its energy. This can be easily understood in the following way. First, we denote the incident momentum and energy of the neutron by p, $E_n(= p^2/2M)$, and the final momentum and energy by k, $\mathrm{E_n}'$ with $E_n{}'(= k^2/2M)$. In this case, we find an equation from the conservation law of momentum and energy as

$$\frac{P^2}{2M} = \frac{k^2}{2M} + \frac{(p-k)^2}{2M}, \tag{5}$$

which can be solved and its solution becomes

$$k = p\cos\theta. \tag{6}$$

Since the observed scattering cross section does not depend on the scattering angles, we can make an average over the angles, and we obtain the average energy after the scattering

$$E_n{}' = \frac{1}{\pi}\int_0^{\pi} \frac{k^2}{2M} d\theta = \frac{1}{\pi}\int_0^{\pi} \frac{p^2}{2M}\cos^2\theta d\theta = \frac{1}{2}E_n. \tag{7}$$

This means that a neutron should lose a half of its energy in each scattering process.

(2) The Mean Free Path of Neutrons inside Water

Now we calculate the mean free path of neutrons after the scattering with protons in one batch solution. The number density of protons in one batch solution is $\rho_p \approx 4.9 \times 10^{22}$ numbers/cm^3. The neutron-proton cross section at low energy is observed as $\sigma_{np} \approx 20b$ [6] and thus the mean free path of neutron in one batch solution becomes

$$\lambda_p = \frac{1}{\rho_p \sigma_{np}} \approx 1\text{cm}. \tag{8}$$

Therefore, a prompt neutron with 1 MeV energy should have its energy after it travels around 25 cm,

$$E_n{}' = 1\text{MeV} \times \left(\frac{1}{2}\right)^{25} \approx 0.03\text{eV}. \tag{9}$$

This neutron does not have to travel linearly, but in any case, it should become a thermal neutron.

(3) Mean Free Path of Thermal Neutron in the $n - {}^{235}U$ Fission Process

We can easily calculate the mean free path of the thermal neutron before the nuclear fission in one batch solution. Since $\sigma_f = 585$b, we find

$$\lambda_f = \frac{1}{\rho \sigma_f} \approx 11 \text{ cm}. \tag{10}$$

From these considerations, we see that prompt neutrons with 1 MeV should travel around 25 cm, and then they become thermal neutrons. Further, after they travel 11 cm, they can induce nuclear fissions. Thus, if one carries 50ℓ of the uranium nitrate solution into the sedimentation tank with 45 cm diameter and 25 cm height, then nuclear chain reactions may well start quickly and proceed further on.

(4) Reaction Time of Neutrons

Now we see that when prompt neutrons travel 36 cm, then they can induce nuclear fissions. Therefore, we should estimate the duration time that is necessary to travel this 36 cm. Since the nuclear reaction time must be smaller than 10^{-15} second, we can ignore this time duration. Since the prompt neutron with 1 MeV should spend $\tau^0 \approx 7.6 \times 10^{-10}$ second to proceed 1 cm, its energy becomes a half of the previous energy after 1 cm walk. Therefore, the time to proceed the next 1 cm becomes larger by a factor of $\sqrt{2}$. In this way, if the prompt neutron proceed 25 cm, then the total time to spend must be

$$T_0 = \left(1 + \sqrt{2} + \cdots + 2^{\frac{25}{2}}\right) \tau_o \approx 15\,\mu\text{s}. \tag{11}$$

After that, this neutron becomes thermal, and it should proceed 11 cm before the nuclear fission. Since the thermal neutron may have the energy of 0.03 MeV, it should take $\tau_{th} \approx 46\,\mu s$. Thus, the total time that is necessary for the prompt neutron to induce a fission reaction should be $T_{\text{total}} \approx 61\,\mu s$.

3.3 Total Energy of Fission with Criticality

Here, we should estimate the total amount of energy which is released from this accident. This evaluation must be very difficult, but we want to calculate it in an approximate way and obtain an order of magnitude of the total energy. First, the number of neutrons which is required for the criticality reactions should be taken as $n_r = 1.001$, which is assumed to be consistent with the total energy released as calculated from the computer simulation. In nuclear reactors, one should make use of all the possible techniques to keep the number as $n_r = 1$. In addition, we assume that the number of nuclear fissions should be $N = 40000$. This number is chosen so that the total nuclear energy release should be consistent with the computer simulation which can reproduce all the observed radiation energies. In this case, the total reaction time of fission becomes $T_f \approx 2.4s$, and the total number of fissions becomes

$$N_{\text{total}} = 1.001^{40000} \approx 2.3 \times 10^{17}. \tag{12}$$

Further, we evaluate the neutron number at the beginning, and this neutron should come from the spontaneous fission of ^{238}U. The number of neutrons in one batch solution must be around 20, and a half of them are assumed to contribute followed reaction. The energy release from the nuclear fission must be around 200 MeV in each reaction, and therefore the total energy becomes

$$E_{\text{total}} \approx 4.6 \times 10^{26}\text{eV}, \tag{13}$$

which is just similar to the result of the computer simulation.

3.4 Why Does the Criticality Stop?

It is true that the criticality accident produced a huge amount of energy by the nuclear chain reactions, and the accident is indeed quite serious. In this sense, we here clarify as to how the chain reactions started and continued by reaching the critical stage. However, we face to the more serious problem at this point. That is, *why the criticality accident could stop?* We should understand any reason why the criticality could stop, namely there were only one burst and not any more burst, but why?

(1) Nuclear Fission in the Seventh Batch

Here, we try to answer for this question, though it should be extremely difficult. In order to find a possible mechanism for the stopping of the criticality, we assume that the uranium compound should settle faster than any other compounds in the solution. Further, we assume that uranium should be settled within 20% height from the bottom of the sedimentation tank.

In this case, after the sixth batch, the uranium should be settled up to the 4.9 cm from the bottom. Thus, water should be found for 19.7 cm long in the sedimentation tank. By taking into account this fact, we can calculate the total energy release by nuclear fission as

$$E_{\text{total}} \approx 4.6 \times 10^{26}\text{eV} \approx 7.4 \times 10^{7}\,\text{J}. \tag{14}$$

The duration time of this nuclear reactions can be estimated and should be around $T_f \approx 2.4\,\text{s}$, which should correspond to the time that the uranium compound is coming down to the bottom.

(2) Nuclear Fission in the Sixth Batch

The same calculation can be carried out for the sixth batch case. In this case, we see that the total energy must be 1000 times smaller than that of the seventh batch case. This is not very large, but at the sixth batch, the nuclear chain reactions already started, and indeed there were a small burst.

From this calculation, we now understand the reason why the criticality stopped. In case the uranium were settled at the bottom of the tank, then the nuclear chain reaction cannot proceed further since the prompt neutrons cannot lose their energy because of the lack of water.

(3) Nuclear Fission in the Eighth Batch

From now on, we only present a possible scenario of nuclear accident, if the eighth batch were carried into the tank. In this case, the number of uranium involved in the nuclear fission must be proportional to the height of water, and thus it should be 22.9/19.7 more than the seventh batch. Thus, the number becomes

$$N = 40000 \times \frac{22.9}{19.7} \approx 46500. \tag{15}$$

This means that the number of nuclear fissions should be also increased and the total number becomes

$$N_{\text{total}} = 1.001^{46500} \approx 1.5 \times 10^{20}. \tag{16}$$

Therefore, the total energy becomes

$$E_{\text{total}} = 3 \times 10^{29}\text{eV} \approx 4.8 \times 10^{10}\,\text{J}. \tag{17}$$

This energy 4.8×10^{10} J corresponds to 11 ton of TNT powder which is quite a serious explosion. The accident of Chernobyl nuclear power plant is believed to correspond to around 100 ton of TNT powder, and therefore, if the eighth batch were thrown away, then the accident would have been more than serious.

4 Design of Risk-Proof Procedure

Table 1 illustrates a procedure, including control factors of the manufacturing system of uranium compound and objectives, designed to prevent criticality accidents in advance from the standpoint of three manufacturing resources that is Human, Machine and Material, grounded in the above theoretical discussion. Proposed procedure mainly aims to reduce the opportunity of accelerated spontaneous occurrence of fission.

For the viewpoint of human, a control factor is the number of times workers carry uranium nitrate into sedimentation tank. Whenever this operation is activated, the neutrons settled in the tank should not contact with water molecule contained in uranium nitrate solution. The opportunity between the two materials must be minimized if possible.

For the viewpoint of a machine, a control factor is the space of sedimentation tank. The shape of the tank id better to be shallow with thinly fill of water because neutrons will be severely scattered in this case. Owing to it, the moving distance of neutrons in the water of tank can be minimized.

For the viewpoint of a material, two control factors are identified which can regarding to two components of uranium nitrate solution i.e. neutrons and water molecule. The former is the core of fission. The more the number of neutrons are, the more the opportunity of fission of neurons increases. It is necessary to control suitable number density of ^{235}U. The latter has the role to reduce

Table 1. Risk-proof procedure

Manufacturing resources	Control factors	Objectives
Human	The number of times workers carry into sedimentation tank	Minimization of the opportunity of neutrons to make contact with water molecule
Machine	Space of sedimentation tank	Minimization of moving distance of neutrons into the water in sedimentation tank
Material	The number density of ^{235}U	Reduction of the probability of induced fission by neutrons
	The amount of water	Prevention of over- slowdown material

energy of neutrons which lead to accelerated fission. Over-input of water may cause diversification of neutron occurrence and losing of their energy. Suitable amount of water should be fixed to prohibit any accident.

The above conditions were derived from consideration on operational resources. In the future, the comprehensive design of effective countermeasures are needed. The accident focused in this paper is old case, however, the proposal approach that intends to develop the procedure based on the principle of physical phenomenon will be useful for experienced IEer.

5 Concluding Remarks

The purpose of this study aims to examine a risk-proof procedure for nuclear materials operation through the causal analysis of JCO accident in 1999. In the analysis, the basic mechanism of the accident is discussed in terms of the nuclear multiple scattering theory. As the result, some specific reasons why the chain reactions can proceed and why the criticality could stop. The control factors of operation resources are extracted referred to physical phenomena regarding to fissions.

This paper aims to assist managers and academic researchers in the area of atomic power generation. As atomic power plants rely on many human operations, mangers have to cope with operational effectiveness and safety. Therefore, they have to concern to provide systematic procedure based on the proposed methodologies.

Especially, this paper proposed control factors to prevent accident. Subsequently, because of its early stage, we hope related studies to this approach is advanced by researchers interested in various areas.

Abstract. When evaluating a logistics system, automobile companies commonly search for the minimum transportation cost, which is significantly influenced by inventory problems. These inventory problems are extensive and varied. In many actual logistics systems, there are the three-stage network models take inventory values into consideration. Safety inventories are kept in distribution centers (DCs). In this study, we adapted a model to set-up a number of plants and DCs. We then performed numerical experiments by using demand data that we created on the basis of data disclosed by an automobile company. In this study, we propose a random key-based genetic algorithm (rk-GA) with the distributed environment scheme, we compared it with random key and spanning tree-based GAs, and report the advantages of the proposed method, random key-based genetic algorithm with distributed environment scheme (des-rkGA).

Keywords: Automobile manufacturing · Multi-stage logistics · Inventory control · Random key-based genetic algorithm

1 Introduction

Many difficult inventory problems involve production control and asset management, but those that involve logistics systems are important and have garnered strong interest in recent years. Particular focus has been paid to inventory problems. Doboshas presented many papers on inventory problems. In 2001, he presented the problem of reverse logistics, adjusting the relationship of holding, production, and disposal costs [4]. In 2005, he investigated production inventory adjustment [5]. In 2007, he presented a paper on the total production cost of two companies for adjustment [6]. Minner et al. [18] have also presented papers on inventory problems. In 2003, they evaluated reverse logistics, where the inventory has several supply methods. In 2005, they presented a paper on the problem of adjusting shipping, replenishment, and lost sales opportunities for two inventories [19]. In 2008, Thangam et al. [28] presented a paper on how to determine

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_63

replenishment for Poisson demand. In 2003, Mahadevan et al. [16] treated a facility as an inventory problem where the returned products are remanufactured. In 2004, Miranda et al. [20] analyzed the inventory decision problem using the Lagrangian relaxation method and subgradient methods; their ordering point method was based on the economic order quantity. In 2009, Rieksts et al. [24] analyzed the inventory problem with ordering intervals using power- of- two policies.

There are many other inventory problems, including the reduction of the total safety inventory quantity, or on-hand inventory [8], and the calculation of the inventory value at each step, or echelon inventory [12].

In this study, we propose a new model where inventories are managed at distribution centers (DCs), taking actual conditions into account. Holding costs only occur in DCs, but additional inventory costs are incurred for the product value because a product near dealers has more value. For inventory costs other than the holding cost, we can get an interest charge if the product is exchanged with cash. Another factor is the lost product value due to age depreciation. We calculated the annual supply and demand value, and created demand data that were based on the Poisson demand of time-series fluctuations. Logistics models such as these are known as the NP-hard problem [3]. Soft computing methods such as simulated annealing, neural networks, and genetic algorithms (GA) are well-suited to solve this problem [1,17,26,29].

In this study, we adopted random key-based genetic algorithm (rk-GA) with distributed environment scheme (des-rkGA) as the proposed method, which is an improved version of rk-GA; we compared the proposed method with rk-GA and spanning tree-based GA (st-GA) to confirm its suitability [9].

We propose a model that addresses many of the different inventory problems studied earlier; we demonstrate des-rkGA algorithm to solve the multi-logistics inventory problem, and present the computational results with the effectiveness by the proposed algorithm.

2 Inventory Problem in Logistics System

In this section, we detail the contents for the inventory problem treated in this study. Inventory costs result from holding costs and other factors. For the model used in this study, the product is held in a DC for general managing. All products have needed costs as their product value, and the production control cost is needed to calculate the safety inventory in a DC. The safety inventory quantity is decided by the service level but is affected by the production control and holding costs. The safety inventory cost is based on the service level and has a trade-off relation with lost costs based on lost sales opportunities.

Figure 1 shows many different kinds of inventories; they are difficult to categorize clearly, but it is important for inventory management to categorize and manage them. The inventory cost without the holding cost includes all inventory, such as the pipeline, production process, lot size and DC inventories. The inventory costs determine the product value, inventory value, inventory time, and inventory holding ratio.

Therefore, the inventory cost without holding costs and the product value, inventory value, inventory time, and inventory holding ratio have a trade-off relation. In this section, we describe the inventory holding ratio, safety inventory, production adjustment, pipeline inventory, and inventory on a production process, lot size inventory, and DC inventory as well as a summary of the inventory problems evaluated in this study. Although there are many kinds of inventories, we adopted the idea of a value chain for the inventories; we used the pipeline, lot size, production process, and DC inventories.

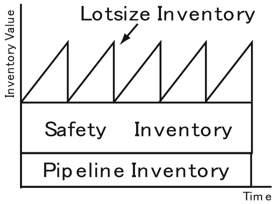

Fig. 1. Inventory category

The general outline of the logistics model used for the inventory in this study is shown in Fig. 2.

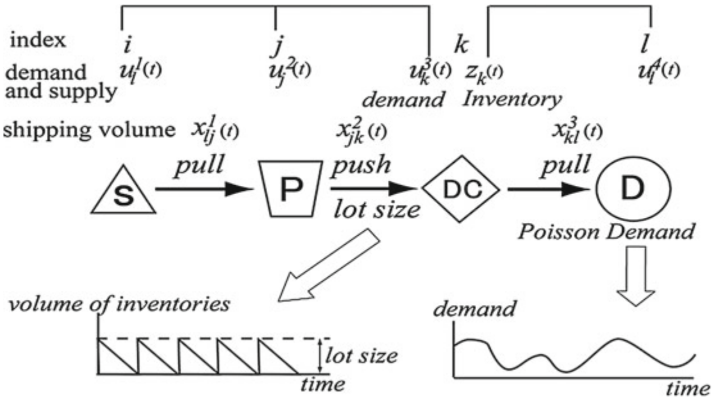

Fig. 2. General outline of logistics model with inventory

Below, we define the indices, constants, parameters, decision variables, and units used in this paper. Units of measurement are in square brackets.

Indices:

$i = 1, 2, \cdots, I$: index of suppliers;
$j = 1, 2, \cdots, J$: index of plants;
$k = 1, 2, \cdots, K$: index of DCs;
$l = 1, 2, \cdots, L$: index of customers;
$t = 1, 2, \cdots, T$: index of cycles in the logistics system. T_{cycle} intervals are described later.

Parameters:

A : number of unit parts to constitute;
c^1_{ij} : shipping cost of unit parts or material from supplier i to plant j [yen];
c^2_{jk} : shipping cost of unit production from plant j to DC k [yen];
c^3_{kl} : shipping cost of unit production from DC k to customer l [yen];
g^1_{ij} : shipping time of unit parts or material from supplier i to plant j [h];
g^2_{jk} : shipping time of unit production from plant j to DC k [h];
g^3_{kl} : shipping time of unit production from DC k to customer l [h];
T_{plant} : producing time of plants [h];
α : safety inventory coefficient;
σ : standard deviation of demand;
T_{cycle} : cycle time in the logistics system. It shows how much time it takes for a load to be moved once [h];
h : inventory holding ratio (2.1 value chain.);
H : holding cost of unit production in a DC [yen];
e_k : inventory cost or DC k [yen];
M_{cost} : material cost [yen];
r^1_j : fixed cost for operating plant j [yen];
r^2_k : fixed cost for operating DC k [yen];
U^1_i : upper limit of supply for parts and materials in supplier i;
U^2_j : upper limit of supply for production in plant j;
U^3_j : upper limit of supply for production in DC k;
p^{const}_j : unit cost production at steady state [yen];
p^{exceed}_j : unit cost production at excess state, [yen];
p^{shortage}_j : unit cost production at shortage state [yen];
I_{total} : total inventory cost without holding cost;
N_{delay} : number of delays for plant production;
W_1 : number of plants that can be operated;
W_2 : number of DCs that can be operated;
R_{average} : production quantity for one period of cycle time as calculated from the annual average production quantity;
S^1_i : supplier production ratio; ratio of supplier i to gross supplier product capability;
S^2_j : plant production ratio; ratio of plant j to gross plant product capability;
z^{level}_k : base inventory level in DC k.

Decision Variables:
$u_i^1(t)$: supply amount of parts and materials in supplier i at cycle t;
$u_j^2(t)$: supply amont of production in plant j at cycle t;
$u_k^3(t)$: supply amont of production in DC k at cycle t;
$u_l^4(t)$: demand amount of production in customer l;
$z_k(t)$: inventory volume for DC k at cycle t [yen];
$S_k^3(t)$: DC demand ratio; demand ratio of DC k to the gross DC demand quantity;
$R_j^2(t)$: shipping quantity in plant j;
$R_k^3(t)$: receive cargo quantity in DC k;
$B_l(t)$: back order quantity in customer l;
$Dl(t)$: order quantity at this period in customer l;
$D_l^{DC}(t)$: request quantity to DC at this period in customer l;
$\Delta z_k(t)$: difference of inventory quantity and base inventory level;
$\Delta z_{\max}(t)$: maximum of difference of inventory quantity and base inventory level;
$z_k^{\mathrm{req}}(t)$: request quantity in DC k;
p_{val}^1 : product value when delivery is completed to plants [yen];
p_{val}^2 : product value when delivery is completed to DCs [yen];
p_{val}^3 : product value when delivery is completed to customers [yen];
U_j^{exceed} : threshold for determination when exceeding production;
U_j^{shortage} : threshold for determination when reducing production;

Decision Variables:
$p_j(uj^2)$: producing cost of unit production in plant j, [yen]
$x_{ij}^1(t)$: amount supplied of unit parts or material from supplier i to plant j at cycle t;
$x_{jk}^2(t)$: amount supplied of production from plant j to DC k at cycle t;
$x_{kl}^3(t)$: amount supplied of production from DC k to customer l at cycle t;
$p_j^1(t)$: operating flag for plant j at cycle t ($= 1$ when plant j is used, $= 0$ otherwise);
$p_k^2(t)$: operating flag for DC k at cycle t ($= 1$ when DC k is used, $= 0$ otherwise).

2.1 Value Chain

When considering the product value and inventory holding ratio in addition to the holding cost, the inventory cost becomes high near the customer (dealer), as shown in Fig. 3 [23]. The inventory holding ratio is determined by the constant number by interest rate when the product is cashed, the decrease in product value, etc. In this study, we treated the inventory holding ratio as uniform because we were dealing with engineered products such as automobiles that do not experience degradation. We adopted the value chain concept for all products.

The value chain can be defined as:

I_{cost} : Inventory Cost;
P_{value} : Product Value;
I_{volume} : Inventory Amount.

$$I_{\text{cost}} = h \times P_{\text{value}} \times I_{\text{volume}} \tag{1}$$

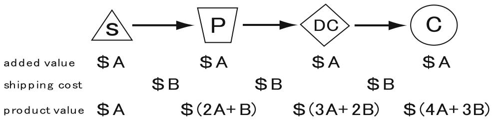

Fig. 3. Value chain

2.2 Safety Inventory

The safety inventory is the inventory required to prevent stock out. The safety inventory and service level have a mutual trade-off relation. The formula for the safety inventory is shown below.

$$I_{\text{safety}} = \alpha\sigma\sqrt{T_{\text{cycle}} + \max(g_{jk})} \quad \forall j, k, \tag{2}$$

where I_{safety} is safety inventory.

