ABSTRACT

800 800 THIS IS THE FINAL REPORT OF AN EMPIRICAL INQUIRY INTO THE WHITE,
801 801 URBAN, ELEMENTARY AND JUNIOR HIGH SCHOOL CHILD'S PATTERNS OF
802 802 POLITICAL SOCIALIZATION. THE EMPHASIS HAS BEEN ON THOSE COGNITIVE
803 803 AND ATTITUDINAL ELEMENTS WHICH LATER PRODUCE DIFFUSE SUPPORT FOR THE
804 804 POLITICAL SYSTEM. THE STUDY IS BASED ON THE RESPONSES OF 12,052
805 805 SECOND THROUGH EIGHTH GRADE CHILDREN IN WHITE, URBAN, PUBLIC SCHOOLS
806 806 TO QUESTIONNAIRES ADMINISTERED DURING 1961 AND 1962. THE RESPONDENTS
807 807 TO THE QUESTIONNAIRES CAME FROM 8 METROPOLITAN AREAS DISTRIBUTED
808 808 AMONG 4 REGIONS OF THE UNITED STATES. THE ANALYSIS CONCENTRATED ON
809 809 THE CHILD'S EARLY RECOGNITION AND EVALUATION OF POLITICAL AUTHORITY
810 810 REPRESENTED BY "THE GOVERNMENT," THE PRESIDENT, SENATORS, THE
811 811 SUPREME COURT, AND POLICEMEN. SOME KEY FINDINGS OF THE STUDY ARE (1)
812 812 THE POLICEMAN AND THE PRESIDENT ARE PARTICULARLY IMPORTANT CONTACT
813 813 POINTS FOR THE CHILD'S GROWING ACQUAINTANCE WITH GOVERNMENTAL
814 814 AUTHORITY. (2) THE DISTINCTION BETWEEN PUBLIC AND PRIVATE LIFE IS
815 815 RECOGNIZED QUITE EARLY. (3) PUBLIC AUTHORITY IS AT FIRST
816 816 PERSONALIZED, BUT BECOMES MORE INSTITUTIONALIZED BY THE FOURTH AND
817 817 FIFTH GRADES. (4) INITIALLY, POLITICAL AUTHORITY FIGURES ARE
818 818 REGARDED AS BENEVOLENT, BUT THIS IDEALIZATION GRADUALLY DECLINES.
819 819 (5) THERE IS A SLIGHT RELATIONSHIP BETWEEN THE ABOVE EFFECTS AND
820 820 INDEPENDENT VARIABLES SUCH AS SEX AND SOCIOECONOMIC STATUS. (DR)

INSTRUCTIONS FOR COMPLETING ERIC REPORT RESUME

The resume is used to identify summary data and information about each document acquired, processed, and stored within the ERIC system. In addition to serving as a permanent record of the document in the collection, the resume is also a means of dissemination. All fields of the form must be completed in the allotted spaces, but inapplicable fields should be left blank. The following instructions are keyed to the line numbers appearing in the left margin of the form:

TOP LINE. ERIC Accession No. Leave blank. A permanent ED number will be assigned to each resume and its corresponding document as they are processed into the ERIC system.

LINE 001. Clearinghouse Accession No. For use only by ERIC Clearinghouses. Enter the alpha code and 6-digit document number.

Resume Date. In numeric form, enter month, day, and year that resume is completed. (Example: 07 14 66)

P.A. Leave blank.

T.A. Leave blank.

Copyright. Check appropriate block to denote presence of copyrighted material within the document.

ERIC Reproduction Release. Check appropriate block to indicate that ERIC has permission to reproduce the document and its resume form.

LINES 100-103. Title. Enter the complete document title, including subtitles if they add significant information. Where applicable, also enter volume number or part number, and the type of document (Final Report, Interim Report, Thesis, etc.).

LINE 200. Personal Author(s). Enter personal author(s), last name first. (Example: Doe, John J.) If two authors are given, enter both. (Example: Doe, John J. Smith, Ted). If there are three or more authors, list only one followed by "and others."

LINE 300. Institution (Source). Enter the name of the organization which originated the report. Include the address (city and State) and the subordinate unit of the organization. (Example: Harvard Univ., Cambridge, Mass., School of Education.)

Source Code. Leave blank.

LINE 310. Report/Series No. Enter any unique number assigned to the document by the institutional source. (Example: SC-1234).

LINE 320. Other Source. Use only when a second source is associated with the document. Follow instructions for Line 300 above.

Source Code. Leave blank.

LINE 330. Other Report No. Enter document number assigned by the second source.

LINE 340. Other Source. Use only when a third source is associated with the document. Follow instructions for Line 300 above.

Source Code. Leave blank.

LINE 350. Other Report No. Enter document number assigned by the third source.

LINE 400. Publication Date. Enter the day, month, and year of the document. (Example: 12 Jun 66)

Contract/Grant Number. Applicable only for documents generated from research sponsored by the U.S. Office of Education. Enter appropriate contract or grant number and its prefix. (Example: OEC-1-6-061234-0033)

LINES 500-501. Pagination, etc. Enter the total number of pages of the document, including illustrations and appendixes. (Example: 115p.) USE THIS SPACE FOR ADDITIONAL INFORMATION PERTINENT TO THE DOCUMENT, such as publisher, journal citation, and other contract numbers.

LINES 600-606. Retrieval Terms. Enter the important subject terms (descriptors) which, taken as a group, adequately describe the contents of the document.

LINE 607. Identifiers. Enter any additional important terms, more specific than descriptors, such as trade names, equipment model names and numbers, organization and project names, discussed in the document.

LINES 800-822. Abstract. Enter an informative abstract of the document. Its style and content must be suitable for public announcement and dissemination.

TABLE OF CONTENTS

Part IV   DETERMINANTS OF DIFFUSE SUPPORT IN CHILDHOOD

Part V   CROSS-SYSTEM IMPLICATIONS

PREFACE

The reader has two options as he approaches this Report. He may read it from a general interest in what children learn about politics. In this event he will find much to inform him, especially about the way in which children make their first connections with the political system and about the kind of sentiments this relationship stimulates. Children, he will discover, are not the political innocents they were once thought to be.

If the reader chooses broader perspectives, however, he will find that this Report goes beyond merely a description of the political attitudes and knowledge of children. It represents an effort to draw together in a new and meaningful way empirical political theory and data about children in the political system. We seek to stretch a slender footbridge between systems (or persistence) theory, as it has been developing within the terms of its own logic, and behavior in the political system. General theorizing has dictated the major hypothesis that the persistence of any kind of political system at all depends on the input of diffuse support to a number of political objects, among them the structure of political authority. As a case study, we wish to know when and how this support for political authority arises in the American political system. Our speculations had led us to believe that it has its origins at a very improbable age, childhood, and that this early source has profound consequences for the functioning of political system.

Our research, therefore, examines aspects of the socialization of children in the area of politics. Our theoretical interest in political socialization began early in the 1950's and it took empirical form as early as 1955. Six years and about fifteen pilot studies later, the final instrument that has provided the bulk of the data analyzed in this Report had been designed and administered under the project of which David Easton and Robert Hess were the principal co-investigators.

In the first phase of our research—the construction of the questionnaire, its administration in the field, and the initial compilation of the data—we had the expert and dedicated assistance of David Jackson as project director with major support from Jack Dennis and Judith Torney. Jack Dennis then joined David Easton in analyzing the data for their relevance to the functioning of political systems. The second principal co-investigator with Judy Torney assumed responsibility for a separate analysis of the specific implications of the data for the psychology of child development. In various periods of our project we were able to rely on the enthusiastic and insightful participation of a number of graduate students most of whom have since that time become actively engaged in teaching and research on their own: Reginald Bartholemew, Keith Billingsley, William Fisher, John Fitzgerald, Ronald Inglehart, Daniel Leatherman, Kenneth McRoberts, Roger Masters, Tadao Okamura, Albert Robles, Margaret Tropp, and Elliott White.

iv

SUMMARY

In this Report we inquire empirically into the nature of
pre-high-school age child's patterns of political socialization. Our
particular problem here has been to analyze the child's early responses to
political authority. The latter includes especially "the government", the
President of the United States, and the policeman as well as the Supreme
Court and the Senator. We deal both with the growth of cognitive and af-
fective orientations. And we place special emphasis on the character of
developing sentiments that pertain to the input of diffuse support for the
political system. Our inquiry is therefore concerned with establishing
propositions that connect early learning to the structures of political
authority and thereby reveal important sources of a belief in its legiti-
macy.

The scope of our analysis is limited by research design and selec-
tion of respondents, type of measuring instruments, time of data collection,
methods of analysis and areas of content included for analysis. The study's
responsdents (in our major test group) have consisted of 12,052 second
through eighth grade children from white, public schools in eight metro-
politan areas of the United States using fixed alternative questionnaires
administered in regular classrooms in late 1961 and early 1962. In addi-
tion, we have collected pilot and pre-test data from a substantial number
of children in the Chicago area in 1960-61. We report here mainly data
collected using our final (CA-9) instrument; and we confine the analysis
to the areas of cognitive and attitudinal content of development that per-
tain to political authority figures (the structure of political authority).

Some key findings are:

1. The President and policemen constitute especially
   salient <u>contact points</u> for the young child in his
   growing acquaintance with the structure of political
   authority.

2. The child early becomes <u>politicized</u> in such respects
   as recognizing the difference between the public and
   private realms of life.

3. He at first <u>personalizes</u> governmental authority, but
   in the middle grades (4 and 5) begins to shift to a
   more <u>institutionalized</u> interpretation.

4. In the early years, the child interprets these poli-
   tical authorities as being highly benevolent; but
   such <u>idealization</u> declines gradually over the grades.

5. To a small extent, these effects can be related to
   independent variables such as sex, socio-economic
   status and broad mechanisms of learning like "ge-
   neralization".

These findings can be further elaborated as follows:

We have been concerned first of all with the more cognitive aspects of the child's early recognition of public authority objects, especially the rather diffuse political object, "the government". The Government serves the child as a major contact point in his growing acquaintance with the political realm and one that draws together the many disparate aspects of the structure of authority. Government becomes, represented to the child as a democratic structure, moving in his vision from a singular, personalized image to one that is multi-person, differentiated and institutionalized. Concomitantly, the child shifts from a "charismatic" to a "legal-rational" interpretation of government authority, as the latter is related to popular and representative rule. (Chapter VI)

We have suggested that government is initially more associated with the law-making than other functions and, is increasingly associated, over the age span with the national level of government. With these shifts in the terms of recognition, there comes, relatively early, an awareness of the difference between the public and prive sectors. (Chapter VI)

Accompanying these developments relative to government, there grows up also a high degree of positive affect. The child interprets the government, just as he interprets the more personal figures of political authority, to be powerful and benevolent. As he moves through this period of development, some depersonalization of the object begins to appear, whereas ratings of more performance attributes of government increase on the positive side. Thus, while affect is high throughout this period there is greater emphasis by the end of the age span upon the more impersonal aspects of government. (Chapter VI)

For the personal representations of political authority--especially the President and policeman--we have argued that their salience is high--especially for the young child--and they serve as major contact points in the child' political development. We have speculated that the high visibility of these two figures who stand, as it were, at the head and tail of the system, together with their easily perceived protective functions, lead the child to choose them as benchmarks in the development of his orientations. (Chapter VII)

Relative to the President per se, children understand him to be situated at the top of the authority structure; but they begin to limit his role somewhat as they get older. He stands especially high in their affections and they rate him very high on such qualities as persistence, dependability, knowledge, power and leadership. (Chapter VIII) In addition, their perception of him is only to a rather small extent colored by partisan identification. (Chapter IX)

The policeman, the child's other major personal point of contact to the system, tends to be seen according to a familiar local perspective. The policeman is definitely a part of the government in the child's estimate, but he is not a particularly salient general symbol for government; nor is he seen to be much a part of the law-making appa-

ratus. On the other hand, the policeman as embodiment of external author-ity is given special prominence vis-à-vis family authority, particularly in the perceived necessity for obedience. (Chapter X).

The child's affective orientation to the policeman, although not as highly favorable as that with respect to the President, is never-the less quite positive: the policeman is seen to be dependable, not much prone to error, and he is fairly high on the more personal, affective, less role-connected attributes as well. (Chapter XI)

Turning to comparisons among various authorities, we have found that considerable aggregate differentiation occurs among different poli-tical authorities, and between these authorities and the child's father, in these years. Whereas the ratings of father are higher on the affect-related items, he is somewhat lower on the more cognitively directed, performance attributes. In this sense, political authority is not a simple matter of generalization from family or a matter of father writ large. Among the public authorities moreover, the shift in the level of positive ratings moves generally to the more impersonal institutions and away from the personal figures in the period. (Chapter XII)

Thus, the child at an early age begins to differentiate "inside" from "external" authority, suggesting somewhat separate socialization to major structural elements of the political system and perhaps a whole range of different expectations pertaining to various types of authority arising therefrom. The child becomes bonded to political objects more directly than had perhaps been supposed in early discussion. Such early bonding to distinctly political objects, particularly the institutions of government, presages later support of, and thus perhaps has in the past contributed to the stability of the system. (Chapter XIII)

That such support is likely to continue into adulthood, with some fluctuation, is suggested by the high level of positive respect shown by adults for the police in this country--a finding that contra-venes much of the folklore about an alleged unfavorable public image of the police. There is a trough, however, in the aggregate level of regard for the police among young adults--suggesting at least partial and temporary resocialization through post-childhood experiences.(Chap-ter XVII)

These are, in brief, the main descrptive propositions that we have evolved.

We attempt also, within the somewhat stringent confines of the independent variables included in the study design, to test a num-ber of explanatory hypotheses that relate to the descriptive hypotheses outline above. Dealing with a restricted list of the latter hypotheses--pertaining to what we have termed in our concluding chapters the "poli-ticization", "personalization", and "institutionalization" phenomena--we have tested first for differentiating effects of major social struc-tural variables like sex, socio-economic status, and region. We have found scattered, relatively small if consistent effects of sex and social class, and relatively small, non-systematic differences by city or region.

The sex and social status differences usually conform to what we have termed the "lead-lag" phenomenon, with girls and lower status children usually lagging a grade or so behind in the direction of aggregate political development. (Chapter XV)

Using a more elaborate set of predictor variables, a multivariate statistical analysis, and focusing especially upon "idealization" of the President and policeman, we find that we can account for these levels of evaluation only to a small degree for either simple "affective" responses or for evaluations of the power of each figure of political authority. For the evaluation of the President's power, and both affect and power evaluations of the policeman, we find some, if small, support for a "generalization" hypothesis, and to a lesser degree support for a "vulnerability" hypothesis. But, on President affect we find almost no evidence of generalization of the child's affective perceptions of his own father to his affective image of the President. (Chapter XVI)

Our findings therefore concern the American elementary school child's development of images of various salient political authorities. We find that a great many changes in political orientation are occuring during this early portion of the life cycle. That children beccme aware of these objects and so positively oriented to them suggest profound system consequences in later years. We have probably located here a major source of a belief in the legitimacy of political authorities that has implications for cross-cultural research.

PART I

A POLITICAL THEORY OF POLITICAL SOCIALIZATION

Chapter I

SOCIALIZATION AND THE POLITICAL SYSTEM

Child: "There's somewhere."
Father: "I can't park there."
Child: "Why?"
Father: "It's not allowed."
Child: "Who say so?"
Father: "I'll get a ticket."
Child: "Uh."
Father: "A policeman will stop me."
Child: "Oh."

When a three and a half year old child, safely seated in the back seat of his father's car, helpfully sought to point out a parking space and entered into this laconic conversation, he learned if not his first political lesson, at least the beginning of an important one. He was being introduced to the notion that his father was not omnipotent, that there is a power external to the family to which even his father had to submit, and that somehow the policeman represents this power.

This episode symbolizes the very tender age, even before entering primary school, at which political learning has its origins. As political theorists from classical days to the present have repeatedly proclaimed, the kind of power called authority and the willingness of people to accept it within specifiable limits is a central phenomenon of political life. It would seem to be an appropriate confirmation of this insight for the child to begin his understanding of his political role in society by sensing the significance of political authority for even the humdrum routines of daily existence.

The Socialization of Support

Even though we begin by talking about children and will extensively analyze data about them, this report is really about political systems. It addresses itself to one major condition--socialization--that contributes to the capacity of a political system to persist in a world either of stability or of change.

A political system is that system of behavior through which society is able to make decisions that most people accept as authoritative or binding most of the time. From the perspectives of a systems analysis of political life[1]* one of the critical features of a political system is that it is open to disturbances from its environment. Through these it is subject to various kinds of stress. One of the conditions that makes it possible for

*Footnotes appear at end of each chapter.

1

an open system of this kind to persist even in the face of stress is the level
of commitment or support that members are prepared and able to extend to it.
Our central purpose will be to investigate the way in which this kind of sup-
port is marshaled through the early socialization of those new to the system
by virtue of being born into it. We focus on the nature of childhood sociali-
zation and its consequences for specified aspects of the political system.
Our starting point is political theory and we shall end on the same note.
But the connecting link between beginning and end is an analysis of a con-
siderable body of data about childhood political orientations.

Through a systems analysis of politics we are led to the hypo-
thesis that every system utilizes a multitude of typical devices for at-
tempting to build up support and sustain it at some minimal level, even though
not all systems are equally successful.[2] A system may match its outputs
more carefully to demands in the hope of keeping its members more contented.
It may persistently nourish a belief system conducive to winning the confi-
dence and trust of its adult members. It may even as a last resort compel
by force those who refuse to commit themselves spontaneously. But among
mechanisms such as these it may also seek to win the members by shaping
their orientations and behavior patterns at the earliest feasible moment after
birth into the system.

Theoretically childhood would seem to be an appropriate starting
point. But what is theoretically imaginable need not always be empirically
feasible. From Plato through Bodin and Rousseau, classical philosophers
have argued on behalf of an early start for political education. What is
learned during the first few years, it has been assumed from time immemorial,
is less easily dislodged later in life. But at what stage can a system in
fact begin to expose its youngest members to political orientations rele-
vant to support or for that matter to any other major aspect of a system,
with any hope of meaningful impact? By orientations we imply all the per-
ceptions (cognitions, knowledge), affect (feelings and attitudes), and
evaluations (values and norms) through which a person relates himself to
a social object. We can gain some insight into a possible answer to this
question if we locate the age at which systems do in fact first manage to
evoke political orientations, favorable or hostile, from their maturing
members. We can reformulate the question therefore and ask: Where do the
earliest roots of political perceptions, sentiments, and values lie? Speci-
fically is there any evidence at all that either negative or positive orien-
tations towards a system have their source in childhood experiences, however
improbable this may at first sight appear?

It is our theoretical interest in the origins of support as a
major mechanism in the persistence of political systems that leads us directly
to children. Notwithstanding preconceptions, until recently very prevalent,
about the political innocence of children, we shall find that by the time
children leave elementary school they have assembled a formidable array of
basic political orientations. Among them are relatively well-defined senti-
ments about the system, and not all of them necessarily favorable or suppo-
tive. But our inquiry will ineluctably lead us to the hypothesis that the
persistence of some kind of system will in part be dependent upon the suc-

2

cess of a society in producing children most of whom do feel positive about it.

In its main objective, therefore, this report is an inquiry about the input of support, a problem dictated by general theory. But because we search for the early sources of this support, we are forced to concentrate on children and an important part of their political world. Here we shall find the formative period for basic political orientations. Derivatively therefore we become concerned with political socialization during childhood.

Our data are based on a purposively selected sample of white urban children, ages 7 through 13-14, in elementary schools selected from four large and four small metropolitan regions in the United States. These are located in four major geographical regions, the Northeast, Southeast, Midwest and Far West.3 From these children we have sought to identify some of the major dimensions in political socialization contributing to the level of support put into the American system, as a test case. What we learn from this single study about children and their basic political orientations will prove suggestive for extending our knowledge about the conditions surrounding the persistence of political systems as a class of phenomena.

But before we can proceed to the analysis of the kinds of data we have assembled about our group of children, certain theoretical issues need to be raised. First, what do we mean by socialization? There are many ways of describing the processes to which the concept is presumed to apply and each helps to predetermine the kinds of data examined, the modes of analysis applied to them and even their final interpretation.

Second, what part does socialization play in helping us to understand the functioning of political systems? Although there has been too little theorizing on this score to clarify the central significance of political socialization, at least two theoretical perspectives appear implicitly in the literature. By examining these we shall put ourselves in a favorable position to assess the alternatives opened up by our own systems analytic approach.

Finally, although we shall begin by assuming that childhood socialization, as contrasted with socialization during infancy, adolescence and adulthood, has vital consequences for the persistence of political systems, we shall have to pause at the outset to examine this presupposition. Is it even plausible to say that political socialization does originate in childhood? An affirmative conclusion is not a foregone conclusion. Some would seem to be arguing against it; others who would acknowledge its occurrence at this early phase in the life-cycle, would contend that whatever is learned has little bearing on subsequent political behavior.

In Parts I and II of this report we address ourselves to these three types of questions. This will pave the way for us to turn in Part III to a description of our research and an analysis of our data as they bear on our major theoretical problems. There we shall seek to penetrate behind the obscuring screen of childhood to observe the way in which children, in one

political system, the United States, begin to perceive critical elements in political life and to learn to put in or withhold support, as the case may be. In Part IV we shall look at group differences in an effort to help explain some of the orientations we find among the children. And in Part V we shall draw together the fundamental implications of the analysis for a theory of political systems.

The Meaning of Political Socialization

What is the theoretical relevance of socialization for an understanding of the way in which political systems operate? This question will engage our attention throughout Part I.

Although in the preceding remarks we have already hinted at our own theoretical perspectives we shall now approach the issue more systematically. To do so, we need to deal with several problems. What do we mean when we refer to the study of political socialization? How have others interpreted the theoretical import of research in this area? For what purposes are these other modes of conceptualization useful? Upon proposing some answers to these questions we shall be in a position to develop an alternative theoretical perspective, one that will inform the body of our research. In this chapter we shall explore the possible meanings of socialization as a concept, leaving the other questions to the succeeding two chapters.

Definition of socialization

We shall define political socialization restrictively as <u>those developmental processes through which persons acquire political orientations and patterns of behavior</u>. Simple as it is, the implications of this conceptualization for theory and research are both numerous and consequential.

Socialization identifies a developmental process, one that takes place over time. It is in this reference to the development of orientations that the study of socialization differs most strikingly from the usual attitude and opinion polls. The latter are primarily cross-sectional in character. They describe the orientations persons hold at a moment in time. Normally research about political attitude turns to existing or immediately preceding conditions to explain a person's views or his actions. The emphasis is on current attitudes and behavior explained by reference to current experiences. Insofar as survey research turns to changes in attitudes, it verges on socializing phenomena and contributes to our understanding of them.

Omitted from this pre-occupation with current determinants, however, is a concentrated effort to discover the extent to which orientations and behavior are molded by circumstances and events from the past. The idea of socialization, however, alerts us to the need to take into account those very past processes through which orientations have been acquired. The past acquisition process itself becomes a determinant with a possible independent influence upon subsequent orientations. It thereby should help to

4

explain the nature of current and future knowledge, values, or feelings of the persons involved. In this meaning of socialization, a cross-sectional study of a set of orientations with no historical depth contributes in itself little to an understanding of the function of prior experiences. It lacks an etiological perspective that might enable us to explain some portion of the present in terms of past events.

But the past itself is not an undifferentiated bloc of time. It represents a process through which persons may (or may not) change as time runs on. Each present moment has as a possible determinant all preceding moments. In this lies the source of an emerging pattern of change for a person or for an aggregate of persons. We often refer to this process by suggesting that a person has "developed" in a certain way. By this we mean that he has been exposed to a particular sequence of events that can be expected to produce a particular or a characteristic outcome.

Identification of time as a determinant therefore inevitably leads to a developmental perspective. We look not at a given moment in the past but at a sequence of periods so as to be able to appreciate the extent to which a characteristic pattern of development contributes to current outcomes of behavior or orientations. The study of socialization signalizes therefore an intention to go beyond simple etiology, a search for origins. It turns to the search for developmental patterns during the originating phases.

Socialization research accordingly directs our attention to questions such as the following: Where do patterns of behavior and orientations come from? How do they begin and how do they change as a person matures biologically over the years? To what extent can the outcome at any moment of time be explained by what has occurred through a sequence of earlier periods?

Where we begin this etiological inquiry will depend upon where our insight informs us that continuing effects over time have had their origins. Although it is common to think of childhood as the major formative period for later behavior, in fact socialization is known to be a continuous process, one that typically continues into old age. An adult immigrant into a society, for example, whatever his age, is in many ways as new to it as a newborn child. But the resocialization of adults suggested in this illustration raises problems that are vastly different from those we meet among children.[4] Thus for an understanding of the way in which new members become integrated into varying degrees into the purposes of, say, an existing business enterprise, an army, a religious organization or a prison, the desocialization of old practices over time and the resocialization of the persons undergoing the new experiences may be central explanatory variables. Hence experiences during the adult phase of socialization would loom large. But in many areas of inquiry we may hold to a theory that what is learned early in the life cycle tends to stick and shape later attitudes and behavior. Here the search for an adequate explanation may impel us to return to the period of childhood as well.

5

Whatever the phase in the life cycle on which we concentrate, an interest in socialization indicates the acceptance of the premise that the present cannot always be explained exclusively in its own terms. An important determinant of current orientations and behavior is to be found in what has happened over a span of time in the past. It is this developmental quality that sets research into socialization apart from cross-sectional studies of current attitudes and practices or from a general interest in attitude change.

Omissions from the definition

In conceptualizing the area in this way we depart from most earlier kinds of definitions. The latter typically refer to phenomena that we consider too variable to include with confidence in the basic description of political socialization. In the first place, for example, unlike standard prevalent definitions of socialization, ours says nothing about the nature of the acquisition processes. It does not specify who or what the agencies and agents of socialization are. It does not even presume to indicate in advance whether children learn their attitudes and behavior from others or acquire it from autonomous experiences. In the second place, our definition does not even allude to the systemic consequences of socialization, such as whether it serves to perpetuate, stabilize or destroy a system.

To be sure, the nature of the acquisition process and the effects of socialization on a relevant system are both central subjects for inquiry. But they are variable phenomena in the socializing processes. Any substantive assertion about them in a definition would be inappropriate if only because it would prematurely foreclose alternative possibilities. Hence we deliberately refrain from identifying any specific acquisition process or systemic consequences. To appreciate more fully these implications of our own definition, it will repay us to look more closely at just what we have deliberately omitted that others typically include.

The nature of the acquisition process

Our definition is restrictive not only because it focuses on the time dimension among determinants of behavior but also because it insists on keeping this developmental factor separate from considerations about the nature of the acquisition process itself. To clarify this point let us look at a representative definition of socialization that contrasts with ours. Socialization, it is frequently proposed, is "a process of learning through which an individual is prepared, with varying degrees of success, to meet the requirements laid down by other members of a society for his behavior in a variety of situations. These requirements are always attached to one or another of the recognized positions or statuses in this society such as husband, son, employee, and adult male".[5]

In addition to implying that there is some process of acquisition going on through time, a point with which we of course have no argument, this typical definition also suggests something about the way in which persons ac-

quire their orientations. It leads us to believe that it is central to the socializing processes that others should lay down for the child what he is to know or how he is to behave, and the "others" normally turn out to be adults. But whoever the socializers may be, the view is usually explicit that socialization consists exclusively of a transmission process whereby orientations and behaviors are passed from one generation to another.

No one could quarrel about this recognition of a transmission belt along which orientations move. Children undoubtedly do learn from their parents and from other significant adults (as well as peers) in their environment. But does this fully describe the nature of the acquisition process?

What this view leaves out is that socialization may signify more than or even something other than the inculcation of a culture or the absorption of orientations from others. It may be a product of what we would call autonomous learning, and the projection of the inferences from these experiences in one sphere to experiences in another one.

Socialization need not always involve a process through which one person, usually an adult, instills orientations in another person, usually a newcomer in a society, such as an infant and child, or an immigrant, or a new member of a group. There may well be circumstances, for example, in which the orientations a child acquires cannot be attributed to any agent upon whom he models his behavior, with whom he identifies, or by whom the child is influenced through a pattern of rewards and punishments.

To be sure, as we have agreed, the process of socialization may and normally does involve a transmission belt connecting younger and older generations. Whatever passes along this belt constitutes the content of socialization. But this describes only one mechanism through which a person may acquire (or fail to acquire) orientations. What is equally pertinent is that a person may just as frequently learn to behave or orient himself in a certain way out of the depths of his own raw experiences. It is too constricting to limit the acquisition process to induction or inculcation by others. This interpretation leaves no room for independent learning. It discounts the empirical variability of the mechanisms of socialization.

Thus a child may learn to approve of the political authorities because he has been taught to do so by his parents or because he has modeled himself on the behavior of his older siblings. But part of his attitudes towards the authorities may also be formed through direct experience, unmediated by transmission from others and interpreted in the light of his inner needs. For example, he may learn to dislike all authorities, including, by transference of affect, the political, because of what he interprets as unjust treatment at the hands of familial authorities, as through inconsistency in discipline and lack of genuine concern. A self-learned orientation such as this may become part of the personality structure of the child overriding alternative specific political patterns that he might otherwise have inadvertently absorbed from the culture or that relevant adults might have deliberately sought to inculcate. But for the possibility of indepen-

7

dent learning we could scarcely account for many instances in which new generations adopt political positions and orientations in direct conflict with preceding generations, as in the case of the so-called protest politics among young people in the United States during the 1960's.

It would not seem useful therefore to include any conclusions about the specific nature of the acquisition process in the conceptualization of socialization itself. By leaving this matter for determination through research we open the door to an understanding of an important source of change over the generations. The maturing generation may turn out differently from its predecessors not because of "failure" in the transmission belt in some way but because of some unique combination of experiences and personality predispositions on the part of children that leads them to interpret life differently. In this way, through autonomous learning, a new generation may be able to elude the hand of the past, however active this hand may seem to be in trying to guide maturing children towards conformity with tradition or some other preconceived goal.

Thus in the initial description of what it is the study of socialization encompasses we leave as a moot point the nature of the acquisition process itself. What the child becomes or what happens to an adult over time may be in part a product of longitudinal patterns gradually altered through other kinds of autonomous experiences. We need not prejudge the matter especially by incorporating it in our definition of the phenomenon.

The systemic consequences of socialization

If the nature of the way in which children acquire orientations and behavior need not be specified in advance neither need we include any specific kinds of consequences for the system under consideration. Yet the representative definition of socialization that we have noted earlier embraces some advance conclusions about the consequences that socialization apparently must have for the system. It predicts that socialization will prepare the individual "with varying degrees of success, to meet the requirements laid down by other members of society for his behavior". Other definitions typically convey the same type of message. At times it is argued, for example, that through socialization the child will develop "the proper (i.e. adult) kinds of interaction with others"6 or that he will be subject to a "process of induction into the political culture"7, presumably the existing culture. These definitions clearly leave the impression that socialization must lead to conformity with established patterns or at the very least with the standards transmitted by the older generations.

We scarcely need to insist, in a world so marked with generational conflict, that each succeeding generation need not pattern itself on its predecessors exclusively. Innovation is not only possible, it may even be considered desirable by the previous generation.8 Not that this is usually overlooked in the literature, whatever the limitations on outcome suggested by the definitions. But what is more likely to be neglected is that regardless of the intentions of the socializers, those being socialized may strike out on their own and create substantially new roles.9 The definitions would

8

seem to exclude or overlook this possibility, a point to which we shall return more fully from a different direction in the next chapter.

Our own definition of socialization, however, leaves the outcome as a moot question. We need not settle in advance whether the process replicates the existing society or ends in vital innovations unexpected or undesired by the older generations. It is not essential for an adequate description of the central characteristics of socialization to include a specification of its consequences for a system. Indeed, predictably, the definitional predisposition so prevalent in the literature, towards identifying socialization as a process for perpetuation of the status quo (or stability, a frequent synonym) has transparent undesirable theoretical implications. We shall return to these in the next section in a somewhat broader context. It is enough here to draw attention to the expected variability in outcomes of socialization and accordingly to the unnecessary limitation in defining socialization in terms only of one or another of its possible results.

It would therefore seem more useful, in order not to prejudice the identification of problems for research and the interpretation of findings, to eliminate from the definition all references to the nature of the acquisition process and to the consequences of socialization. This will free us to use the idea of socialization in a neutral way, as a means for referring only to the developmental processes through which orientations and behavior are acquired.

Disciplinary Perspectives about Socialization

The definition of a concept is only a first step towards spelling out its theoretical significance. It indicates to us in general the nature of the processes we will be examining but it does not point to the kinds of political phenomena with respect to which we ought to examine these processes. We need to probe further into the theoretical relevance that socialization has for an understanding of the political system.

The disconcerting fact is that all political practices and orientations have historical antecedents. We do not inherit our political behavior, attitudes, values and knowledge through our genes. They need to be learned in some way. There is therefore potentially an infinitude of topics that could become the subject of socialization research. We need some theoretical guidance to sort out the political orientations that we will find worth investigating.

By formulating our problem in this way we have already made a major theoretical commitment, implicitly. In advocating criteria for establishing theoretical relevance in politics, we are indirectly affirming that in the study of political socialization we may have objectives distinctive from inquiry using other disciplinary perspectives. Let us glance very briefly at the relevance of socialization in the other disciplines the better to appre-

ciate the need for an independent focus in political science.

As we might expect, because each social science concentrates on a different if overlapping set of subjects, each has appropriately developed its own perspectives on the significance of socialization. There is as yet little sign of a general theory of socialization on the horizon: it is not even clear what such a theory might begin to look like. For example, psychology, in which the vast bulk of research into socialization has been conducted and in which the main guidelines were initially set, has concentrated on the part that early life experiences and training play in the formation of personality. Child-rearing practices have constituted its universe or research with attention to the origins and development of such personality traits as aggression, achievement, oral behavior, dependency, fear, trust, intelligence and moral judgment.[10]

Given the diversity of interests in sociology as a discipline, it is difficult to characterize comprehensively its foci in the area of socialization. But two major concerns have arisen. For those in sociology concentrating on personality as a major determinant of social behavior, personality is often conceived as structurally determined. It has therefore been interpreted as the sum of the particular repertoire of roles a person has learned to play. The characterisitc motives, attitudes and values composing an individual's personality are viewed as deriving from the combination of roles a person learns as he moves through various stages of the life cycle.[11] Other sociologists, more directly drawn to accounting for the structure of social systems, have looked upon socialization as a major mechanism is shaping the social structure. From this point of view socialization helps to assure the fulfillment of various postulated functional requirements of society. Socialization therefore represents a mechanism through which persons learn the skills, motives, knowledge, and evaluations viewed as necessary for the roles they will be called upon to play at various stages in their lives as they act in a specified social strucutre.[12]

Anthropologists have similarly moved in directions appropriate to the theoretical interests of their own discipline. To the extent that anthropology and sociology have overlapping concerns about social structure, they join hands in viewing socialization as one of the means for providing a society with what is presumed to be role structures required to fulfil its functional needs. But beyond that, research on socialization has represented a means for understanding one of the central sources of culture continuity and change. It has led to considerable emphasis on child-rearing practices and the part they play in the formation of personality and the effects of the interaction between the two for culture.[13]

Interest in socialization is so recent in political science—a concomitant of the behavioral revolution of the 1950's and 1960's—that it is not only appropriate but essential to ask whether this discipline has begun to interpret socialization in a way most suitable for its own purposes. This is especially critical since in effect political science has been introduced to the relevance of socialization largely through the efforts of persons from other disciplines.[14] The progress of social science has typically depended upon this blending of the disciplines at their peri-

10

pheries. But as is entirely appropriate, an approach to socialization in the political sphere dictated by the theoretical interests of other disciplines need not coincide with the potential concerns of political science. At the very least we cannot take it for granted that a conceptualization of the relevance of socialization adequate for the problems of other disciplines not centrally devoted to politics will automatically satisfy the major analytic needs of politic science. If there is any rationale behind the division of labor that we call the social science we might even expect that the contrary would be true. It would therefore behoove us as students of political life to spell out the nature of our interest in socialization. This we propose to do in the following two chapters. They will guide us towards a possible political theory of socialization out of which our empirical research, analyzed in Part III, has sprung.

CHAPTER II

THE THEORETICAL RELEVANCE OF POLITICAL SOCIALIZATION

What kinds of special interest might students of politics have in socialization? Clearly we are not particularly concerned with personality formation in and of itself as are psychologists, nor in exploring the way in which developmental patterns contribute to a theory of social structure in general or to the perpetuation and change of a culture, as are sociologists and anthropologists respectively. Major questions such as these in the area of general socialization are not beyond the bounds of our interests but they do not constitute the central focus of political science. They fall within our purview only when it can be shown that knowledge of this kind will somehow help us to understand some specifically political problems better.

But how are we to test the relevance of studies in socialization for political research? To do so, we need some guidance in the form of a theory or conceptual structure that will serve to identify the major variables about which research needs to be initiated.

Types of Theories of Socialization

Theory about socialization might take one of three forms even though no one is completely independent of the other. First, it might be a general theory of socialization. Presumably this would be designed to describe and explain at the most general level the way in which socialization occurs, regardless of subject area. Although such a theory may still lie on a very distant horizon, students of political science could use it to good advantage. Concentration on this type of theory, however, would distract them from their central concerns, the explanation of political phenomena.

Second, we might focus on a theory of political socialization. From this perspective our objective would be to attempt to understand the way in which socialization occurs in the political sphere. The nature of the subject matter and the salience level of politics in a society might give rise to special socializing processes in this area different from socialization, say, of sex roles, economic behavior, or religious patterns. Thus there is little question that the family plays a vital part in transmitting various parts of the general culture in a society and in preparing a child for the kinds of general occupational or sex roles he may be called upon to play. But in the area of politics, some important differences seem to occur. Only certain kinds of orientations may be the subject of family socialization; others may depend more on agencies outside the family.[1] Childhood may be the period for learning basic orientations; adolescence and young adulthood for attitudes on issues and specific candidates for office. We can conceive that in time a specific theory of socialization in

the political sphere--a theory of political socialization--may emerge.
This, when combined with theories of socialization about culture in general,
personality, social structure and the like, will be a source from which a
more gener l theory of socialization might ultimately be constructed. A
theory of political socialization has still to be contemplated in political
science.

But there is a third kind of theory from which the most general
guidance about the relevance of research in socialization might be obtained.
This is a _political theory of political socialization._ Its objective would
be to demonstrate the relevance of socializing phenomena for the operations
of political systems. Logically it is prior to the other two kinds of
theories we have just discussed. Unless we have some idea about why it is
important or significant to study socialization processes in the first place,
there would be little reason even to begin to talk about socialization in
relationship to political life. We must therefore begin by inquiring into
the part that socialization plays in the working of systems. At the theore-
tical level this means that we need to explore the position that we can attri-
bute to socializing processes in a general theory seeking to understand the
operation of any and all kinds of political systems.

It is on a political theory of socialization that we shall focus
in this report. But what we have to say will have implications germane for
both other types of theory.

Alternative Criteria of Relevance

To explain the relevance of socialization for political research
we can find at least four kinds of alternatives in the literature. These con-
sist of a non-theoretical option and three possible political theories of
political socialization--allocative, theory, system-maintenance or stability
analysis, and systems (or systems persistence) theory. The non-theoretical
posture suggests only that we plunge directly into unguided exploration of
this new terrain, political socialization, a strategy not to be belittled·
when an area has hitherto been infrequently traversed. Among the three
theoretical options, however, the first draws our interest to topics of
socialization that fall within the sphere of what we may call political allo-
cations. These topics would seem to be most relevant to a possible but as yet
unformulated allocative theory. The second theoretical alternative draws us
along in the train of presuppositions closely associated in the past with
disciplines other than political science. This alternative would lead us
to interpret political socialization as a means for helping us to under-
stand integration and system-maintenance in the political sphere. The final
theoretical option--discussion of which will be postponed to the next chapter--
represents our own positive suggestion, at the most general level of analysis,
for relating political socialization to the functioning of political systems.

To be able to follow out the full implications of the non-theore-
tical and the first two theoretical options, to which this chapter will be
devoted, requires a very generous rule of interpretation. In the slender

14

writings on socialization, these alternatives appear largely as latent
premises and tendencies uncrystallized into deliberate or systematic for-
mulations. Yet if we wish to evaluate the theoretical implications of past
research and to appreciate the pressure it exerts for some viable theore-
tical alternative, we cannot avoid making the most of these options by attri-
buting to them a coherence they have yet to obtain.

The Non-theoretical Option

Unfortunately the major unstated dilemma still confronting students
of political socialization lies not in the selection among competing theories
but in the decision to work with or without some explicit theoretical design.
The easiest way out of this dilemma is to offer no pretence of operating
within a definable theoretical context. As we have noted, every political
orientation has antecedents of some sort; hence there is no limit to the
subjects that may be adopted for research in the area of socialization. We
might plunge into a discussion of any subject that appears intuitively in-
teresting, especially if we can link it up with later adult behavior that
has already drawn the continuing attention of students of politics. In this
event there need be little theoretical guidance except for the assumptions
that those topics of interest for the study of adults may be equally rele-
vant for children and that childhood learning may point forward to adult
behavior.

If we were to take the research at its face value, without
probing for latent theoretical perspectives, we might conclude that what we
have just said indeed describes the character of the little empirical re-
search in existence. Hyman's inventory of research in political socializa-
tion reveals that relevant research tends to do little more than to trace
back to adolescence or, infrequently, to childhood, attitudes and knowledge
already found useful in one way or another for understanding adult behavior.[2]
For the research worker this has seemed sufficient justification in itself.
Similarly Remmers and Radler have found it cogent to test pre-adults for
their attitudes towards a broad range of topical issues related to American
democratic practices and to daily political concerns, much as one would sur-
vey the opinions and attitudes of adults.[3] The premise would appear to be
that since adolescents will soon be adults, it is helpful to try to get
what may be a preview of the issue orientations of the upcoming adult genera-
tion. The selection of topics of inquiry—such as attitudes towards war, the
atom bomb, civil liberties, medical care and the economic role of govern-
ment—seem to hinge on what the investigator feels most people would consi-
der interesting and significant topics of the day. In most other studies,
even in recent years, it is clear that the main topics of inquiry about
political socialization have derived from or have been dependent upon re-
search about adults.[4] Hence we find an intuitive concern in the studies on
socialization for matters already made popular in the literature on voting
behavior, such as party identification, political interest, political infor-
mation, and issue orientations or ideology.

A non-theoretical approach such as this might have some justifi-
cation in the earliest stages of inquiry, when research workers are still
trying to get their initial bearings in a subject matter. But if theoreti-

cally unfocused research were to continue unabated beyond this initial phase, it could readily lead to an enormous waste of resources. We would have little means except intuition, for testing, either in advance or at the conclusion of the research, whether the results were worth the effort. The results themselves would accumulate into a consistent and scientifically useful body of knowledge only by chance.

Allocative Theory for Democratic Systems

A more fruitful and at the same time more generous rule of theoretical analysis would dictate that where no theoretical context has been explicated, the one that best fits the data might appropriately be imputed. If we were to abide by this rule, we might propose an alternative interpretation to the one just suggested, by way of accounting for the content of current research. In this alternative, the subject-matter focus would represent a kind of interest that is consistent with what we may describe as a possible theory of political allocations in a democracy.[5]

A theory of political allocations would stand as a partial theory about system behavior in contrast, say, to a more general systems theory. An allocative theory for a democratic system would attempt to provide a conceptual structure for understanding how values (valued things) are allocated among members of a democracy. Some efforts in this direction have already appeared in the form of an implicit equilibrium or explicit group theory of politics as they were developed between the two World Wars,[6] and an allocative orientation suffuses the central frame of numerous theories about power and about decision-making.[7]

Not that at the present stage of theoretical development in political science these efforts represent any pervasive, conscious striving towards a partial theory of political allocations. This would be ascribing a kind of awareness about theoretical needs and directions that is extremely difficult to achieve throughout any discipline and is only in process of developing in political science. But even in the existing theoretical literature we can already begin to see the dim outline of a partial theory of political allocation in democracies. However unsystematically the ideas may be presented, we have more than a vague idea of the major variables, and their important relationships, through which policies are made and implemented in democratic systems. The scrutiny of any up-to-date introductory test book about politics will amply testify to this.

Indeed most research about the American political system is likely to be cast in allocative terms and to be consistent with one or another theoretical interpretation of the way in which values are transformed into policies. Voting research, for example, characteristically gains its relevance from the understanding it provides about the way in which the public influences policy and policy-makers and about the means through which this is achieved. Research about legislative behavior reveals the part that legislators play in the policy-making (allocative) process and unearths the the determinants of this behavior, as in party alignments, practices affecting recruitment to legislative office, conceptions of legislative roles, or

16

or sources of power vis-à-vis other branches of government. Similarly most other institutional or behavioral research about American politics can be shown to be consistent with and contributory to an underlying conceptualization of politics as a process through which valued things are allocated.

A great deal of the research on socialization that we have referred to before can now be reinterpreted as being relevant to a possible allocative theory. For example, Hyman organized his inventory about research on socialization so as to bring out its contribution to our understanding of the roots of such adult behavior as political participation (party preferences and identification and political interest) and of ideological predispositions defined along a right-left axis.[8] In dealing with these matters Hyman was inadvertently also focusing on two major sets of determinants of the allocative processes in a democratic system. Others have similarly even if unwittingly enriched our understanding of this theoretical area in their explorations of the impact of pre-adult experiences on such matters as perceptions of political offices and recruitment to them,[9] the acquisition of information about political affairs, and the development of orientations to issues, candidates and parties as a source of political preferences.[10]

Whereas previously we offered a less generous interpretation of topics like these, considering them merely as a follow-up, or more literally, a follow-back on adult research, we can now view them in a new light-- as a way of attacking another major determinant of the allocative process. They seek to isolate and analyze the impact of early experiences and learning on future participation in the struggle over the making and implementing of public policies, that is, on the overall allocative process. In this light, pre-adult socialization would constitute an important set of variables the influence of which would have to be included in any rounded theory of political allocations.

Whatever the promise of these inarticulate premises in the study of political socialization, however, the fact is that no allocative theory has as yet been developed with sufficient coherence to provide explicit guidance for research about adult behavior, even in gross terms. It is not surprising therefore that students of political socialization should find few serious contraints on the range of topics that they might select. Typically they have not even considered it necessary to search for an overall theoretical justification. But even if they had, they would not have needed to do more, to warrant their research on children, than to refer back to the ongoing research about adults. They could place the full onus, for establishing theoretical relevance, on students of adult behavior because presumably inquiry in the area of socialization need merely follow up problems already set in the adult field. Yet if adult research itself lacks an explicit theoretical context, this shortcoming cannot help but work its way back to infect the whole area of preadult socialization as well. Thus to the extent that research in socialization could enable us to understand how time-determinants influence the way a system manages to allocate valued things, the current absence of any sustained and self-conscious theoretical inquiry at the adult level reduces the probability of any explicity theoretical contributions about earlier phases of the life-cycle.

17

Here the interest in socialization from an allocative perspective joins the non-theoretical option. Neither of these two approaches offers a theoretical justification for turning to socialization. Both options simply adopt the assumption that the task of the student of socialization is to explore the roots of existing adult behavior and attitudes and to estimate the impact of this early learning on the future adult.

It is conceivable, however, that we need to go well beyond these two alternatives if we wish to begin to understand the overall place of socialization in political systems. For one thing, what these approaches tend to ignore is that socialization may be as significant for political change as it is for current behavior. This we would fail to appreciate if we literally confined ourselves only to an effort to trace back the roots of present adult orientations. We shall return to this point later. Furthermore, socialization may have consequences for political systems of a broader and more profound sort than is implied merely in its identification as a newly discovered determinant of present adult orientations. It is to the merit of the third option—system stability—to which we now turn that, whatever its other shortcomings, it does strive to draw attention to the broader implications of socialization for the operation of political systems.

A System-Maintenance Theory of Socialization

Although allocative interests represent the mode of analysis most apparent in research about political socialization, interwoven in this approach we can discover the early beginnings of a more general theory, what we might call system-maintenance theory. Most research, with a few notable exceptions,[11] unobtrusively assumes that in one way or another the outcome of socializing processes is to assure the continuity of a political system in relatively unchanged form. Not that change is ignored, as we shall find, but it becomes a residual rather than a central or expected product of socialization. Allocative analysis is also shot through with assumptions such as these. For the most part the way a maturing generation participates in current political processes turns out to be replicative of the adult generation. In this view it would appear that the task and outcome of socialization is to contribute to the stability or maintenance of a political system.

As sparse as theorizing about socialization is in political science, this interpretation has already taken more than a slight, if as yet an unsignalized hold. If it were to become the dominant mode of analysis, it would ultimately and unfortunately distort our understanding of the multiple and divergent consequences that socialization may have for different kinds of systems and in varying circumstances. It would bias research in favor of investigating those conditions favoring the perpetuation of stability or the status quo.

The meaning of stability or system-maintenance.

Stability is a highly ambiguous term in the social sciences.[12] It conveys two different kinds of meanings and both may be implied simultaneously

18

in research on socialization. Frequently it is used to describe a system that incorporates whatever the writer considers to be the political virtues. In a broad usage such as this, to say a system is stable is somehow to impute to it the capacity to solve its problems pacifically and with some modicum of equity. It leads us to speak of systems as unstable when what we mean is that they are prone to violence, to sharp reversals of policies and regime, and to unpredictability of behavior. In this sense stability tends to be an evaluative criterion varying somewhat with the predilection of the user.

But the term may also occur in a narrower, technical sense. It may refer simply to the constancy of a state of affairs over a period of time. Rigorously speaking, a system which charcteristically employed violence and fluctuated wildly in its behavior could be said to be constantly in a state of violent flux. It would be stable with respect to this quality if in the face of any change in its environment there was a tendency for the system to return to its unpredictable behavior. In this technical meaning, very much in the tradition of its use in economics and the natural sciences, stability need not imply peace, order, or any other substantive state. It described only the tendency of the given state of the system to continue over time.

At the very least the idea of system-maintenance embodies the notion of stability in this second or technical sense. A system maintains itself when it remains constant from one generation to the next. Although we would eliminate much confusion if we could confine stability to this phenomenon, unfortunately we shall see that in the social sciences outside of economics the idea also bears inescapable overtones of cohesion, consensus, peace and harmony, states of affairs that are at times associated, however improperly, with the absence of forces pushing towards change. Given the prevalence of the broad usage in political science, it would be artificial and probably ineffectual to try to restrict the idea to its narrower, technical meaning. In our discussion we shall nonetheless seek to distinguish clearly each of these two meanings.

Stability and prevalent definitions of socialization

Political science is not alone in attributing stabilizing consequences to the overall processes of socialization. In fact we might suspect that it has borrowed this assumption from elsewhere in the social sciences. Political science has only recently come to express an interest in socialization and has therefore had to lean on the other disciplines to inform itself initially of the major general issues. In doing so, it is understandable that political science might unsuspectingly absorb system-maintaining assumptions already prevalent in these other social sciences. If we now look again at some typical descriptions of what others from neighboring disciplines have meant by socialization we will quickly see that the evidence does seem to bear this out.

As we noted earlier, the consequences of socialization are often, and inappropriately in our view, included in the definitions of the term itself. The reader might now wish to refer back to our earlier account of

these to reappraise them for their implications about the effects of sociali-
zation for social and political stability.[13] But the hazards of this kind
of theoretical perspective are so serious for future political research that
further evidence of its stabilizing imputations needs to be adduced. To
that end we set forth here a number of additional definitions and descriptions
drawn from several disciplinary contexts aside from political science and
then compare them with a few from political science.

> Socialization covers "the whole process by which an individual
> born with behavioral potentialities of enormously wide range,
> is confined within a much narrower range--the range of what is
> customary and acceptable for him according to the standards of
> the group."[14]

> "Socialization consists of those patterns of action...which in-
> culcate in individuals the skills...motives, and attitudes
> necessary for the performance of present and anticipated roles."[15]

> Socialization describes "the acquisition of dispositions toward
> behavior that is positively valued by a group, and the elimina-
> tion of dispositions towards behavior that is disvalued."[16]

> Socialization is a process "by which persons acquire knowledge,
> skills, and dispositions that make them more or less able mem-
> bers of their societies."[17]

> Socialization is a process "in which the child gradually comes
> to approximate the prevailing attitudes of the adults in his
> culture."[18]

These descriptions could be continued indefinitely so thoroughly
have they become a part of the established literature. Various euphemisms
take the place of the notion of stability but they add up to the same
result. Acceptability according to "the standards of the group", becoming
"an able member of their societies" or "approximating the prevailing atti-
tudes of adults in his culture" are all formulations that reflect the con-
viction that more or less successful adaptation to existing social patterns,
that is, a system-maintaining outcome, is a dominant element in the theore-
tical structure with which socialization is to be approached.

It is understandable that under the pressure from the widespread
acceptance of these assumptions in the other disciplines, many of those who
have come to apply themselves to parallel problems in politics should easily
fit into the same system-maintaining mold.

> "The importance of such a formulation /of politics as learned be-
> havior/ to understanding the stability of political systems is
> self-evident--humans must learn their political behavior early
> and well and persist in it. Otherwise there would be no regu-
> larity--perhaps even chaos."[19]

> "Political socialization is the process of induction into the
> political culture."[20]

"Political socialization refers to the learning process by which the political norms and behaviors acceptable to an ongoing political system are transmitted from generation to generation."[21]

"...the processes through which values, cognitions, and symbols are learned and 'internalized', through which operative social norms regarding politics are implanted, political roles institutionalized and political consensus created, either effectively or ineffectively."[22]

These quotations leave little doubt that regardless of disciplinary affiliation or perspectives, students of socialization typically tend to apprehend the process as one that helps to adapt the behavior of the maturing generation to the existing patterns among adults in society. Whatever the term used in the literature, and they are numerous--inculcation, adequate socialization, customary and acceptable behavior, able member, approximation of prevailing attitudes, effective learning, adaptation, maintenance, consensus, induction of a culture--and however ambiguous each may be, they all share one implication. They suggest that somehow an adult generation is able to mold a rising generation into something like its own adult image. Theoretically, this kind of conceptualization clearly implies that the outcome of socialization is to provide for the continuity of existing forms and actions, that is, to assure the stability, both in the sense of consensus or order (as against chaos) and constancy of the system over time.

The system-maintaining bias of functional analysis

Functional analysis as we find it in other social sciences and as in recent years it has haltingly been creeping into political research, particularly in the comparative field, similarly carries inquiry about socialization in a system-maintaining, stability-emphasizing direction. Functionalism assumes that social mechanisms can best be described in terms of their functions. The function of socialization becomes one of assuring the stability of a political system.

Political science has imported a functional approach from adjacent disciplines. Although the fact of being borrowed bears no relationship to its shortcomings as a mode of analysis,[23] its origins elsewhere suggest that we might look there to alert ourselves to some of the problems associated with its use.

Functionalism, as it appears in anthropology and sociology, stands on two fundamental tenets. It holds that no society can maintain itself or remain stable without meeting certain postulated invariant functional requirements. Derivative from this is the further principle that variable structures and processes in a society serve to fulfill these constant functions. As they appear in functional analysis, system-maintenance and stability are usually interchangeable terms. They both imply not only constancy but subtly suggest peace and order as concomitants of the self-maintenance of a system over time.[24]

From this theoretical perspective, socialization stands as one of the basic functions necessary for system-maintenance or stability. Every society must provide for the fulfilment of such functions as the production

21

of goods and services, the biological replacement of its members, the creation of a sense of common purpose, and the like. Although every scholar is free to specify his own list of functions, all agree that various roles need to be filled if the identified functions are to be met. Somehow the members of the system must acquire sufficient motivation, skill, knowledge and values to induce and enable them to undertake the role activity necessary to serve the postulated social functions. Otherwise as the existing role occupants died or retired, a society would find it lacked the personnel to meet its functional prerequisites.

The specific function of socialization, in this view, is to assure the continuity of those structures through which the other functional requirements are met. Each generation must learn what is expected of it if the postulated prerequisites of society are to be fulfilled. If socialization were to fail, no society could maintain itself; disorganization, even chaos might ensue.

This is clearly brought out in the following typical description of socialization from the field of sociology.

"By the term socialization is meant the inculcation of the structure of action of a society on (sic) an individual (or group). Socialization in this sense is a matter of degree. An individual is adequately socialized if he has been inculcated with a sufficient portion of the structures of action of his society to permit the effective performance of his roles in the society. There is adequate socialization in a society if there is a sufficient number of adequately socialized individuals for the structural requisites of a society to operate."25

The function of socialization in the political sphere has been cast in a similar mold by those who explicitly adopt a functional approach.

"Finally, we shall speak of system maintenance and adaptation functions. For an automobile to perform efficiently on the road, parts must be lubricated, repaired, and replaced. New parts may peform stiffly; they must be broken in. In a political system the incumbents of the various roles (diplomats, military officers, tax officials) must be recruited to these roles and learn how to perform in them. New roles are created and new personnel 'broken in'. These functions (in machines, maintenance and replacement of parts; in political systems, socialization and recruitment of people) were discussed earlier.."26

Consistent with this approach, the language of research is couched in terms that assess the contribution of socialization to system-maintenance or stability. To the extent that socialization does serve this end, the members of the society may be said to be "effectively", "satisfactorily" or

22

"adequately" socialized, depending upon the degree to which they have learned what is deemed necessary to adapt to the prevailing culture or to fulfill the existing roles. Elliptically, the literature speaks of a person as becoming or failing to become "socialized", meaning thereby that he has been adequately socialized or not. Socialization loses its neutral character as a term referring to a process that may have positive, negative or indifferent consequences for society and typically carries a positive connotation for the fulfilment of the postulated functions.

In effect the functional study of socialization represents an effort to understand the way in which persons learn to fit into a pre-existing pattern of roles or culture as though the structure and culture were out there somewhere just waiting to be reproduced on some tabula rasa of the child. In this sense socialization is essentially a process whereby one generation inculcates its patterns of behavior and attitudes in the next. It maybe from adult to child or from adult to adult as in the recruitment of adults to political office. Through this kind of replication of a system, stability in the sense of continuity of the system is implied and indeed is often made explicit, as we have just seen.

Socialization and modes of stability

It is clear therefore that from a strictly functional point of view we would have to assume that socialization has certain functions or specifiable tasks to perform in society and in a political system. But in political science and, indeed, in the social sciences as a whole, there is no overwhelming commitment to a functional approach. The more prevalent assumptions do not embrace any postulated purposes of socialization in a system. Most students of politics only go no further than to indicate that socialization has some possible consequences or outcomes for the system. But the point we need to make is that, as we have noted, regardless of whether socialization is interpreted as a postulated function or merely in the light of its observed consequences, most research does unobtrusively incline towards the conclusion that it leads towards the maintenance of a system, to stability.

But we have also observed that the idea of stability is used ambiguously in a dual sense to mean both a substantive state associated with peace and harmony as well as a formal condition of constancy regardless of the substantive state. If we are able to appreciate fully the hazards of fixing on system-maintenance (in either sense) either as a presumed purpose or as an outcome of socialization, we need to probe much more deeply into how socialization is assumed to lead to stability.

We shall see that socialization is interpreted as contributing to system-maintenance in two fundamentally different ways: vertically (across the generations) and horizontally (within the generations). Not that we find these two terms in the literature as a way of distinguishing the differences they imply. But there is little doubt about the validity of our using them to describe the directions in which discussions of socialization do move. Furthermore there are two variants of the way in which horizontal stability seems to be attainable; through intra-generational group homogeneity and through subjective congruence in orientations and behavior within the individual himself. We now need to examine what we refer to by the terms

23

vertical and horizontal stability.

Vertical (inter-generational) stability

Normally, in speaking of stability as a function or an outcome of socialization, we have in mind continuity or constancy across the generations. Functional analysis postulates that if a system is to maintain itself, the existing generation must replicate itself in the maturing one, as we have observed. This is the vertical or inter-generational dimension of stability. We need not pursue this aspect of the socializing function further, it is so familiar in the literature, as the quotations have shown.

Horizontal (intra-generational) stability

But stability is also frequently linked to conditions that prevail within a single generation. When looking at a dominant generation in a political system we may speak about the similarity of views and behavior, or at least about their compatibility, which contributes to internal harmony for the group. Here the subject is intra- rather than inter-generational. From this view, to say that a system is stable attributes its source to the presence of consensus, the absence of deep internal cleavages and conflicts within the dominant generations. There is little that threatens to upset the existing balance of forces or political accomodations. Here stability depends on the lack of horizontal discontinuities, strains or incompatibilities rather than cross-generational ones.

