#### Abstract

This paper develops a three level model for a continuous wave diode pumped alkali laser by creating rate equations based on a three level system. The three level system consists of an alkali metal vapor, typically Rb or Cs , pumped by a diode from the ${ }^{2} S_{\frac{1}{2}}$ state to the ${ }^{2} P_{\frac{3}{2}}$, a collisional relaxation from ${ }^{2} P_{\frac{3}{2}}$ to ${ }^{2} P_{\frac{1}{2}}$, and then lasing from ${ }^{2} P_{\frac{1}{2}}$ to ${ }^{2} S_{\frac{1}{2}}$. The hyperfine absorption and emission cross sections for these transitions are developed in detail. Differential equations for intra-gain pump attenuation and intragain laser growth are developed in the fashion done by Rigrod. Using Mathematica 7.0, these differential equations are solved numerically and a diode pumped alkali laser system is simulated. The solutions of the differential equations are then utilized to characterize the inversion, the gain profile, the output laser intensity, and the pump intensity absorption profile for many different diode pumped alkali laser systems. The results of the simulation are compared to previous experimental results and to previous computational results for similar systems. The absorption profile for the three level numerical model is shown to have excellent agreement with previous absorption models. The lineshapes of the three level numerical model are found to be nearly identical to previous developments excepting those models assumptions. The three level numerical model provides results closer to experimental results than previous systems and provides results which observe effects not previously modeled, such as the effects of lasing on pump attenuation.

## List of Symbols

Symbol ..... Page
${ }^{2} S_{\frac{1}{2}} \quad$ The ground state term symbol of the three level alkali atom ..... 2
${ }^{2} P_{\frac{3}{2}} \quad$ The upper excited state term symbol of the three level alkali atom ..... 2
${ }^{2} P_{\frac{1}{2}} \quad$ The lower excited stateterm symbol of the three level alkali atom ..... 2
$I_{P} \quad$ The intensity in $W m^{-2}$ of the pump wave ..... 7
$I_{L} \quad$ The intensity in $W^{-2}$ of the intra-cavity lasing wave ..... 7
$g_{j i} \quad$ The lineshape of the transitions from $i$ to $j$ in $H z^{-1}$ ..... 7
$\sigma_{i j} \quad$ The absorption or emission cross section depending on the order of $i$ and $j$ in $m^{2}$ ..... 7
$N_{3} \quad$ The population or number density in the upper excited state, ${ }^{2} P_{\frac{3}{2}}$, of the alkali atom in $m^{-3}$ ..... 10
$N_{2} \quad$ The population or number density in the lower excited state, ${ }^{2} P_{\frac{1}{2}}$, of the alkali atom in $m^{-3} \ldots$ ..... 10
$N_{1} \quad$ The population or number density in the ground state, ${ }^{2} S_{\frac{1}{2}}$, of the alkali atom in $m^{-3}$ ..... 10
$A_{31} \quad$ The Einstein coefficient for spontaneous emission from $N_{3}$ to $N_{1}$ in $s^{-1}$. The subscripts denote the initial sublevel and the sublevel transitioned to. The subscripts follow the same numeration scheme as is utilized for population density $\left(N_{i}\right)$. ..... 10
$B_{13} \quad$ The Einstein coefficient for absorption from $N_{1}$ to $N_{3}$ in $m / \mathrm{Kg}$. The subscripts denote the initial sublevel and the sublevel transitioned to. The subscripts follow the same numeration scheme as is utilized for population density $\left(N_{i}\right)$. ..... 11
$B_{31} \quad$ The Einstein coefficient for stimulated emission from 3 to 1 in $m / K g$. The subscripts denote the initial sublevel and the sublevel transitioned to. The subscripts follow the same numeration scheme as is utilized for population density $\left(N_{i}\right)$. ..... 11
$k_{i j} \quad$ The rate of collisional relaxation from the $i$ level to the $j$ level in $m^{3} s^{-1}$. Where $i$ and $j$ may be 1,2 , or 3 . ..... 11
$g_{p}\left(\nu_{p}\right) \quad$ The input lineshape of the diode pump as a function of diode pump frequency $\nu_{p}$ ..... 11
$\nu_{p} \quad$ The diode pump frequency centered at $\nu_{d}$ with a FWHM of $\nu_{p_{f w h m}}$. ..... 13
$M_{\text {species }} \quad$ The concentration of a particular buffer gas in $m^{-3}$ ..... 13
$h \quad$ Planck's constant in $m^{2} K^{\prime 2} s^{-1}$ ..... 13
$\nu_{l} \quad$ The output frequency at which the laser operates in Hz , which is a single frequency in this model. ..... 14
$f_{j i}\left(F^{\prime \prime}, F^{\prime}\right)$ The statistical distribution between hyperfine structure levels for $F^{\prime \prime}$ and $F^{\prime}$ between fine structure levels $j$ and $i$ out of one ..... 14
$S \quad$ The relative intensity of a hyperfine transition from $F^{\prime \prime}$ to $F^{\prime}$ for an isotope out of one ..... 14
iso Particular isotope of the alkali ..... 14
species Collision partner or buffer gas. Typically methane, ethane, helium, or the alkali itself ..... 15
$f_{\text {iso }} \quad$ The relative natural abundance of each isotope of an alkali ..... 15
$\Delta \nu h_{j i} \quad$ The homogenous broadened FWHM for transitions between $j$ and $i$ in $H z$ ..... 15
$k_{b} \quad$ Boltzmann's constant ..... 15
$\Delta \nu d_{j i} \quad$ The Doppler broadened FWHM for transitions between $j$ and $i$ in $H z$ ..... 15
$F^{\prime \prime} \quad$ The initial total spin state of the lower hyperfine state ..... 16
$F^{\prime} \quad$ The final total spin state of the upper hyperfine state ..... 16
$\nu h y_{j i} \quad$ The frequency of a certain hyperfine transition between fine structure levels $j$ and $i$ and $F^{\prime \prime}$ and $F^{\prime}$ in Hz ..... 16
$\nu_{\text {hysplit }_{j}} \quad$ The hyperfine spacing within a certain fine structure level $j$ for a particular total spin of $F^{\prime \prime}$ or $F^{\prime}$ ..... 16
I The spin of the nucleus ..... 25
$g_{3} \quad$ The degeneracy of the ${ }^{2} P_{\frac{3}{2}}$ state ..... 25
$g_{2} \quad$ The degeneracy of the ${ }^{2} P_{\frac{1}{2}}$ state ..... 25
$g_{1} \quad$ The degeneracy of the ${ }^{2} S_{\frac{1}{2}}$ state ..... 25
$\gamma_{H e} \quad$ The collisional broadening rate of the lineshape in a particular manifold for helium in HzPa ..... 25
$\delta_{H e} \quad$ The collisionally induced shift in hyperfine line center frequencies for helium in HzPa ..... 25
$I_{+} \quad$ The intensity of the intra-cavity lasing wave in the forward direction in $W^{-2}$ ..... 25
$I_{-} \quad$ The intensity of the intra-cavity lasing wave in the backward direction in $\mathrm{Wm}^{-2}$ ..... 25
$I_{\text {sat }} \quad$ The saturation intensity in $\mathrm{Wm}^{-2}$ ..... 25
$\nu_{d} \quad$ The line center frequency of the diode's spectral profile in Hz ..... 26
$z_{0} \quad$ The position of the beginning of the alkali gain cell in $m$, where $z$ is the position in the gain cell ..... 26
$z_{f} \quad$ The position of the end of the alkali gain cell in $m$, where $z$ is the position in the gain cell ..... 26
$\gamma_{\nu} \quad$ The gain coefficient in $m^{-1}$ ..... 27
$\alpha \quad$ The loss coefficient in $m^{-1}$ ..... 27
$\Delta \nu_{f s r} \quad$ The spacing between modes supported by the laser cavity in $H z$ ..... 27
$n$ The index of refraction of the cavity medium assumed to be one ..... 27
$c \quad$ The speed of light in $m s^{-1}$ ..... 27
Iout The output lasing intensity beyond the cavity in $\mathrm{Wm}^{-2}$ ..... 28
$T \quad$ Temperature of cell in $K$ ..... 30
$T_{\text {meth }} \quad$ Temperature of methane in $K$ ..... 30
$T_{H e} \quad$ Temperature of helium in $K$ ..... 30
$T_{\text {alk }} \quad$ Temperature of alkali in $K$ ..... 30
$M_{\text {meth }} \quad$ Partial pressure of methane in Pa ..... 30
$M_{H e} \quad$ Partial pressure of helium in $P a$ ..... 30
$M_{a l k} \quad$ Partial pressure of alkali in $P a$ ..... 30
$N_{t} \quad$ Total population or number density of alkali in $m^{-3}$ ..... 30
$l_{g} \quad$ Length of the gain medium in $m$ ..... 30
$T_{g} \quad$ Transmission coeffcient for alkali gain cell windows ..... 30
$R_{1} \quad$ High reflector reflectivity ..... 30
$R_{2} \quad$ Output coupler reflectivity ..... 30
$I_{p} 0 \quad$ The pump intensity in $W m^{-2}$ at line center frequency of the pump diode $\nu_{d}$ ..... 30
$\nu_{p_{f w h m}} \quad$ Diode pump FWHM in $H z$ ..... 30
$d_{\text {mirror }} \quad$ The seperation distance between the cavity lasing mirrors in $m$ ..... 30

# SIMULATION OF A DIODE PUMPED ALKALI LASER; A THREE LEVEL NUMERICAL APPROACH 

## I. INTRODUCTION

The purpose of this work is to develop a model for the propagation of a Diode Pumped Alkali Laser (DPAL) within a cavity and to use computer modeling software to implement a simulation of this model. The model will be developed to aid in the research and design of new DPAL systems. A DPAL is a relatively new type of laser which relies on laser transitions occurring within an alkali metal. These lasers use electrically driven diodes to create pump photons, which are incident on a gaseous alkali metal. In a process described by Krupke [4], these photons create a population inversion which leads to lasing. Therefore, DPALs are neither solid state not gas phase laser but rather a hybrid.