2.3 Production Adjustment

Order fluctuations mean that factories have to adjust production. Extra charges include extra pay, etc. if production is over the steady state, and extra fixed costs for the equipments if production is under steady state. The formula for production adjustment is shown below.

$$\begin{aligned} P_j(u_j^2(\mathrm{t})) =& P_{\text{const}} + \max\{P_{\text{exceed}}(u_j^2(\mathrm{t}) - U_j^{\text{exceed}}), 0\} \\ & + \max\{P_{\text{shortage}}(U_j^{\text{shortage}} - u_j^2(\mathrm{t})), 0\}. \end{aligned} \tag{3}$$

2.4 Pipeline Inventory

The pipeline inventory denotes the inventory during shipping. There is a trade-off between the pipeline inventory and shipping cost. In this study, we constructed a model based on the idea of an inventory holding ratio. We treated each product during shipping between a supplier and plant and between a DC and customer as pipeline inventory. The formula of the pipeline inventory cost I_{pileline} is shown below.

$$I_{\text{pipeline}} = h\left\{\sum_{t=1}^{T}\left(p_{val}^{1}\sum_{i=1}^{I}\sum_{j=1}^{J} g_{ij}^{1}x_{ij}^{1}(t) + p_{val}^{2}\sum_{j=1}^{J}\sum_{k=1}^{K} g_{jk}^{2}x_{jk}^{2}(t) + p_{val}^{3}\sum_{k=1}^{K}\sum_{l=1}^{L} g_{kl}^{3}x_{kl}^{3}(t)\right)\right\}. \tag{4}$$

The cost is approximated as follows because we presumed that the product has the same value when received by any factory, DC, or dealer. The value of completed product is approximated by material and average shipping costs.

$$p_{\text{val}}^{1} = M_{\text{cost}} + \frac{\sum_{t=1}^{T}\sum_{i=1}^{I}\sum_{j=1}^{J} c_{ij}^{1}x_{ij}^{1}(t)}{\sum_{t=1}^{T}\sum_{i=1}^{I}\sum_{j=1}^{J} x_{ij}^{1}(t)}. \tag{5}$$

The product value when shipped to DCs is approximated by its value when shipped to plants and the average shipping cost.

$$p_{\text{val}}^{2} = p_{\text{val}}^{1} + \frac{\sum_{t=1}^{T}\sum_{j=1}^{J}\sum_{k=1}^{K} c_{jk}^{2}x_{jk}^{2}(t)}{\sum_{t=1}^{T}\sum_{j=1}^{J}\sum_{k=1}^{K} x_{jk}^{2}(t)}. \tag{6}$$

The product value when shipped to dealers is approximated by its value when shipped to DCs and average shipping cost.

$$p_{val}^{3} = p_{val}^{2} + \frac{\sum_{t=1}^{T}\sum_{k=1}^{K}\sum_{l=1}^{L} c_{kl}^{3}x_{kl}^{3}(t)}{\sum_{t=1}^{T}\sum_{k=1}^{K}\sum_{l=1}^{L} x_{kl}^{3}(t)}. \tag{7}$$

2.5 Inventory of a Production Process

For the inventory of a production process, we constructed a model based on the idea of an inventory holding ratio. We treated an unfinished product as inventory on a production process.

The formula is shown below. The product value on a production process changes with the progress conditions of the manufacturing processes. However, in this study, the value was approximated as the material cost and half of the production cost in the plant.

$$I_{\text{production}} = hT_{\text{plant}}\sum_{j=1}^{J} u_j^2(t)(p_{val}^{1} + P_j(u_j^2(t))/2). \tag{8}$$

2.6 Lot-Size Inventory

The lot size inventory is the inventory of the completed products during shipping. We treated completed products as lot size inventory. All products are shipped from plants to DCs in the same interval. The lot size inventory cost was calculated as half the product of the shipping values, production values in plants, and inventory holding ratio, as shown in Fig. 4; we used this formula because all products were shipped from a plant to a DC in the same time intervals. The formula is shown below.

$$I_{\text{lotsize}} = h \sum_{t=1}^{T} \sum_{j=1}^{J} \sum_{k=1}^{K} \frac{g_{jk}^2 x_{jk}^2(t)(p_{val}^1 + P_j(u_j^2(t)))}{2}. \tag{9}$$

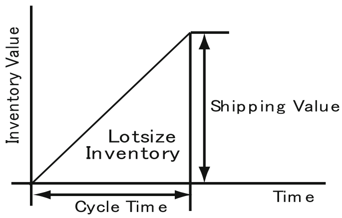

Fig. 4. Lot size inventory value

2.7 DC Inventory

We treated products in a DC as DC inventory. In this study, the DC inventory plays the central role of the inventory of the logistics system; we need extra holding costs for each car in DCs. The DC inventory cost is calculated as the product of the DC inventory amount, cycle time, and production value when shipped to DCs multiplied by the inventory holding ratio. The formula is shown below.

$$I_{DC} = hT_{\text{cycle}} p_{\text{val}}^2 \sum_{t=1}^{T} \sum_{k=1}^{K} z_k(t) + HT_{\text{cycle}} \sum_{t=1}^{T} \sum_{k=1}^{K} z_k(t). \tag{10}$$

2.8 Total Inventory Cost Without Holding Cost

As mentioned above, the formula of the total inventory cost without the holding cost used in this study consists of the pipeline, production process, lot size, and DC inventory costs; it is shown as follows.

$$I_{\text{total}}=I_{\text{pipeline}}+I_{\text{production}}+I_{\text{lotsize}}+I_{DC} \tag{11}$$

$$\begin{aligned} I_{\text{total}} =h\Bigg\{ & \sum_{t=1}^{T}(p_{\text{val}}^{1}\sum_{i=1}^{I}\sum_{j=1}^{J} g_{ij}^{1}x_{ij}^{1}(t)+p_{\text{val}}^{2}\sum_{j=1}^{J}\sum_{k=1}^{K} g_{jk}^{2}x_{jk}^{2}(t) \\ & +p_{val}^{3}\sum_{k=1}^{K}\sum_{l=1}^{L} g_{kl}^{3}x_{kl}^{3}(t))+T_{\text{plant}}\sum_{j=1}^{J}u_{j}^{2}(t)(p_{\text{val}}^{1}+P_{j}(u_{j}^{2}(t))/2) \\ & +\sum_{t=1}^{T}\sum_{j=1}^{J}\sum_{k=1}^{K}\frac{g_{jk}^{2}x_{jk}^{2}(t)(p_{val}^{1}+P_{j}(u_{j}^{2}(t)))}{2}+T_{\text{cycle}}p_{\text{val}}^{2}\sum_{t=1}^{T}\sum_{k=1}^{K}z_{k}(t)\Bigg\} \\ & +HT_{\text{cycle}}\sum_{t=1}^{T}\sum_{k=1}^{K}z_{k}(t). \end{aligned} \tag{12}$$

2.9 Demand Data

In this study, we constructed the logistics system in terms of inventories with Poisson demand [25]. To confirm the availability, we created demand data from an automobile company's public data. Many products flow in the supply chain network (SCN) by dealer's demand, and these demands are approximated with Poisson demand time fluctuations. We created new demand data using Poisson randomization. The Poisson equation is shown below.

$$p(k)=\frac{e^{-\lambda}\lambda^{k}}{k!}, \tag{13}$$

here, $p(k)$ is the demand, λ is the average order values, and k is the number of order times. Figure 5 shows the outline of the Poisson randomization. In this study, we created daily demand data each experiment by applying a Poisson random number to the annual demand.

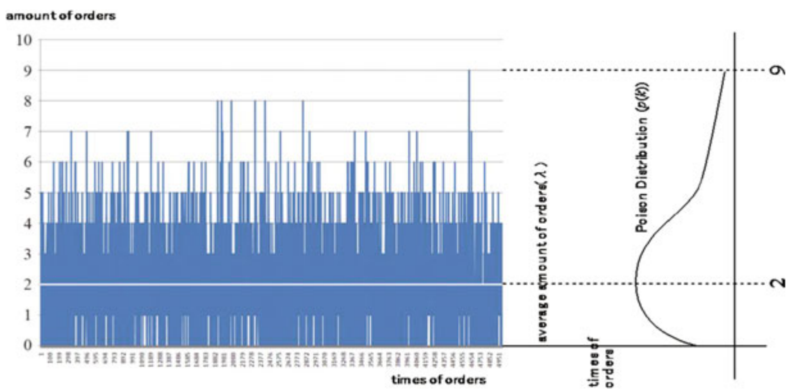

Fig. 5. Relationship between amount and times of orders

3 Mathematical Model of Multi-stage Logistics System with Inventory

3.1 Assumptions

In this study, we constructed the logistics model with the following assumptions.

A1. The transit times are known between suppliers and plants, plants and DCs, and DCs and customers.
A2. The shipping costs are known between suppliers and plants, plants and DCs, and DCs and customers.
A3. The supplies are delivered without delay to a factory in population to the planned production.
A4. In this model, suppliers provide multipurpose parts for effective optimization. The parts are examined and classified for easy assembly work. This process is carried out assuming that A package parts are used in the assembly of one car. The conditions for assembling one car require the package parts of A units. Other parts are not targeted in this model because the supply route is decided from the first time the supplier side is entrusted with delivery, few of the detailed parts have management value in the logistics system, etc.
A5. The products made at a plant are shipped to a DC by lot size.
A6. The DCs have space to accept products from plants.
A7. We consider only the inventory costs in DCs.
A8. The customer addresses are known.
A9. The existence of inventory is known in advance through an inventory check; orders for inventory that is out of stock are treated as reservations.
A10. A product has the same value when received by any factory, DC, or dealer.
A11. All products are delivered within the limits time of a T_{cycle}.

3.2 Multi-stage Logistics System

Generally, when a logistics system is seen from the functional constitutive property, it is modeled by a three-stage production network and distribution system, which is called a supply chain network. The first stage is the supplier phase, which involves parts and a supplier. The second stage is the plant phase, which consists of a production plant or outsourcing. The third stage is the DC phase and consists of a distribution center or storehouse. A sample of an actual automobile company's logistics system is shown in Fig. 6. In many cases, the actual logistics system is comprised of three stages. A three stage logistics system model is shown in Fig. 7. The logistics model used in this study had 14 suppliers, 2 factories, 4 DC, and 22 customers. The mathematical model used in this study is shown below.

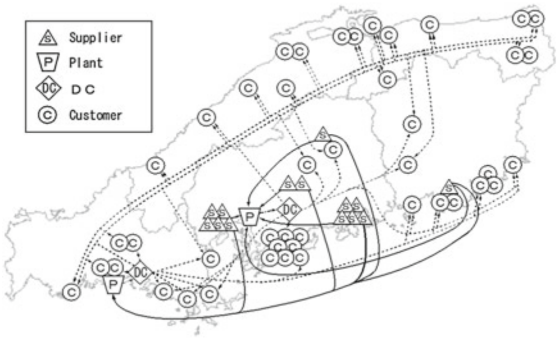

Fig. 6. Sample of actual logistics system

$$
\begin{aligned}
\min Z_1 = &\sum_{t=1}^{T}\Bigg\{A\sum_{i=1}^{I}\sum_{j=1}^{J}c_{ij}^{1}x_{ij}^{1}(t)+\sum_{j=1}^{J}\sum_{k=1}^{K}c_{jk}^{2}x_{jk}^{2}(t)\\
&+\sum_{k=1}^{K}\sum_{l=1}^{L}c_{kl}^{3}x_{kl}^{3}(t)\Bigg\}+h\Bigg\{\sum_{t=1}^{T}(p_{\text{val}}^{1}\sum_{i=1}^{I}\sum_{j=1}^{J}g_{ij}^{1}x_{ij}^{1}(t)\\
&+p_{\text{val}}^{2}\sum_{j=1}^{J}\sum_{k=1}^{K}g_{jk}^{2}x_{jk}^{2}(t)+p_{\text{val}}^{3}\sum_{k=1}^{K}\sum_{l=1}^{L}g_{kl}^{3}x_{kl}^{3}(t))\\
&+T_{\text{plant}}\sum_{j=1}^{J}u_{j}^{2}(p_{\text{val}}^{1}+P_j(u_j^2(t))/2)\\
&+\sum_{t=1}^{T}\sum_{j=1}^{J}\sum_{k=1}^{K}\frac{g_{jk}^{2}x_{jk}^{2}(t)(p_{\text{val}}^{1}+P_j(u_j^2(t)))}{2}\\
&+T_{\text{cycle}}p_{\text{val}}^{2}\sum_{t=1}^{T}\sum_{k=1}^{K}z_k(t)\Bigg\}+HT_{\text{cycle}}\sum_{t=1}^{T}\sum_{k=1}^{K}z_k(t)\\
&+\sum_{t=1}^{T}\sum_{j=1}^{J}u_j^2(t)P(u_j^2(t))+\sum_{j=1}^{J}r_j^1p_j^1(t)+\sum_{k=1}^{K}r_k^2p_k^2(t)
\end{aligned}
\tag{14}
$$

$$

$$

$$\sum_{j=1}^{J} x_{jk}^2(t) \leq u_k^3(t) p_k^2(t), \quad \forall k, t \tag{17}$$

$$\sum_{k=1}^{K} x_{kl}^3(t) \geq u_l^4(t), \quad \forall l, t \tag{18}$$

$$\sum_{j=1}^{J} x_{ij}^1(t) = \sum_{j=1}^{J} x_{jk}^2(t), \quad \forall j, t \tag{19}$$

$$\sum_{k=1}^{K} x_{jk}^2(t) = z_k(t-1) - z_k(t) + \sum_{k=1}^{K} x_{kl}^3(t), \quad \forall j, t \tag{20}$$

$$\sum_{j=1}^{J} p_j^1 \leq W_1 \tag{21}$$

$$\sum_{k=1}^{K} p_k^2 \leq W_2 \tag{22}$$

$$x_{ij}^1(t), x_{jk}^2(t), x_{kl}^3(t), z_k(t) \geq 0, \quad \forall i, j, k, l, t \tag{23}$$

$$p_j^1(t), p_k^2(t) = \{0, 1\}, \forall j, k, t \tag{24}$$

$$\begin{aligned} P_j(u_j^2) = P_j^{\text{cont}} &+ \max(P_j^{\text{exceed}}(u_j^2(t) - U_j^{\text{exceed}}), 0) \\ &+ \max(P_j^{\text{shortage}}(U_j^{\text{shortage}} - u_j^2(t)), 0) \end{aligned} \tag{25}$$

$$p_{\text{val}}^1 = M_{\text{cost}} + \frac{\sum_{t=1}^{T} \sum_{i=1}^{I} \sum_{j=1}^{J} c_{ij}^1 x_{ij}^1(t)}{\sum_{t=1}^{T} \sum_{i=1}^{I} \sum_{j=1}^{J} x_{ij}^1(t)} \tag{26}$$

$$p_{\text{val}}^2 = p_{\text{val}}^1 + \frac{\sum_{t=1}^{T} \sum_{j=1}^{J} \sum_{k=1}^{K} c_{jk}^2 x_{jk}^2(t)}{\sum_{t=1}^{T} \sum_{j=1}^{J} \sum_{k=1}^{K} x_{jk}^2(t)} \tag{27}$$

$$p_{\text{val}}^3 = p_{\text{val}}^2 + \frac{\sum_{t=1}^{T} \sum_{k=1}^{K} \sum_{l=1}^{L} c_{kl}^3 x_{kl}^3(t)}{\sum_{t=1}^{T} \sum_{k=1}^{K} \sum_{l=1}^{L} x_{kl}^3(t)}. \tag{28}$$

4 Advanced Genetic Algorithm

4.1 Random-Key Based Genetic Algorithm

Gen and Lin [7] surveyed genetic algorithms in Wiley Encyclopedia of Computer Science and Engineering and recently many researchers applied GA to various areas in logistics systems. Inoue and Gen [10] reported multistage logistics system with inventory considering demand by hybrid GA, Neungnatcha et al. [22] reported adaptive genetic algorithm (AGA) for solving sugarcane loading stations with multi-facility services problem, Jamrus et al. [11] reported discrete particle swarm optimization (PSO) approaches and extended priority based-HGA for solving multistage production distribution under uncertainty demands

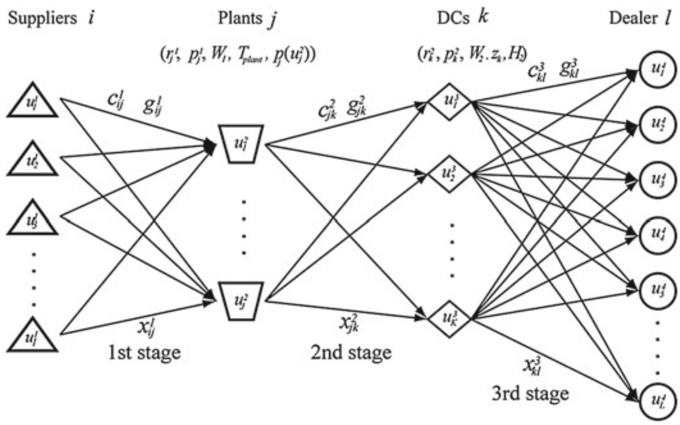

Fig. 7. 3-stages logistics model

and Lee et al. [13] reported multi-objective hybrid genetic algorithm (MoGA) to minimize the total cost and delivery tardiness in a reverse logistics.

Lin and Gen [15] proposed a random key-based genetic algorithm (rk-GA) for solving AGV (automatic guided vehicle) dispatching problem in flexible manufacturing system (FMS). Now we are going to use it for multistage logistics system with inventory. Now we define the following example of the cost matrix:

$$[e_{ij}] = \begin{bmatrix} 67 & 71 & 32 \\ 44 & 51 & 62 \\ 50 & 59 & 35 \\ 38 & 78 & 56 \\ 53 & 65 & 74 \end{bmatrix} \qquad [f_{jk}] = \begin{bmatrix} 39 & 32 & 62 & 44 \\ 45 & 56 & 53 & 59 \\ 47 & 35 & 41 & 38 \end{bmatrix}$$

$$[g_{kl}] = \begin{bmatrix} 48 & 62 & 74 & 20 & 92 & 83 & 32 \\ 51 & 26 & 89 & 17 & 35 & 59 & 86 \\ 34 & 50 & 56 & 65 & 50 & 53 & 47 \\ 71 & 44 & 23 & 38 & 11 & 62 & 29 \end{bmatrix}$$

Fig. 8. Sample of cost matrix

The algorithm created using the rk-GA technique has three logistics stages. Figure 7 shows the third stage process. Figure 8 shows a sample cost matrix. Figure 9 shows a sample rk-GA chromosome.

Gen and Cheng successfully applied rk-GA encoding to the shortest path and project scheduling problems in 2000 [2]. For transportation problems, a chromosome consists of the priorities of sources and depots, which make up a transportation tree; its length is equal to the total number of sources m and depots n, i.e., m + n. The transportation tree corresponding to a given chromosome is generated by the sequential arc between sources and depots. At each

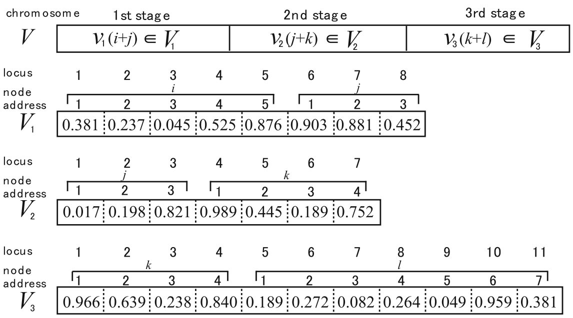

Fig. 9. Sample of rk-GA chromosome

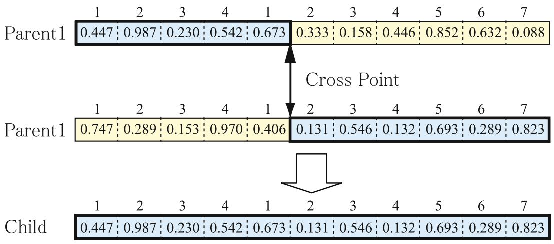

Fig. 10. Sample of one point crossover

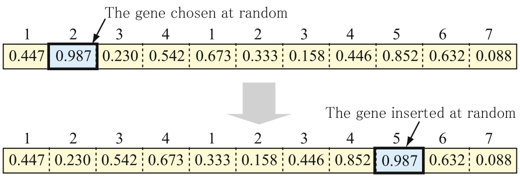

Fig. 11. Sample of insertion mutation

step, a single arc is added to a tree that selects a source (depot) with the highest priority and connects it to a depot (source) to minimize cost.

Figure 13 shows the brief decoding at each stage. Figure 14 shows the process of the m-logistics problem. In this study, we used the one-point crossover, which is the simplest method when using rk-GA. We used insertion and swap mutations. We used the roulette wheel approach, which selects the chromosome in ascending order of fitness. Examples of one-point crossover, insertion mutation, and swap mutation are shown in Figs. 10, 11 and 12, respectively.

The new generated chromosome is evaluated. It is selected in ascending order of fitness based on the number of *popSize* in the parent and newly generated chromosomes. The order of fitness then helps determine the next generation of chromosomes.