In this context stability has the dual meaning previously noted. On the one hand, it describes a substantive state of affairs. The members have become mutually adjusted and are able to solve their problems in some pacific way. On the other hand, it also implies that the members are able to maintain this condition over time. Stability therefore goes further than merely to suggest replication of generations; it depicts a relatively harmonious and continuing condition within one generation.

In this interpretation, the function (or consequences) of socialization would seem to be to work towards this congruence in outlook and behavior within a generation, that is, to bring about <u>collective</u> <u>homogeneity</u>. System-stability would falter if socialization did not help to confine a generation within some minimal range of diversity. Strains and conflict might prevail. Since diversity and intra-generational discontinuities, so-called, are more likely to occur where there are ethnic, regional, economic, occupational, linguistic and religious differences, socialization is presumed to act so as to bring about some congruence along these lines even within the generations, not only between them.

In one way or another most studies of political socialization seek to uncover the extent to which different categories of a population socialize their members differently over the generations. A major task of the study of socialization is to ascertain the extent to which discontinuities across sub-categories of the members in a system can be discovered and explained. The interest in this subject rests on the latent premise that where different ethnic groups, social classes, regional groups, or even school sys-

24

tems, for example, implant contrasting political concepts and patterns of
behavior in children, the rising generation may be that much more likely
to develop diverse and possibly conflicting political points of view. If
the socialization process raises children who upon reaching adulthood have
among themselves conflicting aspirations, conceptions of the rules of the
game, attitudes towards compliance, and feelings about authority, it is as-
sumed that this will probably build social and political cleavages into a
system. Instability would result.

To put the matter in a positive way, stability would seem to re-
quire some congruence in what the varying components of a maturing genera-
tion learns. The implication is that there is some range of variability
in political orientations and behavior within a generation beyond which lie
conflict and stress. A person is often said to be "well or satisfactorily
socialized" or just "socialized" if he fits into the overall pattern in a
harmonious way; "poorly or inadequately socialized" or just "not socialized"
if he deviates beyond some unspecified range. So many studies of sociali-
zation take this theoretical premise for granted that no special reference to
the literature is required. It suffuses most research.

It is clear, for example, that this approach to the contribution
of socialization to system-stability has a particularly close affinity to
the melting-pot assumptions with which most research on one major source of
diversity, ethnicity, is conducted in the United States. From the begin-
ning of multi-ethnic immigration, Americans have hoped that somehow over
the generations ethnic and linguistic differences would slowly disappear.
Educational practice and social policy have been strongly colored by this
expectation. Most social pressures have automatically moved in the same
direction. Indeed immigrants to the United States have arrived psycholo-
gically prepared to blend into the dominant Anglo-Saxon cultural and lin-
guistic environment. The failure to do so, the lingering ethnic differences
and intractable resistance to assimilation by some ethnic minorities needs
to be accounted for in other terms.[27]

The disappearance of diversity into this melting pot was not
sought for its own sake. It accompanied the conviction that social and poli-
tical stability would otherwise be impossible. We shall return to the impli-
cations of this operating assumption in a moment. But here it is enough to
establish that frequently research has treated socialization as a mechanism
for promoting stability because it is seen as carrying out the process of har-
monizing the political and other predispositions within any generation.

But the stability associated with system-maintenance at times has
implied something other than intra-generational homogeneity. Strains within
a generation, it is thought, may arise from the failure of the individual
himself to achieve some minimal inner consistency in his own orientations and
patterns of behavior. System stability may therefore be associated with subective
homogeneity or consistency, in the individual himself.

For example, it might be argued that a democratic system would
scarcely be likely to survive if children were brought up under highly author-
tarian conditions in the family, school, job and voluntary associations and
then were expected to behave in a democratic manner in the political arena.

Conversely if children grew up with a high degree of involvement and responsibility for their own affairs and a significant voice, appropriate with age, in decisions affecting them in family, school and so forth, we might question whether an authoritarian political regime could operate without strain as the children attained their political maturity.

With assumptions such as these about a possible source of instability, we might be inclined to interpret socialization as an important device for bridging these discontinuities and for ameliorating or erasing these longitudinal diversities in the life-cycle of the individual. One might expect the system to display a "strain towards congruence"[28] in order to alleviate subjective discontinuities in experience.

This second variant of horizontal socialization, subjective consistency or homogeneity, therefore emphasizes the effect of discontinuities in the learning of the same individual and requires some exemplification. A good illustration is to be found in the five-nation study by Almond and Verba. There the authors address themselves to the question as to whether experiences in the non-political sphere such as the family, school and job are consonant with those in the political sphere.[29] The problem centers on the extent to which discontinuities in the socialization of members in a system may produce conflicting attitudes and expectations within the individual that would ultimately contribute to political instabilities. As they put it themselves, they are searching for "hypotheses about the kinds of personality tendencies and socialization practices that are likely to produce <u>congruent political cultures and stable polities</u>. Thus in the case of the civic culture, we may say that a pattern of socialization which enables the individual to <u>manage the inevitable dissonances</u> among his diffuse primary, his obedient output /compliance7, and activist input roles supports a democratic polity. We can then look at socialization patterns and personality tendencies and ask just which of these qualities are crucial, to what extent they must be present, and what kinds of experience are most likely to produce this capacity for <u>dissonant political role management</u>."[30]

On the acknowledged uncertain basis of retrospective evidence[31] they find that, depending upon the specific political system and the generation in question, family and school experiences may lean towards the non-participatory side in contrast with the participatory behavior expected in the adult political sphere in democratic systems. The implication is that normally we could expect this "dissonance", as they term it, to contribute to conflicting expectations among the affected members--lack of homogeneity in subjective experiences-- and therefore to some instability in the political arena.

The authors argue that inner "dissonance" and any ensuing political instability is avoided for two reasons. In part it is because early life experiences may fail to carry over fully to adult behavior.[32] But in part it may also be due to the low salience of politics in some systems and the related capacity of the members to handle their internal inconsistencies without strain. In reply to their own query about "whether these inconsistencies cause /the expected7 instability in the civic culture"[33], the authors

argue that inconsistency "creates no undue strain within the citizen; for politics, as much of our data suggest and as the data from many other studies confirm, is not the uppermost problem in his /the citizen's7 mind."[34] Thus by reversing Freud and undervaluing childhood experiences in the political sphere and by relying on low political salience to reduce inner tensions, the authors are able to explain away intra-generational subjective disharmony, a kind that might otherwise have been disastrous, presumably for the stability of a democratic regime.

In the five-nation study the authors in fact had been adducing evidence that seemed to lend weight to somewhat earlier speculations by Eckstein. The latter had addressed himself to the basic issues raised during the 1920's by the Freudian social scientists in Germany about the relationship of attitudes bred in the authoritarian family to the failure of the democratic Weimar constitution to strike deep roots.[35] Eckstein had reconsidered this question by theorizing about the impact of attitudes and practices with regard to authority learned in the family, school and occupational groups, on the behavior of persons towards political authority. Expanding on the Freudian theme about the significance of primary learning, he hypothesized that a "government will tend to be stable if its authority pattern is congruent with the other authority patterns of the society of which it is part."[36] But for him this does not necessarily imply that stability requires the congruence of experiences in all organizations or social institutions, particularly the primary ones. Some heterogeneity is possible but only on condition that those structures in which divergent authority patterns may be learned--as in the family, church or schools-- are not too close to governemhtal institutions themselves. In this the theory visibly departs from Freudian presuppositions. It is social distance from the governmental structure that seems to be the decisive factor in enabling a system to tolerate variations in learned responses to patterns of authority.

Thus Eckstein speculates that "Government will be stable, (1) if social authority patterns are identical with the government patterns, or (2) if they constitute a graduated pattern in a proper segmentation of society, or (3) if a high degree of resemblance exists in patterns adjacent to government /such as parties, civil service7 and one finds throughout the more distant segments /such as families, schools7 a marked departure from functionally appropriate patterns for the sake of initiating the governmental pattern or extensive imitation of the governmental pattern in ritual practice.[37] This theory requires the author to modify the intuitive meaning of congruence and to redefine it to suggest that "social authority patterns /will be considered7 congruent, either if they are very similar, or if similarity to the governmental pattern increases significantly as one approaches the governmental segment itself."[38] In the face of diversity, distance breeds content.[39] The "further" a structure is from government (the structure of authority, we might say), the less likely are contradictory authority patterns to impose strains on the individual as he participates in the political sphere.

27

Regardless of the validity of this theory, its significance for us at the moment is not that early socialization here, as in the five-nation study, turns out to have little meaning for later political behavior. Nor does it matter that in neither of these studies do the authors conclude that instability in the political system can be traced to inner consistency or conflict associated with early socialization. What does matter is that in the elaboration of their ideas about congruence, these studies do turn to political stability as a means for establishing the theoretical relevance of their speculations. Each considers that but for the presence of certain structural arrangements--the "distance" of early political socialization from the political sphere--the members of a political system might find themselves under conditions of subjective strain. This in turn would make it difficult to sustain a stable democratic order. For the authors the key to an understanding of socialization is its consequences, either positive or negative, for the stability of the system.

As we have observed, the literature is not particularly clear about this distinction between vertical and horizontal stability and about the two ways (collective homogeneity and subjective consistency) in which horizontal stability might be impaired. Nonetheless there is little doubt that these are the theoretical modes dominant in the study of socialization. We have a substantive theory with strong functional overtones if we have anything at all. Socialization, it is implied, may produce generations in a political system each of which looks much like the preceding one. Socialization may also contribute to h   ionious political behavior within a given generation and may thereby he   :o reduce internal cleavages. If it fails to do so, the continued stability of a system requires some other kind of explanation. What is clear from all this is that the major focus of research about socialization is on stability and its conditions. This is also the reason why we have looked at these alternative, if latent, conceptualizations as closely as we have. They reveal that the study of socialization has steadily pushed forward in one direction, towards clarifying its place in the production of political stability or system-maintenance.

The Limitations of Stability as a Theoretical Context

The major drawback of a theoretical perspective that emphasizes system-maintenance is that research inspired by a concern for stability, whether in the form of vertical continuity or horizontal integration, must overlook a whole range of consequences that socialization has for political diversity, conflict and change.

Not that change has been completely ignored in ongoing research, or that instability has been denied. By the nature of the case, especially in politics, this would be highly unlikely if not impossible. Discontinuities, both vertical and horizontal, in the transmission of existing political patterns are too apparent to be neglected entirely. But the current theoretical premises do convey the impression that the primary task is to explain something other than change--how systems come to reproduce themselves over time and to sustain themselves in an integrated, relatively homogeneous state at any moment of time. This perspective directs our attention to the

28

effectiveness with which socialization processes draw people together towards the creation of a melting pot or a politically harmonious population.

For much of current research on socialization, whether and how diversity itself may be perpetuated or how change may occur do not appear to be significant or central questions. It is as though system-maintenance and stability are the norms from which all else, such as basic change or diversity and cleavage, are deviations. Theoretically they enter as exceptions to the rule rather than, if not the rule, at least as central to research. Yet in an age in which most children in the world are growing up in a culture alien to their parents and one in which change may be the rule and stability the exception, a theory of socialization that is not broad enough to encompass both change and continuity as equally imperative phenomena immediately reveals its inherent weaknesses.

If we conduct research with the assumption that socialization serves to reinforce stability of systems, we are forced to address ourselves to a limited even though significant order of problems. We would wish to know, for example, how new members learn the existing adult political roles. We would assume that what the new members acquire is supposed to prepare them to step into roles that are already waiting for them. In this way a political structure manages to maintain itself even though the personnel changes from generation to generation. We would attribute importance to socialization because it prepares a person in anticipation for roles the prescriptions for which would seem to be known in advance. We are easily led to conclude that to the extent to which a person learns how he is to behave politically, he has been "adequately" socialized. To the extent that he is unable "to take his place" in the system, socialization has "failed". Similarly where, say, a child learns differential patterns in different sectors of his experiences, or where varying classes of children are trained differently, the system fails, through "improper" socialization, to bring about the degree of homogeneity presumed to be necessary for stability. Other mechanisms need to be activated to achieve this result.

If we adopt broader theoretical horizons, however, we can begin to appreciate that system-maintenance theory with its inclinations for an understanding of the conditions of stability in both senses of the term is far too limiting for revealing the major consequences of political socialization. It elevates one possible major resultant to an exclusive and dominant position.

Socialization is neither inherently conservatizing nor is it for that matter fundamentally destabilizing. It can contribute to disorder just as it does to peace and harmony, depending on the specific circumstances. A useful theory would recognize that the consequences of socialization will depend upon the prior state of the political system (whether it is stable or already in a condition of change), what it is that one generation is transmitting to another one (replicative or otherwise), and what the persons being socialized independently learn from their experiences. Once we accept the fact that an interpretation of the consequences of socialization must be kept widely enough open to incorporate both stability and change as possible

central outcomes, the kinds of questions we ask and the way we analyze data will differ significantly from those that adopt stability as a primary focus. In particular childhood socialization assumes a new character and discontinuities within a group or individual will be differently interpreted.

Replication as an outcome

For example, a major difficulty with the replicative thesis of a system-maintenance perspective is that socialization does not always succeed in recapitulating one generation in the next. It does not always assure stability in the sense of continuity or constancy.

In the first place, the older generation itself may not be interested in perpetuating its patterns in its children. Adults may be only too well aware of the emergence of a new world. In the hope of preparing their children to take advantage of the benefits so made available and to avoid the deprivations that they might ~~that they might~~ otherwise incur, the adults may deliberately train their children for the acceptance of new political goals, norms and structures. Inkeles discovered this to be true for a small sample of the pre-revolutionary generation in the Soviet Union. In spite of their opposition to the new Soviet order, they were not prepared to subject their children to the hazards of opposition. They consciously sought to avoid replicating their own generation.[40] Indeed if they had reproduced their political behavior in their children, this would undoubtedly have increased the probability of political instability. It would have perpetuated rather than ameliorated the post-revolutionary conflicts.

In the second place, replication may also fail to occur because expriences of the rising generation may lead them to reject what their elders seek to instill in them. Where children are socialized "poorly", according to system-maintenance standards, a different theoretical context enables us to interpret this not as a flaw in the outcome but as providing an opportunity for change. It may be that in spite of what their parents and other significant adults would have them learn, as children mature, their own experiences teach them to prefer new ways of handling things politically when they move into the politically more active stages of the life-cycle. They may end up by defining new roles for themselves and searching out new modes of political expression.

From a system-maintenance posture, the student protest movement of the sixties in Europe and the United States, for example, may be interpreted as a disequilibrating force resulting from "inadequacies" in socialization. This would seem to be an implicit inference from judgments such as the following that are so prevalent in the literature on socialization. "Unfortunately for the best adjustment of the adolescent, cultural change has been so rapid that his parents have grown up in a different world, and thus are ill-equipped to teach him how to behave and adjust in the here and now".[41] In this vein we might be inclined to attribute the "inadequacies" in socializing practices to such factors as the excessive permissiveness of parents who are themselves unable to set firm standards. Alternatively we might see in the "deviations" of young people from past adult political norms something that we might call the "cat's paw" effect, a situation where successful

30

middle class parents are subconsciously working out their own stifled liberal sentiments through their children.[42]

Research into problems such as these is suggested if we assume that socialization is supposed to replicate previous outlooks with perhaps tolerable variations. We need to account for its breakdown. But if we broaden our theoretical horizons, we may discover also that the protesting students are purposively in search of new roles. The total impact of their experiences with several wars, aimless affluence, and dangerous and difficult political forces in an atomic age may be leading them, not with the inadvertent inadequacy or connivance of their parents but in opposition to them, to seek a way of defining new purposes and inventing new kinds of structures of implement them.[43] For research purposes the investigator is not called upon to approve or disapprove of these student activities. But as social scientists we must be prepared to enlarge the scope of our analytic tools so that it sees widespread movements--such as the new student left--not only as deviations, for explainable reasons, from a norm called stability, but as an outcome of socializing experiences that may lead towards innovation and change. Novelty in political behavior and orientations is as "legitimate" or expected an outcome of socialization as is conformity.

Replication of instability

As we have said, the trouble with replicative theory is that socialization may not replicate. But even if it does, it need not always replicate stability. Here we now interpret stability to mean not constancy alone but peace and order as well. If a system is in process of change and if socialization tends to reproduce the patterns of the preceding generation, it would be the changing state of affairs that would be continued in the rising generations. A large percentage of the political systems in the modern world lives under conditions of instability. Developing nations have existed and may well continue in this state for long periods of time. Instability seems to be a better description of the political norm in this age than stability.[44] Under these circumstances it would be surprising if the new generations coming to political power necessarily learned patterns of behavior and political outlooks that contributed more to stability than to its contradictory.

Thus to cast research about socialization in system-maintenance or stability terms is to interpret change pejoratively, as though it were a product of error or moral failure. In fact it may prove to be a way of life for many societies in certain historical epochs such as the present. As has been pointed out, "so few individuals may now hope to grow up under conditions of sociocultural /and we may add, political/ stability that we may regard this situation as almost unusual, and its products as in a sense 'deviants'".[45] For long historical intervals political socialization might conceivably contribute more to instability than to peace and order.

The melting pot and the mosaic as outcomes

The emphasis on group congruence or integration as a major expected function or consequence of socialization similarly draws unnecessarily

rigid boundaries around political research. In assuming that socialization somehow tends to level differences, this emphasis unobtrusively commits the research worker to the idea that stability requires the elimination of differences. Assimilation, the melting pot, becomes a precondition of stability.

If however we were to adopt an entirely different posture and assume that what counts, even for the stability of social and political systems, is not the presence or absence of diversity but the way in which it is managed or organized,[46] we could immediately appreciate the fact that socialization may well replicate diversity as well as cleavages and a political system could continue even in some stable state. The responsibility for attaining and maintaining stability or integration might then be shifted back to some other mechanisms. This approach might lead us to substitute a conception of society that sees it as a mosaic of ethnic groups living in cooperative diversity, instead of an image that depends on the assimilative tendencies of the melting pot. But the latent commitment to cultural homogenization is so deeply ingrained in American thinking, both lay and scholarly, that it is extraordinarily difficult to accept the assertion that enduring nonassimilative patterns are consistent with an orderly political life.

Yet it is no longer a moot point as to whether members of a political system need to share all or most political orientations and cultural assumptions in order to be able to support a common regime. Indeed, unless we accept the plausibility of a mosaic hypothesis, it would be difficult to understand how multi-ethnic political systems, as found, say, in Belgium, Switzerland, and Canada--based as they are on a plurality of languages, religions, and cultures--could possibly have continued. Current ethnic discontents and instability in some of these systems may not necessarily indicate that they have failed to manage their differences but only that their mode of management is undergoing some fundamental revisions. Change even if accompanied by turmoil is itself a process of adaptation to new circumstances. In developing systems where ethnic diversity has seemed to put major barriers in the way of creating a viable political system de novo, we may have evidence not of the failure of the mosaic pattern but of the time and ingenuity necessary to discover adequate mechanisms of accompdation. But regardless of the specific impact of diversity on the operations of a political system, it is clear that socialization may be as important for its capacity to retain variability of wide dimensions as for its creation of pressures towards homogenization of a people.

The tendency to interpret homogeneity as a condition of stability is perhaps linked with the almost instinctive dominance of the melting pot concept of society in the United States, for well-known reasons.[47] The levelling of linguistic and religio-cultural differences has hitherto been accepted almost without question as a preferred state of affairs. A theoretical premise about socialization built on this preconception would naturally tend to equate assimilation and stability. But if the major impulse for research in the field of socialization had come from scholars immersed in multiethnic societies, some political systems might have been more congenially interpreted as continuing mosaics of ethnic groups living under conditions of

acceptable mutual accommodations of interests. At the very least, with both melting pot and mosaic patterns as possible polar alternatives, and with many combinations in between, a political theory about socialization needs to be sufficiently broad to embrace them all.

Conclusion

Thinking about political socialization is now too well advanced to be able to fall back on the non-theoretical option as a meaningful alternative. Allocative interests do little but follow up on adult behavior and continue to leave us at theoretically loose ends. System-maintenance theory at least has the merit of adumbrating a possible political theory of socialization. Whatever its shortcomings it does seek to assign relevance of socialization for the operation of a political system as a whole.

But system-maintenance analysis imposes excessively severe limits on the kinds of problems central for research about socialization. Our examination of these drawbacks does however help to reinforce further the utility of our earlier conceptualization of socialization, in a neutral way, as the acquisition of political orientations and behavior, without regard to its consequences or presumed functions for the system as a whole. Were we to continue to define socialization so as to posit some pre-existing structure for participation in which the individual is being trained, it would be necessary to make some instrumental judgments about the adequacy of his learning for taking up his roles in society. This is the conserving, and therefore the conservative, bias of system-maintenance as a theoretical viewpoint.

However, if we start in a neutral vein and accept an interpretation of socialization as just those processes through which an individual learns about interaction with others, it may be that even though his behavior is inappropriate for conforming with the standards of existing generations, or for bringing about political consensus, for his own generation the individual's learning may reflect a search for new patterns of behavior. What may be "inadequate" socialization for maintaining existing political structures may be highly "appropriate" for bringing into being new structures based upon new ideals and new kinds of political accommodations among the members of the system.

For an explanatory science we are not concerned with the appropriateness of the socialized behavior. We simply seek to trace out the consequences for the existing system of whatever results from the socializing experiences of the members of the system. It would be hazardous to assume either indirectly or unwittingly that any given political structure is to be preserved intact. Rather we need a more comprehensive conception of the theoretical relevance of socialization for the political system, one in which change is not interpreted as a failure of the system to reproduce itself but in which change is viewed in positive terms. Change needs to be as integral to the conceptualization as stability is today.

A revision of our approach along these lines calls for a wholesale reconsideration of the way we interpret the theoretical tasks of re-

33

search into socialization. We require a context that will encourage us to explore how it is that members of a system acquire their political orientations and behavior regardless of whether they conform to adult standards, run into conflict with the existing political structure, or just move laterally in a neutral direction. What is of significance for the adoption of a political theory of political socialization is the impact that the socializing processes have on the political system, and the theory must leave us free of any preconceptions about the consequences it should have, or the functions it ought to fulfill. We shall turn to system analysis (or persistence theory) for this kind of uncommitted interpretation of political socialization.

Chapter III

A POLITICAL THEORY OF POLITICAL SOCIALIZATION

As we have argued in the preceding chapter, system-maintenance
would seem to be a singularly inappropriate foundation on which to build
a political theory of political socialization. It offers too restrictive
a conceptualization for interpreting the overall theoretical significance
of socialization in politics. It does not even present a plausible working
point of departure. The unassailable fact is that few systems do maintain
themselves intact, however satisfying a perception of stability may be in
a world filled with turmoil. We clearly require an approach that will
not only include the possibility of socialization contributing to stability
but one that will go well beyond this to recognize the equally frequent
outcome of socialization in the direction of change.

As a step towards broadening the range of consequences linked
to socialization we may pose a kind of theoretical question more inclusive
than any associated with allocative or system-maintenance perspectives. How
do political systems manage to continue as such, that is, as sets of behavior
through which valued things are authoritatively allocated? More precisely
put, how do they manage to persist, whether by remaining stable or by chang-
ing? If we can discern the relevance of political socialization this formu-
lation we shall have taken a major step towards recognizing the variable con-
sequences of socialization for the operation of political sys as and the
first step towards a comprehensive and specifically political theory of
political socialization.

Systems Persistence

We have already described a political system in brief as those
interactions through which values are authoritatively allocated for a socie-
ty, that is, through which binding decisions are made and implemented. Con-
cretely a political system is a set of structures and processes through which
demands of the politically relevant members are converted into binding deci-
sions and related actions. This conversion process becomes feasible as long
as some type of system is able to elicit the support of the relevant members.
Conceptually therefore it is helpful to interpret a political system as a
vast conversion process through which the input of demands and support are
transformed by various structures and processes into outputs, that is, into
authoritative decisions and actions, as depicted in Figure III.1.[1]

We will say that a political system persists when two conditions
prevail: when its members are able to allocate valued things, that is, make
decisions; when they are able to get these allocations accepted as authorita-
tive by most members most of the time.[2] We shall designate these two condi-
tions as the <u>essential variables</u> of any political system.

In this context it is useful to interpret political systems as
open, self-regulating, goal-directed, and self-transforming units of behavior.
Briefly, what this means is that they are influenced by what happens in their
FIGURE III.1 A SIMPLIFIED MODEL
OF A POLITICAL SYSTEM

natural and social environments, that their members can take purposive decisions to change the course of events, and, if necessary or desirable, that these decisions may include modifications or fundamental transformations of the system itself.

Thus in the society we call the United States a political system has persisted over the centuries through the very fact that it has been able to change itself radically, from a relatively decentralized federal system, without extensive popular participation at its founding, to one with a relatively high degree of political centralization and universal adult suffrage. In the 1960's it is undergoing further changes in the informal patterns of the regime and these modifications may ultimately permit effective participation by at least one additional ethnic group, the Negro.

Similarly some kind of political system has managed to prevail in France in the face of fundamental transformations in the regime over the ages, oscillating as it has among monarchical, democratic and authoritarian forms. Indeed, persistence of any kind of political system in France may well have been contingent upon its readiness to respond to environmental and internal changes by regulating itself through such basic political alterations. But for this readiness to accept periodic and radical transformations in the regime, the society we call France might have found itself unable to continue to make and implement authoritative decisions for its members. Not that any particular historical change was inescapable. Many alternative solutions might have existed. But the persistence of a political system of some sort may have hinged upon the ability to propose and adopt important modifications of the status quo.

Relevance of Socialization for Persistence Theory

Two points stand out from a theoretical approach adopting systems persistence as its central concept. In the first place, self-maintenance or stability no longer remains the assumed goal or condition. It becomes converted into only one kind of response that may or may not contribute to the capacity of a society to sustain some kind of political system. System change becomes an equally important type of response.

In the second place, in spite of the latent dominance of allocative guidelines for past research on socialization,--and in the next chapter we shall have more to say about the differences between allocative and system politics--we need no longer follow this lead as we reach towards a political theory of political socialization. How adults come to acquire left-right orientations in politics, why they vote as they do, where they develop their authoritarian or democratic tendencies, how they come to hold particular views on domestic or foreign issues, the way in which elites arrive and survive in the seat of power, and similar matters are undoubtedly of intense practical importance. They shed considerable light on which political party or faction is likely to win high office, on which policies may be acceptable to the members of the system, and on why members participate as they do. Certainly in the final details of political analysis we could not be indifferent to allocative matters such as these. Indeed the predisposi-

tions of the membership in a system, the competence and fate of its leader-
ship, and the forces that move policy in various directions have important
spillover effects for the system as a whole, contributing to or alleviating·
the stress on it.

But for systems persistence theory, identification of these areas
of interest would be derivative matters, even though vital ones. They do
not stand at the forefront, forming the initial issues, as they do from
the perspectives of a partial theory of political allocations. For our
theoretical purposes we need to ask questions pertinent to any and all political
tical systems and having to do with the generic capacity of a society to
support some kind of network of relationships through which binding deci-
sions are made and implemented.

To put the matter in a different way, even if we had a fully
rounded theory of political allocations--which is scarcely visible on the
horizon as yet--it would tell us little about the major dimensions of all
political systems, those aspects we need to investigate if we are ever to
understand, at the most general level, how and why political systems operate
in the way they do. If our objective is to enlarge our theoretical knowledge,
then we have to interpret the behavior we call political socialization in
relationship to such a broader theory.

Analysis of the conditions surrounding the persistence of poli-
tical systems is intended to work towards such a general theory. In this
light the question we must pose about socialization is apparent. We need to
ask: What part, if any, does socialization play in enabling some kind of
political system to persist, even in the face of a variety of kinds of
stresses and strains on the essential system variables, to which most sys-
tems are exposed? We need to be able to answer such a question regardless
of whether a system remains stable or changes and regardless of the nature
of the specific internal processes for allocating valued things.

A full grasp of the implications of this more general theoretical
point of view for the study of political socialization is not easily attained.
As students of politics we are accustomed to dealing with the immediate is-
sues of the day, what we see as partisan politics and its varied determi-
nants. Frequently these very practical issues direct our attention insis-
tently to the study of the conditons of stability, especially for democratic
regimes. These have become deeply ingrained assumptions for testing intui-
tively the validity of the objectives of new directions in research. It be-
comes understandably difficult to shift intellectual direction, reinterpret
what we have been doing in new terms, and isolate the new kinds of problems
this poses for investigation.

Yet to attack the basic problems of how political systems operate,
what makes it possible for any political system at all to hang together in a
society, regardless of the specific type, we have no choice but to pursue a
distinctively different theoretical course. Unless we constantly bear this
fact in mind--that in this work we are concerned primarily with political
socialization as part of a general political theory--and that this leads to
an effort to understand the relationship of political socialization to the

41

conditions underlying the capacity of any society to continue to provide a system for allocating values authoritatively, the significance of our procedures and analysis will be obscured. For other purposes different kinds of data might have been collected about the political system from which our data are drawn--the United States--¯and certainly the data we have would need to be analyzed very differently.

System Stress

Socialization plays a vital part in enabling some kind of political system to persist. In most general theoretical terms, we may interpret socialization as one of a number of major kinds of response mechanism through which a political system may seek to cope with stress on its essential variables. The extent to which any system does in fact utilize this kind of response and the consequences it has for the particular system will be empirical questions varying for each system.

The introduction of the notion of stress suggests that there may be forces at work that threaten to undermine the capacity of a society to sustain some kind of system through which values are authoritatively allocated for that society. The persistence of some kind of political system would therefore depend upon the way in which it handles the stresses that might typically arise.

Clearly if we are to understand the way in which socialization may contribute to the persistence of political systems, we first need to clarify what we mean by the idea of stress. As we would expect from our definition of persistence, we can say that stress will occur in any political system when there is a danger that one or both of two conditions may prevail: that the members of the system will be unable to make decisions for the society; or if they are able to do so, that they do not succeed in getting them accepted as authoritative by most members most of the time.

Stress therefore implies something more than just the inability of a particular kind of political system to function in accord with some preconceived idea or ideal about how it should operate. In the latter, more limited sense, we might say that a democracy experiences stress when the people take to the streets to enforce their will or when the representatives act without concern for the wishes of the represented. But for general theory we are only derivatively concerned with such matters. Our primary focus is on those kinds of conditions that might prevent any and all kinds of political systems from functioning. If circumstances prevented any decisions from being taken, or once taken from being accepted as binding, no political system, democratic, authoritarian, or otherwise, could endure. It is this possible outcome that becomes the test for determining whether a stressful condition has occurred.

But as we have suggested, we cannot help but be derivately interested in what happens to a particular type of system. If a given type does suffer stress for one or another reason and this threatens to destroy that type of system, it could conceivably be the first step on the way to undermining the capacity of the given society for sustaining any kind of politi-

cal system. If a specific democratic system were threatened in the ways de-
picted a moment ago, the society might turn to some other type of system,
such as a dictatorship, to preserve its capacity for making authoritative de-
cisions. In this sense the change may be interpreted as a response that
permits some kind of political system to endure.

Not that we would maintain that a shift towards a dictatorial
regime need necessarily be the only outcome. There might be a whole range
of alternatives that could have been equally successful for assuring the
persistence of some kind of political system. But to the extent that any
specific political system does undergo stress, it immediately raises the
question as to whether the society will be able to take measures to con-
tinue behavior patterns through which political decisions can be made and
implemented. In this sense, every threat to an existing political system
arouses doubts as to whether in its outcome, the stress may undermine the
capacity of the society to provide some means for taking political action.[3]

Stress may come from a number of major directions, and there are
numerous characteristic structures and procedures that have been invented in
systems and that have helped to alleviate (often to aggravate) its causes.
Among these we find socialization itself. But if we are to understand some-
thing about the way in which socialization may or may not operate on stress,
we need to inspect the sources from which stress on systems typically arise.

Although in this book the data will be concerned with only one
type of stress, that occasioned by insufficient support, we can put this
special interest in better perspective if we glance briefly at the range of
types of stress to which socialization itself is relevant. We need to ad-
dress outselves therefore to the question: What are the typical ways
through which stress may arise for a political system? How may socialization
be interpreted as a response to these kinds of stress?

Output Stress

Stress may result from the failure of most of the politically
significant members to accept most of the outputs as binding most of the
time. Outputs refer to those decisions and actions taken by the political
authorities. It requires little argument to demonstrate that unless the
decisions and actions of those members who bear the responsibility for taking
care of the day-to-day problems of the system--the political authorities--are
normally accepted as binding or authoritative, a society would quickly be
reduced to a state of chaos.

Socialization represents an important mechanism that may help mem-
bers of a system to internalize a need for compliance, or, as we say in
legal systems, a need "to obey legally constituted authority". Generally we
might assume that in most systems childhood socialization probably contributes
significantly to the growth of a belief that it is good and neceesary to com-
ply with authoritative outputs.

43

We cannot however take it for granted that the outcome will always be of this sort. In the first place, however purposively socialization may be used to induce automatic compliance, it need not result in implanting this obligation so deeply that it withstands every strain. As revolutions, riots, tumultuous street demonstrations, and individual deliberate violations of the law reveal, even in presumably stable systems, other pressures may build up sufficient strength so as to override any sense of a duty to obey. Most systems find it necessary to devise alternative means to compensate for the possible insufficiency of childhood socialization in maintaining any desired level of compliance. These alternative means act directly on adults, often in the form of threats of coercion, promises of special benefits, or calculated appeals to deep underlying feelings of patriotism.

In the second place, not all the members in a system need necessarily seek to implant in children the desire to comply with political outputs. On occasion, in developed systems, such as the United States, new adult patterns towards political authorities--as among the Negroes and other ethnic groups--may offer children kinds of behavior models that encourage the rejection of many kinds of political decisions. Changing ideas of morality, as we find it in the New Left in the United States during the 1960's, have already led significant numbers of pre-adults to search for new political roles in which automatic obedience to the political order does not rank high.

Similarly in many developing systems, where opposition to the regime may be intense and widespread, it is not clear that children either directly or inadvertently learn to prefer compliance to resistance and change. The experiences of children may lead in opposite directions. On occasion, as in South Vietnam during the early 1960's, children and young adolescents appear to have been used as shock troops in street demonstrations opposing the existing leadership. In much the same way in stable systems children are frequently mobilized to swell the crowds lining the streets during national holidays or in celebration of local and national heroes.[4]

Although we might suspect that the autonomous experiences of childhood and the teaching of adults might lead most children to acquire sentiments favoring compliance, there is no guarantee that this will be the outcome in fact or that adults will universally seek to encourage such obedience. Socialization under some circumstances may therefore serve to aggravate rather than ameliorate stress. But regardless of the outcome, one aspect of the theoretical significance of socialization is the consequences it may have for stress due to the reluctance to accept outputs as binding.

Demand Input Stress

Another major source of stress lies in the overload on a system that may result from an excess of demands put into the system. If a system is confronted with too many demands in a given interval of time, the communication and processing structures can become so clogged that the system will be faced with a possible breakdown.

44

Systems have typical ways of handling this condition in order to preserve some way of processing demands through to outputs. They may modify the structure of the regime so that more channels are opened up. They may speed up the processing of demands through existing channels. They may invent rules for cutting off discussion on any single demand. But among the varied means at the disposal of the system, the development of a sense of self-restraint in the conversion of social wants into political demands represents a major device in every age. The individual member's own sense of what it is or is not appropriate to inject into the political process imposes limits on the volume and variety of demands which a system is called upon to process.

The assumption here is that the members of every society possess many wants. Some of these can be satisfied or handled through the autonomous interaction of the members themselves, severally or in groups. Typically the members will not feel it proper to attempt political settlements for all their wants. In only a limited number of areas, depending upon the particular culture, will wants be converted into political demands.

For example, in no two types of systems will the members necessarily agree about the kinds of wants considered appropriate for political negotiation. In small tribal systems, it may be that most matters, including those that in larger systems might be considered exclusively family concerns, may be handled by the elders in their councils. But in most large industrialized systems, severe cultural restrictions may be imposed on introducing many matters into the political arena. If many disputes among the members of large scale systems were not settled autonomously, without invoking the complex machinery of the political processes, it is doubtful whether any kind of political system could operate at all, let alone operate according to any established criteria of efficiency. No two types of political systems therefore need show toleranace for the same kinds of political demands or equal capacity for handling the same proportion of wants politically.

Furthermore, no two eras in any single type of system need utilize the same standards for determining the appropriateness of converting wants into political demands. In Western political systems, during the mercantilist period, no detail of commerce was considered too small as a subject for government regulation. But in the succeeding laissez faire epoch, new standards emerged. In its ideal formulation political regulation was to be countenanced only for the maintenance of law and order. With the modern welfare state, however, a far broader range of subjects are typically accepted for political settlement even in the ideologically most conservative systems. But regardless of the criteria employed, even in one and the same type of system each age produces knowable cultural restraints on the kinds of matters it will entertain for political discussion.

Whatever the nature of the cultural restrictions imposed on political demands, empirically few systems postpone to adulthood all instruction in the kinds of restraints to be expected. At a very early age the members in every system probably begin to acquire some sense of what the members in that particular system consider appropriate matters for political discussion. At the very least they probably learn that they ought not to

45

consider it necessary or desirable to turn to political means in order to satisfy all wants. Beyond this they will be exposed to cues about various specific types of demands that may lie beyond the political pale.

Not that maturing members of a system need abide by the conventions of the past. Indeed we may find that a major source of change in political systems is the way in which a rising generation, from its own experiences, seeks to transform the nature of the raw material which forms the subject matter of political contention. Each generation may develop a unique sense of the kinds of matters they ought to inject into the political process and those that ought to remain outside. This may be a major source of intergenerational political conflict, as differences in the youthful radicalism of the Depression years and the New Left of the 1960's would suggest. But whatever the nature of the process governing the input of demands, socialization may serve as a system-response through which each generation learns some degree of self-restraint, if the system is not to suffer from the stress of demand input overload.

Stress from the Input of Support

Stress from outputs and from the input of demands are both subject to possible regulation through the socializing processes in a political system. The way in which this may operate lies beyond our present concern, even though for a rounded view of the theoretical relevance of socialization, it has been necessary to touch on these sources of system stress. Our research concentrates rather on the stress that may arise from the inability of a system to keep the input of support at some minimal level.

But even here we need to continue to narrow our focus for purposes of manageable research. We shall not be able to consider the input of support for all political objects. Our attention will be confined in this report to support only for the structure of authority. But in order to appreciate the specific theoretical focus of our interest in political socialization we need to contemplate in some detail the general part that the input of support plays in a political system.

The meaning of support

Support we may define simply as feelings of trust, confidence or affection, and their opposites, that persons may direct to some object. If support is positive, a person favors an object; if support is negative it means that he has withdrawn his faith in the object. Support will vary in degree from absolute hostility to blind loyalty. Typically we use the notion of support in its positive sense. For negative support we usually use such synonyms as hostility, discontent, dissatisfaction and distrust.[5] But in our discussion, unless the context indicates otherwise, when we speak of support we shall mean both negative or positive support. This convention will spare us the tedium of needlessly repeating that support may move in both directions.

The objects of support

When we speak of support for a political system, it may appear satisfactory to view the system as an undifferentiated whole. But this is probably the least helpful way of approaching the study of support. When positive support declines in a political system, for example, it typically does so only for certain of the basic aspects of the system and not in others. The members may become disaffected from the existing rulers but continue to place confidence in the constitutional order. They may become dissatisfied with the constitutional order but retain a strong identification with those whom they typically see as part of their political system. Support--attachment for a system, confidence and trust in it, and similar kinds of feelings--is better understood if we see it as directed to specifiable aspects of a system, not to all its elements without differentiation. By identifying the basic components of a political system that seem relevant to the input of support, we shall obtain a useful tool for analyzing the specific nature of the stress on the system and thereby a way of sorting out the particular part that socialization may play.

For theoretical purposes that go beyond the objectives of the present research, it is helpful to break a political system into three major components: the political community, the regime, and the authorities. These categories are discussed in great detail elsewhere so that here we need only describe their meanings briefly.[6] Major sources of stress are to be found in the decline of support (that is, the growth of negative support) for any one of these political objects.

The political community refers to that aspect of a political system that we can identify as a collection of persons who share a division of political labor. Part of what uniquely identifies a member of the French political system, for example, is his belief that there are others with whom he should participate in making and implementing most day-to-day decisions and these he calls his fellow Frenchmen or countrymen. It does not matter that in fact he is totally uninvolved in politics and cooperates with the other members of the system only to the extent that he complies with political outputs. He shares a political community with others in that he does not expect that these daily political issues will be resolved through a structure that will normally include, say, those in Germany or Great Britain. The mode of resolving differences may change radically in France, from a democracy in the Third and Fourth Republics to a semiauthoritarian system in the Fifth. But the persons with whom he expects to cooperate or join in making, implementing and accepting binding decisions--regardless of his own role in the process--may remain relatively constant.

Departure from the political community is possible and this is the final act of dissatisfaction or withdrawal of support. If a person were sufficiently unhappy with life in France and if he had the resources to execute his desires, he could throw his lot in with members of some other system and, for example, migrate to French-Canada. In this event the person would be in process of transferring his identification to a new political community. Aspirations and actions that look towards emigration, separatism, irredentism, and cargo sectarianism usually reflect at least some decline in support

47

for the political community. Whatever the specific motivation may be—such as the search for an improved standard of living, increased social tolerance for deviant relations, the pursuit of adventure, or the longing for a release from current frustrations—the consequences for the input of support is for us the politically relevant aspect.

The _regime_ describes that part of the political system that we may call its constitutional order in the very broadest sense of the term. It refers to the underlying goals that the members of the system pursue, the norms or rules of the game through which they conduct their political business, and the formal and informal structures of authority that arrange who is to do what in the system. Political science has given birth to many different ways of classifying regimes ranging from the classical Aristotelean set—monarchy, aristocracy and polity with their corrupted forms—to the extremely variable modern categories of democracy, totalitarianism, authoritarianism, dictatorship, competitive party regimes, one party regimes, and the like. Each type reflects a unique combination of goals, operating norms, and structural arrangements.

The assumption here is that no aggregate of persons would be able to resolve its differences authoritatively unless it had developed some minimal structure of authority, even if it was represented only in the difference between elders in a tribal group and the rest of the members. Neither could they hope to continue as a group if they did not share some minimal goals and abide by some kinds of rules for solving their differences in common, at least for those cases where private settlements could not be achieved. In this sense it is difficult to conceive of any kind of society, however small, in which a political regime did not emerge for handling those kinds of differences we would call political, that is, those that require some kind of settlement through the making of binding decisions.[7]

Finally, _the authorities_ refer to those members of a system in whom the primary responsibility is lodged for taking care of the daily routines of a political system. In democratic systems we describe them as the elected representatives and other public officials such as civil servants. In other systems we may identify them as the rulers, governors, or political elite. In our terminology they are the actual occupants of the seats of political authority, excluding the aspirants and contenders for office who are usually also vital forces in a political system.

It is clear that no system could hope to persist unless it had some members who saw it as their duty or responsibility to conduct the routine business of the system. It is not enough that members identify strongly with their political community and have faith in some regime. Most of the politically relevant (or effective) members must also be prepared to lend their favor to some set of authorities and accept their actions as binding, even if only tentatively, reluctantly or under coercion. At the very least their support must take the form of acquiescent neutrality, if some kind of political system is to persist.

Stress on the essential variables therefore may flow from a condition in which support declines below some determinant level for one or

another of these three basic political objects. Below this level of support, one or another of these fundamental components of a system would be inoperative and the system could not continue in any form at all. For some kind of system to persist, a society to persist, a society must be able to assure itself that its members wish to share a division of political labor, that there is a regime acceptable to most politically relevant members, and that some authorities are ready and able to govern. If a society is unable to sustain any one of these three objects, we hypothesize that its political system—a network of relationships through which authoritative allocations of valued things occur—will not endure for long.

It should be clear that change in any of the objects need not necessarily destroy the capacity of the society in question to allocate values authoritatively. The form of the regime, the occupants of the authority roles, or the size, composition and degree of cohesiveness of the political community may vary enormously. Yet the society might still be able to make decisions and get them accepted as binding.

What this points up is the fact that our interest is in the conditions for the persistence of any and all kinds of political systems, not of any special type such as a democracy or dictatorship. If we were primarily concerned with democratic systems we would want to inquire into the conditions for the persistence of that type of system, as a type. We would ask: How do democratic systems manage to avoid stress of the various sorts already described? But our point is that regardless of type, no system for making and implementing binding decisions could hope to persist unless it can provide for the existence of some kind of political community, regime and set of authorities.

Types of support

The support that a member extends towards any political object is not always of a uniform kind. In some instances he may be favorably disposed towards one or another object because of the specific benefits or advantages he associates with it; in other instances he may develop some diffuse, generalized sentiments which tie him firmly to the object even though he may at times suffer considerable inconvenience as a result. Because each of these two types of supportive orientations is differently linked to the capacity of a system to persist over time, this suggests the utility of dividing support into two basic types, specific and diffuse. We shall examine each of these briefly.

To some extent members of a system may be willing to praise or blame the authorities for the benefits or deprivations they associate with membership in the system. The benefits or rewards and disadvantages or deprivations may be attributed to something that those thought to be responsible for making decisions do or fail to do. The responses of the members are in part a quid pro quo for what they see themselves as obtaining from membership in the system. In this sense the support the members extend is

is _specific_. It will increase or decline depending upon the way in which the members interpret the consequences of the various outputs of the system.

It is clear that if members feel that the existing authorities are not providing them with the kinds of outputs they feel they have a right to expect this may be the source of one kind of stress on the system. If the system could not provide some set of authorities over time that met these expectations, the inability to generate specific support might become critical. In time discontent with outputs might spill over to the regime. If each succeeding set of authorities proved unable or unwilling to satisfy the demands of the politically relevant members in a system, these members might begin to believe that there was something basically deficient in the regime. Similarly if changes introduced into the regime did little to satisfy the situation, or if it were impossible to obtain such changes, the decline of specific support might shift from both the authorities and the regime to the political community itself. The relevant members of the system might begin to feel that there is little point in seeking to share a common division of labor. Groups of persons participating in the system might begin to lose their sense of political solidarity and they might seek to form new political systems, independent of each other. Alternatively, some significant part of the membership might break away, as in a separatist movement, to link themselves with other systems.

But regardless of the particular outcome by way of stability or change for the basic political objects, we can recognize the independent contribution that specific support--both negative and positive--makes to the capacity of a system to persist. Through specific support we are able to isolate those sentiments that are linked to what the members see the authorities as doing or failing to do. Although specific responses may begin as feelings about the authorities, they may ultimately spill over to infect that attitudes towards the regime and political community itself.

Of course stressful negative sentiments need not necessarily destroy a system. The discontented members require the resources and the will to act on their feelings. Many compensating mechanisms may also be activated to help reduce the stressful impact of increasing dissatisfactions. Yet if the members in a system who count--those whom we may call the politically relevant or significant members--begin to lose confidence in all basic objects of the system, as manifested through the decline of their specific support, the presence of stress is apparent. The persistence of some kind of system would have to be ascribed to other factors, probably to the level of what we call _diffuse support_.

Diffuse support is a second line of defense, as it were, against the stress in a system. By diffuse support we mean the generalized trust and confidence that members invest in the various objects of the system as ends in themselves.[8] The peculiar quality of this kind of attachment to an object is that it is not contingent on any _quid pro quo_; it is offered unconditionally. In its extreme form it may appear as blind loyalty or unshakeable patriotism.

But for the presence of diffuse support it is difficult to understand how a political system would be able to weather the discontent brought

on by objectionable policies (outputs) and resultant cleavages in a system. Diffuse support forms a reservoir upon which a system typically draws in times of crises, such as depressions, wars or internecine conflict, when perceived benefits may recede to their lowest ebb. A system must also rely on diffuse support on a day-to-day basis as outputs frequently call upon members to undergo hardships for the system in the form of taxes, hazardous military service, or other sacrifices of time, labor and even life. An ideally rational member might bring himself to balance present sacrifices and deprivations against specific future benefits. But not all members pursue such a calculus. Yet even if they did and it was notoriously out of balance on the side of hardships, there might be little question in the mind of the member as to whether he ought to continue to extend support to the various objects in the system. By adulthood he may have acquired a deep-rooted attachment to the system that can withstand enormous pressures of dissatisfaction.

The presence of diffuse support helps us to understand why the fabric of a political system is not always rent asunder by cleavage and conflict among its constitutive groups as each seeks to increase its share of the goods and to shift to others a higher part of the costs. Rational self-interest at times might dictate holding out to the bitter end for one's goals. But conciliation and concessions may be a response to a learned need and desire, reinforced throughout life, to abide by conditions that will permit the given political system to work. Attachment to the system may override particular needs. But when a society fails to breed such internalized positive sentiments in its members about some kind of political system or when the experiences of the members militate against such feelings, stress is likely to occur.

Withdrawal of diffuse support from a given regime or political community need not mean of course that the society is unable to sustain some other type of regime or community. The decline of diffuse support may only mark the occasion for members to seek important changes in the nature of the regime or community. If timely and appropriate, these changes may enable some kind of political system to persist even though the previous regime or political community may have disappeared.

We do not hypothesize therefore that all members must learn to extend unrequited love for their system, or its component objects. Rather we are only suggesting that <u>for some kind of system to persist over time--</u> either with the same authorities, regime or community or with one or another of these changed--most of the politically relevant members must have learned to put in a minimal level of diffuse support for the various political objects, whatever their form. In this way a system can hedge against the breakdown of specific support. But when both diffuse and specific support fall to a low level, the system will be in difficulties and we can say that stress has occurred. There is a danger that the society will not be able to provide some structures and processes for handling political differences.

For the persistence of some kind of political system, therefore, support is a theoretically critical dimension in all political systems. The extent to which and the way in which socialization contributes to the input of support becomes a centrally relevant problem.

Structural Stress

As we have observed, a political system is in effect a vast and complex set of processes through which inputs of support and demands are converted into authoritative outputs. This suggests that even if members should learn behaviors that avoid stressing the essential variables on the input and output sides, breakdown might occur in the structures and processes through which conversion itself takes place.

Every specific type of system is distinguished by the different kinds of structures and processes through which demands are collected, reduced in numbers, and organized into some kind of agenda for action.[9] Similarly positive support needs to be mobilized and moved towards the appropriate basic political objects. Outputs of some kind also need to be formulated and put into effect if differences left unregulated through autonomous processes are to be settled authoritatively.

All these kinds of activity will take different form depending upon the kind of reigme under consideration--whether it is a democracy, dictatorship, tribal system, or the like. In some systems the basic units participating in one way or another in the conversion processes may take the form of interest groups, parties, legislatures, administrative organizations, courts and aggregated publics. In other systems the structure may consist of only a group of elders who gather in the fields of an evening, supplemented by informal channels and roles through which communication between these informal authorities and the ordinary members of the system take place. But however well-differentiated the political roles and organizations may be, if some kind of system is to be able to persist, processes need to occur within the society that permit at least some members to acquire the knowledge, skills and motivations to take some active part in political life. In other words, stress on a system may derive from the failure of the system to provide the personnel for helping to convert inputs into outputs and for implementing the outputs.

As with stress from demands, support, and outputs, we need to be careful not to construe our remarks about structural sources of stress as implying that the members of a system necessarily learn how to perform the existing specific roles in a system. Any implication of this kind would impel us towards unacceptable system-maintenance assumptions. It follows logically from our analysis to this point that a system may fail to prepare its members in any way for the particular kinds of political roles to be found in the society at a given time. Indeed, as we have noted, the older generations might deliberately "unprepare" the young people for the existing way of doing things. Change may be deliberately sought and therefore new kinds of roles may be defined and new goals set for these roles.

What we are suggesting here is that regardless of whether the members of the system seek to perpetuate the given conversion structure in identical form or whether they search for a diametrically opposite way of doing things, the essential variables will not be able to operate unless some kind of converters or conversion structures are present in the system. From the point of view of a political theory of socialization, therefore, one of its important tasks would be to inquire into the way in which a system introduces its members into the structural aspects of the system. Socialization is a

mechanism available for a system to help it handle possible structural stress.

Socialization, Change, and Stability

We may conclude therefore that a political theory of socialization need not be restricted to tracing out the roots of adult behavior relevant to the allocative processes of a system or to exploring the childhood origins of political stability. Each of these are areas in which early socialization may well play some part. But there are also numerous other possible consequences that socialization may have for a system. In the prevailing implicit theories, these tend to be ignored or to be of peripheral concern. We need to operate within a theoretical design that alerts us to a broader range of outcomes. This is precisely the purpose of casting our understanding of socialization within the theoretical framework of systems analysis.

From this point of view, political socialization is one major kind of response by which a system may seek to avoid stress on its essential variables. It must be able to reduce such stress if it is to continue to operate as a system of behavior through which values in a society may be authoritatively allocated. On the output side, through socialization the system may be able to assure itself of the acceptance of decisions as binding. On the input side, socialization may help to limit the volume and variety of demands so as to prevent the communication networks from becoming overburdened to the point of collapse. Socializing processes may prepare members to undertake those roles relevant for the conversion of inputs into binding outputs. Finally, socialization also acts as a major response by which a system may seek to generate at least a minimal level of positive support for those basic political objects without which no system could operate at all. It is all these major systemic consequences that need to be included in any possible theory about the political relevance of socialization.

What bears repetition, however, is that systems analysis does not possess a built-in conservative bias. This theoretical posture does not allow us to predict in advance whether the particular content and methods of socialization will in fact enable some kind of political system to continue. Indeed, if we include non-literate or tribal societies in our sample of political systems, more systems have probably disappeared in the past than have endured. In some important instances the socializing processes may have made their small contribution to the destruction of these systems. At least this is a possible source of system failure that needs to be investigated. On the other hand, those societies under stress that have been able to devise some kind of system for making and implementing binding decisions have probably in no few instances adopted socializing procedures and content to which part of their success may be attributed.

It is clear, therefore, that socialization may have many broad outcomes. In principle it may contribute to the maintenance or replication of a given system, to its transformation, or to its total destruction.

53

Socialization and Diffuse Support

It is from the broad perspectives of a political theory of political socialization such as this that our present research interest draws its guidance. Out of the total range of subjects of dominant theoretical importance to the area of socialization as it bears on systems persistence, our inquiry limits itself to diffuse support. By seeking to unearth the roots of diffuse support, we hope to shed some light on the way in which socialization operates as a response mechanism to potential stress on support. Subsequently we shall impose additional constraints that further narrow our research concerns to the input of diffuse support for the structure of authority.

In this search for an understanding of the way in which socialization acts as a system response, certain major questions present themselves. To begin with, does socialization contribute to the input of support at all, or is this simply a theoretical possibility without empirical reference? But if socializing processes do bear on the stimulation of support for basic political objects, at what age do members typically begin to learn to extend support? In what ways does it become possible for them to acquire their sentiments, whether they are positive or negative?

Diffuse support in childhood

We cannot take it for granted that the introduction to supportive sentiment begins in childhood. Indeed it is possible and even plausible that so theoretically and empirically vital a sentiment could be postponed to adolescence or early adulthood. Presuppositions in the little speculation available on this subject suggest starting points as late as these and we shall examine their validity in the next chapter. But whatever the period of the life-cycle at which they strike root, supportive orientations are not biologically inherited; they need to be acquired. The extent to which socialization makes a contribution to their presence needs to be explored and understood.

If we assume temporarily that children may be able to acquire supportive sentiments about so apparently abstruse a subject as basic political objects, one point is clear. Diffuse rather than specific support is likely to be particularly relevant in the study of childhood socialization. Only under very unusual circumstances could we conceive of children being motivated to extend specific support to any of the political objects. They are seldom aware of the relationship between what happens to them on the cone hand and the specific outputs of the authorities on the other. Not that they fail to envisage government as being concerned about them and their families and even as being vigilant and active on their behalf. We shall discuss this in detail in later chapters. But this perception is not related to specific outputs from which they consider themselves to benefit. At best, if children are to have sentiments about the various political objects, it will probably be some diffuse kind and it will not fluctuate directly with perceivable variations in the way the outputs of the authorities.

This is not to argue that we should expect children to learn only to love or to feel positively towards political objects, any more than this is a legitimate expectation about adults. If, for example, the children were part of a minority group, the adults of which felt oppressed or unjustifiedly deprived, neglected or rejected, we would expect that the children would be likely to pick up similar kinds of sentiments. In each system we need to determine the degree to which, if children do indeed learn to put in diffuse support, it moves in a negative or positive direction.

We cannot assume, therefore, that socialization of diffusely supportive sentiments will necessarily lead either to stability or to change, to the perpetuation of a given type of system or to its destruction. Even if supportive orientations have their beginning in childhood, the consequences for the system will depend upon the content transmitted or learned and, because not all members need be socialized in the same direction, also upon the nature of the distribution of these attitudes throughout the population of children. This is an additional reason why we need to disassociate ourselves carefully from prevailing assumptions about socialization that see it usually as contributing to the maintenance of existing patterns of behavior.

Nevertheless even if the systemic consequences of socialization will always depend upon the orientations young people acquire, one thing is clear. Unless a system is able to fashion some bond between a member and its authorities, regime, and political community, no kind of political system could possibly endure. It is from this primary and overarching hypothesis that we are led to investigate the nature of political socialization in childhood in the American political system as its relates to the input of diffuse support for basic political objects.

Diffuse support in the American system

Why do we turn to the American system as the subject of our research? At least two reasons lie behind this choice. For one thing, it is impossible to examine directly the feelings of a person for the basic political objects in the abstract. We need to look at children in the concrete setting of a specific political system. Some specific system or systems had to be chosen.

But more than this is involved. Although the comparative study of a number of systems was an available option, it seemed to be the least productive way of initiating research in this area. When we began our research in the late 1950's, we were still at the earliest stage of inquiry about primary socialization and support. We had no bench marks to guide us in establishing a design for the comparison of political systems. It seemed appropriate therefore to begin with a system in which a rich body of ancillary knowledge, especially about adults, such as we have for the American system, would permit us to make the best use of what we could learn about children.

But we do recognize the ultimate limits this imposes on our findings. Only when a number of different types of systems, in addition to the American, have been explored, will it be feasible to propose reliable generalizations about the sources of diffuse support and its connection with the persistence of political systems.

Because we have selected the American system, furthermore, most readers will find in our data and conclusions much of interest about the early forces shaping adult political behavior in democratic systems; or because the American system has been stable over the years, some inferences may be drawn about the conditions of stability. There is little doubt that our analysis will present substantial spin-off benefits of these kinds. We recognize, however, that in this there lurks the danger that our intentions will be misconstrued and that our analyses may be misunderstood. It should be clear by now that these kinds of interpretations will be incidental to our major purposes. Our primary objective is to expand the boundaries of general theory, not to add to a partial or special theory of democracy or about the conditions of political stability. It is only incidentally that we present a case study of that class of systems we call democracies. Our long-range interest is in political systems as such in contrast with other kinds of social systems. It is within this context that our interpretations ultimately need to be evaluated.

Footnotes

1. For a full discussion of this way of describing a political system, see D. Easton, _The Political System_ and _A Framework for Political Analysis_.

2. For the theoretical implications of these concepts and their related ideas see D. Easton, _A Framework for Political Analysis_ and _A Systems Analysis_.

3. We do not suggest of course that just because a given political system may experience stress, from an ethical point of view this is undesirable. Stress is a neutral term. A philosophy of politics may call for radical changes and thereby deliberately seek to undermine the prevailing order. The stress on the persistence of any political system is here incidental to the higher good embodied in the proposed political order. The mere fact that the members of every society must act so as to make it possible to arrive at political settlements, if the society itself is to continue, has nothing to say about the relative merits of one kind of system as against another. The purpose of this analytic formulation is not to pass judgments on efforts to bring about change but to provide a framework for analyzing the significance of the changes that do or do not take place.

4. The involvement of children in politics is exemplified further in the life of one of the leaders of the guerillas in Guatemala during the 1960's. Cesar Montes, at age 13, was reported to have been "expelled from a Catholic school, due to his fury over the CIA's coup against the leftist Arbenz regime. At 18 he led student demonstrations and saw his fellow students shot dead before his eyes. At 20 he went to the mountains. By 24 he was the leader of one of the most important guerilla movements in Latin America." E. Galeano, "With the Guerillas in Guatemala" 6 _Ramparts_ (1967) 56-9, at p. 57.

5. For a fuller discussion of this concept in its positive and negative implications see D. Easton, _A Systems Analysis of Political Life_, ad hoc.