The vast majority of past and current research within the Air Force has centered around chemical laser systems like the Chemical Oxygen-Iodine Laser (COIL) and Hydrogen Fluoride (HF) lasers. These systems offer high output powers of at least a megawatt or more, but chemical lasers have a finite magazine associated with their reactants and usually require large facilities to create and sustain the conditions needed for lasing. Because of the difficulty in deploying chemical laser systems, the Air Force is studying other types of laser systems to characterize their abilities and their potential to be used in future weapon systems. DPAL systems are attractive as one possible alternative to chemical lasers as they are pumped by electrically driven diodes, and therefore are capable of being powered by a conventional electrical generator or an aircraft's onboard power plant. To date, DPAL systems are not well
characterized compared to other laser systems. Most of the research and development on DPAL modeling has focused on relatively simplistic theoretical models used to make rough estimates and trial and error lab characterization of DPAL systems.

In general, the alkali metal chosen for a DPAL is either cesium (Cs) or rubidium $(\mathrm{Rb})$; however, other alkali metals have been used to successfully create a DPAL. Most DPAL systems currently are three level lasers whereby the ground ${ }^{2} S_{\frac{1}{2}}$ state is pumped to the excited ${ }^{2} P_{\frac{3}{2}}$. This is then collisionally relaxed to the ${ }^{2} P_{\frac{1}{2}}$ state by a buffer gas, which is usually helium or a hydrocarbon such as methane or ethane. Photons in the ${ }^{2} P_{\frac{1}{2}}$ state proceed to lase to the ground state. The ${ }^{2} P_{\frac{3}{2}}$ state and ${ }^{2} P_{\frac{1}{2}}$ state are the analogous features in any alkali corresponding to the well-known doublet in Na . Other, more novel, DPAL systems based on other possible transitions within the alkali metals have been proposed, but have not yet been published. DPAL systems offer a much higher stimulated emission cross section than most laser species, and therefore, have the possibility of delivering sufficient output intensities and power needed for a weapon system. A major drawback to DPAL systems is that they require the ground state to be depopulated by at least half to create an inversion. This is true with any three level laser. To create the required inversion demands that approximately half of the atoms in the ${ }^{2} S_{\frac{1}{2}}$ be pumped into one of the two upper states. The required inversion will only occur when fewer atoms are in the ${ }^{2} S_{\frac{1}{2}}$ than in the ${ }^{2} P_{\frac{1}{2}}$. With modern diode pumping sources this is achievable albeit somewhat difficult. Currently, the theoretical models used by researchers at the Air Force Institute of Technology were developed by Lewis [5] and Hager [3]. The Lewis and Hager models offer many benefits, but do not completely characterize a DPAL system. So, a model has been developed which takes into account a greater amount of parameters and phenomena than [5] and [3]. Throughout this document, "simulation" refers to a computer construct of a "model", which is a theoretical construct of a physical system.

Simulation and model are not interchangeable. The model developed will provide the output power of a DPAL system based on the characteristics of the pump diodes and the lasing cavity. However, this model will not be capable of developing all the necessary physics for the engagement of a target with the DPAL system. Instead this model focuses on developing the output characteristics of a DPAL system which then might be added to current target engagement scenarios or could be used as a research tool to direct the flow of future DPAL research.

## II. BACKGROUND

### 2.1 Overview

DPAL systems are gas electric hybrid lasers. In general, a gaseous cell of an alkali metal has photons incident on it from a narrow banded diode. Alkali atoms are used because of their large absorption cross sections, well-known properties, and similarity to atomic hydrogen [5]. In most current DPAL systems, the diode pumps the ${ }^{2} S_{\frac{1}{2}}$ $\rightarrow{ }^{2} P_{\frac{3}{2}}$ transition (the D2 manifold). The incident light from the diode must have spectral broadening of less than approximately 20 GHz to pump only the ${ }^{2} S_{\frac{1}{2}} \rightarrow{ }^{2} P_{\frac{3}{2}}$ and to ensure that the majority of the pump energy is absorbed by the alkali. A buffer gas is also present in the gaseous cell. This gas serves to collisionally de-excite atoms from the state ${ }^{2} P_{\frac{3}{2}}$ to the ${ }^{2} P_{\frac{1}{2}}$ state [3]. This transition is optically forbidden, so the buffer gas is required for a DPAL to operate. Most often, the gas chosen is ethane, methane, helium or some combination of the three. These gases are generally selected because of their large collisional cross sections with alkali atoms. The alkali metals currently used most often are Rb and Cs. These metals are generally chosen as they have large energy gaps between the ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$ states [5]. Usually, the laser transition occurs between the ${ }^{2} P_{\frac{1}{2}}$ and the ${ }^{2} S_{\frac{1}{2}}$. The DPAL scheme previously mentioned is the most common method used, but other systems have been theorized and a few have been tested [6]. One such system uses collisional excitation of the alkali to the ${ }^{2} P_{\frac{3}{2}}$ state by a collision of multiple noble gas and alkali pairings. These pairings then dissociate after excitation, and the alkali is then induced to lase by the same process aforementioned [6]. Other proposed systems include pumping to upper states beyond ${ }^{2} P_{\frac{3}{2}}$ with double photon absorption and creating laser transitions in the upper manifold of the alkali atoms. No working demonstration of such a system has been published.

To date, most work on the simulation of DPAL systems has focused on modeling the attenuation of the diode pump upon entering the alkali gain medium and on determining the output lasing intensity of DPAL systems under Continuous Wave (CW) conditions. Two of these simulations were developed by Hager [3] and one by Lewis [5]. In general, the key to developing the output lasing intensity is ascertaining the number densities of each of the three levels in the DPAL system, and then calculating the resulting attenuation of the pump intensity. The intra-cavity lasing intensity is deduced by the attenuation of the pump wave based upon the conservation of energy. To determine these number densities and intensities, a simplifying assumption known as the quasi-two level system is used to some degree by both models. However, later developments of the Hager model are three level and not quasi-two level.

The quasi-two level model approximates that the transition rate between the ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$ level due to the buffer gas is fast enough that no other excitation or deexcitation processes occur to atoms in the ${ }^{2} P_{\frac{3}{2}}$ state. That is, the number density of the atoms in the ${ }^{2} P_{\frac{3}{2}}$ level is assumed to maintain an equilibrium distribution in relation to the ${ }^{2} P_{\frac{1}{2}}$ level based upon statistical mechanics. Thus, the ${ }^{2} P_{\frac{3}{2}}$ state and the ${ }^{2} P_{\frac{1}{2}}$ state are essentially one state. This approximation is not completely valid, but vastly simplifies the problem. The Lewis model works under the quasi-two level approximation, but attempts to achieve better fidelity by simulating the effect of the lasing waves in the cavity after threshold have been reached. To actually simulate the true effect of lasing, one must assume that lasing can always effect the number densities. Without this effect the model is not completely accurate. The Hager model assumes that the number density along the alkali cell can be longitudinally averaged, and this number density can be used to formulate the rate equations and the intracavity pump and lasing intensities. This is known as Longitudinally Averaged Number Density (LAND). This also, is not a wholly accurate approximation and under certain
conditions will be inaccurate. Indeed, in most cases the LAND approximation is valid. Only in certain regimes near threshold does the LAND approximation begin to fail [3]. Also, the Hager model does not account for spectrally broadband pumping. It is assumed that all pump photons have the same frequency. Therefore, both the Lewis and Hager models are able to give the user of the simulation an idea of how certain systems will perform. Both models offer a great deal of insight into the operation of DPAL systems under many circumstances and regimes. Physical systems cannot be tested to sufficient fidelity to replicate the results of laboratory experiments. Further, these models have been unable to produce results which describe a three level DPAL system to the fidelity required to perform testing and investigation of new systems without the creation of an experimental apparatus. Hence, to better characterize DPAL systems a more accurate model of the DPAL system must be simulated.

### 2.2 Experimental DPAL Development

One of the earliest developments of a laser system similar to DPAL was done by Beach in 2004 [1]. Beach suggested the use of diodes to pump an optically emitting Rb or Cs laser similar to a diode pumped solid state laser, but using a gas phase alkali. In this paper, Beach used a Ti:S laser to pump a Cs system. Beach then showed that a diode could also be used as a pump source if the diode was able to emit an output sufficiently narrow in frequency to limit the pumping of the lasing transition. To achieve this a diode's pump output must have a lineshape of approximately 10 $G H z$ at 400 Torr of He to successfully pump the Cs D2 line [3]. In practice, this is somewhat difficult to achieve but diodes have been successfully used to pump low power systems [10]. Beach further suggested that such lasers could produce powers comparable to solid state pumped diode lasers in CW operation [1]. A quasi-CW power of 48 W with a 52 percent slope efficiency have been achieved by Zhdanov
by pumping with diode systems [9]. It is believed that DPAL systems can produce even higher output powers as diode technology improves. DPAL systems under pulsed operation have the potential to be the basis of a megawatt class laser system [5] So, as DPAL technology improves it would be extremely advantageous and cost effective to use computer modeling to characterize DPAL systems prior to building such systems.

### 2.3 Hager Model

The Hager model can be either quasi-two level or three level. The LAND method is utilized to determine the number densities used in the three level rate equations. A two level model cannot create the inversion needed for a laser [8]. The earlier quasi-two level model discussed by Hager assumes that the collisional relaxation rate between ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$ is fast enough that the two populations are statistically disturbed as aforementioned. This model is, therefore, not a truly 2-level model, but an approximation to simplify analysis. The rate equations are then developed based on these assumptions. It is assumed that the laser is operating in CW conditions. The rate equations are used to develop the pump intensity $I_{P}$ and the laser intensity $I_{L}$ as functions of cavity position via Rigrod analysis [3]. The equation for $I_{P}$ is inherently transcendental. The set of differential equations is solved numerically.