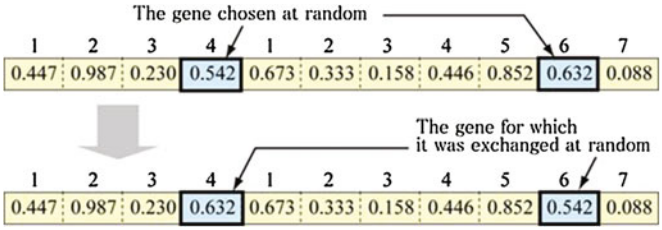

Fig. 12. Sample of swap mutation

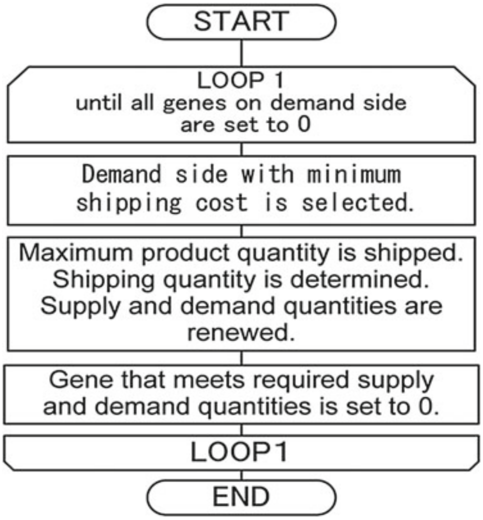

Fig. 13. Brief decoding of each stage

Inversion and displacement mutations are used in st-GA. The inversion mutation select two positions within a chromosome at random and then inverts the substring between these two positions. The displacement mutation selects a substring at random and inserts it in a random position.

4.2 Total Logistics Process

The total logistics system process can be explained as follows. Figure 15 shows the whole logistics system process in logistics cycle periods. The safety inventory is given first each cycle period. The inventory quantity is renewed last in each cycle period. The plant product shipping quantity is based on past demand, because of the production time in plants. In this study, this is called the number of delays for plant production N_{delay} where the plant production time is the number of order times. This is shown below.

```
procedure total m-logistics:
input: shipping data, GA parameter
output: minimum m-logistics cost
begin
   t ← 1;
   initialize P(t) by Random Key-based encoding routine;
   fitness eval(P) by total decoding routine;
   while (not terminating condition) do
      crossover P(t) to yield C(t) by partially matched crossover;
      mutation P(t) to yield C(t) by insertion and swap mutation;
      fitness eval(C) by total decoding routine;
      select P(t+1) from P(t) and C(t) by roulette wheel selection;
      t ← t + 1;
    end
output best m-logistics cost
end;
```

Fig. 14. m-Logistics Process

$$N_{\text{dalay}} = \frac{T_{\text{plant}}}{T_{\text{cycle}}}. \tag{29}$$

Here, we use an example for the shipping products when the customer's total demand quantity changes from 600 before delay cycle times (N_{delay}) to 1200. A pull-type demand quantity is applied to DC-customer and supplier-plant product distributes based on the demand quantity at the time. The shipping quantity is 1200. A push-type demand quantity is applied to plant-DC product distributions based on the demand quantity before the number of delay times for plant production (N_{delay}). The shipping quantity is 600.

The load of the customer's demand is shared by the total inventory quantity in DCs and total production in plants and suppliers. An example process is shown in Fig. 16. Step 1 shows a renewal of the demand quantity (u_l^4) and back order quantity (B_l). Step 2 calculates the planned order quantity ($u_j^2(t)$). Step 3 calculates the order quantity in suppliers ($u_i^1(t)$). Step 4 calculates the planned shipping quantity ($R_j^2(t)$). Step 5 calculates the quantity of cargo received in DCs ($R_k^3(t)$).

```
procedure total m-logistics in cycles period:
input: shipping data, inventory data, GA parameter
output: minimum total cost
begin
  t ← 1;
  z_k = ασ√(T_cycle + G_1);              // initialize inventory quantity
  while (not termination condition) do
    initial setting routine;      //initial setting process
    m-logistics routine;
    t ← t + 1;
   end
output best total cost;
end;
```

4.3 rk-GA with Distributed Environment

The immigration scheme is an independent genetic operation where each island is made up of several divided populations for the same generation. The basic concept of immigration is shown in Fig. 17. Immigration is an information exchange that is performed continuously for a group of chromosomes. The ratio to the number of immigration populations is called the immigration ratio, and the generation interval during which immigration occurs is called the immigration interval. In 2008, Lin et al. [14] solved the shortest route problem for cost and time using a priority-based GA with immigration, and reported their result.

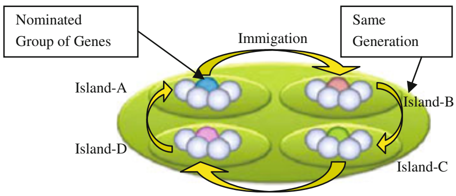

Fig. 17. Basic Concept of Immigration

In this study, we propose rk-GA with a distributed environment scheme (des-rkGA) that changes the crossover and mutation rates for each island. Miki et al. [21] proposed multi-objective genetic algorithms with a distributed environment scheme (MoGA-DES). We adopted an immigration rate of 0.1; we selected other islands randomly and changed the chromosome asynchronously. There are two methods for parallel processing [27]. The multithread method performed by one programming using time sharing. The multi-task method performs several tasks at the same time [21]. In this study, we adopted the multi-task method because it is easy to disperse processing to several PCs. There are also two processing methods for GA. The synchronous method synchronized the time for each generation. The asynchronous method does not do so. We adopted the asynchronous method because we would need a wait time for the slowest island if we adopted the synchronous method. We created nine islands with crossover probability (PC) and lower mutation probability (PM) than the center island. Two of nine islands were chosen at random with the generation timing of the center island. The direction of immigration was decided at random, and the populations immigrated at a 0.1 immigration rate. Next, 10% of each island's worst chromosomes were destroyed, and 10% of other islands' best chromosomes were adopted as immigrations. The concrete values of PC and PM used by this study are discussed in detail in the next section. We performed the experiment using parallel processing with three PCs.

5 Numerical Experiments

We performed prior experiments to determine PC and PM for the center island and obtained the solution is shown in Table 1. We adopted $P_C = 0.4$ and $P_M = 0.6$ as the center island values for st-GA and $P_C = 0.6$ and $P_M = 0.4$ as the center island values for rk-GA because they provided the best solutions.

We adopted $P_C = 0.6$ and $P_M = 0.4$ as the center island values for des-rkGA, because it is based on rk-GA. We created 9 islands with $P_C = (0.4, 0.6, 0.8)$ and $P_M = (0.2, 0.4, 0.6)$ for the experiments.

popSize denotes the population size. maxGen is the maximum generation size used as the terminating condition for the experiments. We performed experiments repeated 20 times using maxGen $=$ 5000 and popSize $= (20, 50, 100)$. However, we reported maxGen $=$ 1000 as sufficient for the evolutive process because no more improvement was detected after 1000 generations. Table 2 shows the evolutive processes for the best value by each method. The best value Z_1 was at gen $= (300, 500, 1000)$.

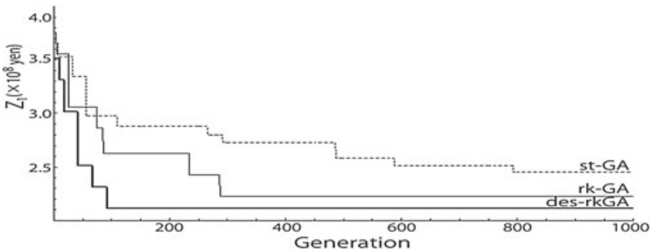

Fig. 18. Evolutive process for each method

Figure 18 shows the evolutive processes for each method when popSize was 100. The proposed Des-rkGA produced the best final result because its evolutive

H	548, 377, 594	520, 688, 854	446, 742, 473	378, 950, 050
I	572, 220, 316	493, 015, 494	415, 259, 267	382, 084, 372
des-rkGA	545, 289, 874	493, 015, 494	412, 034, 067	378, 950, 050

speed was faster than the other compared methods. As shown in Table 2, Z_1 was (402, 412, 188) when st-GA was used. It was (364, 869, 285) with rk-GA and (345, 695, 925) with des-rkGA. des-rkGA showed 16.41% and 5.55% improvements compared to st-GA and rk-GA, respectively. des-rkGA was confirmed to provide stable results because the standard deviation was only 3210 compared to 20, 338 with st-GA and 7780 with rk-GA. Table 3 shows the evolutive process of each island when popSize was 100 as in Table 2. The highlight shows the best solution for each generation, of which the best was with des-rkGA. In a prior experiment, the PC and PM for island E were the best combination. However, in the evolutive process for each island, many of the best solutions were produced at other islands. Table 4 shows the solution at each immigration rate, and the best solution by rk-GA is shown as reference. The experimental results show that if the immigration rate surpassed 50%, the results become bad. Figure 19 was created from Table 4; the best value was produced at 10% migration rate.

Table 6. Experimental results

	st-GA	rk-GA	des-rkGA	
			Each PC	Total PCs
maxGen	55.56	29.96	32.47	97.41
For 1d	35.78	19.98	20.45	61.35
Time to arrive at the maxGen value	55.56	11.07	5.74	17.22
Time to arrive at the rk-GA value	-	-	3.15	9.45

was 100. As shown in Table 2, there were differences when the number of generations was small.

In this experiment, we used three PCs of the same kind dual core AMD1212 2.0 GHz/2 MB; the memory size was 2 GB, and the development language was C#.

The computational time is shown in Table 6. We experimented with the test data for 90 days. When converted to 1 day, the computation time was 35.78, 19.98, and 20.45 s using st-GA, rk-GA, and des-rkGA, respectively. The average generation number when the solution arrived at the maxGen value was 685, 467, and 78 using st-GA, rk-GA, and des-rkGA, respectively. The generation time is shown in Table 6 as time to arrive at the maxGen value. The time was 55.56, 11.07, and 5.74 s using st-GA, rk-GA, and des-rkGA, respectively. There was no drastic improvement because the total CPU processing time was 9.45 s, but the CPU processing time could be distributed. Moreover, the average of the generation numbers when the des-rkGA value became better than maxGen of rk-GA was 165, and it took 3.15 s. We also confirmed the advantage of des-rkGA in terms of computer time. This was due to using parallel processing with 3 PCs of the same kind. We believe that the PC environment affects the solutions.

6 Conclusions

Using date of an actual automobile company in this study, we proposed random key-based genetic algorithm with distributed environment scheme (des-rkGA), for a multi-stage logistics system that calculates inventory values for many different cases. We proposed a logistics system that keeps the safety inventories only in DCs and that can cope with the location allocation problem. We performed numerical experiments with test data that were based on the disclosed data of a certain automobile company. The proposed des-rkGA showed improvements of 16.25% and 5.43% compared to the performances of st-GA and rk-GA, respectively. The des-rkGA also showed a small dispersion of solutions compared with the other methods. For future work, we intend to investigate the effectiveness of the logistics system in actual conditions while continuing to advance research and analysis of case studies.

Abstract. Temporary employment, compared with permanent employment, impacts on employees' attitudes and behaviors. This study provides empirical evidence on the relationships between temporary employment and employee's turnover intention and organizational citizenship behavior. Using a two-wave panel design, we collect data from a sample of 355 employees from 66 teams in four Chinese organizations. Our results show that, temporary employees have higher turnover intention than permanent employees, but in terms of employee's OCB, the difference between temporary and permanent employees is not significant. Further, we also explore the mechanism how employee'ss organizational identification as a moderator-for temporary employees high in organizational identification, the negative relationships between temporary employment and OCBs and the positive relationships between temporary employment and turnover intention would be both attenuated.

Keywords: Temporary employment · Organizational citizenship behavior · Turnover intention · Organizational identification

1 Introduction

To be competitive in a globalized economy, many organizations have been using nonstandard work arrangements to reconstruct their workforce to improve flexibility, to reduce employment-related costs, therefore improve competitiveness in product market [2]. One wide-adopted flexible employment practice conducted by Chinese firm is temporary employment. Kalleberg and his colleagues define standard work as "work done on a fixed schedule-usually full-time-at the

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_64

employer's place of business, under the employer's control, and with the mutual expectation of continued employment"; any arrangement that lacks one or more of these attributes is nonstandard [7]. There are many different forms of nonstandard work arrangements, such as temporary, contract, part-time and temporary agency work, to enhance organizational flexibility and reduce employment-related cost [7]. The temporary employment, as a most widely adopted form of nonpermanent employment, refers to employment featured with shorter length of contracts and lower expectations of continued employment.

According to the latest report by United Nations International Lab our Organization, in the United States, one in four employees worked part time in 2014, up from 19.6% in 2009. In 33 European countries, 12.3% employees were averagely on temporary contracts in 2014. In Asia, the portion of temporary workers are even higher, ranging from 24% in Philippines to 67% in Viet Nam. The percentage is sizeable in China, India, Indonesia and Malaysia.

In response to the growing use of nonstandard workers, more scholars are conducting empirical and theoretical research on this phenomenon. Much of the studies focus on the differences between standard and nonstandard employees in work-related attitudes, including satisfaction, commitment, loyalty, and in-role & extra-role behaviors, like organizational citizenship behavior, turnover and work performance [2,5,12,14].

Other than permanent employment, Contrast with the wide-acceptance in management practices, scholars have argued that there are quite a few drawbacks of temporary employment. Many studies reported that temporary jobs are connected with lower work status, characterized with low-wage, low-welfare and high-stress [4]. Scholars also observed that temporary employees often put in less effort than standard employees, hence alternative work arrangements increase the difficulty in human resource management [12].

Previous studies in U.S. and Euro examined the relationship between temporary employment and employee's work attitudes and performance. Christin and Linn [14] recruited a sample of 350 entry-level employees from 6 restaurants in United States, and found that part-time workers did show some organizational citizenship behavior (OCB) differences compared to their full time colleagues. Thorsteinson [5] did a meta-analysis to demonstrate that, full-time employees were more involved in their jobs than part-time employees and there was little difference between full-time and part-time employees in job satisfaction, organizational commitment, and turnover intention.

Compared with the abundant empirical studies in western countries, research on temporary employment has not attracted enough attention in China. To bridge the gap in the literature, we use a two-wave panel design study to examine whether the different work arrangements would influence employees' OCB and turn over intention. We have two major contributions to the literature. Firstly, this study is to investigate the relationship between temporary employment status and OCB and turnover intention in Chinese cultural context. Our research fills this gap in the literature and advances current understanding on blended workforce arrangement and employees' OCB and turnover intention.

Secondly, we test the hypothesized moderating effects of individuals' organizational identification on the relationships between work arrangements and employee's OCB and turnover intention. We propose that, the negative relationship between temporary employment and OCB will be attenuated, while the positive relationship between temporary employment status and turnover intention will be we propose that organizational identification play the role of moderating the relationship between temporary employment, OCB and turnover intention. The moderator is of great importance for us to understand how the effect works.

This paper is organized as follows. Section 2 presents concepts and hypotheses. Section 3 introduces the methodology. Section 4 summarizes the results and Sect. 5 concludes the paper.

2 Concepts and Hypotheses

2.1 Temporary Employment

During the twentieth century, the "normal" or "standard" work arrangement for most workers was that they were hired full-time and would work for the organization until they retired [14]. However, to deal with the changing internal and external environment, an increasing number of enterprises realize that they should not only boost productivity but also maintain flexibility. Therefore, many of them started to adopt a "non-standard" employment, hiring both "contingent" or "fixed-term contract" workers and standard employees [5].

The differences between "standard" and "contingent" employment arise from two fundamental criteria: the duration of their employment relationship and the level of HR investments [6]. While standard employees have sustained employment relationships and receive higher level of HR investments (e.g., economic incentives, training, empowerment opportunities), contingent ones have employment relationships of limited duration and generally receive lower level of HR investments [13].

2.2 Temporary Employment and Organizational Citizenship Behavior

There are some studies on the relationships between temporary employment and OCB. Van Dyne and Ang [3] tested their hypotheses based on a sample of 155 professional workers from 2 large service organizations, a bank and a hospital in Singapore. They found that the relationship between two kinds of commitment and psychological contracts and OCBs were stronger for temporary workers than standard employees. In contrast, Conway and Briner's analyses [1] showed that the relationships between psychological contract fulfillment and outcomes were rarely moderated by work status, suggesting that part-time employees would respond in a similar way as full-time employees to adjust their psychological contract. It seems that the relationship between temporary employment and OCB remains in dispute.

Thus, we propose the following hypothesis:

Hypothesis 1: Temporary employees are less likely to engage in organizational citizenship behavior, as compared to permanent employees.

2.3 Temporary Employment and Turnover Intention

Turnover intention can be measured by ideas of quitting, expectation of finding alternative employment, job search behavior and intention to quit. It is an important indicator to measure employees' emotional condition. If an employee has a high turnover intention, it is likely that he will not perform his job with all the effort.

Regarding existing studies on turnover intention, Peter, Jackofsky & Salter [11] found that there was differential predictability of turnover across full-time and part-time employees, suggesting that the two groups may have a different "psychology of work". Accordingly, we come up with the second hypotheses:

Hypothesis 2: Temporary employees are more likely to have turnover intention, as compared to permanent employees.

2.4 The Moderating Effect of Organizational Identification

Organizational identification is defined as a perceived oneness with an organization and the experience of the organization's successes and failures as one's own. The more people identify with an organization, the more the organization's values, norms, and interests are incorporated in the self-concept [8]. Knippenberg and Sleebos [8] found that organizational identification has a significant impact on turnover intention. Following this direction of this analysis, we propose the hypothesis below:

Hypothesis 3: Organizational identification will moderate the relationships between temporary employees and employee's OCB. Specifically, for employees high in organizational identification, the negative relationships between temporary employees and OCB will be attenuated.

Hypothesis 4: Organizational identification will moderate the relationships between temporary employees and employee's turnover intention. Specifically, for employees high in organizational identification, the positive relationships between temporary employees and turnover intention will be attenuated.

The framework of this research is shown in Fig. 1.

3 Methodology

3.1 Data

This study was conducted in 4 hospitals in Shaoxing City, Zhejiang Province of People's Republic of China (PRC), which are Lingzhi Town Hospital, Mashan

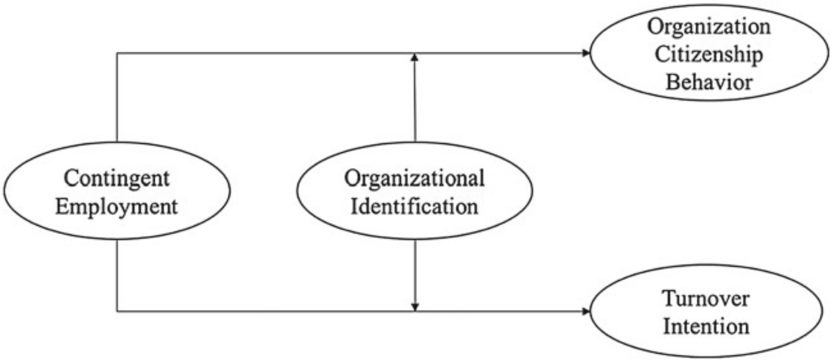

Fig. 1. Theoretical model of this study

Town Hospital, Sunduan Town Hospital and Fushan Community Hospital. All the hospitals are public community hospitals with more than 150 employees, providing service to people living in the town or the community.

The sample consists of both standard employees and temporary employees, including doctors, nurses and other employees like drivers and accountants who provide assistant service. Using information obtained from the leaders of 4 hospitals, we distributed questionnaires to each individuals separately. We finally got 209 valid questionnaires with a response rate of 80.2% (shown in Table 1).

Table 1. Summary of the sample

		N	%
Sample	Valid sample	209	57.89
	Invalid sample	152	42.11
	SUM	361	100

3.2 Measurement

Unless otherwise noted, we use a 5-point Likert scale ("strongly disagree" = 1 to "strongly agree" = 5) for all scales. Each scale's coefficient α is noted below in Table 5. Because the questionnaires are distributed in Chinese organizations, we follow the strict procedure of translating, back-translating and cultural adjustment of the original scales to generate a Chinese version.

(1) Employment Status
We collect the information of subordinates' employment status with a three-step procedure. Firstly, the supervisors are asked to report the subordinates' employment status two weeks before the survey. Then in the first wave survey, the subordinates report their own employment status. The survey question is "You are currently 1 'permanent employee', 2 'contract employee', or 3

Table 2. Organizational citizenship behavior used in this study

	Strongly disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
m56. I will attend functions that are not required but that help the hospitals image	1	2	3	4	5
m57. I will keep up with developments in the hospital	1	2	3	4	5
m58. I will defend the hospital when others criticize it	1	2	3	4	5
m59. I will show pride when representing the hospital in public	1	2	3	4	5
m60. I will offer ideas to improve the functioning of the hospital	1	2	3	4	5
m61. I will express loyalty toward the hospital	1	2	3	4	5
m62. I will take action to protect the hospital from potential problems	1	2	3	4	5
m63. I will demonstrate concern about the image of the hospital	1	2	3	4	5

'dispatched employee"'. Lastly, we identify the respondents' employment status through crosschecking the employment status information obtained from both parties and asking the HR department to verify inconsistent information. In the empirical analysis, the three different employment types are categorized into two: 1 is the standard employee, 0 is the temporary employee (contract employee and dispatched worker).

(2) Organizational Citizenship Behavior
Organizational citizenship behavior was measured by using an 8-item OCB scale developed by Organ [10]. Here we only used 8 items which are beneficial to the organization. Examples are: "I will attend functions that are not required but that help the hospital's image", "I will keep up with developments in the hospital" (Cronbach's α = .90). All the items of the OCB scale are listed in Table 2.