PART II

PRIMARY SOCIALIZATION OF SUPPORT

FOR THE STRUCTURE OF AUTHORITY

Chapter IV

THE BEGINNINGS OF POLITICAL SOCIALIZATION

We have noted the shortcomings of allocative and system-maintenance models for assessing the significance of political socialization and have turned to systems persistence theory, a mode of analysis that favors neither stability nor change. It looks upon political interaction as a system capable of coping with environmental and internal conditions either by stabilizing or changing one or another of its basic components. Specifically, we have argued that one of the unalterable conditions for the persistence of a political system, whatever its types, is its capacity to evoke a minimal level of support for these basic objects.

A system may take a number of alternative paths to promote sentiments of this sort. It could, for example, ignore pre-adolescents or even all pre-adults and concentrate on marshalling support among the adults only. But it could also hedge against placing all of its eggs in the adult basket and seek to nurture supportive sentiments in children. In this chapter we shall examine the plausibility of assuming that this is indeed where support has its roots. We shall seek a preliminary answer to the following question: At what stage in their life-cycle do members of a political system first become capable of expressing favorable or unfavorable sentiments towards the basic political objects?

When we have some initial sense that childhood is indeed a sensible place to begin looking for one source of basic political commitments or alienation, we will then be able to pass on to other kinds of questions about the specific targets and nature of these sentiments. We will be able to ask: At what points or locations in the system do members make their initial contacts with the political objects? To examine how members begin to feel about theoretically significant aspects of politics, however, we need to know what it is that they perceive. What the child reacts to may serve as important linkage points to the system. In addition, the very nature of the perceived political objects may limit or expand the kinds of emotions that the child can express about them.

This suggests a final question. What kinds of perceptions and sentiments do the members of the system acquire for the political objects at these various points of contact? We need to lay bare the nature or quality of the support, its negative or positive tendencies.

In effect these three questions sketch out the major paths of our research. We shall seek to discover whether at an early stage in the life-cycle members become capable of relating themselves to important political things, what they see on their political horizon to which they can become attached at that stage, and the kinds of supportive sentiments they entertain about these objects together with the potential consequences for the political system.

In this chapter we open up the first subject. When may we reasonably assume that political learning begins and on what a priori grounds can we support our answer? Analysis of our data will of course later give

us positive evidence for the preliminary theoretical conclusion here that childhood is a period of rapid political learning in certain areas. But it is also important, in order to get some sense not only of the novelty of political research about children but of its sound theoretical underpinnings, to inquire, if only briefly, into how children have happened to be overlooked, and why students of politics have almost universally put political learning off until after childhood. In seeking therefore to justify on theoretical grounds our turning to socialization during childhood, we shall find it mandatory to isolate and assess theoretical assumptions that in the past have led to the neglect of this period of significant political learning.

Early Socialization vs. Its Systemic Consequences

Before setting out on this task, however, we need to be completely clear about what we plan to do. We shall not be seeking to prove that what is learned early is likely to be more influential than what is learned later and that therefore students of adult behavior have underestimated the impact of childhood socialization on the political system. This may well be true, at least in certain political areas, and we shall affirm this position at numerous later points. But we would not mislead the reader into thinking that we plan to test this assumption or that we have direct and reliable evidence about its validity. For us it will always remain just a plausible working assumption. In this we are no worse off than the rest of social science. Nowhere has any solid evidence been adduced about the longitudinal impact of early socialization. Surprisingly, even in an era shot through with Freudian preconceptions, the effect of childhood experience on adult behavior is still a moot question. The answer to it is typically based largely on the overwhelming weight of impressionistic or loose circumstantial evidence. The technical requirements for seeking to ascertain the validity of this assumption are so complex and time-consuming that it has hitherto discouraged any reliable testing efforts.

At this point in our discussion, however, we are not as yet concerned with the systemic consequences of early political socialization. We only wish to ascertain how it happens that students of politics, as distinct from those interested in other types of social behavior, have not considered childhood a period in which maturing members of a system are exposed to important kinds of political orientations. Yet we shall not be able to cope with this problem unless we are able to talk about the potential significance of early learning for adult behavior. Whether children do undergo direct political learning seems to be intertwined almost inextricably with the conviction that even if they did, it would have little importance for subsequent behavior. It comes too early in the life-cycle not to be washed out by later experiences. Inevitably a presupposition such as this about the insignificance of childhood political learning for the later adult helps to turn research away from this period. Thus even though we cannot escape paying some attention to the significance of early learning, we shall do so here only to help us understand better why past research about political socialization has uniformly turned its back on children.

The Case Against Early Political Socializatic

At what age would it be reasonable for us to expect persons to be
ready to absorb information about political life and to develop initial
feelings about it? If we define childhood arbitrarily as the years between
6 and 13, can we give any credence to the idea that children of so tender
an age, particularly in the early years of this stage, can hold political
views and express political feelings? Unless on theoretically plausible
grounds we are able to adjudge children are capable of orienting themselves
cognitively and emotionally to political things, there would be little
point in trying to search out their supportive attitudes, whether negative
or positive.

The prevailing trend

From time immemorial, social philosophers have thought that
political education should have an early start. For Plato or Rousseau
there was also little question about the feasibility of such early instruc-
tion. To them common sense alone would seem to give evidence enough that
young children could be educated in fundamental political matters. They
felt little need to exert themselves trying to demonstrate this. The only
unknown was the nature of what should be taught.

What the classical social philosophers over the ages have as-
sumed, indirectly modern research has seemed to challenge, at least unwitting-
ly. Socialization of many non-political roles and traits are known to begin
as early as infancy. Yet for political roles and attitudes, there has been
a strange reluctance even to entertain the possibility of the same early
origins. Extensive studies have contributed to the belief that oral, aggres-
sive, dependent, delinquent, achieving, sexual, neurotic, affiliative, and
other behavior can be traced to infancy[1] and childhood, and even politically
relevant personality dispositions towards authority in general.[2] However,
few scholars have been ready to leave room during this period for direct
political learning of significant political orientations. It is as though
there could be little question that political learning has its origins at
some later point, and for good reason. Until recently the entire weight
of evidence, such as it was, pointed firmly towards adolescence and early
adulthood as the politically formative stage, although not always for the
same reasons.

On what grounds has this obtrusive judgment been based?
Several types of reasons can be identified. It is worth examining them to
assess the kinds of assumptions that have led to this neglect of childhood
as an important stage in the acquisition of political orientations.

We can discern at least three fairly well-defined if latent ex-
planations for believing that political socialization begins only in some
period well past childhood. For some, the personality school, childhood is
a period in which only a pre-political personality takes shape and molds
subsequent reactions to political phenomena. For others, those whom we shall
designate as the "proximity theorists", children may in fact learn some

things about politics. But the significance of this is seriously diminished because what is learned later in life, being closer to adult political experiences, overshadows any earlier political learning. Finally, still others would stand on the ground that past research reveals that children are really not in a "state of readiness", as the argot of professional educationists puts it, for political learning. They are capable of absorbing little by way of political knowledge or attitudes. In addition they show such a slight interest in politics that there is little reason for believing that they would be affected by the political sphere.

On examining each of these positions in turn we shall find that the validity of assigning socialization to post-childhood periods rests essentially on an excessively narrow conception of politics. If we change one of the premises central to these positions--about the meaning to be ascribed to politics--we greatly increase the plausibility of important direct political socialization among children.

Pre-political personality

Most theorizing about the early socialization of personality removes politics from the sphere of primary (infancy and childhood) socialization and places it at the secondary (adolescence and adulthood) level. It sees childhood primarily as a period of non-political but politically relevant learning.[3] It is a position that has often been tied to widely accepted psychoanalytic presuppositions about the significance of infancy and childhood and the early family milieu for later life.

Peculiarly, the emphasis of this approach is upon primary socialization as the fundamental determinant of later political attitudes. Yet it carefully excludes direct or even inadvertent learning of a specifically political nature. Adult political behavior is interpreted as a derivative [projective, by] of basic personality, model personality type, or character structure; personality itself is considered to be a product of modes of child-rearing typical of a culture. The emphasis of this personality-in-culture thinking is to postpone the acquisition of political attitudes to secondary phases of the life-cycle. In this view politics is largely the acting out of predispositions developed at an earlier stage. At the very least, later political behavior filters through the individual's culturally shaped personality.

Pye, for example, clearly reflects this conception. He postulates that individuals "become members of first the society and then the polity".[4] Indeed he elaborates a three-stage theory according to which, in the first stage, that of basic socialization, "the child is inducted into his particular (general) culture and trained to become a member of his society". In the second stage "comes political socialization, through which the individual develops his awareness of his political world...Just as he was first socialized to his political culture..." Finally, "there is the process of political recruitment, when the individual goes beyond the passive role of citizen and observer to become an active participant..."[5]

Although this theory of the socializing sequence is not central to Pye's study, it does help to accent the important elements of those who adopt personality-in-culture as a point of departure. It designates infancy and childhood as politically preparatory phases in which direct political learning is either absent or, if present, of so little consequence that it can be ignored. At some later point, the basic personality predispositions so formed express themselves in the political sphere. They may account for the individual's way of reacting to political authority (for example, in authoritarian or democratic patterns), they may influence mode of political participation, and they may even pre-determine the particular political roles for which a person is equipped or which he may seek.[6] But whatever the precise influence on later political behavior, little room is left for the independent effect of direct political learning during childhood.

To the extent that the emphasis is on politics as the arena for playing out earlier general personality characteristics or predispositions, we have here a kind of personality determinism. It is as though exclusive explanatory claims were being lodged for the following kind of paradigm: culture----›child-rearing practices----›basic or modal personality types or predispositions----›patterns of adult political behavior and roles. Politics becomes the end-product of a sequential chain of determinants that roughly parallels the progression of stages in the life-cycle.

This paradigm probably overstates the case somewhat but it does typify the kind of thinking that underlies a considerable part of the extensive and varied literature on character structure and personality formation as it relates to adult patterns of interaction.[7] As this paradigm suggests, personality-in-culture interpretations ask for a considerable prior commitment to the idea that of all the variables that might affect the adult, personality is the decisive one. It leads almost to a monocausal explanation of behavior.

But the fact is that it is possible to give due weight to personality structure, as formed in the early stages of life, and yet also to accept the possibility of direct political learning during the same period. In other words, we may adopt the normal multicausal explanation of political behavior in which we may conceive of the child acquiring specific political orientations even while his personality is in formation. Indeed, if we were concerned with expanding not only our knowledge of political socialization but personality theory as well, we might even wish to draw attention to the strong possibility, usually overlooked, that under certain circumstances general predispositions may be permanently shaped by the political context itself. We require a rounded formulation of the relationship among culture, personality, and politics, even in childhood, a formulation that provides for the independent effects of variables other than personality. Our theoretical assumptions ought to be such as to allow us at least to keep an open mind, until we have more evidence than has hitherto been available, to the possibility that some of the variance in adult political behavior is accounted for not only by personality but by the direct learning of political orientations.[8]

Our data will reveal that it proves more useful and revealing to assume that in childhood a person is subject to at least two major sets of experiences. Each may have an independent but interactive effect on his later political orientations. The kind of personality an individual acquires will undoubtedly be reflected in the way he handles political matters, both as a child and as an adult. About this we shall have nothing to say empirically. We have no reliable devices for measuring or delineating the personality of children considered in large aggregates through survey techniques. But at the same time the various facets of the child's specifically political learning, as transmitted by adults and as refracted through his own direct experiences, will begin to provide him with a repertoire of developing attitudes and responses to meet political situations as he moves through subsequent phases of his life. Since our data will reveal that specifically political learning does begin at a surprisingly early age even within the period of childhood itself, any special reverence for a "staging" theory of political learning which confines childhood to the acquisition of broad general predispositions cannot be easily sustained, at least for the political sphere. But this raises the question of what we mean by politics and we shall have to return to this matter if we are to be able to support this last assertion.

The proximity hypothesis

Although personality theory probably presents the strongest argument against the presence of pre-adolescent political learning, there is some suggestion from other kinds of research that points in the same direction, although for very different reasons. The underlying hypothesis here is deceptively simple. That which is nearest to the adult in time is likely to leave the greatest impact on his political behavior. The proximity in time of the experience is the decisive element. This "proximity hypothesis", as we may designate it, stands Freud on his head. What is learned later is likely to be more influential than what is learned earlier in life. Even if children do acquire political orientations, this is of little consequence for them or for the system. We have already encountered this argument in another context in Chapter II but here we can analyze it fully for the first time.[9]

Unfortunately all that we have to represent this important opinion are a suggestion or two, and even these have yet to be systematically pursued. However, on purely a priori grounds what seems to lend credence to this position is the past literature on pre-adult socialization. Most of it treats almost exclusively with adolescents and early adulthood as though we can take it for granted that this is where political socialization or significant political socialization begins. This concentration on post-childhood phases has been so impressively unanimous as to discourage any serious conceptual reflection about children and politics, an effort that might have led students of socialization to reconsider their theoretical premises.

Thus the single major analytic inventory of research on socialization reports only an exceptional investigation or two that push their inquiries below age 13.[10] The same study refers to a piece of research in which "adolescence was reported most frequently as the age at which politi-

cal views were first formed".[11] In an earlier résumé another author found
that "it is difficult, if not impossible to make any reliable estimate, on
the basis of empirical evidence, of the age at which politics becomes
meaningful to children or youth. Examination of the skimpy research data,
plus general agreement by psychologists, anthropologists, and sociologists,
lead us, however, to focus on adolescence".[12]

By far the strongest defense of the postponement of direct poli-
tical socialization to some period beyond childhood comes from the Almond
and Verba cross-country survey. As we noted in Chapter II, the data are
retrospective and are acknowledged to be less reliable than desirable.
Nonetheless the authors do offer the judgment, based on these dubious data,
that there is little consequential political learning among children. The
authors are even doubtful about the importance of nonpolitical experiences
in childhood for later political behavior. They argue that "there is some
evidence that later experiences have a more direct political implication.
Early socialization experiences significantly affect an individual's basic
personality predispositions and may therefore affect his political behavior,
but numerous other factors intervene between these earliest expriences and
later political behavior that greatly inhibit the impact of the former on
the latter."[13] They conclude that "those institutions closer to the poli-
tical realm and in which authority patterns become more similar in kind to
authority patterns in the political system may be <u>more crucial</u> for the for-
mation of political attitudes."[14] Since a person does not participate in
institutions with greater proximity to the political system until he is
himself closer to adulthood, this apparently reduces the significance of
earlier learning.[15]

It is clear therefore that periods beyond childhood, such as
adolescence or young adulthood, are selected as most salient politically.
Not that the authors of the previous quotations are arguing that childhood
is devoid of political learning. They reserve judgment on this. But even
if the child should absorb some political orientations, the critical modi-
fying words in these quotations--"meaningful" and "more crucial"--indicate
that this early learning is thought to have little later impact of signi-
ficance on adult behavior or on the system in general.

By underplaying early life expriences for later political beha-
vior the authors do of course part company with the personality-in-culture
proponents and with strict psychoanalytic theorists. Both of these groups
impute highest significance to infancy and childhood for later adult poli-
tical development. But in maintaining that specifically political experi-
ences of significance first come after childhood, this proximity theory
joins forces with personality-in-culture and psychoanalytic theory. By dif-
ferent paths each comes to the same conclusion: There is little of import-
ance that children directly learn about political life.

In a moment we shall see that the qualifiers "meaningful", "more
crucial", "important", and "significant" are critical words. They immedi-
ately provoke us into thinking of the kind of criteria that are being used
to determine when political learning is to be considered more or less mean-
ingful or crucial. Some implicit classification of political learning is

apparently taking place. According to one conception of politics the con-
clusion may indeed be valid, we shall argue. But if the conception itself
is changed--and we shall suggest that it does need to be broadened--it may
turn out that early socialization can indeed be described by precisely
these adjectives, meaningful and crucial.

The child's "state of readiness" for politics

These prevalent impressions about the absence of specific politi-
cal socialization during childhood both reflect and reinforce the whole folk-
lore that has inhibited systematic exploration of political orientations in
this period of life. Until the 1960's few references can be found to the
possibility that children may be going through direct political experiences
of a kind consequential for the operation of political systems. At most
children were seen as possessing some information about the formal structure
of government, the contents of constitutions, the names of occupants of
some political offices, and other facts that can readily be committed to
memory, and as easily forgotten.[16] But this was considered to be pre-politi-
cal learning, preparatory to the development of good adult citizens, outside
the realm of politics.

Indeed adults were and are likely to consider politics to be part
of their own world. Tolerantly they may share it with adolescents who are,
after all, approaching their legal majority. But as for children, adults
typically think of politics as beyond their ken and competence. Children
are not ready for it intellectually. Further, the strife and turmoil of
politics, its image as a somewhat sordid business, a dirty game, probably
encourages adults to seek to shield children from it in the same subtle way
as their own Victorian forefathers had carefully sheltered them, the present
adults, from the distasteful facts about sex.[17] Children are thought to be
too young to know about politics. They are not ready for it morally.

If from the side of adults children were not yet prepared to
cope with politics, from the point of view of the children themselves this
impression could not help but gain strong reinforcement. It does not require
very intimate knowledge of children to realize that politics stand very low
in their hierarchy of concerns, either in its own terms or when compared with
other activites such as play, sports, television, movies or reading.[18]

If adults in general do not see children as intellectually or
morally ready for the business of politics and if children themselves show
little inclination towards it, we can readily understand why scholars should
reflect this and expect little of a direct political nature to be happening
to children. In fact, in the initiation of our research, at a period well
before recent publications in political socialization, we ourselves became
caught up in this prejudice and we comfortably began our inquiries about
political socialization by turning to the high-school age group. We assumed
with everyone else that it was there that we would find significant begin-
nings for the kind of political orientations in which we were interested.
Only when we found to our surprise and puzzlement that for a variety of
basic attitudes high-school did not seem to change very much from freshman

65

to senior year, were we compelled to reconsider our own presuppositions—and simultaneously those prevalent in the literature—about where political socialization has its beginnings.[19]

When we turned to children and also broadened our conception of politics to include more than political controversy and party politics, the typical subjects about which adolescents are tested—we discovered broad changes occuring over the years.[20] A search for the beginning of at least certain kinds of specifically political orientations forced us down to the age group in elementary school. We have had to conclude that knowledge about the low political interest of children and a predisposition to view politics as an inappropriate or improbable subject for their tender minds constitute shaky and misleading premises from which to begin an exploration into what children do in fact learn.

The Meaning of Politics in Primary Socialization

On various a priori grounds, therefore, related to the presumed function of early socialization in the formation of personality, the dominance of proximate political experiences, and the immaturity of children's most previous thinking on the subject would seem to delay any significant political socialization to some point beyond childhood. Although we have clearly expressed our doubts about the general validity of this conclusion as it stands, we need not wholly challenge it. In fact, if we are prepared to impose one condition, we might even be able to give this proposition our blessing, at least as a useful working hypothesis. This condition is that we recognize the limited conception of politics on which this hypothesis must rest.

Those who argue that political socialization occurs or is meaningful only after childhood or when the socialization of basic personality is complete, usually refer to only one category of political interaction, what we may call partisan politics. It would appear that what they must have in mind is the controversial, competitive areas of political life. It is an aspect of the political system with which a person probably becomes familiar only as he grows older. The experiences that come with maturation improve a person's capacity to handle the complexities of this part of life and tend to arouse at least a minimal interest in politics, in some systems and for some of the members. In literate societies, age also brings with it formal school instruction usually in the history and politics of a country, adding to the fund of knowledge upon which a member may draw to interpret surrounding political events.

What this means is that for the area of a political system which we have been calling the allocative processes, we can expect older rather than younger members, adolescents rather than children, to be better informed and more concerned. But it may be that in order to detect the areas in which children are likely to have the capacity and opportunity for acquiring political orientations we need to distinguish the partisan allocative processes from what is often, although not neceesarily always, a less contentious political area, what in a moment we shall describe as system politics.

The extent of political socialization discovered during childhood may be an artifact of the area of political behavior selected for investigation.

Allocative politics and political controversy

It all depends on how we define politics as to whether we are willing to hypothesize that children are acquiring orientations of a political nature, or whether we consider that what they absorb can reasonably be considered significant for later life. In the personality literature, for example, the political phenomena to which modal or basic personality traits are related frequently fall into what we would describe as the allocative processes in a system, the specifically partisan or controversial aspect of politics. Thus efforts have been made to understand the degree to which personality influences a vast body of party political phenomena such as political apathy, involvement in and commitment to positions on issues, ideological postures, modes of participation, and styles of political leadership. Although there are notable exceptions, as, for example, in the considerable literature in which personality is brought to bear on an understanding of fundamental responses to political authority,[21] nonetheless allocative interests are prominent.

We find a similar restrictive if legitimate conception of politics in that literature dealing specifically with socialization of political orientations.[22] As has become clear from our previous discussion, the research that touches on direct political socialization is still very small in quantity. But the little that does exist has placed greatest emphasis on how and to what extent pre-adults acquire their right-left ideologies, political interest, party identification, and various other characteristics related to political participation. When children are described as having a low interest and concern for politics, what is normally implied is that they are not likely to get excited or have much information about current political events and issues. They are innocent of what to them is esoteric knowledge about who is running for office, how Congress conducts its affairs, what the parties stand for, how they operate in the system, what the different levels of government are, or the nature of the differences among the major world ideologies. It is these kinds of matters that both laymen and scholars frequently have in mind when they speak about politics.

There is little wonder then that students of socialization draw the conclusion that children are unlikely to be an appropriate subject for study. For the very reason of their immaturity we would expect children to receive relatively little preparatory training or experience that would be directly cogent for their participation in allocative processes. Ideological positions, policy preferences on issues, and most areas of political conflict probably do not make deep inroads into the child's consciousness, even though there is reason to believe that even in these areas, remote as they are for the child, some slight beginning is probably made in the United States.[23] But by and large allocative matters are difficult subjects for a child to grasp. In fact, in testing younger children particularly, it is very difficult to find a way to open up these partisan kinds of topics without feeding the answers to the child, so far beyond his experience and knowledge are many of these allocative topics.

But if we were to join those who discount childhood socialization or see it as unlikely, and if we stopped at this point, we would be misled about what the child is acquiring in the field of politics. To conceive of politics solely as partisan activities in which conflict over the allocation of values dominates, would ascribe far too restrictive a content to it. We would be omitting a whole range of political matters vital to the functioning of political systems, about which, as our data will amply attest, children do have some experience, opinions and sentiments. What is even more to the point, it is an area of prime theoretical importance. We describe it as "system politics".

System politics

In a way, in the United States and in most other politically self-conscious systems, we are prone to view various kinds of system-oriented behavior as somehow above politics. Patriotism, a commitment to the form of government and to the rules of the political game, the acceptance of certain fundamental aims for society, these all normally transcend the realm of partisan dispute in the United States and other similarly stable systems. We are reluctant to describe them as political matters in the usual meaning of the term.

We may demur at this, however, only if we insist on limiting the idea of politics to its party-political, controversial sense. If, however, we are prepared to consider that there may be many other kinds of activity that take place in a political system and that need not be a subject of controversy (although on occasion they are), we arrive at a different conclusion. It may be that we can appropriately designate as political, even those activites that appear to be above politics. They may be just as much a part of political behavior as ordinary political controversy.

What we seldom discern, unless there is some public dispute about it, is that behavior particularly meaningful for system persistence is as integral a part of all political systems as any activity normally in the sphere of partisan strife. In addition to all those familiar processes through which particular authoritative allocations are made and put into effect, we can identify numerous other sorts of behavior that have a different kind of system relevance.

In "system politics" we would embrace all those behaviors and orientations relevant for the persistence of some kind of system. We refer therefore to the input of demands. At least some members of a system have to acquire those kinds of behavior that lead to the making of demands and their conversion into issues, otherwise there would be no cause for a political system to continue in a society. We refer also to behavior about the input of support for some authorities, some kind of regime, and a political community. System politics would include such other areas as the orientation to the roles and rules of conduct relevant to the conversion of demands into outputs and the implementations and acceptance of these as authoritative.

68

As we have mentioned, on occasion some of the behavior and
rules about these areas of a political system may be subject to political
conflict and they thereby become issues about which a maturing member may
or may not be familiar. But what we are suggesting is that whether or not
they are in dispute, they are areas of behavior found in all political
systems and it may be that here we are likely to find some early sociali-
zation. The probability of this is increased considerably when, as in
stable systems such as the United States, these areas turn out to re-
flect political assumptions about which there is normally the least con-
troversy.

The special concern of our research will be with that area of
system politics that we have called supportive behavior. This describes
those orientations--knowledge, values, and attitudes--through which mem-
bers express their approval or discontent with the authorities, regime,
and political community. Our conjecture will be that it is in childhood
that a member, born into a system and, therefore, without previous poli-
tical conceptions at all, first learns how to "see" or cognize parts of
the political world, how to feel about them, how to evaluate the$_R^m$ and how
to identify and react to representative systems of this world, such as
"government", "party", "Washington", or "Uncle Sam" for the United States.

Common sense alone would suggest that our area of special con-
ern, supportive behavior, is clearly not so remote from childhood sociali-
zation as we might initially think. If we were to rephrase the matter
and ask those who think about children and politics whether they believe
that children develop any sense of loyalty to their government and coun-
try, or whether they acquire an ability to perceive some of the general
properties of government, we would probably get a quick reply in the af-
firmative. We might even obtain acquiescence to the suggestion that it is
reasonable to think of children as beginning to understand and develop
feelings about such regime norms in the United States as those that exhort
people to be interested in politics, to vote and be active in other ways,
and to take partisan positions on public issues.

To insist on intuitive acknowledgement of this might however
be asking for too much.[24] But regardless of the range of subjects that
this interpretation of the content of politics might include, we have
to face the argument that even though we could expect children to acquire
some appreciation of subjects such as these, this is not what we normally
mean by the word "politics". If nothing else, this word is normally laden
with connotations of partisan strife.

For lay purposes we cannot doubt that this is so. But in the
realm of general theory, especially in connection with one that searches
for a fundamental understanding of the functioning of all political systems,
topics such as those in the broad area of support are of central signifi-
cance. They refer to behavior found in all political systems. They too
are part of politics if by this word we seek to identify all those beha-
viors more or less directly related to the making and implementation of
binding decisions.

In this sense the normal assumptions in research about politi-
cal socialization are contradicted. We cannot share the conviction that

"in examining the beginning of such political difference /primarily in the area of allocative politics7 in childhood, we shall be treating of phenomena that are only _precursive_ forms of politics as such is the prerogative of adults".[25] In our interpretation there is a level of politics that is as much the prerogative of children as of adults and this we have called system politics.

If we can show empirically that children begin to acquire orientations relevant to one of the major kinds of system-related behaviors, such as to the input of support for a system, we shall thereby have demonstrated that political socialization does begin in the primary period. What is true of this area of system behavior we would speculate is equally so for other major areas such as the input of demands and the acceptance of outputs as authoritative (compliance behavior).

By redefining in this way what we mean by politics, both to enlarge its lay meaning and to enhance its theoretical importance, we simultaneously add the color of plausibility to the notion that childhood may indeed be a part of the life-cycle vital for the acquisition of political orientations. We now understand politics to include more than just party political matters, even though here, in anticipation of adult roles, some limited amount of early or anticipatory socialization is not beyond the realm of probability. Through this reconceptualization we manage to open up a new door of inquiry into the political aspects of childhood socialization. It is a door that offers us an empirical means of entry into problems that systems analysis has sought to elevate to a level of theoretical significance.

General Socialization Theory: Its Implications for Political Socialization

When we re-assess and broaden the meaning normally given to the idea of politics, we are able to bring into range new areas which seem appropriate for childhood socialization. It also happens that when we now consider a particular general theory of socialization (in contrast with a political theory of political socialization[26]), we find that it strengthens our conclusion that children are more capable of acquiring political orientations falling under the heading of system politics.

The kinds of subjects a child can absorb would seem to militate against the acquisition of those very orientations that are associated with partisan politics and would seem to throw the weight of probability in favor of system politics. It has been argued, in one of the few attempts at a general theory of socialization, that childhood is a period peculiarly adapted to a concern with values and motives rather than with overt behavior, to the absorption of general rather than particular demands of society, and to idealism rather than realism.[27] Each of these areas describes characteristics that accurately reflect the general content of system politics, as will be borne out in detail in Part III.

According to this theory, the socialization of children is likely to concentrate on fundamental motivations and the basic values in a society. Less attention is devoted to the overt behavior of specific roles and to the knowledge and skills that go with them. It is thought to be a period when basic commitments (or, as we would qualify it, failure to make them) may occur. The child will be prone to develop, for example, the general desire to assume a given role and to appreciate some of the underlying values that the culture associates with it rather than to learn the knowledge and skills actually required to perform the role. He will learn to want to work, for instance, rather than the skills to fulfill a specific occupation.

Complementing this is the probability that the values a child does learn will not themselves be specific. Rather, he is likely to develop general values and motives which will characterize most roles in his culture. At a later stage in his maturation, as he moves towards specific roles, the style in which they are carried out will be colored by the general values that he has already acquired. As this theory of socialization puts it, general values learned in childhood, such as those related to achievement, nature, and the family, "give shape and tone to the performance of many roles in society".[28]

Finally, in most areas of socialization, the child learns to see life in ideal terms. This is not idealism, in the sense of attachment to very high ethical goals, although an element of this may be present. It refers rather to the fact that children first learn the formal aspect of roles rather than the informal: How they ought to behave rather than how people do in fact behave. Only as the child matures is he expected, in American society at least, to recognize the informal components. "In socialization the child is shielded from contact with the informal systems of society--or, at least, knowledge is not formally taught. This serves to maintain and legitimize the formal status differentiations and to protect them from change."[29]

If these qualities do describe the general nature of socialization in other basic social roles, it would be difficult to understand why we should choose to make an exception of fundamental political roles. It rests upon those who would argue otherwise to demonstrate that political interactions, of all areas of social existence, are somehow so profoundly different, that here socialization does not occur in childhood, or if it does, it is of negligible importance.

We shall propose on the contrary that what is true for other basic social roles is equally so for introduction to the most general political role, that of being a member of a political system. We may for this purpose disregard whether the form of the membership is as a subject, participant citizen, national, kinsman, or the like. We shall see that a child does begin to appreciate some of the general values implicit in the various basic political objects, he does acquire early motives and feelings about these objects, and he seems to interpret them in general and idealized or formal terms.

71

Thus in the political sphere we may conjecture that he will be likely to acquire general orientations about support. He may begin to relate himself positively or negatively to the political community. That is to say, in the United States he will probably be introduced to the notion of what it is to consider oneself an American as distinct from an Englishman or Frenchman, even though much more than political differences may be involved. But very early he undoubtedly learns that Americans have primary responsibility for deciding what happens in America. They share a division of political labor among themselves, and not with Englishmen or Frenchmen.

The child may also learn to commit himself (or otherwise) to the general range of goals associated with the regime of his system. He becomes familiar with the notion of democracy and may begin to absorb some general impressions about theoretically fundamental regime norms, already noted, such as the desirability of being politically interested, feeling ablt to participate in the political process, and adopting a partisan stance.[30] Only later may he begin to learn the minimal knowledge and skills associated with the roles through which these general regime norms may be fulfillled.

On grounds of socialization theory itself, therefore, we ought not to expect that children would be likely to begin to develop very many specific modes of behavior, even in anticipation, such as those involved in partisan politics.[31] The role of a voter, participant in campaigns, ideologue, party member and the like are all so specific that on general theoretical grounds we would be inclined to exclude them from a prominent place in early direct socialization. This is true at least if socialization of political roles is not substantially different from that of other social roles. For the moment we set aside the obvious fact that children are not likely to have the capacity to move far along the way to learning these roles. Whatever a child may learn of a specific sort may well be less influential for his later behavior than those experiences closer in time to adulthood, as the proximity theory has it. But before adolescence it seems safe to operate on the premise that, following what is known about orientations to other social roles, the child is probably ready to absorb knowledge and feelings of a general, formal sort towards many later political roles. He is probably learning fundamental ways of relating himself to the political sphere. It is during childhood that we may expect or at least look for some of the basic commitments about a political system to take shape, whether they are positive or negative.

15. Although these quotations perhaps reflect the dominant opinion, recently
a few voices have been raised on behalf of the possible significance
of earlier socialization, just as more than an occasional expression
of this view may also be found in writings scattered through the ages.
From Plato to modern times social philosophers have revealed an intui-
tive awareness about the potential impact of early political learning
on later life. In both theory and practice authoritarian systems have
sensed the necessity of bringing their ideologies to bear on members of
their systems at the earliest possible age. Even democratic sys

tems may devote more time in elementary and secondary schools to
political matters than is true of some non-democratic systems. See
G.Z.F. Bereday and B.B. Stretch, "Political Education in the U.S.A.
and the U.S.S.R.", 7 <u>Comparative Education Review</u> (1963) 9-16.
More recently research has begun to catch up with insight and prac-
tice. Beginning with R.D. Hess and D. Easton, "The Child's Changing
Image of the President", 24 <u>Public Opinion Quarterly</u> (1960) 632-44,
and F. Greenstein, <u>Children and Politics</u>, an increasing number of
publications have begun to hint at the possibility of primary poli-
tical socialization with carry-over effect for adults. See R.
Sigel (ed.), "Political Socialization: Its Role in the Political
Process", 361 <u>The Annals of the American Academy of Political and</u>
<u>Social Science</u> (1965), special issue on political socialization;

<u>President</u>; K. Prewitt, "Political Socialization and Leadership
Selection"; and with others, "Political Socialization and Political
Roles"; D. Jaros, H. Hirsch, and F.J. Fleron, Jr., "The Malevolent
Leader: Political Socialization in an American Sub-Culture",
62 <u>American Political Science Review</u> (1968) forthcoming; and R.E.
Dawson, "Political Socialization". See also M. Oakeshott, "Politi-
cal Education" in P. Laslett (ed.), <u>Philosophy, Politics and Society</u>,
(New York: Macmillan, 1956), pp. 1-21, especially at pp. 17-8.

16. H. E. Wilson, <u>Education for Citizenship</u>, (New York: McGraw-Hill,
The Regents' Inquiry, 1938).

17. "...children tend to be shielded by society from the realities of
life"; O.G. Brim, Jr., and S. Wheeler, <u>op. cit.</u>, p. 30. Some con-
firmation of this is offered by P. Peterson and K. Orren in "Presi-
dential Assassination: A Case Study in the Dynamics of Political
Socialization", 2 <u>Journal of Politics</u> (1967) 388-404. There they
show that adults reported a reluctance to tell their children about
suspicions of a conspiracy behind the assassination of President
Kennedy. In this way, we might suspect, an idealizing mythology is
retained among children.

18. This is supported by other research. For example, neither children
nor adolescents are likely to rebel against their parents politically,
so low is the level of political interest among young people as well
as among adults themselves. For children, see F. Estvan and E. Estvan,
<u>The Child's World</u> (New York: Putnam, 1959), c. 19; for later age
groups see E. Erikson, <u>Childhood and Society</u>, (New York: Norton,
1950) pp. 323-4; R.E. Lane, "Fathers and Sons: Foundations of Poli-
tical Belief", 24 <u>American Political Science Review</u> (1959) 502-11;

Political Beliefs", 41 <u>Social Forces</u> (1963) 377-83, and "Political
Expression of Adolescent Rebellion", 68 <u>American Journal of Socio-</u>
<u>logy</u> (1963) 527-35; and D. Easton and R.D. Hess, "Youth and the
Political System" in S.M. Lipset and L. Lowenthal (eds.), <u>Culture</u>
<u>and Social Character</u> (New York: The Free Press of Glencoe, 1961),
pp. 226-51.

19. Our unsystematic findings have apparently now been supported, if in-
directly, by more intensive and controlled research. See K.P. Lang-
ton and M.K. Jennings, "Political Socialization and the High School

Civics Curriculum in the United States", _American Political Science Review_, forthcoming, 1968.

20. Apparently there are equally "far-reaching" changes in attitudes about things other than politics in the elementary school years so that it would indeed be strange if something of the same kind did not happen in the political sphere itself. "It cannot be emphasized too strongly that attitudinal changes which take place during the elementary school years are far reaching. The kinds of attitudes expressed by first and sixth grade children were significantly different in each phase of the interview except the last where greater uniformity would be expected in reasons given for selecting or rejecting pictures." F.J. Estvan and E. Estvan, _op. cit._, p. 262.

21. See the extensive literature on personality and political change. A useful review and analysis appears in G.J. Bender, "Political Socialization and Political Change", 20 _The Western Political Quarterly_ (1967) 390-407.

22. See H. Hyman, _op. cit._, and F. Greenstein, _op. cit._ Although Greenstein deals with childhood socialization of basic system-oriented attitudes, his work too is devoted largely to those relevant to partisan politics.

23. The early awareness of party preferences, for example, has been well documented for the United States, and our data show that this may influence the child's perceptions of basic political objects. But data such as these and others related to political participation need to be carefully interpreted. They may have a different meaning for children than for the adult. See D. Easton and J. Dennis, "The Child's Acquisition of Regime Norms: Political Efficacy", 61 _American Political Science Review_ (1967) 25-38.

24. Although we do not report our data on these regime norms in this book, they are used as examples because we have found that children are familiar with them and have opinions about them. For our data on the norm of political efficacy--that a person should feel he is able to influence the course of government--see _ibid._

25. H. Hyman, _op. cit._, p. 26, italics in original. For the possible impact of political events even on children as young as four to five years of age see J.J. Zilbach, "The Impact of the Assassination of President Kennedy on Child Psychiatric Patients" in M. Wolfenstein and G. Kliman (eds.), _op. cit._, pp. 135-56, especially at pp. 140-2.

26. We need to recall our discussion in Chapter II of the difference among the following types of theories: General socialization theory, a theory of political socialization, and a political socialization.

27. O.G. Brim, Jr., and S. Wheeler, _op. cit._, p. 24ff.

28. _Ibid._, p. 31. S.N. Eisenstadt in _From Generation to Generation_ (New York: Free Press of Glencoe, 1956) at pp. 322-3 confirms this in more general terms.

29. O.G. Brim, Jr., and S. Wheeler, _op. cit._, p. 29.

30. As we have repeatedly tried to indicate, socialization may be negative as well as positive. That is to say, it may lead children to feelings of disinterest, inefficacy or political neutrality. The direction of socialization is always an empirical matter.

31. Since we began reporting our findings and interpretations others have supported our premise here. M.K. Jennings, University of Michigan, in "Pre-Adult Orientations to Multiple Systems of Government" (mimeo,

presented at Midwest Conference of Political Scientists, Chicago, 1966) points out that childhood is a period of basic commitments to various parts of a political system. Adolescence, he surmises, is a period of greater responsiveness to political inputs, greater capacity to argue and reason about political positions, and of higher concern for political issues.

Chapter V

SOCIALIZATION OF SUPPORT FOR THE STRUCTURE OF AUTHORITY

If in light of our preceding chapter we may now accept primary
political socialization as plausible, we have still to decide on where
we might begin empirical research. In that chapter we have observed
that the area of political socialization in childhood covers an exten-
sive range of subjects, already identified under the heading of system
politics. Any one of these might appear to be an appropriate topic with
which to begin. In this book, however, we shall carefully narrow our
focus to the structure of political authority.

Persuasive reasons account for this decision. First, political
theory demonstrates that authority is a crucial and inescapable pheno-
menon in all political systems, regardless of type. Second and of the
highest importance in our pretest finding that as the child begins to
learn about the political system in the United States, the structure
of authority offers him a number of easy points of contact with the
system, however devoid he may be of orientations to other political
objects. Happily, theory and facts thereby join together in dictat-
ing the scope of our initial research.

The Theoretical Significance of Political Authority

As we shall note in a moment, empirically a child finds many paths
of access to the political system. Our interviews, pretests, and final
instrument give us hints about many areas in which socialization goes
on apace. Simultaneously the child learns to put in support--whether
negative or positive, high or low--to the political community, to the
regime goals and norms, to the structure of authority, and even to the
specific occupants of the authority roles. Theoretically these are
all vital aspects of any system. No system could persist for long
without some minimal level of support for all these basic political
objects.

But this is not all that the child is absorbing about the politi-
cal sphere. If our group of children is not atypical, they may also
be acquiring some understanding of the kinds of things it is appropriate
to ask for through the political process. For example, our data in-
dicate that initially children characteristically see the authorities
as possible sources of nurturance, a resource to which one can turn
in very much the same spirit that a child expects to be able to turn
to his parents. As they grow older, many children come to learn that
government plays a much more restrained role and, therefore, that many
demands that one might make of one's family are "inappropriate" in the
United States to direct towards government. We can see here the be-
ginning of the growth of cultural restraints on the input of demands.[1]

Children also begin to acquire attitudes towards political outputs, especially in their form as laws in the United States, and towards their acceptability as authoritative. Through this we can detect the beginning of some understanding of the conditions related to compliant (and non-compliant) behavior. These and many other kinds of political orientations are to be found during childhood.

Clearly there is much that is happening to the child politically in the broadened sense of the term. From among these varied and numerous areas of political socialization we have selected, as our first major subject of analysis, socialization about support for the structure of authority. We also have data on the child's orientation towards selected regime norms and some much less adequate data about his attachment to the political community, his conceptions of the political process, and his developing sense of compliance to outputs. But both because of the critical place of authority in the functioning of political systems and the richer and extensive data we possess about this area, we confine our attention to it alone in this book.[2]

As heirs to centuries of recorded thinking about political authority we scarcely need to be reminded about its fundamental importance for politics. But systems analysis enables us to place the structure of authority in its broadest context.[3]

Put briefly, if any system at all is to be able to function there must be formal or informal roles through which persons are expected to care for the daily business of running a group or country. The presence of some kind of structure or pattern of authority (or system of government, in ordinary but sometimes misleading language) is necessary if any aggregate of persons is to take decisions and act on them. Without such a structure a group would be unable to act in pursuit of any objectives.

This conclusion becomes evident if we recall our description of a political system. At the most general level we may interpret it as a type of system through which the human and physical resources of a society can be rallied and committed to specific objectives and general ends. In particular it represents a set of processes through which inputs called demands are converted into binding outputs called authoritative decisions and actions. But demands cannot be negotiated through to outputs without a variety of characteristic activities occurring in any political system. Among these we may identify three: the making of decisions, the obtaining of compliance, and the assurance of implementation.

The system must provide a way for considering alternatives as formulated in conflicting demands and transforming them into decisions through some kind of settlement of the differences. It must also be able to obtain the commitment of the relevant members of the system for the adoption and attainment of the decided objectives of neutralize those who might be opposed. Finally, it needs to provide continuing energy to put the decisions into effect and to supervise their implementation. This variety of activities is as likely to be present

in a small, non-literate tribal political system as in the largest and industrially most advanced type.

In every political system at least some minimal specialization of political labor occurs through which the power and responsibility for the day-to-day performance of these activities may be assigned. In most large-scale systems, special roles rise through which acknowledged members are able to take the initiative in considering demands, help arrange for a settlement among competing demands, and effectuate any decisions that have been taken. The occupants of these roles give impulse and direction to action taken in the name of the system. The power and responsibility usually converge on some few and this is so even in the smallest political system, as among Bushman bands which may not exceed fifty persons.[4]

In some systems these roles may be set forth formally in a table or organization or written in the form of a constitution or other body of laws. In others, the roles may remain only as informally recognized patterns of leadership and administration. But regardless of the extent to which they are affirmed, in writing or otherwise, no system is able to do without some special roles to which are attached the ongoing responsibility and power for converting demands into accepted out-puts; that is, for helping to bring about political settlements of differences in the system, and for implementing the outputs.

Speculatively we could imagine a situation in which even though such structural means for meeting this special responsibility existed, the occupants of the roles might need to justify each exercise of power in which they engaged. Each of their decisions and actions would have to receive specific endorsement from the political relevant members in the system, those who count for most. Empirically it is difficult, iff is not impossible, to find a system of this kind. Usually some roles will have been traditionally endowed with continuing authority or will have acquired it through successful assertion. Normally the authority will not be associated exclusively with the individual person who occupies the role, aside from the case of the leader who arises at moments of political crisis. Weber had argued that even then there is a tendency for the authority of the personal leader to become "routinized" and therefore for authority to become associated with the role.

In most systems, authority usually becomes attached to the role itself rather than to the person alone. It is in part because of this that the paramount tribal chief, the lineage head, the monarch of a state, the administrators, legislators and chief executives of a modern democracy, even a sole dictator, are all able to perform their routine tasks in the process of arranging for political settlements and converting competing demands into outputs. Without recognized authority, any and all of these political rulers would be in constant danger of exhausting their energies and resources in compelling or repeatedly persuading the members of the system to conform with the decisions. This capacity to transform demands into outputs routinely, depends on

the expectation from the rulers' side and the reciprocal expectations from the other members of the system, that within the limits of the roles of the rulers, their actions will be accepted as authoritative or binding.

The occupants of these roles therefore have the special capacity, formally granted or implicitly acquired, to direct, order, or command, supported in many systems, although not in all,[6] by the power to compel through the use or threat of force. Hence the power associated with these roles consists of authority. It is the set of these roles in a system that we describe as the structure of political authority. The roles seldom stand discretely and independently; they tend to be related and complementary, part of some patterned division of political labor.

Whatever form of organization these authority roles take - democratic or authoritarian, representative or appointed, federal or unitary, and the like - they need to be distinguished from their occupants. The roles consist of rights and obligations with respect to the conversion process. They tend to represent regularized patterns of behavior and expectations about the way in which the occupants of the particular roles will behave--what his rights and obligations are and ought to be--and about the way in which others are expected to act towards them, the role occupants. Typically we designate the particular occupants fo these roles at any moment of time as the political authorities, and the set of roles as the structure of authority. Political science has never developed a separate set of acceptable concepts to differentiate the role from the occupant and in this lies much confusion.

There are many reasons usually for obedience to the occupants of these roles, that is, for the acceptance of the authority of the roles. Members of the system may accept decision out of fear, expediency, habit or lethargy, or some combination of these. But typically, at least during periods when the political authorities are not being fundamentally challenged, the capacity of the authorities to rule is closely connected to the presence of an ingrained belief that the occupants of the authority roles have a right to command and other members a duty to obey. The roles are considered to carry legitimate power.

In stable systems the major source of authoritative power for these roles resides in the prevalence of this conviction about their legitimacy; in changing systems this belief may be undergoing serious erosion. Stability and change will vary with the belief that it is right and proper to accept the decisions and actions of those who occupy the roles of authority in the system. We may describe these varying convictions about the legitimacy of the authorities as one measure of the support being put in for the structure of authority.

This does not exclude the possibility and indeed the probability that to backstop and supplement power derived from a belief in their legitimacy, the occupants of authority roles will have important other sources of power, such as in force or rational persuasion. Nor ought

it to lead us to ignore the fact that by virtue of their occupancy of
these roles, the authorities cannot escape certain limitations on their
powers. But these are aspects of a theory of political authority that
do not concern our immediate research objectives and can be set aside.[7]
Our sole point here is that no system can persist, regardless of its
specific type or character, without some structure of authority, how-
ever limited or unrestrained the powers exercised through this struc-
ture may be. There must be some minimal input of support or attachment
for the structure of authority, and a belief in its legitimacy empiri-
cally turns out to be the most dependable and continuing kind. With-
out this structure of authority the system could not sustain the mini-
mal organization necessary to rally and commit, on any kind of recurring
basis, the human and other resources of the system for the production
and implementation of outputs. There could be no political system.

Hence we have selected socialization of orientations towards the
structure of authority, during childhood, as a theoretically signifi-
cant focus for our research. It opens the door to an understanding of
how members of a system begin to acquire a sense of the legitimacy of
the authorities. We assume that the attitudes towards political au-
thority that are learned early will have some impact on the ability
of any political system to operate in a society and upon the future
stability or change of the particular political system in which the
socialization occurs.

The Child's Political Images

Theoretically, the structure of authority, as part of the regime,
stands as a postulated necessary condition for the persistence of any
kind of political system. It turns out, happily, that what is theoreti-
cally of highest significance, empirically plays a crucial and prior
part in linking the child to the political system in the United States.
Theory and fact here converge. Among other things, primary socializa-
tion involves the acquisition of some knowledge about the structure
of political authority and the development of varying attitudes towards
its parts.

To discover how and where diffuse support has its origins it be-
came imperative to inquire into the development of images about the
structure of authority and its components. How do children see and
interpret the points of contact that constitute the structure of au-
thority? How do they fell about them?

An image itself is not a homogeneous object. We shall find that
the images children form about authority have two basic dimensions, one
weighted on the cognitive side, the other on the affective, and in the
latter we shall include evaluative elements as well because of the dif-
ficulty of sorting out the two for children. Children have some know-
ledge about the figures and institutions of authority. Not that it is
"accurate" by adult standards. This is less material than trying to
understand the nature of the child's knowledge and its consequences

81

for his developing support for political authority. Children also have feelings about political authority. They are able to rate it on what has been called "scales of betterness and worseness"[8] which necessarily include some evaluations. Thus we find that the child is able to express certain beliefs about the constituent parts of political authority as he sees it and these beliefs incorporate various kinds of feelings and judgments.

It is not a simple thing to differentiate these two aspects of an image empirically. The mixture at times may be virtually impossible to separate out. As will appear later, we do not suggest that our efforts have been entirely successful, so complex a psychic entity is an image in children. But a major task of our pre-tests was to discover its basic dimensions.

What the child sees: cognitive image

If a child is to develop feelings about the political authorities, he cannot do so unless he is at least aware of their existence in some shape or form. Something must be seen to exist "out there", beyond the walls of home and school, about which the child is able to develop ideas and feelings. He must be able to carry around in his mind, a picture, however, fuzzy, obscure and tentative, or what it is towards which he may be extending some feelings. The political system must take some kind of empirical or symbolic form for the child member even if it is only in the shape of a great occasional force somewhere over the hills as appears to be true for adults in some peasant societies.[9]

On a priori grounds we might have expected that the early ties of the child to the political system are few and simple. Children have a low interest in political matters of any kind when compared with other fields of activity. Their comprehension of this adult area would seem to be extremely circumscribed. Yet surprisingly it turns out that for the input of support the child finds no one clear and well-defined point of entry into the political system. From second through fourth grades, as the child becomes increasingly aware of things outside of his family, school and immediate neighborhood, he is not led by the hand to one or two points of contact with the basic political objects. Extensive preliminary testing and interviewing revealed that as political matters unobtrusively begin to cross the child's horizons, several objects become sufficiently visible or meaningful for him to be able to hold opinions about them or to express some knowledge of them. He has spread before him aspects from each of the major levels of the political system--the political community, the regime, and the authorities--and develops some knowledge, however vague and inchoate, about them. In particular, for the input of support, the connective tissues between child and system are more varied and extensive, less delicate and tenuous than we might have expected.

It became clear, from pretesting, that in our group, for example, the child very early comes to think of himself as an American. We

could see that he had begun to identify himself with what on theoretical grounds we have interpreted as the political community. At the same time, by fourth grade at least, he had also acquired the notion that somewhere beyond the family and neighborhood lay some force or persons called "the government". In this concept we were able to identify the most comprehensive conception that the child possesses of the regime and the authorities. Not that "government" has a precise meaning for the child. Certainly in grades 4 and 5, if not beyond, it would have defied the comprehension of the child to provide a description of the term more than modestly acceptable to knowledgeable adults. But, as we shall note in detail, even at these grades the child was not devoid of some understanding of what might be included within the idea of government.

"Government" will prove to be a central notion. It is the closest approximation to the theoretical concept "structure of authority". It is precisely through this symbolizing of the authority structure, we shall later estimate, that the child finds one way to begin to incorporate what adults in law terms often refer to as "our system of government". Because we could find no other idea that had as general an import for the child and that seemed, in one act of apprehension, to embrace the whole structure of authority, our search for the roots of support led us to probe more deeply into the significance of this notion for the child. Chapter VI will analyse the child's image of government and its implications for his attachment to the system.

But simultaneously with his increasing awareness of something out there called the government, hovering over the country and caring for it, our pretesting revealed a peculiar phenomenon, one that we shall designate as the "head-and-tail effect" in political socialization. Traditional educational theory, currently subsumed in the curricula of many elementary school systems, has presupposed that the child broadens his range of awareness by moving through a series of neat and orderly concentric circles. At the core lies the nuclear family; it is about this social unit that he is first able to learn formally. From this, as he matures and his intellectual and emotional faculties together with his broadening experiences permit it, he gradually extends his range of knowledge and interests outwards to the immediate neighborhood and school, and from there to the city, state, region and nation as a whole. Finally, his perspective embraces even the international sphere. The content of the curriculum for the child is built on these assumptions. Instructions is geared to the state of readiness implied in each widening ring of experience and perception.

How accurately this pattern describes the growth of other areas of knowledge and interest we do not presume to know. But in the political sphere two things quickly became apparent in our pretests. First, there is no linear progression either from close to distant objects or, for that matter, from simple to complex one. The introduction of the child to political life follows a much less orderly pattern.

He proves capable of simultaneously making contact with both the inner and outer rings of traditional curricular theory, and at a number of different levels. We found the child to be absorbing ideas and expressing feelings about remote politic 1 things, such as the government and the President, even while he was becoming familiar with objects very close to home, such as the policeman, a staunch traditional symbol of authority.

Although in interviews children tended to disclose very little capacity to engage in discussion about politics or political structures in the city or state or, for that matter, until later grades, even about national politics or structures, there was no doubt that they could readily talk about the head-and-tail of the political system, the President and policeman. These two were politically relevant objects about which most children had something to say. It was clear that in the area of the structure of authority, the child is likely to become aware initially of some distant objects and some closer to home. Those structures in between seem to remain, until later childhood at least, a truly blooming buzzing confusion.[10]

Towards the older end of our age group, however, by grade 8, the child's political images contained many more details and certainly more figures and institutions. By that time most children had been exposed at the very least to some political history about the United States, including the Constitution, and often to courses in civics. Few would have no knowledge about the existence of a mayor, if relevant in his locality, or a governor, for example. But as we shall observe in a later chapter, the importance of these objects for children whom we tested and interviewed was sufficiently low to lead us, in settling on necessary priorities for research, to focus on what were obviously the most visible and salient political objects for the child. These turned out to be the President and the policeman for the younger children in our group. Chapters VII through XI deal with these figures as vital linkages between the child and the American political systems for the input of diffuse support.

At this more distant, national level, the President does not cross the child's political horizon alone. As we shall see, when the child leaves the earliest grades, the President is accompanied, in the child's image, by such other political figures and institutions as Senators, Congress and the Supreme Court. They too become concrete political objects for the child and, like the President, seem to have sufficient meaning to come to the child's attention early and to lodge in his consciousness. In Chapters XII and XIII we shall consider their place as linkages between growing children and the regime.

It is clear that in politics the child does not progress through those concentric rings of awareness that have been presupposed for other areas of social life. Indeed, if we had to choose among the levels at which the child is likely to become initially most thoroughly immersed in political objects—always bearing in mind the low relative level of interest that children have in the political sphere—we would

be forced to point to national politics. Not only does the child feel able to talk about government in general, meaning thereby initially the national government, and the President in particular, but he acquires at least some knowledge of other political figures and institutions in the same distant arena.

These political authorities have a degree of visibility of palpability that permit us to appreciate how, if the child should know anything at all about political life, it might take the form of such well-defined objects. But we would be doing less than justice to the overall processes of political socialization if we were to leave the impression that in a system like the United States its maturing members become informed about the political sphere through these points alone. The resources that the American political system has at its disposal are far more varied and subtle. Our pretesting revealed that the child at the same time may become quickly aware of the existence of certain political norms about what is expected of a person in the political realm, as we have already noted. He comes to realize that as an adult he will be expected to be interested in politics, to feel as though he does or can have an effective voice in politics in the United States, that some degree of partisanship is viewed with approval, and that he ought to expect to participate at some time in political processes. In other words, at the same time as he is learning to see that major component of the regime that we have called its structure of authority and to develop feelings about it, he is becoming apprized of the nature of another component, regime norms, and he is learning about them as well.

We can see that the child steps into the political system through a number of different doors. We can expect that what makes some more inviting than others and the feelings he entertains while entering them, will undoubtedly depend in part upon the characteristics of the child himself, on his personality. But it will also be a function of the nature of what he sees. As we have already indicated, analytically we may treat the regime norms as distinct from that part of the regime that we call its structure of authority. Our political theory has accordingly proved to be a useful way of dividing our research efforts. In the present work we deal only with the kinds of images that children develop about the political authorities. As we have indicated, we leave for separate and independent analysis, elsewhere, the way in which children acquire knowledge and sentiments about regime norms.

What the child feels: affective image

Our purposes in baring the points of contact between a child and the political system are not solely to establish the resources available to a particular political order for socializing its young, although this knowledge in itself would carry us far beyond what is currently known about the sources of the input of support for a system. But once we establish the objects toward which maturing members of a system are capable of reacting, we need to inquire into how they

feel about what they see. The image formed by children as they become socialized has affective and judgmental as well as cognitive components.

For the input of diffuse support, the feelings and associated evaluations incorporated in these images will be central. To the extent that children have positive feelings about and estimates of the political authorities, we can assume that they provide us with evidence that they have begun to put in support for the regime. The folklore about the American system, especially about its relative lack of instability, presupposes a high level of input of positive support among adults. Nonetheless even if we were to grant in advance that this has probably been correct, at least for much of the recent past, we can anticipate that like most social phenomena, there is undoubtedly some variability among adults. As we lack longitudinal studies of members of the system, carried forward from childhood through adulthood, we are unable to establish the precise linkage between child and mature member. Nevertheless we can anticipate that there ought to be some variability among children themselves. At the very least our research will raise the question as to whether some significant association between childhood experience and adult outcome ought not to be suspected.

Conclusion

Our plan of analysis is therefore laid out for us. To probe into the sources of support for the regime structure, we seek to learn about the way in which children make their early contacts with the political system, especially for that part of it that we call the structure of authority. On general theoretical grounds we see this as a central phenomenon in any political system if some set of processes for making and implementing political decisions is to persist.

To detect, document and understand the significance of the precise way in which children reach out to the authorities we need to discover those figures and institutions of political authority that the child first sees and the way he sees them and feels about them. In this way we shall be able to arrive at some judgment about how diffuse support for the political authorities in one system, the United States, emerges and perhaps begins to take the form it does. It will give us an empirical purchase on a difficult and amorphous concept in political inquiry, that of legitimacy. Those who are learning to support the structure of authority (negatively or positively) are also beginning to establish some attitudes towards its legitimacy. A sense of legitimacy, in turn, represents a major mechanism through which the political authorities in most systems are able to stimulate support for the regime.

It has become apparent by this time that throughout our analysis we shall be adopting an important assumption about the consequences of early socialization. This premise is that to the extent that children

begin to develop positively supportive feelings towards the political authorities, they will tend to grow into adults whose attachment to the system will be less easily undermined than for those who early acquire negative, hostile sentiments.

We would not contend that this durability attaches to all political acquisitions in childhood. We have already suggested that in areas related to allocative politics, there may well be a different kind of outcome. Early political acquisitions here may only be selectively consequential for adult behavior. But for those subject matters that deal with the basic political objects, embraced in our notion of system politics, we shall presume that perceptions and feelings formed early in life are most difficult to dislodge than those of later life. They are likely to remain as underlying latent sentiments that can be evoked in later years, under the proper circumstances, either on behalf of or in opposition to the basic political objects, depending upon their initial direction. Alienation may be as durable over the years as identification.

Not that early images will necessarily withstand the onslaught of all future events. Childhood events may be diluted and overriden by subsequent experiences. All we would contend is that basic childhood sentiments are less easily dislodged and modified than those acquired later in life.

As we have already observed, this is an hypothesis that is supported mainly by a vast body of folklore but with extraordinarily little hard research. "Most psychologists and social scientists agree", it has been said, "that there is a special significance attached to first or early learning. There is good evidence for this assumption. What we do not know, are unable to discover from the culture-personality [or other sources], is what precisely it is that is learned in early infancy and what its exact significance may be for later learning. As D.O. Hebb tersely remarks: 'In such matters, our ignorance is virtually complete'".[11] Yet unreliable tests demonstrate otherwise in the political sphere; it seems to make sense to stand by this hypothesis as it applies to basic sentiments about the structure of political theory.