Hager also develops the lineshape $g_{j i}$ of the transitions and their absorption cross sections $\sigma_{i j}$. The $g_{j i}(\nu)$ and $\sigma_{j i}$ derived include the effects from hyperfine structure. The order of the subscripts determines whether $\sigma$ and $g$ are related to absorption or emission. If $i$ is first then it is absorption; if $j$ is first then it is emission. The effects of hyperfine structure on $I_{L}$ and $I_{P}$ are not examined. As $I_{L}$ and $I_{P}$ are the main pieces of information required to characterize a DPAL system, $I_{L}$ and $I_{P}$ are the focus of this development [3]. Quenching or collisional de-excitation from levels above the ground state to the ground state are not examined. Cavity reflectivities are input parameters
and are utilized to determine loss. The later three-level model developed by Hager assumes that the number densities are still given by LAND, but that the ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$ levels are not given by their statistical relation. Each of these populations must be found independently [3]. Both models developed by Hager assume single frequency pumping, which is, in general, not valid for modern diodes. Hager also assumes that multiple isotopes of the alkali may be present in the gain medium in the quasi-two level and three level cases. The Hager model does simulate the operation of a DPAL system under most cases well. However, the Hager model is not accurate in all cases and can be improved. Further, in some systems the processes not examined by Hager can come to dominate the operation of the DPAL system and must be handled if a complete three level model is to be developed [3].

### 2.4 Lewis Model

Lewis's model is a quasi-two level model. As mentioned previously this assumes that the ${ }^{2} P_{\frac{3}{2}}$ state and the ${ }^{2} P_{\frac{1}{2}}$ state are statistically distributed only. For simplicity, it is assumed that many of the optical transitions are much less likely than the pump and lasing transition. Quenching can be examined, but is not because of a lack of data on the quenching. Several isotopes of common alkalis are examined simultaneously. Lewis also handles the effects of hyperfine structure on $g(\nu)_{i j}$ and $\sigma_{i j}$ [5]. Lewis develops the three level rate equations and proceeds to solve them for the CW case based upon the quasi-two level approximation. The equation developed for $I_{P}$ is, again, transcendental. Lewis uses an analytic solution based upon the Product Log function. This is the main benefit of the Lewis model. Because it develops an analytic solution for $I_{p}$, Lewis is able to provide the equation for the pump intensity as a function of position for any system. It should be noted that the pump intensity does not account for lasing or the shifting of population densities due to pump in-
tensity. For simplicity it is assumed that lasing is not achievable in general. Lewis modeled lasing as a phenomena that would occur only well above threshold and affected the pump attenuation globally not with any frequency dependence of the input photons. Lewis used this method to show how lasing effects the pump intensity by drastically increasing the attenuation of the pump. The assumptions made to develop this model hinder it from working accurately in regimes near threshold and in cases when processes other than those assumed to occur come to dominate the operation of the DPAL system [5]. Currently, no model has handled the effects of pulsed laser operation, the effects of all possible three level optical and collisional transitions, and the effects of the intra-cavity pump and lasing intensity on the number densities of the populations within the system.

## III. DPAL Theory and Model

### 3.1 Overview

This chapter outlines the theoretical equations and chemical kinetics required to model a DPAL system. The three level system of alkali atoms used by DPAL is explained in detail and the hyperfine structure of the ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$ manifolds of Rb and Cs is shown. Chemical kinetics are discussed to develop the three level rate equations and their dependencies. A lineshape for the ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$ transitions is developed using a Voigt profile. The lineshape is used to determine the stimulated emission cross sections and absorption cross sections. The relative intensities of each hyperfine transition are given to find the total stimulated emission cross section. The rate equations are then solved for the population number densities known as $N_{1}, N_{2}$, $N_{3}$. For a CW system the differential equations which govern attenuation and growth of lasing and pump intensities in the cavity are given. The gain coefficient for the DPAL is explored, and the cavity mode spacing is given. The combination of these effects and equations constitute a complete picture of a CW DPAL system.

### 3.2 Three Level System

The three level DPAL system encompasses many possible optical and collisional transitions. For this model, the transitions considered are given in Figure 1 and involve the number densities $N_{3}, N_{2}$, and $N_{1}$ of these levels respectively. These transitions are all of those between the ${ }^{2} P_{\frac{3}{2}},{ }^{2} P_{\frac{1}{2}}$, and ${ }^{2} S_{\frac{1}{2}}$ levels which have population number densities $N_{3}, N_{2}$, and $N_{1}$. For the remainder of this thesis, a subscript $i$ or $j$ denotes the fine structure energy level. $i$ and $j$ can take on values of 3,2 , or 1 each corresponding to ${ }^{2} P_{\frac{3}{2}},{ }^{2} P_{\frac{1}{2}}$, and ${ }^{2} S_{\frac{1}{2}}$ levels respectively. $A_{31}$ and $A_{21}$ are the spontaneous emission Einstein coefficients (EC) for the ${ }^{2} P_{\frac{3}{2}} \rightarrow{ }^{2} S_{\frac{1}{2}}$ transition and
${ }^{2} P_{\frac{1}{2}} \rightarrow{ }^{2} S_{\frac{1}{2}}$ transition respectively. $B_{13}$ and $B_{12}$ are the ECs of absorption for ${ }^{2} S_{\frac{1}{2}} \rightarrow$ ${ }^{2} P_{\frac{3}{2}}$ transition and ${ }^{2} S_{\frac{1}{2}} \rightarrow{ }^{2} P_{\frac{1}{2}}$ transition respectively. $B_{13}$ corresponds to the pump transition. $B_{31}$ and $B_{21}$ are the ECs for the stimulated emission. $B_{21}$ corresponds to the lasing transition. All $k_{i j}$-coefficients are the rates in cycles per second $(H z)$ of excitation or de-excitation between an alkali and some collision partner (methane, ethane, helium or an alkali) an intitial level indicated by the first subscript and a final level indicated by the second subscript $k_{i j}[5]$. The $k_{i j}$-coefficients for excitation $k_{13}$ and $k_{12}$ are approximately 4 orders of magnitude smaller than the corresponding quenching rates $k_{31}$ and $k_{21}$ [5]. The $k_{32}$ and $k_{23}$ rates are the most important for DPAL systems and represent the collisional relaxation between ${ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}}$, which allows for lasing to occur. $k_{32}$ and $k_{23}$ are approximately 4 orders of magnitude larger than the quenching rates [5]. Transitions to other atomic states not listed in Figure 1 can occur, but they are much less likely than those listed for a pump source whose wavelength closely matches the wavelength of the ${ }^{2} P_{\frac{3}{2}} \rightarrow{ }^{2} S_{\frac{1}{2}}$ transition for a given alkali. Note that the transition from ${ }^{2} P_{\frac{3}{2}} \rightarrow{ }^{2} P_{\frac{1}{2}}$ is optically forbidden, and hence, no ECs are listed on Figure 1. Henceforth "population" and "number density" are used interchangeably

From Figure 1, rate equations for the rate of change in time of each of the number densities $N_{3}, N_{2}$, and $N_{1}$ can be constructed in the same manner as done by Lewis [5]. An in depth treatment is given in [8]. For the CW case, these rate equations are set equal to zero [8]. The integrals in Equations (1), (2), and (3) arise from the different possible wavelengths for the pump and laser transitions due to lineshape and hyperfine structure. The sums over species are present to allow for the possibility of different alkali collision partners, such as methane, ethane, and helium, being present simultaneously. Each species corresponds to a different collisional excitation and de-excitation rate and each must be handled separately. $g_{p}\left(\nu_{p}\right)$ is the lineshape of

Figure 1. The three level chemical kinetics used for the development of the DPAL model. $N_{1}$ corresponds to the population in the ${ }^{2} S_{\frac{1}{2}}$ state. $N_{2}$ corresponds to the population in the ${ }^{2} P_{\frac{1}{2}}$ state. $N_{3}$ corresponds to the population in the ${ }^{2} P_{\frac{3}{2}}$ state. The pump transition corresponds to $B_{13}$. The laser transition corresponds to $B_{21}$.
the input pump as a function of $\nu_{p}$. The concentration of a given collision partner is $M_{\text {species }}$. Also, the excitation rate coeffcients $k_{13}$ and $k_{12}$ are neglected because of their extremely small size under normal temperatures for operation of a DPAL system (less than approximately 1000 K ) and for most collision partners typically used (methane, ethane, and helium). However, if one were to use another gas as a collision partner these terms might need to be reinserted. It is suggested that the reader use the list of symbols provided at the outset of this document while reading these equations to avoid confusion. $h$ is Planck's constant.

$$
\begin{align*}
\frac{d N_{1}(z, t)}{d t}= & \sum_{\text {species }}\left[N_{3}(z, t) A_{31}+N_{2}(z, t) A_{21}+N_{3}(z, t) k_{31_{\text {species }}} M_{\text {species }}\right. \\
& \left.+N_{2}(z, t) k_{21_{\text {species }}} M_{\text {species }}\right]+\int_{-\infty}^{\infty}\left[-\frac{N_{1}(z, t) I_{P}(\nu, z, t) \sigma_{31}\left(\nu_{p}\right)}{h \nu_{p}}\right.  \tag{1}\\
& \left.+\frac{N_{3}(z, t) I_{P}(\nu, z, t) \sigma_{31}\left(\nu_{p}\right)}{h \nu_{p}}+\frac{I_{L}(\nu, z, t) \sigma_{21}\left(\nu_{l}\right)}{h \nu_{l}}\left[N_{2}(z, t)-\frac{g_{2}}{g_{1}} N_{1}(z, t)\right]\right] d \nu
\end{align*}
$$

$$
\begin{aligned}
\frac{d N_{2}(z, t)}{d t}= & \sum_{\text {species }}\left[N_{3}(z, t) k_{32_{\text {species }}} M_{\text {species }}-N_{2}(z, t) k_{23_{\text {species }}} M_{\text {species }}-\right. \\
& \left.A_{21} N_{2}(z, t)-N_{2}(z, t) k_{21_{\text {species }}} M_{\text {species }}\right] \\
& +\int_{-\infty}^{\infty}\left[-\frac{I_{L}(\nu, z, t) \sigma_{21}\left(\nu_{l}\right)}{h \nu_{l}}\left[N_{2}(z, t)-\frac{g_{2}}{g_{1}} N_{1}(z, t)\right]\right] d \nu
\end{aligned}
$$

$$
\begin{aligned}
\frac{d N_{3}(z, t)}{d t}= & \sum_{\text {species }}\left[-N_{3}(z, t) k_{32 \text { species }} M_{\text {species }}+N_{2}(z, t) k_{23_{\text {species }}} M_{\text {species }}-\right. \\
& \left.A_{31} N_{3}(z, t)-N_{3}(z, t) k_{31_{\text {species }}} M_{\text {species }}\right]+ \\
& \int_{-\infty}^{\infty}\left[\frac{N_{1}(z, t) I_{P}(\nu, z, t) \sigma_{31}\left(\nu_{p}\right)}{h \nu_{p}}-\frac{N_{3}(z, t) I_{P}(\nu, z, t) \sigma_{31}\left(\nu_{p}\right)}{h \nu_{p}}\right] d \nu
\end{aligned}
$$