(3) Turnover Intention
Four items were used to assess each employee's turnover intention. Examples are: "I have frequent thoughts of leaving this hospital", "I often seek information

Table 3. Turnover intention items used in this study

	Strongly disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
m25. I have frequent thoughts of leaving this hospital	1	2	3	4	5
m26. I intend to find a new job	1	2	3	4	5
m27. I often seek information about other job possibilities	1	2	3	4	5
m28. I will quit my job soon	1	2	3	4	5

about other job opportunities" (Cronbach's $\alpha = .94$). All of items of the turnover intention scale are listed in Table 3.

(4) Organizational identification
Organizational identification was measured by using a 6-item scale developed by Mael and Ashforth [9]. Examples are: "When someone criticizes my team, it

Table 4. Organizational identification items used in this study

	Strongly disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
e24. When someone criticizes my team, it feels like a personal insult	1	2	3	4	5
e25. When someone praises my team, it feels like a personal compliment	1	2	3	4	5
e26. My teams successes are my success	1	2	3	4	5
e27. I am very interested in what others think about my team	1	2	3	4	5
e28. When I talk about my team, I usually say "we" rather than "they"	1	2	3	4	5
e29. If others criticized my team, I would feel embarrassed	1	2	3	4	5

feels like a personal insult", "I am very interested in what others think about my team" (Cronbach's $\alpha = .91$). All the items of the turnover intention scale are listed in Table 4.

(5) Control Variables
We controlled five demographic variables, which are age, gender, education background, organizational tenure, and employees' difference. Age and tenure were measured in years. Gender was measured as a dummy variable, 1 for male and 0 for female. As for education background, we used 1 to represent bachelors and above, 2 to represent technical school graduates, 3 to represent senior high school graduates and below. Treatment difference is employees' cognition on the organization's treatment differences between temporary workers and permanent workers on income level, welfare, uniform, training opportunities, etc.

4 Results

4.1 Descriptive Analysis

Tables 5 and 6 provide the descriptive statistics and correlations of the variables in this study. In the Table 5, the mean, standard deviation, minimum and maximum value of each variable are reported. As the figures in Table 5 shows, in a final sample ($N = 209$), 26.3% are male. The average age of the participants are 37.6 years old ($SD = 8.76$). The average organizational tenure is 11.7 years ($SD = 8.83$). As for education background, we used 1 to represent bachelors and above, 2 to represent technical school graduates, 3 to represent senior high school graduates and below. The average education background of participants is 1.41 ($SD = 0.69$).

Table 6 reports the correlation matrix of the research variables. As expected, independent variables of employment status are significantly correlated with organizational identification ($r = 0.17$), turnover intention ($r = -0.12$) and OCB ($r = 0.12$). The significance of correlation between employment status and the organizational identification, turnover intention and OCB indicate that permanent employees show higher organizational identification, less turnover intention and more OCB compared, as compared to temporary employees.

The Cronbach's alphas of major variables are listed in Table 6. The Cronbach's alphas of organizational identification, OCB and turnover intention's Cronbach's alphas are 0.91, 0.91 and 0.94. All the figures exceed the acceptable criteria, which is 0.70, which suggests that the validity of the scales chosen in this study is acceptable.

4.2 Confirmatory Factor Analysis

To further determine the factor structure of your data set, we conduct the confirmatory factor analysis of OCB, turnover intention and organizational identification. For OCB, the factor loadings are range from 0.60 to 0.85. For turnover

Table 5. Descriptive statistics of research variables

Variable	Number	Mean	Std. Dev.	Min	Max
Age	209	37.56938	8.755011	20	67
Edu	209	1.416268	0.689149	1	3
Gender	209	0.2631579	0.4414046	0	1
Tenure	209	11.70793	8.831362	0	46
Treatment difference	209	1.516373	0.358681	1	2.888889
ES	209	0.8373206	0.3699591	0	1
OI	209	3.844169	0.6415724	2	5

Note: $N = 209$; $^{*}p < 0.1$, $^{**}p < 0.05$, $^{***}p < 0.01$.

intention, the factor loadings are from 0.82 to 0.95. For organizational identification, the factor loadings are from 0.67 to 0.90. The detailed factor loading of each item of OCB are listed in Table 7 as an illustration. Since component reliability of each items are higher than the criteria, i.e., 0.45. The measurement in this study is acceptable.

We then test the *Hypotheses 1* and *2* first. Then after we mean-center the variables, we use moderated regression analyses to test *Hypotheses 3* and *4*.

4.3 Employment Status and OCB, Turnover Intention

The results of OLS regression are presented in Table 8. In Model 1, we put in 5 control variables, including age, education background, gender, tenure and participants' difference. None of these five control variables has significant impact on employees' OCB. When the independent variable, "temporary employment", is added into the regression in Model 2, the results show that permanent employment has a positive impact on OCB but the impact is insignificant ($\beta = 0.202$, $p > 0.1$). In Model 3, we remove the control variable of education background, then we find that permanent employment has a significant positive impact of OCB ($\beta = 0.251$, $p < 0.1$). These results suggest that if education background is not considered, standard employees show more organizational citizenship behavior than temporary employees.

In Model 4, the dependent variable is turnover intention. We also put in 5 control variables, including age, education background, gender, tenure and participants'difference. Results show that age ($\beta = -0.018$, $p < 0.1$) has a negative impact on turnover intention while gender ($\beta = 0.272$, $p < 0.1$) has a positive impact on turnover intention. When the independent variable, "temporary employment", is added into the Model 5, results show that permanent employment has a significant negative impact on turnover intention ($\beta = -0.402$, $p < 0.1$). Therefore, *Hypothesis 2* is supported.

Table 8. Regressions results

Variable	Dependent variable				
	OCB			Turnover intention	
	M1	M2	M3	M4	M5
Age	0.108	0.010	0.009	−0.018	−0.018
Edu	−0.115	−0.055		0.108	−0.116
Gender	0.028	0.025	0.024	0.273	0.279
Tenure	−0.008	−0.010	−0.010	−0.156	−0.012
Difference	−0.100	0.038	0.040	−0.638	−0.160
ES		0.201	0.251**		−0.402**
R^2	0.020	0.029	0.027	0.077	0.090
ΔR^2	−0.004	0.000	0.003	0.054	0.070
F	0.830	1.000	0.636	3.380	3.470

Note: $N = 209$; $^{**}p < 0.1$, $^{**}p < 0.05$, $^{**}p < 0.01$.

4.4 The Moderating Effect of Organizational Identification

We also conduct OLS regression to examine *Hypothesis 3*. The results are reported in Model 6 of Table 9. In this model, besides the control variables, we introduce the independent variable Employment status (ES), the moderator organizational identification (OI) and the interactions of $ES \times OI$ (both variables are mean-centralized). Results show that the interactions of $ES \times OI$ has a positive impact on employees' OCB, but it is not significant ($\beta = 0.178$, $p > 0.1$). Therefore, the *Hypothesis 3* is not supported.

We follow the same steps to test *Hypothesis 4*. The results are demonstrated in Model 7 of Table 9. In this model, besides the control variables, we introduce the independent variable Employment status (ES), the moderator organizational identification (OI) and the interactions of $ES \times OI$ (both variables are mean-centralized). We find that the interactions of $ES \times OI$ has a significant positive impact on employees' turnover intention ($\beta = 0.638$, $p < 0.1$). Therefore, our *Hypothesis 4* is supported.

5 Conclusion

In this study, we investigate the relationships between temporary employment, employees' OCB and turnover intention. We also propose that employee's organizational identification is a moderator in the above relationships. Results show that if education is not controlled, standard employees show more OCB than temporary employees. Compared with temporary employees, standard employees show less turnover intention. Organizational identification positively moderates the relationship between temporary employees and turnover intention, indicating that if a standard employee has a higher organizational identification, the impact of employment form on turnover intention would be much stronger.

Table 9. Moderating Effect

Variable	Dependent variable	
	OCB M6	Turnover intention M7
Age	0.009	-0.019^{**}
Edu	-0.048	0.001
Gender	0.144^{**}	0.202

OI	0.561	-0.385
$EF \times OI$	0.178	0.638^{**}
R^2	0.35	0.159
ΔR^2	0.324	0.126
F	13.45	4.74

Note: $N = 209$; $^{**}p < 0.1$, $^{**}p < 0.05$, $^{**}p < 0.01$.

Our research makes two contributions to current literature. First, we have examined a conceptual model in cross cultural context. Although several studies in west have investigated the relationships between temporary employment and in-role/out-role performance, we do not know whether their results are consistent in Chinese context. Therefore, it is theoretically important for us to investigate these relationships in China. Second, our research demonstrates the important role of organizational identification. More specifically, we contribute to the literatures by examining and confirming organizational identification as a moderator in the above relationships.

Our paper also provides some managerial implications. To maximize temporary employees' work efforts, it's vital to increase their job satisfaction by improving their salary and welfare. Meanwhile, human resource department need to take effective actions to promote enterprise culture among temporary employees, thus raising their organizational identification and loyalty to work.

This paper also has some limitations. First, all data were collected within a single industry, which decreases external validity. Second, we use the self-reported data for the analysis, which may raise the possible common method bias. We recommend that future research could collect the data from different resources. Whether the findings of our study apply to workers in other settings or to other types of workers, should be examined by future studies.

Abstract. To detect sleep apnea syndrome (SAS), we propose a method that integrates sound and image processing results using overnight sound and video data. In sound processing, snoring sounds are initially extracted using an unsupervised method. The zero-cross ratio (ZCR) and power (PWR) are calculated for the snoring sounds, and the total validations (TV) for ZCR and PWR are calculated using the sound data. Then, a support vector machine (SVM) is used to classify SAS and non-SAS subjects using TV values. In image processing, inter-frame absolute difference values are calculated every 1 s from video data, and multiscale entropy (MSE) is calculated using the time series data. Then, an SVM is employed to classify SAS and non-SAS subjects using two MSE values selected based on the Bhattacharyya distance. To integrate sound and image data, we focused on the number of detected snores. When two results do not match and the number of extracted snores is greater than five per hour, the sound processing result is adopted. When the number of snores is less than five per hour, the image processing result is adopted. The proposed integrated method demonstrates better accuracy than that obtained using only sound or image processing results.

1 Introduction

Sleep apnea syndrome (SAS) is a disorder in which breathing stops during sleep. SAS can cause sleepiness during the day, which may lead to traffic accidents. In addition, SAS induces a serious circulatory organ disease [6]. SAS symptoms

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_65

occur in approximately 4% of men and 2% of women. If people without subjective symptoms are included, this increases to 24% of men and 9% of woman [11], which is a significant portion of the population. In Japan, the prevalence of SAS is thought to be the same or more than in the United States [9]. Apnea is a temporary cessation of breathing for more than 10 s while sleeping, and hypopnea is an abnormally low ventilation, i.e., less than 50% of normal, lasting more than 10s. The apnea hypopnea index (AHI) represents the occurrence frequency per hour. Apnea is diagnosed when the AHI is five or more. Apnea and hypopnea can be classified as obstructive, central, or mixed. Simple noninvasive SAS diagnostic tools include pulse oximeters and apnomonitors. More reliable diagnoses can be obtained by polysomnography (PSG). PSG is performed in a hospital and requires multiple sensors. To collect data, the subject is required to stay in hospital overnight. Various techniques to detect SAS have been proposed. These techniques use sound data [2], video data [4], and a combination of depth video and sound [10]. Previously, we proposed a method that uses microphones and cameras, which are widely used noncontact sensors [7].

2 Methods

In this study, we have improved the previously proposed method. We used PSG data and evaluated the accuracy of the improved method to classify SAS and non-SAS more precisely by integrating the results of sound and image processing.

2.1 Data Acquisition

Overnight PSG data were collected from the sleep studies of 55 patients (nine females, 61.2 ± 12.4 years) who were suspected to suffer from SAS and referred to the Kanazawa Medical University (Ishikawa, Japan). The subjects provided written consent to participate in the sleep studies, which were conducted in 2014. Four subjects were diagnosed as normal and 51 were diagnosed with different levels of SAS. To obtain more non-SAS subject data, overnight pulse oximeter data were collected from 24 employees of the Industrial Research Institute of Ishikawa or CosmoSummit Co., Ltd. in 2014–2015. These employees, none of whom complained about sleep apnea symptoms, also provided written consent, took data according to a data acquisition manual themselves. From the analysis of the pulse oximeter data, three subject datasets were considered to indicate SAS, and 24 subject datasets were considered to indicate non-SAS. Subject information, such as age, gender, height, and weight, was also collected (Table 1).

The overnight sounds of the participants were recorded using a microphone (SONY ECM-360) placed near the subject's head. The sampling rate was 11025 Hz at 16-bit resolution. Overnight video of the participants was recorded using a camera (IDS UI-1220LE-M-GL) with a lens (TAMRON12VM412ASIR) that is sensitive to infrared light. The camera was placed at the side of the bed. An example video frame is shown in Fig. 1:

Table 1. Overview of subject data

Parameter	SAS subjects: 44 male, 10 female		Non-SAS subjects: 26 male, 2 female	
	Mean $\pm$ σ	Range	Mean $\pm$ σ	Range
Age	59.4 ± 14.2	26–88	38.5 ± 9.9	23–66
BMI	25.8 ± 3.6	17.2–33.4	22.8 ± 3.2	17.8–30.2
AHI	38.8 ± 18.8	5.5–76.0	2.6 ± 1.1	0.6–4.7

Fig. 1. Example video frame

2.2 Sound Processing

Since various sounds, e.g., subject and bedding movements, and coughs, are included in the recorded sound data, we used an unsupervised method proposed by Azarbarzin et al. [1] to extract snore sounds. The unsupervised snoring sound extraction was performed as follows. After applying a band pass filter (BPF, 150–5000 Hz) to the recorded data, a section in which the volume is greater than a predefined threshold continues for 0.4 to 2.0 s was extracted as an episode. Extracted episodes include snoring episodes and episodes due to noise other than snoring. For one episode, 50% overlap is multiplied by a 50-ms window, and short-time Fourier transform (STFT) was performed. The STFT results for an episode were averaged, and the spectral intensities in the range 0–5000 Hz (in practice, BPF in the range 150 to 5000 Hz) were summed every 500 Hz to create a 10-dimensional vector. Principal component analysis was performed using the 10-dimensional vector of all episodes. We reduced the dimensionality of the feature space to a two-dimensional vector, and classification was performed using the Fuzzy c-Means clustering method. In this study, we adopted the number three classes employed in Azarbarzin's method. Among the three classes, clusters with a greater number of episodes were considered snoring clusters, and episodes in this cluster were considered snoring episodes.

For snoring episodes extracted by unsupervised methods, SAS and non-SAS were classified using the method proposed by Azarbarzin et al. [2]. The zero-crossing rate (ZCR) and power value (PWR) were calculated for the extracted snoring episodes. Snoring sounds are highly variable relative to the severity of SAS. As severity increases, characteristics, such as frequency, will vary; thus, ZCR and PWR were used to calculate the amount of change (total validation norm, TV), i.e., TVzcr and TVpwr. The calculation of TVi is shown in Eq. (1). These two values are output as a two-dimensional feature amount for the recorded data from a single night. However, TVzcr and TVpwr output 0 when no snoring sounds were detected. The two-dimensional features are used for support vector machine (SVM) classification. A radial basis function kernel (RBF) was used with the SVM, and parameters C and were determined by grid search.

$$TV_i = \frac{1}{N}\sum_{k=1}^{N-1} |f_i(k+1) - f_i(k)|. \tag{1}$$

2.3 Image Processing

The video recordings had a duration of approximately 6 hours and were recorded in MJPEG format at a resolution of 752×480 and an average frame rate of 5 frames per second (fps). Considering that the fastest physiologically important body movements associated with SAS during sleep are respiratory movements and the respiratory rate for adults at rest is on average 12–18 breaths per minute, the frame rate was reduced to 1 fps. The overall motion signal was derived by calculating the mean absolute pixel difference between successive frames.

Multiscale entropy (MSE) analysis was performed using the obtained signal. MSE analysis is an analytical method proposed by Costa et al. [3], which is highly useful for physiological indices, especially heart rate variability. Generally, for a signal with high periodicity, the values obtained are lower, and the values obtained for waveforms with lower periodicity are higher. Therefore, by adapting the MSE analysis to the respiratory motion signal, the disorder degree of the periodicity of the respiratory signal was evaluated and used as a classification parameter.

MSE analysis is primarily performed in two steps. First, a coarse grain process averages the original data $x = \{x_1, x_2, \cdots, x_n\}$ by t to obtain data $y^{(t)} = \{y_1, y_2, \cdots, y_{N(=n/t)}\}$. Next, entropy is measured for each coarse-grained time series corresponding to t. Different measures of entropy can be employed for this step. Here, sample entropy proposed by Richman and Moorman [8] was used as the entropy metric. This metric takes two parameters, i.e., pattern length m and similarity criterion r, which is the tolerance for accepting pattern matches. r is a positive real value and is typically chosen between 10% to 25% of the standard deviation of the time series. Two patterns of length m match if each point in the first pattern is within distance r from the corresponding point in the second pattern. The distance between two vectors is defined as the maximum absolute difference between the components of those two vectors. A vector $x_m(i) = \{x_i, \cdots, x_{(i+m)-1}\}$ where $1 \leq i \leq N - m$ is defined as a pattern of length m, Note that i can only go up to $N - m$ to ensure that vector x_{m+1} of length $m + 1$ is also defined. $n_i^m(r)$ is defined as the number of vectors $x_m(j)$ that have distance less than r with $x_m(i), (i \neq j)$ to exclude self matches. $U_i^m(r) = n_i^m(r)/(N - m)$ is the probability that the distance between vector $x_m(i)$ and any other vector $x_m(j)$ is less than r. $U^m(r)$ is the probability of any two vectors of length m being within distance r of each other.

Therefore, the probability $U^m(r)$ is expressed as

$$U^m(r) = 1/(N - m) \sum_{i=1}^{N-m} U_i^m(r). \tag{2}$$

The sample entropy is defined as

$$H_{SE}(m, r) = \lim_{N \to \infty} - \ln \frac{U^{m+1}(r)}{U^m(r)}. \tag{3}$$

This is estimated by the following statistic

$$H_{SE}(m, r, N) = - \ln \frac{U^{m+1}(r)}{U^m(r)}. \tag{4}$$

The sample entropy was calculated for each subject's motion signal over scale factors $t \in T = \{1, \cdots, 60\}$, pattern lengths $m \in M = \{2, 3, 4, 5, 6\}$, and similarity criteria $r \in R = \{0.10, 0.15, 0.20, 0.25\}$. Therefore, a total of 1200 sets of entropy values were calculated for all subjects.

The Bhattacharyya distance [5] is a measure of similarity of two continuous or discrete probability distributions. In classification, it is used as a measure of separability between two classes. The distance is calculated from the Bhattacharyya coefficient ρ, which is a measure of the amount of overlap between two probability distributions. For discrete distributions p and q over a domain X, the Bhattacharyya coefficient is defined as follows

$$\rho = \sum_{x \in X} \sqrt{p(x)q(x)}, \tag{5}$$

where $0 \leq \rho \leq 1$. The Bhattacharyya distance Δ_B is defined as follows

$$\Delta_B = - \ln(\rho), \tag{6}$$

such that $0 \leq \Delta_B \leq \infty$. Low ρ values or high Δ_B values indicate little overlap between p and q. The 1200 combinations of MSE parameters were analyzed and ranked based on the distance between their corresponding sample entropy distributions of SAS and non-SAS subjects. Larger Bhattacharyya distance between the two distributions indicates that the sample entropy values are better feature candidates for classification.

An SVM with an RBF kernel was used for classification of SAS and non-SAS subjects. The features used in the classification were the sample entropy values, and parameters C and σ were determined by grid search.

2.4 Integration of Sound and Image Processing Results

We performed final classification from the results obtained by image processing and sound processing. If both results match, the result can be the final classification result. On the other hand, when each result differs, either result is adopted by considering the reliability of the acquired data. In this study, we considered the snoring number extracted from the sound data. When the number of extracted snores was greater than five per hour, the sound processing result was adopted. When the number of extracted snores was less than five per hour, the image processing result was adopted. In the data acquisition environment, the image data could not be acquired successfully because the degree of installation difficulty of the camera is greater than that of the microphone, and the distance is too close or the angle does not match. Therefore, when the extracted snore number is detected as 5 per hour or more, the sound processing result was adopted. In addition, several cases were confirmed where snoring did not occur even before and after the occurrence of apnea, and such cases could not be distinguished from cases where recording failed; thus, if snoring was not detected, the image processing result was adopted.