PART III

IMAGES ABOUT THE STRUCTURE OF AUTHORITY

Chapter VI

THE IMAGE OF GOVERNMENT

If on impressionistic grounds we had been called upon to ad-
vance an opinion about the candidates likely to act as concrete points
of contact between the political system and children, we might have
expected to find them in those figures that are prestigious and salient
for adults, such as the President, Senators, and perhaps even justices
of the Supreme Court, at the very least. Without a monarch in the
United States who might have stood out as a single and major honorific
symbol, it would not be far-fetched to consider that figures such as
these step into the breach. We shall observe later that to some ex-
tent they in fact do, and this is especially true of the President.
But it would not have been likely to occur to us that the mundane
idea of government itself might somehow also take over part of the
function that a highly prestigious, sometimes neutral figure such as
a monarch may play in other systems.

Yet our data tell us that in the American political system
most children in our group do acquire an overview of the structure of
authority, and at a very early stage. They achieve it through an
ability to handle the idea of government and to give it some kind of
concrete meaning. It is here that we find one of the first and major
points of contact between children and the regime. It is certainly
the only one that comes at all close to the theoretical notion of a
structure or pattern of authority.

That the child may come very early to some ideas about govern-
ment as symbol or substance has marked theoretical as well as empirical
significance for his developing relationship with the system. If the
child were only to apprehend the political authorities one by one, it
would be difficult for him to arrive at the point where he could even
visualize, much less articulate, some overall structure of which the
authorities are part. To the extent that this area of political life
remained structureless for him and fragmented, he would be linked to
the political system only through individual strands connecting with
specific figures of authority. The child would have little initial
sense of an enduring structure of authority that encompassed more than
a summation of the individual authority figures familiar to him.

Furthermore, without some generalized conception of authority
to which to relate himself, it is difficult to imagine how a child
would incorporate into his developing cognitive image any new politi-
cal figure or institution about which he learned or that was created
as he matured. In effect we would expect that as he became aware of
new political figures, he would have to be persuaded of their legiti-
macy on an ad hoc basis. He could not be expected to assimilate them
to an existing perceived pattern of authority, automatically attribut-
ing to the new figures or institutions the same kind of legitimacy as
he extended to the whole existing configuration of authorities. We
are not prepared to say that the idea of government does in fact pro-
vide the child with a general intellective container, as it were,

into which he can put each new object of authority. But we shall see that at the very least it does serve to generalize his limited experiences with or perceptions of discrete political authorities.

The theoretical implications of a conception of government therefore are considerable. It would seem to provide the child with a conceptual device for grasping, however inchoately and awkwardly, the presence of some structure of authority.

The Child's Early Recognition of Government

Crystallization of the concept "government"

When do our respondents first begin to recognize the general category of things labeled "government"? One simple way of exploring this is to see whether the child himself thinks he knows what the word "government" means, even if no verbalization of his understanding is called for. On this simple test we find that even the seven- and eight-year old child, in grade 2, is likely to feel that he has attained some rudimentary grasp of this general concept.

From the simple data presented in Table VI.1 we find that 27 per cent of the second-grade children feel some uncertainty about the concept. This proportion declines rather regularly over the grades, however, so that for the eighth-grade children, only 10 per cent express this uncertainty. In general, these data suggest that a considerable portion of the youngest children felt it had already crystallized some concept of government prior to our testing. With each higher grade level the likelihood that the children did not feel they had formed some concept decreases. With these data--and similar data from other protocols--as a background, it is plausible for us to proceed to a more detailed consideration of the content of the child's understanding of government.

Symbolic associations of the concept "government"

As it appears that the child is rather likely to develop some working conception of government in these early years, we can move on to ask: Is there any specific content to this concept, especially of a kind that is political in character? We might well expect that because of the inherent ambiguity and generality of the term, even for adults, considerable differences and disjunctiveness would characterize it for aggregates of children. Our findings do, in part, support this expectation. Yet there are clearly some dominant patterns in these collective conceptions, and these patterns vary to a large degree with the age and grade level of the children.

To get fairly directly at the dominant patterns in this period and at the way in which they change, we devised a pictorial representation of government. It took the form of t(eh) ten symbols as shown in Figure VI.1. These symbols emerged distinctively in our pre-test data when children were asked either to define government or to free associate with a list of words, one of which was government.

Table VI.1. Development of a Sense of Confidence in Understanding the Concept of Government: Percent at Each Grade Who Mark That They Are Not Sure What Government Means.[a]

Grade	%	(N)
2	27	(1655)
3	19	(1678)
4	18	(1749)
5	11	(1803)
6	12	(1749)
7	8	(1723)
8	10	(1695)

[a]CA-9, page 12, item 55. "Some of you may not be sure what the word government means. If you are not sure what government means, put an X in the box below."

Figure VI.1.   CA-9 Questionnaire Item #24, Page 4.

Here are some pictures that show what our government is.   Pick the two pictures that
show best what our government is.
1. [ ] POLICEMAN   2. [ ] WASHINGTON   3. [ ] UNCLE SAM   4. [ ] VOTING
5. [ ] SUPREME COURT

6. [ ] CAPITOL
7. [ ] CONGRESS
8. [ ] FLAG   9. [ ] STATUE OF LIBERTY   X. [ ] PRESIDENT   Y. [ ] I DON'T KNOW

The pattern of response to these ten symbols is shown in Table VI.2. Several interesting facts are suggested. If we take 20 per cent as a rough guide to what we might expect purely by chance as a maximum level of response to each of the ten symbol options (for two-answer format), we see that only four of these pictures were chosen with a frequency greater than chance. These four were George Washington, Voting, Congress, and President Kennedy. These are selected with considerably greater frequency than any of the others, but this dominance varies by grade level. For the youngest children, the two most popular options are the two Presidents, Washington and Kennedy. But these choices drop in the later grades. In Figure VI.2, the developmental curves for the four dominant options are plotted over the grade span in order to interpret more easily the major changes that are taking place.

It would appear that, in terms of these symbols, the youngest child's perception of government is quite likely to be framed by the few personal figures of high governmental authority that cross his cognitive horizon, probably both in the school (where the portraits of presidents are often prominently displayed) and outside. The young child focuses most directly upon personal or perhaps "charismatic" aspects of the political authorities for his interpretation of what government is. But as he moves into the middle years, there is a greater likelihood that his attention will be turned to rather different, prominent aspects of the authorities. Thus he revises his notions to include the Congress and drops George Washington—who suffers a precipitous decline after his initial showing.

Undoubtedly, the growing adoption of Congress reflects an awareness of several things, and these are supported by various other data. First, the older children become more aware of the goup character of government rather than simply identify it with single persons. Second, the more frequent choice of Congress probably also reflects a greater awareness of governmental institutions—particularly the on-going organizations engaged in law-making (as suggested undoubtedly in the beginning social studies, history, or civics texts). Children move from a very personalized conception of governmental authority to one that emphasizes the "legal-rational", institutionalized aspects, to continue the Weberian parallel. We may characterize this more generally as a shift from a personal l to an impersonal image of government.

Third, children appear to reflect a greater awareness of the representative character of these institutions. Impersonalization of authority is coincident with some growth in the recognition of regime norms, in this case of the rules of behavior that contribute to representation. This conclusion is borne out to some degree by the marked age shift which occurs as represented by the older child's greater tendency to pick "voting" as the best picture of our government. By grade eight nearly half the children choose voting. This suggests some beginning awareness of the regime rules associated with popular democracy and the expected role of ordinary people in it.

The child's conception of government is, therefore, brought in stages from far to near, from one small set of persons to many

93

Table VI.2. Development of a Cognitive Image of Government: Symbolic Associations[a]

(percent of children and teachers responding)[b]

Grade	Police-man	George Wash-ington	Uncle Sam	Voting	Supreme Court	Capitol	Congress	Flag	Statue of Liberty	Presi-dent Kennedy	Don't Know	N Re-sponding	N Not Responding
Grade 2	8 %	39	16	4	5	14	6	16	12	46	16 %	1619	36

[a] CA-9, page 4, item 24: "Here are some pictures that show what our government is. Pick the two pictures that show best what our government is."

[a] Percentages should add to 200 in the two-answer format, but do not, because of the failure of some children to make two choices; this is especially the case for those answering "I don't know." We have added, at the bottom, the responses of the teachers of these children, for the sake of comparison; the teachers were given a similar questionnaire at the time of administration of the children's questionnaire.

Percent

level varies from 1619 to 1789)

95

people, from a personalistic to an impersonalized form of authority, and toward an awareness of the institutionalization in our system of such regime norms as are embodied in the idea of a representative, popular democracy. Not that all of these children are going through these stages of cognitive development.[1] But the patterns which emerge seem very striking and they are supported in various ways from our other data.

Generally, therefore, in these data about the cognitive development of this rather abstract category of the individual's political thought, we detect more than a mere glimmering of a concept. Furthermore, the mergent conception in this instance reflects some fairly wide and regularly changing comprehension for aggregates of children.

This suggests that society is probably expending considerable energy in an effort to transmit a concept deemed appropriate in the American political system. If we compare children with their teachers, for example, (Table VI.2) we find that the latter most roundly endorses the two options dominant for the eight-grade children. The proportions are even higher for the teachers, however, so that in terms of the statistical norms, they stand perhaps closer to the end-state suggested by the direction of movement of the children. Thus the teachers --who may be important agents contributing to the child's political and general conceptual development--have a concept that is in line with the child's apparent maturational tendencies. One could hypothesize, therefore, that a part of society's efforts to inform the child is reflected in the teacher's responses.

The concept of government and the lawmaking function

A supporting piece of evidence which is connected to the general pattern of development just described, but supplements it from the standpoint of governmental functions (rather than from the structural aspects of the concept alone), has to do with the child's changing awareness of the chief law-makers in our system of government. One thing we found was that, of the various kinds of political or other functions that the child most readily associates with government, the making of laws is very prominent. When the child is asked, "What does the government do?", he is quite likely to answer that he, it, or they make the laws. In one instance, Patrick, age 8, son of a truck driver and loader, and in third grade at a Chicago area school, when asked in a personal interview, "What is government?", replied: "It's like governor. It keeps all the laws." In the same vein, but at a little older age, Andrew, 10, son of a commercial photographer and in fifth grade in the Chicago area, replied: "That's where they make the law, pass it on, and give it to the Supreme Court, then to the President, and then it is passed on to us and it--well, we are supposed to abide by it."

We could use this transparent awareness of the law-making activity to probe further into the child's image of government. A questionnaire item that we presented in this connection read: "Who makes the laws? Put an X next to the one who does the most to make the

laws." The options were: (1) Congress, (2) President, (3) Supreme
Court, (4) I don't know. The same pictures as before were used. In
Table VI.3 we see the patterns of change over the grade span for this
aspect of the child's understanding.

Here the President's early dominance is apparent, but Congress
gradually supplants him by grade 5. Thus, by the middle grades the
child is both increasingly prone to identify Congress as the chief
source of law-making as well as a more representative symbol of our
government than the President.

If this trend should continue into adulthood, we would expect
considerable support for Congress as the primary institution of govern-
ment vis-à-vis the President. We would expect that, of the opposing
observations of Max Lerner and Robert Lane, for example, those of Lane
would be given greater credence. Lerner observed (as cited by Lane)
that "When the American thinks of his government, he thinks first of
the President as its symbol."[2] If "first" means while he is a second
or third grader, then Lerner is correct. But this does appear to be
the sense in which he is using the word.

In light of the developmental trends we see in our data, our
respondents seem to resemble more closely the "common men" in Lane's
Eastport study. Lane found that his respondents were more likely to
perceive government in terms of its legislative functions than its
administrative or judicial ones.[3] Government is thought of in terms
of its products, the laws it makes.[4] As far as the common men in
Eastport were concerned, Congress was the most important focus of
their concept of government. These subjects consider government and
Congress as benign, helpful, and responsive—an organization "work-
ing for the people, not merely restraining them".[5]

All of these findings converge with our data as far as the
developmental trends are concerned. The oldest children in our test
group are those who most resemble the common men of Eastport. One
can therefore interpret what we find as an indication that this image
of government is not confined to the period of Lane's study but seems
to have more general application. Our respondents tend over the grades
toward the adoption of a vision of government which puts great empha-
sis upon Congress as the center of government, upon law as its most
visible product, and upon benign, helpful, protective, and responsive
qualities as those most appropriately describing its manner of opera-
tion. The latter, more affective part of their image will be discussed
shortly after we present some further findings on their cognitive de-
velopment.

A further item bears out this emphasis that the child gives
to Congress in his conception of government. In our final instrument
we asked our test group in the eight cities "Who does most to run the
country?". This emphasis on executive activity is not as salient in
the child's conception of government as is the law-making function.
Nevertheless it is an important subsidiary one. As one ten year old
child from fifth grade in a Chicago suburban school put it in reply
to our question, "What is government?": "A group of people that make

Table VI.3. Development of an Awareness of the Chief Law-Maker[a]

(percent of children and teachers responding)

98

the rules and sort of in charge of what's going on but not completely
in control in the United States."

Table VI.4 indicates that among the options provided, the
President is selected with highest frequency. Yet even in this ques-
tion Congress moves from 4% at grade 2 to 35% by grade 8. We also
need to note that the movement is in the direction of the collective
opinion levels of the teachers, 61% of whom pick Congress.

This question strongly hints at an executive rather than a
legislative activity of government. Yet even with this emphasis,
Congress develops considerable strength in these years in the cogni-
tive map of government, in comparison with the President.

Differentiation of the public sector

Even though the children assert a growing awareness of govern-
ment as an idea and object, are they, in fact, able to distinguish it
as a sphere separate from other areas of social life? If attitudes
towards the authorities as an object are to have relevance for later
ties to the system, we need some evidence indicating that even in their
earliest grades children are, in fact, able to recognize some minimal
difference between that which is governmental and that which is not.
Only under such conditions could we infer that attitudes towards govern-
ment--to which we shall turn in a moment--refer to distinctively politi-
cal bonds.

To discover whether the child's declared knowledge of what
government means includes a capacity to discriminate governmental
from nongovernmental objects, we chose to test his awareness of the
difference between what we normally view as the public and private
sectors of life. A variety of contexts could be used to explore this
differentiation--activities of various kinds, organizations, symbols,
or personnel. We have chosen the last for our test because we found
that the formulation, "people who do various jobs to help the communi-
ty", is a rather familiar context for the child who has been exposed
to the beginning social studies texts. The child learns that a var-
iety of "community helpers" exist, ranging from doctors and nurses
to firemen and street sweepers.

What we asked was very simple. Taking various occupations--
milkman, policeman, soldier, judge, postman, and teacher--we said:
"Here are some people. Which ones work for the government?" Then
followed six questions with an appropriate picture for each such as:
"Does the MILKMAN work for the government?". The options were: (1)
Yes, (2) No.

Only the first of these people was considered by us to be
clearly outside the governmental system as determined by his occupa-
tion.[6] Of the rest, two were more directly local government workers
--the policeman and the teacher; two were clearly national govern-
ment workers--the soldier and the postman; and one was indeterminate
as among levels--the judge.

99

101

Several things are apparent from Table VI.5. Of these workers, the milkman is the one (as we would expect) who is least often identified as a member of the public sector. Around 70 per cent of the youngest children were able to make an accurate assessment of his nongovernmental status. From grade 4 on, this proportion steadily increased so that by grade 8, less than 10 per cent were in error.

For the rest, the youngest children most easily recognized that the policeman and the judge belong in the governmental sector. Then come the soldier, postman, and teacher in that order. Both the soldier and postman—the more nearly exclusively national government workers—increase in the proportions of children endorsing them at successively higher grade levels, until, by grade 8, they are the ones who, with the judge, get the greatest governmental identification.

The teacher, on the other hand, does not really make any major gains over the grades; her governmental status remains somewhat ambiguous. This effect holds for the teacher respondents as well. Somehow the status of the teacher is a more complex one.

That something else is probably at work in the children is seen when we compare their perceptions of the teacher and the policeman—both local-governmental in status with the other figures. Over the grades both teacher and policeman suffer some net decline in the proportions of children endorsing their governmental status while the other government workers show gains. Possibly the older child is more likely to direct his attention to the national level of his image of government, and, therefore, his differentiation is conflicted for local government workers. This would fit other somewhat similar findings about the child's greater awareness of the national than of the lower levels of government.[7] It also explains the markedly lower percentage of teachers who identify policemen and teachers as working for the government.

In general, the child is his elementary years attains the capacity to differentiate the governmental sector of behavior from the nongovernmental. This does not mean that he is able to do so in every conceivable way. Our data suggest only that he is increasingly able to do this for the personnel of government. His concept of government, therefore, does become a differentiated one, at least in these terms. Again, this suggests a development beyond that of only a rudimentary grasp of this complex object in these early years of political awareness.

There is thus sufficient content in the child's perception of government for us to have some confidence that when we now come to talk about his attitudes toward this object, it will reflect affect towards genuinely political (that is, public) authorities. It will also prove significant for our interpretation that there is even a tendency to think of government at the national rather than at the local level.

102

Views of the informal processes of government

It is apparent that as the children in our test group acquire some understanding of government, they see it largely in what as adults we would conceive to be formal terms. They see those roles that have official recognition in the American political system. These are well-defined offices for which requirements and behavior are formally prescribed.

That the child should become familiar with this aspect of the structure of political authority accords well with the more general theory of socialization already mentioned. It holds that adults tend to communicate the formal, recognized structure first.[8] According to this theory only as children grow older would adults feel that they are equipped to understand and appreciate the other things that go in a structure, what in social science we recognize as the important informal processes and infrastructures through which the business of a group gets done.

Our data would seem to bear out this general hypothesis. However it is not at all clear that the children acquire absolutely no knowledge about the informal areas of politics. At least for the overall structure of authority, we do have some evidence that the image gradually building up in the child's mind, about which he is beginning to develop feelings, also includes some discernible informal aspects. It is true, our pretest data suggested that this aspect of governmental awareness was relatively low in these early years. As a result, we found it difficult to devise instruments to tap the properties of the small degree of awareness likely to be present. Nevertheless we were able to detect some of the earliest beginnings of the informal parts of the image, if only from the fourth grade onwards.[9]

We had the child rate various people in the extent to which they helped to make laws for the country. We asked: "How much do these people help decide which laws are made for our country? Very much, Some, Very Little, or Not at All? Put an X for each person or group of persons listed below." We included: rich people, unions, the President, newspapers, churches, the Average Person, Policeman, and Big Companies. We hoped to get some overall assessment of the child's relative awareness of participation by these various actors in the processes of government. The way these actors lined up over the grades in the child's perception is in Table VI.6

The children who responded to these items are clearly willing to assess the relative influence of these political actors differently and there are marked age trends for some of them. The President is far and away the actor of most importance in the law-making process, according to the child's perception. We might have suspected this from our knowledge of the child's previous emphasis on the formal aspects of government. This assessment remains high across the grades. At a considerable distance are various extragovernmental groups and strata, parts of the political infrastructure—rich people, unions, big companies, newspapers, and churches. Of these unions (which were

read out the children as "labor union") evoke the greatest image of influence for these urban children, and from the earliest grades.

Policemen, the other official government actors, do well at first, but quickly decline as participants in the law-making process. The child in this instance moves away from an over-estimation of the role of policemen and thus towards the distribution exhibited by their teachers.

The interpretation of the average person's role is below that of the groups, strata and official actors yet it does show again just at the end of the period. Thus, there is some movement on this item toward a greater assessment of the weight of the individual in the political process.

On most of these items, the teachers (who perhaps represent the adult view here) are at some distance from the child. They slightly devalue the role of the President, policeman, and churches compared to the children's aggregate judgment, but the children are moving in their direction. For the other actors, the teachers are somewhat more inclined, as a group, to rate them higher in their level of participation. The teachers' awareness of the role of interest groups such as big companies, opinion leaders such as newspapers, and more heavily weighted social strata like "rich people" is higher and perhaps closer to the one professional students of politics would endorse. The children would seemingly have some distance to go, therefore, in the development of an image of government which includes informal, group-related actors and the informal dimensions of American government. At least this is suggested by these somewhat indirect data.

In spite of this only partial realization of the existence of a political infrastructure there is some sorting out of the informal actors in these years, even if the process looks as though it may be one still subject to considerable later development. The President, as chief individual actor in the system, gets a very high rating and is clearly set off from the others. The child is thus acutely aware of the role of formal authorities. To this extent, the child has a developed orientation. The other informal actors are not greatly differentiated and all are allocated some influence. Thus the children's second major orientation seems to be one which sees political influence as diffuse, even if some actors are accorded slightly more influence than others. The children seem to lack, however, a third element which is more likely to present for the teachers. This is a relatively heavier weighting of some of these actors, such as unions, big companies and newspapers. But it is clear that in reacting to government as a political object the child has begun to pick up a few hints that its actions may not be entirely accounted for by the behavior of the President or other formal authorities alone.

Summary of the child's developing cognitive image

As a possible object toward which affect might be directed, the idea of government undergoes far-reaching changes in the cognitive development of the child in our test group. As he passes through grades

two to eight, he begins with a rudimentary notion in which government
is personal in character, represented by a few high-ranking and visible
leaders. But as he grows older, the child sees government in less
personal terms. He becomes increasingly aware of its group character
and its major institutions; he learns something about the norms (vot-
ing) of a representative and popular democracy. In addition, it is
crucial that the child proves increasingly able to identify govern-
ment as something that is different from the private sector of life,
however the latter may be defined in different epochs of society.
All of these perceptions suggest that, aside from any feelings that
may be associated with government, the efforts by society to convey
some representation of this abstract object are by no means in vain.
Most children in our group are not devoid of some conception about
an overall structure of authority by the time they leave elementary
school. Indeed they even begin to discern the far more subtle infor-
mal influences at work on the authorities, in only as through a glass
darkly.

The Child's Affective Response to Government

Although analytically we are able to separate the cognitive
aspects of the image of government from accompanying feelings towards
it, empirically they go hand in hand. For an understanding of the way
in which the American political system stimulates diffuse support for
the structure of authority it is critical to appreciate the fact that
from the very beginning of his awareness--at its most rudimentary
stage--the child interprets government as something provided to fur-
ther his welfare and that of the people around him. The benevolent,
protective, helpful, and otherwise positive qualities of government
constitute the first and continuing overall context of evaluation.
Even at the end of this period--when the child is thirteen or fourteen
years of age, and government and individual authorities, such as the
President and the policeman, are beginning to be seen less ideally--
the child still regards them as great blessings, if slightly mixed
ones.

The child thus continues to endorse government even though
what he understands it to be is changing. Having started off his
evaluation in highly positive terms, he seems reluctant to give it
up. In this we see, perhaps, the early formation of a bond that is
hard to loosen. It is a bond that may predispose the future adult
to extend diffuse support for the governmental system, assuming no
major deflective experiences.

The child's approval of government's role

In our pilot data we found such a uniformly favorable affec-
tive image of government, from the earliest grades onward, that we
felt no special large-scale effort was necessary in our final instru-
ment to demonstrate this sentiment. For example, in our early inter-
views and open-ended test questions, we found this feeling in state-
ments ranging from "Government is a good man" or "Government is love"

to "He [government] is a man that helps people when they are in need. He gets the taxes to help the people with. He sees that everything is all right in the United States."

But we do have some more systematic data from our eight cities which bear upon the question. First, however, we shall present a few examples of our considerable body of pilot data to show how highly consensual our younger children's approval of government is over the whole grade range.

In an instrumental administered in the Chicago area, we proposed that the children either agree or disagree with statements such as these:

1. "The government is getting too big for America."

2. "The government meddles too much in our private lives."

3. "The government has too much power."

4. "The United States government usually knows what is best for the people."

5. "The government ought to give money and food to people out of work."

6. "The government should have more power over the people."[10]

We attempted as far as possible to retain the original wording of statements of children from our pretest interviews—but reversing the items in several cases. The patterns of response to these statements are shown in Table VI.7.

We see that children at all of these grade levels roundly approve of government. They reject, at a fairly high level of agreement (75 per cent or more), the first three statements about the scope of government becoming too large. States 4 and 5, on the other hand, reflect approval of the role of government in guiding and caring for the people, and these statements elicit a high level of agreement. Only for the last statement do we see any impetus toward restricting the role of government; the children like it the way it is.

The overall response in one which is better characterized as a collectivist endorsement than individualistic disapproval of our restraint about government. In spite of the great myth of rugged individualism which is presumed to pervade the American consciousness, these children, at least, seem to be inclined toward the opposite kind of feeling about government. The government knows what is best and ought to care for the less fortunate (as so one's parents for members of the family, we may infer). The child as revealed in this limited test is inclined to see government as wise and succorant. He begins as something of a natural collectivist, and whatever individualistic tendencies he may exhibit are developed later on.

8	11	(149)	14	(148)	15	(147)	84	(147)	77	(145)	19	(145)

[a]These questions are from one of our pilot questionnaires, "In My Opinion, # III," items 50, 125, 169, 170, and 151, respectively.

The sixth item suggests, moreover, that the child is likely to be a "conservative collectivist" in that he is not much in favor of extending the scope of government beyond what he sees as its present limits. He is rather happy with government as it stands and would not give it "more power over the people."

Thus, these and other pretest data revealed that the child's early contentment with government is fairly complete. He exhibits a high acceptance of government as a given, necessary part of the natural environment. If the child is to develop discontent and a desire for change, it is undoubtedly yet to be learned. But it will be overlaid upon an early base of high regard for the government.

The child's rating of government's qualities

The same early positive regard for the government is shown, as well, over a larger group of respondents in some ratings of the government in our final eight cities questionnaire. Using five role attributes and qualities of government as descriptions, we asked the children in grades 4 through 8 to "think of the Government as it really is." The items read as follows:

Think of the *Government* as it really is . . . (Circle the number of your choice) α

1	2	3	4	5	6
Almost never makes mistakes	Rarely makes mistakes	Sometimes makes mistakes	Often makes mistakes	Usually makes mistakes	Almost always makes mistakes

1	2	3	4	5	6
Would always want to help me if I needed it	Would almost always want to help me if I needed it	Would usually want to help me if I needed it	Would sometimes want to help me if I needed it	Would seldom want to help me if I needed it	Would not usually want to help me if I needed it

1	2	3	4	5	6
Makes important decisions all the time	Makes important decisions a lot of the time	Makes important decisions sometimes	Makes important decisions seldom	Almost never makes important decisions	Never makes important decisions

1	2	3	4	5	6
Knows more than anyone	Knows more than most people	Knows more than many people	Knows less than many people	Knows less than most people	Knows less than anyone

[a]CA-9, p.31. items 32-36.

A full explanation of why we used these ratings for unearthing the child's assessment of the government, as well as of specific authorities, will be presented at a later point.[11] Suffice it to say here that within the limits of testing time and the conceptual capacity of the

110

maturing child as revealed through extensive analysis of pretest data, these ratings were selected. Each represented a class of attributes in terms of which children were capable of thinking about the role of these political objects. Thus for role attributes, the item "almost never makes mistakes" refers to the culturally approved virtue of infallibility, "makes important decisions all the time" and "knows more than anyone" to expected leadership qualities, "can punish anyone" to perceived power (even though the word political power is not yet in the child's vocabulary), and "would always want to help me if I needed it" to benevolence, a succorrant-related property.[12]

Each of these ratings represents characteristics of which our culture normally approves. To be close to infallible (make few mistakes), to be succorrant in case of need (helps if needed), to display qualities of leadership (make important decisions and to be more knowledgeable), and to exert power (can punish, revealed as a good indicator of power through pretest data), are all qualities held in high regard by our culture, especially for those seen to be in a superior status. Hence to judge a person or object as high on rating scales pertaining to these qualities gives us a plausible if indirect measure of the degree of approval.[13] This is the way in which we shall interpret the child's evaluation of government on these characteristics.

On these premises, it is clear that children have considerable respect for the leadership role that they see government as playing. They rank it high on making important decisions, with the mean moving from 1.87 to 1.51 over the grades. Some ratings, both for government and, as we shall see later, for specific authority figures, drop off with age. But unlike these, the assessment of government on this leadership quality moves in the opposite direction. It suggests that the child comes to place increasing importance on the role of the government in the country. By grade 8, the percentage that sees government as making important decisions, all the time, rises from an initial low of 35% to 58%, the largest increment in any of the extremes on our government scales.

In addition, the older the children grow, the more likely are they to believe that government has greater knowledge than many people, coming close (for the mean) to knowing more than most. 59% at grade 4 would say that government has more knowledge than anyone or most people and this increases to 73% by grade 8. The mean rating rises from 2.37 to 2.15 across the grades.

Similarly, if we accept the child's perception of the capacity of government to punish as a rough indicator of his view of the government's general power, at the same time as the children conceive of the government as playing an increasingly significant leadership role, they consider that it has a growing power to do so. The mean rating of the government's capacity to punish, increases from 2.94 to 2.50, with 57% of our eighth graders alone considering that the government can punish anyone or almost anyone.[14]

Aside from any other meaning that these three ratings convey, the ability to make important decisions, knowledgeability, and the

possession of power are themselves valued properties in our culture.
At grade 4 most children already have a high estimate of the govern-
ment on these qualities. The fact that the older the children, the
more likely are they to see government as improving along these lines
would suggest a parallel growth in the respect with which government
is held.

When we now add the last two scales we can appreciate the
unusually high positive affect with which children contemplate govern-
ment. We interpreted the rating "makes mistakes" as offering an esti-
mate of dependability, or specifically of degrees of infallibility,
if we may be permitted the grammatical misdemeanor of scaling an ab-
solute. "Would want to help me if I needed it" we adopted as an in-
dex of the child's view of the responsive benevolence of government
and therefore as an indication of his trust in it. Although, unlike
the three characteristics just dealt with, assessment of both these
qualities shows some decline with age, they nevertheless do elicit a
high regard for government, in absolute terms, over the whole span of
grades.

Most children in our group, in each grade, see the government
as being virtually infallible. The youngest wear the rosiest colored
glasses and report that the government rarely makes mistakes, with a
mean rating of 2.02. Although the eldest children, in grade 8, lose
some of this rosy tint, they still are close to contending that the
government rarely makes mistakes, dropping only to a mean rating of
2.31. Even at this grade 59% still believe that the government almost
never or rarely makes mistakes, a rare kind of response about anybody
from the 13 or 14 year old with his growing skepticism or worldly
awareness. Confidence in the government's wisdom is amazingly high
for this age group.

Of all our items about government, "would want to help me"
is undoubtedly the least indirect measure of affect. It reflects the
child's conception of the concern that government has for him, especial-
ly in time of need. As we might expect, with a growing sense of in-
dependence, the older child would be less likely to express likely to
express any need for help from others. This is confirmed in the de-
cline of the mean rating from 2.47 to 2.81. Nevertheless the absolute
level, even for the eighth graders, remains fairly high. The percen-
tage of those who see government as always or almost always helpful,
a strong expression of the expectation that government will respond
in time of need, ranges from 57% at grade 4 to 42% at grade 8.

What significance, however, can we attach to the fact that
as the ratings of the performance items--leadership, power and know-
ledgeability--increase across the grades, the most affect-laden item,
dealing with succorrance and responsiveness, declines (Figure VI.3)?
Does this mean that the child is changing his relationship to govern-
ment from one based largely on generalized favorable sentiments to one
in which he just learns to judge its capacities to perform well in
various ways, a kind of efficiency rating?

115

As children mature they are increasingly able to differentiate qualities in the objects they see. We would therefore expect them to be able to make finer discrimination among the characteristics of the government. This is an essential part of growing up. But the fact that at the same time their least indirect expression of affect for the government, in our succorance rating, falls off, need not necessarily be interpreted as evidence that the child's attachment to or affection for government is also receding. Other things may be happening.

In the first place, the child may be responding faithfully to perceptions of reality. He may begin to see that government is not always at the beck and call of the members of society. The shift in the mean rating towards the somewhat less helpful points on the scale would reflect this.

In the second place, the child's sentiments may also be undergoing a transformation in the way they are expressed. This interpretation would fit consistently with what we already know about the cognitive aspects of the child's image. As he grows older the child sees government in more impersonal terms, as institutions rather than people. It seems plausible to infer that this too would inhibit the expression of the kind of sentiment normally reserved for people, such as that of seeing them as wanting to be helpful in case of need. But at the same time as the child depersonalizes his image of government, he does come to believe that government has more and more of the culturally approved capacities to do its job, such as leadership, power and knowledge. These ratings are in themselves clear expressions of confidence and trust in government. It would seem, therefore, that even though the level of response to the one specifically affect-laden item, "would want to help", drops off with age, this need not signal a parallel decline in the level of the child's attachment to government. What may be changing is only the child's mode for displaying his feelings. As the child grows older he becomes more reticent about expressions of emotions and more capable of detecting specific performance qualities. Positive sentiment is more likely to be revealed indirectly in his high estimate of the government's capacities to perform its roles than in measures that seek to test affect more directly.

The conclusion that we draw, therefore, is that the child's affect begins high and does not diminish but actually increases with age, as he learns more about the political world. Whatever later modifications and limits he may come to put upon his trust and approval, he does begin life with considerable sympathy for the government.

Conclusion

The findings which grow out of this analysis will, perhaps, surprise those readers who are accustomed to think of children as innocent of political thought. For not only does the child quite early begin to orient himself to the rather remote and mystical world of politics, but he even forms notions about its most abstract parts—such as government in general. The political marks on the tabula rasa are entered early and are continuously refurbished thereafter.

We will, perhaps, disappoint as well those readers who are accustomed to think of the American as one who is brought up on the raw meat of rugged individualism, which supposedly nourishes our national frame. We find that the small child sees a vision of holiness when he chances to glance in the direction of government—a sanctity and rightness of the demigoddess who dispenses the milk of human kindness. The government protects us, helps us, is good, and cares for us when we are in need, answer most children.

When the child emerges from his state of political innocence, therefore, he finds himself a part of a going political concern which he ordinarily adopts immediately as a source of nurturance and protention. His early experience of government is analogous to his early experinece of the family in that it involves an initial context of highly acceptable dependency.[15] Against this strongly positive affective background the child devises and revises his cognitive image of government.

If a political system is to persist, it must somehow seek to provoke a flow of information about and continuously create feelings about its basic forms. One of these is its general structure of authority. Although we typically do not think of the concept "government" in this way, it turns out to be a major device for introducing [16] and orienting the child to structural aspects of the political system. It is a stable term of reference for a system in which the occupants of leading authority roles may change frequently. Government thus appears as a primary focus for the generation of politically supportive (or disaffective) orientations.

To maintain a social construct as varied, extensive and demanding of social resources as government, a broad panoply of forces probably needs to be set in motion. The political socialization of new members is undoubtedly one of the most far-reaching and most consequential of these forces.

Our data suggest that in the United States a positively supportive image of the general structure of authority is being widely and regularly reproduced for young new members. The average grade school child of our test group appears to experience some rather basic changes in his conception of government—changes which move him toward a cognitive image that harmonizes with adult formal conceptions of the American democratic political system.

He begins, as a "political primitive", with a vision of government as the embodiments of a man or a small set of men who constitute a yet dimly recognized form of external authority. This authority applies to the immediate environment of the child in a rather abstract way as well as to the wider world beyond. Probably one of the first recognizable shadows that flickers across the wall of the cave of the child's unformed political mind is that of the President. He forms an initial visible image of the political world, and around the President the child builds a political world, gradually incorporating more and more objects until his political image becomes rounded and complex.

117

The child, moving toward a plural, complex, conception of government (as our later chapters will continue to show) runs upon representative and popular institutions. He raises Congress and voting in his mind's eye to positions of dominance as symbolic associations and thus unwittingly elicits democracy in his interpretation of what his government is. At the same time, he is beginning to sharpen his knowledge about the boundaries of government by sorting what is outside the realm of government from what is within it.

This finally adds up to a picture supportive of the American democratic regime, a picture that becomes rapidly and forcefully exhibited in these years, as other data, not fully reported as yet,[17] confirm. The child is initiated into a supportive stance by what is probably high exposure to cues and messages about government, even while he is essentially unconcerned with such matters and too young to do much about them even if he wished. He learns to like the government before he really knows what it is. And as he learns what it is, he finds that it involves popular participation (voting) and that this is a valuable part of its countenance. It is further reason for liking it; and liking it is what the child continues to do. The child has somehow formed a deep sympathy for government even before he knows that he is in some way potentially part of it.

We know of course that such a process of changing understanding and feeling must go beyond these early years. Later experiences may also upset these earlier formed images. It could be, for example, that during the 1960's, the generational impact of the Vietnam war, racial conflict and urban deterioration and poverty are slowly nibbling away at the expected level of support input from many sections of the adult population.[18] Yet from what little direct evidence there is about support for government per se, we can surmise that typically adult Americans have also been highly supportive of their government.[19] In these exploratory data that we have presented, we think we see growing the deep roots of this past supportive sentiment.

Furthermore, our data enable us to link up our discussion of the cognitive and affective aspects of the child's image of government, at least in a speculative way. Two things stand out in our data. First, the child begins with a view of government as composed of palpable, visible persons--such as the President or a past president, Washington. Second, as he makes his initial contact with government, it becomes a symbol of orientation to political life that is charged with positive feelings. If we now make the plausible assumption that a child of seven or eight is less likely to develop such feelings about impersonal organizations or institutions, we can appreciate the significance of the fact that his first glimpse of government is in the form of the President. It permits the child to express toward a figure of political authority sentiments that he is already accustomed to displaying to other human beings in his immediate environment.

From this we would draw the hypothesis that the personalizing of the initial orientation to political authority has important implications for the input of support to a political system--especially

to its structure of authority—as the child continues through his
early years into adolescence. As he fills in his picture of govern-
ment, adding, to leading figures, such institutions as Congress and
such regime rules as voting, we would suggest that the feelings ori-
ginally stimulated by his personalized view of government subtly spill
over to embrace other aspects of the regime itself.

But for this process it is difficult to see how impersonal,
remote, and complex organizations such as Congress of practices such
as voting could possibly catch the imagination of a child and win his
approval. Yet our data do show that positive sentiments towards gov-
ernment, even after the child has begun to see it in impersonal terms
as he moves into the later grades in elementary school, continues high.
When we add to this the fact that the children in our group tend to
view government as national rather than local in its scope, we can
appreciate the cementing strength that this image must have in a sys-
tem such as the United States.

9. Because children in earlier grades were less able to handle questions of this sort, we did not administer them below fourth grade.

10. These questions are from our pilot questionnaire "In My Opinion--#III," items 50, 125, 169, 170, and 151, respectively.

11. See Chapter 000.

12. Since we are seeking evidence about the nature and degree of the child's attachment to the structure of authority, we would have preferred to obtain a simple, unambiguous measure of affect. We might have been able to do so if it had been possible to ask dirently whether he liked the government or whether it was his favorite, items we found useful for individual authority figures, as will become evident in the following chapters. But unfortunately this direct expression of feeling for government, even during the early grades when the image is personalized, did not occur in the natural idiom of the child. Hence we had to rely exclusively on a less direct means, through estimates of role qualities, for eliciting the child's feelings.

13. Compare with the following procedure adopted for the study of images of federal officials, part of the structure of authority in the United States: "Our perceptions of the sort of people who are engaged in a given type of employment play a large role in shaping our image of that employment. What we think of the professions of teaching, for example, is based to an important degree on the stereotypes we have made for ourselves about teachers. One of the aims of this study was to obtain as precise a notion as possible of the images that come to people's minds at the mention of 'federal civil servants'. To the extent that these pictures embody qualities which are generally admired, respected, and sought after in an occupational setting, they can be said to exert a positive effect on the image of the federal service as a place of employment. To the extent that the perceived qualities are not admired, respected, and sought after, the effect can be said to be negative." See F.P. Kilpatrick, M.C. Cummings, Jr., and M.K. Jennings, _The Image of the Federal Service_ (Washington, D.C.: Brookings Institution, 1964) p. 207.

14. For some evidence that adults continue to conceive of government as powerful and that this is an important ingredient of the general image, see R.E. Lane, op.cit., pp. 197-9.

15. For a suggestion about the broad, structural source of a child's "collectivist" orientations—from family and later, from youth groups—see S.N. Eisenstadt, From Generation to Generation, p. 302. Lane finds a corresponding view among adults in his Political Ideology. He reports that his adult respondents charge the "government...with unlimited responsibility for the general welfare" (p.191) and see also pp. 130 and 145-6.

16. For additional confirmation of the structural significance of government for the child, see E. Estvan and F. Estvan, The Child's World: His Social Perception, p. 191. Their group of children, grades 1 through 6, interpret pictures of state and national Capitol buildings in structural rather than functional terms. They talk about what the government is rather than what it does.

Delaney, Public Administration and the Public: Perspectives Toward Government in a Metropolitan Community (Ann Arbor: Bureau of Government, University of Michigan, 1958), pp. 31-55; and Donald E. Stokes, "Popular Evaluations of Government: An Empirical Assessment," in H. Cleveland and H.D. Lasswell (eds.), Ethics and Bigness, (New York: Harper, 1962), pp. 61-72.

Chapter VII

VISIBILITY AND SALIENCE OF POLITICAL AUTHORITIES

In the preceding chapter we have seen that the closest the child comes to an overarching conception of a structure of authority is in his idea of government. But the tendency for children to see people and then institutions as constituting government gives us a further hint about other important points of contact between the child and the regime. It shows that children may do more than just relate themselves to the symbol "government". They are capable of differentiating other concrete objects of authority. For them the faces of authority may be plural.

If we are to sort out the kinds of feelings children acquire about the political authorities in a system, we need to discover who or what stand as the major embodiments of authority. Political concepts or categories are tools by which the child organizes the political world. What he does not perceive or conceptualize, he can have no feelings about. Alternatively, what he relates to emotionally needs to be defined, as the child perceives or conceives it, so that we may interpret the implications of the child's cognitive development for his attachment to the regime. We need to know what the child orients himself to if we are to discover any political significance to his emotional acceptance or rejection of the regime.

It is apparent that even with the limited intellective and emotional capacities of the child in the early grades, the political world is not the overwhelming confusion that we might have anticipated. We already know that the child sees an order in which government appears. In its concrete manifestations for the child it takes the forms of a President, historic figures such as George Washington, and as the child grows older, institutions such as Congress and voting. But we must now push our inquiry somewhat further into the initial contact points between the child and the system. Is an image of government, however the child may define it, the only path the child can take to apprehend the structure of authorities? Is this the only means at the disposal of the system to link the maturing member to it?

We shall find that in the earliest years of our age span, the child acquires more than just this sense of government with its emphasis on the primacy of the President. Our preliminary interviewing impressed on us the extent to which children gloss over other figures that we might have expected to appear on their cognitive horizons, such as mayors, judges, governors, Senators, or institutions. Rather, they spy a figure of much lower status in the adult's hierarchy of authority, the policeman. It is as though at the outset the child saw the head-and-tail of the political animal with relative sharpness and salience. What lies between such as a mayor, governor, Senator, or judge, is not invisible or unimportant but just less distinct and less significant except where special local circumstances may bring

one or another figure such as these to the foreground. Otherwise, only
as children move into the higher grades of elementary school do other
figures and institutions of authority begin to fall into some kind of
recognized place.

Relative Visibility and Saliency

The data discussed in our previous chapter suggest that the
child sees these two figures, the President and policeman, and con-
siders them of some importance. We need say little at the moment
about the significance of the President for the child. For the police-
man, we need merely remind ourselves that no less than 80% of our group
of children, in each grade, see him as an employee of government (Table
VI.5), and therefore as a person somehow connected with political au-
thority.

Even though we begin with this knowledge about the presence
of these figures in the mind of the child, it does not help us to
understand the relative visibility and saliency of policeman and Presi-
dent. It could be that as prominent as these two figures are to the
child, in comparison with other figures of authority not evoked by our
questions about government, they do not loom so large, even in the early
grades. In this event, if we are seeking to understand the way in which
children become attached to a political system, we would be misled if
we concluded, without further evidence, that these are really the most
effective avenues through which the child moves towards the political
regime.

In this chapter we shall present data that will help us to
draw some conclusions about which political authorities are most easily
seen by the child and are accorded greatest status. These are also the
ones which will seem to us to leave the deepest impact on the conscious-
ness of young children. We shall then be able to move on to discuss
the attributes of these authorities that seem most significant to the
child. It will permit us to understand how a child comes to perceive
some kinds of authorities and to attribute to them the sense of legi-
timacy that is vital for the input of long-term positive or negative
support for the system.

The Visibility of Authorities

From the time we began to collect our preliminary interviews,
we were concerned with the comparative status of various figures of
authority. We needed to discover who it is the child could even be
expected to see, let alone cathect in the political sphere. It be-
came quickly apparent that children in our group initially personalize
authority and only later focus on institutions--something, as we have
seen, that our final data confirmed. Hence we confined our attention
to personal figures. Some of these were political and others non-
political in character. Our objective was to find out how the child

123

assigned, relative to each other, such roles as those of father, teacher, policeman and mayor, how important he considered each, the ones he liked the best and knew most about. We expected that questions like these would give us some idea of the visibility and salience of various figures of authority for the child. Conversely, those figures, in the political sphere, visible and important for the child, would provide the system with an important means of access to the child's sentiments.

From these initial interviews we learned that the child by the earliest grades had already sorted out the relative weights of various of these figures in society. He also knew more about some of them and like some better than others. One striking feature of these preliminary data was the degree to which the President emerged as a person of special distinction. One eight year old decisively expressed this sentiment in an interview.

Q. "What does the President do?"

A. "He runs the country, he decides the decisions that we should try to get out of and he goes to meetings and he tries to make peace and things like that..."

Q. "When you say he runs the country, what do you mean?"

A. "Well, he's just about the boss of everything..."

When presented with a set of cards bearing the pictures and names of eleven different figures--President, Senator, governor, mayor, policeman, soldier, fireman, postman, judge, teacher, and father--interviewed children characteristically identified the President as the most important in general. But specifically they also selected him as being the most important in running the country, in making laws, in helping the country, and in being the one whom the children would most like to be.

In our subsequent questionnaire data we found this effect repeated. For example, we had 338 children in the Chicago area rank ten figures of authority as first, second, or third, on each of five questions. The questions were:

1. Who do you know the most about?

2. Who would you most like to be?

3. Who is most important in making the laws?

4. Who helps you and your family the most?

5. Who do you like the best?

These questions were intended to test for the importance of the authority figures as well as their visibility, although at the

moment we are primarily interested in talking about the latter quality. The average ranking of each of the ten figures on the five questions appears in Table VII.1.

On the first question ("Who do you know most about") which can be thought to tap directly the familiarity of each of the figures to the child, the policeman and the President are second only to father and teacher for the youngest children. The policeman and President also score high for the third and fourth graders on "who helps you and your family the most?".

The President, moreover, is a primary model, an ego-ideal, for the youngest children. He ranks first for them on "who would you most like to be?". They also consider him at the top of the list, across all grades, in response to "who is most important in making the laws?". On the fifth question, "who do you like the best?" the President is outranked only by father and teacher.

Overall the President stands out both as one whom the child knows about and as one whom the child sees as playing a major role in the system. The policeman is the next most visible symbol of authority of those listed, exceeded only by the child's parent, his teacher, and the President.

However little direct political meaning they may have for the young child, the policeman and the President are nevertheless fairly well-known to him and accepted by him from the very beginning of these years. They elicit a sharper response, therefore, than do the mayor, the judge or the Senator. The policeman becomes a "significant other" in several respects more easily than do the equivalent figures of soldier, fireman and postman.

When we followed up some of these questions in later questionnaires we found very nearly the same effects. Although our understanding of the child's awareness as revealed in the previous tests led us to narrow the range of authority figures in these later efforts, we did expand the size of our test groups. We could then extend the reliance we were willing to put on the data.

A question that we repeated, in slightly different form, provides a direct measure of visibility. We asked approximately 1,300 children in Chicago and Atlanta to "Put an X by the two people below that you know the most about". The options were: soldier, judge, Senator, policeman, postman and President. The results are shown in Table VII.2.

On this measure, the policeman and the President again dominate, even though the postman makes an early but declining showing. The early prominence of the postman—as one of the front runners in visibility—suggests that proximity may be one of the things that increases visibility for the child. The President, we may speculate, is visible because of his high status and the attendant publicity. Adults are more likely to talk about him in the presence of children

Table VII.1. Relative Visibility and Saliency of Authority Figures[a]

[b]No eighth grade children in Atlanta were asked this question.

and the mass media are known to pay more attention to the President
than to Congress and probably other figures and institutions.[1] But
the policeman and postman are much lower in the status hierarchy of
society, and their prominence to the child, we would infer, derives
in great part from everyday familiarity and propinquity. Familiarity
of authority figures in the political sphere may depend in part, there-
fore, on formal status in the political structure; but it may also
come from the simple fact of being close and ever-present to the child.

Aside from the President and policeman, the other figures
fall much where we might expect. The Senator is a highly invisible
authority on this measure, the least well seen of all. The judge
fares only a little better. These findings bore out our preliminary
interviewing.

On the whole we could conclude from our pretesting that of
all the figures of authority in the political system, there can be
little doubt that children see the President and policeman first and
continue to hold them in prominent view over the grades. In the pres-
sure for space on our final questionnaire there seemed little point
to belabor what by now had become obvious. We were prepared to take
the high visibility of these two figures of political authority for
granted without further special testing. We could build part of our
test of the development in supportive sentiments towards the structure
of authority around these two figures. In the complex world of poli-
tics they at least could be seen.

Nonetheless our final instrument does give us some supportive
evidence about the perceptual primacy of the President and the police-
man. As we have already witnessed in our analysis of the child's image
of government, the President and the policeman both are strongly as-
sociated by the child with government, although in different ways.
At the beginning of the grade span, the President is the best overall
r presentative of government, from the children's point of view. He
is still relatively important in this respect even among our oldest
respondents.

We have also seen in passing that although for the child the
policeman is not very representative of government as a whole (Table
VI.2), he is nevertheless regarded in the vast majority of cases as
a government worker (Table VI.5). This identification is fairly con-
tinuous across the grades. The policeman is also considered to be
very important in making laws, and the young child, our interviews in-
dicated, detected little difference in the source of the laws, whether
they are in fact local ordinances or national statutes. The item we
have already examined in the preceding chapter, "how much do these peo-
ple help decide which laws are made for our country?" (Table VI.6),
begins to point up the high significance of the policeman for the
child. Through grades 4 to 7 the child ranks the policeman immedi-
tely below the President and unions as being more influential. The
mean ranking for policeman through grades 4-7 is higher than for any
others except President and unions. Although the child senses the
inappropriateness of associating policemen directly with the govern-
ment, he does feel that this figure has something vital to do with

laws--which in our conceptualization we designate as the outputs of political authorities.

Conversely, what is particularly clear from these data is that in the early grades the child is not likely to conceive of Congress or the Supreme Court as playing a very significant role among the authorities. When we asked the child to pick the two best pictures representing the government, only 5% and 6% in grades two and three chose the Supreme Court. What is more revealing, only 6% and 13% in these grades even came down in favor of Congress, as against 49% by grade 8. In the lower grades, therefore, a number less than chance turned to Congress (Table VI.2). Similarly when we asked our respondents to indicate those who do most to make the laws (Table VI.3), in grades 2 and 3 Congress and the Supreme Court continue to draw fewer choices than we could account for by chance alone.

These data, reinforced as they are by interviews, leave little doubt about the low visibility of formal organizations for the younger child in our group. He gives little evidence of being aware of them and if he is, they appear to have little meaning for him as part of the structure of authority in the system. It would appear that the younger child finds some difficulty in conceptualizing remote political structures and relating himself to them.

In effect, these findings give us confidence that the children in our group see personal figures, the President and the policeman, as particularly prominent in the general structure of political authority. We are therefore able to consider these figures at least as appropriate starting points for further investigation of the child's developing relationship to the regime.[2]

What these tests did not answer, however, was whether the prominence of these figures for the children had any meaning for them so that we might consider that they were salient objects. Did they carry emotional significance for the child even within the low limits of concern that children have for the political sphere? We can readily appreciate that children may see something in the political system and be able to talk about it. If however it has no relevance to their lives it could play but little part in relating them affectively to the system.

The Saliency of Various Authority Figures

We may surmise that if a person is considered to be nurturant and helpful, he probably has some importance for children that goes beyond mere presence and familiarity. It was with this in mind that in our final, eight-city questionnaire we continued to ask a pretest question by which we intended to ascertain as directly as we could which figures of authority had most significance for the life situation of the child. We would then be able to understand whether the

visibility of the political figures of authority conveyed any meaning for the child other than awareness alone. We were confident that among those figures tested, the child would have greater awareness of the policeman, President, postman and soldier than of the Senator and judge and because of the poor drawing power of the last two figures we could conveniently drop them. We could omit the postman as well since the ramifications of his role ~~of his role~~ for the relationship of the child to the political system appeared less interesting than for the other roles.

With a restricted list of characters in our final instrument, we repeated the question, "who helps you and your family the most?". We added to this question the instruction "put an X by the two who help you and your family the most." The options we provided were the policeman, soldier, father, teacher, and President.

What we find suggests the high saliency of the policeman and the President for the youngest children, among political and other authority figures. The changing pattern of relative perception of these selected representatives of authority is shown in Table VII.3A and 3B.

Here once more it is the policeman, not the President, who receives the highest endorsement of all at grade 2, although the President follows closely. With succeeding grade levels the standings of the authority figures change so that greater weight is given to the two more immediate authorities, father and teacher. The image of policeman and President as perhaps "bigger than life" is cut down and the child works out what we might no doubt think to be a more realistic conception—in adult terms—of their relative roles in his own life.

Nevertheless what is remarkable on this measure of saliency for the child is the fact that the positions of policeman and President remain in exactly the same order of significance in almost all grades. A somewhat greater number of children always see the policeman as most helpful regardless of the high prestige that the President of the United States would seem likely to command. The child seems to have fairly well-defined feelings about the policeman in his helping role.

We might be inclined to interpret this as a clue that the child thinks about helpfulness in a concrete immediate sense. A policeman but not a President could be expected to be standing close by to help. Undoubtedly this accounts for the way in which the child orders policeman and President along this quality. But there appears to be more than a sense of presence or immediacy in the child's selection of these two symbols of political authority. For example, in grades 2 and 3 a larger percentage of children select the policeman and President combined than father and teacher together. Yet it would seem that if proximity and availability alone determined the younger child's choice, the higher percentage might have gone to father and teacher as most helpful.

130

Table VII.3A.   The Relative Saliency of Selected Authority Figures[a]

(per cent of children responding)

Grade	Policeman	Soldier	Father	Teacher	President	Total[*]	N
2	51%	22	38	29	49	189%	1655
3	47	19	48	33	43	190	1678
4	38	16	59	35	35	183	1749
5	37	17	64	34	31	183	1803
6	34	15	68	36	30	183	1749
7	28	17	74	38	28	185	1723
8	30%	15	74	40	24	183%	1695

[*]Not every child gave two answers to this question. Thus the percentages do not
add to 200%. Every child did respond to this question at least once, however,
so that there are none classified as "not responding".

4	2	5	1	3	4
5	2	5	1	3	4
6	3	5	1	2	4
7	3	5	1	2	4
8	3	5	1	2	4

[a]CA-9, page 13, item 58:   "Who helps you and your family the most?   Put an X by
the two who help you and your family the most."

Further, when, across the grades, we compare the percentages that see father and teacher combined as being most helpful with those that select the policeman and President together, we find the distributions as indicated on Table VII.4. In grades 2 and 3 the two political authorities outdraw the two personal authorities as we have noted. But even though a reversal begins in grade 4, by grade 8 53% (out of a possible 200%) of the choices still considers the clear political options to be more attractive.

The strength with which the political authorities in this question draw the youngest children testifies at the very least to the fact that these figures do more than just appear on the horizon of the child. The continuation of the appeal of the political figures of all ages at a relatively high level reveals the surprising capacity of these symbols of the political system to impress themselves on the minds of children, at least for their quality of helpfulness.

In summary, it would appear that, for the younger child in this age span, the President and the policeman show up as somewhat special figures. This occurs in several sorts of questions and over several samples of children. As representatives of the authorities for the child--the policeman is seen as working for the government and the President is the government--both figures are highly visible and have some psychological importance for the child. They take on this saliency as the maturing child begins to orient himself to the wider world by interpreting the roles and expectations of people who help define that world and the child's place in it.

Simultaneously the child in our group is able to relate himself to both extremities of the structure of authority. However distant the President may in fact be, he is brought psychically closer to the children as they sense that he may be helpful for them and their families. But the system does not rely exclusively on this mechanism for linking the child to itself. It spreads its risks, as it were, by also drawing the child into the ambit of the authority structure through the agency of a local representative with whom the child has frequent opportunities for face-to-face contact. Through the head-and-tail effect it is possible for children to be introduced to symbols and representatives of the political system--government as well as President--at the most inclusive level at the same time as they make even more direct contact with proximate manifestations, the policemen.

The Policeman in the Structure of Political Authority

Have we been assuming too much in placing our emphasis on these two figures, the President and the policeman? We are exploring the nature of the child's developing support for the structure of political authority. Have we any reasonable grounds for including both these figures as part of this structure?

The designation of the President as a political authority presents no difficulty although in Chapter IX we shall want to assure

Table VII.4. Relative Saliency of Selected Authority Figures Combined[a]

7	55	112	1723
8	53 %	113 %	1695

[a]See Table VII.3A.

ourselves that the children orient themselves to the President in his
structural role rather than in his personal capacity. But it is not
equally clear that the policeman is part of the structure of politi-
cal authority, especially in the American political system where this
office is largely under local or state rather than national jurisdic-
tion. Yet if we cannot reasonably consider the policeman to be an in-
tegral part of the structure of authority in the political system, his
visibility or importance to the child would have little relevance for
our study, important as it may be for other purposes.

From the perspective of a systems analysis of politics it is
clear why we must consider the policeman to be as central a part of
the regime structure as are all the other august figures and institu-
tions usually included within it. Authorities are those who have the
day-to-day task of formulating and implementing system outputs, what
we have called policies or binding decisions. In a large scale system
such as the United States, the authorities are not concentrated at one
level of the system alone. At the national level, in addition to exe-
cutives, legislators and the like, we find administrators many of whom
have little contact personally with the publics they serve. But in
addition these national administrators also include officials who stand
in close contact with members of the system at the local level, those
who are most directly affected by administrative acts. A clerk in the
local office of a federal licencing agency or a county agent in the
employ of the Department of Agriculture exemplify such figures of au-
throity. They are part of the national organization of the political
system, the output structure, through which policies or legal outputs
are put into effect. The fact that typically they engage in specific
personal and detailed interaction with members of the system may dis-
tinguish them from those who are typically more remote, such as higher
officials whose range of activities forces on them a more impersonal
role. But these administrators at the tail end of the hierarchy are
no less part of the structure of authority than those at the top.

In the American type of federal system, the policeman,
unlike terminal officials in a national administrative structure, is
not so easily located in the structure of authority. It is true,
federal police such as the FBI, Treasury officers, or revenue agents
are part of the national organizational structure. Conceptually there
would be little with which to cavil if we included these police as
part of the structure of political authority. They are the operatives
of national administrative agencies and as such are in direct contact
with their publics.[3] Through the mass media, especially television,
some police agencies, such as the F.B.I. or G-men, have successfully
impressed themselves on the minds of children as well as adults. But
as we shall contend in Chapter X, in the context in which we queried
children the policeman, especially for the child in the lower grades,
is typically the cop on the beat, in the patrol car, on the motorcycle,
at the school crossing, or at the intersection directing traffic.

From a theoretical point of view, however, this kind of police-
man is part of the general structure of authority in a political sys-
tem even if he does function at the local level. The American political

system embraces a vast network of local subsystems--cities, towns, villages, and other municipal units--nesting within the broader system. Within each of them there is produced a large variety of outputs in the form of traffic regulations, licensing, taxing and the like. In part these are enforced through the efforts of the local police forces. Policemen therefore fulfill important roles in this part of the output structure of a political system. They apply the law, a form of outputs.

But they do even more. The notion of application or implementation obscures the processes that actually occur. In applying the law, policemen unavoidably also make decisions upon which they themselves and others, such as judges and jailers, may need to act. Policemen thereby produce outputs of an authoritative character. For example, it is they who decide on the spot whether to write a ticket, arrest an offender, or even to use the most fateful type of violence, the taking of human life. However narrow the scope of their decisions, these outputs are generically at one in their authoritativeness with the grand policy decisions of national legislatures.

In this sense we cannot exclude policemen, on theoretical grounds, from being important participants in the structure of political authority. It permits us to designate any kind of relationship that the child has with the policeman as a form of contact between the child and the regime. Even if children were able to recognize policemen as local officials, this would not vitiate the role of the policeman as a link to one part of the total output structure of the regime.