Equations (1), (2), and (3) may then be set equal to zero in the CW case. The CW case also eliminates the dependence on time in $I_{P}(\nu, z, t)$ and $I_{l}(\nu, z, t)$. These equations constitute two independent equations, not three, as all of the rates between the three levels are present in two of the equations simultaneously. Hence, these equations do not form an independent set of three equations, but only two dependent equations. Therefore, to solve for the corresponding population number densities $N_{1}$, $N_{2}$, and $N_{3}$, which is the ultimate goal of this development, another equation must be added. This is Equation (4), where $N_{t}$ represents the total number density of alkali in the system.

$$
\begin{equation*}
N_{t}=N_{1}+N_{2}+N_{3} \tag{4}
\end{equation*}
$$

### 3.3 Cross sections and Lineshapes for DPALs

With three independent equations, $N_{1}, N_{2}$, and $N_{3}$ may be solved unambiguously. This is performed via Mathematica in Appendix A. With this level of detial in the rate equations, this is a non-trivial task without a computational aide. Armed with $N_{1}, N_{2}$, and $N_{3}$ the individual terms within the rate equations must now be developed to actually compute the populations $N_{1}, N_{2}$, and $N_{3}$. The stimulated emission cross section $\sigma_{j i}$ for a DPAL system is given by Equations (5) and (6) where $\sigma_{i j}$ is the corresponding absorption cross section. If $j$ and $i$ correspond to $N_{3}$ and $N_{1}$, the pump frequency $\nu_{p}$ is used, and if $j$ and $i$ correspond to $N_{2}$ and $N_{1}$, the pump frequency $\nu_{l}$ is used. The lineshape $g_{j i}(\nu)$, the natural abundance of hyperfine states $f_{j i}\left(F^{\prime \prime}, F^{\prime}\right)$, and relative intensity of the hyperfine transitions $S\left(F^{\prime \prime}, F^{\prime}, i s o\right)$ used all follow the same employment scheme for $i$ and $j$ as $\sigma_{i j}$. It is of note, that while the lasing frequency is a single value in CW single mode operation as per [8], the pump frequency $\nu_{p}$ has a lineshape associated with the output of the diode. This requires
that while $\sigma_{21}\left(\nu_{l}\right)$ has a single value, $\sigma_{31}\left(\nu_{p}\right)$ is a continuous function. This point is easily overlooked and is important to accurately model a broadband pumped DPAL system. The functional dependence on a particluar isotope is shown as (iso) and relates to the particular alkali isotope being used. In Equation (5), iso denotes the particular isotope species and its particular $g_{j i}(\nu), S\left(F^{\prime \prime}, F^{\prime}, i s o\right)$, and $f_{j i}\left(F^{\prime \prime}, i s o\right)$. $f_{\text {iso }}$ is the natural abundance of a particular isotope as a fraction out of one.

$$
\begin{gather*}
\sigma_{i j}(\nu)=\sum_{i s o} \sum_{F^{\prime \prime}(i s o)} \sum_{F^{\prime}(i s o)} \frac{g_{j}}{g_{i}} \frac{c^{2}}{\nu^{2} 8 \pi} A_{j i} S\left(i s o, F^{\prime \prime}, F^{\prime}\right) g_{j i}(\nu) f_{j i}\left(F^{\prime \prime}, i s o\right) f_{i s o}  \tag{5}\\
\sigma_{j i}(\nu)=\frac{g_{i}}{g_{j}} \sigma_{i j}(\nu) \tag{6}
\end{gather*}
$$

The lineshape $g_{j i}$ is a convolution of the Doppler broadening (a Gaussian), the pressure broadening (a Lorentzian), and the lifetime broadening (a Lorentzian)[8]. The lifetime and pressure broadening are known as the homogenous broadening and are given by $\Delta \nu h_{j i}(i s o)$ in Equation 7. The Doppler broadening is $\Delta \nu d_{j i}(i s o)$ given by Equation (8) [8]. Using these quantities, the Voigt lineshape $g_{j i}(\nu)$ is given by Equation (9) from [8]. $k_{b}$ is Boltzmann's constant.

$$
\begin{align*}
& \Delta \nu h_{j i}(i s o)=\frac{1}{2 \pi}\left(\frac{1}{\tau_{\text {rad }_{j i}}}\right)+\sum_{\text {species }} \gamma_{\text {species }} M_{\text {species }}\left(\frac{T_{\text {species }}}{T}\right)^{\frac{1}{2}}  \tag{7}\\
& \Delta \nu d_{j i}\left(F^{\prime \prime}, F^{\prime}, i s o\right)=\nu h y_{j i}\left(F^{\prime}, F^{\prime \prime}, i s o\right)\left(\frac{\left.8 k_{b} T * \log (2)\right]}{m(i s o) c^{2}}\right)  \tag{8}\\
& g_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)=\left(\frac{m}{2 \pi k_{b} T}\right)^{\frac{1}{2}} \int_{-\infty}^{\infty}\left(\frac{\Delta \nu h_{j i}(i s o)}{2 \pi\left(\left(\nu-\nu_{0}-\nu_{0} v_{z} / c\right)^{2}\right)+\left(\Delta \nu h_{j i}(i s o) / 2\right)^{2}} \exp \left(-\frac{m v_{z}^{2}}{2 k_{b} T}\right) d v_{z}\right) \tag{9}
\end{align*}
$$

$\Delta \nu d_{j i}\left(F^{\prime \prime}, F^{\prime}, i s o\right)$ depends on the particular hyperfine line to which $\Delta \nu d_{j i}\left(F^{\prime \prime}, F^{\prime}, i s o\right)$
corresponds as each hyperfine transition has its own associate FWHM. The FWHM depends upon $F^{\prime \prime}$, the original transition state in either $N_{1}, N_{2}$, or $N_{3}$, and $F^{\prime}$, the final state in $N_{1}, N_{2}$, or $N_{3}$ [5]. Note, $\nu h y_{j i}\left(F^{\prime}, F^{\prime \prime}, i s o\right)$ is the hyperfine frequency, in $H z$, for a transition from one state to another for a particular $F^{\prime}, F^{\prime \prime}$, and isotope. $\nu h y_{j i}\left(F^{\prime}, F^{\prime \prime}, i s o\right)$ is not the splitting between hyperfine levels within a single fine level. That is $\nu_{h_{\text {hspplit }}^{j}}\left(F^{\prime \prime}, i s o\right)$. Figures 2, 3, 4, 5, 6, and 7 show the transitions between each of the hyperfine states of the D1 and D2 transitions for Cs, ${ }^{85} R b$, and ${ }^{87} R b$. The selection rule for $F^{\prime \prime}$ to $F^{\prime}$ is $\Delta F=+1,-1$, or 0 with $F^{\prime \prime}=0$ to $F^{\prime}=0$ being forbidden. Figures $2,3,4,5,6$, and 7 are taken from [5].

In practice, Equation (9) is difficult to use. An approximation using an error function can be made as is employed as per [7]. The intermediate quantities given by Equations (10), (11), and (12) are developed in this process. In Equation (12), the $i$ in front of $u_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)$ is the square root of negative one. For the remainder of this thesis, Equation (13) will be used for $g_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)$, not Equation (9).

$$
\begin{gather*}
a_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)=\log (2)^{\frac{1}{2}} \frac{\Delta \nu h_{j i}(i s o)}{\Delta \nu d_{j i}(i s o)} \\
u_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)=2 \log (2)^{\frac{1}{2}} \frac{\left(\nu-\nu h y_{j i}\left(F^{\prime \prime}, F^{\prime}, i s o\right)\right)}{\Delta \nu d_{j i}\left(F^{\prime \prime}, F^{\prime}, i s o\right)} \\
z_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)=a_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)+\imath * u_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right) \\
g_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)=\frac{4 \log (2)^{1 / 2}}{\pi} \frac{1}{\Delta \nu d_{j i}\left(F^{\prime \prime}, F^{\prime}, i s o\right)} \operatorname{Re}\left(e^{z_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)^{2}} \operatorname{Erfc}\left(z_{j i}\left(\nu, F^{\prime \prime}, F^{\prime}, i s o\right)\right)\right) \tag{13}
\end{gather*}
$$

To calculate the lineshape, the relative strength $S\left(\right.$ species $\left., F^{\prime \prime}, F^{\prime}, i s o\right)$ of a transition between hyperfine levels must be known [5]. The relative intensities of each of

Figure 2. The D1 manifold for ${ }^{133} \mathrm{Cs}$ without possible transitions listed. The frequency spacing of each hyperfine state is listed [5].

Figure 3. The D2 manifold for ${ }^{133}$ Cs without possible transitions listed. The frequency spacing of each hyperfine state is listed [5].

Figure 4. The D1 manifold for ${ }^{85} \mathrm{Rb}$ without possible transitions listed. The frequency spacing of each hyperfine state is listed [5].

Figure 5. The D2 manifold for ${ }^{85} \mathrm{Rb}$ without possible transitions listed. The frequency spacing of each hyperfine state is listed [5].