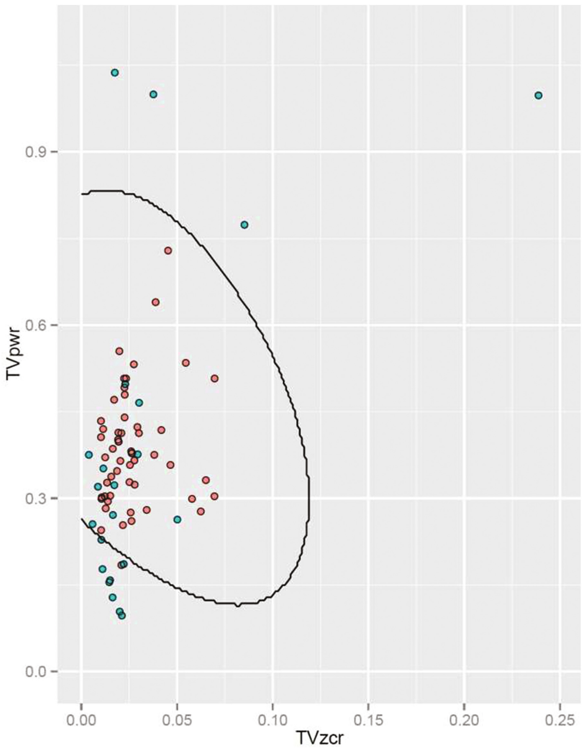

Fig. 2. SVM result in sound processing using all data

3 Results

In sound processing, non-SAS data with a small snore count were greatly deviated from the origin when plotted on $2D$ feature coordinate graph, and learning in the SVM did not provide proper results. The SVM result obtained using all data is shown in Fig. 2. Since snoring was not detected sufficiently, data with than five snores per hour were assumed to be non-SAS, and data classified by the SVM for the remaining data were taken as the sound processing result. The SVM result using data with less than five snores per hour is shown in Fig. 3:

In image processing, MSE analysis was performed to calculate the Bhattacharya distance, and the parameters sorted in descending order are shown in Table 2. The top of 2 parameter sets of $(m, r, t) = (4, 0.10, 30), (2, 0.25, 34)$ were adopted for SVM. The sample entropy when $(m, r) = (4, 0.10)$ is shown in Fig. 4. The result of SVM is shown in Fig. 5.

Accuracy was calculated by leave-one-out cross validation. With only image processing, the accuracy was 81.7%, sensitivity was 81.5%, and specificity was 82.1%. With only sound processing, the accuracy was 85.4%, sensitivity was 85.2%, and specificity was 85.7%. These results show that sound processing

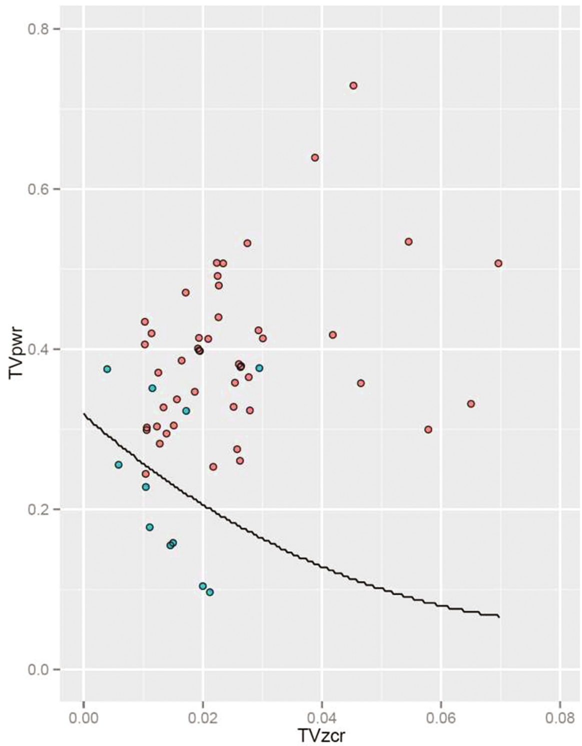

Fig. 3. SVM result in sound processing with more than five snores per hour

Table 2. Sample entropy parameters of the highest bhattacharyya dist

Order	Bhattacharyya dist	m	r	t
1	0.7140	4	0.10	30
2	0.7135	2	0.25	34
3	0.7119	2	0.25	44
4	0.7100	3	0.10	38
5	0.7074	2	0.10	49

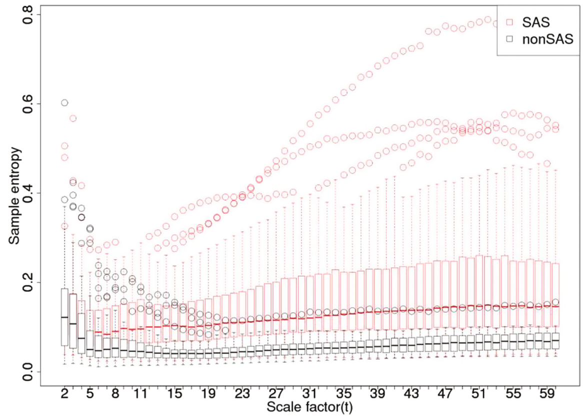

Fig. 4. Sample entropy when $(m, r) = (4, 0.10)$

outperformed image processing. In the integrated result, the accuracy was 89.0%, sensitivity was 92.6%, and specificity was 75.0%, which shows a decrease in specificity compared to the sound processing results; however, improvements to accuracy and sensitivity were observed. Table 3 compares classification results and the final results for image and sound processing.

Overnight PSG was used to obtain the number of apnea events and the number of hypopnea events. Subjects were classified as apnea or hypopnea type by comparing these events. In the sound processing results, there were eight false negatives out of 54 positive cases; however, in the integrated results, false negatives were reduced to four. In this case, among the four subjects that changed from false negatives to true positives, three subjects were hypopnea type. Of the 19 apnea type subjects, only one was mistaken as a false negative with sound processing. Thus, sound processing is effective for detecting apnea type SAS but less effective for hypopnea type SAS. However, by integrating the sound and image processing results, it is possible to reduce errors by half.

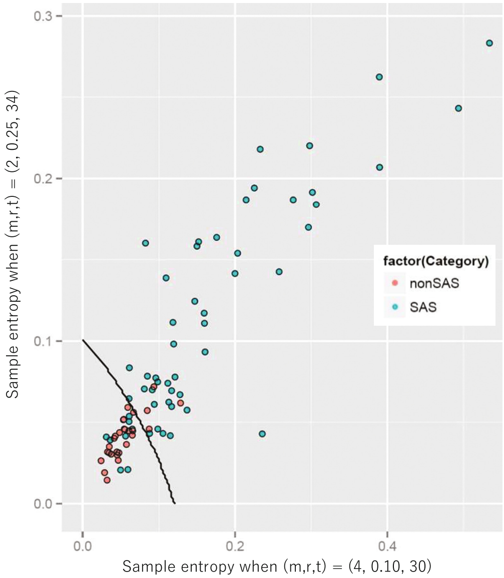

Fig. 5. SVM result in image processing using all data

Table 3. Individual results

Process	Image	Sound	Integrated
Accuracy (%)	81.7	85.4	89.0
Sensitivity (%)	81.5	85.2	92.6
Specificity (%)	82.1	85.7	75.0
Positive predictive value (%)	89.8	92.0	87.7
Negative predictive value (%)	69.7	75.0	84.0

4 Discussion and Conclusion

Screening methods that can easily detect SAS are expected. Therefore, we analyzed sound data and image data obtained using microphones and cameras, which are inexpensive and familiar sensors. We have proposed a screening method to classify SAS and non-SAS subjects. In this study, we focused on the number of snores per hour. When the number of extracted snores was large, we used sound processing due to good accuracy. However, low accuracy was obtained with sound processing when the number of snores was small; thus, we proposed a method using image processing. The experimental results demonstrate that the proposed integrated method (sound and image data) can screen at high accuracy compared to screening with only sound or image data. Furthermore, the proposed method is effective for screening hypopnea SAS.

Microphones and cameras are standard sensors on smartphones; therefore, it can be expected that SAS screening can be performed easily using smartphones by applying the results of this study.

Abstract. The pricing strategy of crowdfunding has always been its highlights and difficulties. A pricing strategy formula concerning with the price discrimination is obtained through the in-depth studies of the price discrimination theory and the mechanism of crowdfunding pricing, considering the crowdfunding financial limits which constitute constraint conditions. This article carries out a study on the effect of advertising profit of crowdfunding and founds the profit function. Furthermore, it studies the model of crowdfunding based on the 1P theory to solve this issue. Finally, the article provides a corresponding pricing strategy on product crowdfunding based on the above studies. It is expected to contribute to the field of theoretical research on crowdfunding and the pricing strategy through this article, and provide inspiration and reference for enterprises and entrepreneurs when they make the pricing strategy decisions.

Keywords: Crowdfunding · Pricing strategy · Price discriminate · Profit

1 Introduction

Product crowdfunding refers that the investors put their money into developing a product or service in accordance with the fundraisers; when the product or service begins to be pre-sold or has the conditions for external sales, the fundraisers will provide the developed product or service for the investors. Product crowdfunding needs a third party to be supported by the public. The relevant information of the products, services and producers can be obtained through the platforms, which would save transaction cost while realizing a certain advertising effect.

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_66

The consumers participating in the crowdfunding have strong interests in the project products when these are in the creating or initial stage, willing to provide funds to make the products available as soon as possible, and the price paid for each unit may not be lower than that of the product later on. It is an external direct financing that a project can be conducted smoothly when the crowdfunding reaches the planned fixed amount, which can reduce the difficulty of financing for the companies and can predict the market's reflection and selling through probing the participating action.

It is necessary to establish an adequate pricing and feedback module for a successful project. In general, in order to attract the public to support the participation of supporters, the project launchers will announce the prices of the products and a combination of preferential prices on the platform pre-sale in advance to the market. In addition, the use of the price discrimination strategy can tell the people who have different needs apart to sell. Grasping the psychological expectations of consumers and taking differentiated pricing not only can promote the products and return the funds ahead of time, but also can maximize the corporate profits.

2 Literature Review

For the platforms of the product crowd funding, pre-sale is generally the main way, which functions to find prices well and can help the project launchers or entrepreneurs to create some favorable conditions for price discrimination. Pigou [8] defines that the price discrimination refers to different prices charged by firms for different markets, consumers or different numbers of purchases, and he also puts forward a three-level price discrimination theory. As a kind of theory, price discrimination belongs to the category of the pricing strategy without judging. In the industries with more competition, price discrimination is widely used in a variety of flexible forms. It is an effective pricing strategy, not only helping to enhance the competitiveness of enterprises to achieve its business objectives, but also adapting to the psychological differences of consumers to meet the needs at multiple levels. Rochet and Thanassoulis [10] declares that the price discrimination is an economic phenomenon and a trading strategy, which is popularly used by the sellers; and according to economic thinking, the implementation of the price discrimination strategy for the sellers is positive in terms of the welfare and can thus expand their own profits.

Nocke et al. [7] studied the relations between the product crowd funding and the price discrimination in the context of asymmetric information. In an intertemporal setting in which the individual uncertainty is resolved over time, advance-purchase discounts can serve to the price discrimination between consumers with different expected valuations for the product. Consumers with a high expected valuation will purchase the product before learning the actual valuation at the offered advance-purchase discount; consumers with a low expected valuation will wait and purchase the goods at the regular price only in the occasion where their realized valuation is high. The consumers with higher expectations of participation in the product quality in the case of unknown product quality should enjoy discounts and have the lower prices than those for the regular customers. Enterprises have to target at the customers with different expectations. Belleflamme et al. [11] isolated some important features of crowdfunding on the basis of a unique, hand-collected dataset and proposed a model of crowdfunding that encompasses several of these key features. By constructing the profit function, they obtained the pricing expression of the product and the ownership of the product. On this basis, the enterprise financing limit is given, and the uncertainty of the product quality and information are elaborated. Hu et al. [2] and Ping [9] maximized the profits of producers as the objective function optimization model to analyze the pricing mechanism of the crowdfunding products, drawing the conclusion that the model will help to open up the initial public offering of the product market, and the profits of manufacturers can be expanded with the same total sales.

Lawton and Marom [5] pointed out that crowdfunding is not only a new source of funding for projects, but also a way to quickly attract the attention of users, form early user communities; and because of the large number of media reports and discussions, pre-release has become a common corporate marketing strategy, so crowdfunding is still a very effective marketing tool. Based on the choices of consumers, Bayus [1] applied the model of maximizing their own profits to jointly determine the time choice and pricing decision from the consumer utility function. Zhang et al. [14] and Luo et al. [6] constructed a two-stage pricing model based on the impact of IWOM on customers' perceived value to the product. IWOM can change the cognitive value of customers to the products, the customers who have profound insight seek the overall effectiveness of maximizing products purchasing and brands spreading, and the dominant sellers can maximize the two-stage total profits through using reasonable pricing strategies. Huang [3] and Krishnan et al. [4] elaborated the pricing strategy and analyzed four strategies, such as new product pricing strategy and discount strategy, which can help enterprises make full use of pricing strategy to provide reasonable market prices to obtain the most competence. But all the above literatures just study the traditional price strategy and cannot explain the popular free phenomenon nowadays. 1P business model proposed by Wang [12, 13] breaks the pricing space of the business strategy by integrating the third party to obtain a new competitive advantage, with putting the pricing into the center position and innovatively stressing positioning and locking the third party to pay, which can make profit with the price that is lower than the average cost and can promote with the price that is higher than the expectation of customers.

In this paper, through the deep research on price discrimination theory and crowdfunding pricing mechanism, we not only consider the influence of crowdfunding price on needs, but also further study the effect of network brand spreading and advertising, constructing the maximum profit function of the product crowdfunding in the two occasions to obtain the pricing expression under the constraint for financing amount. This paper also studies the pricing theory of business model proposed by Wang [13] and applies it into the crowdfunding business model with drawing the corresponding pricing strategy.

3 Crowdfunding Pricing Model

3.1 Crowdfunding Pricing Model for Price Discrimination

According to the level of discrimination, the price discrimination can be divided into three levels. The first-degree price discrimination, also known as complete price discrimination, regulates the price according to the possible maximum amount of money paid by each buyer to obtain the full consumer surplus. Based on different consumptions or "segments" to obtain a different price, the second-degree price discrimination only regulates different prices for different segments and thus obtains part of the consumer surplus. The third-degree price discrimination classifies the customers according to a particular standard to make clear which category each customer belongs to, with taking different prices in different markets or to different customer groups for one kind of product.

The first and the second degrees of price discrimination enable the manufacturers to grab the consumer surplus wholly or partly, and this part of the consumer surplus will be transferred into profits, achieving the principle of effective allocation of resources $P = MC$ (equilibrium price equals to marginal cost. That is the requirement of maximizing profits). However, the first-degree price discrimination cannot be fully realized in reality. The pricing of crowdfunding products will usually take the pricing strategies of the first and second degrees of price discrimination, using direct information on needs to choose the consumers indirectly through the choices done by them about different packages. The inverse elasticity rule is taken for different consumer groups, meaning that the consumers who have a high price elasticity will be charged low and the consumers who have a low price elasticity will be charged high. The maximization of profits can be obtained through the price combinations.

By the function of demand and price

$$Q_d = d(P).$$

The demand function of the consumers belonging to different levels in the price combinations is

$$Q_n = (A_n - P_n)/E_p,$$

here A_n is the price that the consumers are willing to pay and E_p refers to the price elasticity of demand.

Assuming that β is the variable cost component of producing a unit of this product and the initial funding amount K is the fixed cost amount put by the firm to produce the required product smoothly. The total cost of product is

$$C = K + \beta \sum_{i=1}^{n} Q_i.$$

The total profit of the project producer is

$$R = \sum_{i=1}^{n} P_i Q_i - K - \beta \sum_{i=1}^{n} Q_i.$$

Only if the total payment of the participant is not less than the total amount of financing K can the raisers get the money from the platforms smoothly. It requires:

$$\sum_{i=1}^{n} P_i Q_i \geq K.$$

To maximize the profits of crowdfunding, it is required to consider how to design the relations between various levels of prices and quantities, that is, to figure out the maximum profit objective function with some constraints

$$\max\ R = \sum_{i=1}^{n} P_i Q_i - K - \beta \sum_{i=1}^{n} Q_i$$

$$\text{s. t.}\ \begin{cases} P_n = A_n - E_p Q_n, \\ \sum\limits_{i=1}^{n} P_i Q_i \geq K, \\ P_i \geq 0. \end{cases}$$

3.2 The Crowdfunding Price Model Concerning with the Advertising Effect

As a result of extensive and effective brand and spreading effects, the product crowdfunding not only can sell the products but also reach the goal of advertising through the release on the Internet platform. Compared with the common advertising tunnels, the influences of crowdfunding include a lower price and sound effects. However, considering that the effect is related much to the demand and price, it is still necessary to research the pricing strategy prudently to maximize the profits.

Assuming the same amount of customer traffic, denote the conventional unit of product advertising budget by G_r and the cost of crowdfunding platform by K_c, the function relation between effect profits and the demands of the rather common advertisements is

$$G_c = G_r \sum_{i=1}^{n} Q_i - K,$$

where the function relation between the price and the demand is

$$Q_n = (A_n - P_n)/E_p.$$

A_n refers to the price which the crowdfunding consumers are willing to pay and E_P is the price elasticity of demands.

Assuming that β is the variable cost component of producing a unit of this product and the initial funding amount K is the fixed cost amount that the firm can produce the required product smoothly. The total cost of product is

$$C = K + K_c + \beta \sum_{i=1}^{n} Q_i.$$

The total profit of the project producer is

$$R = \sum_{i=1}^{n} P_i Q_i - K + G_c - \beta \sum_{i=1}^{n} Q_i.$$

Only if the total payment of the participant is not less than the total amount of financing K can the raiser get the money from the platform to produce smoothly. It needs to meet with:

$$\sum_{i=1}^{n} P_i Q_i \geq K.$$

Taking the advertising effect into account, it is needed to figure out the maximum of profit objective function with constraints to obtain the maximum profits of the crowdfunding

$$\max R = \sum_{i=1}^{n} P_i Q_i - K - K_c + (G_r - \beta) \sum_{i=1}^{n} Q_i.$$

3.3 The Crowdfunding Pricing Model Using the 1P Theory

1P theory refers that the enterprises can expand the profit space through integrating the third party to benefit mutually, to participate in income payments and cost sharing and to break the upper and lower limits of strategic pricing. The third party represents the value of all associated networks, and is the value of the associated network of the enterprise and its customers and partners.

Crowdfunding as a business pattern can also be explained by the 1P theory which wields the third party to pay, and all the crowdfunding patterns can be categorized in the 1P theoretical business model. The product crowdfunding views that the investor as a third party to share some or all of its fixed cost, channels and promotional cost, thereby reducing the cost of the product and improving the total profit of the product. Therefore, the product is also the value logic and trading structure in which the companies, customers and other third-party partners can jointly create and trade value to make mutual benefits.

In the 1P theory, the 4Ps are separated according to the nature of the income and cost, where the price P is the income per unit of product; the product P, the channel P and the sales promotion P are referred to as 3P, which is the unit cost (that is, the average cost AC and $3P = AC$). π refers to the unit profit, and Q means the production, and $\pi = P - 3P = P - AC$, therefore the total profit is $\pi = Q(P - AC)$. Here, $P - AC$ is both the pricing space and profit margin.

According to the linear value hypothesis of strategic marketing, the product price P is paid by the target customer C, so $P = PC$. The unit product cost AC is burdened by the enterprise E itself, so $AC = ACE$, and the product price must be greater than or equal to the average cost $P \geq AC$, that is $PC \geq ACE$, or there is money loss. When the profit is zero, $\pi = P - AC = 0$, i.e. $\pi = PC - ACE = 0$, $PC = ACE$.

The introduction of the third-party investors in the product pool will make the unit product price P no longer equals to the target customer's payment price PC, for it should be added with the price of PB paid by the third-party investors B, that is, $P = PC + PB$, $PC = P - PB$; when the profit is zero, $\pi = (PC + PB) - AC = 0$, $PC = AC - PB < AC$. This proves that even if the price of the product sold to the target customer is less than the price of the product and the average cost, it is also profitable, and how much the profit will be depends on the price paid by the third party and the number of the shared cost.

The theoretical business model of 1P whose pricing space breaks the upper and lower limits of pricing is shown in Fig. 1.

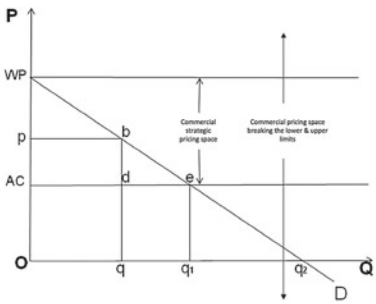

Fig. 1. The business pricing space model of 1P theory

4 Crowdfunding Pricing Strategies

4.1 The Crowdfunding Pricing Strategy Using the Price Discrimination

The crowdfunding products are faced up with different consumer groups who have different demand elasticity to products, creating some conditions for the implementation of price discrimination. The consumers who have higher elasticity can be charged with lower prices to increase sales to gain profits while the consumers who have lower elasticity can be charged with higher prices to raise the profit without decreasing the sales obviously. Considering from elasticity, the supporters of crowdfunding are willing to pay higher prices. When considering uncertainty about the quality of products, supporters of the crowdfunding will face a greater degree of uncertainty, then they need to be given with discounts and the price should be lower. Hence, it is not clear which part of the consumers will face higher prices in the crowdfunding projects. In addition, because the consumers in the crowdfunding projects can choose whether to participate in at their own accordance and the products are marked with personalized features, it is assumed that consumer groups do not trade with each other, and producers can implement price discrimination.

Obviously, price discrimination can make the sellers benefit as much as possible, for the consumer surplus belonging to the buyers will also be transferred to the sellers through price discrimination. Price discrimination is economically efficient. The maximum benefit of sellers equals to the value of social welfare maximization through price discrimination. Of course, the sellers have to be able to distinguish different characteristics of the buyers to make price discrimination work. This difference may exist in the buyers' demand intensity, the quantity of purchase or the price elasticity of demand. The basic principle of implementing price discrimination is that the marginal returns in different markets are equal and equal to marginal cost. The crowdfunding management can regulate a higher price for the market with less price elasticity of demand, implementing the strategy of "less sales but more profit", while a lower price can be regulated for the market with greater price elasticity of demand, and the maximum profit can be obtained through the implementation of "less profit but more sales".