But the fact is that the child is not a political scientist. He does not see political life through the eyes of the adult of the student of politics. In the early grades especially, the local political scene is hazy and obscure. Empirically, as far as the younger child is concerned, the policeman becomes assimilated to the general structure of authority outside home and school. National, state and local structures are not easily distinguished by the child; all fuse into an ambiguous picture of authorities external to home and school. Chapter X will reveal that we found no preliminary evidence to suggest that children think of the policeman as any less compelling or authoritative than most other political authorities they perceive regardless of structural level.

It is just at this point that theory and practice converge. For the child, especially the younger ones, the policeman is out there, in the world beyond the family, with a power of a peculiar sort. Like the President and yet in a way the child knows to be different, as Chapter X will disclose, the policeman also represents something related to the political system and authority in it. Later the child may come to know much about the status and role of the policeman as part of the overall structure of authority in a political system. But in the early part of the life cycle in which we see the child, political life is still too ambiguous for us to expect a clear structural definition to be present.

We are contending therefore that when the child reports that he sees the President as the government and when he considers that the policeman works for the government and exercises some special powers, the child is developing some image of the actual structure of authority in the system. Phenomenally both figures fuse into a composite if hazy picture of authority, something different and compelling out there beyond the boundaries of the family and school.

Sources of Visibility and Saliency of President and Policeman

It is not difficult to speculate on why the younger child might find the President and policeman to be salient and visible figures of authority even though we have little hard data on this. Unlike Congress or the Supreme Court, which are complex impersonal institutions, the President and policeman are individual persons much like many other human objects in the familiar environment of the child. We might expect to find that the child would be able to respond more readily to them. Even for adults it has been argued that "displacement of emotion on persons is easier for most people than displacement upon groups or issues or even symbols..."[4]

But much more than this is undoubtedly at work. There are many kinds of persons in the surroundings of the child, political as well as others. From among these we need to be able to account for the emergence not of just any kind of figure from the total structure of authority but of the President and policeman in particular. Why from among all possible authority figures in the American system—administrators, governors, mayors, judges and the like—should these two from the beginning catch and hold the attention of the child?

Here some probable reasons are not difficult to find. Sheer exposure alone would help to float these figures across the child's horizon. Policemen, for example, come into range from many different directions. In fantasy they appear in the guise of toy figures, bogeymen to induce obedience to parental demands, or characters in the game of "cops and robbers". In life they are seen as crossing guards, as directors of traffic, or as guardians against theft and violence. The settings, real and imagined, in which the child encounters this "symbol of authority" are so numerous and varied that it would be the extraordinary child who entered school without the word "policeman" within easy reach of his vocabulary.

Exposure operates as well to draw the President within the cognitive span of the child. Undoubtedly the child has fewer opportunities to see or hear about the President, and yet by the time he enters grade 2, at about age 7, we have no evidence of any child who was unable to recognize the word of its basic meaning.[5] It is not surprising that this should be so in the American system. Since the first World War the chief executive has attained increasing prominence and the child's awareness is probably related to the frequency with which adults themselves have occasion to discuss the Presidency. The role

136

of the political executives has been radically altered in modern political systems. The domestic problems of industrialized societies and the demands of foreign policy have everywhere dramatized the part of chief executives. But in part too the Presidency is thrown into sharp relief by the very nature of the American political structure with its emphasis on the separation of powers and the grounds it thereby provides for recurring, open competition between Congress and the Presidency.

Empirically the prominence of the Presidency reflects itself in the attention it obtains from the mass media, as in the newspapers and television.[6] Children could be expected to sense this current of interest among adults if only as it is channeled to them inadvertently through the conversation of their own parents.

The drama of Presidential election campaigns undoubtedly also impresses the office on children. If we take 5 years of age as the earliest point at which a presidential campaign might leave some imprint on the child, all of our children had undergone one campaign at least, by the time of our testing in late 1961 and early 1962, that between Kennedy and Nixon in 1960. In addition, all children in grades 5 through 8 had probably also experienced at a conscious level the Eisenhower-Stevenson election of 1956 and were therefore exposed twice. It seems plausible to assume that few children could pass through recurrent Presidential electoral campaigns without their curiosity being piqued, especially by the intense competitive element resonant of a similar feeling the child may experience in his own life, as in games and sports.

One perhaps indirect indicator of the child's exposure to the phenomenon of the election and its psychological importance to him is a question we asked which goes as follows: "How much did you learn from the last election for President?" Answer options were: (1) I learned a lot (2) I learned some (3) I learned very little. When we cross-tabulate the responses to this item by grade we find a farily stable pattern of relative saliency over the grades. Only the lowest grade that we tested (grade 4) is different. But this one difference would support, if rather faintly, the hypothesis that the child who has been of school age during two general elections is likely to be more attuned to political affairs.

If this question is an indicator of the degree of sensitization of the child to politics through Presidentail elections, we can then ask whether responses to the item are associated with the child's perceptions of the President in any way. More particularly we can ask whether the child who indicates that he has learned a substantial amount from the election is also likely to regard the President more highly.[7] Causality could of course run in either direction, but our guess would be that the child who becomes more aware of the election is more likely to generate positive feelings towards the winner.

Our test of such a possible effect is to cross-tabulate responses of the "How much learned" item with an index of the child's

Table VII.5. Saliency of the 1960 Presidential Election[a]

(percent of children responding)

Grade	I learned a lot	I learned some	I learned very little	Total	N Responding	N not Responding

138

affective response to the President. This is shown in Table VII.6.

We find an association at every grade level tested. The child
who perceives himself to have been more affected by the election is
also more likely to see the President in a more favorable way. There
is at least a _prima facie_ case for the hypothesis that the election
has socializing effects, (positive in this case) even though such ef-
fects may be confounded by other factors which predispose the child
to pay attention to the election or to regard the President more favor-
ably anyway. Yet is is suggestive for future research into these ques-
tions that we do find evidence, however tenuous, for the proposition
that the drama of the Presidential election is apt to sensitize the
child to awareness of political authority, and in particular to a
more favorable reaction to the winner of such contests. Both socia-
lization and legitimation consequences are suggested.

Furthermore the classroom itself would seem to generate addi-
tional awareness and to provide historical continuity for the role
of the President. It is the unusual school that does not have busts
or pictures of past Presidents in the corridor and classrooms. Few
curricula even in the early grades would fail to give some special
attention to the office. As an indication of how much attention might
be given to various figures and institutions of political authority
we can turn briefly to some data obtained from a curriculum question-
naire sent to a sample of the teachers subsequent to the testing of
the children. It is hard for us to estimate how representative this
small sample of teachers might be. Yet in Table VII.7 we are able
to see some trends in emphases relative to the authorities we asked
about, in the amount of time these teachers estimate that they spend
on each authority in an average school year.

Dividing the same by grade with which the teacher is mainly
concerned (and bearing in mind the small numbers that therefore re-
sult for any one grade)[8] we find that there are more teachers who give
more than minimal attention in the early grades to the President and
policeman than there are those who give such attention to the other
authorities. Thus the emphasis of the school no doubt reinforces
whatever other stimuli exist to make the two figures so salient to the
young child.

The simplicity and concreteness of the policeman and President
as individual figures of authority and their immediacy for adults,
in and out of the classroom, help us to understand why children should
perceive these figures at the early phases of their own lives. But
it still does not explain an important phenomenon that we have ignored
to this point. If we return to Tables VII.3 and VII.4, there we can
see that even though the President is clearly a visible, salient figure
for many children, this becomes decreasingly so over the years. The
younger child is the one who is most impressed. In grade 2, one half
of the choices go to the policeman and President as being most help-
ful whereas by grade 8 this proportion has declined to 53% (out of a
possible 200%). Yet since the eighth graders had witnessed two

[a]Curriculum Questionnaire, pages 1-3, items 2, 14, 19, 11, 15, and 20.

presidential elections as compared with only one for those in grades 2 through 4 and had had a longer time to hear from adults about the President and policeman, we might well have expected a reversal of these percentages. This clearly means that something more than sheer exposure to information about the Presidency and the emotional drama of campaigns is at work.

Here we can only speculate on the relevant forces. What draws the child to these figures of authority probably also has something to do with the psychological context in which the child himself interprets both policeman and President. As we shall see in the next chapters, younger children in particular conceive of these two authorities in highly glowing terms. Children see them as nurturant, benign, and protective, almost in the image of an ideal father 'as he might be described in our culture. In part, as the child grows older, some of this idealization may rub off when he learns more about these figures. But there remains the question as to why so many children in the early grades describe the President and policeman in hyperbole and correspondingly see him as so salient.

In seeking an explanation we would suggest that this may derive in some measure from the inner needs of the younger child. As he moves out of infancy into early childhood and initially becomes aware of the complexities of life beyond the family and of his own dependence on adults as a shield before this outer world, the accompanying sense of vulnerability may induce the child to attribute greater importance and more benign powers to figures of authority than in fact these authorities need possess. Regardless of what the "real" significance of these authorities may be for the adult members of a system, if we accept the proposition that younger children do feel a greater sense of vulnerability to the world outside the family, we can appreciate why, from among the political authorities, the child might choose those that seem best able to serve his immediate psychic needs. Here what he hears from adults about these figures dovetails with these needs. Protective figures would be selectively perceived and emphasized, in this interpretation, because they fit with the child's inner needs of the time. Hence we can understand why the political authorities should decline in importance as the child grows older. By grade 8 he is more confident of his capacity to cope with life and is less inclined to attribute the same importance to political authorities even though he still ranks them relatively high.

For the political system, however, the feelings of vulnerability that might have led him to elevate two authority figures to positions of considerable prominence have important consequences. They may help to lock the child into the political system and to provide the system with a mechanism for encouraging those kinds of sentiments without which, we have hypothesized, no system could hope to persist, whether in constant or changed form. As we have already observed in Chapter V, contrary to presuppositions built into curricula at the elementary school level, children do not enlarge their knowledge of the world, at least in the political sphere, by working in concentric circles

from far to near, if far and near are considered to be geographic
terms. The least that we have found is that psychic distance differs
from spatial distance.[9] Figures at the tail-and-head ends of the
political creature--the policeman and the President--seem to be close
psychologically however distant one of them may in fact be spatially.
This capacity to incorporate even distant objects makes it possible,
in the American political system, for the child to establish ties
with the political system at the most inclusive level--the national
unit--at the same time as he reaches out to a representative at the
spatially closest point.

The Expanding Public Image", 36 <u>Journalism Quarterly</u> (1959)
275-83, cited in F. Greenstein, <u>Children and Politics</u> p. 76.
2. In earlier reports we have suggested other findings with which
the present ones converge. See David Easton, with R.D. Hess,
"The Child's Changing Image of the President"; "Youth and the
Political Systems", in S.M. Lipset and L. Lowenthal (eds.), <u>Cul-</u>
<u>ture and Social Character</u>; and "The Child's Political World",
6 <u>Midwest Journal of Political Science</u> (1962) 229-246.
3. In the police system of the United States three basic types pre-
vail: the <u>local</u> police which includes urban police forces, sher-
iffs, rural constables, county police, parkway police and the
like; the <u>state</u> police; and <u>federal</u> police. Typically the lat-
ter fall into two classes: those concerned with the national
revenue such as the Intelligence Unit of the Bureau of Internal
Revenue, the Enforcement Division of the Alchol Tax Unit, and
the Division of Investigations and Patrol of the Bureau of Cus-
toms; and those involved with protecting life and property and
the enforcement of national criminal statutes, such as the F.B.I.,
the Secret Service Division, the Bureau of Narcotics, Post Office
Inspectors, and the Immigration Border Patrol. See B. Smith,
<u>Police Systems in the United States</u> (New York: Harper, 1949).
Undoubtedly few adults, not to speak of children, have any clear
picture of the multiplicity of police agencies in the country
and their possible areas of overlapping jurisdiction.

of the President" 122 <u>American Journal of Psychiatry</u> (1965) 523-
529; R. Lane, <u>Political Life</u> pp. 318-319; R.E. Neustadt, <u>Presi-</u>
<u>dential Power: The Politics of Leadership</u>, (New York: Wiley, 1960).
For some remarks on the latent socializing influences of the Presi-
dentail campaign, see J. Wahlke, et. al., <u>The Legislative System</u>,
pp. 88-89.
7. Research on the effects of the Nixon-Kennedy T.V. debates upon
adult perceptions of the candidates showed that simple exposure
to the other party's candidate had the effect of reducing hostility
and generating positive feelings toward him, especially for John
F. Kennedy. We might expect a similar "campaign communication"
effect for children. See S. Kraus (ed.) <u>The Great Debates</u> (Bloom-
ington, Ind.: Indiana University Press, 1962), especially at pp.
218-219.

8. We sent out these questionnaires by mail to the teachers in six of the cities (excluding Jackson and Tacoma) and had a return rate of 59%. Some of our losses are due to the fact that our original sample contained a number of substitute teachers.

9. Another study involving political content reports the same kind of phenomenon. F.J. Estvan and E. Estvan, _The Child's World: His Social Perception_, indicate that "both first grade and sixth grade pupils were more conscious of the nation as the setting for life situations than the state or region in which they lived. The former, it would appear, is 'psychologically' nearer than areas or divisions which are actually closer geographically speaking. In other words, children tend to skip such intermediate areas as the state or region in their expanding awareness of space rather than moving outward systematically in terms of size of unit." (pp. 260-1) "Influence", the authors say elsewhere, "is not necessarily a matter of [spatial] distance." (p. 39)

CHAPTER VIII

THE PRESIDENT AS A FOCAL POINT OF POLITICAL SOCIALIZATION

To this point we have seen that children connect with the structure of the political system in two basic ways at least. Not later than grade 4 they acquire some idea that there is a general structure called government, and they are able to express a variety of feelings about it. We saw that initially attachment to the structure of authority occurred under a form of personalization of government. But at the same time our interviews and pretests put us on the path of two central figures of authority, the President and the policeman. Even children in grade 2 were fully aware of their presence. Since these are two of the first representatives of political authority from the world outside the family and school to become known to our children, we could easily anticipate that the way in which the child perceived these two figures would also play some important part in his overall relationship to the regime.

In what follows we shall try to explore the texture of the initial image that the child creates of the President and the policeman. We shall then be able to speculate on some of its implications for the bond between the child and the regime.

To anticipate the conclusion of this chapter, there will be little doubt that younger children particularly see these figures of political authority in highly idealistic terms. But we shall discover that more than a purely personal bond is being fashioned with the man who happens to be President or a police officer. From the earliest grades, we shall find that our children probably look at the incumbents of these offices as representative figures and that their attitudes pertain to the role, not to the persons who occupy it. From this we shall be able to conclude that our children are in the process of constructing an image of the structure of political authority. The sentiments incorporated in this image will permit us to make some informed guesses about the nature of the child's developing ties to the regime itself.

Components of the Child's Image of Political Authority

Our basic hypothesis has made the investigation of the child's image of these figures of authority critical. Variability in the input of support, we have presumed, is related to the complex psychological constructions of which a child's image is composed. As a first step to exploring this relationship, it becomes vital to design a way to fathom the child's conception of these salient figures of authority.

In our chapter on government we have already concluded that the image children hold of political authorities contains a mixture of cognitive and effective elements. To a certain extent it proved possible to elicit either one or the other part of this mix. Yet because

in most cases these elements exist as a package of orientations, it was hard to ascertain precisely what proportion of each was contained in the responses elicited by individual questions. Even those ratings which seemed to border on the most affective elements of the image were themselves subject to mixtures of content depending upon the precise context and meaning.

Bearing in mind this difficulty in sorting out affect and cognition clearly, we sought to select a variety of questionnaire items, in the form of ratings, that would accord with the child's own way of seeing and feeling about political authorities. But these items also had to bear upon the most theoretically interesting aspects of an image of authority, those that would help us to understand the way in which children begin to put in support, whether negative or positive, to a system.

Since the points of contact with the authorities proved to be numerous and varied, and included institutions (organizations such as government or the Supreme Court) as well as persons, at least some of the qualities had to be of a kind that would be appropriate for all types of objects of authority. Because we wished to know what it is that the child does in fact see as the object to which he is reacting, as well as how he feels about it, the ratings needed to elicit the cognitive as well as the affective components of the image. Furthermore, the literature on authority in general is replete with references to the relationship between attitudes to parental authority and those to authorities outside the home. It seemed appropriate to try to search out some of the connections between at least feelings about the authority of father as compared to some political authorities. The dimensions of authority that we selected for testing therefore had to be of a kind that would permit such comparison.

In short we sought to test for cognitions and affect, to compare ratings of personal and impersonal political authorities, to relate these to non-political authorities such as father, and to isolate qualities that were relevant for an understanding of our basic concerns with the input of support. These constraints governed our ultimate selections of ratings. Added to them were the additional limitations of available testing time and the capacity of children across the grades to handle the items.

Within these bounds we devised thirteen different item ratings for each of three authorities, the President, the policeman and the child's father. We also used either five or six of the same ratings for government, as we have already noted, the Supreme Court and "the average U.S. Senator", with a special set of ratings for "people who try to get elected". Given the restrictions on testing time as well as the relatively low tolerance of young children for a long series of rating scales, we were not able to use our series of thirteen ratings for each of the six authorities. Nor did we administer the questions about the Senator, Supreme Court and Government below the fourth grade. The second and third graders appeared, in our pretesting, to be relatively unfamiliar with these more remote and abstract embodiments of authority.

The thirteen ratings used, the grades to which they were adminis-
tered, the figures to which they applied, together with the dimensions
of the image of authority to which we presumed the ratings to be re-
lated, are presented on Table VIII.1. These ratings are the kinds of
qualities that extensive pretesting and analysis of pretest data, in-
cluding factor analyses, suggested as typically the way in which chil-
dren are apt to think about political authorities. The phrasing of
the items follows closely the actual words of the children themselves.

As we can readily see from Table VIII.1, the ratings touch on
a variety of aspects of authority and are designed to elicit a greater
or lesser degree of cognition and affect. They run from two which most
nearly approximate purely affective content, (I like him and he is one
of my favorites), to four dealing with leadership. The latter contain
a greater admixture of cognitive content. In between we have a number
of items which evoke a fairly complex mix of emotion and knowledge.

How the Child Sees the President

Although the child's feelings about the President are scarcely
distinguishable from cognitive aspects it is nonetheless useful to in-
troduce ourselves to the child's image by emphasizing what it is that
he sees the President as doing and the significance the child may attach
to this. From the earliest grade the child sees the President as on a
commanding height, far above adults as well as children. The President
flies in on angel's wings, smiling, beneficent, powerful, and almost
beyond the realm of mere mortals.

Our interviews disclosed that the child knows about the Presi-
dent and is able to express an estimate of him before there is much
understanding of or information about the actual role. A strong posi-
tive attitude prevails in advance of knowledge of what it is that the
President in fact does and this colors the child's perceptions. Younger
children especially see the President at the top of the whole system
and in control of it. The mayor takes orders from him and Congress is
there as his helper. Local, state, and national governmental structures
fuse into a single pyramid of authority with the President at the top,
supreme in power and authority. This appeared repeatedly in our in-
terviews at various ages. As one 8 year old child, the son of a lawyer,
told us:

I. ..We were talking about laws earlier. What is the law?

S. The law is something that you're supposed to obey. And
if you don't usually something might happen, you know.

I. Can you name a law?

S. Don't go through a red light.

I. Who makes the laws?

148

Table VIII.1. Outline of Ratings Used in Testing the Child's Images of Authority

S. Usually the President. Or if the President doesn't he'll tell somebody, a least bit lower—like a vice-president or so, and they'll discuss the law.

A 10 year old child from a different school responded in a similar fashion.

I. And what does the President do?

S. He decides what people should do and things like that.

I. Tell me more about that, I don't quite understand.

S. Well, he decides usually what laws people should go by, and things like that...He makes the street laws so that you stop at the red light and people won't crash or anything, and he makes the state laws.

The other side of the picture, however, is that the President is seen as using his power and unbounded knowledge to help people, protect them from whatever dangers may lurk in the great unknown beyond the habitat of the child. Yet this powerful and virtually omniscient figure is within easy reach. Children feel they can write to him, visit him in Washington, even call him on the phone. As one 9 year old put it:

I. Can you ever tell the President of the United States what kind of things you think he should do?

S. Yeah, you can talk with him...

I. How...just call him up on the telephone and tell him, or what?

S. Yeah, you go to the White House, most people do...

I. Some people do go and tell him what they want?

S. Yeah...

Although as the children grow older they draw him closer to the position of an ordinary mortal, they never quite bring him down to earth.

From an operational standpoint, there is a great variety of properties of the Presidency which could serve as points for testing the child's changing conception. In a number of different preliminary excursions in this area, we tapped a few of these. Fragile as have been some of these data, they give us some flavor of the shifting knowledge embodied in the child's early image.

150

The importance of the President's role

A few questions from one of our pilot questionnaires show us
parts of the cognitive base underlying the child's image from the
very beginning. We asked some children to respond to a variety of
statements about the President in a simple agree-disagree fashion.
Three items bear upon the cognitive image. They concern the relative
weight of the President's role in the system. These items were for-
mulated from statements taken almost verbatim from an early series
of individual interviews. They are shown in Table VIII.2.

From the overall pattern of response to the first question, in
column 1, we can discern that the child regards the President right
from the beginning (grade 3 in this case) as highly important. There
is little doubt in the minds of most of these children that the Presi-
dent has grave responsibilities. This does not change as the child
grows older and acquires increasing knowledge about the Presidency,
even though with age many other evaluations do shift significantly, as
we shall later see. Somehow, by grade 3, the children have placed the
President in a central position in the country. The importance they
thus attribute to him seems to color all other attitudes and perceptions.
There is at the same time a growing realization of the limitations of
his role as an authority as shown in columns 2 and 3, Table VIII.2.

In our final instrument, we included a question which confirms
this conception of the President's high significance in the political
system and adds some further dimensions to it. We asked the following
question: "Here are some things that boys and girls have said about
the President's job is. What do you think the job of the President
is? Put an X beside the two things below that say what you think the
job of the President is:

1. His job is to keep us out of war.

2. His job is to make friends with other countries.

3. His job is to help people in our country.

4. His job is to stand for our country.

5. His job is to make people obey the laws.

6. His job is to make sure our country is run well."

These data indicate that in all grades a solid majority of our
children see it as the task of the President to make sure that the
country is run well. They interpret this as his general responsibility.
But in grades 3 through 5, the next two most popular choices represent
relatively specific tasks such as keeping the country out of war and
making friends in the area of foreign relations. The younger children
are less certain that the President has an overall obligation to care
for the country. They see his job as divided between this and some
narrower tasks in foreign affairs.

Table VIII.2. The Child's Assessment of the Importance of the President's Role[a]

Grade	1. "If the President made a big mistake in his job, it would hurt America a lot!"		2. "If the President does not approve of a law, it should not be passed."		3. "The mayor should get his orders from the President."

[a] CA-9, page 22, item 44. "Here are some things that boys and girls have said about what the President's job is. What do you think the job of the President is? Put an X beside the two things below that say what you think the job of the President is."

As our children move into the upper grades, however, they are more likely to interpret the President's job in overarching terms. By grade 8, the three most preferred items all stress the general executive responsibility of the President for running the country. Correspondingly they tend to give somewhat less importance to the more specifically defined parts of the President's role. Thus the items, helping people in our country, standing for our country, and making sure our country is run well (cols. 3, 4, 6) are diffuse functions identifying different aspects of the most general nature of Presidential responsibilities. Combined, these options draw 102% out of a possible 200% in grade 3 and rise to 14? by grade 8, with each of the items increasing continuously over the grades. Without necessarily denying the other kinds of jobs that the President may have, in a forced choice situation as represented by this question, almost three-quarters of our group, by the end of the elementary school year, attribute the greatest weight to his general responsibilities for doing what is necessary to help the country and to make sure it is run well. The President is not only one of the first to be seen among all public institutions, as we saw in the preceding chapter, but being seen, his major work is also considered to bear the most general, and therefore the most onerous responsibilities. As the last row in Table VIII.3 shows, in this they also look very much like their teachers who completed the same questionnaire as their students.

The President's authority status

Although consistency is not necessarily any more a mark of the child than of the adult, it would seem only reasonable that if children in general tend to aggrandize the role of the President, at least the younger children who have little knowledge of the President might interpret his status in a way that gives him the power to meet his apparent position and attendant responsibilities. In our final survey we have some data on the extent to which children see the President as a powerful person and this will appear shortly. But our pretest findings are suggestive about the location of the President in the authority structure, an aspect we did not test in our final instrument.

The child sees the President at the top of the authority structure in the country, at least in the early grades. The President is the one who should decide on what is to be done. As the questions reported in columns 2 and 3 of Table VIII.2 show, a large majority of the children in grade 3 see the President as the person who should be the great law-maker, almost the same percentage as attribute outstanding importance to his job as President. This conception changes quite rapidly, however, so that by the time we reach the children in grade 8, only a small percentage continue to hold the belief that the President should have a final veto in law-making. Apparently knowledge tempers the image of the kind of power the President should have. We know that as children grow older they realize that representative bodies exist and that they help to make the laws.[1] We can now see that children also begin to understand the correspondingly more limited legal powers of the President.

Another rapid revision occurs in the child's conception of the position of the President in the hierarchy of political authority. In responding to the item that "the mayor should [and for younger children especially this is usually equivalent to saying that he does] get his orders from the President", a majority in grades 3 and 4 agree. We found this also to be the case in our interviews.[2] By grade 5, in this test group, —ages 9 to 10—there is a marked decline in the number who see the mayor as subordinate. Only a minority think that he ought to get his orders from the President and presumably they attach some degree of autonomy to his position.

These limited data from our pilot studies and our final questionnaire suggest that in the early grades children may view the President as a person upon whose shoulders lie the primary responsibilities for running the country. If anything, this perception spreads to increasing numbers of children as we move into the upper grades. At the outset, the child may innocently expect that if the President has the overall obligation to care for the country, he ought also to be top boss. But as the child grows older he learns that the President's competence does not extend fully to making all laws or to giving order to lesser executives at lower levels of government. Our pilot data at any rate suggest that on most items the child's cognitive map becomes less distorted, with age, from an adult viewpoint. The older child shows signs of finding his way among the rather abstract and complicated contours of authority that exist for the Presidency in the diffuse federal system of the United States.

Cognition and support

At the same time that these changes in cognitive orientation are taking place, the child seems to be accumulating a store of affect. This becomes apparent at times even in the more cognitively relevant kinds of questions. In ascribing towering status and authority and in placing the case of the country in his hands, there is little doubt that the child must be expressing latent approval of the President. Logically we could argue that it would be possible for the child to see the President in a position of power and responsibility and yet refuse to think well of him. But psychodynamically this is as little likely to be the case for children as it is for adults. If they see a person in an elevated status the probability is high that they will also believe that he is a wonderful person, especially if the status is one approved by adults and if it remains at a distance remote enough so that little capacity exists for a child to test his evaluations through direct experiences.

It would appear therefore that some of the kinds of knowledge children acquire about the President help to provide a hardrock base for the input of support. The limited pieces of the child's cognitive map of the President that we have explored are at least not inconsistent with inferring that children feel that the President is worthy of considerable esteem.

155

But the picture delineated here only sketches out roughly how the child sees and feels about the President and therefore only begins to tell us about the nature of the support to which the child is being socialized. We need to look at numerous other ways in which we sought to elicit as directly as possible the kinds of feelings the child learns to extend towards the President. Incidentally we will learn much more as well about the knowledge he has about the President insofar as information and affect are here distinguishable.

How the Child Feels About the President

In all our testing and interviewing, we were unable to find a child who did not express the highest esteem for the President. The descriptions of him were universally so approving that we can only describe them as a form of idealization, especially if we compare them with the usual evaluations of people in the American culture. What this idealization means will be discussed at a later point, but here we need to ascertain the various terms in which the child expresses his sentiments.

Most children have little difficulty in describing the President in glowing phrases. He is seemingly a store-house of inexhaustible virtues--wise, benevolent, powerful, worthy of the deepest trust, and capable of exemplary leadership. Figure VIII.1 shows the mean ratings given by the children on each of the thirteen qualities discussed earlier, by grade. Tables VIII.4a to VIII.4m provide the distribution of opinions for each point on each of the rating scales about the President.

If we scan the tables, the first thing to observe about the ratings is that although we offered the child a six point scale on each item, in virtually no instance are more than a very few children able to bring themselves to make the kind of negative or low-keyed judgment that would lead them to select the last two positions.[3] The responses are overwhelmingly skewed to the positive side of the ratings in each instance.

For only two items ("protects" and "I like") do the means fall between the third and fourth positions and in only two other instances ("my favorite" and he can "make people do") do the means for any grade fall below the midpoint of the scales. Thus in all but four of the thirteen ratings, on the average the child ranks the President exclusively on the upper three points of each scale. This is true even though none of the attributes remain constant over the age span. This one datum alone impresses on us the high esteem with which our children have come to regard the President in their first thirteen or fourteen years of life.

Figure VIII.1 permits a second general observation. Most of the mean ratings decline as the child moves towards grade 8. Only three show any increase and this will prove to be an important fact. With
Figure VIII.1.   Mean Ratings of the President on Thirteen Attributes by Grade

*Means of this rating were subtracted from 6.0 to make them
more comparable with the rest.

[a]CA-9, page 10, items 43-48, and page 27, items 64-70.

these general comments in mind, let us now examine each of the ratings
to see what they suggest about the child's assessment of the President.

Attachment or affiliation

The rating "I like him" is a forthright test of the child's sense
of attachment to the President. It draws the lowest mean ranking. Most
children only feel that they like him more than some or many people
(Table VIII.4a) but they would not go so far as to say that they like
him more than anyone or even more than most people.

In comparison with the extreme statements selected on other scales,
this expression of affection appears to be restrained, and perhaps two
reasons help to account for this. We administered this item only at
grade 4 and up and it is the children in the lower grades who typically
select the most positive values on most scales. But even more important,
liking is probably a term that the child confin s to persons with whom
he is in primary contact, well within the range of his daily experiences
and comprehension.

This interpretation of the less extreme level on this quality is
partly supported if we look at "is my favorite". At grade 2 the mean
for this rating begins at about 2 and does not fall below 3 until grade
7. If we look at the distribution of choices (Table VIII.4b), 72% of
the children in grade 5 consider the President as their favorite of all
or almost of all and this drops below 50% only in grade 6 when the
child is 10 or 11 years old. Even in grade 8, with children 13 and 14
years old, 59% still count the President as at least more a favorite
than most people. But in comparison with other scales the child's feel-
ings here drop most precipitously, as Figure VIII.1 reveals. This sug-
gests that where a public political figure such as the President in in-
volved, older children are more reluctant to wax so enthusiastic as to
exclaim that he is their favorite or best liked person. Nonetheless
it is apparent that a large majority of our younger children were able
to extend a rather high level of affection towards the President even
in the kinds of vocabulary more likely to be reserved for movie stars,
baseball players, or similar public entertainers dear to the hearts
of children.

Benevolence

Not only do most of our group of children feel warmly towards
the President. They also feel that he is benevolently disposed towards
them and would respond to their needs. This would seem to be the ob-
verse of the coin of affection. Those whom the child feels would help
him are likely to be the same ones of whom he would be fond; and those
he likes he is apt to consider would be ready to help him.

Children seem relatively convinced that the President would al-
ways or almost always want to help them. Beginning with 81% in grade 2,

162

52% continue to express this sentiment in grade 8. (Table VIII.4c)
The mean rating in grade 2 is the highest we have at that age although
like the other items that are more directly affective, the mean drops
considerably with increase in grade.

On our final instrument, we included an additional item designed
to evoke something of the same sentiments, yet from a little different
perspective. We wanted to get some further idea of the extent to which
the child perceived that the President would be benignly responsive to
his own needs and requests. If the child were unable to envision that
the President would care about him as an individual, then the kind of
global affect which typifies the child's image of the President would
probably not have any very direct or intense personal meaning for him.
The attachment to the President would have been somewhat superficial.

A way of adding depth to this personal significance of the Presi-
dent was suggested by interview responses that we had obtained from
several children concerning the possibility of writing letters to the
President.[4] Many children felt that they could write letters to the
President and that he would be interested and concerned on receiving
them. If the child could perceive that his writing to the President
would be noted and that the President would actually heed his requests,
the affect generated would therefore be quite tangibly based. The child
would have a valid personal rationale for liking the President in much
the same way that he might come to regard his parents or Santa Claus
or a guardian angel as both good and useful.

What we proposed therefore was comparatively simple. We asked,
"Which do you think is the most true? (Choose one.)

1. If you write to the President, he cares <u>a lot</u> what
   you think.

2. If you write to the President, he cares <u>some</u> what
   you think.

3. If you write to the President, he cares <u>a little</u>
   what you think."

In Table VIII.5 we see the pattern of response to this question over
the grades. We find that the younger children overwhelmingly pick the
option reflecting an image of the President's high concern for them.
This sense of responsiveness is depleted over the grades, but even at
grade 8, for close to half our group, the image is remarkably positive.

The child is somewhat less certain about the protective help that
he can expect. On Figure VIII.1 this scale joins "I like him" as the
lowest among all our items. Nevertheless 49% in grade 4 and 28% in grade
8 still consider that the President is more protective than most other
persons. (Table VIII.4d) We can assume here too that if we had used
scale in the second and third grades, a substantially larger percen-
tage would have chosen the higher rankings.

163

Table VIII.5. The Child's Perception of the President's
Responsiveness to Individual Requests[a]

(percent of children responding)

	If you write the President...					
Grade	he cares a lot what you think	he cares some what you think	he cares a little what you think	Total	N Responding	N Not Responding
2	75 %	20	5	100 %	1639	16
3	69	26	5	100	1664	14
4	56	36	7	99	1738	11
5	51	40	9	100	1795	8
6	46	42	11	99	1744	5
7	45	44	11	100	1710	13
8	43 %	43	14	100 %	1686	9

[a]CA-9, page 7, item 34. "Which do you think is the most true? (Choose one)
1. If you write to the President he cares a lot what you think. 2. If you
write to the President he cares some what you think. 3. If you write to
the President he cares a little what you think."

In these items we get a firmer feeling for the overall tone of
the feelings our children have for the President. He is not just out
there to be observed and admired. Our children feel an intimate con-
nection with him. The President is concerned enough to help and pro-
tect children. Clearly they consider that the bond between themselves
and the President is reciprocal. Affection for him from them and benevo-
lent guardianship for them from him go hand in hand.

Dependability

The President is also dependable. We can expect him to keep his
promises, not to make mistakes, and we can rely on him to persist in
what he is doing. Among adults we would have expected that statements
such as these could be made on the basis of observation and therefore
would reflect some knowledge about the President, either first or second-
hand (historical) in origin. But certainly our youngest children, those
who have little actual information about the President, can only be pro-
jecting their expectations about him. Estimates of general dependability
are likely to represent more in the way of feelings rather than actual
knowledge. As the children grow older new information may temper their
earlier unrestrained enthusiasm.

Thus although few of the youngest children would know whether
the President does in fact keep his promises, their expectations about
him are such that this item reports the highest mean for grade 2 and even
by grade 8 it has dropped only from 1.6 to 2.1. In aggregate terms, 84%
in grade 2 feel that the President always or almost always keeps his
promises, and even with what the child must learn from history, 'civics
courses and incidental sources, this only falls off to 70% by grade 8.
(Table VIII.4e) Trustworthiness appears to be an outstanding charac-
teristic of the President.

But he is also dependable in another sense, in his expected infalli-
bility. The younger children, in grade 4, again choose the extreme posi-
tion with 72% saying that he almost never or rarely makes mistakes (Table
VIII.4f). If we had been able to test in grades 2 and 3 we would un-
doubtedly have found that a considerably larger number of children felt
the same way. To most of the younger children the President is less
likely to fall into error. Even by grade 8, 51% continue to share an
extraordinary confidence in his judgment. An insignificant proportion
only can harbor the thought that the President might often take the
wrong course of action.

Finally, the President is also trustworthy and reliable by virtue
of the fact that he is less likely to give up when things are hard to
do. Here we have one of three of our scales that moves in a direction
opposite from most. The mean rating rises with the grade, if only
slightly. Well over 50% of the children across the grades, beginning
with grade 4, hold the opinion that the President never or almost never
gives up, with 71% in grade 4 rising to 79% in grade 8 (Table VIII.4g).
Persistence in the face of adversity is a Presidential virtue for an
increasingly larger number of the children.

Power

The likeability, benevolence, trustworthiness and reliability
are all personal kinds of qualities with which the child colors in
his picture of the President. But our group of children perceives
another kind of property that may seem to have more direct political
implications. The President is considered to be a person with not in-
considerable power over others. Adults take this for granted in an
era when the chief executive in most industrial political systems has
achieved a position of preeminence. But it comes as not a little sur-
prising that at an age when adults would imagine children are innocent
of a social phenomenon such as power, our children are in fact sensi-
tive to this kind of potential in a President, even though it is ex-
pressed only in very concrete terms, within the limits of a child's
conceptual abilities.

In our interviews the youngest children, in grade 2, were al-
ready talking about the President as one who directs and orders people,
who makes laws, keeps the peace, works for the good of the people, and
does important things such as taking trips around the country and abroad.
There was little doubt about the President's prominence in the country.
With it goes the impression that he has the capacity to execute his
wishes.

For operational purposes we did not find that the term "power"
was very useful. The child is not familiar with it, at least for the
way in which we wished to use it. But to get at the underlying meaning
of the term, we used both a connotative and a denotative description.
The child is able to comprehend the basic idea of power--being able to
get other people to do what one wants them to do--even if the word is
normally outside his vocabulary in the early grades. To get at this
suggestion of general control over others, we asked the child whether
the President "can make others do what he wants". The child is also
able to understand what it means to be able to enforce one's will through
the employment of sanctions. We therefore asked him whether he felt the
President "could punish anyone". In our interpretation this is clearly
an important instance for the child in the exercise of power. These
two aspects, general control and sanctions, seemed to cover the kinds
of subjects children typically mentioned in the area of power during
our pretesting.

We probed the first dimension of power by asking the child to
rate the President (and other authorities) according to his capacity
to make people do what he wanted them to do. As Figure VIII.1 reveals,
the younger children, in grade 2, are on the average prone to hold that
the President falls somewhere between being able to make almost anyone
and being able to make many people do what he wants. Even by grade 8
this estimate of the controlling capability of the President has not
dropped very much. In aggregate terms the child's image of this capaci-
ty stands out with greater prominence. In grade 2, 59% feel the Presi-
dent can make anyone or almost anyone do what he wants and this declines
to 40% by grade 8 with most of the difference shifting towards the opin-
ion that he has control only over many persons (Table VIII.4h).

When we look at the coercive component in this perception, we find that children are less certain of the President's power. On the average, children from grade 4 through 8 hover in the neighborhood of the relatively restrained opinion that the President can punish only many people, not everyone or most. But again, if we look at the actual proportions, we have slightly more information. In grade 4, our earliest grade, 50% do think that the President can levy sanctions on anyone or almost anyone and even by grade 8 37% continue to stand by this conviction (Table VIII.41).

However benign the President might be seen in other respects, there is little doubt that many younger children consider him to be a relatively powerful figure. It is equally clear that a sizeable minority even think of him as virtually omnipotent, with 36% in grade 2, 29% in grade 3, and 24% in grade 4, indicating that the President can make anyone do what he wants and even 20% in grade 4 holding the opinion that he can punish anyone (Table VIII.41). Most older children, however, express a more moderate opinion on this capacity to manipulate and punish people.

Leadership

We have already learned that however poorly informed younger children may be about politics, they do have some knowledge about possible activities in which the President engages. From grade 3 on, children were able to make a meaningful selection among the possible activities of the President that deal with domestic and foreign affairs (Table VIII.3). Our discussion of the image of Government has also demonstrated the extent to which children associate the President with making laws and running the country.

Already implicit in this knowledge is the suggestion that the child must interpret the President as a person who offers some kind of leadership to the country. If for many young children he best represents what our government is, makes laws, and does the most to run the country, these activities may be accepted as virtual definitions of leadership. But we were also able to obtain a direct evaluation of the President as a possible leader.

In our leadership ratings it appears as though we are asking the child exclusively for information about the President. In fact, as we have already indicated, although there is undoubtedly some informational content in these items, there is also a high evaluative component. For children, leadership is not an emotionally neutral idea. It connotes approval as well, especially in the American cultural setting. In the abstract many children might want to be a leader. It is reasonable, on this assumption, to interpret our ratings about leadership traits as reflective of the feelings that the child holds for the President.

When we asked the child about the extent of the President's knowledge, his capacity for hard work, the importance of his decisions,

and forthrightly, about his leadership abilities, the image was amazingly stable over the grades. On the average (Figure VIII.1), most children think that he does know more than most people and that he works harder than most people. As we move into grade 8 the mean ratings on these items decline only slightly. But when asked about the frequency with which the President makes important decisions our children thought that he did so a lot of the time. As they grow older they tend to move towards the opinion that the President does so all the time. The proportions believing that he makes important decisions all or a lot of the time rise from 83% to 95% from grades 2 to 8 (Table VIII.4j). Similarly across this span, the mean ratings of the children range between assessing the President to be a leader "all the time" and "usually", moving somewhat towards the former as they grow older. Thus 86% in grade 4 see him as always or usually a leader rather than a follower and this increases to 92% by grade 8 (Table VIII.4k).

It is clear that children are impressed by the special role that the President holds from the moment we are able to test them. Not only is he knowledgeable and persevering, but by grade 8 they are virtually unanimous that the President is never a follower, possesses the qualities of leadership, and that his duties are always of supreme importance.

Idealization and Support

In summary, the evidence is overwhelming that young children view the President through rose-colored glasses. No taint of criticism, mistrust, or indifference creeps into the picture. Even those who rank lowest on our scales are nonetheless positive in their evaluations. Most of these children think the President is inherently likeable and benevolent since he would help and protect them more often than not. He measures up to the cultural ideals of being very trustworthy, not too fallible and very persistent in his effort. He has the power to perform whatever it is that he does and in doing so, he displays qualities associated with leadership. For most of these judgments the child does begin to revise the benign image that first emerges. But he does so from the direction of high initial approval. He has already committed himself to the judgment that the President is a bening helper, protector and leader.

It is important to recognize the full meaning of the positive assessment of the President along these various qualities.[5] In each instance, these properties are of the kind that our culture tends to value. We consider people to be good and virtuous if they are protective, helpful, trustworthy, correct, persistent, knowledgeable, hard working, and possessed of leadership qualities. Our culture is more ambiguous about power. Might does not always make right. But power is also a mark of success where it is not clearly associated with evil. In the President it would seem to be a positive attribute, at least for our test children.

If we cluster all these properties together in this way and bear in mind the high rating that the child extends to the President on almost all of them, it is evident that behind them there is something more than just an acquired affection for the President. With little knowledge about him, especially in the earliest grades, the child may be reporting less about what the President is than what he is expected to be. But what should we expect a President to be like? It appears that to fill in the gap in his actual knowledge the child may be falling back on the ideas in which his culture has already begun to instruct him. The President should have the cultural ideals associated with good adults.

What the President should be is therefore probably expressed in the child's cultural ideals for the good adult. Idealized, the President should be protective, helpful, trustworthy, strong and so forth and this is therefore what he is for the child. Certainly these perceptions must also share some of the judgments held by adults in his environment. The child may learn directly from adults to feel this way about the President. We can easily imagine that the child would have arrived at a different assessment if adults had considered Presidents typically to be timid, fearful, and vacillating, unable to place their imprint on the affairs of state, and thwarted in every major effort to exercise power. But adults are not likely to hold this image in general although they may feel this way about a particular President.[6] Hence children would not be likely to learn from them to deny the cultural ideals to the President.

It seems plausible therefore to assume that for the children in our group, it is as though the President had become an authority object on which they feel able to project certain ideals absorbed from the culture. When we deal with other authority figures we shall return to this notion. But at the moment, whether this is or is not an acceptable interpretation of why the child comes to hold the President in high regard, the indisputable fact is that the child does express what looks like a strongly idealized image of the President.

The children are responding to the system in terms of this person who for them best represents it even if for them this relationship is not apparent and even though they have little consciousness of the political relevance of their ideas and feelings. For the youngest of our test children at least, their acceptance of this symbol of political authority appears to come well before their awareness of and therefore before their acceptance of the myriad of institutions that underpin and surround the Presidency. Attachment to the President would seem to give these broader and more diffuse institutions through which political authority is expressed, called the government, a visible and personal incarnation. Although for the youngest children the institutions of government which originate and extend the realm of political authority are still almost hidden from view, the man at the top is not. The youngest children accept him wholeheartedly, without question, and no significant number of the children at any age deny him a good measure of approval. If the President is indeed the living symbol of the political system--"our government"--for the young child, the main conduit

through which a child moves into the fuller stream of political life in the United States, we may suspect that support for the regime arises easily and naturally.

As we move through our further analysis of the child's image of political authority figures and agencies, we will be presuming these findings. Our further data will involve a variety of ratings of other authorities as compared to those about the President. In these ratings we will see the exceptional comparative position the President enjoys in the eye of the child, again and again. We will also see something of how these feelings compare with those of other figures of authority. But before this analysis is undertaken, we need to examine more carefully what it is that the child is being connected to when he admires the President.

Footnotes

1. See Chapter VI.
2. As one 9 year old child put it in an interview:
   Q. "Do you think the mayor should get his orders from the President?"
   A. "Yes."
   Q. "Why?"
   A. "The President is smart, and one ought to do the things the President wants us to do."
3. Table VIII.4m appears to be an exception. But this was only because the scale was reversed in order to assure ourselves that the children were not checking the higher points solely because of acquiescence response set.
4. For an interesting and amusing collection of letters which actually were written see W. Adler, Kids' Letters to President Kennedy, (New York: Morrow, 1962).
5. For reinforcing data related to reaction of children to assassination of President Kennedy, see essays in M. Wolfenstein and G. Kliman, Children and Death of a President, especially R. Sigel, "An Exploration into Some Aspects of Political Socialization: School Children's Reactions to the Death of a President", pp. 30-61.
6. We say this somewhat tentatively given the state of research on public attitudes towards the President and Presidency. Popular reaction to the assassination of John F. Kennedy certainly suggests that the public is apt to idealize the Chief Executive and to hold some fairly far-reaching, if ordinarily unconscious, feelings about him. See, for example, B.S. Greenberg and E.B. Parker (eds.) The Kennedy Assassination and the American Public (Stanford, Calif.: Stanford University Press, 1965). For data about the reaction of children and youth see M. Wolfenstein and G. Kliman (eds.), op. cit. Neither of these books gives a precise answer to our question, however; nor does any other research that we have been able to locate. Greenstein notes indeed that "It is one of the anomalies of scholarship that more is presently known about young children's image of the President than about how adults conceive of him." ("Popular Images of the President", at page 525.) Some additional information has become available more recently which is suggestive, however, if not an exact answer to our question. Sigel reports, using a 1960 sample from Detroit, that respondents more often than not favor a strong President and prefer Presidential to Congressional leadership (52% vs. 40% respectively). For these and other relevant findings see R. Sigel, "Image of the American Presidency", 10 Midwest Journal of Political Science (1966) 123-137.

CHAPTER IX

THE PRESIDENT, THE PRESIDENCY

We have argued that since the President is one of the first
objects in the political structure of which children are aware and
about which they are capable of developing sentiments, we have un-
covered a major way through which maturing members of the American
system may become attached to it. We have seen that in fact chil-
dren do discern the President through a mist of praise, high status
and beneficence. They display an early and strong tie to the Presi-
dent and, we have surmised, through him to the general structure of
authority.

The Person Versus the Role

But may we be taking too much for granted? It is not enough
to be able to demonstrate that the school child has put the President
on so lofty a pedestal. Could it be that we have only been picking up
clues about the way in which the child is reacting to the particular
person who happened to be President during our test period? If the
children are reporting only that the incumbent, President Kennedy, as
a person was likeable, powerful, dependable and the like, this gives
us little direct information about their orientation to the role of
the Presidency as one of the critical components in the American struc-
ture of authority. To the extent that the child is responding only
to the qualities of the occupant of the Presidency and not to the
characteristics that he sees associated with all presidents, we would
learn little about how he is evaluating the presidential role.

Not that this, even if true, would necessarily destroy the value
of our findings. If we had been driven to the alternative conclusion
that the children in our group were only evaluating the purely perso-
nal characteristics of Kennedy as President, it would only require
us to add another link in our interpretive chain of reasoning. Con-
ceivably the way the child feels about a person who holds an office
might in due course spill over to the office itself. Children who
were fond both of Eisenhower and of Kennedy uniquely as persons might
in time come to think well of the office of the President itself or
they might at least develop similar expectations about all Presidents.
Undoubtedly even among adults admiration for the man helps in some
part to sustain a belief in the validity of the office. But if we
were forced back to this interpretation it would prohibit us from
drawing direct inferences from our findings about the way in which
the child feels about the structure of authority. Yet it is exactly
statements of this kind that we would like to be able to make, and
have in fact made.

172

We are left with a problem then as to what we have been testing.
If we can show that the child is capable of directing expressive at-
titudes towards the presidential role rather than merely to the Presi-
dent as the particular occupant of this authority role, we will be
able to say that we have established something about the evolving re-
lationship between the child and the structure of authority. This in
turn will make it easier for us to adduce some probable connection
between the child and the regime.

The Role Relevance of Our Findings

We have no decisive proof one way or the other but we do have
several kinds of evidence suggesting that the child is reacting to
the presidential role. To begin with, at the time of our earliest pre-
occupation with the child's image of the President, the incumbent of
the role was Eisenhower. Since this was in the initial stages of our
thinking about socialization, we do not have test items strictly com-
parable with those administered in our survey when Kennedy held office.
But some similar ones have already been reported in detail.[1]

We asked the child to express his views comparing the President
with most men, about how hard he works (diligence), how honest he is
(honesty), how much knowledge he has (knowledgeability), and how much
he likes people (friendliness). We also asked the child to rate the
President as the best in the world, a good person, or not a good per-
son. Although the number of children tested is small, the ratings
move in a direction similar to those for our study made after Kennedy
became President. The child's evaluations during the Eisenhower test
period are uniformly high over the grades, with the more effective
items declining somewhat as the child grows older and the more cogni-
tive ones, such as "works hard" and "knows more", increasing. These
findings give us some confidence that at least one important personal
quality of an incumbent of the Presidency, his party identification,
need not be the decisive determinant of the child's perception.

But this conclusion does not permit us to go to the opposite
extreme and to argue that the role of the Presidency must therefore
account for all of the variance, that it is the only factor shaping
the child's image. Data from our present study indicate that some
part of the child's attitudes towards the President can be accounted
for by his party preference. Where he is of the same party as the
President, the child is more enthusiastic about him. If this is so,
at least one personal characteristic of the Presidency, his party
identification, does contribute something to the intensity with which
the child approves of him.

Thus when we combined the items "I like the President" with
"He is my favorite" to form an Index of Affect or Attachment[2] and
correlated this index with the party preference expressed by the

173

child[3], we found a significant, even if fairly weak relationship between them. At grade 4, the earliest grade for which we were able to develop this Index, the correlation between affection for the President and the party preference of the child is scarcely significant. But as we move through the grades, the correlation increases in a negative direction for those children identifying themselves as Republicans, as we would expect (see Table IX.1). For those children who in effect declared themselves to be Independent[4], there was no significant correlation with affection for the President, either positive or negative. It is apparent therefore that the party of the President does influence in some degree the extent to which the child approves of him.[5]

The effect of party is brought out even more vividly in Table IX.2 which shows the distribution of Republican and Democratic children on our Index of Affect for the President by grade. In each grade a larger percentage of Republican children consistently fall into the low category. In this category (low), the percentage differences between Republicans and Democrats in each grade remains relatively constant through grades 7 (at an average 15%), but in grade 8 it leaps about an extra ten points (to 25%). This would seem to reflect the growing capacity of the child to appreciate the significance of party alignments and therefore to take it more into account in his estimate of the President.

But even this conclusion about the impact of party identification on expressions of approval needs to be interpreted with caution. We may well doubt whether it applies to our younger children. It would seem reasonable to project downwards our correlations for grade 4. In this event since a significant correlation[6] between party preference and attachment (Table IX.1) just begins to emerge at grade 4, we could assume that the lower grades would show none higher. Yet we will recall that in all but a small number of instances it is in the lower grades that our ratings reach their peak and children report their highest evaluations of the President. We can safely assume that the party identification of a President would have little meaning for the perceptions of our youngest children.

Two possible inferences may be drawn on these assumptions. We could argue that all children may base their judgments purely on the kind of person they take a particular President to be. If so, as they learn to assert a party preference and as they also learn that the President stands with one or the other party, their initial estimates may be influenced somewhat. This would account for the somewhat less positive assessments by the children who identify themselves as Republicans.

It seems more plausible to put forward an alternative explanation. The children have very little knowledge about the Presidency, especially those in the earlier grades. It is unlikely that they would have enough information about the personal qualities of a given individual to be able to think of making judgments about him. They must therefore be making assumptions about the characteristics of all Presidents as persons who hold this office. In effect they are describing what they see as aspects of the typical personality in that

174

Table IX.1. Correlation between Party Preference and Index of Affect for the President[a]

(Pearson r's)

Party Preference	Grade				
	4	5	6	7	8
Democrat vs. other	.11	.14	.18	.16	.17
Republican vs. other	-.11	-.13	-.18	-.17	-.22
Independent vs. other	.00	-.01	.00	.00	.03

[a]Each category was scored as high on a dichotomous variable, namely, Democrat or other, Republican or other, Independent or other. Party preference is determined by answers to CA-9, page 9, item 42. Affect for the President is measured by a linear combination of responses to two items: CA-9, page 10, item 48 and page 27, item 68.

175

Table IX.2. Relation of Republican or Democratic Party Preference to Affect for President, by Grade[a]

(percent responding)

Grade	Party	Low Affect	Medium Affect	High Affect	Total	N Responding	N Not Responding
4	Republicans	39 %	26 %	35 %	100 %	520	3
	Democrats	24	33	43	100	329	2
5	Republicans	43	30	28	101	534	4
	Democrats	31	31	38	100	450	2
6	Republicans	44	32	24	100	489	3
	Democrats	27	32	40	99	497	5
7	Republicans	49	31	20	100	415	5
	Democrats	34	31	36	101	537	10
8	Republicans	64	22	14	100	336	9
	Democrats	39 %	31	30	100 %	542	6

[a]High is equal to scores 9-11, medium is 7-8, and low is 1-6.

role, the role personality. As the children grow older, we can expect them to acquire a better sense of their own party identification and also to be able to understand something about what the President's own party coloration may mean. They should gradually be able to modify their evaluation of the general presidential role personality with information about the particular President. In this interpretation the acquisition of party preferences represents the first opportunity the child has to introduce personal criteria into his previously learned expectations about the role.

The kind of evidence we have presented leads us towards the conclusion that the child is probably less concerned with the President as a particular person than as a symbol of political authority. If the child is indeed reacting to the symbol in large measure, it is highly probable that he is expressing sentiments about the Presidency as part of the structure of authority.

The fact that the child absorbs expectations about the personal qualities of the occupant of the presidential role is not at all unusual. It is well-known in other spheres of life. As we mature in the American society, for example, we anticipate that physicians as such will have certain personal properties regardless of individual idiosyncracies. However ill-tempered, intolerant, self-centered or even mercenary he may be in other spheres of life, we expect the physician to listen patiently and sympathetically to our complaints, to provide honest diagnoses and treatment, and even to sacrifice some of his own comforts, such as sleep and regular hours, to help us in distress. We also expect him to be motivated by more than a mere desire for financial gain.

But as we become acquainted with a particular physician we usually have to alter our expectations in light of the actual personal characteristics that we encounter. We may also modify our generalized expectations about the role personality of physicians by what we now know about this particular physician. But the relationship between physician and patient and in fact the position of the physician in the social structure is very dependent upon the initial and subsequent generalized perceptions that we develop about him.

Similarly for the President, what we find is that at the outset the maturing member of society, as represented in our group of children, acquires sets of dispositions towards this political role which also happens to be a central unit in the structure of political authority. In the immaturity of childhood it is the personal qualities that are most easily perceived and understood. There is little reason to be surprised that children should seize, not upon the complex duties and behavior of a President, but on his clearly personal qualities as elements of the role that help them to orient themselves to him and, we would infer, through him to the political structure.

177

The Meaning of Personalization of the Presidency

Probable as this inference may be, it does leave us with an apparent contradiction. In Chapter VII, on the "Image of Government", we argued that it was very meaningful to find that the child initially personalizes government by seeing it best represented in such personal figures as the President. Only later does he turn to such impersonal institutions as Congress or voting. Yet in our present chapter we are proposing that initially the child's image is shaped largely by the Presidency as an institution with only some small influence being exercised by the qualities of the incumbent President as a particular person.

The contradiction is apparent only. To say that the child personalizes authority is not the same as asserting that he sees only the person or incumbent in the authority role. In Chapter VI we were only trying to show that in the whole range of objects of political authority, the child is drawn to that object which could be most easily symbolized by some person. Given the marginal status of political things in the daily concerns of the child as well as his acute inability to cope with a concept as abstract as "political authority", he is able to deal only with very tangible manifestations. Among other things, initially the child sees not some complex, imposing and over-arching structure of authority but an Eisenhower or a Kennedy. To some limited extent he may be impressed by them as partisans and the older he grows the more does partisan identification constrain his judgment. But to a much larger extent it does not matter what the idiosyncratic qualities of the incumbents are. To the children a named President is more than the man. An Eisenhower or a Kennedy is <u>our</u> President and this growing awareness evokes a set of generalized expectations about his benevolence, dependability and the like, that is, about his role personality.

Transparently most younger children at any rate are not able to distinguish consciously between the Presidency and the role occupant. For this reason in designing our questionnaire we felt free to use a hand-drawn sketch of President Kennedy to represent the general role of President without fearing that the child would really be relaying to us his image only of Kennedy, the man. As our data indicate, children are able to talk about the particular incumbent as though he were "the Presidency" in adult parlance, that is, the institutionalized role.

Peculiarly it appears that the child begins political life not by concentrating on the unique person, although this is not entirely neglected, but rather on the occupant as representative of our country and government. The general symbolism of the role overpowers the particular characteristics of the occupant. It is for this reason that we are able to conclude that the child has begun to be aware of an important part of the structure of authority. The fact that previously we concluded he did this through personalization of that structure is not inconsistent with our conclusion in this chapter that the child is able to see and cathect the role.

The System Effects of Personalization

What are some of the consequences of this high degree of personalization of the Presidential role? To recapitulate the essence of our findings in this area, we have discovered that a large proportion of younger children wax so enthusiastic about the President that he seems to become something just less than a paragon of virtue as measured by our various criteria. It might be suggested that this is not surprising since children are known to be prone to exaggerage, to see things in black and white. But for the Presidency at least, this is not the case. Usually something less than 50% hold the most highly positive notions; the remainder of our group distributes its opinions over a gradient even if the children seldom fall below midpoint on our rating scales. Furthermore, as we shall see later, children are also able to discriminate between the President and other authority figures such as father, policeman, or Senator. Their judgment of the Presidency is not part of a wholesale, uniform and extreme idealization of all authorities.

Our data also suggest that children are not thinkint in these exceptional terms about any particular President alone. At the young age when we test them they are already able to see numerous expected generic qualities of Presidents, the office rather than the man.

The implications of these findings for the political system are varied. We shall now examine a few of them.

Personalization as the child's mode of contact

Personalization identifies a process whereby the child is able to establish contact with the structure of authority in a way that is plausible and congenial to his mental and emotional capacities. Without some connection such as this it is difficult to imagine how a child would begin to develop an identification with the system in which he finds himself.

Although we seldom think of the child's position in the following way, when he is born and begins to mature in a society, as we suggested earlier, he is in many ways similar to an immigrant who has just entered the system. Unlike real immigrants, however, he does not undergo a resocializing process. The child does not have to learn to transfer his allegiance; he has no preconceptions and predispositions to cast off or revamp. But as with immigrants, the child for the first time does have to learn to recognize parts of an unknown map about political authority. Depending upon what he sees and his experience with it, he may extend some measure of support. The fact that in the American system the child's eye catches not some impersonal set of institutions such as Congress or even the Supreme Court first, but rather a figure of authority, and the fact that he sees this figure as a bundle of personal qualities associated with the role, make it relatively easier for him to reach out to the structure.

One of the reasons for this is that the President is the kind of element in the political structure that can bring the child's image of the regime to a sharp focus. The idea of "government" of which some children are simultaneously aware by grade 2 is certainly much more diffuse, more difficult to grasp, both for adults and children. Indeed, insofar as children do comprehend it, we have seen that it is often initially also in terms of the President as its best expression. The singularity of the President, his eminence, visibility and power give the child a handle to grasp as he seeks to interpret the phenomenon of an authority external to the family, a kind of authority that he is quickly aware of as his eye and mind wander beyond the home.