Figure 6. The D1 manifold for ${ }^{87} \mathrm{Rb}$ without possible transitions listed. The frequency spacing of each hyperfine state is listed [5].

Figure 7. The D2 manifold for ${ }^{87} \mathrm{Rb}$ without possible transitions listed. The frequency spacing of each hyperfine state is listed [5].
the transitions for the D1 and D2 transitions may be found in Tables 1, 2, and 3. The data in Tables 1, 2, and 3 comes from [5].

The relative natural abundance of each hyperfine state as a fraction of one is $f_{j i}\left(F^{\prime \prime}, i s o\right) . f_{j i}\left(F^{\prime \prime}, i s o\right)$ is given by Equation (14). The relative natural abundance is the fraction of atoms in each of the initial hyperfine states $F^{\prime \prime}$. It is of note that $\nu_{h y s p l i t_{j}}\left(F^{\prime \prime}, i s o\right)$ is not equal to $\nu_{h y_{j i}}\left(F^{\prime \prime}, F^{\prime}, i s o\right) . \nu_{h y s p l i t_{j}}\left(F^{\prime \prime}, i s o\right)$ is the frequency in $H z$ of the splitting between a particular hyperfine level and the center frequency of the fine structure level which the hyperfine level is in. While, $\nu_{h y_{j i}}\left(F^{\prime \prime}, F^{\prime}, i s o\right)$ is the frequency in $H z$ of a $F^{\prime \prime} \rightarrow F^{\prime}$ hyperfine transition between two fine structure levels. Simply put, $\nu_{h_{\text {hsplit }}^{j}}\left(F^{\prime \prime}, i s o\right)$ is an energy splitting in $H z$ given on Figures 2, 3, 4, 5, 6 , and 7 and $\nu_{h y_{j i}}\left(F^{\prime \prime}, F^{\prime}, i s o\right)$ is the absolute difference between two hyperfine levels in different fine structure levels.

$$
\begin{equation*}
\left.\left.f_{j i}\left(F^{\prime \prime}, i s o\right)=\frac{\left(2 F^{\prime \prime}+1\right) \exp \left(\frac{h\left(\nu_{j i}-\nu_{h y s p l i t} j_{j}\right.}{}\left(F^{\prime \prime}, i s o\right)\right)}{k_{b} T}\right)\right) \tag{14}
\end{equation*}
$$

### 3.4 Alkali and Collision Partner Properties

Several other important material quantities are needed to calculate Equation (6). Table 4 provides these quantities for Cs and Rb .

From the numbers in Table 4 and using equations from [8], several more needed quantities are developed. These include $B_{j i}$ and $k_{j i}$.

$$
\begin{gather*}
B_{j i}(\nu, i s o)=\frac{c^{3} A_{j i}(i s o)}{n^{3} 8 \pi h \nu^{3}}  \tag{15}\\
B_{i j}(\nu, i s o)=\frac{g_{j}}{g_{i}} B_{j i}(\nu, i s o) \tag{16}
\end{gather*}
$$

\end{equation*}
$$

### 3.5 Lasing and Pump Intensities

To find the output lasing intensity one must first determine the intra-cavity lasing intensity and the intra-cavity pump intensity as functions of $\nu_{p}$ and time. A nearly accurate treatment of this is done by [8] and is known as Rigrod analysis. Rigrod analysis involves the propagation in the cavity of a pump wave, $I_{P}$, a forward traveling lasing wave, $I_{+}$, and a backward traveling lasing wave, $I_{-}[8]$. The saturation intensity $I_{\text {sat }}$ is also required to perform Rigrod analysis and is given by Equation (18). Equations (18), (19), (20), and (21) are the initial differential equations for the attenuation or growth of intra-cavity pump and lasing waves. Notice that Equations
(19), (20), and (21) are transcendental. Also, remember that $N_{1}, N_{2}$, and $N_{3}$ depend on $I_{P}, I_{+}$, and $I_{-}$. This dependence is extremely lengthy and is shown in Appendix A. These two facts greatly increase the solution difficulty of these differential equations. Equations (19), (20), and (21) require numerical differential equation solution techniques to solve. Equations (20) and (21) appear without the terms which go as the inverse of $I_{+}$plus $I_{-}$divided by $I_{\text {sat }}$ because the population densities $\left(N_{1}, N_{2}\right.$, and $N_{3}$ ) maintain their dependence on $I_{P}, I_{+}$, and $I_{-}[8]$.

$$
\begin{gather*}
I_{\text {sat }}\left(\nu_{p}\right)=\frac{h \nu_{p}}{\sigma_{31}\left(\nu_{p}\right)} \sum_{\text {iso }}\left(\frac{1}{\tau_{\text {rad }}(i s o)} f_{\text {iso }}\right)  \tag{18}\\
\frac{d I_{P}\left(z, \nu_{l}, \nu_{p}\right)}{d z}=\sigma_{31}\left(\nu_{p}\right)\left[N_{3}\left(z, \nu_{l}, \nu_{p}\right)-\frac{g_{3}}{g_{1}} N_{1}\left(z, \nu_{l}, \nu_{p}\right)\right] I_{P}\left(z, \nu_{l}, \nu_{p}\right)  \tag{19}\\
\frac{d I_{+}\left(z, \nu_{l}, \nu_{p}\right)}{d z}=\sigma_{21}\left(\nu_{l}\right)\left[N_{2}\left(z, \nu_{l}, \nu_{p}\right)-\frac{g_{2}}{g_{1}} N_{1}\left(z, \nu_{l}, \nu_{p}\right)\right] I_{+}\left(z, \nu_{l}, \nu_{p}\right)  \tag{20}\\
\frac{d I_{-}\left(z, \nu_{l}, \nu_{p}\right)}{d z}=-\sigma_{21}\left(\nu_{l}\right)\left[N_{2}\left(z, \nu_{l}, \nu_{p}\right)-\frac{g_{2}}{g_{1}} N_{1}\left(z, \nu_{l}, \nu_{p}\right)\right] I_{+}\left(z, \nu_{l}, \nu_{p}\right) \tag{21}
\end{gather*}
$$

The crux of the simulation lies in solving Equations (19), (20), and (21). The solution to these differential equations requires three boundary conditions. Initial conditions are not used as the solution is time-independent for the CW case. Equations (22), (23), and (24) provide these boundary conditions as given by [8] for Rigrod analysis, where $\nu_{d}$ is the line center of the diode's spectral profile in $H z . z_{0}$ is the position of the beginning of the gain cell and $z_{f}$ is the position of the end of the gain cell. Note, that $z$ denotes the functional dependence of an equation upon longitundinal position in $m$ in the alkali gain cell.

$$
\begin{equation*}
I_{P}\left(z_{0}, \nu_{l}, \nu_{p}\right)=I_{P} 0 \frac{g_{31}\left(\nu_{p}\right)}{g_{31}\left(\nu_{d}\right)} \tag{22}
\end{equation*}
$$

$$
\begin{align*}
& I_{+}\left(z_{0}, \nu_{l}, \nu_{p}\right)=R_{1} T_{g}^{2} I_{-}\left(z_{0}, \nu_{l}, \nu_{p}\right)  \tag{23}\\
& I_{-}\left(z_{f}, \nu_{l}, \nu_{p}\right)=R_{2} T_{g}^{2} I_{+}\left(z_{f}, \nu_{l}, \nu_{p}\right) \tag{24}
\end{align*}
$$

Other important and oft used benchmarks for the system are the gain coefficient $\gamma_{\nu}$ given by Equation (25), the loss coefficient $\alpha$ given by Equation (26), and the cavity mode spacing $\Delta \nu_{f s r}$ given by Equation (27). Under CW operation, the gain coefficient will equal the loss coefficient once threshold is reached [8]. This forces the gain to operate at the loss. The cavity mode spacing and the gain coefficient are important as they determine what the operating frequency of the laser $\left(\nu_{l}\right)$ will be as the mode with the greatest gain coefficient will be selected preferentially over all other modes [8]. By the time threshold is reached, all of the power in the laser will be focused in this single mode. This is the idea of single mode operation. This is only true for lasers operating in a single TEM mode and not multiple modes [8]. $n$ is the index of refraction. $c$ is the speed of light.

$$
\begin{gather*}
\gamma_{\nu}\left(z, \nu_{l}, \nu_{p}\right)=\frac{d I_{+}\left(z_{0}, \nu_{l}, \nu_{p}\right)}{d z} \frac{1}{I_{+}\left(z_{0}, \nu_{l}, \nu_{p}\right)}=\sigma_{21}\left(v_{l}\right)\left(N_{2}\left(z, \nu_{l}, \nu_{p}\right)-\frac{g_{2}}{g_{1}} N 1\left(z, \nu_{l}, \nu_{p}\right)\right)  \tag{25}\\
\alpha=\frac{1}{2 l_{g}} \ln \left(\frac{1}{R_{1} R_{2}}\right)  \tag{26}\\
\nu_{q+1}-\nu_{q}=\frac{c}{2 n d_{\text {mirror }}} \tag{27}
\end{gather*}
$$

These equations constitute a completely-modeled DPAL system.