4.2 The Crowdfunding Pricing Strategy Considering the Advertising Effects

Plenty of crowdfunding products are marked as innovative products. If the products are new to the market, it can be considered in the price combination about the three pricing strategies including skim-milk pricing, penetrating pricing and satisfying pricing. Also, as a new product to come out, to select the crowdfunding is also a working advertising way which can lead to a sound effect. Thus, the advertising effect needs to be considered in the crowdfunding pricing strategy, and the ways mentioned above should be implemented flexibly according to the actual situation to achieve profit maximization.

Skimming pricing is a high-priced pricing strategy in the early stage of a new product, provided that the product's quality and image must support the high price of it. Also, consumers have a strong desire for consumption and there is no potential competitor in the market. In this case, consumers are willing to pay for high prices; also, the elasticity of demand, sale and the overall profit income are rather high.

Penetrating pricing strategy is a low-priced strategy when a new product first comes into the market, in which many consumers will be attracted by the low price to win a sound reputation and a comparatively large market. The prerequisite of this pricing is: the market is highly price-sensitive and the cost of producing and selling will be reduced with increasing sales. Also, the competitors can be expelled through a low price. Such a disruptive and innovative pricing method tends to stimulate consumers' willingness to buy and bring about sound advertising effects, resulting in more profits.

Satisfying pricing strategy is a strategy between skimming pricing and penetrating pricing. It is an intermediate pricing which can satisfy both producers and consumers. The prerequisite of such a pricing is that this product is comparatively mature and the consumers are familiar with the product. Also, the information is symmetry. The consumers can buy this product according to their own preferences. If the consumers are satisfied with the price, more attention of them will be placed on the product experience, then the high-quality product will win a good name, and the manufacturers will thus obtain rich profits.

In short, it needs to take the actual situation of crowdfunding products into account to choose skimming pricing, penetrating pricing or satisfying pricing. Considering the cost of advertising and error-trying, the maximum product profit can be gained with using a crowdfunding way to sell and make a sound pricing strategy because of the novelty and advertising needs of these products.

4.3 The Crowdfunding Pricing Strategy Using the 1P Theory

The 1P theory claims that any business model is a revenue-cost transaction structure in which customers, third-party associated customers, and third-party production partners participate in co-creating and trading network values. In the business model of the product crowdfunding, the consumer may be a producer or the producer may be a consumer at the same time. The third-party associated customers who pay the prices can be either consumers or enterprises; the third-party production partners who share costs can be either a business or a consumer. Transaction cost is the most common network value in the network economy, and the emergence of the third parties makes transaction cost lower. The reduction in the number of transaction equals to the result of the number of brands multiplied by the number of customers minus the number of brands then adds the number of customers, and the difference will be multiplied by the cost of each transaction. The result is the transaction cost saved by the third-party integrated brands and the customers. Therefore, the number of the third parties can be expanded through the pricing strategy to lower the transaction costs in a greater degree to maximize profits.

The business model innovation of crowdfunding should break the lower and upper limits of the commercial competitive pricing to access to new competitive advantages and expand profit space through discovering, creating, trading network values and integrating the third-parties' paying. In the formulation of pricing strategies, it should be focused on discovering, creating and capturing the network values, paying attention to the cooperation among businesses, customers and partners to jointly benefit from expanding the total values. Also, it needs to be considered to use the ecological network thinking to re-examine the economic nature of the businesses, customers, competitors, suppliers and even the whole commercial environment to assess the values of the associated network within or outside the enterprise and find out the high-volume crowdfunding-targeted customers to jointly create and trade network values, achieving the purpose of win-win cooperation.

5 Conclusion

5.1 Theoretical Contribution

In this paper, we studied profoundly the price discrimination theory and the pricing mechanism of the crowdfunding pricing. By considering the effect of the crowdfunding pricing on demand to compose the profit function and the constraint conditions of the financing, it was figured out the crowdfunding pricing expression concerning with the price discrimination. Compared with the traditional sales modes, the total sales of the crowdfunding products remain the same, while the proportions of crowdfunding consumers and conventional consumers change oppositely. The crowdfunding mode can distinguish the different preferences of different consumer groups, according to which the market's attitude towards the products is likely to be judged. The unit price given by crowdfunding consumers is higher than that of conventional consumers. The crowdfunding raisers are faced up with a funding ceiling, and if the ceiling is touched, the crowdfunding will be a failure. Not only can the new medium and small enterprises finance without much difficulty by crowdfunding, but also more profits can be achieved for the businesses compared with the traditional sale modes.

Also, we further studied the maximum profit function of the product crowdfunding with the advertising effects. Finally, we studied the pricing theory of the business model in which the third parties pay in the theory of 1P, and then applied it to the business model of crowdfunding to get the corresponding crowdfunding pricing strategies, aiming to obtain the maximum profit. The paper is expected to contribute to the theoretical research in the crowdfunding financing and pricing field, and also provide references for enterprises and entrepreneurs to make decisions on pricing strategies for their products.

5.2 Marketing Significance

Pricing strategy is an important part of the marketing combination for a business. Enterprises need to prudently formulate the pricing strategies of the products when making the crowdfunding plans. Only by innovating and conforming to the objective laws of the market economy can the enterprise win more profits in the target market and achieve a better reputation and advertising effects. Making the right crowdfunding pricing strategy is not only an important factor in maintaining the interests of manufacturers and customers, but also the key to overcome competitors, develop and consolidate the market.

5.3 Limitations and the Future Research Prospects

Due to the short rising period of the Internet crowdfunding, the domestic and foreign literature about its product pricing is correspondingly scarce. Crowdfunding product pricing research also belongs to the emerging field, which has great research value and profound potential. Moreover, with the rapid iteration of technologies and business models, the industry of crowdfunding is changing incessantly and the pricing strategy research should follow the development of the situation. This paper gives the theoretical expression of the crowdfunding pricing using the price discrimination as well as the maximum profit function considering the effects of advertising, and there may be more factors which should be taken into account when planning the actual cases.

With the support of the policies, the developing potential of crowdfunding model is not to be limited, especially in the items of culture innovation and technologies. Young people are more likely to express themselves and communicate on the Internet, thus, the consumer groups of the products of culture innovation and technologies match well with the main active users on the Internet. With the help of the crowdfunding platforms and the social network, the crowdfunding projects can be focused as soon as possible. Not only can the money be obtained but also the sound advertising effects can be achieved. If we introduce the analyzing technologies of large data into pricing strategies, it may be more accurate in terms of dimensions and data processing to make the strategies more effective.

Abstract. The theory of Innovation System has been used to understand the complexity and instability of innovation. Recently Strategy management researchers have found Innovation-Driven Strategy is transferred from national level to enterprise level. The dualistic Innovation System is dominated by government agencies and enterprises in parallel, which is less conducive to innovation of private enterprises. The dualistic main-body Innovation System is converted into the multi-nested Innovation Support System by building a Support System of Innovation-Driven Strategy (SSIDS) in private enterprises. Through analyzing the connotation, structure and characteristic, a new theoretical model is pioneered that serves as a guide for innovation strategy in private enterprises.

Keywords: Private enterprises · Innovation-driven strategy · Support system

1 Introduction

Managers should put additional importance on innovation that plays a significant role as a bridge between competitive strategies and firm performance in a developing economy environment [1]. As stepping into the "new normal", the development of economy is not investment-driven, but innovation-driven in China, which reflects the reconstruction of economic engine and switching of developmental strategy [12]. Much of research has examined that private enterprises (PE) are superior to state-owned enterprises (SOE) about innovative ability [8]. According to the statistics, private enterprises have more R&D projects, R&D investment and patents than state-owned enterprises. Therefore, private enterprises with innovative potential play a leading role in innovation-driven strategy. However, market mechanism with inherent weaknesses has blocked the development of innovation in China. "Perfect market" also breeds Opportunism which jeopardizes innovative performance of PEs [4]. Although with huge innovative potential, PE faces systemic risk. When in the immature market, entrepreneurs improve transformational leadership with the expectation of favorable

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_67

business environment that the government creates. The dualistic Innovation System dominated by government agencies and enterprises in parallel is extensively implemented in China [16]. There are some divergences concerning relationship between the government and enterprises, which roots in complexity and instability of innovation. The theory of Innovation System cannot solve new problems of PEs.

How does PE build the internal support system to keep innovative performance? How does the government improve the business ecosystem without interference to PE This article will solve these problems and develops a theoretical model of Innovation-driven Support System, which can change traditional innovation paradigm and offer a framework to further empirical studies. To do this we build our discussion on extensive relevant literatures and enterprise practices. Using methods and theories of the system, the Support System of Innovation-Driven Strategy (SSIDS) is built.

In the following sections, we first review current researches and state deficiencies. We then go on to analyze connotation, structure and characteristic of SSIDS. Finally, we discuss the implications of our theoretical model for managers and provide directions for further research.

2 Literature Review

The inflexion point theory demonstrates that according to the decreasing law of marginal utility, contribution degree of basic elements, such as natural resources and capital, present descending trend. Therefore, the long-term development of economy depends on intellectual and technological factors. The inflexion point theory promotes innovation-driven theory, which manifests investment-driven strategy is replaced by innovation-driven strategy. The concept of innovation-driven was initially used by Porter [13]. Porter argued that economic development could be divided into four periods: factor-driven stage, investment-driven stage, and innovation-driven, wealth-driven stage. In innovation-driven stage, the effect of basic factors and investment is led by innovation and a system of innovation-driven strategy taking technological innovation as core is built.

After that innovation-driven development became national strategy, Chinese academics conduct quiet a few examinations regarding innovation-driven strategy. Liu [11] contended that the innovation-driven development means the change of economic engine in China. And he further demonstrated that the growth of economy has transformed from depending on learning and imitation into relying on self-designing, R&D, knowledge-creating. In addition, Zhang [17] analyzed the main features of innovation-driven development, i.e. people oriented, acquiring first-mover advantage and entrepreneur-driven. Li and Wang [10] proposed internal innovation-driven elements including enterprise culture, leaders full of entrepreneurship, expected return; and external innovation-driven elements including technical progress and institutional environment. Meanwhile, WANG Tao and Qiu [16] emphasized that the innovative environment dominated by entrepreneurs is immature and constructed innovation-driven strategy of "two-way drive" effect model that dominated by government and enterprises in parallel.

Innovation origins in Economics, gradually progresses to Management. Meanwhile, innovation-driven development transfers from national strategy to enterprise strategy and entrepreneurs play a major role in innovation. Implementing the innovation-driven strategy is complicated and nonlinear systems engineering. Therefore, many studies have advanced the combination between innovation and system and developed the theory of Innovation System, such as National Innovation System (NIS) [15], Regional Innovation System (RIS) [5], Technological Innovation System (TIS) and Innovation Ecosystem (IE) [2,6]. However, more recent studies argued that Innovation Support System (ISS) is different Innovation System and suggested the performance of innovation actors is restricted by environment, in China. He and Li [7] proposed how the Innovation Support System is established. In the process of innovation, various innovative elements generate and spread new knowledge and technology by interaction to form a network system.

In summary, innovation-driven strategy not only depend on the core competency of enterprises, but need a favorable business environment. Previous studies built the Innovation System that is a dualistic model, which cannot clarify the role of the government and enterprises. The Innovation Support System provides a feasible theoretical framework for innovation-driven strategy in private enterprises. It is how private enterprises effetely combine their core competency and environmental support from the government mostly, which is the deficiency of present literature.

3 The Structure of SSIDS Model

It is complex system engineering for private enterprises to implement the innovation-driven strategy, which is influenced by various factors inside and outside the system. Elements form inherent complex relationships by interaction, such as resources, capabilities and environment, which is regarded as a system. Therefore, it is necessary to build a system to support the innovation-driven strategy in private enterprises.

3.1 Strategic Support System

Strategic support system is a collection of subsystems composed by a set of key managerial issues, which support the realization of strategic objectives. This system can be divided into internal and external support subsystems. Internal strategic support subsystem is constituted by internal key managerial issues within the process of strategic implementation and usually includes three parts: impetus subsystem, behavior subsystem and capability subsystem. Specifically, the focus of impetus subsystem is to form power of strategic implementation; the focuses of behavior subsystem include deciding, organizing, motivating and controlling behaviors during strategic implementation; the focuses of capability subsystem is mainly about the optimization of enterprise capabilities including strategic management, R&D, capital operation and marketing. External strategic support subsystem is the collection composed of various external factors and their interactions in the process of implementation of strategies. It mainly refers to external supportive environment, for example, market competition environment, resource environment, policy & laws environment and public service environment.

Support System of Innovation-Driven Strategy (SSIDS) in private enterprises refers to the organic integration and coupling operation of enterprises' internal and external supporting elements. In this system, various elements promote and restrict mutually to seek the balance point supporting the implementation of private enterprises' innovation-driven strategy. Therefore, this system will help to enhance the willingness of private enterprises to implement innovation-driven strategy, facilitate the exchange of internal and external factors such as material, energy and information during strategy implementation process, and further improve their innovative performance.

SSIDS in private enterprises includes two basic parts: internal and external support system. It covers every supportive element inside and outside enterprises during the process of the implementation of innovation-driven strategy, centering on the improvement of innovative performance.

3.2 Internal Support System of SSIDS

Internal support system is a relatively stable network system formed endogenous in private enterprises, consisting of innovation support elements and their mutual relationships. The process of innovation-driven development in private enterprise can be described as: generate innovation impetus, implement innovation behavior, form innovation capability, which leads to the formation of innovation impetus subsystem, innovation behavior subsystem and innovation capability subsystem, as illustrated in Fig. 1.

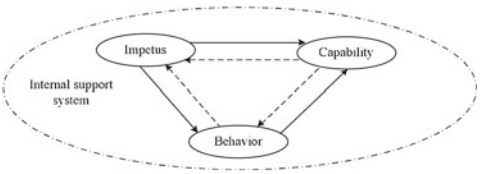

Fig. 1. Internal support system

(1) Impetus Subsystem

The degree of innovation impetus directly influences the speed and scale of innovation in private enterprise. According to the different sources, innovation impetus can be divided into internal impetus supply and external impetus supply. As showed in Fig. 2, internal impetus supply includes resource, entrepreneurship and corporate culture; external impetus supply includes technological advancements, market demands, competitive pressure and the support from government. Impetus of resource comes from continuously innovation resources' injection to internal innovation system by enterprises. These innovation resources include technical personnel, innovative capital and technical equipment etc. Abundant resource can improve the success rate of innovation, increase innovative returns, and thereby strengthen the willing of implementing innovation strategy.

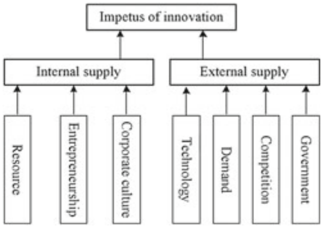

Fig. 2. Impetus subsystem

Entrepreneurial spirit becomes the impetus of continuous innovation in private enterprises through entrepreneurs' self-driven and self-motivation. The innovative spirit of entrepreneurs can motivate more members to participate the practice of innovation-driven strategy and further improve the market performance.

Enterprise innovative culture can influence staff's values, thoughts and behaviors, which infect and motivate innovation of organization, intrinsically and intangibly. Innovative culture performs its function as guiding, constraint, coherence and motivation [14].

When converted to differentiated products or services, achievements in scientific and technological progress can bring higher monopoly profits. Also that motivates enterprises consistently to absorb new results of scientific and technological progress and to re-innovate. The impetus and influence of technological progress performs as: the induction of new technology ideas, technical track and technical expectations.

Market demand is the basic starting point of implementing innovation-driven strategy for private enterprises, which provide new market opportunities and innovative ideas for enterprises. In fact, the market demand has the function of guiding the direction of technological invention, testing the results of technological innovation and providing technical promotion space.

The pressures of competition enhance the crisis awareness of private enterprises. Meanwhile, the incentive of innovation can also be triggered by more market share and monopoly profit. Under fierce competition, the private enterprise will have more intense willing of innovation, more emphasis on market intelligence, more advanced concept and shorter product update cycle.

The government support can make up inherent weaknesses of market. Innovation activities characterized of high risks and externalities, lead to the decline of innovative impetus of private enterprises. To reduce this negative effect, the government should give private enterprises appropriate support such as making up for the overflowed loss of innovation, building innovative infrastructure and sharing risk in innovation.

(2) Behavior Subsystem

When facing various stimulations from external environment, private enterprises make responses by implementing innovation-driven strategy. The behaviors of innovation-driven strategy integrate the interaction of macro and micro, vertical and horizontal, external environment and internal factors, and finally, form a closely related dynamic open system. Figure 3 illustrates the composition of innovation behavior subsystem of private enterprises, the subsystem includes four aspects: policy-making, organization, motivation and control. According to the theory of organizational behavior, the evolution direction of private enterprises' innovation behavior is: policy-making behavior organization behavior motivation behavior, moreover, the control behavior is penetrating in each behavior stage. As the elements of the system, different behaviors also have reverse exchange of information and energy. The detailed path is shown in Fig. 3.

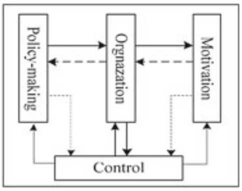

Fig. 3. Behavior subsystem

Behaviors of policy-making imply that managers revise innovation utility function and the risk function by collecting information and decide whether to carry out the innovative activities, which intends to reduce the uncertainty during innovation process. Managers with strong policy-making ability can not only grasp the market information accurately and enhance the willingness of implementing innovative activities, but also can form effective methods and means to improve the success rate of innovative activities.

Behaviors of organization refer to that private enterprises conduct optimized recombination of innovation elements such as technical knowledge, innovation capital and intelligent team in the process of strategic implementation [3]. The quantity, quality and synergy of these factors determine the output and risk of innovative activities. Technical knowledge is the foundation of innovation, which determines the feasibility and risk of innovation. Capital is the blood of innovation, which ensures stability and continuity of the innovative activities. Intelligent team is the brain of innovation; high quality and compound innovative team provides innovation activities the insurance of science and sustainability.

Behaviors of motivation include a series of specific regulations and reward-punish system, by which behaviors of staff are in line with the goal of innovative activities, and their potential are exerted fully. The implementation of innovation-driven strategy is catalyzed by innovation incentives such as spiritual incentives and material incentives. The intensity of incentive will affect the desire and responsibility of innovative activities. Meanwhile, the way of incentive will influence the relationship between innovation behavior and expected returns.

Behaviors of control imply that managers diagnose, adjust and feed back all other behaviors, which can reduce the loss of error behavior, and improve the incomes of correct behavior. Specifically, behaviors of control includes performance evaluation, risk monitoring, modification, feedback and so on. Remarkably, control behavior should run through the whole innovation process because innovation activities are characterized of extreme complexity and uncertainty.

(3) Capability Subsystem

Innovation capability refers to the probability, efficiency and continuity that enterprises carry out innovative activities and obtain innovative income. As shown in Fig. 4, the capability is mainly embodied in knowledge stock and innovative output. With strong innovation capability, enterprise can constantly develop new products, expand the development of the enterprise space, and improve the level of its profitability to maintain strong innovative motivation [9].

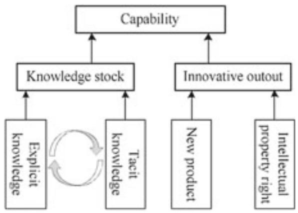

Fig. 4. Capability subsystem

Knowledge stock consisting of explicit knowledge and tacit knowledge is the key element of enterprise growth, resource allocation and innovation. The flow and upgrading of knowledge can nurture flexible thoughts and enhance the recognition of innovation strategy. It is the basis of implementing innovation-driven strategy to improve quantity, quality and structure of the knowledge stock.

Innovative outputs, generally speaking, include new products and intellectual property rights. Once the innovation results are converted into new products with competitiveness, enterprises can attain revenue from innovation. The higher the market value of new products is, the stronger the willingness of enterprise to innovate will become. As the means to ensuring the benefits of innovation, intellectual property rights have an important impact on the sustainability and stability of the strategy. The more intellectual property rights you have, the more security your innovative performance will gain.

3.3 External Support System of SSIDS

There are lots of external elements of enterprise that are closely related to innovation-driven strategy. External support system is exactly consisted of these elements and their mutual relationship together. It is necessary to implement the innovation-driven strategy and can be generalized as the environmental subsystem of innovation. As shown in Fig. 5, the system commonly includes market environment, policy environment and service environment.

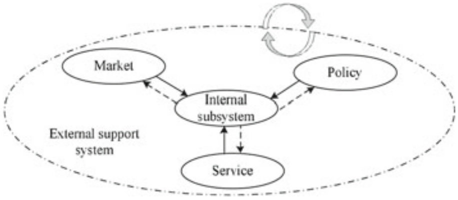

Fig. 5. External support system

(1) Market Environment

Influenced by historical reasons and institutional factors, Chinese private enterprises are facing more and special market environment. Market environment mainly includes the market rule, the fairness of market competition and the degree of government's intervention to market. With the help of adequate market rules, essential market ethics and credit, less intervention from government, private enterprises can compete in a fair market environment and further improve their willingness and performance of innovation.