The personalization of the President reflects the fact that what the child sees are warm, palpable characteristics, much like those of human beings with whom he already has developed primordial ties. Personalization facilitates the development of those very elemental kinds of feelings of which children are capable: love and hate. It summarizes a host of other attributes that children are accustomed to associate with ordinary people, such as leadership, power, or benevolence.

Structural versus personal legitimacy

But in spite of the extraction of personal characteristics in the presidential role, in our interpretation the child relates himself not to the occupant as a man but to the role itself. This is of vital significance for the input of diffuse support for a political system. It may be a singular mainstay of the Presidential structure in the American system.

If the child fixed his attention on the man and revered the particular qualities of the incumbent, one of his first lessons in politics would be that the legitimacy of the authorities depends on their individual qualities. He would be acquiring a sense of the personal legitimacy of the President, his charisma. Presumably if he retained this orientation, on the change of the President the child would need to start afresh and renew this support only if he continued to consider the new President had qualities that he could admire. Each President would be faced with the task of revitalizing a belief in his legitimacy. To command acceptance, each President would have to stimulate a belief in his personal adequacy. Leadership succession would be a constant source of political strain. In Weberian language, the routinization of charisma would have difficulty in developing.

Undoubtedly there are systems, even in a mass industrialized society, in which the qualities of the man rather than the position he occupies may temporarily be basic to his acceptance. Some would argue that this is indeed the case with de Gaulle. But our data suggest that in the United States personalization is not the same as the acceptance of the legitimacy of a figure of authority on purely personal grounds. Children are able to accept the President because

they have certain idealized expectations about the occupant of the
presidential role regardless of who he may be. The tensions and cri-
sis of succession resulting from the need for each occupant to recre-
ate a loyalty uniquely due to him—the Weberian charismatic type of
base for legitimacy—is thereby avoided for the child. Any President
merits his esteem because he is President, even if he is of an opposite
political complexion.

We cannot overemphasize the surprising nature of this finding.[7]
Here we have stumbled upon a possible means through which a political
system manages to transmit respect for at least one of the major offices
in its structure. We are tapping a major source of continuity in a
regime. In most large-scale political systems, persistence requires
some belief in structural legitimacy, the acceptance of the basic or-
ganization of political relationships, formal and otherwise, as right
and proper.[8] Our findings hint at the dynamic forces that enable matur-
ing members to learn for the first time that persons may come and go
but that the structure—or more cautiously, one basic structural compo-
nent, the Presidency—can go on, if not forever, at least beyond the
lifetime of the current occupant.

This is why we may interpret the image of the President as an
indication of the kind and level of support that our group of children
are prepared to put into the structure of authority. Certainly this is
a plausible conclusion for the younger children in our group. For
them the President is seen as the one who does most to run the country
and he is one of the best symbols of the government, itself a vague,
omnibus term for the authorities as a whole. We have been arguing in
Freudian vein that emotions experienced this early are apt to color
behavior in later life. In this may lie the ultimate significance of
childhood attachment to and belief in the legitimacy of the structure
of political authority as represented in the President and, as we shall
see, in other figures and institutions as well.

Political controversy and structural legitimacy

We may also have some clue here about the origins of that capaci-
ty among adults that permits them to criticize and condemn the President
and yet retain respect for the office. In the short-run at least, the
passions surrounding the role do not seem to undermine support for it
or for the rest of the structure of political authority. If it were
not that as adults we have become so accustomed to considering the con-
troversy surrounding the office as normally immaterial to the accepta-
bility of the Presidential system itself, we might long ago have been
struck with wonder at the ease with which we can differentiate man from
role. We might otherwise have felt an urgent need to inquire into its
source.

In party politics, the specific qualities of the man as a nego-
tiator, arbiter, leader, strategist and policy-maker[9] may be paramount
for judging an incumbent. But for most adults, regardless of the

degree of competence of the President, the office as a symbol of the whole regime continues unimpaired. Furthermore, however much members may differ about the qualities of the man, once he steps into office they anticipate that he will conform to certain personal standards in meeting its requirements.

We have seen that this is not a capacity that is left to adult-hood for its development. Our group of children have already acquired this posture towards the Presidency before they have left elementary school. We might expect that in this respect the adult is but the child writ large. Our research has guided us towards an understanding of how in childhood the future adult members of the American political system learn to distinguish between the role and the man. Not that we would contend that adults have the capacity to keep the two so separate that what they think of the man does not ultimately influence their judgment about the role. Spill-over from one to the other undoubtedly occurs. It contributes perhaps to a certain ambiguity in adult perceptions of the Presidency, something we know little about as yet. There always remains the latent fear in the United States that excessive, harsh condemnation of a President may undermine the authority of the Presidency as an institution. But without the capacity to make the distinction it is unlikely that a sense of structural legitimacy could be maintained. In this event other sources of support for the political structure would have to be sought.

Without doubt it is useful for a regime that combines in one office the figurehead of the system and the active executive, to train its members to distinguish the role from the man. But our findings imply more than this. They also contain a suggestive hint about the source of diffuse support for the structure of authority, not among children alone but for adults as well.

It is conceivable that idealization during the early years of life will leave a residue of positive sentiment within the later adult. Manifest affect in childhood may continue as latent affect in adults. If this is indeed true, this may be an added reason why, among adults, criticisms of the occupant do not readily shake one's confidence in the Presidency. However much members of the system may despair of the man as President, early idealization of the office may leave enough respect as a latent force to sustain a belief in its legitimacy. If so we have come upon a major tap-root of diffuse support in a system.

Personalization and personal political identification

The consequences for the system may not be independent of what personalization does for the child as well. The Presidency may be a point in the complex social world which guides the child towards a sense of political identity. Regardless of party, the President is his President, even though partisanship does introduce some distracting noise into the system. We may suspect that personalization of the office helps the child to become aware of who and what he is politically; he sees himself reflects in the President. If we were

182

pressed into it, we might even hazard the guess that in the past the assured and cocky air of some Americans at home and abroad, their national brashness, has been not only a product of national wealth and power, but of a deep feeling of political assurance, a strong air of self confidence that they have known who they were politically. We are led to wonder whether the psychic roots of this phenomenon do not lie partly in the opportunity to attain a secure sense of the politically self through the personalization of authority in the Presidency. If so, in this respect as well, early socialization through the Presidency may have far-reaching consequences for the input of diffuse support to the American regime.

The Universality of Personalization

Our interpretation of the possible system-effects of personalization carries us far beyond its immediate significance for socialization into the American political system. In effect, we may have encountered here a central mechanism available to many political systems for building up diffuse support in each wave of children as they enter a political system through birth into it. The fact that the new member is a child rather than an adult with a pre-existing set of attitudes towards political life, creates a need for special devices to build support for the regime and authorities. Each system will, of course, have its own specific mode of personalization. It may take the form of a monarch, a paramount chief, a renowned elder or ancestor, a charismatic leader, or a forceful dictator.[10] But the pattern of making government or the structure of authority a warm and immediate object through its initial symbolization as a person, the high affect that this permits for a child, and the possible subsequent overflow of this feeling to cold and impersonal institutions and norms may be vital. It provides a complex yet not unfamiliar mechanism for attaching to the system those members who are new to it by virtue of their birth in it.

From the peculiar position that the President comes to hold in the American system, however, we cannot directly infer that every system must provide some kind of personal point of contact, central in the political structure, if the maturing generation is to learn to put in support for the regime. Certainly we would be going beyond even the broadest implications of the data to argue from our knowledge about the visibility, saliency, and idealization of the American President that every system requires some estimable personal chief executive.

There is a confluence of several forces in the American system that projects the President into the foreground. The first is the considerable importance of chief executives in all modern industrialized systems; the second is the prominence of the Presidency because of the peculiar nature of the American political regime; the third is the child's own sense of vulnerability and need for a powerful protector. It is difficult if not impossible in a one-system study such as ours to disentangle what may be common to all systems from

what is unique to a single system. We cannot tell whether in the American system the President arises as a point of contact for the child because of the growing visibility of all chief executives in modern times, because of the special properties of the American political structure, because of the child's need to feel protected, or as a result of some peculiar combination of these factors.

If, however, we are willing to subscribe to the idea that the personalization of authority for the child represents a phenomenon that transcends this time and place, the prominence and importance of personal figures such as the President raise some interesting questions about the input of support to political systems in general. Suppose a system developed a structure of authority that contained no central personal figure to which the maturing members could direct their attention and affection. How then might we expect a child to make contact with the regime, especially if we assume that in his earlier years his ability to conceptualize and relate himself emotionally to impersonal objects, such as organizations or institutions, is very low?

It is clear that under these conditions, with our assumptions, the system might have considerable difficulty in socializing its members so that they develop positive sentiments early in the life-cycle. But if the system did _not_ show signs of weakened support, it would alert us to the need to look for other kinds of mechanisms that might have come into operation and through which the members could begin to accent the legitimacy of the political authorities.

For example, if there is a low level of support in the early years, it might be compensated for by mechanisms in later years that serve to increase the input. In some systems the maturing members might put in no direct support at all to the structure of the regime. Intermediate figures and organizations might exist through which the child is bonded to the system. The child might learn to esteem the head of a lineage who might mediate between the system and the child. A church, ethnic group, linguistic unit and the like might similarly play a mediating function. Regardless however of the specific devices through which a system might seek to encourage the input of diffuse support for the structure of authority, the means it developed would have to take into account the apparently low capacity of younger children, if our test group is typical of most children, to relate themselves to impersonal institutions.

But whatever the way in which other systems may handle the socialization of support, in the United States the President as a personalized figure is a towering, glittering mountain peak for the younger child, easy to single out from the whole range of authority. As the child grows older his eyesight becomes stronger and hidden peaks appear that may even soar higher, such as Congress. But we have suggested that what he initially sees and the feeling he develops for it may remain as an undercurrent of his attitudes towards the authority structure. Even though the older child may see authority in more critical and less enthusiastic terms, early idealization may create latent feelings that are hard to undo or shake off. This is the major significance

of the first bond to the system through the Presidency. The positive
feelings for political authority generated there can be expected to have
lasting consequences.

This does not deny the patent possibility and reality of change.
Children as well as adults may be loosened from their ties to the system.
But our data on the regime in the United States do not permit inferences
about the nature of the processes of change insofar as they are influenced
by childhood socialization. Our sample of children show little evidence
of being disconnected even marginally from the structure. Neither for
that matter would we imply that this is the whole story explaining how
socialization may contribute to the stability of the American system.
The political structure is only a limited although a significant aspect
of the political system. Regime values and norms, the political community
and the specific authorities as such are other parts which may also en-
dure or change and these, it must be recalled, we do not explore in this
work.

2. We did so after undertaking a series of factor analyses which isolated these two items as measuring a separate attitudinal dimension. See Part IV.

3. Our party preference item read as follows: "If you could vote what would you be? 1. A Republican. 2. A Democrat. 3. Sometimes a Democrat and sometimes a Republican. 4. I don't know which I would be. 5. I don't know what Democrat and Republican mean". CA-9, p.9, item 42.

4. They selected the option, "Sometimes a Democrat and sometimes a Republican."

5. The impact of partisanship is demonstrated in other studies. "We further predicted that [upon the assassination of President Kennedy] children who identified with the President's party (those children who said they would vote Democratic if they were old enough to vote) would show more signs of grief and fear over the future of the country than those not so identified...this was indeed the case, although it showed up mainly in the area of emotional responses. Democratically inclined children reported more trouble sleeping, more loss of appetite, crying, etc. More of them identified with the President-'worried how the U.S. would get along without its leader' (Democrats 66 per cent, Republicans 58 per cent). And, not unexpectedly, more of them showed feelings of aggression toward Oswald (Democrats 50 per cent, Republicans 38 percent). The President may have a firm niche in American children's affections and admiration, but partisanship is apparently an intervening variable, which either strengthens or loosens their partisanship-although not to a very marked degree." Young, "The Meaning of the Coronation" 1 Sociological Review (New Series) (1953) pp. 63-81 and by the Earl of Balfour in his introduction to W. Bagehot, The English Constitution (New York: Oxford University Press, 1928), World's Classics edition.

Chapter X

HOW THE CHILD SEES THE POLICEMAN

The policeman, we have already discovered, joins the President as one of the figures in the political world first apparent to the child. For the child the policeman may be just a person with some special power. But for the student of political socialization the policeman carries far deeper meaning. He helps to link the maturing child to the political structure. This will form the subject of the present chapter.

With respect to the policeman we shall find that several politically significant things happen to the maturing children in our group. Through this figure, they discover that there are persons outside the family who have authority. They recognize that these persons are persuasive and powerful enough to impose their will on other adults, as well as children. Finally, the children learn to respect the agents of this authority and by implication the legitimacy of their power. Although our data do not permit us to trace out the full set of relationships through which the children receive vital messages like these about the presence and legitimacy of political authority in general, we can clearly discern one of their important sources in the image of the police.

Police in the Political System

Vital as the police are as an institution in a legal society, it is strange that they have never been considered of central significance in the functioning of political systems. As a result they have always fallen into a position so peripheral to the core of political science that it is virtually impossible to find a sustained theoretical discussion of the varied functions they fulfill in political systems.

Historically, the limited attention they have received from students of politics falls into two major theoretical areas, more through the accident of practical interest than from the conscious design of theoretical analysis. On the one hand, the police have been implicitly conceptualized as agencies for the enforcement of law and order, especially for those systems committed to the rule of law. But a theoretical proposition such as this is normally just assumed rather than explored. There is little conscious effort to expand on the implications, for the political system as a whole, of police activity directed to the maintenance of law and order or to compare police forces with parallel and alternative institutional devices.

The main thrust of research in this area is normative in character rather than analytical. The underlying goals hinge on current policy concerns. Standards of performance are posited and the task

187

is to discover the conditions that will permit the police to measure up to them. The central question would seem to be: How can a society encourage the development of a police force that is expert, incorruptible, highly motivated, and intent on the reduction of crime yet cognizant of the limits of its authority in a democratic, humanitarian society?

From this perspective a few sociologists have recently explored the major dimensions of the police force as a professional occupation and the impact of society upon its operations.[1] The administrative sciences have inquired into the kind of organization and regulations necessary for recruiting the appropriate personnel and enabling them to perform their duties in an efficient and morally acceptable way. Students of public law have analyzed the legal norms and rules that crystallize what is conceived to be a desired relationship between the powers of the police and the goals and values of members in a democratic system. Research in urban politics has mapped out the connections among crime, the police, and politics and has looked for a pattern of relationships that would promote effective civilian control but prevent unwarranted interference with specifically police activities.

On the other hand, the police have sometimes been approached from a different theoretical perspective, one that is particularly apparent in the literature on political development and change and about authoritarian systems. Here there is less concern about the effectiveness of the police as a law-enforcing institution. Implicitly it is interpreted as an instrument of political power, one that groups in a political system may manipulate to their own advantage. For Marx and others exploring the conditions of social change, the police are weapons of control in the hands of the ruling class or an elite. For students of developing societies and authoritarian systems, the police may represent social agencies which join with the army in the application of violence. From this standpoint, interest in the police as an agency for the suppression of crime and for the enforcement of the law recedes visibly.

But even in these two respects--as institutions for the preservation of law and order and as paramilitary organizations for the maintenance of power--there has been little by way of sustained theoretical inquiry into or conceptualization about the overall relationship of the police to the political system. Equally important there has been seriously lacking an effort to roam further to probe for other ways in which the police might be significant in the functioning of political systems. Thereby we might hope to round out a theory of the police as a political institution and draw the study of the police more intimately into the general framework of political research.

It testifies to the dividends of theory in general and of systems persistence theory in particular that from it we can deduce some additional critical consequences of police institutions. These institutions do more than enforce the law, provide services of various kinds or, in some systems, openly partake in the political struggles of the day. In posing questions about the sources of support in any political system, persistence theory leads us to inquire into the function of the police

as central connecting points between maturing members of a system and the structure of political authority. Indeed from our limited data we shall be led to hypothesize that probably few regimes in mass societies would be able to obtain the minimal level of cognition and approval they require but for the contribution of such local representatives as the police in awakening the appropriate sentiments of its members. Not that the police as such need be considered an inescapable part of all political structures. But if a political system does not provide for a police establishment, our findings impress on us, some corresponding substitute means for obtaining a visible local representative of authority may well be necessary.

Thus theory alerts us to the need to broaden our perspectives about the part that the police forces may play as a specific kind of institution, in large-scale political systems at least. Over and above the obvious and vital consequences they may have for helping to sustain or change a prevailing system of law and order, they may also be serving as a bridge between maturing members of the system and the broader political structure. This is especially true for the American political system.

The Child's Cognitive Images of the Policeman

The peculiar and interesting aspect of the introduction of children to the American political system, as we have already hinted, lies in the immediacy of their contact with the system. Not only do they see a President somewhere off in the geographical distance but psychically close. They also come into direct contact with the policeman who, it turns out, is both spatially and affectively close. For the child, we shall see, the policeman also becomes a physical symbol connected with a felt obligation to obey something outside the family circle.

Objectively the policeman is a part of the structure of authority in a political system. He belongs to the output structure helping to implement the decisions of other governmental agencies. But he also produces outputs of his own. He makes decisions on what rules to evoke in a given situation and on whether or not to apply a rule in a given instance. "The role of the police as decision-makers", it has been observed, "must be expressly recognized."[2] In this sense the policeman in any way at all, objectively he would be establishing ties of some sort with the structure of authority, at its tail-end, as we have observed before (Chapter VII).

This link to the political structure may occur unwittingly. It is not necessary that members of the system be aware that their contacts with the policeman and the way they feel about him help to shape their ties to the structure of the political regime. What is true for adult members in general would apply with even greater force for children. The objective position of the police in the political structure in no way guarantees that the child will see him in that position or have any understanding of what the role of the policeman involves politically. The policeman could serve as a vital relay point between the child and the structure of authority and yet neither policeman nor child need have any inkling of the nature of this function.

But to the extent that the child has some understanding of the place that the policeman occupies in the structure of authority, it will lend greater force to our argument that the policeman is a significant link between the child and the system. Perception can be expected to reinforce objective reality.

As the data in this chapter will suggest, empirically it does turn out that the child is not without some important cues about where the policeman stands in the political state of things. As the child grows older he comes increasingly to develop an image that puts the policeman close to the government. If the child understands the policeman to be related somehow to the government, we can expect that sentiments about him would have some direct bearing on how we can interpret the child's feelings for the structure of authority.

Who is the policeman?

Before we can proceed to explore how the child relates the policeman to the political structure, if he does at all, we need to ask: Whom does the child have in mind when he entertains our questions about the policeman? Is he thinking of all police agencies, from the local neighborhood cop to the FBI or sheriff? We need to know what object the child has in view when speaking of the policeman.

In our final instrument we did not test specifically to identify the object of the child's responses. Evidence from our preliminary interviews convinced us that most children probably think largely of the local policeman, typically on view in uniform whether in school-books during the early grades, or as he moves about the neighborhood.

Very early in our investigations we had interviewed a small number of children in a middle class suburb of Chicago. Our discussions with them were not without some ambiguity; typically, with little knowledge of the political sphere and even the broader neighborhood, the responses tended to be vague, sometimes apparently contradictory. Thus when we asked our small selection of children whether the policeman were part of the government, almost all those from grade 2 and above replied affirmatively (Table X.1). But when we asked the same children whether their town had a government, the great majority from grade 1 through 4 replied either no or that they did not know. Only in grade 5 did the majority shift to an affirmative answer.

It would appear therefore that for the younger children, at least, the government was not local in character. As we know from our chapter on "The Image of Government", younger children do tend to see the President or some other national, personal figure as most representative of the government. We might infer that for children in these age groups, all government seems to be national in character; the distinction between national and local is not one that has much meaning for younger children. All government tends to fuse into one mass undifferentiated as to level.

Table X.1. Two Items from Informal Interviews of Children in Town of Riverside, Illinois)

(frequencies)

Grade	"Does Riverside have a government?"				"Are police part of the government?"				Total N
	Yes	No	Don't Know	NA	Yes	No	Don't Know	NA	
1			3	1	8		2	2	4
2	2	1	7	2	4				12
3	1	1	2		7	2			4
4	3	2	4		5	1			9
5	3	1	1	1	5				6
6	5				3				5
7	4				3				4
8	3								3

If we could expect children to be consistent in the adult sense of the term, we might infer that if the younger ones see government as national and if they acknowledge that the policeman is part of government (as we also noted earlier in Table VI.5), they would also be inclined to think of the policeman as somehow unconnected with the local scene. But the child is not so certain or informed about differences in the levels of government or so interested in the policeman as to be concerned with consistency in the logical sense of adults. Hence when we inquired into what he thought the policeman did, it was clear that regardless of the child's failure to see government as locally based, police activities were certainly viewed from a local perspective. In this suburban town the few children tested from grade 1 considered that the police took care of people, got mad at people, put them in jail, told them where places were, and gave tickets. The "people" to whom the child refers seem to be somewhere in the immediate environs. In grade 2, the police are more likely to be thought of as catching criminals and helping people. Grade 3 adds keeping traffic rules to the list, and grade 4 conceptualizes more broadly by indicating that the police enforce the laws or run this suburban town.

It would seem, therefore, that however little information children may have about government and the relationship of the policeman to it, they do intuitively think of the policeman as a local person; he performs activities associated with the nieghborhood or local community. The word "policeman" did not seem to arouse in the child's mind an image of the multifarious police agencies at other structural levels in the United States such as the sheriff, state troopers, FBI, G-men, or lawmen of Western movies. In spite of the fact that in metropolitan regions in the United States, policemen tend to travel in cars or on motorcycles rather than on foot, the child still evolves an early picture of him that is close to what we would have expected in a prior period when foot patrols were more prevalent. In part we might suspect that his localized image comes from the crossing-guard police and uniformed surrogates.

This is not to imply that the younger child has any awareness of the position of the police in the political structure. In fact, he appears to be more alert to what he thinks the police do than to their structural position. The younger child is functionally rather than structurally oriented. Yet in the very specifications of the kinds of activities in which the police engage, the limited group of children whom we initially interviewed did seem to detect a peculiarly immediate and local aura about the policeman. If the younger child has any idea at all of the structural location of the police, he would place them at the local level, even though with apparent illogic he sees the police as working for the government and cannot as yet disentangle government itself from the national sphere. The evidence in various subsequent interviews confirmed this inference so decisively that there was no incentive to consume valuable space in our final instrument for further testing of the object of reference in the child's idea of the policeman.

The child's location of the policeman among the authorities

The object of our inquiry is therefore the ordinary neighborhood policeman. He is the one the child is most likely to see, in the earliest grades, together with the President and a vaguely defined government. But even though the children in our group place the policeman in their local community, it would appear from our data that for them the policeman blends into the diffuse structure of political authority, or the government, in the child's own vocabulary.

Here again however we have to work through the child's way of seeing and interpreting the position of the policeman and infer from this its consequences for the child's ties to the political system. Even though in the end we shall maintain that the children do connect the policeman explicitly with the political authorities, this unadorned conclusion would not tell us enough. In what way do the children make this connection? Do they go so far as to consider the policeman part of the authorities who stand at the center of the decision-making process, those whom the child looks to as the government? Or are the policemen only peripherally related? Does the nature of the observed relationship affect the way in which the policeman may operate as a linkage point? Although we cannot answer these questions definitively we do have some evidence that bears on them and points to some plusible inferences.

There is little doubt that for the children the policeman is neither a good representative of the government nor a person who plays a significant part in running the country, as a lawmaker. Thus in contrast with the symbolism he attaches to the President, the child rejects the policeman as a good overall representative of government. On our question about the best representative of government, among the youngest children a percentage less than chance selects the policeman[3] even in grade 2, at an age when if at all we might have expected the child to value the policeman in some way as a close and visible symbol of government.

Furthermore, even though, as we would expect, the child links the policeman in an important way with laws, he does not go so far to consider that the policeman has an important part to play in the making of laws. Indeed, our pilot studies indicated that the child associated the policeman with this task so seldom that we did not find it worth including the policeman as an option in one of our basic questions on who makes the laws. There the options we finally settled on were Congress, the President, and the Supreme Court, the most likely choices.[4]

This low ranking of the policeman on a law-making function emerges strikingly in one of our pretests. Here we asked the child directly whether or not the policeman is involved in making laws; Table X.2 presents two items in which we asked about the policeman's tasks in this area. We see that the younger children more easily reject the broader statement that "the police make laws" than perhaps the more credible observation that "traffic laws are made by policemen and highway patrolmen". By grade 8, nearly all of these children turn down both statements.

Table X.2. The Child's Understanding of the Role of the Policeman as One Who Does <u>Not</u> Make Laws[a]

Grade	"Policemen make laws."		"Traffic laws are made by policemen and highway patrol-men."	
	% Agree	N	% Agree	N
3	16	69	51	69
4	15	118	25	118
5	8	116	15	117
6	7	145	13	142
7	9	141	10	139
8	5	145	4	145

[a]"In My Opinion #III," items 144 and 165.

But the child does not fully disassociate the police from the making of laws. We ought perhaps to expect that in a legalistic society such as the United States, law and police would be inextricably intertwined and children would very early sense the presence of some kind of relationship without necessarily being able to articulate it very well. In fact our group of children do feel that even though the police are not to be held directly responsible for making laws, they do help in some undefined way.

When we asked the children to indicate how much each of a number of persons and organizations "help to decide what laws are made for our country", the police are seen to fall somewhere between having some and very little part. In grade 4, Figure X.1 shows that, among the options offered, the policemen are exceeded in their influence only by the President and unions. This emphasizes the strong connection that the younger child is apt to put on law-making and police, and if we had been able to test the children in grades 2 and 3 on this set of items, the curves on Figure X.1 suggest that policemen might have ranked next to the President. Although the child starts out rather impressed by the involvement of the police in the making of laws, by grade 8 the police recede to a more modest position. Nevertheless even at the latter grade, they do seem to carry about as much weight, in the child's mind, as rich people and big companies, somewhat more than churches, and somewhat less than newspapers and the average person. Yet aside from the President and unions, even at grade 8 all these persons and organizations are thought to possess a relatively low measure of influence in shaping the laws, on the average less than "some" on our scale.

It is clear therefore that among most of the children the policeman does not directly participate in the legislative processes in the manner of Congress, the President, or the Supreme Court even though because of the close association of the police with law it would have seemed simple for the child to have thought otherwise. The child rejects the notion that the policeman occupies the foreground of the formal political stage.

But it is one thing to exclude the police as good representatives of government and as potential law-makers of importance and another matter to disassociate them from the governmental (political) structure entirely. Even though the child may not conceive of the policeman as possessed of legislative powers, he has little doubt that the policeman is part of the governmental structure. However uncertain the child's image of government may be and however much the younger child may confound local with national structures, as we have already seen, our children do recognize that the policeman is a person who works for the government. He is part of the overall if vague structure of political authority apparent to the children, namely, the government. Nor is this conception peculiar to any grade level. As we have already noted, over 80% in each grade describe the policeman in this way (Table VI.5).
Figure X.1. Mean Ratings by Grade on Who Helps Decide Which Laws Are Made for Our Country

It would have been enough for our purposes to demonstrate only that the child has some conception of the existence of the policeman or relates to him in some manner. As long as in objective, theoretical terms we could assign the policeman some place in the political structure—as we have in Chapter VII—this would have been enough to justify our further inquiry into the child's interpretation of and feelings about the policeman as we pursue our study of the sources of support for the political authorities.

But we now see that we can go further. It is clear that the child has acquired a subtle, discriminating awareness, at even the earliest grades, about the location of the policeman in the political structure. Even though the local policeman is a figure well-known to all our children, they do not give him excessive prominence in the direct law-making processes, much as we might have anticipated the contrary in the early grades at least. The children seem to have a more modest conception of the part that the policeman plays in the system. They have little doubt that the policeman is part of the system since he is seen as a person who works for the government. They have learned to discriminate between having something to do with governnment, as an employee, and running the country, as in the case of the President, between what we would call an administrative and a legislative location in the structure of authority. The older the children are, the more clearly are they able to capture this difference. But even though the policeman does recede in importance in this sense, all children whatever their grade, do continue to connect him with the government and thereby, in our terms, with the structure of political authority. This subjective awareness reinforces our theoretical grounds for identifying the policeman as a meaningful point of contact between the child and the authorities.

The Authority of the Police

Support for the structure of authority includes more than just an awareness of the presence of a figure or institution as part of that structure. It involves perhaps some understanding of what that figure or institution does and at the very least a readiness to accept the object and its actions as valid or authoritative.

It is a basic assumption of our research that no system could persist without some means for making allocations that are accepted as binding or authoritative by most of the politically relevant members of the system most of the time. We can assume, without fear of contradiction, that for children in our age group the authority of parents in the family is generally conceded, even if specific decisions may be questioned. But how does it happen that maturing members of a political system are able to identify and accept the right of persons outside the family, even those whom they may not know personally, to exercise authority over them and over adults as well?

197

The problem

Authority we interpret as just one kind of power. Power in general we see as the capacity to bend another to one's will. A person can be said to have the kind of power we call authority over B if A sends a communication to B and B accepts it as a basis for action regardless of his independent judgment about the advisability of doing so. The communication carries with it a quality of oughtness. B feels he _should_ obey even though he may strongly disagree with the wisdom of the specific message. Why he feels this way can be ignored at the moment although typically, in political systems, the sense of obligation derives from the attitude that it is right and proper to do so, that the authority is legitimate.[5]

Children are typically subject to the power of the authority of most adults in their environment. The child learns that he is expected to obey certain types of adults, that they have the power to tell him what to do, and it is right and proper to accept their judgments within certain undefined limits.

But in the United States, as in most other systems, we take it for granted that as the members of a system grow up, somehow they learn that there is a power external to the father and mother and even to most other adults they know. All persons, not only the children, are subject to it. What is usually assumed we here consider problematic. How is it that the members of a society are indeed prepared to accept the authority of persons external to the family, such as those who are part of the political structure?

We might reply that in most modern political systems a person would soon realize his error if he failed to obey, assuming the political authorities were acting within the limits of their powers. Typically force would be applied in no unmistakable sense to seek to bring about conformity. But we also know that in the normal course of events adults do not live in fear and trembling of political authority even as it may be represented in law-enforcement agencies. Most people usually abide by the injunctions of the authorities because they think it is right to do so, within vague but definable zones of obedience. They come to consider the authorities as legitimately endowed with power. It is this sense of legitimacy that constitutes a fundamental source of support for most regimes.

Yet members of a political system are not born with this propensity to accept authority. It is a complex set of attitudes and perceptions that they acquire in varying degrees by virtue of membership in a system. How does this form of support come about?

One major source we have found to be associated with the upper reaches of the structure of authority in the United States. Something looms over the children with power and virtue and they can identify this as the government; a person is closely associated with it whom they call the President. As they grow older other institutions such

198

as Congress join an increasingly complex image of these external au-
thorities. But simultaneously the system impresses its authority on
the child from another direction, from the tail-end, as we have sug-
gested. It is as though these remote objects, visible in part, intang-
ible but symbolically present, could not be depended upon to assert
the dominance of the political sphere on all appropriate occasions.
It is here that we have found the policeman, closely tied as he is to
law, to play an important function in molding the child's understanding
of and feelings about political authority. The policeman is a tangible,
personal agent of authority and to the child, therefore, a plausible
one. Through the policeman, we shall conclude, the child is impressed
with the presence of a power over and beyond that of father or mother and
one that even parents, as potent as they may appear to the child, cannot
escape. Here lies a seed out of which a sense of the legitimacy of the
authority structure springs.

Police authority as an external power

That the policeman is a compelling force, one whom there is a
special obligation to obey, is apparent to the child from the earliest
moment at which we have been able to test him. When given a number of
options about what it is important for the policeman to do (Table X.3),
77% of our test children in grade 4 consider that his job was to make
people obey the law and catch those who break it as against helping
people who are in trouble. Even in grade 8 a clear majority, 61%,
continue to hold this view. The power of enforcement is paramount in
the minds of the children even though it is estimated that in reality
about 90% of the time of the local police is spent in performing ser-
vices only marginally related, if at all, to enforcement.[6]

This emphasis on the power of the policeman, especi 'ly for the
enforcement of the law, appeared time and again in our pretests. One
of our preliminary investigations proved to be particularly revealing
along these lines. At the outset we had assumed that many if not most
adults held rather disparaging opinions about the police and that one
way or another these might be subtly transmitted to the child. Yet
we did not seem to be picking up anything but positive sentiments from
the child. We speculated that perhaps the trouble lay in our techniques
of inquiry. Could it be that by virtue of our mere presence in a ques-
tion and answer setting, we inadvertently constrained the child from
expressing honest opinions? An argument could be made that in the
presence of one adult authority, the interviewer, a child would be
somewhat reluctant to give verbal answers expressing hostility towards
or some depreciation of other adult authorities such as policemen.

We sought to overcome this possible limitation of the interview
and questionnaire format by asking over 600 children to draw pictures
of various authority figures, including the policeman. Although in-
teresting additional feelings and judgments of the child could be in-
ferred from their drawing, the small increment in knowledge did not
seem to justify extensive further use of this method.[7] On the whole

Table X.3. The Child's View of the Most Important Job of the Policeman[a]

(percent of those responding)

Grade	Make people obey the law	Help people who are in trouble	Catch people who break the law	Total	N Re-sponding	N Not Responding
4	38 %	23	39	100 %	1526	223

8	42 %	40	19	101 %	1680	15

[a]CA-9, page 31, item 31. "Which is the most important for the policeman to do?"

the new information gained in this way just reinforced what we had already learned through interviews. The children depicted the policeman as physically dominant in their drawings suggesting the magnitude of his power. With relatively few exceptions the children, in the two lowest grades especially, drew the policeman as several times larger than other objects such as cars or ordinary people. Since he is seen as biggest, it suggests that he is in command of the scene, and indeed the action of the drawings clearly makes this point.

In the drawings the police are rarely pictured as inert figures; they are commonly shown in both verbal and motor activity interacting with other persons. We divided the pictures into three functional areas of activity: protective, as when a policeman helps a child across the street; prohibitive, as when a policeman appears with arms extended directing traffic and saying "stop"; and punitive with the drawing showing the apprehension or jailing of a criminal.[8] Although the children portray the police in a multitude of situations and evoke many facets of their activities, over 50% of the drawings have distinctive elements of an interpretation that emphasizes prohibitive and punitive qualities. The propensity of the police to direct and punish rather than help looms large. It would appear to be the power of the police that captures the unstructured imagination of the child.

Essentially the same kind of message comes through, although less dramatically, in the child's response to our ratings (Figure X.2). They also convey his early sensitivity to the special power of the police. The children are perhaps a little doubtful about the punitive component in the power of the policeman although the views are relatively stable over the grades. On the average, as the mean ratings over the grades show, they consider that the policeman can punish close to the point on the rating labelled "many people". But a comparatively large proportion of the children do attribute considerable punitive capacity to the policeman. From 37% in grade 4 to 30% in grade 8 declare that the policeman can punish anyone or almost anyone (Table X.4).

The children are, however, more convinced of the power of the policeman to order people about. On the average our grade 2 children feel that the policeman can make many people do what he wants and this conception drops only slightly over the grades (Figure X.2). Table X.5 fleshes out this mean rating. About 48% in grade 2, falling gradually to 36% by grade 8, consider that the policeman can make anyone do what he wants, a considerable measure of control over others by any standard. This is particularly significant for the older child. Many at age 13-14 are still convinced of the extraordinary compulsory capacity of the policeman.

From their earliest years, therefore, the children have come to recognize the competence of the police to impose sanctions and to exercise some considerable measure of control over people. The significance of this for us is that the child who, as we would expect, is impressed with the power of parents, also realizes that there are others, beyond the walls of the home, who have important sanctions and control over people.

Figure X.2. Mean Ratings on Thirteen Attributes of the Policeman by Grade.

*Means of this rating were subtracted from 6.0 to make them more comparable with the rest.

This is no subterranean, amorphous feeling. Children are able to express it clearly in more than one way. In the first place, when we compare the child's image of the power of the policeman with that of his own father, we find that for both ratings that we have been considering, on the average father ranks much lower. However powerful father may be for children, he does not measure up to the policeman.[9]

In the second place, this inferiority of parental authority emerges more forcefully and directly in the child's response to another item. In it we sought to elicit a direct comparison of the rightness and wrongness in disobeying one or another figure of authority. The item reads as follows: "<u>Disobey</u> means to do something someone tells you not to do. Which of these is most wrong? Put an X beside the <u>one</u> that is the most wrong: (1) to disobey your <u>mother</u>, (2) to disobey your <u>teacher</u>, (3) to disobey your <u>father</u>, (4) to disobey the <u>policeman</u>." Table X.6 reports the pattern of response.

Three-fourths of the youngest children choose the policeman as the one most wrong to disobey. External political authority in the guise of the policeman apparently has special weight for the young child. As the children get older, they reevaluate somewhat this great weight of the policeman and become more responsive to family authority. They feel that the policeman can be disobeyed more easily. The youngest child rather clearly recognizes, however, that the policeman's authority is high and that his demands for obedience are somewhat less avoidable. But in all grades a minimum of about 50% considers it most wrong to disobey the policeman.

The pattern changes in an opposite manner to what we might have expected. We might have thought that the acceptance of law-enforcement authority would be higher as the child learns more and more about the political system. This is clearly not the case. It is the younger child who sees this authority as possessing greater compulsory qualities and it is the older child who resists this idea. Familial loyalty comes increasingly to offset the authority of the political system as it is represented by the policeman.

In part this shift away from police authority may be due to generic tendencies in the maturation of the child. Piaget notes the inclination of younger children to accept rules as sacrosanct but to question them as they reach 8 and 9 years of age[10] and to begin to exercise rational judgment in assessing them. But in connection with the policeman, this decreasing concern for his authority may also be a special effect connected to the ambivalence with which he is probably regarded by adults. Regardless of the kinds of positive feelings adults may express about the policeman—and we shall touch on these in the following chapter—we can assume that they often view the policeman as a person who is at least occasionally wrong or corrupt. At times he may be regarded as the enemy who has to be outwitted, as in the area of traffic violations. These kinds of sentiments in parents may help the older child to modify his own acknowledgment of the superior power of the police. Yet although we see perhaps a modest tendency

towards the abrogation of police authority, it occurs nonetheless in the context of initial acceptance and the latter comes relatively early in the child's cognitive development.

The item we have just discussed substantially confirms the continuing awareness over the grades of the presence of an authority external to the most familiar world of the child, a power that for most younger children dominates over the injunctions of such close figures as mother, father, and teacher individually considered. We can have little doubt that the tail-end of the structure of political authority --the policeman--has left a distinctive imprint on the mind of the child. Through the policeman the child learns an important lesson about the power of external authority and about the need to accept as obligatory or binding the actions and decisions of others from the broad world beyond the family.

Here, we suspect, lies an important source of that support for the structure of authority that we may call recognition of the legitimacy of its authorities. Of course the child has no consciousness of the policeman as a representative of political authority on the output side. Neither have most adults. But this is of little significance compared with the child's clear awareness of the authority of the policeman. He does not question the appropriateness of this power. The large majority of children indeed see it as initially superior to that of close adults. Therein may lie a vital mechanism for generating support for the authorities at large. Through the policeman the child is encouraged in the belief that external authority should and must be accepted. It reinforces a similar posture that he is early encouraged to adopt towards government and the President.

CHAPTER XI

HOW THE CHILD FEELS ABOUT THE POLICEMAN

In the last chapter we have seen that the children in our test group, especially the younger ones, have little knowledge of where the policeman stands in the formal structure of political authority, even though they do realize to some extent that the police operate outside the centers of decision-making. In addition the child perceives rather clearly that the police are a power to be reckoned with in the world beyond the family.

Yet however conscious the child may be of this external authority, it will appear in this chapter that the American political system does not rely on this perception alone to bring about the acceptance of authority by maturing members. Cognition is reinforced by affect. In the socialization process we shall find that as for the President, the child acquires feelings for the policeman that bear considerable significance for the growth of an attachment to the structure of political authority.

We need to turn from perception to feeling, for good reason. It is entirely conceivable that under certain circumstances the child might well recognize the authority of the police, as in an autocratic system in which the police impose a virtual reign of terror. Yet if fear and disaffection were widespread among adults, the child might be as resistant to this authority as are his parents. The police might be a symbol of fear and hatred. It would be doubtful that children growing up in this kind of climate would express very much esteem for the police however fully the children might be compelled to recognize the ever-present power of that authority. The texture of the acceptance of political authority and its validity will be vastly different where it is underpinned by positive feelings rather than only through an acknowledgment of its inescapable power. By moving beyond the cognitive level to the affective we may hope to capture the full flavor of the reception of police authority by maturing members of the system.

The Position of the Police in Modern Society

The police hold a special place in modern democratic societies, one that arouses an unusual combination of feelings among adults. If we were to deduce the child's feelings about the police from those that people often assume adults hold, we might well imagine that what is a well-recognized authoritative role for the child would not necessarily be one that is well-thought-of.

What is there about the role of the police that gives them a unique position in society? Above all else, the peculiarity of their role in democratic systems flows from their capacity to use violence in the pursuit of occupational ends.[1] No other public servants aside from the military are permitted to apply force to the individual members of the system. In the last resort, as we have already noted in Chapter VII, the police have the extraordinary power of life and death. "'I'm only a cop,' says Patrolman Frank Foucault, 41, of Precinct 10, Livernois and Elmhurst, in Detroit. 'But you look at me real close and you will see something that has more power than even the President of the United States. I don't mean me, Frank Foucault; I mean me, the cop. I have the power of life and death. In ten seconds, I can kill someone or let him live, and I don't have a jury or judge or anybody there to say Yes or No.'"[2]

Although legal rules and conventions impose severe restraints on the exercise of this power, ultimately it is of the very nature of crime detection and prevention and law enforcement that a wide range of discretion must belong to the police. The individual policeman, often entirely on his own, must produce certain kinds of outputs in the system. It is he who makes the final decision, whether to write out a ticket for an offence, order an action to cease, or undertake whatever force may be necessary to effect an arrest.

In a society that values individual freedom and responsibility and in which the frontier disregard for law still plays an important part in its traditions, neither police nor the ordinary individual ever feel completely at ease about the possible relationships that may flow from these powers.[3] The police are one of the few representatives of authority who are ubiquitous and in continuous potential contact with the individual members of the system. At the same time the visibility guaranteed by their uniform leaves them particularly vulnerable "as easily identifiable targets for the expression of hostility towards authority".[4]

Probably because of the peculiarity of this position of the police, adults do not display totally unmixed feelings about them. Indeed, so ambiguous does the role become in some systems that it carries over to the policeman's family which may suffer varying degrees of social isolation.[5] In the United States, if we were to rely on popular and even professional conceptions about how people feel, we would be forced to conclude that adults generally hold the police in very low

esteem. It would appear that the police are seen as venal, prone to roughness if not brutality, tainted by the very criminals with whom their occupation forces them into contact.[6] We are apt to believe that suspicion and fear rather than trust and respect would characterize the overall popular image of the police.

The evidence that we shall present later will dispute this folkloric interpretation of the popular view of the police. But at this point we can at least accept the plausibility of the notion that adults are not without ambiguity about their attitudes towards police authority. We would expect therefore that the cross-generational transmission of this ambivalence would become apparent in the responses we get from the children on our questions about their affective orientations towards the policeman.

What we do in fact find among the children in our group is a surprisingly favorable reception of the policeman. This affect declines as the child grows older. But overall feelings about the policeman are fairly positive on most measures.

This approval will raise a puzzling problem for us. If the popular adult conception of the police were indeed deprecatory, it would be most unlikely that parents could conceal their view entirely from their children, even if they wished to. We would expect that younger children particularly, least exposed as they are to competing views from outside the family, would mirror these sentiments of their parents. Yet is is the youngest children in our test group who turn out to be most favorably disposed towards the policeman. The data will therefore pose a conundrum for us that we shall have to resolve at a later point.

Overall Respect for the Policeman

In face of the unusual position occupied by the policeman in modern society, how do we find the children of our test group to feel about him? In particular, do these children display some marked reservations about him which color his function as an intermediary between the child and the structure of political authority? Can we say that the general regard or respect for the policeman is predominantly positive?

Overview of the rating scales

We administered the same thirteen rating scales about the policeman that we had used for the President. As we saw from Figure X.2, the most positive response on the ratings occurs among the youngest children. This image continues over the grades except that some of the more idealistic aspects rub off. The decline in the level of favorable sentiment takes place, however, upon a base of fairly high affect.

210

From Figure X.2 we saw that a few of the average ratings on the policeman are relatively high and stable over the whole span: his benevolence (willingness to help, protectiveness), power (capacity to control others and to punish), his leadership (as represented by our leadership rating and frequency of making important decisions) and even to a limited degree, his dependability (doesn't give up when things are hard to do). On these qualities the child's impressions of the policeman seem to become fixed early in the life-cycle and to remain at about the same level.

The remainder of the ratings begin fairly high on the scales but the changes that take place in these perceptions as the child grows older are striking. The ratings that directly express the child's attachment to the policeman (I like him, he is my favorite) decline markedly as do some of the items that are involved in the child's perception of the policeman's dependability (keeps promises, makes mistakes) and some aspects of his leadership (knows a lot, capacity for hard work).

If a higher rating is a measure of the average child's greater readiness to accept the policeman as an authority figure, it is instructive to note that regardless of the constancy or decline of the perceptions over the grades, on the average all qualities are rated above the midpoint on our scales, with the lone exception of the attachment items. Few children have developed a negative image of the policeman, even by grade 8. As we have already argued for the image of the President, all of the ratings probably represent ideal qualities or virtues in the American culture. Few people would contend that it is not desirable for policemen to be benevolent and dependable and to exercise qualities of leadership. The children display differences in the degree to which they incorporate elements of these general cultural characteristics as part of their ranking the policeman high. As with the Presidency, we have a comparatively idealized image of the police at the outset, although at an overall lower level.

As the children age, it is true, there is a decline in some of the ratings. But even for the few that do drop sharply, with the exception already noted about attachment, the ratings remain within the top half of the scale. It would appear therefore that the children see the policeman possessed of all the cultural virtues and any diminution by grade 8 does not seriously interfere with the fairly high esteem in which they continue to hold this figure of authority.

Direct attachment to the policeman

It might be argued, however, that the most general measures of affect for the policeman, our attachment items, run contrary to the general trend of all other items and that this apparent contradiction cannot be ignored. If we look at the proportions of the children who rank the policeman at various points on these two ratings, "I like him" and "he is my favorite", we can indeed see the low affiliative sentiment that the policeman evokes. Apparently by grade 4 the child as

211

begun to develop some relatively well-defined feelings about the police and these prevent him from expressing a strong personal attachment to them. Although in grade 2, 65% of our group could say that the policeman is either their favorite of all or of almost all, by grade 8 this falls to a mere 16% (Table XI.1). Similarly only 27% in grade 4 are able to declare that they like the policeman more than anyone or than most and this recedes to 10% by grade 8 (Table XI.2). Clearly there the policeman has little personal charisma for the child, especially as he grows older.

How can we account for this low level of attachment as compared with the patently higher regard that the child displays on the other ratings? The first explanation that readily comes to mind is the thought that this simply demonstrates that the child has not got an unambiguous image of the policeman. Somehow he is conflicted and it manifests itself in these contradictory ratings.

What lends an air of plausibility to this line of reasoning is the general impression that we gain, from the folklore, about the feelings of adults for policemen. If, as it is thought, adults do have little respect for them, we could anticipate that children might find themselves somewhat conflicted about the kinds of signals they were receiving from adults. Adults might want them to think well of the police—on the principle that children need to be sheltered from the harsh realities and sordid details of life—and yet they might not be able to conceal their true feelings entirely from the children.

As we have already hinted, however, available information on adults would seem to refute the notion that they do hold the police in low regard. On the contrary, most adults normally have considerable respect for the police as we shall see in Chapter XIV. There is little need for them to transmit conflicting messages to the children. The high respect of the children conforms rather to what we would expect; the children are probably being socialized by adults to think well of the police because this is the way most adults genuinely feel themselves. If this is so, the level of our attachment items needs to be explained in other terms.

In part there may be a simple explanation. At the same time as the children are learning about the policeman, they observe that he is responsible for punishment and enforcement of the law. They may develop mixed feelings about this. He is helpful but also a person to be feared in some measure. This may interfere with a direct expression of affection for the policeman. However this conclusion needs to be tempered by what we shall have to say later about the policeman as a figure of power. We cannot take it for granted that for children the possession of power necessarily breeds distrust.

There may be other reasons that better account for the low level of the attachment ratings by grade 8. We have already witnessed and discussed the same tendency for the likeability rating about the President. There, too, this item and "he is my favorite" also drop sharply,

and to what we would regard as a relatively low point. However, for the Presidency, these two attachment ratings do not fall so far. This difference in levels between the ranking of the President and the policeman is not difficult to explain. In doing so, it will help us to understand why both attachment items may fall so low for the policeman.

For the obvious reason of differences in occupational importance, we would expect the President to fare much better than does the policeman. Both figures are salient for the child, as we have seen, but for different reasons. The President runs the country and the child cannot help but pick up cues from his environment about the critical importance of this role. The policeman is not so distant spatially, it is true, and in this sense may be better known to the child. But those in the child's environment are unlikely to attach the same significance to the policeman's role. This alone would help to account for the lesser decline of the President on our attachment ratings.

Although this difference between President and policeman does not tell us why the child should express so little direct attachment to the policeman, it does point us in the proper direction. Unlike the President and unlike entertainment figures in the movies, television, or the sports world, there is little that is vividly unique about the policeman or that would be especially appealing to the child, particularly as he grows beyond the "cops and robbers" stage. Although television and the movies do dramatize the role of "lawman" in various ways, it is not usually the cop on the beat or in the patrol car but the sheriff, FBI, G-men, private detective, or special forces. The average child is less likely to come into personal contact with these kinds of police. Perhaps is we had asked the child to relate to a particular policeman by name or other specific identification—such as a known crossing guard—he might have been more prone to assert a personal attachment. But in the normal course of events, the policeman in the general role being tested is too undramatized a figure, without real individuality, at least in the form in which we posed our ratings, to evoke a high assessment on our attachment items.

To say that a person "is my favorite" or that "I like him" is an extremely personal thing, especially as the child grows older. It would appear that however much the child may respect a figure, there may be only certain types of public figures—those that are dramatized in one way or another—that are able to forge this kind of restricted relationship with the child. The fact that the policeman ranks relatively low on the attachment items need not of itself discourage us from concluding that he may nonetheless be in a position to provide an effective point of contact for linking the child to the structure of authority.

The benevolence of the policeman

When we look at the other ratings it is clear that the low level of affiliative sentiment does not interfere with the child's more

213

positive image of the policeman in other respects. What stands out from among the other ratings is the high degree of benevolence that the child attributes to him. Likeable or not, he is seen as very willing to help the child personally; of all thirteen ratings on the policeman this one receives the highest average ranking through grade 7. It appears to be the dominant quality in the child's image. In grade 2, 85% of the children indicate that they think he would always or almost always want to help in case of need, and this remains almost at the same level in grade 8 (Table XI.3). The realistic quality of this assessment has already been noted.[7] Furthermore, over 60% of the children in both these grades also consider that the policeman would protect them more than most or many people would (Table XI.4). That he is seen as a benign, responsive figure needs no further comment.

However, this outcome of our analysis was more than a little surprising. We might excusably have expected otherwise. Adults in the American culture tend to be suspicious of persons with power, or so it is thought. We might have inferred that children follow their parents in this. If so, because for them the policeman is a powerful figure (Tables X.4 and X.5), he would also be a person to fear and suspect, not one to whom a child could be expected to turn for help. But this is not what happens and we shall return to this theme in Part IV when we seek to explain more generally why children should have so high a regard for political authorities. Here, however, we need to note that at the same time that the child is learning about the power of the policeman, he appears to seize on that power for his own purposes, as it were, and to be convinced that it will be used benignly, to help and protect him.

Dependability

The policeman is also interpreted as a fairly dependable person. Very few children feel that he is anything less than very persistent in his efforts and this sentiment remains stable at this high level across the grades (He "doesn't give up when things are hard to do", Figure X.2). He is trustworthy. The younger children on the average locate him somewhere between always and almost always likely to keep his promises. Although this mean rating drops considerably by grade 8, the children still feel that they can rely on him to keep his promises more than just "usually". Finally, they are not convinced that he is infallible. In grade 4, however, 60% of the children feel that he almost never or rarely makes mistakes, an unusually high level of trustworthiness (Table XI.5). If we project this proportion downwards to grade 2, we might have expected an extremely high percentage to select these two options. Although by grade 8 a preponderance of children express a more modest trust in the policeman, a substantial 27% of the 13-14 year olds continue to retain the high level of trust of earlier years. On the whole therefore the image of the policeman does not tarnish readily in the area of His dependability.

Leadership

As we would anticipate, the children do not imagine that the policeman shines as a leader. They are somewhat restrained in their assessment of the qualities that we have assumed are associated with leadership (Table VIII.1 and Figure X.2). Nevertheless even though the child is not convinced that the policeman is outstanding for the leadership he displays, he is not thrown unceremoniously into the category of nonleader. Apparently the child does see the policeman as possessing a sufficiently different and prestigious role to merit something better than average in an assessment of leadership qualities. Hence in no instance does the average rating fall below the midpoint.

Furthermore, it is interesting that this conception that the children have of the policeman is not modified radically by age. Although grade 8 children are clearly more likely to see the policeman as fallible than those in grade 4, little change takes place in the evaluation of the other qualities over the grades. Little "disillusionment" would seem to occur. Even though the children think the policeman is only a moderately important decision-maker and even somewhat less significant as a leader, they retain this estimate of him through grade 8. There is a rather unshakeable conviction among the children of all grades that the policeman possesses something a little better than average prominence as a leader.

Summary

In comparison with the President there is little doubt that the child's feelings about the policeman are considerably muted. But if we consider the ratings on the policeman independently, it is clear that the child does rank him fairly high on all the cultural virtues to which the ratings refer. Certain qualities stand out in the child's image. The policeman is dependable by virtue of his capacity for persisting in what he does, he is quite trustworthy, and he plays some role as a decision-maker. Above all else he is a benign figure, one who will help the child.

It is difficult to conclude that in comparison with the President the child idealizes the policeman. By _adult_ standards the children are more "realistic" here. But if we had been able to construct some index of respect by collapsing all our ratings into a single measure[8], we would have found that the child has a fairly high level of respect for the policeman, one that declines somewhat over the years but not substantially.[9] The child feels positively about the policeman but not overwhelmingly so except perhaps for some aspects of his benevolence and dependability.

Respect and Legitimacy

It would be reasonable to infer that from the general respect that children show for the policeman they would probably be ready to

217

accept his authority on the grounds that it is right and proper to obey him. It would scarcely be likely that a child, or for that matter, even an adult, would express even such moderately favorable sentiments about a policeman without at the same time accepting the appropriateness or legitimacy of his powers. Piaget argues for the same point. "It is not the obligatory character of the rule laid down by an individual," he has written, "that makes us respect this individual, it is the respect we feel for the individual that makes us regard as obligatory the rule that he lays down. The appearance of the sense of duty in a child thus admits of the simplest explanation, namely that he receives commands from older children (in play) and from adults (in life), and that he respects older children and parents."[10]

But if this is true, we have succeeded in exposing one of the tap roots of support for any regime. It is axiomatic that few systems could persist if, for each decision, the authorities had to persuade or compel the members of the system to conform to it. In most systems the members do in fact come to accept the validity of the power of the authorities, within varying limits. The police represent an output terminus of the authority structure that is personally nearest to the daily lives of the members in a system.[11] If as children matured, they came to despise the police, distrust, scorn, or reject them, the probabilities would be considerable that acceptance of the whole structure of authority at all levels would suffer, assuming no compensatory mechanisms came into operation in later years.[12]

Not that esteem in childhood for the police necessarily guarantees a continuing high level of input of support by adults. There are many years of experiences ahead of the child which may deflect his sentiments away from the regime, and we shall have more to say about this in Chapter XIV. But if in the United States the nearest representatives of authority were rejected at the outset, because of the very few connecting points between the child and the structure of authority a major impediment would stand in the way of the growth of feelings about the structure of authority. The Presidency might remain virtually alone for the earliest years of childhood; this office would be forced to carry the full burden for generating (or failing to generate) diffuse support among younger children. However unaware research has been of this probable systemic consequence of the police, it is apparent from our data that the police do play a vital role in laying part of the foundation for the input of support.

Our analysis also incidentally points up the extent to which a major set of institutions--the law-enforcement agencies--have been neglected in political research and the need to bring the police back into the study of politics in a more meaningful way. As we mentioned at the outset of our discussion, scholars have paid considerable attention to other aspects of the police but have generally failed to appreciate the central part that the police may play as a component of the authoritative output structure of a political system. As producers of outputs they are in a peculiarly appropriate and visible position to mediate between the members of a system and the rest of the structure of authority. It is a mediation that reveals itself

particularly through the way in which the police may or may not con-
tribute to the growth of a sense of legitimacy. By focusing on this
aspect of the police we are able to bring knowledge of this institu-
tion to bear on an understanding of the process of legitimating politi-
cal authorities, a central phenomenon in all political systems.

As important as the police, along with the President, may be
for the generation of support, this does not diminish the importance
of other possible major points of contact between the political system
and the growing child, especially as he moves out of the early grades.
We do find a number of alternative objects crossing his political hori-
zon as his attitudes towards political authorities continue to evolve.
It is to these objects that we shall now turn.

7. In chapter X. In practice by far the largest percentage of the policeman's time is in fact spent not in crime detecting and prevention and law enforcement but in helping others: giving directions, providing emergency medical and ambulance services, regulating traffic, rescuing lost children, assisting stranded motorists, intervening in family quarrels, reporting neighborhood needs to the proper authorities, and the like.

8. We did not construct such an index in fact. Our various correlational and factor analyses indicated that these ratings do not combine into a single stable attitude across the grades. Hence we speak here only of an a priori index.

9. Six of the ratings decline with age and the remaining seven are fairly stable (Figure X.2).

11. This has at times been intuitively observed. "Mechanized police forces have by their very nature taken away some of the closeness that prevailed when beat men were the rule rather than the exception, and this naturally has taken away to some extent the personal contacts that policemen formerly had with neighborhoods and their peoples. In fact, the whole tenor of life has tended to get people away from the 'neighborliness' that was prevalent years ago. This in my opinion is responsible for some of the delinquency today among both juveniles and adults. Years ago, the beat man knew most of the people on his beat. Today, the police car is the symbol of authority, and the car and its occupants must now relate to the children is some positive way. This can and is being done." A.A. Ballard, "Policeman-the Children's Friend" 35 Childhood Education (1958) 108-10, at p. 109.

12. We must bear in mind that our study includes almost exclusively white children. There may be some question as to the way in which Negro children might have responded to our items. With the mounting numbers and intensity of riots in the Negro ghettos during the 1960's and the hostility that all law enforcement agencies have drawn down upon themselves, Negro children might be undergoing some important new generational experiences. But some very preliminary drawings

by Negro children in one major slum suggest that they too may hold the policeman up as a model worth emulating, although, as we would expect, some important ambivalences begin to creep in. But even if young Negro children have absorbed white attitudes towards the police in the past we would expect that if the polarization of the races continues, significant changes in the orientations of Negro children will also occur. The potential impact on the early generation of support among Negroes for the structure of authority is self-evident.

Chapter XII

AUTHORITY OBJECTS IN LATER CHILDHOOD

The initial major points of contact between the children in our group and the structure of authority, we have seen, are to be found in the symbol "Government" (personalized at first), in the President and in the policeman. In the early years no other objects of authority loomed so large for the child as to merit special treatment.

In some systems we could conceive that feelings and perceptions about the various figures of authority might come into serious conflict with each other. This would be especially likely where the individual authorities were themselves in open opposition—as where a monarch might be struggling against a parliament, a tribal chief against a new secular representative, or local officials against a strong centralizing government. In the face of contradictory messages sent out by authorities in the throes of conflict, primary socialization would undoubtedly leave a residue of tensions and uncertainty in the developing political outlook of children.

As the children matured, their early experiences might help to push them in any one of a number of directions. Some might find themselves in an ambiguous state of mind about whom to regard as the legitimate authorities. Others might end by drifting aimlessly about in the contradictory political currents. Still others might even be repelled by the regime entirely and feel constrained to retreat into an apolitical existence.