## IV. Simulation Description

### 4.1 Overview

The simulation of the model developed in Chapter III is performed in Mathematica 7.0 for Windows XP on a 2.0 GHz AMD processor. The simulation reads in a list of input parameters, then uses all of the equations developed in Chapter III to simulate a DPAL system. Then using the differential equation solving, data analysis, and visualizations packages in Mathematica the system is characterized as detailed in Chapter III. The outputs required of the system are $I_{p}\left(z, \nu_{l}, \nu_{p}\right), I_{+}\left(z, \nu_{l}, \nu_{p}\right), I_{-}\left(z, \nu_{l}, \nu_{p}\right)$, $\gamma_{\nu}\left(z, \nu_{l}, \nu_{p}\right), \alpha, N_{1}\left(z, \nu_{l}, \nu_{p}\right), N_{2}\left(z, \nu_{l}, \nu_{p}\right), N_{3}\left(z, \nu_{l}, \nu_{p}\right)$, and the output laser intensity, $I_{\text {out }}$, which is the output at the single laser frequency, $\nu_{l}$

### 4.2 Assumptions

Without simplifying assumptions simulating the DPAL model discussed in Chapter III would not be practical as a single threaded process on a desktop computer. Assumptions were made to simplify the problem, but these assumptions were chosen such that a high degree of fidelity is maintained in the simulation's outputs. The DPAL system is assumed to be CW in its pump and response. Hence, all time dependence is eliminated. For any system which runs for longer than approximately one $m s$ this is an adequate assumption because the population densities will reach their equilibrium values within that time. Only transitions within the three level system shown in Figure 1 are assumed to occur. All other transitions within the alkali atom are ignored. This assumption is somewhat valid as the absorption and emission cross section for the ${ }^{2} S_{\frac{1}{2}} \rightarrow{ }^{2} P_{\frac{3}{2}}$ and ${ }^{2} P_{\frac{1}{2}} \rightarrow{ }^{2} S_{\frac{1}{2}}$ are much larger (approximately $10^{4}$ times larger) than any of the other transitions.

It is assumed that no forbidden hyperfine transitions occur within or between the
sublevels. The effects of the hyperfine structure beyond its effects on the lineshape $g_{j i}(\nu)$ are neglected. The hyperfine structure in a physical system does play a part in the rate between each sublevel. Hence, a fully complete model would need to create rate equations, such as Equations (1),(2), and (3), for each possible (including the forbidden transitions) hyperfine transition. The populations of each hyperfine level would also have to be independent of one another. Transitions between hyperfine levels due to collisions, absorption, and emission would also have to be tracked. Further, the lasing intensity would not be single quantity but a set of intensities each associated with a transition on the D1 manifold. Each intensity would require an individual plus wave and minus wave differential equation like Equations (20) and (21). Thus, the system would contain not three coupled non-linear ODEs, but instead 13. Also, the collisional excitation and de-excitation rates between hyperfine levels are unknown. Adding this complexity to the model is both extremely complicated and computationally difficult without the use of multi-threading. The laser modeled is assumed to operate only in the $\operatorname{TEM}(0,0)$ mode and to not operate in any other modes. The mode volume is assumed to be completely filled. The energy lost because of unfilled mode volume is not considered. This assumption is only somewhat valid, but it is difficult to simulate the effects of partially filling the mode volume of a DPAL because these effects are not yet fully characterized in the literature.

### 4.3 Simulation Input Parameters

The inputs to the simulation are listed in Table 5. Each parameter is given with its normal range of values. The input parameters are not physical constants, but are rather variables which are dynamic between different DPAL systems. Collisional relaxation rate coefficients such as $k_{32}$ are not considered input parameters. These are considered physical constants of the system and are not input by the user. The
simulation has the ability to include more collisional relaxation rates than those for methane and helium, but does not currently. Appendix B shows a list of the physical parameters used by the code. It is of note that the three level numerical model takes all inputs in meters, kilograms, and seconds (mks) and the derived units of the mks system. Units with metric prefixes other than kilograms should not be used. Table 5 presents the inputs with prefixes for simplicity.

Table 5. Simulation Input Parameters

| Input Parameter | Units required | Normal Range | Symbol |
| :---: | :---: | :---: | :---: |
| Temperature of Cell | $K$ | $250-2000$ | $T$ |
| Temperature of Methane | $K$ | $250-2000$ | $T_{\text {meth }}$ |
| Temperature of Helium | $K$ | $250-2000$ | $T_{H e}$ |
| Temperature of Alkali | $K$ | $250-2000$ | $T_{a l k}$ |
| Partial Pressure of Methane | $k P a$ | $20-2000$ | $M_{\text {meth }}$ |
| Partial Pressure of Helium | $k P a$ | $20-2000$ | $M_{H e}$ |
| Partial Pressure of Alkali | $k P a$ | $2-200$ | $M_{a l k}$ |
| Total Alkali Number Density | $m^{-3}$ | $10^{18}-10^{24}$ | $N_{t}$ |
| Length of gain medium | $m$ | $0.005-0.5$ | $l_{g}$ |
| Transmission of windows around gain | Unitless | $0.95-1.0$ | $T_{g}$ |
| High Reflector Reflectivity | Unitless | $0.95-1.0$ | $R_{1}$ |
| Output Coupler Reflectivity | Unitless | $0.2-1.0$ | $R_{2}$ |
| Initial Pump Intensity at linecenter | $W c m^{-2}$ | $10^{2}-10^{6}$ | $I_{p} 0$ |
| Diode Pump Line Center frequency | $T H z$ | $384.0-384.4$ | $\nu_{d}$ |
| Diode Pump FWHM frequency | $G H z$ | $10^{-1}-10^{2}$ | $\nu_{p_{f w h m}}$ |
| Space Between Cavity Mirrors | $m$ | $0.01-1.0$ | $d_{m i r r o r}$ |

### 4.4 Simulation Outline

The simulation begins by reading the input parameters in Table 5 . Then the program develops each equation listed in Chapter III from Equation (1) to (27) except Equation (9), to which an approximation was used as detailed in Chapter III. These equations are supplemented by the physical parameters of the system given in Tables 1-4 and Figures 2-7. During this development the assumptions listed above are made by the simulation or were made during the simulation's design. The code then
constitutes a fully-developed model of a DPAL system. If the differntial equations (19), (20), and (21) can be solved numerically for this system, then all of the parameters needed to characterize the system can be developed from that solution. In practice, the solution of Equations (19), (20), and (21) is difficult and requires the use of Mathematica's innate numerical differential equation solver. The differential equation solver is utilized with a shooting method and the boundary conditions of Equations (22), (23), and (24). To solve Equations (19), (20), and (21) requires that a shooting method be performed for different initial values for $I_{+}$and $I_{-}$at $z_{0}$. Each shot is then solved by the numerical differential equation solver for a solution to the differential equations in $z$ or position. An algorithm then assigns the best starting $I_{+}$ and $I_{-}$values based upon the occurrence of gain above loss and on the degree of adherence to Equation (24). This solution architecture is then utilized for a select set of pump frequencies spanning three times the pump's full width at half max (FWHM). The solutions which best match the boundary condition for each discrete pump frequency are then interpolated between by Mathematica's data analysis software and are plotted. This architecture is detailed in Figure 8. The complete Mathematica notebook can be found in Appendix B.

### 4.5 Simulation Outputs

The outputs of the simulation are the way in which the model is both compared to other models such as [2],[3], and [5], and then, the outputs are compared to experimental results. To achieve these comparisons several different outputs are provided. A profile of the pump intensity $I_{P}\left(z, \nu_{p}\right)$ is shown throughout the entire cell. $I_{+}\left(z, \nu_{p}, \nu_{l}\right)$ and $I_{-}\left(z, \nu_{p}, \nu_{l}\right)$ are plotted. The population densities, $N_{1}\left(z, \nu_{p}\right)$, $N_{2}\left(z, \nu_{p}\right)$, and $N_{3}\left(z, \nu_{p}\right)$ are plotted. The output lasing intensity $\left(I_{o u t}\right)$ is determined. The simulation selects the lasing mode with the greatest gain and outputs its fre-

Figure 8. The architecture used to develop the simulation of the DPAL model. Octagons are output plots or printed output system characteristics. Rectangles are algorithms.
quency, as this is the frequency of the laser's output. $\gamma_{\nu}(z)$ is plotted for the system. The average value of $\gamma_{\nu}$ over $z$ is compared to $\alpha$ and should be found to be roughly equivalent. A determination of the degree to which the chosen solution matches the boundary conditions is provided.

## V. Results and Simulation Comparisons

### 5.1 Chapter Overview

To validate the model this thesis develops, which is henceforth known as the three level numerical model; it must be tested against similar previously vetted systems like the Lewis model and the Hager model. If the outputs of the model developed are comparable to those developed by Lewis and Hager in the regime where those models are known to operate well, then the model's output outside of those regimes is more believable. The model will also be tested against experimental results. Further, the model will be shown to simulate a DPAL with an extremely high initial pump intensity and other features typically found only during pulsed operation. The model will also perform Rigord analysis for a general DPAL case. Together these outputs will show the effectiveness and utility of the model and its simulation.

### 5.2 Comparison to Lewis Model

### 5.2.1 Inputs.

The inputs of Table 6 are derived from the DPAL quasi two level regime of Lewis's thesis [5]. The inputs are listed in the units used by Lewis in [5] rather than units used by the three level numerical model. If an input was not listed by Lewis, a suitable value was devised. This applies specifically to the temperature of the alkali for plots provided in [5]. The alkali used for this comparison was Rb , which is used throughout the comparison between the three level numerical model and the Lewis model. These inputs will be used throughout the comparison to Lewis's model and the three level numerical model for the remainder of this section unless otherwise noted. Lewis lists one of his buffer gases as ethane in [5]. However, his theortical development and plots list methane as the buffer gas used. Further [5] lists methane, not ethane, as his
buffer gas on all other tables. Therefore, methane, not ethane will be used for this development [5].