(2) Legal Environment

Laws & regulations play an important role of ensuring and adjusting innovative activities of enterprises. Therefore, government should focus on creating suitable environment and help to promote innovative activities in enterprise. For example, the authority can exert its influence on launching, organizing and implementing of enterprises' innovative programs by constantly adjusting and perfecting the laws and regulations on intellectual property rights and the standards of environment & energy. These laws, especially intellectual property protection regulations, can help private enterprises to enhance technical barriers, protect the property rights of innovation, and improve performance from innovation.

(3) Service Environment

The insurance of technology, personnel and capital is necessary for private enterprises to implement innovation-driven strategy. Therefore, service environment is vital for innovative activities. First, it can serve as bridge connecting technology and economy by providing private enterprises mature intermediary institutions technology and market. Second, it helps to introduce and select all

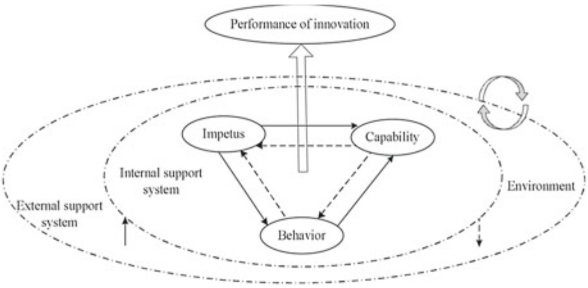

Fig. 6. Support system of innovation-driven system

kinds of innovative talents for private enterprises. Finally, it promotes the formation of a sound financial market so that private enterprises can raise innovation funds from this important capital source.

Based on above analysis of internal and external support system, we build a new support system of innovation-driven strategy in private enterprises with the purpose of improving performance of this strategy (as illustrated in Fig. 6). The support system of innovation-driven strategy totally differs from the traditional innovation systems that define the role of the government and private enterprise. The SSIDS is an open, dynamics and complex system as it involves a wide range.

4 Conclusion

This article analyzes internal support system form innovative impetus, behavior and capability, discusses external support system from market mechanism, laws and regulations, service. Based on internal support system and external support system, a new theoretical model, SSIDS, is built, which is conductive to innovative practices of private enterprises.

Innovation is unpredictable system engineering. According to Schumpeter's theory of innovation, entrepreneurs are situated in primary status. However, at the initial stage of the market, Chinese private enterprises lack of mature entrepreneurs. Therefore, traditional theory of Innovation System insists that both the government and enterprises are situated in primary status, which is harmful to development of Chinese entrepreneurs. Contrary to the dualistic main-body Innovation System, the SSDIS with a multi-nested structure is instrumental and assistant. In the SSDIS, the government provides service and supervision; private enterprises carry out innovative practice. This article builds a theoretical model and change innovation paradigm. Nevertheless, many empirical studies are necessary to the validation and optimization of SSIDS model. How the SSIDS model operates is a valuable question for further research.

The Emission Reduction and Recycling of Coal Mine Water Under Emission Allowance Allocation of Government

Ning Ma and Shuangyi Zheng(✉)

Business School, Sichuan University,
Chengdu 610065, People's Republic of China
zhengshuangyi@scu.edu.cn

Abstract. Water shortage and water pollution problems have become increasingly severe, especially in these areas with the coal mining industry. In this paper, a bi-level multi-objective optimization model based on the trade-and-cap mechanism with fuzzy coefficients is developed to deal with environmental water problems in large scale coal fields, in which both the emission right and mine water recycling are considered. This model fully considers the relationship between the government and the coal mines and also the equilibrium between economic development and environmental protection. To deal with the inherent uncertainties, the model is defuzzified using a possibility measure, and a solution approach based on the Karush-Kuhn-Tucker condition and interactive fuzzy programming is designed to search for the solutions. A case study is presented to demonstrate the practicality and efficiency of the model. The results showed practicality and efficiency in the proposed model of reducing the coal-water conflict. Finally, a comprehensive discussion is provided and some propositions is given as a foundation for the proposed management recommendations.

Keywords: Water environment · Coal mining · Mine water recycling · bi-level multi-objective programming

1 Introduction

Coal is still the most abundant fossil fuel in 2015 and it provided around 30.0% of the global primary energy need, though oil and natural gas reserves have increased over time. As such an important fossil fuel contributing to worldwide energy generation, coal will still takes a huge market share in world energy and coal mining is still a major industry for developing economy. But coal mining can cause a lot of pollution for water, soil and air environment, and these ecological environment issues will deepen the contradiction between the land and humans, and constrains economic and social development. However, for safety, significant quantities of groundwater are discharged in underground mining [17,19]. If

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_68

untreated, the water combining with heavy metal ions such as iron and mercury ions would definitely pollute the groundwater [7], which has many pollutants and waste the cherish water resource [16,18]. Thus, it is of importance for the coal mine to control the mine drainage.

In order to mitigate the environmental damage, several policy instruments have been developed to attempt to reduce pollution emissions, such as emission taxes, command-and-control, and cap-and-trade [5,6,9]. The cap-and-trade mechanism, also known as the emission trading scheme (ETS), is an application of Coase [3], and has showed its effectiveness of controlling emissions and has been successfully applied in practice [2]. Therefore, this paper adopts this mechanism to control the mine drainage. In this mechanism, the initial carbon emission allowances are defined and allocated by local government for free or at auction or a combination of both [4,20] and coal mines decide their coal production under the emission allowance. Based on this mechanism, there are two kinds of decision makes in this problem. However, government only concerns the whole benefit and coal mines only consider their individual benefits. There is a conflict between government and coal mimes. Therefore, in order to solve this conflict, this paper adopts bi-level programming to balance the benefit between the whole and individuals. Meanwhile, this paper also considers the effect of mine water recycling on reducing waste water emission. Coal mines can have more coal production by recycling mine water to reduce waste water emission under the limited emission right.

Based on the above discussion, this paper proposes an optimization model that integrates a trade-and-cap mechanism and waste water recycling to mitigate mine water pollution. In Sect. 2, the government use to control pollution through emission allowance allocation, and the coal mines treat and reuse mine water to guarantee production under limited emission right. Then, as an abstraction of the real problem, a bi-level multi-objective model is built based on the discussion and a algorithm is applied in Sect. 3. In Sect. 4, a case study is presented to demonstrate the significance of the proposed model and solution method. Conclusions and future research directions are given in Sect. 5.

2 Problem Statement

In this paper, we consider a trade-and-cap mechanism to control the total waste water emission. Government decides the number of permits to discharge specific quantities of a specific mine water per time period. Coal mines need to decide their production plan according to permits allocated by government, because the quantity of mine water is related to the coal production. Meanwhile, coal mines can reduce their actual waste water emission though mine water recycling. In this problem, government hope to minimize the total waste water emission in the terms of ecology. But coal production is an important finance source for government. It's unreasonable to only consider ecology or economy singly. Therefore, government have to make a balance between economic and ecological benefits. And coal mines as profitable organizations only consider their economic benefits. The relationship between government and coal mines is shown as Fig. 1.

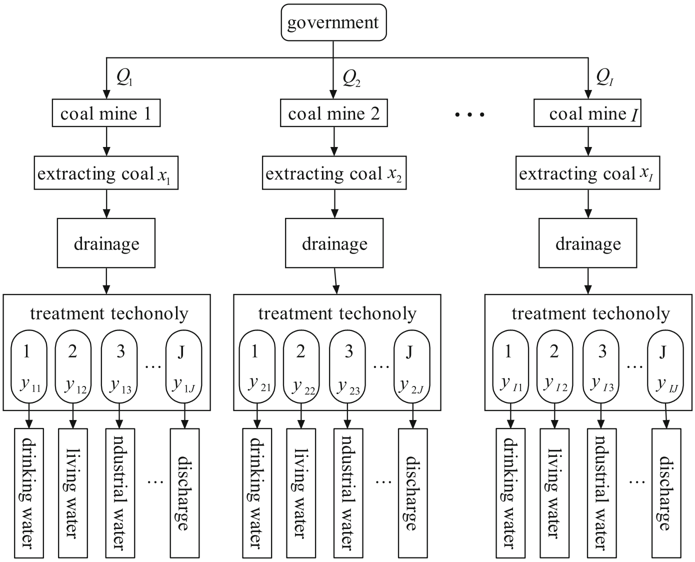

Fig. 1. The logic diagram of emission right allocation and mine water recycling

3 Modelling

Based on the analysis above, the hierarchical interests equilibrium between government and coal mines, and the economic and ecological conflicts are respectively the key points of solving the mine water emission reduction. Therefore, we adopt the bi-level programming to achieve the interests equilibrium which DMs in a hierarchical relationship to solve the emission right allocation, and the multi-objective programming to balance the economic and ecological benefits.

3.1 Notation

Index:

i: Coal mine index, $i = 1, 2, \cdots, I$;
j: Coal mine water treatment method index, $j = 1, 2, \cdots, J$, and the quality of treated water is from high to low when j from 1 to J, and method J can just make the mine water reach the emission standard.

Parameters:

ω: Tax rate of coal sale;
H: Maximum environment carrying capacity;
P^C: Unit coal price;
C_i^C: Unit coal mining cost of coal mine i;

B_{ij}^R: Unit economic benefit of reusing the waste water treated by method j in coal mine i;
C_{ij}^R: Unit economic cost of treating the waste water by method j in coal mine i;
θ_i: Coal drainage coefficient when coal mine i produces unit coal.

Decision variables:

Q_i: Waste water emission allowance of government allocating to coal mine i;
x_i: Coal production amount of coal mine i;
y_{ij}: Waste water amount of coal mine i treating by method j.

3.2 Objective for Government

(1) Economic Objective
For the region with abundant coal resource, coal industry is generally the main industry influencing the local economic development and human salary level. Therefore, local government must consider the economic objective, especially in developing country. Generally speaking, the financial revenue of the local government is determined by local tax revenue, central tax returns and transfer payments. The coal industry's contribution to regional financial revenue comes mainly from taxes. Therefore, the economic objective of government can be expressed as:

$$\max F_1 = \sum_{i=1}^{I} \left[(P^C - C^C) \times x_i \right] \times \omega, \tag{1}$$

(2) Ecological Objective
Environmental protection is a major responsibility for local government, and this is especially important in large scale coal mining regions. In terms of environmental protection, government hopes to minimize the actual waste water emission. Therefore, it is the optimal for ecological objective when total emission allowance is minimum.

$$\min F_2 = \sum_{i=1}^{I} Q_i. \tag{2}$$

3.3 Constraints for Government

(1) Maximum Environment Carrying capacity
Emission right allocation is to control the environmental damage effectively. Therefore, the total waste water should be under the maximum environment carrying capacity H. However, it is very difficult to estimate the exact value of the constraint due to the inherent uncertainty and complexity. Therefore, we adopt fuzzy number to express this kind of uncertainty.

$$\sum_{i=1}^{I} Q_i \leq H. \tag{3}$$

3.4 Objective for Coal Mine

For the market-based coal mines, pursuit of the highest profit is the absolute priority when the managers make decisions. Generally, coal mines' profit come mainly from coal production and sales. In this paper, we also consider the recycling and utilization of coal mine water. So the economic influence coming from waste water reuse and selling or buying emission right should be considered in the economic objective.

$$\max f_i = (P^C - C^C) \times x_i + \sum_{j=1}^{J} (B_{ij}^r - C_{ij}^r) \times y_{ij} - C_i^d \times (x_i \times \theta_i - \sum_{j}^{J} y_{ij}). \tag{4}$$

3.5 Constraints for Coal Mine

(1) Mining Ability Restrictions
Coal mines' mining ability is limited and can not be quickly improved. Therefore, when coal mine i makes a decision about the quantity that should mined, this quantity must not exceed its mining ability:

$$x_i \leq C_i^{\max}, \quad i = 1, 2, \cdots, I. \tag{5}$$

(2) Available Waste Water Restrictions
The amount of mine water drained by coal mine is relevant to the coal exacting amount, and the total amount of treated mine water cannot exceed the total mine water amount. Therefore, we can get

$$\sum_{j}^{J} y_{ij} = x_i \times \theta_i, \quad i = 1, 2, \cdots, I. \tag{6}$$

(3) Recycling Technology Restriction
To clean mine water to different quality, coal mine needs to use different methods. Obviously, the treated mine water amount by method j cannot exceed the maximum treatment capacity of this kine of technology the coal mine having. Therefore, the relationship can be described as:

$$0 \leq y_{ij} \leq T_{ij}, \quad i = 1, 2, \cdots, I, \quad j = 1, 2, \cdots, J. \tag{7}$$

(4) Recycling Water Demand Restriction
The treated mine water will be used in different method according to their qualities respectively, but users' demands for water are limited. Therefore, treated mine water cannot exceed the user's demand, otherwise, the excessive water will be wasted.

$$0 \leq y_{ij} \leq D_{ij}, \quad i = 2, \cdots, I, \quad j = 1, 2, \cdots, J - 1. \tag{8}$$

(5) Environmental Protection Restriction
To protect water environment, the actual waste water emission cannot exceed the allowance allocated by government. And the actual waste water emission should be the waste water without recycling. So the relationship is as following:

$$x_i \times \theta_i - \sum_{j}^{J} y_{ij} \le Q_i, \quad i = 1, 2, \cdots, I. \tag{9}$$

3.6 Global Model

Based on the previous discussion, by integrating Eqs. (1)–(9), the following global expected model of bilevel programming can now be formulated for the problem:

$$\begin{aligned}
&\max F_1 = \sum_{i=1}^{I} \left[(P^C - C^C) \times x_i \right] \times \omega \\
&\min F_2 = \sum_{i=1}^{I} Q_i \\
&s.t. \begin{cases}
\sum_{i=1}^{I} Q_i \le H \\
Q_i \ge 0, \quad i = 1, 2, \cdots, I \\
\max f_i = (P^C - C^C) \times x_i + \sum_{j=1}^{J} (B_{ij}^r - C_{ij}^r) \times y_{ij} \\
\qquad\qquad - C_i^d \times (x_i \times \theta_i - \sum_j^J y_{ij}) \\
\begin{cases}
x_i \le C_i^{\max}, \quad i = 1, 2, \cdots, I \\
x_i \times \theta_i \le \sum_{j=1}^{J} T_{ij}^r + T^d \quad i = 1, 2, \cdots, I \\
\sum_j^J y_{ij} \le x_i \times \theta_i, \quad i = 1, 2, \cdots, I \\
0 \le y_{ij} \le T_{ij}, \quad i = 1, 2, \cdots, I, \quad j = 1, 2, \cdots, J \\
0 \le y_{ij} \le D_{ij}, \quad i = 2, \cdots, I, \quad j = 1, 2, \cdots, J-1 \\
x_i \times \theta_i - \sum_j^J y_{ij} \le Q_i, \quad i = 1, 2, \cdots, I.
\end{cases}
\end{cases}
\end{aligned} \tag{10}$$

4 Solution Approach

In this section, we adopt a KKT to solve the bi-level problem and fuzzy goals programming to solve multi-objective problem.

4.1 Fuzzy Goal Programming for Bi-Level Multi-objective Model

The basic concept of fuzzy goal programming approaches is that each lower level DM considers the upper level DM's goal when seeking to optimize their own objective function. In the decision process, the fuzzy goal membership functions for all the DMs' variables are considered and the fuzzy programming problem is solved using a constraint on the overall satisfactory degree of any upper levels. [13,14]. As membership levels are in the same dimension, this method can also solve the weighted sum scalarization with different dimensions in model (10)

Meanwhile, this method has been previously adopted to solve multi-objective model problems in different areas [1,10] and has proved to be highly effective. Therefore, this paper adopts fuzzy goal programming to transform the bi-level multi-objective model into a single level and single objective model.

First, the optimal solution for each objective of each decision maker f_ξ^B is calculated and the DMs decided on the worst value f_ξ^W they can accept (ξ is the objective index), from which the fuzzy goal $f_1(x,y,z) \gtrsim f_1^B$ and $f_2(x,y,z) \gtrsim f_2^B$ can be determined, and their membership functions are as Eq. (11)

$$\mu_\xi(f_\xi(q,x,y)) = \begin{cases} 1, & \text{if } f_\xi(q,x,y) \le f_\xi^B, \\ \frac{f_\xi(q,x,y)-f_\xi^W}{f_\xi^B-f_\xi^W}, & \text{if } f_\xi^B < f_\xi(q,x,y) \le f_\xi^W, \\ 0, & \text{if } f_\xi(q,x,y) \ge f_\xi^W. \end{cases} \tag{11}$$

Using Eq. (11), the multi-objective model can be transformed into a single objective model by weighting and summing the negative deviations between the actual satisfactory level and the aspiration satisfactory level for each objective, as shown in model (12):

$$\begin{aligned} &\max F = \sum_{\xi\in\Xi} \omega_\xi \times \mu_\xi(F_\xi(q,x,y)) \\ &s.t. \begin{cases} \bar{\mu}_{ij} - \mu_{ij}(f_{ij}(q,x,y)) \le \hat{\sigma} \\ (q,x,y) \in S, \end{cases} \end{aligned} \tag{12}$$

where the auxiliary variable ω_ξ is the importance degree for objective ξ and $\sum_{\xi\in\Xi}\omega_\xi = 1$; $\bar{\mu}_{ij}$ is the individual aspiration levels of each coal mine; $\mu_{ij}(f_{ij}(q,x,y)$ is the actual the practical satisfaction level of each decision maker; $\hat{\sigma}$ is the maximum deviation between the practical satisfaction level and the aspiration satisfaction level of each lower decision maker; S is the feasible region of Eq. (10). By minimizing the weighted sum of these deviation, decision makers can determine an overall satisfactory solution close to the optimal solution.

However, based on these characteristics, however, there is a limitation to the use of interactive fuzzy programming as it can only be used to solve decision making problems in organizations with cooperative behavior. And the solution of model (12) is not optimal for lower decision makers. To solve this problem, we adopt KKT to transform the lower model to guarantee the optimal solution of lower decision makers.

4.2 KKT

Karush-Kuhn-Tucker (KKT) approach has been proven to be a valuable analysis tool with a wide range of successful applications for bi-level programming [11]. The fundamental strategy for the KKT approach is that it replaces the follower's problem with its KKT conditions and appends the resultant system to the leader's problem [8,12]. Based on previous work by Shi et al. [15], we transformed the bi-level model into a single-level model. However, KKT cannot guarantee the equality between lower decision makers when there are multiple lower decision makers in a bi-level problem. But in this paper, we have used fuzzy goal programming to transform the bi-level model into single model and can guarantee the benefit balance between lower decision makers by the satisfactory deviation. Therefore, in this paper, we just adopt KKT to seek the optimal solution of lower model under upper decision maker's strategy. And the model (10) is finally transformed as Eq. (13).

$$
\begin{aligned}
&\max F = \omega_1 \times \mu_\xi(F_1(q,x,y)) + \omega_2 \times \mu_\xi(F_2(q,x,y)) \\
&s.t. \begin{cases}
F_1 = \sum_{i=1}^{I} \left[(P^C - C^C) \times x_i\right] \times \omega \\
F_2 = \sum_{i=1}^{I} Q_i \\
\mu_\xi(f_\xi(q,x,y)) = \begin{cases} 1, & \text{if } f_\xi(q,x,y) \le f_\xi^B, \\ \frac{f_\xi(q,x,y) - f_\xi^W}{f_\xi^B - f_\xi^W}, & \text{if } f_\xi^B < f_\xi(q,x,y) \le f_\xi^W, \\ 0, & \text{if } f_\xi(q,x,y) \ge f_\xi^W, \end{cases} \\
\bar{\mu}_{ij} - \mu_{ij}(f_{ij}(q,x,y)) \le \hat{\sigma} \\
\sum_{i=1}^{I} Q_i \le H \\
Q_i \ge 0, \quad i = 1,2,\cdots,I \\
x_i \le C_i^{\max}, \quad i = 1,2,\cdots,I \\
x_i \times \theta_i \le \sum_{j=1}^{J} T_{ij}^r + T^d \quad i = 1,2,\cdots,I \\
\sum_j^J y_{ij} \le x_i \times \theta_i, \quad i = 1,2,\cdots,I \\
0 \le y_{ij} \le T_{ij}, \quad i = 1,2,\cdots,I, \quad j = 1,2,\cdots,J \\
0 \le y_{ij} \le D_{ij}, \quad i = 2,\cdots,I, \quad j = 1,2,\cdots,J \\
x_i \times \theta_i - \sum_j^J y_{ij} \le Q_i, \quad i = 1,2,\cdots,I \\
(P^C - C^C) - C_i^d \times \theta_i + v_1 + (v_2 - v_3 + v_{11}) \times \theta_i = 0 \\
\sum_{j=1}^{J} (B_{ij} - C_{ij}) + C_i^d + v_3 + v_4 - v_5 + v_6 - v_{11} = 0 \\
v_1 g_1(Q_i,x_i,y_{ij}) + v_2 g_2(Q_i,x_i,y_{ij}) + v_3 g_3(Q_i,x_i,y_{ij}) \\
+v_4 g_4(Q_i,x_i,y_{ij}) + v_5 g_5(Q_i,x_i,y_{ij}) + v_6 g_6(Q_i,x_i,y_{ij}) \\
+v_7 g_7(Q_i,x_i,y_{ij}) = 0 \\
g_1(Q_i,x_i,y_{ij}) = C_i^{\max} - x_i \ge 0, \quad i = 1,2,\cdots,I \\
g_2(Q_i,x_i,y_{ij}) = \sum_{j=1}^{J} T_{ij}^r + T^d - x_i \times \theta_i \ge 0, \quad i = 1,2,\cdots,I \\
g_3(Q_i,x_i,y_{ij}) = x_i \times \theta_i - \sum_j^J y_{ij} \ge 0, \\
g_4(Q_i,x_i,y_{ij}) = T_{ij} - y_{ij}, \quad i = 1,2,\cdots,I, \quad j = 1,2,\cdots,J \\
g_5(Q_i,x_i,y_{ij}) = y_{ij} \ge 0, \quad i = 1,2,\cdots,I, \quad j = 1,2,\cdots,J \\
g_6(Q_i,x_i,y_{ij}) = D_{ij} - y_{ij} \ge 0, \quad i = 2,\cdots,I, \quad j = 1,2,\cdots,J \\
g_7(Q_i,x_i,y_{ij}) = Q_i - x_i \times \theta_i + \sum_j^J y_{ij} \ge 0.
\end{cases}
\end{aligned}
\tag{13}
$$

5 Case Study

5.1 Case Presentation

Lu'an coal field is located on the southeastern edge of the middle eastern Qinshui coal field, which is in the center of Shanxi Province. There are nine major collieries (i.e., $i = 4$) in this area. These are the Shiyijie mine, the Changcun mine, the Zhangcun mine and the Wangzhuang mine.