But in the American system it is apparent that for most children their orientations to political authority, whether at the national or local level as represented by our figures, or whether on a personal or institutional plane, are not antagonistic to one another. Indeed, if anything, all move in common to bolster up diffuse support. Any cursory inspection of the discrete analyses of the three objects of authority already completed testifies quickly to this essential congruence in outlook. Even with the decline for most items on the three objects that occurs by grade 8, the level of overall respect remains fairly high, as we have observed.

Nonetheless we have unobtrusively been taking several matters for granted, and it is time that we brought these to the foreground for more careful scrutiny. We refer to three interrelated matters each of which will help us to understand more fully the way in which our subjects continue to maintain their respect for the structure of authority as they move through childhood, even in the face of their declining enchantment with the personal facets of authority.

How acceptable is our assumption that the child is indeed aware of political authority as contrasted with authority in general? What happens to the child who may be unmoved by one or another of the objects

of authority? How does the system manage to keep the respect of the child for the structure of authority after the earliest years when the personal component no longer exercises its pristine powers; that is, does the process of political socialization then cease or fall into desuetude, or do other mechanisms arise to carry on the task?

Answers to these questions will help us to follow the political socialization of our subjects through the later years of their childhood. Let us briefly examine the nature of the problem posed by each question and then search for answers in this and the succeeding chapter.

Analysis of the Problems

Political versus parental authorities

Whatever the results of our analysis of the three objects of authority, we have assumed that through them the child is being connected is some way with the political system. But what evidence have we that those whom on theoretical grounds we designate as political authorities, the children do in fact treat differently from other kinds of authorities. We have already touched on this in our consideration of the policeman. There we found some indication that in the policeman the child sees a power outside the family to which even adults are subordinate. Certainly in our interviews there was no question about the youngest child mistaking the policeman for a member of the family, nor was there any sign that the child thought either he or adults could escape the long arm of the law.

However, we require more evidence than this one instance to demonstrate that the child has the capacity to differentiate at least between family and external authority. If the child is just evaluating the political authorities as though they were father surrogates this would lead us to suspect that all authority is homogeneous for him and we are really not tapping any specifically political orientation in process of development. Yet without making some beginning not only in identifying political authorities but in differentiating them from parental authority, a political system would have to leave initiation into the political realm—early "politicization"—to some post-childhood phase of the life cycle.

The risk of support failure

Furthermore, to assert as we do that because most of the children pile up on the positive side of the scales there is thus a pyramiding of respect for the three authority figures, is certainly true for the children in the aggregate. But it neglects a simple yet vital consideration. What happens to those children who find themselves in a minority for one or another of the figures of authority and who therefore may be less than enthusiastic about these authorities? Is their support lost

to the system? Can the system hope to win them to a supportive stance towards political authority only at a later stage of the life-cycle?

We are raising here the matter of how a system manages to cope with the risk that some children will be negative or indifferent to some of the authorities or about some of their qualities. To this point we have ignored these children. Now however we can take our phase "most children display a favorable image towards the political authorities" and reverse it by asking: What provisions, if any, are found in the system for those who rate one or another authority low on one or another items? Do we find in the system any general way of compensating for the low regard that some children may have for some specific authorities?

Personal versus organizational objects of authority

Finally, although we have emphasized repeatedly the personal nature of the initial bond between the child and the structure of authority, we have also seen that for the older children this mechanism seems to operate less effectively. For most qualities their estimates of the objects of authority tend to decline. It is possible that the process of attachment might stop at this point. The members might be so approving of the authorities as to require no further reinforcement. But even if they were, we would be left with the problem of understand-ign how a maturing member acquires the capacity and will to relate himself not to the personalized authorities but to those very imper-sonal institutions (organizations) by which at least all large-scale systems are governed. We can scarecely assume that just because the child may favor personal figures such as the President and policemen, or those organizations or authority to which he attributes initially some personal content, such as Government, he must automatically spread his positive evaluations to cover impersonal institutions, such as the Supreme Court. About these he usually knows little even by grade 8. Yet without attachment in some way to these organizational aspects of political authority and their acceptance as legitimate, the system could scarcely operate except through constant coercion.

It is of course possible that all socialization about these im-personal units might be relegated to a later phase in the life-cycle, beyond our period of concern. We need however to test whether this is indeed so or whether even during the pre-adolescent period some begin-ning is made towards linking the child to these impersonal points in the system as well.

We plan, therefore, to explore the extent to which children as they grow older are able to differentiate parental and political au-thority, the process through which the system copes with unsuccessful efforts to generate diffuse support for some authorities some of the time, and the way in which orientations shift from personal to insti-tutional objects of authority. To do so, we shall find it profitable to undertake a systematic comparison of the child's images of various

authorities. It is to such a comparison, therefore, that we shall now address ourselves. In the outcome we shall be able to understand better the way in which in the American political system some of the possible gaps in the earliest phase of the socialization of diffuse support are closed.

The Subjects under Comparison

In entering upon a comparison of the ratings of the various authorities, we shall seek to increase the potency of the analysis by adding to the kinds of authorities to be considered, over and above those we have already examined. Although the primary points of contact between the child and the political system are the policeman and the President, along with the idea of Government itself as an over-arching symbol of the structure of authority, this does not mean that these are the only objects through which the child relates himself to the structure of the regime. Other figures and institutions embodying political authority come within view of the child as he progresses into the higher grades of elementary school. Indeed we already know that he is aware of the existence of Congress[1] and we can reasonably suspect that most of the other major figures and institutions of authority leave some imprint on the average child.

Nevertheless for purposes of our inquiry several matters militated against any extensive analysis of the child's orientation to other objects. The President and policeman represent without question the most salient and visible objects for the child from grade 2 upwards. On occasion, as we have already noted, because of special circumstances, a mayor, an alderman, a governor, or other public official may gain sufficient prominence to have an important meaning in the political socialization of the child. But we suspect that these are idiosyncratic events and concentration on them would have led us into too great a degree of specificity in our study before the broad trends had been sketched out. Aside from special figures under certain circumstances, most other major objects of political authority, such as the Government, Congress, the Senate or the Supreme Court become known to the child during a period somewhat later than grade 2. In a developmental study such as ours, such objects therefore did not lend themselves as readily to cross-grade comparison through the elementary school span. Among those that emerge in mid-childhood years, we selected Government for more intensive analysis because it was the only concept through which the children seemed to be reaching out, even if vaguely and hesitantly, to the whole structure of authority.

Yet it did not seem wise to omit all other objects entirely, however late they moved into the child's range of vision, if only so that we could obtain some preliminary ideas about the extent to which they joined the early objects as major socializing devices. It would help us to detect any special socializing experiences associated with the nature of other objects to which the child is exposed.

For the purpose, therefore, of adding to the variability of our authorities, we selected two additional objects of authority, known to most children from at least grade 4, "the average United States Senator" and the Supreme Court. As we shall presently learn, even the slight attention we gave to these two objects paid off handsomely. We discovered, to our surprise, that the average Senator has far less salience in the political socialization of the child than any of the other figures and institutions examined. The inclusion of the Supreme Court, by contrast, does enable us to gain some new insight about an entirely different means through which in the American political system, the child is impressed with the virtues of the authority structure. Although originally we expected to use the Court primarily for the analysis of orientations towards legal rules--the regime norms and outputs of a political system--we also find that the Court occupies a unique place in the process by which children relate themselves to the structure of authority.[2]

In one instance we have also gone beyond the political authorities for purposes of the additional light that comparison might shed on the development of the child's orientation to the political structure. On the assumption that there might be a relationship between the child's attitude towards political authority and parental authority, as Freudian-oriented psychology has been insisting for decades, we added "Father" to the figures of authority. Although we leave to a later chapter discussion of the influence of attitudes towards father on orientation towards political authorities--within the limits of our inquiry--we will find it helpful here to introduce the data on father as something of a base line against which we can compare orientations towards political authority. In particular it will help us to re-examine the notion, advanced in the analysis of the policeman, that the child is able in the earliest years to differentiate political from familial authority, a critical capability if support is to be generated for the political sphere directly.

In all, therefore, we shall be able to compare six objects of authority towards which the children in our group orient themselves: Government, the President, the Policeman, the average United States Senator, the Supreme Court, and Father. For some of these, it will be recalled, we have thirteen different qualities on which we have solicited the child's ratings. For others, because of certain requirements related to the child's mental capacity and to the availability of testing time, we do not have data at all grades, either for each characteristic or for each object.[3]

These data provide the basis for a comparison of the way in which the children view the authorities. At the outset, it is important to bear in mind that the congruence of orientations already encountered for the Government, President, and policeman continues for the other political objects we now include. Yet even though all ratings for all authorities lie at the positive end of the scales, within the limits of this range there is considerable variability. Rating by rating and figure by figure variations do lend unavoidable complexity

to the presentation of the findings. Nevertheless some patterns in orientations can be discerned and these will help us to answer the questions we are posing about the developing ties between the children and the structure of authority as represented by our objects.

Differentiation between Political and Parental Authorities

If we look at the previous graphs for each figure of political authority and, on Figure XII.1 for father as well, one difference stands out prominently.[4] For father, the average ratings on each of the thirteen items at the different grade levels are fairly constant. The average child at grade 2 is likely to rate his father somewhat the same as does the average child at grade 8. A few ratings do show some trends and this is especially so for "the making of important decisions". But by and large the variation in any rating is slight. The relative stability of these feelings and perceptions implies that most children in our group are not likely to modify by very much their expectations about how their fathers will behave or about the general attributes of their fathers. This holds true even as these children grow older and learn more about their fathers.

The situation is notably different for political figures and institutions. If we now include the data we have on the average ratings for Senators and Supreme Court, on Figures XII.2 and XII.3, and if we briefly scrutinize again the ratings we have already presented for the Government, President, and Policeman it is apparent at once that the orientations of the older children are quite different. Most of their average ratings on the political items do not remain constant; they either rise or fall as shown in Table XII.1. It would seem that as the average child in our group matures, what he learns about the political authorities encourages him to modify the points of view he might have expressed in an earlier grade.[5]

This single datum reinforces a conclusion that we have already had occasion to draw from our findings on the child's orientations towards the policeman. The children in our group do not confuse familial authority, as manifested by father, with the political authorities in the outside world. Their feelings towards and perceptions of these external authorities change for the dimensions we examine; those about father either remain constant or shift to a far more limited extent.

Furthermore, if we look ahead for a moment to the figures compared in the rest of this chapter and note the rank in which the children place father on each item, we discover a strikingly uniform pattern. On those items that best express affectional content, such as the ratings about attachment and benevolence (Figures XII.4 through XII.7), father consistently ranks higher than any of the political figures or institutions of authority. The children display a higher level of affection for father and view him as more benevolent than they do any of the political authorities. As warmly as the children may feel towards the President in particular, but towards other political authorities as well, there is little doubt that father merits their highest affection.

Highest
Rating

"would help me if I needed it"

"is one of my favorites"

"I like him"

"he protects me"

	Makes mistakes[c] (infallibility)	-.29	-.47	-.56	-.54	-.02	-.32
	Gives up[c] (persistence)		.24	-.01			.10
Power	Can make others do[b] (control)		-.53	-.18			.19
	Can punish[c] (sanctions)	.44	-.36	-.09	-.88	.64	-.03

Set Name	Item	Government	President	Policeman	Senator	Supreme Court	Father
(Leadership)	Knows more (knowledgeability)	.22[c]	- .34[b]	- .53[b]	- .06[c]	.31[c]	- .05[b]
	Makes important decisions (decision-maker)	.36[c]	.31[b]	- .09[b]	- .09[c]	.44[c]	.32[b]
	Works harder[c] (diligence)		- .09	- .30			.12
	Is a leader[c]		.16	.01			- .09

[a] A minus sign (-) indicates that the eighth-grade rating is less positive or favorable than that of the earlier grade. Except on the persistence item, the eighth-grade mean would actually be a higher number on the rating scales used.

[b] grades 2-8.

[c] grades 4-8.

But as we move towards the more heavily cognitive items, where the child is asked to judge the extent to which father in comparison with the figures and institutions of political authority possesses certain role performance properties, the child discriminates decisively in favor of the political authorities. On almost every item father recedes towards last place. Whether we look at the ratings denoting dependability, power, or leadership (Figures XII.8 through XII.16), father consistently ranks lowest at each grade, with one or two exceptions. For persistence (never gives up) and diligence (works hard), father occupies a position between the President and policeman. In the only two other cases (out of nine) in which father does not fall into last place in the rank order--trustworthiness (always keeps promises) and importance as a decision-maker--the difference between father and the lowest object of political authority is slight.

Certainly by grade 4, the young child whose knowledge of the political sphere is not yet very extensive, has nonetheless grasped the basic notion that the political authorities are different from father in important respects. They may be less loveable but they are more capable. The children in our group are obviously not reacting to the authority figures--parental or political--without some pronounced differences in expectations about their behavior and outright likeability. They have taken an important step towards becoming "politicized", towards recognizing a difference between the familial and political spheres.

We are of course not surprised that children should like father more; we would have expected this to be so. But common sense might have led us to assume that proximity of father and general admiration for him that we attribute to the average pre-adolescent would have induced the children to have ranked him equal with or above all the political figures on most other characteristics as well. At the very least we might have imagined that the President alone, because of the peculiar position the chief executive plays in the American system, might have surpassed father. But such is not the case and this perhaps helps to explain the very early stage in the life cycle at which diffuse support seems to take root in American society. If children confused political and familial authority there would be little opportunity to begin the acquisition of supportive sentiments about specifically political objects. Not that the child spontaneously has the vocabulary to articulate the difference that he senses between the familial and political worlds. It is enough that in their particularity he is able to identify specifically different feelings and perceptions about these orders of existence. In the next chapter we shall return to the significance of this differentiating capacity as it affects the input of support for the structure of authority.

Differentiation among and
Institutionalization of Political Authorities

Not only does the child sort out political authorities in the aggregate from father. The child also gradually becomes aware of

of the existence of differences among political authorities themselves. He does not like all political authorities equally well. Nor does he consider them all to be endowed with similar degrees of role competence. He develops a finer level of discrimination, one that will turn out to be of considerable consequence for the extension of support to these authorities.

Aside from any consideration of the child's subjective capacity to discriminate in the political sphere, there are objective, theoretical grounds why we could not be satisfied with the idea that maturing members simply orient themselves to political authorities in the aggregate, undifferentiated as to type or characteristics. If this were so, we would have to conclude that a political system depended entirely on one omnibus set of objects for socializing its members with respect to authority. Although it is thoroughly possible that in a given system all eggs might be put in one basket in this way, it does seem likely that through trial and error the risks in a system would be spread more widely. It might not be essential for the maturing member to hold all authorities in uniformly high regard. A member's support might still be won if he held a favorable image of only some of the authorities.

In any event, whether or not the risks are spread in all systems in this way, we shall find that the American political system does offer maturing members, as found in our subjects, alternative paths for relating themselves to the political authorities. In the outcome it will appear that if the child fails to develop supportive sentiments about the general structure of political authority from his understanding of one object of authority, he might develop them with the next. We shall conclude among other things that the availability of these alternatives may be one determinant of system stability in the United States, although both system comparisons and intra-system longitudinal research would be necessary to confirm this speculation.

High affect ratings of the authorities

We can appreciate the differential impact that varying objects of political authority might have, and therefore the way in which the American system in fact manages to spread the risk of failing to generate diffuse support, by comparing the way in which children see these authorities and feel about them. We shall begin with the area of the developing sentiments the children express for various individual figures of authority. This will again point up one device for linking the child to the system: the emphasis in the earlier grades on personal figures of authority rather than impersonal organizations. But we shall now find that not all personal figures act with equal potency on the child across the grades and that in this variability lie alternative routes, for the child, to the structure of authority.

As we have observed, father emerges at the top of the list on all attachment and benevolence ratings (Figures XII.4 through XII.7)

234

commanding far more affection than any one of the political authorities. He provides us with a maximal level of affection against which others may be compared. But among the political authorities not all objects are able to elicit a uniform measure of affective response. For our most openly affective items, in Figures XII.4 and XII.5, as we would expect from our previous detailed analysis, the President stands closest to father in the degree of affection displayed by the child. The President evokes far more affiliative sentiment than does the policeman or Senator. What is also noteworthy is the position of the Senator. He falls well below the policeman on our scale of like-ability. By grade 8 he lies for the aggregate somewhere near the weak statement that the children just like him "more than some people".

Thus to the extent that affect spills over from our political objects to the regime structure as a whole, the President as a linkage point for the child would seem to be of considerably greater potency than either the policeman or Senator. To be sure, the feelings for all figures move in the same positive direction even if there are clear differences in the level of feeling, depending upon the object and attribute being considered. But from these differences we can infer that the President has greater potentiality for trying the child to the structure of political authority than either of the other figures of authority tested on these items.

The real diversity and multiplicity of mechanisms available in the system for stimulating diffuse support begin to become evident from the shift in the rank of political objects. We see this with special clarity when we turn to the area of perceived benevolence. The system does not need to rely in each case on how the child feels about or sees the President. Other objects of authority move in to bear a prominent part in the positive socialization of new members about the structure of authority.

In Figure XII.6 we see a comparison of father, policeman and the President on our protectiveness rating at grades 4 through 8. We find here that the child on the average thinks that the policeman is more protective of himself than is the President, and the father is most protective of all three. All of these authorities are fairly stationary in the level of endorsement on this rating across the grades. The President drops a little but for the most part the order or perceived protectiveness of each is established early and continues at the same level to grade 8.

For helpfulness, on the other hand, Figure XII.7 shows that a somewhat greater sense of psychic distance appears for the President. After the earliest grades the policeman and father remain at the same general higher level. The child regards the two "close-in" authorities as more likely to help him than the spatially more remote figures of President and Senator, or than the impersonal authorities, the Supreme Court and Government. Again the Senator is the most remote

of all, even more so than the impersonal authority, the Supreme Court. We see a radically different perception of these authorities for this part of the child's image.

Propinquity seems to be highly important for perception in this area. The expectation that the child has of aid and comfort varies with the spatial distance of the authority in question. Among the remote authorities, however, the President is still the most salient and the Senator the least. For benevolence—help and protection—therefore there is a fairly sharp degree of sorting out among authorities.

Generally speaking, then, the child readily distinguishes among authorities on the various ratings about affection and about their benevolence. For all authorities the high level of regard rules out any question about the encouragement of negative support. But feelings run higher at the earlier grades for all the political authorities. Although the average child shows a fairly clear pattern of images differentiation along these dimensions, the precise rating of each figure depends a good deal on the content of the item. Each is somewhat different. The child likes the President better than the policeman but regards the latter as a more likely source of assistance. The Senator ranks considerably lower on all items and the institutions do not fare much better.

To catch the younger child's sentiments, therefore, heaviest reliance is placed on two different representatives: the President when direct affect is at stake, or the policeman in the matter of direct benevolence. On the limited measures that we have, the Supreme Court and Government as institutions and the Senator make far less of a contribution. But they do draw favorable responses even if at a lower level. It is clear therefore that objectively speaking, there is some spreading of the risk here, ensuring that a favorable effective contact is made at one or another point in the structure of authority.

High cognitive ratings

When we move on to those items that reveal a more distinctive mixture of affect and perceptions, several observations press themselves upon us. First, the child gives evidence of a continuing ability, even when dealing with attributes other than those representing higher affect, to distinguish his perceptions of father from other kinds of authorities such as the political. Second, the child also displays a subtle capacity for differentiating among the individual political authorities themselves. He does not blanket them with a single, monotonic evaluation or locate them all in a uniform role of authority. The child reports authority-specific kinds of perceptions and discerns differentiated roles of political authority. Third, especially as we move to the older children, we find that they gradually re-order their orientations as between personal figures of authority and institutional representations. The last two conclusions will be derivable particularly from the items having highest cognitive content, those touching
239

Figure XII. 7. Mean Rating by Grade on "Would help me if I needed it" for Senator, Government, Supreme Court, President, Policeman, and Father.

240

on performance in political roles (power and leadership).

To present these findings we shall now examine the ratings set by set. We shall then be in a position in the next chapter to draw some of the possible general implications for the socialization of diffuse support.

On the dependability items as a whole, (Figures XII.8, XII.9, and XII.10) covering trustworthiness, fallibility, and persistence, the tendencies just noted begin to emerge. However, as we have seen before, [6] because these items entail a considerable commingling of affect and cognition, we would not expect the effects to be as pronounced as with other items of higher cognitive content.

In Figure XII.8, the child's rating of policeman, father, and President are shown for their trustworthiness ("keeps his promises more or less often"). This Figure also reports evaluations about an additional category of political actor, "people who try to get elected", that is, politicians who are candidates for public office. Candidates are of course not political authorities. But we included them on our questionnaire in a different context of theoretical interest, and on this rating we have data comparable with the three authorities.

Of these the President is the one most apt to keep his promises even though all the authorities are close over the whole range. Father however drops to last position until sixth grade when he moves up into second place. The candidates, on the other hand, remain at some distance, receiving a considerably lower average rating than any of the other three. We see here the first suggestion of a theme that other data, unreported in this book, bear out more fully. There is a distinctive gap in evaluation between the formal political authorities and those political actors who participate in the system more informally.

Thus the child rates the candidate lower than his own father in trustworthiness. Relatively speaking even the ten or eleven year old has internalized a view of a person as he runs for public office. The child is by no means as unequivocally positive about political candidates as he is about those who are already in public office. By the middle grades a little distrust and skepticism has already crept into the consciousness of the average child in our sample. The candidate comes off second best right from the beginning even before the child has very much of an idea of what electioneering is about. His evaluation drops as he grows older when presumably he is learning more about who these candidates are. For present purposes the item on the candidate helps to confirm our conclusion about the early capacity of children to differentiate rather finely various types of objects in the political sphere and to react to them differently.

A full understanding of the implications of this assessment of candidates for the political system must await some future publication

publication presenting an analysis of the child's perceptions of the political process. But here it can be said that there is no necessary inconsistency in the child holding a positive image of the political authorities and a somewhat more jaundiced view of the occupants or potential occupants of these roles as they act in a somewhat different capacity. He may be skeptical about the trustworthiness of candidates or even of authorities when they act as politicians or contenders for office—as most elected authorities regularly do while in office, in anticipation of future elections. But he may at the same time hold these very persons in high esteem while they act within the expected limits of an authority role. This is a rather fine discrimination, one that a child might not be able to understand intellectually. But in practice it would seem that the child is indeed groping for it intuitively.

On our persistence item (Figure XII.9), all three authorities are rated fairly high. Here too we find that the President outranks father. But father in turn is perceived as less likely to give up than is the policeman. Only for the President is there much change over the years and in a positive direction.

On the last item of those connected with the general trait of dependability, the fallibility rating (Figure XII.10), we touch upon a quality that children show they associate specifically with political objects, in this case, political institutions. The Supreme Court emerges as the authority least likely to make mistakes, with the Government running a close second, and the President, Senator, policeman and father appearing in that order. At grade 4 the young child is less able to distinguish the variable performance between two institutions (the Supreme Court and the Government) and the President, placing all three at about the same average position on the scale. But by grade 5 the children are able to discriminate among these authority objects clearly and this continues to the end of our age span.

The special position of one institution, the Supreme Court, is emphasized. All of the authorities except the Court show an increase in their fallibility as the age of the children increases; the evaluation of the Court is virtually constant. Somehow the aura of wisdom which most adults probably associate with the Court[7] becomes apparent very early and continues undiminished throughout childhood.

This special status for the Court seems to be part of an orientation that leads the children, the older they become, to attribute lower degrees of fallibility to institutions than to persons in the political sphere. Aside from the Supreme Court all authorities decline at about the same rate. But the institution of Government holds up a little better and maintains second place at grade 8.

In these ratings we get the first inkling of the possibility that age brings with it a reorientation in the saliency of objects of authority. The younger children, below grade 4, found it hard to grasp

the meaning of institutions as well as they did that of personal fig-
ures. Institutional terms were not known to most of them or when they
were, as with Government, a personal meaning was imputed to them. But
among the older children we now find there is little difficulty in
coping with such political concepts as the Supreme Court or Government.
More importantly, they clearly treat these institutions differently from
the personal figures. We can only wonder whether if we had been able
to include institutions in the previous two items of this set, the same
pattern in favor of institutions would have arisen.

What is first noticeable in our analysis of the previous dependa-
bility ratings becomes fully apparent in the more highly cognitive items,
those reflecting performance through power and leadership. For the three
ratings on which we were able to seek evaluations about the institutional
figures (Figure XII.11 on p. ... and Figures XII.13, and XII.14 on pp. ...),
there is a tendency for these objects of authority to obtain an ascendant
position over the personal figures. In two out of three ratings, by
grade 8, Government and the Supreme Court stand highest (Figure XII.11
and XII.13). In the third, although the President emerges supreme,
Government and the Supreme Court follow very closely on his heels (Fig-
ure XII.14). Furthermore, the differentiation of parental from political
authority continues unabated.

On our power ratings the institutions quickly assert their primacy
in the eyes of the children. On our item dealing with the ability to
punish (Figure XII.11), by grade 5 the average child concludes that
the Supreme Court and the Government have the greater capacity. The
policeman and the President run a close second with the Senator and
father falling far behind. This ordering suggests that if we had in-
cluded the institutions on our next rating, the power to make others
do something (Figure XII.12), we would probably have discovered some-
what the same ranking as between institutions and personal figures.

But these power items tell us something more. In Figure XII.12
we observe the average ratings for the three primary authorities on
"he can make anyone do what he wants". The father is considerably
below the President and the policeman over the whole range. There
is some narrowing of the differential in the later grades but it is
still large. The child thus sorts out once again very early, the
relative capacities of the political authorities with respect to father.
But unlike the items tapping affect, in the present ones father drops
well behind the political authorities. This reversal itself gives
unmistakable evidence that here too the child makes fairly well-defined
assessments of parental authority. He feels differently about it and
he has some well-articulated ideas about what it can and cannot do in
comparison with other authorities such as the political.

It is interesting, moreover, that the child underrates the power
of the President relative to the policeman. The child is not so much
in awe of the President as to gloss over his limitations, and this
propensity increases in the later grades. The policeman as seen by
the child is a moderately powerful agent of law enforcement. His

coercive capacities seem to the child to be fairly high.

There are plausible reasons for thinking why the child might bring policemen close to President in their punitive and coercive potentials. As we have observed in our chapter on the policeman, the child has the opportunity, in his own experience or from mass media, to perceive the policeman in the process of exercising his powers. The most unusual category of observed acts has to do with controlling the actions of others. But the President's power, although much greater in scope, is considerably less visible. He is not usually observed in the performance of punitive or coercive acts, nor are such acts as intimately and directly associated with his role as they are with the policeman. Rather, the President is generally seen by the child as smiling, waving, talking, shaking hands, or in other agreeable postures.

The probable effect of these different images presented by the President and policeman is clearly reflected in Figure XII.11; where the policeman's rating on the capacity to punish is somewhat higher than that of the President from grade 6 on. He is exceeded only by the government and the Supreme Court. It is the latter which is perceived by the growing child to have greatest punitive powers, of the authorities included. This capacity in the mind of the child becomes ever more apparent as he matures. The President, on the other hand, is losing ground, but not as precipitously as is the Senator. The Government seems to take on a kind of average value between policeman and Supreme Court and increases in a linear fashion on perceived capacity to punish. Father, by contrast, is low and stable in the child's perception across the grades.

Thus, even by grade 4 the child has sorted out quite clearly, on the power dimension, the general role of political authorities from the role of parental authority. He already knows that the representatives of political authority (even if he cannot identify them explicitly in these terms) far exceed his own father in power, in the limited sense of our items. Among the personal figure the policeman, for special reasons associated with the attributes used, vies even with the President in this perception. But the President holds his own very well relative to the Senator who declines very rapidly. Finally, from grade 4 on there is again a well-defined differentiating process which occurs among the political authorities. The institutions begin to loom large in these in these terms and the personal authorities to decline.[8]

In our other major set of performance characteristics, those included in our general category of leadership, we find similar tendencies for the child to single out institutions of authority and to view them with the highest regard. In comparing the objects of authority on their knowledgeability, father is clearly in the lowest rank across the grades (Figure XII.13). President and policeman stand at the top. But when we test for all authorities in grade 4, we find that the rank of these two personal figures have already declined, and by grade 8 the Government and Supreme Court edge out even the President in the extent to which children consider them to possess expertise. Similarly

in the matter of making important decisions (Figure XII.14), although the President always stands out as the paramount decision-maker, for obvious reasons, the increasing authoritativeness of institutions becomes manifest. The Government and Supreme Court together run a very close second and third by grade 8.

Some important shifting to institutional authorities therefore begins to take place by grade 8 and this represents a highly significant change in the points of contact with the child for the American system. We shall pursue this further in the succeeding chapters. But now if we add our two other performance items to the two just discussed— "works harder" in Figure XII.15 and "is a leader" in Figure XII.16—we can appreciate that the child never drifts too far from what was one of his very earliest objects of political awareness, the President.

On his working capacity and leadership ability the President draws some of the highest mean scores among all the ratings. Unfortunately we do not have comparable data about institutions on these items but it would be surprising if either Government or the Supreme Court would have surpassed the President. The strength of the President's appeal here and on the previous leadership item, "makes important decisions" would lead us to believe that however much the child may readjust his sights about those authorities initially considered worthy of the highest esteem, on any overall comparison the President would continue to have a great deal to do, even in grade 8, with setting the tone of the child to the structure of authority. But whether this is so because he is the President or because he is a personal figure of authority, and the child can consequently relate to him with relative ease, is a question to which we shall return in the next chapter.

Conclusion

To sum up what we learn from a comparison of the ratings, the children do not see or feel about all objects of authority in identical terms. Especially as they move into the higher grades, the children are able to discriminate among these objects, and in three different ways. First, they clearly consider that there is a sharp difference, on affective and performance characteristics, between the father as an authority and that kind of authority outside the family that we have designated as political. Political authority is not just parent write large; some politicization or capacity to differentiate political from familial authority has begun. We have here reaffirmed a previous finding of the same sort.

Second, among the political authorities themselves, the children differentiate according to their own feelings and perceptions. The world of political authority does not present a flat, uniform surface to the child; he sees mountain peaks and valleys and has little difficulty in describing these differences to us. In other words, ther is not just one universal role of political authorities. The child

has different expectations dependent on the object and the quality. He sees a variety of political roles. We have perhaps discovered a way in which some systems, if the American is not unique, may vary the contacts between children and objects of authority. In this way political systems may be able to hedge against the risk of support failure, a result that might easily follow from excessive reliance on any single means to win the respect of the maturing member.

That by grade 8 the child has acquired a considerable ability to identy and describe varying kinds of political roles and to separate all political roles out from the parental role of father is in itself no mean capacity for the 13-14 year old. It reveals a relatively high level of socialization during childhood about structural phenomena in politics. However much or little the child may have absorbed from his environment about politics in the party-political (allocative) sense, he has achieved some degree of sophistication in breaking down his external world into some of its components, one of which is the political structure. In the next chapter we shall find how vital this capacity is as a means for insuring diffuse support during childhood.

Finally, even though the children are initially attracted to personal objects in the political sphere, and this tendency persists in some degree across the grades, this does not mean that the child remains fixed in this mold. Somewhat earlier we had some forewarning of what we could expect to occur. In our chapter on "The Image of Government" we witnessed a decided shift from persons as the best representative of government to institutions such as Congress or practices such as voting. We have now discovered that this is symptomatic of a more general capacity, with age, to establish ties with and to take note of impersonal units of authority such as the Supreme Court. Institutionalization begins to displace personalization of political authority.

But of what significance are these findings for our understanding of the early sources of support? As interesting as these findings may intrinsically be, we know that our main purpose does not lie in determining how children come to distinguish the political from the non-political world or now they acquire knowledge and feelings about the political world in some vague and amorphous general sense. In themselves these matters could scarcely offer a justifiable primary focus for political research. Our concern rather is with a theoretical problem in understanding the functioning of political systems: How do systems, such as the American, create support, whether positive or negative, with respect to the regime structure? Unless our comparative analysis of the ratings points towards some significant consequences in the area of diffuse support, it would have little meaning for our objectives. It is to these system implications therefore that we must turn in the following chapter.

Footnotes

1. See Chapter VI.
2. We now suspect we might profitably have included Congress as another institution for intensive analysis, especially in light of its prominence during later years in the child's image of government.
3. See Table VIII.1.
4. For Government, on p. ; for President, p. ; for policeman, p. .
5. We would draw attention again to the major assumption of our synthetic longitudinal design: that in their political orientations, our younger children look like our older children would have looked if we had tested them at the appropriate chronological age.
6. See Table VIII.1 and discussion about it.
7. See M. Dolbeare, "The Public Views the Supreme Court," in Jacob (ed.), Law, Politics and the Federal Courts (Boston: Little, Brown, 1967), pp. 194-212; M. Dolbeare and E. Hammond, "The Polical Party Basis of Attitudes Toward the U.S. Supreme Court," Public Opinion Quarterly (forthcoming, Winter 1967-68); F. Murphy and J. Tanenhaus, "Public Opinion and the United States Supreme Court: A Preliminary Mapping of Some Prerequisites for Court Legitimation of Regime Changes", a paper delivered at the Shambaugh Conference on Judicial Research, University of Iowa, October 1967; J. Kessel, "Public Perceptions of the Supreme Court," 10 Midwest Journal of Political Science (1966) 167-191.
8. We could perhaps speculate that it is law-enforcement and application which hold special sway in the child's early judgments about which authorities are the punishing kind. This function is not so connected to the President or the Senator probably because their main functions are focused elsewhere – upon initiation of policy or making the laws in the first place, according to which transgressors can be punished. Somehow lurking beneath the surface of the child's response to political authority in these terms is a triad of law, crime and punishment. Research is needed to probe more fully into this aspect of political socialization. For the time being we can only guess at the meaning of Figure XII.11, and how it reflects the significant role of law, law making, law-abidingness and law-enforcement in the young child's introduction to the power of political authority in the American system.

Chapter XIII

SHIFTING IMAGES AND SUPPORT FOR THE SYSTEM

The comparative analysis of the ratings for the various objects, in the preceding chapter, reveals the way in which during later childhood images of the political authorities undergo some substantial changes. These changes open the door to some suggestive speculations about the implications of our findings for the input of diffuse support to the structure of authority.

What we have to say applies of course only to our 12,000 children. However, until further research demonstrates the contrary, we may temporarily but profitably assume that the distribution of orientations in our subjects is not atypical for white, metropolitan, public school in the society as a whole. At a minimum this assumption will provide us with a set of hypotheses for subsequent testing; at most, it will help to illuminate some probable early sources of diffuse support in the American system as a whole.

Early Politicization and the Input of Support

Let us turn first to the support implications of our findings about the child's capacity to differentiate political authorities and persons such as father and political candidates. This capacity has been confirmed in two ways: by the consistency with which the children favor father on the affective attributes and the political authorities on those dealing with performance; and by the clear difference that children discern between the formal political authorities and those would-be authorities, the political candidates. This has helped to reinforce the earlier evidence we found for the policeman in Chapters X and XI. There we had noted that through the police the child is encouraged to conceive of a power outside the family and superior to it. It is clear that the child has little difficulty in discriminating rather narrowly between qualities that he would associate with parental authority and those he would use to describe the external authority we have been labeling as political. He orients himself differently to each type, and this presents us with some important evidence about the growth of a not-so-faint consciousness concerning a uniquely extra-familial sphere of authority. In this sense the child learns to be sensitive to the political dimension of his world; he is becoming politicized.

But more than that however is implied is our data. We clearly have here the beginning of a discrimination in roles. The child has different levels of expectations as between father and the external authorities. We cannot say that he has qualitatively different expectations about the characteristics of their behavior for we have tested both father and the external authorities on the same attributes. But our investigation does demonstrate that the child expects father to be more loveable and benign, with the political authorities displaying greater

257

dependability, power and leadership. These are marked and systematic differences in expectations. Their frequency distribution among our subjects suggests that these expectations have the regularity about them that we find in other kinds of role identifications.[1] At the very least the child is distinguishing between internal roles of authority, those found within the family and external roles, those found outside.

This is a phenomenon of fundamental importance for a political system, especially for the input of support. Undoubtedly in some systems, such as those in which there is little structural differentiation between parental and political authority--for example, in a society in which the basic social unit is the extended lineage group --the political system can claim no support that is readily distinguishable, formally, from the family head.[2] But in structurally differentiated societies such as the United States we can now identify the way in which an autonomous support base may begin to evolve.

As the child at an astonishingly early period begins to discern a difference between a familial authority role, represented by father, and external authority roles, reflected in our various political objects, a solid base is laid down in the system for the development of two different capabilities critical for its persistence. First, the child moves towards a growing awareness of regularized differences in expectations about authorities. Thereby he is in fact being socialized about structural elements in the political system. He is coming to recognize specific components in the political structure as contrasted with the family.

For so highly differentiated a social system as we find in the United States, this is a central outcome of the socializing processes. As in all other modern industrialized societies, if the child confused political with familial authority roles, the political system would find itself hard put to draw the child out of the family environment. This would impair the ability of the system to activate him, at a later period in his life, for non-familial, society-wide purposes, unless of course in the interval some other kinds of socializing experiences were to bear the whole burden for moving the maturing member in the same direction.

Indeed in many developing political systems in which lineage groups are carried over from the original tribal societies, it is this very reluctance to acknowledge authority outside the extended family group that interferes with the capacity of the newly-formed political systems to win enough support to provide viability for their political authorities. Where lineage groups are able to lay prior claim to the loyalty of their members, we may well wonder whether primary socialization does not help to produce this result by reversing the process we find in the American system. That is to say, we would expect to find that children in lineage-dominated systems would learn to view external authority as inferior to lineage authority.

258

To return to the American system, however, it is true that we have not determined whether this outside authority is itself broken down by the child into different spheres. If he did not do so, he would not be able to distinguish _political_ authority from the authority that others may exercise over him from time, to time, such as a church, Scourt organization, gang leader, or musical director. Our study leaves this as a moot point. But the weight of evidence would indicate that the child, by grade 4 or 5, is not likely to confuse the authority of other institutions with that of the President, policeman, or Supreme Court. We would conclude, therefore, that there is a strong probability in the American system that through the central elements in its structure of authority the child develops very early a sense of the political sphere.

As the child becomes aware of the structure of political authority and can relate to it in role-specific terms, conditions are created in the system that make it possible to begin to evoke diffuse support. This occurs during childhood, well before the maturing member has the capacity for rational evaluation of alternatives. At the same time as the child begins to perceive authorities beyond the small circle of the family--as he becomes politicized--he develops positive sentiments about them. The system thereby begins to build up diffuse support on which, if later experiences do not deflect the child, members of the system may subsequently call. The early origins of the support would seem to fortify the probability that support would be available later in the life-cycle, if what is impressed on a person early, endures. It would seem to offer some grounds for understanding an important source of the relative durability of the American structure of authority.

The Institutionalization of Authority

In the previous chapter we adduced some considerable evidence of the child's capacity to shift his attention and regard from personal to institutional objects of political authority. We shall now return to this point to establish it more firmly and to pursue its implications for explaining a further source of diffuse support.

Our earlier comparison of the individual items revealed that the older the child, the more likely is he to offer a higher evaluation of the institutions of authority (Government, Supreme Court) on our measures of role performance. We can now see this even more clearly in Table XIII.1 which presents the way in which the child ranks each object of authority, at all grades, on each of the attributes. If we confine our attention only to those attributes tested for all five objects of political authority, we can observe that the older children tend to give a higher ranking to our two institutions on the performance items.

Thus for fallibility, at grade 4 the rank order was President, Supreme Court and Government. By grade 8 President drops to third place. In the matter of sanctions (can punish), the ranking in grade

4 is Supreme Court, President and Government; by grade 8 Government moves up to second position displacing the President. Perhaps the greatest reorientation in favor of institutions is for knowledgeability. At grade 4, President is first, Government second, and Supreme Court fourth. But by grade 8, Government has moved to first place and Supreme Court to second. Only in the making of important decisions do these two institutions not improve their position, but they do retain second and third place.

On these performance ratings, therefore, the institutions or organized roles of authority succeed in winning the highest esteem of the children most frequently, by the end of our age span. This is displayed in Table XIII.2. For this Table we have excluded father and reassigned rank order on each attribute accordingly. We have then calculated the average rank on each attribute for the objects of political authority. At grade 4, the average rank of the President exceeds that of the Supreme Court and Government in that order. But by grade 8, the Supreme Court has moved up to first place followed by the Government and President.

The elevation of the impersonal institutions to a paramount position of respect is particularly evident for the Supreme Court. Our data do not penetrate very deeply into the child's attitudes towards this body. But even with the cursory material we have, the esteem the Court commands from the children is of a very special sort as we can see from Figure XII.3. Unlike many of the sentiments for and perceptions of other objects of authority, in this case all but one of the ratings are relatively stationary or increases with age. The Court is seen as rarely making mistakes and this holds up across the grades. In grade 4 the children consider that it makes important decisions a lot of the time and this judgment increases to all of the time by grade 8. Similarly its power (can punish) and knowledge (knows a lot) increases markedly with age.

Whether in each new generation of adults this is an important source of the public image of a peculiar sagacity, wisdom and prudence not enjoyed by other authorities and of a special sanctity that has surrounded the Supreme Court even in the face of unpopular decisions, we cannot say. Nor can we even begin to speculate as to whether this sentiment has anything to do with the willingness of many members of the system to tolerate decisions by the Court that run ahead of popular conviction as in the school desegregation decision of Brown vs. Board of Education. But at the very least we can be permitted to infer that a high level of regard for this impersonal unit in the structure of authority has been built up in children by the time they are ready to leave elementary school.

But what is the significance of this increasing tendency to lift the impersonal institutions to a position of high esteem? For the American system with its emphasis on the power of the office, not of the occupant, and with its commitment to collective participation in the making of political decisions, the capacity of the maturing member to re-orient his thinking from personalized figures of authorities to institutions (organized sets of roles) is critical.

Table XII.2. Rankings and Average Ranks for Political Authorities on Selected Ratings

Set Name	Item	Grade	Government	President	Policeman	Senator	Supreme Court
Benevolence	Would want to help (helpfulness)	4 8	4 4	2 2	1 1	5 5	3 3
Dependability	Makes mistakes (infallibility)	4 8	2.5 2	1 3	5 5	4 4	2.5 1

Rank order of average rankings		4 8	2.5 2	1 3	4 4	5 5	2.5 1

A system that sought to attach its members to its structure of authority solely by relying on the culturally approved virtues of its personal representatives of authority would undoubtedly run the danger of overpersonalizing its whole regime. In a system of this kind we might expect each leadership succession to precipitate a "crisis of authority" for other political institutions. It raises the query as to whether this kind of emphasis does not find a significant place in the socializing of each new generation in systems such as Spain, France or in many Latin American systems. Certainly the excessive stress on personalized figures would encourage the maturing members to attach themselves ultimately to persons rather than to organizations as the appropriate wielders of authority.

Of course for a system that depends largely upon personal legitimacy[3]--charisma in Weber's terminology--and sought to perpetuate itself, this would not only be satisfactory; under certain circumstances it might be mandatory. But where the regime depends upon the legitimacy of institutions as does the American, some way must be found for attaching the members to the roles involved, not to their occupants. Institutional support, not personal support, is clearly a defining condition for the continuity of this kind of system.

The capacity to identify and admire faceless organizations is no easy or ordinary achievement for children, particularly in an area such as politics that has little intrinsic interest for them. The difficulties standing in the way have already been implied. We have looked at a considerable body of data demonstrating that for our group of children, the personal figures of authority became almost inescapable initial points of contact with the regime. We have, it is true, concluded earlier that the younger child shows signs, not of relating to persons as such but to the institutionalized role, to the Presidency rather than the specific President, for example. Nevertheless we were also impelled to propose that the child can more easily make a meaningful contact with those roles that are personalized in the form of some palpable human being, such as a visible President or a nearby policeman.

But not all objects of authority lend themselves to such a personalization. Political organizations such as the Supreme Court consist of an aggregate of persons and it may be difficult to personalize its organized collection of roles. Few adults, much less children, know the name of its Chief Justice, to say nothing of its ordinary justices. Hence in some systems such as the American the maturing members may somehow need to acquire the capacity to esteem impersonal institutions.

To a limited extent this may be equally true of all systems, even of those in which personal legitimacy dominates as a bonding device. It would seem plausible to expect that at some point in his development, a member of most systems will lose his early childhood dependence upon personal elements among the various objects of authority and accept those objects as well that display less personal, institutional qualities. Somewhere in the socializing processes therefore we can expect a shift in orientation to take place wherein the member

finds he no longer needs to have his senses excited by the personal
component of the authority but is able to accept (or reject as the
case may be[4]) the more impersonal authority of organizations.

What has surprised us is that the process begins so early, in
the American system at least. To all appearances, as the child de-
velops the intellectual and emotional capacity to relate himself to
non-personal, distant things such as institutions, he does so in the
area of political authority as well. We do not have to wait until
adolescence or adulthood for the maturing member to acquire a sensitiv-
ity to the exercise of authority by organizations in the regime.

As a specific consequence, systems, such as the American, which
attribute authority to offices and institutions rather than to men,
are able to orient the maturing member increasingly towards these im-
personal objects. But the child is not only able to react to the in-
stitutions of authority as he grows older. The favorable sentiments
first extended to the personal figures he now tends to shift towards
those very organizations that he previously had failed to notice.

The import for the system needs little elaboration. These posi-
tive evaluations undoubtedly reflect and simultaneously help to re-
inforce the large measure of stability the American regime has in the
past achieved. Support is being socialized firmly on behalf of the
structure through which authority is being exercised even without the
mediation of the personal element. The danger is correspondingly di-
minished that the changing persons who happen to occupy positions of
authority at a given time will draw off the child's support.

The Personalization of Authority

Our data have repeatedly brought us back to the refrain that the
personal figure involved in an object of authority--as in Government,
during the early years, and in the Presidency and the policeman--eases
the generation of positive support among younger children. Our compari-
tive analysis in the preceeding chapter now bears this out decisively--
and yet forces a certain qualitication on the hypothesis.

Table XIII.2 shows us the reasons for the reinforcement of our
previous conclusions. It indicates the undisputed primacy of the
President in grade 4 for those five attributes on which we have a
comparison with institutional forms of authority. There is little
reason to believe that if we had been able to test the child's evalua-
tion for all objects on all attributes the President would have fared
any less well. By grade 8 we know that the child has reordered his
perceptions in favor of the impersonal institutions.

But our comparative analysis now compels us to modify our con-
clusions about personalization at the early grades in a modest yet
important degree. Not all personal figures of authority need serve
with equal impact as points of contact between the child and the re-
gime. This is particularly clear for the policeman. As the child

266

grows older, he has changing expectations about the policeman. On Table XIII.2, even by grade 4 the policeman ranks only fourth and continues steady in this position through the later grades. But the Senator is even more revealing of the limitations of personalized authorities. He is an undisputed personal figure of authority and yet all our five objects he possesses the lowest degree of effectiveness in evoking expressions of positive sentiments from the child.

If we return to Table XIII.1, of the six qualities on which we have ratings for the Senator, the children consistently put him towards the last. His rank ranges between third and fifth place, if father is excluded. Not even at grade 4, the more personalizing phase among children, do they rank the Senator among the first. In spite of his elevated position in the political system for the professional observer, the children do not esteem the Senator, on our measures, so highly as they do the lower status (for adults) policeman. At grade 4 the children rank the policeman higher on five out of the six attributes on which we have ratings. Even in grade 8, when the 13-14 year old child has considerably more knowledge about government (if only through exposure to history and a course on civics), in three out of the same six attributes the policeman still draws a higher rank than the Senator. The lower rating for the Senator may perhaps be partly an artiface of the kinds of qualities we posed for rating. But when we consider that even the impersonal institutions of Government and the Supreme Court also call forth a more favorable response on most qualities, we can see that the inferior evocative power of the Senator must also be a function of the nature of the role as perceived by the children.

This is not to say that the children are hostile to or suspicious of Senators. Figure XII.2 in the previous chapter shows that in terms of the meaning assigned to our cutting points on each item scale, the average Senator does rate high, somewhere above the midpoint for four out of the six qualities tested. But in comparison with the rankings given to other objects of political authority the Senator does tend to bring up the rear. The personalization of authority that the Senator represents is apparently not enough in itself to draw the higher regard of the children in face of other figures that have some greater cultural meaning at work for them. As a mechanism of attachment to the structure of authority the Senator operates as a considerably less influential point of contact with the child.

Clearly not all personal figures of authority play an equally prominent part in the socializing process. Although the child is able to attach to personal figures earlier than to other objects of authority, he does not do so with equal fervor in all instances. Only some figures of authority possess the qualities necessary to catch the eye of the children and elicit highly positive assessments. Personalization is a necessary but not sufficient condition. For the personal element to be activated as a link between child and object of authority, apparently the system must already have provided the figure of authority with some visibility, such as a psychic or physical prominence for the child. Perhaps the figure needs to be

267

dramatized in some way, as in the periodicity of elections for the President or the crime busting folklore surrounding police activities. The culture would thereby harmonize with the capacity of the child to relate to personal, non-familial objects and in practice the culture sets before him only select figures of political authority. The Senator was clearly not as important one of these.

The Hedge Against Failure

In brief, therefore, the system does not concentrate its efforts in one direction alone in stimulating diffuse support for significant elements in the structure of authority. It is protected against failure, as it were, by the presence of a number of open doors through which the child may enter supportively into political life.

Image congruence

We must bear in mind what we have already noted well, that in spite of the relative position of the authorities among themselves, all the authorities are rated fairly high on most attributes. We continue to assume what we have argued in earlier chapters, that high ratings reflect a positive evaluation because most of the rated attributes represent a favorable cultural values in American society. In this sense each object at the very least adds a modest increment to the growth of positive support. Negatively put, no object presents an adverse image to the children that might discourage the majority from viewing the authorities favorably. However poorly a figure shows up comparatively, there is no question of the child developing a sense of distrust of political authority. Even for the Senator who fares worst in this respect, the ratings remain relatively high.

It is also evident that however differently the child may see the various political authorities and however his perception may shift with age, his images as reflected in our ratings do not reveal any fundamental inner tensions. They all move in a congruent direction, towards some overall and consistently favorable interpretation of the political authorities.

The significance of this homogeneous outlook in each child cannot be overestimated. The high level of unconflicted evaluation of all authorities severally, and in aggregate, would seem to reflect and at the same time help to account for primary forces that have contributed to the hitherto relatively stable character of the American regime, assuming our tested children are not atypical.

Variations of appeal

Furthermore, the socializing processes seem to work in such a way as to spread the risk for the system over a number of figures. This is a consequence of the fact that the esteem the child builds up for the authorities depends on the kind of characteristics he

associates with them. He likes the President, considers him very trustworthy and persistent, sees him as a very powerful person, an important person, an important decision-maker, an increasingly hard worker and leader. But even though he does not place the policeman so high on these attributes, the child does consider him to be particularly benign (helpful and protective). He finds the Supreme Court admirable at least for its infallibility and power to punish. The Government as a whole stands out particularly in the oldest child's mind for its wisdom--it knows more than any of the other figures or organizations of authority. With the exception of the average Senator, it appears that at some point across the grades there is always some quality in which one or another of the authorities excels relative to the others. If a child does not share the consensus of the children on one object of authority, he is not lost to the system. The system has a hedge against failure to win the diffuse support of this particular child; he may join the majority in regarding highly one or more of the other objects of authority.

The socializing processes also act in such a way as to take advantage of the capacity of the child to orient himself to things political. The political system need not rely exclusively either on personal figures of authority or on institutions to begin the process of attaching members to the political authorities. In the early years, because of the clear incapacity of the child to handle impersonal units in the structure, there is no recourse but for the generation of diffuse support to begin through the emphasis of personalized components. The child develops a high estimate of the President and policeman; he also begins to reach out to institutions, such as government. But at this early stage in the political socializing processes, the inner conceptualizing limitations of the child lead him to interpret the institution in personalized terms.

Nevertheless even though the primary socializing process in the American system take advantage of the personal components in the structure of authority at those stages in the child's maturation when palpability of the occupant counts for most, the general thrust of these processes in in a different direction. They move decisively towards stimulating diffuse support for the institutions, either initially for institutionalized roles (the Presidency as against a particular President) or later for institutions defined as impersonal organizations of authority roles. As the child grows older, this shift in orientations protects the system from any failure to capture some kind of favorable response. Without abandoning personal figures entirely as a linkage point, the child no longer needs to lean so heavily on them alone. As the child acquires the capacity to orient himself to the impersonal institutions, he begins to reorganize his perceptions somewhat. The organizational component in the political authorities--such as the Supreme Court and Government--come closer to the foreground of his feelings about the political world.

From this analysis we are led to conclude that in some part the persistence of the authority structure in the American regime in

relatively stable form over the generations is not alone a product of any "success" in meeting routine political problems and intermittent crises or of any peculiarity about its institutional arrangements such as the separation of powers and its federal structure. Early politicization seems to free the child from his family or other group ties at least sufficiently to enable him to begin building up some ideas and feelings about the political authorities. His subtle intro- duction through the personalized elements of these authorities yields with age to esteem for institutions. If our findings apply to the recent past as well, they also suggest that for each rising generation alternative ways have been provided in the system for hedging against the chance of failure in keeping the reservoirs of diffuse support full. But aside from the validity of so broad a generalization, we can say that no effort to explain tne consequences of political so- cialization in the American political system can afford to neglect the impact that early political experiences may have had in these specific ways for the input of diffuse support for the structure of authority.

4. Although the monotony of repetition forbids it, in each case where we speak of the input of support or acceptance of authority, unless the context indicates otherwise we assume that the maturing member may be acquiring either negative or positive support. That is, he may be acquiring disaffective as well as conforming sentiments. Without this caveat about the use of the notion "support", it would appear that we are examining only the conditions of stability whereas we are seeking to understand change as well. Unfortunately _from a theoretical_ point of view, the American system has been relatively stable and research on it does not offer much help in understanding the nature and conditions of political change. Because of this bias of the system towards stability it becomes more important than ever to bear constantly in mind that in speaking of support for the system or of the bonding of members to the system, the negative character of the support (alienation or disaffection) may in other systems be the major consideration.

CHAPTER XIV

POLITICAL STABILITY AND CHANGE AFTER CHILDHOOD

If our sample of children is at all indicative, in the American system the child becomes tightly linked to the structure of authority. The overwhelming thrust of primary socialization must therefore be towards political stability. Early orientations would provide a solid supportive base for the regime as the members grow older. Even if later events should disillusion members about the structure of authority, the rate of decline in support might at least be restrained somewhat by the pull of latent childhood sentiments.

We are of course not surprised that in the United States the overall tendency of primary socialization should be towards political stability. For better or worse, this system has been relatively stable over the years, and we would expect children to mirror the behavior and hopes of their parents. Alternatively, if in a stable system we would look for the cutting edge of political change, we would not be likely to find it during the stage of childhood socialization.

The fact that we interpret primary socialization in the American system in this way, however, raises certain dangers. It might be thought that we are implying that socialization always tends to act as a stabilizing factor in political systems. Nothing could be further from our thoughts. Indeed in Chapter II we were clearly loath to accept any assumption like this, in principle. We even suggested that in some systems childhood socialization might conceivably be an important means for inducing change. Now, however, with a solid body of data behind us, we propose to go further and to inquire whether our study of children gives us any hint at all about where we might expect socialization to be hospitable to political change and innovation. Here we will need to digress somewhat from our main theme, the sources of diffuse support for the structure of support in childhood. But this is necessary if we are to appreciate the conflicting systemic consequences political socialization may have for support, at different ages, in the same system. Even in the United States, we shall find, stable as it has been, the child is not coupled to the system with the same strength in every phase of the life-cycle.

Here events of the 1960's in the United States can help us out. Even though the child begins his contacts with the political system in a strongly positive spirit, the increased rate of political activity of young people in the 1960's may well lead us to suspect that something may characteristically be happening by late adolescence and early adulthood to change substantially the political sentiments of maturing persons. The mood among many young people in the 1960's has been one of too great definace of political authority for us to believe that early sentiments always or necessarily continue unimpaired.

Can socialization with regard to authority possibly held us to account for this change between the affiliative mood in which we leave the child in grade 8 and the numerous less than enthusiastic adolescents

and young adults of the 1960's? If we can, it will help us to appreciate more fully the limits on the consequences of childhood socialization for a political system. It might also throw a beam of light on those special age groups in the political system through which political innovation and change, the frequent consequence of instability, are more likely to have their beginning.

It is clear that we cannot explain the rebellious sentiments and activities of many young people in the 1960's and the political climate among them critical of political authority solely by what we know about political socialization in childhood. If anything, these early political orientations should lay a restraining hand on adolescents and young adults, assuming sentiments acquired in childhood are not easily dislodged. Yet the new political spirit among young adults in the 1960's seems to run contrary to the warm attachment to the structure of authority characteristically acquired by our test children.

The failure of the tendencies so dominant in childhood to persist at least among many young people suggests that we look at post-childhood stages of the life-cycle for some assistance in understanding how it happens that tight bonds to political authority may begin to loosen. We shall find that because of lack of any significant kinds of data about public regard for most authorities, it will prove extremely helpful to pick up the threads of our discussion about the police from Chapters X and XI. The availability of some data about adult attitudes towards the police will give us some rich new leads---although no firm inferences ---into why it might be that during the 1960's it is young adults who break out of the stabilizing restraints so clearly applied during childhood.

Instability and Political Socialization

In contrast to the 1960's, in most earlier periods the United States has represented a relatively stable political system. Not that many changes have not come about. But with two or three exceptions these changes have resulted from slow accretions rather than from sudden transformations or violent intrusions. The American system has moved from a decentralized federal type to one in which considerable power over states and localities resides in the national government, from a system in which government was involved only marginally in the economy and other social spheres to one in which government is the largest employer and there is large scale governmental regulation, direction and innovation in many major areas of life. We have also in recent years witnessed the transformation of the rules governing the rights of some minorities, especially the Negro, under revised interpretations of the Constitution without formal modifications of this document. Even with the far-reaching transformations in political life that these changes represent, in comparison with other political systems, the United States has hitherto appeared to be quite stable. From our data we would assume that childhood socialization has contributed its share to this outcome.

An unfolding decade of instability

But events in the 1960's at least, permit us to pose the question
as to whether the United States may not be about to enter a vastly dif-
ferent decade, one in which political change may move far more quickly
and in which the path of change will be strewn more frequently with open
and violent conflict. Could the United States be on the threshold of an
entirely new epoch of political unrest in which even the style of politi-
cal participation will shift radically from debate, the hustings, and
the ballot box to the streets, the bullet and the torch? In the 1960's
there has already been visible a clear progression in the frequency and
intensity of violence. At first street demonstrations and peace sit-ins
began to supplement open debate. In the face of hostile opposition, noisy
but peaceful assemblies gradually shifted to the use of force in self-
defense. From here it was but a step for political frustration and an-
ger to express themselves positively through open resistance to authority.
Street demonstrations blended into urban riots, non-violent dissent against
policies in Vietnam into outright resistance, and conformity with legal
rules into civil and violent disobedience in the name of higher moral
law.

Does the new and apparently growing propensity to turn to the
dramatic use of force for the expression of political demands and for
signalizing the withdrawal of political support—a new politics of con-
frontation—mean that the United States is entering a period in which
basic attitudes towards political authority are undergoing profound
changes? Does it portend a new phase of American life in which insta-
bility may for some time become an intrinsic part of the political fabric?

Clearly it is too early to say whether the unrest of the 1960's
marks the beginning of a long period of civil turmoil in which the threat
of violence backstops the vote, even though as social scientists we can-
not escape raising the question for objective analysis. There have been
other periods of violence, during the 1860's and the 1930's particularly,
when it also might have appeared that the basic texture of political life
was being unalterably transformed. Yet a non-coercive constitutional
political style was able to reassert itself within a decade in each case.
It is entirely possible that the unrest in the 1960's will be equally
short-lived.

We cannot help but acknowledge, however, that the political cli-
mate of the 1960's has been unusually disturbing. There have been deep
political crises in the past. Yet not all of these have sparked a pas-
sion that carried opposition into the streets as it has in this period.
This prompts us to ask whether there may be something unique about the
conditions of the 1960's that can help us account for the changing atti-
tudes towards the legitimacy of the policies of the political authorities,
if not indeed towards the legitimacy of the very authorities themselves?