Table 6. Simulation Input Parameters from Lewis Model

| Input Parameter | Units required | Value | Symbol |
| :---: | :---: | :---: | :---: |
| Temperature of Cell | $K$ | 455 | $T$ |
| Temperature of Methane | $K$ | 455 | $T_{\text {meth }}$ |
| Temperature of Helium | $K$ | 455 | $T_{H e}$ |
| Temperature of Alkali | $K$ | 455 | $T_{\text {alk }}$ |
| Partial Pressure of Methane | Torr | 600 | $M_{\text {meth }}$ |
| Partial Pressure of Helium | Torr | 200 | $M_{H e}$ |
| Partial Pressure of Alkali | Torr | 0 | $M_{\text {alk }}$ |
| Total Alkali Number Density | $\mathrm{cm}^{-3}$ | $6.1 \times 10^{12}$ | $N_{t}$ |
| Length of gain medium | $c m$ | 8.00 | $l_{g}$ |
| Transmission of windows around gain | Unitless | 1.0 | $T_{g}$ |
| High Reflector Reflectivity | Unitless | 1.0 | $R_{1}$ |
| Output Coupler Reflectivity | Unitless | 1.0 | $R_{2}$ |
| Initial Pump Intensity at linecenter | $W c m^{-2}$ | 200 | $I_{p} 0$ |
| Diode Pump Line Center frequency | $T H z$ | 384.23 | $\nu_{d}$ |
| Diode Pump FWHM frequency | $G H z$ | 3 | $\nu_{p_{f w h m}}$ |
| Space Between Cavity Mirrors | $c m$ | 50 | $d_{m i r r o r}$ |

### 5.2.2 Cross Section Broadening Comparison.

Lewis details that the main mechanism for broadening in the DPAL system is the pressure of the buffer gas [5]. Lewis then investigates the effects of pressure broadening at several different pressures on the emission cross section of the 3 to 1 transition, $\sigma_{31}$ shown in Figures 9 and 10. The analogous results for the three level numerical model are provided by accepting that the Lewis model neglects the terms $f_{\text {iso }}$ and $f_{j i}$ by assuming only one isotope is present and the hyperfine states all are equally populated in Figures 11 and 12. The Lewis model uses units of $\mathrm{cm}^{2}$ as opposed to $\mathrm{m}^{2}$ which will induce a shift of $10^{-4}$ when comparing cross sections between the Lewis model to the three level numerical model. Notice that Figures 9 and 11 differ slightly most likely due to a difference in temperature as Lewis did not list the temperature
he used to create Figure 9. Figures 10 and 12 are identical. This implies that the lineshapes and cross sections developed by the three level numerical model agree well with those of the Lewis model especially at high pressures. Note Figures 9, 10, 11, and 12 are all offset in frequency space by $\nu_{31}$.

Figure 9. $\sigma_{31}$ for 100 Torr helium and 100 Torr methane from the Lewis model [5]

### 5.2.3 Absorption Profile Comparison.

The absorption profiles for the DPAL regime from the Lewis model are given by Figure 13 from [5]. The same inputs were provided to the three level numerical model and the comparable output is given by Figure 14. Notice that the frequency axis in Figure 13 is offset based on pump line center frequency $\nu_{d}$, the intensity is in $W \mathrm{~cm}^{-2}$, and the position within the gain medium $(z)$ is in cm . Figure 13's units are based on the $M K S$ system. Figure 14 shows similar features to Figure 13, however, small changes from the more complete rate equation analysis and the use of the terms $f_{\text {iso }}$ and $f_{j i}$ are noticeable at the far end of the cell. Hence, the Lewis model captures a

Figure 10. $\sigma_{31}$ for 1000 Torr helium and 1000 Torr methane from the Lewis model [5]

Figure 11. $\sigma_{31}$ for 100 Torr helium and 100 Torr methane from the three level numerical model

Figure 12. $\sigma_{31}$ for 1000 Torr helium and 1000 Torr methane from the three level numerical model
great deal of the absorption effects within the gain medium, but it does not develop a wholly accurate picture of the attenuation of the pump wave.

The Lewis model also develops the attenuation of the pump intensity under the quasi-two level approach (QTLA), and based upon the QTLA assumption, is able to develop the amount of attenuation of the pump intensity due to lasing. This development is somewhat $a d-h o c$, and will not work properly at threshold and will not give a spectral profile for the occurrence of lasing. That is, the pump is assumed to cause lasing to occur and then will be attenuated to a greater degree based upon an assumed lasing intensity which will occur over all pump frequencies to an equal degree. This effect can be seen in Figure 15 with the inputs of Table 6. In actuality only those pump photons which cause lasing to occur in the gain medium will see this effect. Hence, only certain pump frequencies will exhibit this effect; those that induce lasing to occur. Those pump frequencies which do not provide enough energy

Space and Frequency Representation of DPAL Regime Absorption

Figure 13. The Lewis model 3D absorption profile without lasing for inputs of Table 6. Note the units of the plot are not $M K S$ and the frequency is offset by $\nu_{d}$ [5].

Figure 14. The three level numerical model 3D absorption profile without lasing for inputs of Table 6
to maintain gain above loss will not observe this effect. This can be seen in Figure 16, created with the inputs of Table 6 by the three level numerical model. Lasing is observed to occur in the frequency domain between the two peak features which propagate through to the end of the cell. Also, note that it appears that the pump intensity in the area without lasing has grown between Figures 14 and 16. This is simply an optical illusion due to the degree to which a discontinuity appears in frequency space due to achieving threshold inversion. A close inspection of Figures 14 and 16 will reveal this fact. By comparing Figures 15 and 16, one can see that the Lewis model is able to only approximate the effect of the attenuation of the pump due to intra-cavity lasing. This effect is negligible well above threshold ( 30 times $I_{\text {sat }}$ ). The three level numerical model also simulated $\gamma(z)$ for the lasing region of Figure 16 given in Figure 17. Figure 17 only shows the area with positive gain. An effective laser should end when gain dips below zero as the intra-cavity lasing waves will be absorbed beyond this point.

### 5.3 Comparison to Hager Model

### 5.3.1 Spectral Profile Comparison.

In [3], Hager develops a spectral line profile of the absorption of the D1 transition for all hyperfine states of Rb . The data Hager presents is based upon experimental data and is then fit to his development of the Voigt profile. The absorption profile calculated by Hager is given in Figure 18. The analogous emission spectra is provided for the three level numerical model in Figure 19. Figure 18's absorption features are shown to be exactly mirrored in the emission profile given by Figure 19. Thus, the three level model is able to fit both experimental lineshape data and the Hager model lineshape for a spectra including all of the naturally occurring isotopes of Rb and all of the hyperfine transitions of the D1 manifold.

Figure 15. The Lewis model 3D absorption profile with QTLA lasing inputs of Table 6. Note the units of the plot are not $M K S$ and the frequency is offset by $\nu_{d}$ [5].

Figure 16. The three level numerical model 3D absorption profile with lasing for inputs of Table 6. Lasing is only occurring, in frequency space, in the region between the two peak features which propagate throughout the cell.

Figure 17. The three level numerical model determination of $\gamma(z)$ for inputs of Table 6 within the lasing region. Notice that the gain is only provided while $\gamma$ is above zero.

Figure 18. The hyperfine absorption profile for the Rb. D1 manifold offset by $\nu_{21}$ [3]

Figure 19. The three level numerical model lineshape for the Rb. D1 manifold offset by $\nu_{21}$

### 5.4 CW Simulation of a Pulsed System

Pulsed DPAL systems typically operate at extremely high intensities compared to CW systems, however, as long as the population densities reach their equilibrium values a CW simulation is apt for a pulsed system. Even in systems which do not achieve equilibrium, the rate equations for the population concentrations remain unchanged from Chapter II. So, if the rate at which populations change with time is small with respect to the time scale of the pulse width of the diode and the populations are assumed to reach semi-equilibrium quickly after interaction with the pulse, then, this development is still at least somewhat valid. Hence, the three level numerical model can be applied to high intensity systems and may be used to give rough estimates of the characteristics of some pulsed DPAL systems. Typical inputs for the operation of a pulsed DPAL system can be found in Table 7.

Table 7. Simulation Input Parameters for CW Simulation of a Pulsed System

| Input Parameter | Units required | Value | Symbol |
| :---: | :---: | :---: | :---: |
| Temperature of Cell | $K$ | 500 | $T$ |
| Temperature of Methane | $K$ | 500 | $T_{\text {meth }}$ |
| Temperature of Helium | $K$ | 500 | $T_{H e}$ |
| Temperature of Alkali | $K$ | 500 | $T_{\text {alk }}$ |
| Partial Pressure of Methane | Torr | 1000 | $M_{\text {meth }}$ |
| Partial Pressure of Helium | Torr | 1000 | $M_{\text {He }}$ |
| Partial Pressure of Alkali | Torr | 0 | $M_{\text {alk }}$ |
| Total Alkali Number Density | $m^{-3}$ | $3.79 \times 10^{19}$ | $N_{t}$ |
| Length of gain medium | $m$ | 0.01 | $l_{g}$ |
| Transmission of windows around gain | Unitless | 1.0 | $T_{g}$ |
| High Reflector Reflectivity | Unitless | 1.0 | $R_{1}$ |
| Output Coupler Reflectivity | Unitless | 0.5 | $R_{2}$ |
| Initial Pump Intensity | $G W m^{-2}$ | 5 | $I_{p} 0$ |
| Diode Pump Line Center frequency | $T H z$ | 384.23 | $\nu_{d}$ |
| Diode Pump FWHM frequency | $G H z$ | 50 | $\nu_{p_{\text {fwhm }}}$ |
| Space Between Cavity Mirrors | $m$ | 0.1 | $d_{\text {mirror }}$ |

The outputs of the three level numerical model for the inputs of Table 7 are
given in Figures 20-23 and Table 8. Figure 20 provides the degree to which the diode pump lineshape was matched with the lineshape of the alkali atom. In this case, the areas overlap about 80 percent. In general, the pump lineshape should be well matched to the transition it is attempting to pump, otherwise energy will be lost. Based on Figure 21 most of the pump's input intensity is still present at the output coupler, implying that the gain cell should be extended if possible. Unlike in Figure 16, the pump intensity in Figure 21 is not observed to have a region which is being attenuated by laser operation and a region which is not. This is due to lasing occurring across the entire pump spectrum provided in Figure 21. Figure 22 shows the gain as a function of $z$. The gain can be seen to decrease as the pump attenuates. However, the gain does not decrease linearly with position, which implies that approximations such as LAND may not be valid in this case. The total gain in Table 8 is the average value of the gain in Figure 22. In Table $8 \gamma($ total $) / \alpha$ is a measure to how well the system followed the approximation that gain equals loss. At infinite fidelity $\gamma($ total $) / \alpha$ should equal unity. So, $\gamma($ total $) / \alpha$ is a measure of merit of how well the system performed. The average residual in solutions listed in Table 8 is the of average of all residuals of the routine which chose the best adherence to the boundary condition at the output coupler, i.e. Equation (24). This average is only computed for those cases in which lasing is determined by the simulation to be occurring. Figure 23 shows the forward traveling wave (upper) and the backward traveling wave (lower). Notice that difference between the upper wave and the lower wave at the end of the cell is equal to the reflectivity of the output coupler times the square of the transmissivity of the gain cell, which in this case is 0.5 .