In Lu'an coal field, there is average annual rainfall of 584 mm, and an average annual evaporation of 1732 mm. With the capacity expansion of the coal mines, coal mining quantity has significantly increased, and this caused mine drainage increases simultaneously. Moreover, untreated mine water damages the surrounding water environment. Meanwhile, due to the water from the mine drainage, the groundwater supplement is insufficient, which affects plant growth and adds to environmental degradation. Therefore, this paper adopt Lu'an coal field as a case to show the practicality of the model.

5.2 Data Collection

Detailed data for the research region were obtained from the Statistical Yearbook of Chinese coal industry (National Bureau of Statistics of the Peoples Republic of China (2013)), the Statistical Yearbook of Chinese energy (National Bureau of Statistics of the Peoples Republic of China (2013)) and field research. Certain parameters taken from the Statistical Yearbooks and data published by the companies are shown in Tables 1, 2 and 3.

5.3 Results and Discussions

First, the upper and lower bounds of the government and coal mines objective functions were calculated to identify the membership function for the fuzzy goals, as shown in Table 4.

Then, we can build the fuzzy goals though the optimal solutions and worst solutions of each objective of government and coal mines. And we set $\omega_1 = \omega_2 = 0.5$, $\bar{\mu}_1 = \bar{\mu}_2 = \bar{\mu}_3 = \bar{\mu}_4 = 1$. Finally, through adapting the maximum deviation $\hat{\sigma}$, we can get some groups optimal solutions under different attitude of government, as Table 5.

	$i = 2$	210.74	136.87	0.00	15.00	100.00	76522.63	0.66			
	$i = 3$	175.46	123.28	0.00	10.00	140.00	69062.40	0.62			
	$i = 4$	303.80	227.60	3.00	34.00	210.00	127427.93	0.62			

From Table 5, when the maximum deviation $\hat{\sigma} = 1$, which means government doesn't consider the equality between coal mines fully, government can get its optimal solution and the satisfactory is 0.5044. When government begin to decrease the maximum deviation from 1 to 0.38 to consider the equality between coal mines, its satisfactory level drop continuously. Because coal mines only concern about economic benefit, the ecological benefit decreases faster than economic benefit with $\hat{\sigma}$ draping. $\hat{\sigma}$ from 1 to 0.6, the ecological objective value drop to the worst value. And $\hat{\sigma}$ from 0.6 to 0.38, the whole economic benefit decreases and the benefit balance between coal mines is improved. When $\hat{\sigma} < 0.38$, there is no feasible solution for model (13).

Comparing these results, we can find government prefer allocate emission right to these coal mines with better waste water recycling capacity because which can guarantee the economic and ecological benefit simultaneously in the biggest extend. And when government consider the whole satisfactory level, the upper benefit would be damaged. Therefore, government should push these coal mines faster the reformation step to achieve the economy and ecology development together.

6 Conclusion

This paper proposed a bi-level multi-objective programming model to deal with economic and ecological conflicts in large scale coal fields. An environmental protection based mining quotas competition mechanism was established using the proposed model which considers not only the relationship between the government and coal mines, but also the equilibrium between economic development and environmental protection. To solve the complex bi-level multi-objective programming model and an extended KKT and fuzzy goal programming approach were combined as a solution method. The proposed method was then applied to the Lu'an coal field which includes four major coal mines. By inputting the data into the model and computing it using the proposed solution approach, the effectiveness of the model was demonstrated.

Abstract. Considering that the customers could accept service in multiple time periods and the fuzziness of service time periods, this paper deals with the multiple time windows as fuzzy variables and quantifies the customer satisfaction level according to the membership function of the beginning time to be served, on the basis of the given acceptable satisfaction level, the vehicle routing model with multiple fuzzy time windows is constructed in order to minimize the transportation cost and number of vehicles and maximize the satisfaction level. Then according to the model characteristics, we use the punishment factors to deal with the constraints and apply particle swarm operations to solve the proposed problems. The experimental results show the effectiveness of proposed algorithm in solving the vehicle routing problems with multiple fuzzy time windows. Comparing the calculated results with the hard time window model results, it is found that our proposed model is more effective to reduce the cost of distribution.

Keywords: Multiple fuzzy time windows · Particle swarm operations · Vehicle routing · Customer satisfaction

1 Introduction

Vehicle routing problem was first proposed by Dantzing and Ramser [5]. After more than 50 years of research, it has attracted wide attention of scholars in the field of operations research and combinatorial optimization. The vehicle routing problem with time window (VRPTW) is add the time window constraint on the basis of the capacity constraint model. At present, domestic and foreign scholars have done a lot of research on the VRPTW problem, Desrochers et al. [6] solved VRPTW problem by combined branch-and-bound algorithm and column generation algorithm. Bent and Hentenryck [3] proposed a two-stage hybrid algorithm for VRPTW problem. In addition, the algorithm for the VRPTW problem is also includes genetic algorithm [15], particle swarm optimization algorithm [1], ant colony system [17], etc. However, considering the customer service time requirements are not completely rigid, Lin [12] considered customer satisfaction

J. Xu et al. (eds.), *Proceedings of the Eleventh International Conference on Management Science and Engineering Management*, Lecture Notes on Multidisciplinary Industrial Engineering, DOI 10.1007/978-3-319-59280-0_69

level and proposed vehicle routing problems based on the fuzzy time window. Ghannadpour et al. [9] presented a multi-objective dynamic vehicle routing problem with fuzzy time windows considered customer-specific time windows and proposed the genetic algorithm (GA) and three basic modules to solve the problem. While these studies have contributed significantly to solving the vehicle routing problem with single time window, customers usually have more than one time period to receive service, they ignored the vehicle routing problem with multiple time windows (VRPMTW).

The vehicle routing problem with multiple time windows (VRPMTW) is an extension problem of the traditional vehicle routing problem, refers to each customer has a number of non overlapping time windows to receive services, delivery vehicles must choose one time window for service, and compared with the single time window of vehicle routing problem, VRPMTW is much closer to the reality. The research on VRPMTW is mainly focused on two aspects: model and algorithm. In the aspect of model, Doerner et al. [7] presented the model of vehicle routing problem with multiple interdependent time windows and solved the problem by several variants of a heuristic constructive procedure as well as a branch-and-bound based algorithm. Ma et al. [14] considered delivery can be splited and established the split delivery vehicle routing problem with multiple time windows (SDVRPMTW) model. Yan et al. [18] applied VRPMTW model in military oil transport path optimization and solved problem with particle swarm optimization algorithm. And the research of algorithms mainly focus on the ant colony system algorithm [8], simulated annealing algorithm [13], hybrid intelligent algorithm [4], hybrid variable neighborhood-tabu search heuristic [2] and intelligent water drop algorithm [11], etc. However, customer usually have multiple fuzzy time windows and service time requirements are not completely rigid in reality. This kind of problem is more complicated and more realistic than VRPMTW, so it is necessary to carry out relevant research.

In this paper, VRPMTW in a fuzzy environment is considered and customer satisfaction is quantified by the time to start service. We aim to minimize transportation cost, minimize vehicles, and maximum customer satisfaction, thus establish the model of vehicle routing problem with multiple fuzzy time windows. The particle swarm optimization algorithm is used to solve the problem and the experimental results are analyzed and discussed.

2 Problem Statement and Modeling

2.1 Problem Statement

The vehicle routing problem with multiple fuzzy time windows can be stated as: A distribution center has m cars to serve n customers, customer i has W_i non overlapping fuzzy time windows. Each customer's needs, the maximum loading capacity of each vehicle and the distance between any two customers is known. Vehicles starting from the distribution center, select one time window of customer to serve and return distribution center until completion of distribution.

On the basis of satisfying customer demand, vehicle loading capacity and customer time window, the objective function is optimized through the reasonable path planning. The model considers the following constraints: (1) Vehicle loading capacity constraint: the actual loading of each vehicle must not exceed the maximum loading capacity. (2) Multi fuzzy time windows constraint: each customer has multiple fuzzy time windows, but vehicle can only choose a time window service. (3) Customer satisfaction constraint: customer satisfaction is greater than the value of the decision maker. (4) Visit uniqueness constraint: each customer can only served by a car and can only serve once. (5) Central constraint: vehicle start from the distribution center and after implement the customer service to return. (6) Loop elimination constrain: the path of each vehicle can only exist the loop between the starting point and point, there can be no other circuit.

2.2 Notations

The variables and parameters used in the model are:

$L = \{1, 2, \cdots, n\}$	: customer set, with 0 and $n+1$ said distribution center
$K = \{1, 2, \cdots, m\}$	: vehicle set;
Q_k	: the loading capacity of vehicle k;
C	: vehicle start-up costs;
q_i	: the demand of customer i;
D_k	: the longest running distance of vehicle k;
c_{ij}	: the cost of traveling from nodes i to j;
t_i	: the service start time of customer i ;
s_i	: the service duration time of customer i ;
t_{ij}	: the travel time from customer to customer i to j ;
W_i	: the number of customer time windows;
$[E_i^\alpha, a_i^\alpha, b_i^\alpha, L_i^\alpha]$	: the fuzzy time window α of customer i;
E_i^α	: the endurable earliness time of time window α of customer i;
a_i^α	: the earliest start service time which customer i expect to be served in time window α;
b_i^α	: the latest start service time which customer i expect to be served in time. window α;
x_{ijk}	: a binary variable, $x_{ijk} = 1$, if vehicle travels from customer i to customer j, otherwise, $x_{ijk} = 0$;
y_i^α	: a binary variable, $y_i^\alpha = 1$, if vehicle serve the time window α of customer i, otherwise, $y_i^\alpha = 0$.

2.3 Fuzzy Time Window

Trapezoidal fuzzy time windows is used in this paper, as shown in Fig. 1. Each customer can own multiple trapezoidal fuzzy time windows, customer is satisfied when be served in the expected time period and the satisfaction level is 1, while customer satisfaction will be reduced when the service time is not met or exceeded the customer expected service time.

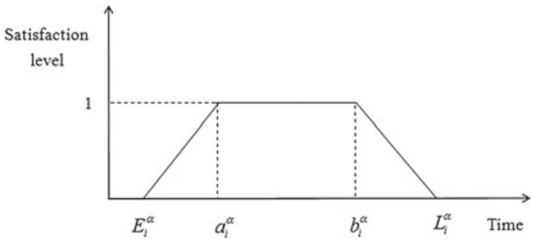

Fig. 1. Trapezoidal fuzzy time window

When the customer has multiple trapezoidal fuzzy time window can accept the service, customer satisfaction can be defined by the membership function of the service start time:

$$\mu_i(t_i) = \begin{cases} 0, t_i < E_i^\alpha \\ (t_i - E_i^\alpha)/(a_i^\alpha - E_i^\alpha), E_i^\alpha < t_i < a_i^\alpha \\ 1, a_i < t_i < b_i \\ (L_i^\alpha - t_i)/(L_i^\alpha - b_i^\alpha), b_i^\alpha < t_i < L_i^\alpha \\ 0, t_i > L_i^\alpha. \end{cases} \tag{1}$$

2.4 Modelling

The vehicle routing problem with multiple fuzzy time windows is as follows:

$$\min \ Z_1 = \sum_{i=0}^{n} \sum_{j=0}^{n+1} \sum_{k=1}^{m} c_{ij} x_{ijk} \tag{2}$$

$$\min \ Z_2 = C \sum_{j=0}^{n} x_{0jk}, \tag{3}$$

$$\max \ Z_3 = \frac{1}{n} \sum_{i=1}^{n} \mu_i(t_i), \tag{4}$$

$$\text{s. t. } \mu_i(t_i) \geq \eta_i, \forall i \in L, \tag{5}$$

$$\sum_{i=1}^{n} \left(q_i \sum_{j=0}^{n} x_{ijk} \right) \leq Q_k, \forall k \in K, \tag{6}$$

$$\sum_{i=0}^{n} \sum_{j=1}^{n+1} d_{ij} x_{ijk} \leq D_k, \forall k \in K, \tag{7}$$

$$\sum_{j=1}^{n+1} x_{0jk} = 1, \forall k \in K, \tag{8}$$

$$\sum_{i=1}^{n+1} x_{in+1k} = 1, \forall k \in K, \tag{9}$$

$$\sum_{i=1}^{n}\sum_{k=1}^{m} x_{ijk} = \sum_{i=1}^{n}\sum_{k=1}^{m} x_{jik} = 1, \forall j \in L, \tag{10}$$

$$\sum_{i,j \in S \times S} x_{ijk} \leq |S| - 1, S \subseteq L, \forall k \in K, \tag{11}$$

$$L_i^{\alpha} \leq E_i^{\alpha+1}, \forall i \in L, \alpha \in \{1, 2, \cdots W_i - 1\}, \tag{12}$$

$$\max \left\{ \sum_{\alpha=1}^{W_i} y_i^{\alpha} E_i^{\alpha}, (t_i + s_i + t_{ij})\, x_{ijk} \right\} \leq t_j, \forall i, j \in L, \forall k \in K, \tag{13}$$

$$t_j \leq \sum_{\alpha=1}^{W_i} y_j^{\alpha} L_j^{\alpha}, \forall j \in L, \tag{14}$$

$$\sum_{\alpha=1}^{W_i} y_i^{\alpha} = 1, \forall i \in L, \tag{15}$$

$$x_{ijk} = 0 \text{ or } 1 \forall i, j, k, \tag{16}$$

$$y_i^{\alpha} = 0 \text{ or } 1, \forall i \in L, \alpha \in \{1, 2, \cdots, W_i\}. \tag{17}$$

Objective (2) minimizes the total travel cost of all vehicles which is the most important objective to the decision makers. Objective (3) minimums the number of vehicles. Objective (4) maximizes the average customer satisfaction. Equation (5) ensures that each customer satisfaction is higher than η_i, η_i is given by the decision maker based on experience. Equation (6) ensures that the loading of each vehicle is not more than the maximum loading capacity. Equation (7) makes sure the distance of each vehicle is not more than the longest running distance. Equations (8) to (10) ensure that each customer is served by a car and the vehicle flow keep balance. Equation (11) is to eliminate the sub loop. Equation (12) is to sort time windows by time. Equations (13) and (14) makes sure that customer is served in time window. Equation (15) ensures each customer has a time window to be served. Equations (16) and (17) is the variable range.

3 Particle Swarm Optimization

Particle swarm optimization algorithm was first proposed by Kennedy and Eberhart [10], and it is a kind of stochastic optimization technique based on population. Compared with other evolution algorithm based on population, their initialization is a set of random solutions and through the iterative to search the optimal solution. The difference is that evolutionary computation follows the principle of survival of the fittest and PSO simulates the society. PSO express each possible solution as a particle of group, each particle has its own position vector and velocity vector, as well as a fitness which is determined by the objective function. All particles are flying at a certain speed in the search space, by following the optimal value of the current search to find the global optimal value.

3.1 Structure of Solution

Construct the expression of the solution and make the solution correspond to the particles in the PSO algorithm is the key link of the algorithm. Salman et al. [16] described the expression of solution in detail, we draw lessons from this method. A $3L$-dimensional matrix is used to represent the solution of the proposed model with L customers, each customer corresponds to three dimensional: vehicle number vector, vehicle ranking vector and time windows number vector. In order to express clearly and calculate conveniently, the $3L$-dimensional matrix of each particle is divided into three L-dimensional vectors, they are X_v (vehicle number vector), X_r (vehicle ranking vector) and X_w (time windows number vector). Corresponding velocity vectors V are X_v, X_r and X_w.

For example, there are three vehicles to complete the distribution tasks of eight customers, the position vector of a particle is: Due to the original assumption that the vehicle starting from the distribution center and finally return to

Consumers	1	2	3	4	5	6	7	8
X_v	1	1	1	2	3	3	3	3
X_r	1	3	2	1	4	1	3	2
X_w	1	2	1	1	1	1	2	1

the distribution center, the corresponding vehicle routing is:

Vehicle 1	$0 \to 1 \to 3 \to 2 \to 0$
Vehicle 1	$0 \to 4 \to 0$
Vehicle 1	$0 \to 6 \to 8 \to 7 \to 5 \to 0$

In the coding, the 0 omitted in order to simplify the calculation. The third line represents the time window number of each customer to be served, customer 1 choose the first time window service, for the customer 2 choose second time window service and for customers 3 choose the first time window service, etc.

3.2 The Fitness Value Function

According to the objective function (2), (3), (4) and the constraint conditions design the fit value function, as shown in the following

$$\min Z = Cm + \sum_{i=0}^{n}\sum_{j=0}^{n}\sum_{k=1}^{m} c_{ij}x_{ijk} + \beta_1 \sum_{k=0}^{m} \max\left\{\left[\sum_{i=1}^{n}\left(d_i \sum_{j=0}^{n} x_{ijk}\right) - Q_k\right], 0\right\}$$
$$+ \beta_2 \sum_{i=1}^{n} \max(E_i^{\alpha} - t_i, 0) + \beta_3 \sum_{i=1}^{n} \max(t_i - L_i^{\alpha}, 0) \tag{18}$$
$$+ \beta_4 \sum_{i=1}^{n} \max\left[\eta_i - \mu_i\left(t_i\right), 0\right],$$

where β_1, β_2, β_3 and are punishment coefficients, β_1 is the penalty factor for overloading, β_2 and β_3 penalty coefficient for violation of the time windows, β_4 is the penalty coefficient for violation of the customer satisfaction. Decision makers can set the punishment coefficient base on their predilection, thus eliminating the infeasible solution.

3.3 Particle Updating

Suppose there are n particles in the D-dimensional search space, the position vector of the particle i is $X_i = (x_{i1}, x_{i2}, \cdots, x_{iD})$, the optimal position of the particle i during the flight is, global best position is $P_{i\text{best}} = (p_{i1}, p_{i2}, \cdots, p_{iD})$, $V_i = (v_{i1}, v_{i2}, \cdots, v_{iD})$ is the flight speed of particle. Using the update method of Li et al. [11] to update, the update formula is as follows:

$$v_{id}\left(k+1\right) = \omega \times v_{id}\left(k\right) + c_1 \times \text{rand}\left(\right) \times \left[p_{id}\left(k\right) - x_{id}\left(k\right)\right] + c_2 \times \text{rand}\left(\right) \times \left[p_{gd}\left(k\right) - x_{id}\left(k\right)\right], \tag{19}$$

$$x_{id}(k+1) = x_{id}\left(k\right) + v_{id}\left(k+1\right) 1 \quad \leq i \leq n; 1 \leq d \leq D. \tag{20}$$

w is the inertia factor which is calculated by the following formula:

$$\omega(\text{t}) = \omega(\text{gen}) + (\text{t} - \text{gen})/(1 - \text{gen}) \times [\omega(1) - \omega(\text{gen})], \tag{21}$$

where c_1 and c_2 are accelerating factor, rand () generate random number between 0 and 1.

3.4 The Procedure of PSO

Step 1. Randomly generated the initial position and velocity of the particles within the range of the values.
Step 2. Based on formula (18) to calculate the fitness value of each particle.
Step 3. Calculate the fitness value of each particle and compared with the fitness value of the best position it has experienced, if the fitness value of the current location is better, set the current position as its personal best.
Step 4. Compare the personal best fitness of each particle with global best fitness, if the fitness value of the current location is better, set the current position as its global best.
Step 5. Update the particle velocities and positions according to the formulas (19) and (20).
Step 6. If the stopping criterion is met, stop; otherwise, return to Step 2.

4 A Case Study

In this section, we use an example to illustrate the model of vehicle routing problem with multiple fuzzy time windows. Example is as follows: a distribution center with six vehicles to provide services for 15 customers and each customer has two fuzzy time windows, the maximum loading capacity of each vehicle is 50 tons and the furthest distance is 120 km, the average vehicle speed is 35 km/h with the driving cost is 5 yuan/km and the start-up cost of each vehicle is 100 yuan, the average customer satisfaction level is set to 0.7 (Table 1).

Table 1. Customer information

Customer	d_i	s_i	Coordinate	E_i^1	a_i^1	b_i^1	L_i^1	E_i^2	a_i^2	b_i^2	L_i^2
1	4	0.3	(1,8)	6.5	8	9	10.5	12.5	14	15.6	17.1