Table 8. Simulation Outputs Characteristics for CW Simulation of a Pulsed System

| Input Parameter | Units | Value | Symbol |
| :---: | :---: | :---: | :---: |
| Output Laser Intensity | $M W m^{-2}$ | 63.7 | $I_{\text {out }}$ |
| Output Laser Frequency | $T H z$ | 377.107 | $\nu_{l}$ |
| $I_{\text {out }} / I_{p}$ | Out of 1 | 0.128 | $\mathrm{n} / \mathrm{a}$ |
| $I_{p} / I_{\text {sat }}$ | $\mathrm{n} / \mathrm{a}$ | 5002. | $\mathrm{n} / \mathrm{a}$ |
| $\gamma($ total $) / \alpha$ | $\mathrm{n} / \mathrm{a}$ | 1.001 | $\mathrm{n} / \mathrm{a}$ |
| Average residual in solutions | $\mathrm{n} / \mathrm{a}$ | 0.0094 | $\mathrm{n} / \mathrm{a}$ |

### 5.5 Simulation of a System Near Threshold

One of the more difficult regimes to model in most cases is the regime at or near threshold. The three level numerical model is able to simulate threshold systems effectively. The inputs for three level numerical model for a threshold system are given by Table 9 . Under these conditions, only a the center bandwidth of the pump wave can induce a population inversion, and thus lasing. This effect is visible in Figure 24. The outputs of the three level numerical model are provided in Table 10. Near threshold the three level numerical model had difficulty obtaining an interpolation for $\gamma($ total $)$ so it is not listed. The difficulty seems to arise from the sharpness of the gain profile for a threshold case.

Table 9. Simulation Input Parameters for a Threshold System

| Input Parameter | Units required | Value | Symbol |
| :---: | :---: | :---: | :---: |
| Temperature of Cell | $K$ | 450 | $T$ |
| Temperature of Methane | $K$ | 450 | $T_{\text {meth }}$ |
| Temperature of Helium | $K$ | 450 | $T_{H e}$ |
| Temperature of Alkali | $K$ | 450 | $T_{\text {alk }}$ |
| Partial Pressure of Methane | Torr | 500 | $M_{m e t h}$ |
| Partial Pressure of Helium | Torr | 500 | $M_{H e}$ |
| Partial Pressure of Alkali | Torr | 0 | $M_{\text {alk }}$ |
| Total Alkali Number Density | $m^{-3}$ | $6.1 \times 10^{18}$ | $N_{t}$ |
| Length of gain medium | $m$ | 0.02 | $l_{g}$ |
| Transmission of windows around gain | Unitless | 1.0 | $T_{g}$ |
| High Reflector Reflectivity | Unitless | 1.0 | $R_{1}$ |
| Output Coupler Reflectivity | Unitless | 0.9999 | $R_{2}$ |
| Initial Pump Intensity | $k W m^{-2}$ | 600 | $I_{p} 0$ |
| Diode Pump Line Center frequency | $T H z$ | 384.23 | $\nu_{d}$ |
| Diode Pump FWHM frequency | $G H z$ | 5 | $\nu_{p_{f w h m}}$ |
| Space Between Cavity Mirrors | $m$ | 0.1 | $d_{m i r r o r}$ |

Table 10. Simulation Outputs Characteristics for a Threshold System

| Input Parameter | Units | Value | Symbol |
| :---: | :---: | :---: | :---: |
| Output Laser Intensity | $W m^{-2}$ | 11.2 | $I_{\text {out }}$ |
| Output Laser Frequency | $T H z$ | 377.109 | $\nu_{l}$ |
| $I_{\text {out }} / I_{p}$ | Out of 1 | 0.000020 | $\mathrm{n} / \mathrm{a}$ |
| $I_{p} / I_{\text {sat }}$ | $\mathrm{n} / \mathrm{a}$ | 1.25 | $\mathrm{n} / \mathrm{a}$ |
| $\gamma($ total $) / \alpha$ | $\mathrm{n} / \mathrm{a}$ | $\mathrm{n} / \mathrm{a}$ | $\mathrm{n} / \mathrm{a}$ |
| Average residual in solutions | $\mathrm{n} / \mathrm{a}$ | 0.35 | $\mathrm{n} / \mathrm{a}$ |

Figure 24. The laser output intensity's spectral width within the pump profile. To get total output intensity one must multiply by $g_{p}$ and integrate over all space.

## VI. Conclusions

### 6.1 Comparison to Other Models

The three level numerical model is able to replicate the results of both the Lewis model and the Hager model and to produce expected results that neither of these models are able to. The three level numerical model offers a much higher fidelity under many circumstances, but with that added fidelity comes a much more cumbersome development and a lack of intuitive understanding of the problem, which is a hallmark of the Lewis and Hager models. Hence, the three level numerical model provides another option for the simulation of DPAL systems, but does not supersede previous developments.

### 6.2 Use as a Research Tool

Though the three level numerical model can be somewhat difficult to utilize and to interpret, it provides a great deal of fidelity for research into many areas which no other DPAL simulation can provide. The three level numerical model handles broadband pumping, produces a complete analysis of the rate equations for the three level DPAL system, selects preferential gain from cavity mode spacing, develops the hyperfine lineshape for multiple isotopes, allows the use of multiple buffer gases, allows for quenching to be simulated, and solves a set of three coupled non-linear transcendental differential equations to characterize any three level CW DPAL system under any regime to high fidelity. Hence, the three level numerical model is an excellent tool for the simulation and characterization of any CW DPAL system. Further, the three level numerical model can be used as a tool to approximate the parameters of many pulsed systems.

### 6.3 Future Model Development

### 6.3.1 Mode Volume.

The three level numerical model does not account for the incomplete filling of cavity mode volumes by the pump and currently does not have the ability to simulate the lost energy from this effect. Any further iteration of the three level numerical model should include this effect as it is a persistent issue for DPAL systems and without its effects a model cannot hope to completely capture the effects observed experimentally. The main hurdle to implementation is the lack of references on the subject of mode volume characterization for DPAL systems.

### 6.3.2 Pulsed DPAL Systems.

Probably the most important addition to the three level numerical model would be the addition of time dependence. Though this would add a great deal of complexity any high power system will most likely utilize pulsed operation. Much of the current research in DPAL systems involves the use of pulse operated DPAL system. Therefore, any further development of the model should include the ability for pulsed operation. While theoretical models do exist for the pulsed operation of lasers the inherent complexity of a time dependent laser system forces super-computing as a near necessity for any high fidelity systems.

        k32Eth A21 g1 MEth + k23Eth A31 g1 MEth + k32Eth B21 g1 Il MEth + k23Eth B21 g2 Il MEth +
        k32Eth B21 g2 Il MEth + k23Eth B13 q1 Ip MEth + k32Eth B13 q1 Ip MEth + k23Eth B31 g1 Ip MEth)
FullSimplify[
    f]
```

```
        (k23Eth + k32Eth) (B21 g2 Il + B13 g1 Ip) NEth )
```

## III. Limiting Cases for $f$

1. Case Ip approaches 0
Limit $[\mathbf{f}, \mathbf{I p} \rightarrow \mathbf{0}]$
$\frac{\mathrm{k} 31+\mathcal{A} 31+\mathrm{k} 32 \mathrm{Eth} \text { NEth }}{\mathrm{k} 31+\mathcal{F} 31+(\mathrm{k} 23 \mathrm{Eth}+\mathrm{k} 32 \mathrm{Eth}) \text { NFth }}$
2. Case II approaches 0
```
Limit [f, Il \(\rightarrow\) 0]
\(\frac{\mathrm{k} 32 \mathrm{Eth} \text { 人Fth }}{\mathrm{k} 21+\mathcal{F} 21+(\mathrm{k} 23 \mathrm{Eth}+\mathrm{k} 32 \mathrm{Eth}) \text { 人Eth }}\)
```

3. Case Ip approaches 0 and II approaches 0 in said order
```
FullSimplify[Limit[Limit[f, Ip l 0 ], Il -> 0]]
```

4. Case Ip approaches 0 and II approaches 0 in said order

```
FullSimplify[Limit[Limit[f, Il \ 0 ], Ip -> 0]]
k\mp@code{k32Eth NEth}
```

5. Case MEth approaches $\infty$
```
FullSimplify[Limit[f, MEth }->\infty\mathrm{ ]]
    k32Eth
k23Eth + k32Eth
```

It is of note that if A31, $\mathrm{k} 31, \mathrm{~A} 21, \mathrm{k} 21$ are relatively small (which they should be) and Ip and Il are zero then the same result is obtained for all 5 cases.

# Appendix B. Three Level DPAL Model Notebook for Rb Sample Input and Without Sample Output 

## Three Level DPAL CW Model for Rb

## I. User Inputs (in mks units)

```
Temperatureofcell = 450(*K of cell*);

## 13. SUPPLEMENTARY NOTES

## 14. ABSTRACT

This paper develops a three level model for a continuous wave diode pumped alkali laser by creating rate equations based on a three level system. Differential equations for intra-gain pump attenuation and intra-gain laser growth are developed in the fashion done by Rigrod. Using Mathematica 7.0, these differential equations are solved numerically and a diode pumped alkali laser system is simulated. The results of the simulation are compared to previous experimental results and to previous computational results for similar systems. The absorption profile for the three level numerical model is shown to have excellent agreement with previous absorption models. The lineshapes of the three level numerical model are found to be nearly identical to previous developments excepting those models assumptions. The three level numerical model provides results closer to experimental results than previous systems and provides results which observe effects not previously modeled, such as the effects of lasing on pump attenuation.