It goes almost without saying that there are many reasons for the
increasing political malaise of the 1960's. A world that seems doomed

274

to hang precariously on the edge of atomic self-destruction is not likely to be one in which reactions to international crises will follow past "normal" patterns. A political system as in the United States that has placed a high priority on political involvement by its people and participation in decision-making is not likely to be one in which fateful policies will be accepted without fundamental challenge, however high the costs in terms of personal sacrifices. Furthermore, the events of this decade have perhaps themselves been sufficiently unsettling if not traumatic to help undo the bonds so tightly welded in childhood. But in spite of such obvious causes, if our study of childhood socialization has sketched a political profile of a child who is deeply attached to the structure of authority as he sees it and if in the succeeding phase of youth and young adulthood we see signs that many have become wary of if not openly hostile to political authority, we may credibly ask whether socialization in these later phases of the life-cycle may not also help to explain this phenomenon.

The police as a generic symbol of authority

Unfortunately our inquiry into the child's perception of the Presidency and other political authorities did not permit us to pursue the process of political socialization in the later stages of the life-cycle. In addition, very few data are available from other sources that could be construed to tap the adult's attitudes towards the office of the Presidency as against specific Presidents and towards the other institutions and figures of authority with which we have dealt.

But we are in a somewhat better position for the policeman, looked at as a symbol of political authority. Here the very nature of our investigation concerned not the specific policeman but the general role as perceived by the children. Recently there has been a growing number of efforts probing for the views of adults about policemen in matters that overlap with ours for the child. We are therefore able to take advantage of studies on the images adults hold of the policeman to see whether the available data can shed any new light on the later systemic consequences of the socialization of children. In the process we shall find some clues about the way in which socialization itself helps to leave youth and young adults in the 1960's susceptible to some loosening of their bonds to political authority.

We shall find that political crises in the 1960's, domestic and international, have been occurring at a time in the life-cycle of the younger generations when the latter may be most likely to question their earlier attachment to the political authorities. This happenstance could contribute significantly to the forces making for instability in the American political system. Lacking comparable data about other figures and institutions of authority, we are forced to rely exclusively on the maturing person's attitudes towards the authority of the police as a rough indicator of possible incipient feelings about the legitimacy of political authority in general. However adequate this assumption may

have been for children, we recognize its greater questionability for older persons. Yet this decision need not be as hazardous as might appear on the surface. The police symbolize the law, and in a constitutional, legal society such as the United States, the authorities assert their power formally through the law. It is not far-fetched therefore to interpret orientations towards the authority of the police at least as symptomatic of these that may be developing towards political authority in general. Furthermore, most of the curves on our ratings for all authorities other than the policeman move in the same direction, during childhood, as do those for the policeman himself. We might expect that they might continue to parallel those for the policeman even beyond childhood.

But having gone this far with our assumptions, we are nonetheless very much alive to their speculative nature. Not all curves of respect for all the authorities need follow the same path, especially as we move into adulthood. Hence, however useful our assumptions may be for breeding what we feel are significant and provocative hypotheses, we do not pretend that even with the hard data we are able to present, we have gone beyond insight and informed speculation. It is in this spirit that analysis in this chapter is presented.

The Image of the Police among Adults

It will be recalled that at the point at which our inquiry left the child, at age 13-14, however favorably he may think of the policeman on the whole, the glow is beginning to dim. We may now raise the question of the kind of consequence this early respect has for the stability of a system when it may be slowly sinking towards a far more depreciative image. Have we any data that would throw some light on whether later experiences accelerate the downward trend of the curve of respect, arrest it or even reverse it?

The striking thing, we shall discover, is that the image of the police held by older adults looks more like that of our children than is true of teenagers and young adults. Between childhood and late adulthood—after age 14 and before about 35—the modest evidence available reveals a pronounced dip in expressions of respect for the police. We will be in a better position to interpret the potential systemic consequences of post-childhood socialization if we ascertain the nature of this dip and examine some of its more likely causes.

276

We have already intimated that the literature on adult percep-
tions of the police repeatedly speaks of the very low opinion that
most people hold. There are, it is commonly said, "widely held be-
liefs that policemen are uneducated and of low mentality; that they
are selected for physical strength and courage alone; that they are
of doubtful honesty and integrity; that they are engaged in a con-
tinuous offensive against society; that they are often rude and domi-
neering..."[1] It may be that these beliefs accurately reflect prevail-
ing attitudes in some localities in the United States. But strangely
enough the few national urban and statewide studies that have been
undertaken do not confirm this. From the fragmentary and varied mea-
sures that we have, it would appear--with some ambiguity due to diver-
gent findings, varying time periods, and differences in the specific
qualities being appraised--that there is a considerable gap between
what writers think the popular image of the police in recent times to
be and the findings of local and national surveys about actual beliefs.
In fact, as we look at adults, undifferentiated by age, we are impressed
by the close similarity of their views to those we have already found in
children.

One component of the general image that adults hold of the police
consists of their status or general standing in the community as com-
pared with other occupations. Numerous studies have included the police
in the prestige structure of occupations. One review of these studies
concludes that these "prestige rankings of occupations have yielded
surprising concensus in the ranking of 'police' as an occupational
category. In general, the police are placed in the middle ranks.
What is surprising is that these ratings of the police appear relatively
stable through time, are relatively constant across national boundaries,
and seem relatively unaffected by difference in scaling techniques."[2]
In one of these national surveys in the United States, in 1947, 41%
of the sample gave the policeman an excellent or good standing; in a
replication in 1963, the figure had risen to 54%.[3]

Occupational prestige is not necessarily synonymous with respect
even though in many instances prestige and respect may go hand-in-hand.
It is possible, for example, to estimate that the military rank high on
a status scale and yet to display little fondness or respect for the
military as an occupation. Typically, occupations considered necessary
evils may acquire some glamor and prestige from their social importance

or influence, yet personal esteem need not accompany the judgment. But it is not too farfetched to see in occupational ratings of the police some modest admixture of respect.

There are many constituent parts to an image of the police, and other studies have tapped a number of these. They all definitely add up to an unexpectedly favorable adult assessment of the police. During the fifties in a survey of the city of Los Angeles, 29% of the population considered the police to be persons of unquestionable honesty and 53% felt that they are usually men who are fairly honest. All in all, on such ratings as courtesy, dedication to their job, competence and impartiality, with some reservations of an important kind, this police force at the time seemd to elicit a favorable reaction from its public.[4]

In another sample, this time about attitudes towards the police of a particular state, the image that emerges appears to be about as positive as among the children in our sample. The state police are viewed as "an honest, impartial, objective police organization whose job in general is about the same as most with respect to the time and effort involved, but one which involves frequent exposure to risk and danger. What they do is important and they do it well. Their rewards are an above-average income and high prestige in their community...87% of the responses describing the nature of public-police contacts depict that interaction as 'friendly, helpful, and courteous'".[5]

Finally, a national survey in 1965 posed a question that forthrightly sought the opinion of the adult on his respect for the police he is most likely to know best. In response to the quest, "How much respect do you have for the police in your area?", 70% of a national sample indicated that they had a great deal of respect with only 22% and 4% replying some or hardly any, respectively.[6] In a repetition of the question in 1967, those answering "a great deal" rose to 77%.

It is of course risky to generalize from these few studies. There are said to be 40,000 separate and distinct police agencies in the United States with 420,000 policemen.[7] It may be that attitudes are to some extent agency-specific and variable by community and region. We know little about the specific referents that the word "policeman" calls up in the minds of adults. Nevertheless the little evidence we do have does move unmistakably towards affirming that most people have higher regard for the policeman as a generalized role than we might have anticipated if we had relied on the folklore in the literature as our sole guide.

We can now see that from our evidence on children alone we would have grounds for making an intelligent guess about the attitudes of adults. If children tend to acquire the attitudes of their parents, we might have anticipated that, regardless of the contrary indications of the literature, adults would be favorably disposed towards the police. The puzzling disparity between the presumed low estimate of the police by adults and the more positive views of the children is revealed only as a product of misformation. Children and adults in the aggregate do not seem to be too far apart in their estimate of the police.

The Trough in the Early Years among Adults

If adults do indeed take a positive view of the policeman, we are immediately confronted with what might appear to be a new puzzle. By the time the children in our group reach age 13-14 their favorable image of the policeman is either stabilized or declining, depending upon the component that we select. If we assume that our ratings for children tap the same general sort of qualities, summarized in the notion of respect, as the kinds of items already noted in the studies for adults, it appears that even though the child's regard for the police is on the whole declining, that of adults is relatively high. How can we explain an apparent rise in the curve of respect at some point beyond childhood?

Since we lack strictly comparable data for adults and children, we can only speculate about the answers. But the speculations are useful in drawing out several alternatives, and even the limited data we have on adults will enable us to make some informed guesses about what may be taking place and its possible implications for the political system, especially for its stability or change.

There are several possible explanations for the discrepancy between the declining level of respect we find in our 13-14 year olds and the high level reported for adults. First, the respect of the children may begin at so high a level that even if it does continue to decline slowly with age, it never falls below a relatively high point. We would therefore expect to find that adults assess the police very favorably even if somewhat less so than the children.

But second, it could be that in the past, when the present generation of adults were children, they learned and maintained a high level of respect for the police. However, the present generation of children which we are testing may be different. With them respect may begin to decline at an early age and it may continue to fall as these children move on through the adult phases of the life-cycle. The differences between the children in our group on the one hand and current adults on the other, could therefore be attributed to generational shifts in attitudes towards the police.

Finally, we might hypothesize rather that both past and present generations are not too dissimilar. Esteem for the police does decline with age among children and even beyond but at some point it stabilizes itself and then reverses direction and climbs to the level of regard which the surveys among adults report. It is possible that there is a middle-years dip in respect with this low point extending from the late teens to somewhere in the thirties.

Although the indeterminancy of the evidence in the face of complex socializing processes does not rule out any of these explanations or variations on them, the available data do lend some greater credence

to the third interpretation, The reason for believing that there may
be a middle-years trough in respect resides in the relationship between
age and contact with the police. In the United States the child is apt
to see the policeman as something of a model of the "good guy". In
cops and robbers, for most children the cops stand on the side of virtue
and the robbers are the outlaws. But as the child moves into the teens
and young adulthood, his experiences with the law begin to change. In
the modern age he becomes part of the car culture; and this together
with the greater mobility, assertiveness and exuberance of youth raises
the probability of increased conflict with the police over safety and
order. Most recent studies report the highest rate of contact between
members of society and the police to occur in the teens. Generally,
beginning with the late teens, contact with police varies inversely with
age. In one study, 75% of those over 65 reported no police contacts in
the past five years but only 4% under 21 fell into this category.[8]

But as the young adult grows older and, we would assume, takes
on the responsibilities of job and family and acquires additional stakes
in life, he probably also revises his relationship to the immediate en-
forcement agencies. He comes down somewhat more heavily on the side of
law and order, and his previous conceptions may be re-awakened. Not
that they need to or are likely to stand out as prominently as in the
past. Adults may not be so favorably disposed towards the police. But
the curve of respect ascends again.

The data we have are at least consistent with this kind of ex-
planation although we hasten to add that there are some disturbing ad-
ditional analytic problems. Because of the complex interlacing of the
major socializing influences over time, it is impossible to disentangle,
through survey data of the kind available, the relative influence of
biological aging, social aging in the sense of the particular pattern
of influences through which a person moves as he matures, and generation
of birth. Generation we interpret as the major temporal events to which
an age set has been exposed and which leave a deep imprint on the outlook
of that group. But the serious if inescapable limits of this sorting
problem for interpretive purposes do not reduce the significance of the
various studies to which we refer. They do reveal a middle years dip in
respect for the police.

This tendency for the policeman to rank low with teenagers and
younger adults and to improve with age, in recent years, is confirmed
in a number of studies. In a survey of public attitudes toward police
in Los Angeles reported in 1953, the older people, 55 years and above,
were found to be the most favorably inclined, and the severest critics
on a variety of traits were reported to be those between 15 and 44 (Fig-
ure XIV.1). In the 25 to 45 age group the respondents were inclined to
feel least favorably disposed towards the Los Angeles police. If we
assume a much more favorable evaluation among children, as estimated
for the 7-14 year olds in Figure XIV.1, decline in approval sets in
at age 15, reaches a low point by age 25, maintains this for about twenty
years and begins to ascend again. The younger and older groups are more
accepting of the police, the middle groups more rejecting.[9]

Figure XIV.1. Overall Evaluation of Los Angeles Police, by Age[+]

*Estimate of where children would be.

+ Percent who answer, "One of the best police departments in the country".
(Adapted from G. D. Gourley, Public Relations and the Police, page 65.)

In a 1959-60 study of state police, on a ranking on close to
twenty characteristics the rank order of favorableness by age showed
a direct, practically linear relationship. "Younger persons are less
favorable and older persons are more favorable with respect to this
composite image of the police".[10]

In the A.I.P.O. national survey already referred to, a similar kind
of association between age and respect for the police emerges. As Figure
XIV.2 shows, the proportion that has a great deal of respect for the
police rises from 53% for those between 21-25 to 84% by age 56-60. At
this point some additional decline occurs.

Finally this tendency for persons, as they grow older, to improve
their estimate of the police even prevails across national boundaries.
A national sample in Great Britain also reveals a close relationship
between respect and age. The proportions having great respect for the
police move from 63% for those 18-21 years of age to 88% for the 45-65
age category, as shown in Figure XIV.3. Even when length of potential
contact with police is controlled, age still dominates as a determinant.
Thus among motorists, the group most likely to have contact with the
police and to come into conflict over the enforcement of traffic regu-
lations, analysis shows that the tendency for respect to increase with
age persists.[12] It may be that the closer connection between age and
respect that tradition seems to give to the British policeman.

If we now join together the bits and pieces of evidence about
how aging correlates with the image of the police, we seem to have a
pattern of the following kind. Children such as those in our group,
on making contact with contact with external authority as represented
by the police, acquire a relatively high level of regard. We have only
a slight hint about the movement of this sentiment between 14 and 21.
But if we can interpolate, we would think that given the nature of teen-
age culture in the United States, regard for the police might continue
to drop. This declining feeling seems to bottom out somewhere in the
late 20's or early 30's when it reverses direction and slowly rises again
to some high point among the 60 year olds. Even after it declines be-
yond the latter age on the one measure we have reported for this group
(Figure XIV.2), it does not drop to the low point of the 20's. If we
were to construct a curve to represent our speculations about fluctua-
tions in respect for the police over the whole life-cycle, it would look
something like Figure XIV.4, given the kind of data we have examined.

The Significance of the Early-Years Trough

Of what significance for attachment to the structure of authority
is this trough of respect during the early years? It discloses several
noteworthy things about the relationship of the individual member of the
American system to its regime and thereby about possible sources of in-
stability and change.

High Respect for Police: A Theoretical Distribution

The police as a continuing linkage point

In the first place, the existence of this trough helps us to understand the implications of the decline in respect for the police that we detect in grade school. The diminution in the child's positive image as he moves through the grades may not be just a temporary phenomenon. It probably parallels the general decline in the growing child's proclivity for idealizing persons. It undoubtedly also in part reflects the growth of a youthful sense of independence and social autonomy, expressed through opposition to adult authority in many areas of life. But in addition, the child's initial feelings are probably deflected by specific kinds of experiences and values associated with special periods in the immediately succeeding phases of his life-cycle. We have already observed this in the nature of the kinds of contact many teenagers are likely to have with the police.

As the individual moves out of these early stages of his life into later adulthood, however, some of his positive sentiments towards the part of the structure of authority represented by the police revive, perhaps either because they had continued in latent form, waiting to surface again, or because they are re invigorated through new experiences. Undoubtedly both influences are at work. Whatever the source, however, of primary significance to us is the probable continuity in the United States of the police as a positive linkage point between the members of the political system and the structure of authority.

Whether for the present generation of young adults, the police will continue to serve a stabilizing function, as they probably have prior to the 1960's, will of course depend in part on the extent to which respect survives the strain being put upon it during the 1960's. The violent confrontations between police and young adults on campuses and in the inner cities may so disturb the growing generation as to create a new breed of disillusioned older adults in the years ahead.[13] The ascent of the respect curve, therefore, cannot always be taken for granted. It may depend in part on the particular experiences of young adults during their typical early-year dip.

But we must bear in mind a caveat mentioned previously. Even if the data had pointed towards a possible continuation of the decline we found in grade school, with no subsequent reversal of direction, we could not allow this in itself to lead us to underestimate the kinds of sentiments generated to that point. Respect for the police as a symbol of authority is still relatively high in grade 8. If we believe that feelings acquired early in life are not easily shed, they would at least serve to cushion the impact of later negative impressions.

In the second place, these fluctuations in sentiment about political authorities may have the deepest significance for the fate of the political system. The accessibility of the members of a system for mobilization for or against political authorities could be partly a function of the phase of the life-cycle in which one catches the members. If, for example, it

should turn out that for the President and other major political institutions, the decline we see in grade school continues as it does for the policeman, and only during the late 30's or early 40's begins to surge back to some earlier level, this could have profound implications for stability and change in a political system. If the low point in attachment to the authorities were indeed the same point of the life-cycle for all objects of authority, it would mean that the part of the population in that age group would be more susceptible than others to appeals leading towards a modification in the regime. Their ties to the structure of authority (and to regime norms if it were equally true in this area, and this we do not know) would be at their lowest ebb. Empirically these members in the political system would be in a greater state of readiness to disengage themselves from the existing regime than they were when younger and than they will be when older.

Age-distribution and stability

An interpretation such as this throws a new light on the possible significance of the age-distribution in a population for the stability and change of a political system. The larger the percentage and absolute numbers of the population in, say, the 15 to 35 year age bracket—assuming the validity and generality of our tentative inference—the greater the proportion of the members of a political system that can be more easily detached from it. Systems with a younger population of this kind should turn out to be more volatile and more prone to reassess traditions critically. Indeed it may be that from these younger ranks are recruited the counter-elites. It may help to explain the phenomenon of youth and relatively young adults at the forefront of many changes, revolutionary and otherwise. They are at an age when we can expect them to be least committed to the support of authority and most prepared therefore to challenge tradition.[14] This gives new meaning to the notion that older persons tend to be ideologically more conservative than they were during their youth. It reveals that the basis may lie in part in a general maturational pattern of fluctuations in sentiments towards some of the political authorities.

Some plausibility for these inferences is offered by events in the 1960's. It does appear that as the proportion and absolute numbers of young people in the population of most societies in the West and elsewhere have increased during the 1960's, there has been a corresponding heightening of the political activity of youth in opposition to formal symbols of authority. Everywhere during these years young people have tended to become more politically involved with issues sparked by the particular crises of the time.[15] Confrontations with political authorities through violent protests, street demonstrations, and other coercive measure have been appropriated as the hallmark of youth. Passionate concern for substantive justice has often taken the place of unquestioning confidence in traditional social forms and legal rules.

In the United States the pool of young people, those in ages 15-24 (in whom, according to the thesis being presented here, esteem for police authority should be dropping towards its lowest ebb) have increased from 13.7% of the population (24,500,000) in 1960 to 16.2% (almost 32,000,000) in 1966 and can be expected to continue to rise.[16] Critical issues have arisen to mobilize them for action, as in their concern for civil rights, for poverty in an affluent society, and for a loftier morality in what is viewed as an immoral war in Vietnam. At the same time they have been sparked into action by a desire for greater effectiveness in guiding their own destinies and this is paralleled by deep frustrations at their own apparent powerlessness against the "Establishment", as expressed in the goal of "student power".

Sources of Youthful Discontent

Of course our inference from the patterns for the police to all other parts of the structure of political authority and to other elements of the regime as well, represents a sizeable speculative leap in the dark. But even if we accept its plausibility for the moment, this does not imply that just because the younger age brackets in the population may have weaker feelings of attachment, the system need under all circumstances experience change. Negative sentiments may not be sufficiently intense to leave members readily available for action against the authorities. Furthermore, even if their attachment has sunk to a very low level, there may be no issues or conditions to make them sufficiently dissatisfied with political life to lend their support for any significant change. Beyond that, even if discontent were rife, there need not always be the institutional and organizational resources, and the absolute numbers needed to achieve a "critical mass" for effective protest. Nor need there always be waiting a competent leadership to initiate any plausible effort for change. Thus even if we had evidence that belief in the legitimacy of the authorities had declined temporarily, it would only describe a significant sufficient condition for political transformations. We have no basis for indicating what would in fact occur historically. This would depend upon these other kinds of factors—the numbers, resources, leadership and provocative circumstances. But it is the fact that these other factors are present in the United States during the 1960's that makes this combination of circumstances so politically inflammable.

We are not of course suggesting that the emergence of critical issues at home and abroad at a moment in time when young adults constitute an increasingly larger element in the population of the United States represents a single valid explanation for the rising political discontent among young people as seen during the 1960's. The issues themselves have certainly been deep and provocative enough to stimulate unusual political measures to alleviate them even if young adults had remained an unchanging proportion of the population. Furthermore, it may be, as some have maintained, that the middle class protesters who in the 1960's form the core of the New Left, on campuses at least, are

288

playing out the liberal sentiments of their parents who had been close
to the old left of the Great Depression during the 1930's. It might
also be argued that in the 1960's more young people have more years of
education than ever before, and there are reasons to believe that the
more educated a person, the less likely is he to submit uncritically to
authority.[17] Nor does it seem too fanciful to suggest that it could
possibly be that for once young people have taken the exhortations of
their elders seriously and have become politically committed, unlike
their predecessors, the "silent generation", of the 1950's. They could
be seeking to create a new, more serious and consequential political
role for young adults in the political system.

But in addition to all these plausible sources of present discon-
tents and pressures towards political instability, we would be over-
looking a vital confluence of contributing causes if we failed to take
into account: first, that young people constitute larger numbers in
the population of the United States than ever before; second, that
they represent an age group in which respect for and attachment to
political authority may typically have declined to its lowest ebb;
and third, when this is coupled with urgent, frustrating issues such
as have been present during the 1960's, we have a combination of cir-
cumstances ripe for swelling the number of those ready to defy politi-
cal authority on behalf of what they consider just.

Through the erosion of support for the structure of authority
in this way, stability could be undermined. If our chain of inferences
withstands the assault of further research, we have here possibly put
our finger on one of the age groups whose socializing experiences may
prepare it to serve under certain circumstances as a major vehicle of
political change. But regardless of the specific implications of our
analysis for attachment to the political authorities in the 1960's, our
research does press more generally for a massive increase in attention
to several different aspects of the regime. There is an urgent need
for a far better understanding first, of the early origins of a sense
of legitimacy for the structure of political authority; second, of
the pattern of change in these sentiments as members age; and third,
of the implications of age variations in these sentiments for the sta-
bility and change of regimes under differing conditions.

What relevance has this discussion for our broader theoretical
interests? After all, we did note in the early chapters that our
major preoccupation is not with an analysis of socialization as a means
for producing stability in a system or for that matter, for bringing
about change. What we have been searching for is some understanding
of the processes underlying the attachment of members to a structure
of authority on the assumption that unless this linkage occurs no po-
litical system, stable or unstable, could persist. As we will note
in our final chapter the stability or instability of the structure is
of concern for us only as it can help us to understand better the pro-
cess of attachment to the structure of authority.

But it does so happen that the American system has been relatively stable, at least for the period in which we tested our group of children. This has created certain problems of interpretation for us. The findings in our previous chapter were unavoidably and heavily weighted towards pointing up the stabilizing consequences of primary socialization. We have feared that this emphasis of our interpretations could easily leave the entirely false impression that socialization must always and inevitably perpetuate the status quo.

This chapter has helped us to appreciate that this need not be true. Aside from what the consequences might be if primary socialization occurred under conditions of political instability--and we have little data on this--, even in as stable a system as the United States has appeared to be socialization may work in one or another direction, depending upon the phase of the life-cycle under examination. If we had remained with our data for the childhood stage, we might easily have concluded that socialization inevitably encourages stability. What is now also clear is that secondary socialization, the period beyond childhood, may under certain circumstances work in an opposite direction. As a result, we can anticipate that the early adult years may reflect some tension between childhood affect and later disenchantment, with the net outcome dependent on the particular situational events.

To suggest that there may be unstabilizing consequences associated with certain phases of socialization does not imply of course that the system must therefore show signs of instability. The general stability of a system depends on more than what happens in this area alone. Manifestly we should not expect to be able to conclude from our analysis only of socialization in the postchildhood phase that the members would necessarily become so detached from the structure of authority that they could not support any authorities. Even if disenchantment sets in with respect to one type of authority structure, this might simply be the signal for a change of structures. In that event there would be a shift of allegiance to a new way of organizing political authority. Hence the outcome of the discontent in the 1960's need have little relevance for the capacity of the members of the American system to cathect some kind of structure of political authority. Only under very special conditions, where succeeding structures repeatedly failed to capture the support of the members, might a situation arise in which some kind of system would be unable to continue.

In this chapter, however, we have hoped to nip in the bud any thought that we might be implying that socialization must always reinforce support for the structure of political authority. Although in Chapter II we had already denied this, with the analysis of our data still ahead of us we could not make the point too persuasively. We still cannot argue from our data alone that primary socialization may contribute to change or instability; this must await research in a different kind of political system, one in which instability is pronounced. But we now have some tentative grounds for estimating--if only through scattered and patently preliminary data--that socialization beyond childhood, even in a system that has been as stable as the American,

may operate so as to dampen rather than heighten the ardor for the structure of political authority. In the American system, as elsewhere, this may be a critical stage, so far as socializing processes are involved, for the introduction of change and innovations.

9. On two qualities, however, liking and fearing the police, the
    youngest group tends to drop below the level of the average for
    all respondents. See G.D. Gourley, op.cit. pp. 65 and 71.

10. J.J. Preiss and H.J. Ehrlich, op.cit., p.130.

11. The reduction of respect among the very old, those beyond 70,
    may be partly a function of the general disengagement process
    characteristic of the aged although we would need to know more
    about aging to explain this decline adequately.

12. Royal Commission on the Police, (London: H.M. Stationery Office,
    1960-62) p.6 and Appendix V.

13. Apprehension along these lines is already implicit in testimony
    recommending "that the National Guard members be substituted for
    policemen as soon as possible after major civil disturbances be-
    gin...This would lessen animosity toward policemen taking part in
    'actual combat' and thus permit them, when order is restored, to
    'go on the next day picking up the pieces, putting it back togeth-
    er...The police then perhaps are in a better position to move in
    and assume their rightful role as the over-all law enforcement
    agency and crime prevention agency in the area, without quite as
    serious a stigma hanging over them.'"

14. To obtain some initial insight into the impact of age variations, it would be useful to generate correlations between age distributions in a population and some indicators of the propensity of a regime to change. Similarly studies could be undertaken of the extent to which parties seeking changes are more likely to be composed of younger generations. Research might also be usefully devoted to analyzing the age composition of elites on the assumption that they might be consistently recruited from the least attached generations, in our terms.

15. This has been equally true, for example, even for such divergent political systems as those of the United States and China. In the latter, Mao was able to use the Red Guard—the organization of militant adolescents and young adults—as the spearhead of the Cultural Revolution, a force directed against the authority of local and national Party officials. During 1967-68 young people of college age also engaged in demonstrations and encounters with police or military forces in Berlin, Rome, Madrid, Tokyo, Moscow, Warsaw, Amsterdam and other major centers in the world.

16. See Statistical Abstracts of the United States—1967, (Washington, D.C.: U.S. Department of Commerce, U.S Government Printing Office, 1967), pp. 10 and 26.

17. We are indebted to Philip Auerbach, a graduate student in the Department of Political Science at the University of Chicago, for drawing this to our attention.

PART IV

DETERMINANTS OF DIFFUSE SUPPORT IN CHILDHOOD

CHAPTER XV

EXPLANATION OF THE CHILD's DEVELOPING IMAGES

Our analysis thus far has been directed toward illuminating several of the most important aspects of how the young new member of the American system orients himself to political authority in the elementary school years. Our major focus has been upon maturational trends in the child's capacity to relate himself to such key figures as the policeman and President and to the overarching structure of government. As we have progressed in this analysis, we have presented a series of hypotheses which describe the trends that we have discovered and which lead to a variety of suggestions about the possible impact of early orientation to public authority upon the later course of events in the political system.

A task remaining, however, is to push the analysis back, in so far as possible, to the causes of the effects that we have detected. To accomplish this, it is first appropriate to restate briefly some of the major developmental hypotheses that we have proposed. Second, we shall attempt to suggest some broad categories of explanation that we might use in relation to our descriptive propositions already set forth. When these preliminary steps have been taken, we can then move to more specific further analysis of our data, employing the independent variables that seem appropriate and that are available within the limits of the study. The restatement of our problem in relation to various categories of explanation will occupy the balance of this chapter; and the consideration of specific explanations in our data will constitute the next two chapters.

In our attempt to give an account of early developmental trends in orientations towards or images about political authority, we have set out hypotheses of several basic descriptive types. We have described the relative levels of diffuse support according to our measures, as those pertain to children at different grade levels. Such descriptions have involved both cognitive and affective aspects of other images about a variety of authority objects. Further description in these same terms could also be directed to patterns of variation among the several sub-units of our samples, particularly such key groupings as sex and socio-economic status. We will presently offer such an elaboration to sex and social class categories.

Our analysis calls for more than elaboration of the inductions we have made, however. We need to advance to the area of explanatory statements to give some better account of the origins, processes, and precipitating factors that lie behind the phenomena we thus describe. Some of our central hypotheses are the most appropriate entry points for this analysis.

Hypotheses and Descriptive Propositions

One set of hypotheses that we have thus far emphasized concerns the more cognitive aspects of the child's early response, particularly towards that ambiguous political object, the government. Government serves the child as a major contact point and one that we shall contend in Chapter XIX, draws together the many disparate aspects of the structure of authority. Government becomes represented to the child as a democratic structure, moving in his vision from a singular, personalized image to one that is multi-person, differentiated and institutionalized. Concomitantly, the child shifts from a "charismatic" to a "legal-rational" interpretation of government authority, as the latter is related to popular and representative rule (Chapter VI).

We have suggested that government is initially more associated with the law-making than other functions and, increasingly over the age span, it is associated with the national level of government. With these shifts in the terms of recognition, there comes, relatively early, an awareness of the difference between the public and private sectors. (Chapter VI).

Accompanying these developments about government, there also arises a high degree of positive affect. The child interprets the government, just as he interprets the more personal figures of political authority, to be powerful and benevolent. As he moves through this period of development, some depersonalization of the object begins to appear, whereas ratings on more role-related attributes of government increase at the positive end. Thus, while affect is high throughout, there is greater emphasis by the end of the age span upon the more impersonal aspects of government. (Chapter VI).

For the personal representations of political authority -- especially the President and policeman -- we have argued that their salience is high, especially for the young child, and they serve as major contact points in the child's political adjustment. We have speculated that the high visibility of these two figures who stand at the head-and-tail of the system, together with their easily perceived protective functions, lead the child to choose them as benchmarks in the development of his orientations. (Chapter VII).

As for the President himself children understand him to be situated at the top of the authority structure; but they begin to limit his role somewhat as they grow older. He stands especially high in their affections, and they rate him very high on such qualities as persistence, dependability, knowledge, power, and leadership. (Chapter VIII). In addition, this perception of him is only to a rather small extent colored by partisan identification (Chapter IX).

The policeman, the child's other major personal point of contact with the system, tends to be seen according to a familiar local perspective. The policeman is definitely a part of the government in the child's

estimate, but he is not a particularly salient general symbol of govern-
ment; nor is he seen to be much a part of the law-making apparatus.
On the other hand, the policeman as an embodiment of external authority
is given special prominence vis-a-vis family authority, particularly
in the necessity for obedience (Chapter X). The child's affective
orientation to the policeman, although not as highly favorable as that
for the President, is nevertheless quite positive. The policeman is
seen to be dependable, not much prone to error, and he is fairly high
on the more personal, affective, less role-connected attributes as
well.(Chapter XI).

Turning to comparisons among various authorities, we have found
that considerable aggregate differentiation occurs among different po-
litical authorities, and between these authorities and the child's
father. Whereas the ratings of father are higher on the affect-related
items, he is somewhat lower on the more cognitively directed, role-
performance attributes. In this sense, political authority is not a
simple matter of generalization from family or a matter of father writ
large. Among the public authorities, moreover, the shift in the level
of positive ratings moves generally to the more impersonal institutions
and away from the personal figures (Chapter XII).

Thus, the child at an early age begins to differentiate "inside"
from "external" authority, suggesting somewhat separate socialization
to major structural elements of the political system and perhaps a
whole range of different expectations about various types of authority
arising therefrom. The child becomes bonded to political objects more
directly than had perhaps been supposed in earlier discussion. Such
early bonding to distinctly political objects, particularly the insti-
tutions of government, presages sources of direct support for the poli-
tical system (Chapter XIII). We shall return to this theme more fully
in our conclusions.

That such support is likely to continue into adulthood, with some
fluctuation, is suggested by the high level of positive respect shown by
adults for the police in this country -- a finding that contravenes much
of the folklore about an alleged unfavorable image of the police. There
is a trough, however, in the aggregate level of regard for the policy
by young adults -- hinting at perhaps partial and temporary resocializa-
tion through post-childhood experiences. (Chapter XIV)

These are, in brief, a few of the main hypotheses and descriptive
propositions that we have evolved thus far, and we shall use them as
the major orientations calling for explanation in our succeeding dis-
cussion.

They represent our dependent variables. One main task will be to
elaborate some of the most significant group differences with respect
to these propositions, showing the nature of the variations in the way
members of different sex or social status categories respond to politi-
cal authority in the elementary school years. Another main task will

be to elaborate some of the most significant group differences with respect to these propositions, showing the nature of the variations in the way members of different sex or social status categories respond to political authority in the elementary school years. Another main task will be to use such independent variables as sex, social status, religion or I.Q. as explanatory devices, attempting to suggest the determinants of the varying orientations towards political authority. What we shall now do, in anticipation of our later discussion of these determinants is to turn to a general consideration of strategies appropriate to the explanation of the key hypotheses that we have evolved.

Strategies of Explanation

Our study as originally conceived did not place high priority upon locating and measuring the effects of explanatory variables. There was a prior task to be done. One most appropriately explains phenomena only after they have been accurately described. In this case it was thought that the greatest share of the research resources ought to be devoted to giving a better description of what the young child learns about the political realm and when he learns it. Once the maturational events were established, it would be suitable to explore the circumstances and causes of these events.

Without such a strategy the investigator of childhood political learning could easily be caught in endless confusion by attempting to identify, measure, and connect causes like early family influences that are considerably remote from their effects upon actual political behavior. Studies that have relied upon the retrospective reports of adults about their childhood political learning experiences and about how various agents of socialization interacted with them are very susceptible to the pitfalls of remote causation -- just as they are prone to the unreliabilities of adult recall of childhood events.[1]

A more profitable approach, it would seem to us, is to attempt first to pinpoint the periods of basic change in political orientation and only then to mount a major effort to locate the more proximate causes. Indeed, we have assumed that the changes we sought were likely to occur over a somewhat extended period of the life-cycle. If this assumption were valid, then a likely corollary would be that there exists a fairly complicated set of causal circumstances. A further implication would be that the tactic of deciding a priori when the most crucial time of socialization might be, then observing causal conditions existing at that time would, given the strong probability of choosing the wrong point in the life-cycle, be uneconomical and possibly a complete waste of time.

When we come presently to the consideration of our own set of explanatory variables, therefore, we do so in the realization that

this analysis was not our main effort but that it necessarily consti-
tuted only a secondary objective for the time being. We regard our
data as precursory and suggestive for the main investigation of causes.
We do hope to obtain guidance for the future from these data and to be
able to outline what some of the explanatory variables of high merit
might be. We did become aware in the course of our research of a
number of major causal circumstances of the development in childhood
of images of political authority. We will thus indicate in brief
outline an overall strategy of explanation which at this stage we
would deem appropriate; and we will relate to it our own explanatory
data as we present them subsequently.

As we emphasized in the early chapters, political socialization
is a long-term process of change of political attitudes and behaviors.
It is probable that a complex set of forces act to induce these changes.
General cultural conditions, structural properties of the system, the
available means of political communication, system-level changes in
the phenomena of politics, certain patterns of individual and social
attributes that exist at a given time, and many other influences may
help to account for changes in what a given set of new members of the
system think and feel about politics and in the initial output of dif-
fuse support. But these various determinants need to be specified
more discretely and operationally.[2] Let us discuss them in what we
would guess to be their approximate order of importance.

Developmental change

Grade (or its close correlate, age), as we have used it, repre-
sents an essential causal nexus and summary independent variable.
Grade serves as the surrogate for several maturational forces. From
one point of view the variable is the rough analogue of level of edu-
cational attainment used so widely in studies of adult political be-
havior. It provides a convenient, if implicit, summary of the many
influences of formal education upon the child -- teachers, curriculum,
textbooks, school activities, the social, cultural, and economic milieu
of the school and the like. But in our study grade in school is con-
ceived more broadly in its meaning -- going beyond the formal and in-
formal contributions of the educational system. Grade contains var-
iance, that is, from a specified number of years of non-school ex-
periences. The fifth-grade child is normally in his sixth year of
exposure to the educational system but in his eleventh year of direct
family influence and probably in his ninth year of heavy exposure to
television. Thus, in temporal priority and frequency of exposure,
the school is merely a third force reflected in year-to-year changes
of political orientation. In addition, by the middle years of ele-
mentary school, a child's peers are probably beginning to mark his
thinking about the social world.[3]

The child also becomes cognizant of where he and others stand
in various social hierarchies, defined by race, social class, religion,
sex, and national origion or otherwise. He must learn, therefore, to

respond to a number of different roles; son or daughter, sibling, pupil, economically well-off or not, male or female, playmate, and so forth. Through any of these roles, the child may increasingly begin to relate himself to the wider political system. As he gains such consciousness through these several means, changes which take place will reflect his location on the educational and age-level hierarchies.

Grade in school carries a significant dosage of intellectual development, moreover. This should perhaps be emphasized. In a rough way, society represents the standardized intellectual development scores of young individuals by their placement at various school grade levels. Thus, when we refer to grade level changes in perceptions we are in part referring (implicitly) to the child's arrival at various levels of intellectual maturity. His increasing capacity to understand subtleties such as the political system is no doubt reflected in his answers -- as a result either of the overt actions of the educational system or of other agencies that enhance his intellect.

Of possible special consequences as well is the grade-related introduction of specifically political or "civic" education in the schools. One way of interpreting grade-level changes is to connect them to the child's early introduction in the schools to the concepts of American citizenship -- in beginning social studies, history or civics instruction. There is at least a prima facie case for asserting a connection of such school inputs to the political awareness that we observe. In fact, if there is to be such a connection it almost has to be found in the pre-high school years for the kinds of children included in our test group, given the recently found general lack of correlation of basic attitudes with efforts in civic education at the high school level.[4]

Grade as an independent variable therefore suggests a number of more specific, underlying conditions affecting political socialization. It includes not only the general program of the school in promoting social learning and the more directly political aspects of school education, but also more general factors of increasing intellectual maturity and the contributions of family, mass media, and peers. Grade represents, therefore, some "linear transformation" of a number of influences that accumulate from year to year as the individual and society attempt to adjust the individual's responses to the political and other social realms of behavior. Grade takes us a certain distance in the direction we want to go; but its main use in explanation is to suggest a number of influences that lie behind it. It is to the latter that we need to turn.

Before doing so, however, one final point should be made about age and grade. Looking for the moment at political socialization from the standpoint of its uses in explaining system-level phenomena (rather than as something in need of explanation) we can point to some further hypotheses. The major utilization of grade or age is in connection with the familiar hypothesis that what is learned earliest is most

fundamental to further behavior and will have most lasting effects --
particularly in moments of crisis in later life in which the likelihood
that a person will regress to his most basic beliefs is high.[5]

Part of this effect is no doubt connected to the special psycholo-
gical circumstances of early learning. The child learns from those who
protect him from the hazards of the world and whose authority he is most
apt to accept without question. Thus, in an atmosphere of warmth and
protection, the young child is susceptible to appeals for his allegiance
that enter his consciousness through the auspices of those people
closest to him.[6]

The main thrust of our analysis has been to present a more pre-
cise description of the nature of changes in the child's images of poli-
tical authority and to relate these to system level processes. But we
have attempted also to draw certain inferences about patterns of ex-
posure reflected in grade related changes that we observe, particularly
for the profound system consequences of early exposure to political
structures (and norms as well.) There is much more to be said about
what age trends represent in the way of causal circumstances than we
have adumbrated. To some extent we are able to pursue these further pos-
sibilities below as we consider some explanatory variables such as I.Q.,
sub-group memberships of the child, and other variables. We will at-
tempt, that is, to drive the analysis back to these underlying and in-
tervening variables. To say that political attitudes are deep-seated
when formed early, and that they are in fact formed early, although
essential to the tasks we have set ourselves, is nevertheless only
a first step in causal exposition. Let us turn, then, to some other
possibilities.

Political structure

In addition to employing age-related developmental factors as
explanations, we have also used at a number of points explanations
related to the nature of the political structure. We proposed that
certain key features of political authority play an important role
in the way the young child becomes acquainted with the system and
simultaneously begins to acquire orientations of a supportive kind.
We have spoken at some length of the "head-and-tail" effects in the
early personalization of political authority and about the way in which
the robust image of benevolence begins to fade as the child matures.
The psychological cementing functions of these personal images corres-
pondingly decline in importance. Part of what one can say about long-
term change of political orientations is found in certain distinctive
features of the political system which provide the opportunity for
early political learning -- in this case to representatives of authori-
ty who uniquely combine simplicity, personal palpability, visibility,
and salience.

The availability of such tangible, cathectable incarnations of
political authority as the policeman and President in the United States

allows the child to be introduced to the system at a very early age
-- with greatest potential long-term impact. In systems where objects
in the structure of authority are less capable of losing their abstract
character -- where they are less amenable to being personalized, made
highly visible and salient, or where the collectivity of authorities
cannot readily be typified by a few strategic individuals or types of
roles -- we would expect the child to establish contact with the sys-
tem less readily, more clumsily and abstractly, and probably at a later,
less impressionable age. It would be interesting, for example, to
test our generalizations through cross-cultural research in such col-
legial regimes as Uruguay or in other systems which lacks one or another
of these properties that we have hypothesized as important to the manner
in which the young child becomes attached to the system, if he does.

The trappings and symbolization of those aspects of the structure
of authority that serve as contact points, moreover, may be very im-
portant later on in establishing the terms of legitimacy. For example,
if the chief figure of authority -- say, the king or premier -- is
always seen by the child in military uniform, then incursions by the
military into civilian politics may subsequently be less readily re-
sisted than in those systems where political authorities usually appear
in civilian dress. The mantle of authority is also likely to have
consequences for what is learned and its subsequent political meaning,
therefore, in the same way that the political figure or object that
serves to focus socialization may have an effect upon this child's
growing awareness and thus upon his later interpretation of what is
legitimate authority.

In a system where the chief authorities appear to the child
clothed in military attire, military force may be more readily accepted
at an early age as a legitimate instrument of political authority.
Rule of law, which limits military intervention in politics, or civi-
lian elections, political parties and other devices may become less
firmly based if the main myths and symbols of the system unite war-
rior and ruler. In the American system, where civilian rule at the
"head" and the means of violence at the "tail" are separate and yet
both apparent to the child, the possibility of the pre-eminence of
violence is limited -- especially in that the contact point for legi-
timate violence has generally been the police rather than the military.
The police are interpreted as enforcers of the law while themselves
subject to it. The new experiences during the urban riots of the 1960's
in which the military were involved may, of course, have new and differ-
ent socializing consequences.

Now these are all structural interpretations along the lines that
our analysis has suggested. Much needs to be done in such terms in
distinguishing different types of early contact points and their pos-
sible results. It may make a considerable political difference which
points of contact are most readily available and presentable -- both
for the symbolization of authority and for the ease with which the
child becomes assimilated to the system at an early age -- which in
turn has consequences for the deep-seatedness of support for a given

set of authorities. Our analysis just begins to scratch the surface
of the possibilities that exist for this level of analysis as a stra-
tegy of explanation. But, however little we have done with it, we
would think it a most strategic one in future research.

Learning processes

Whatever are the benchmarks of political understanding to which
the child is drawn, there must be certain processes in which he parti-
cipates in order to find these points of reference. He does not come
to them and extend diffuse support to them simply because they exist.
Rather, the child engages in specific activities and interacts with
ot..ers in such a way that he learns who the authorities are and what
they are like. Thus part of the variance we need to bring into our
explanatory equation is described by the nature of these activities
and interactions.

From one point of view, age itself -- as aging -- is a process.
In this sense our grade-level comparisons are indexes of a process
of political learning. But grade trends do not measure the processes
which underlie them. They only measure the effects of such processes.
We must turn, therefore, to the underlying interactions themselves
for true process explanation.

To discuss the latter it is perhaps helpful to divide them into
two broad categories. First we have the processes of political com-
munication or education that go on between the socializers and the
socializee. Certain cues are passed from the agent of political learn-
ing to the young new member within a situational context which denotes
the general relationships they share and the resources of communica-
tion and reinforcement (or resistance) available to each. A short-
hand way of describing these processes is to refer to the effects of
the agencies or agents of political socialization -- parents, family,
teachers, schools, peers and the like -- upon the person being sociali-
zed. The standard method of showing such effects is through the degree
of correspondence between socializer and socializee -- as with per-
centage agreements or correlations. But to account fully for the
similarities and differences we would need to probe into the nature
of the interactions themselves. We would have to understand the type
of child-rearing practices employed, the frequency, warmth and power
of interactions between child and parent or other socializing agent,
the competition among socializers, and the order of exposure to var-
ious socializing influences.

The second major class of process phenomena in need of explana-
tion concerns the changes that take place within the individual as he
receives the stimuli of political communication and adapts his orienta-
tions accordingly. Here the processes may be described by the individual's
growing capacities of assimilation, his changing needs for certain kinds
of information, his building of expectations and values to orient him-
self in a heterogeneous and changing environment, and his psychological

reactions to the bearers of stimuli. Our own data shed little light on such processes of internal adaptation, although in one sense, I.Q. serves as a measure of the capacity to respond to new political information and thus is an indicator of relevance here. We shall deal with I.Q. in Chapter XVII.

No one has really probed deeply into these processes in a political context, so that it is especially difficult to know precisely what explanations would look like at this level. A number of existing models might be adopted, however, as analogues for the description of internal political cue processing: for example, Piaget's stages of intellectual development and the attitudinal maturation processes that he postulates,[7] balance or dissonance theory of attitude change,[8] Freudian concepts of identification,[9] imitation, imprinting, role-learning theory, or a variety of other possibilities.[10] To the present, these applications to the <u>internalization</u> aspect of political socialization are essentially unexplored. At some point the explanatory potentialities of internalization (or rejection) or political orientations and behaviors will need to be investigated. As perhaps the most difficult feature of the total problem, it has seemingly been left for last. Our data, on this dimension, are virtually non-existent.

We detect, therefore, two major parts of the explanation of political socialization through its processes. One relies upon the context and content of interactions between the individual and his social environment from the standpoint of who interacts with him, under what psychological conditions, with what kinds of messages, and with which types of reinforcement resources.

The other process category contains the internal processes of adaptation: how the person responds to the stimuli thus presented to him -- understanding them, being converted by them, resisting them, adapting them, and the like. Our own data tell us relatively little of what we need to know about these two aspects of political socialization. Yet we are not totally without suggestive evidence; and these will be presented shortly.

Generational influences.

Another explanatory strategy thus far little pursued in research on political socialization is to consider the effects of generational phenomena. There are a number of ways to define a 'generation', but the one we have used, in Chapter XIV, emphasizes common experiences of a set of people who mature and live through the same historical era, and whose behavior reflects the impact of these experiences. Normally, the common experiences that a generation shares and that separate it from other generations result from broad changes in society and its institutions, or dominant problems of the system in a given epoch, as reflected in the way we speak of the "Depression generation", the "World War II generation", the "silent generation" (of college students who were educated prior to the student activism and protest of the 1960's),

and the like. In one sense, generational variables reflect the in-
dividual's interaction with the society at large rather than forces
of change within himself or the processes of interaction with people
in his immediate social environment. It becomes important, therefore,
to distinguish between generational factors and those associated with
aging (social and biological) and those which concern experiences in
such face-to-face groups as family or classroom.

A case in which these types of variables impinge upon the child's
political consciousness so that they are difficult to untangle is in
"teen-age rebellion",[11] or less pejoratively, teen-age differentiation
from adults. As the child loosens his bonds with his family as part
of growing up, he shows aging or developmental effects. Family ties
are loosened as a function of maturing physically, socially, and in-
tellectually. At the same time, it is not simple capacity to be in-
dependent that is involved. There are a number of frictions that the
child experiences with his family simply because he begins to look
elsewhere for cues and values -- especially to his peers. Thus a new
pattern of interaction with his own family develops that becomes mani-
fested in various forms of "rebellion" or differentiation: an opposing
style of dress, manners, morality, and even politics in some cases.[12]
In addition, however, there is the generational effect of growing up
in a period where a rather different set of values, problems and con-
cerns are at the center of attention from those during his parents'
period of development. As a result, response patterns of people from
the two generations will differ.

Our data, confined as they are to a single point in time and
covering a restricted number of years (relative to the 20-25 years
usually thought necessary to the idea of the generation), are simply
not very helpful in ferreting out the effects of generations. Indeed
we have, for all practical purposes, controlled for the effects of
generations in our study. This does not relieve us from the responsi-
bility of suggesting that a special cast to political learning may be
given, even in these early years, by system-level social change.

Social structure

Were our explanatory matrix not complicated enough already, there
is one further general category of variables that we would want to in-
clude for studies of political socialization within a given system.[13]
This class of variables concerns the effects of the individual's member-
ship in various sub-units and categories of society. The explanatory
value of such categorization of individuals lies mainly in the differen-
tiating effects of social memberships -- such as sex, social class,
religious affiliation, or geographical position.

Greatest attention of past research has been placed upon sex and
social class. General findings have been that the young member of the
political system is affected at least marginally in his pattern of
political learning by his social locations of these two kinds.[14] We
will give special attention to them below because sub-group differentia-
tion by sex or social status may portend considerable political impact

in future years. More generally, we could hypothesize that subgroups that maintain or represent significant sub-cultural variations, such as the classes or regions in the United States, are the ones most likely to impress their differences in childhood. Those like sex differences -- which may be becoming increasingly marginal in political salience in this country -- should show less marked differentiation. Sex, like grade in school, is a summary variable, however, so that whatever differences are found between males and females may suggest not only certain cultural patterns but also somewhat different psychological conditions of the two sexes which bear upon a few realms of political behavior -- such as regard for political authorities.

A number of differentiating effects might be postulated about social structural variables. Differences that we might expect between the social classes, for example, could include:

(a) A difference in perception that appears fairly early and is constant throughout childhood -- suggesting that the child is quickly brought to an awareness akin to the people of his social milieu; and this difference then persists into later life.

(b) A lead-lag effect wherein all children move, over the grades, toward certain common orientations; but those of higher social standing move more rapidly. Assuming that the period of learning is long enough, the lower status child may catch up eventually; and the social differences in political images will be erased.

(c) An increasingly divergent perception which starts early and becomes continually reinforced in the disparate social experiences of the classes, as their new members mature.

Any one of these three models of age-related class differences may have political consequences. The first pattern suggests that a distinctive pattern of behavior is set for each stratum in the earliest years. This is, in a sense, the "medium impact" case. The second pattern of development may result in a more ambiguous adult response. The classes will see things in roughly the same way, with two exceptions.:

(a) The higher status child will have learned his lessons earlier, and thus such lessons may well have taken root more firmly.

(b) If the lag for the lower status child postpones some political learning beyond the most plastic periods of childhood, many political orientations may be less likely to strike deep roots.

305

These sorts of effects may apply to other categories also like
geographical area. One of the strategies of the present project has
been to investigage such differences from the standpoint of constant,
increasing or decreasing differences among sex, social class, and geo-
graphical categories over the grades. We undertake these analyses in
the next chapter. There we shall describe some of the differences
for several areas of political content within the general realm of
supportive response to political authority. As we will pursue this range
of questions in detail later on, we need not describe it further here.

In sum, we propose that several key levels of explanation are
called for in the investigation of childhood political socialization.
We have become increasingly aware of these possibilities in the course
of our research. At this juncture, given our research purposes in
more accurately describing the nature and course of childhood support
for political authorities, we are not able to give a fully satisfactory
account of these possibilities. Our purposes were exploratory and we
were not fully aware of what causal data to collect when we began.
Nonetheless, we have offered certain explanations already -- particu-
larly those related to maturational factors and what they portend, and
some of the political structural determinants of the child's response
that we find. In addition, we shall be able to say something about
the effects of sub-group memberships. We are least able to deal with
process and generational influences except in a generally speculative
way. Our data do not readily lend themselves to clear connections
between patterns of political learning and the internal processes of
assimilation by individuals. Neither can they really be used to assess
the relative contributions of family, school, peers, or media -- where
we have some data they are usually very unreliable and highly tentative
-- nor, indeed, to say much about the effects of the communication
patterns that obtain in these social interaction processes. We are
weakest of all in trying to indicate what generational forces are at
work; cur data in effect cancel such causes from the analysis.

Thus, not having especially high hopes for our treatment of de-
terminants, we are not apt to be disappointed when we are unable to
give good explanations of these phenomena. Our work has been carried
on at too early a stage for such hopes to be realistic. Yet we do have
some limited explanatory power in our data.

We turn then to our data. We shall proceed in two stages.
The first part (Chapter XVI) considers a few key sub-group differentia-
tions about several of our central developmental hypotheses. There
will be special emphasis also upon the more cognitive aspects of the
child's images, particularly about government as a focus of political
authority. In the second section (Chapter XVII), analysis will move to
the policeman and President, with special attention to the affective
response of the child. In addition, a broader range of independent
variables will be considered simultaneously than was feasible for the
less easily indexed government items.

Chapter XVI

PREDICTORS OF COGNITIVE RESPONSES TO POLITICAL AUTHORITIES

Childhood is a period of intense political socialization. The processes through which the child acquires his political orientations may be described as personalization, institutionalization (later in childhood) politicization, and idealization. These concepts briefly if perhaps inadequately sum up much of what we have already learned about the socializing processes.

The child reaches out to the political system through the structure of authority and at the beginning find palpable human objects such as the President, the policeman, and Government interpreted in a personal way. His contact points have been personalized. Simultaneously most children quickly become sufficiently politicized to distinguish between the internal authority of the family and the external superior authority of society as represented in these personalized political figures. The older the child grows, in our test group, the more likely is he to extend his perceptions so that they embrace other figures and institutions such as the Supreme Court. At this stage personalization tends to give way to or joins what we may call institutionalization of political authority. The child now possesses the emotional and perceptual equipment not only to take cognizance of the existence of impersonal institutions (such as the Supreme Court or Government now interpreted as Congress or voting) but he is also able to acquire and express decided sentiments about this impersonal institutional authority. The idealized image he initially developed for the personal figures he is now able to extend, in more moderate but nonetheless still relatively high measure, to these impersonal political objects. Although regard for all authority does decline with age, it never falls to a very low point, on the average. In this esteem, we have concluded lies the potential source of support for that part of the regime we have designated as the structure of political authority.

The processes through which a child is socialized to this structure in the United States need not, however, be uniform in nature. We would not anticipate that all children in our group need perceive the representatives of political authority in the same way or that they need extend the same measure of warmth to the authorities. Nor need politicization proceed at the same pace for all. It would be too much to expect that all children, regardless of social category, such as sex, social class, or region, and regardless of subjective characteristics such as intelligence or personality, would move in a solid phalanx and at the same rate in the average direction of the aggregate of our test group.

308

In the last chapter we suggested that major group differences might be anticipated. In this chapter we shall treat with the cognitive side of authority and in the next with variations relevant for the affective aspect. In both instances we shall see differences emerging but we shall find them to occur much less frequently than we might have predicted. In describing these differences we shall also be led to some understanding of why they should appear. In addition we shall be able to explore some of their potential consequences for the political system.

Variations in the Images of Authority

With respect to the age-related cognitive and attitudinal changes that we have observed, we shall find that cues flowing to the child pass through several filters, any one of which could conceivably have lasting effects upon the orientations acquired. The filtering influences upon which we shall focus here can be classified either as aspects of the social environment of the child or as factors pertaining to his internal capacities and resources. In acquiring his new role towards the external political authorities, the child is likely to do so within certain differentiating social contexts -- especially sex, social class, geographically-based subcultures, ethnicity, family, race, religion, and party identification. In addition, he is apt to be affected by his ability to receive and assimilate relevant messages -- in particular as a function of his personality and general intellectual development. Either of these sets of factors will serve to screen political communications.

As can be seen from this simple listing, incomplete as it is, the number of overlapping filters is considerable, and we shall encounter additional ones in the next chapter. The effect on the socializing "messages" that get through to the child is enormously complex and we can hope only to begin to shed a little light on a few of the screens. In this chapter we shall concentrate on the impact of such basic social categories as sex, social status and geo-cultural region and, as we have indicated, only in relation to cognitive components of the child's image. In the next chapter we shall add a few more possible independent or explanatory variables but relate them to affective components.

Empirically it will appear that our data have led us to identify two main screening potentialities among groups of the children differentiated by these social and subjective criteria: "lead-lag" differences in patterns of political socialization and persisting substantive variations in the kinds of images children of various subgroups acquire. The first outcome suggests either earlier or later learning, but perhaps eventual similarity among all children. The second suggests an ingrained difference that may be continually reinforced into adulthood. Each could be expected to have important consequences for the input to the structure of authority.

The other major political effect of early social or ability dif-
ferentiation would be upon the kinds of images and commitments the in-
dividual forms by which his later behavior may be regulated. The young
male may become more attuned to the abstract or impersonal properties
of political authority early in life, whereas the young female may con-
tinue longer to personalize and thus to restrict her image. In this
side of early differentiation, the significant political effect concerns
early reinforcement of the terms or content of orientations that allow
each person to see the political world in a way that is dissimilar to
those who belong to the counterpart social and ability groupings.

Both from the standpoint of the substantive terms of the response
and its intensity or deep-rootedness, therefore, such early differen-
tiation may be of considerable explanatory interest for the input of
support. Let us then turn to an investigation of possible differences
in social location. We shall return to those substantive areas in the
socialization of the children about political authority already explored
for the aggregate as a whole. We shall seek to discover those differences
in the processes and outcomes of socialization about political authority
that can be accounted for by the factors already mentioned, keeping in
mind both the "lead-lag intensity" hypothesis and the "reinforcement of
substantive differentiation" hypothesis.

Sex Differences in Political Socialization

One of the social structural variables of continuing interest to
students of political socialization and to students of politics more
generally has been that of sex. Scholars in this century have investi-
gated the origins, nature, and consequences of political differentiation
between men and women. With the extension of suffrage to women in the
Western democracies, a number of important issues concerning sex-typing
and variation in political behavior have been raised for public discus-
sion and scholarly inquiry. In particular, attention has centered upon
possible differences in electoral behavior of women. The rates of
female participation have been found to be significantly lower than
for men; and the direction of female voting has somewhat less clearly
been found to be more conservative.[1]

The electoral consequences of sex differences, for what we have
called allocative processes,[2] have been a major stimulus ingenerating
interest in the circumstances of political socialization. Beginning
at least with Hyman's inventory of early evidential sources, there has
been considerable emphasis upon the possibility of variation in politi-
cal behavior stretching back into childhood. Hyman concludes at one
point, after viewing the existing data: "Thus already at early ages,
boys are directed toward politics and here lie the seeds of the adult
differentiations everywhere found in studies of political participa-
tion."[3] The ego-ideals of boys are more likely than for girls to be
public figures.[4] Boys are apt to be better informed politically, more
interested in public affairs, and more attuned to the politically rele-
vant aspects of the news media and other communication.[5] All of these

310

differences have a fairly direct connection to electoral phenomena and
to the theories of electoral behavior. The areas of attitudinal and
conceptual content which were thought worthy of investigation about
early sex differences in political learning are those most intimately
associated with subsequent behavior as voters — political interest,
information, attentiveness to political communication, participation
levels and the like.

Our own theoretical focus upon system persistence and the growth
of support for political authorities suggests, however, that we need
to expand what is known about childhood political sex differentiation
to other content areas. We are concerned with such differences not
so much for their explanatory power about possible effects upon elec-
tion outcomes and thus upon the nature of political leadership and
policy. Neither are we concerned with such differences for what they
show about the continuity of the wider cultural sex-typing of politi-
cal role-behavior. It is not our main purpose, that is, to show how
sex differences in political learning are still in progress — as a
way of suggesting that the mores of an earlier era are still very much
alive today. (The latter is no doubt relevant to our inquiry, as a
partial explanation for why such sex differences occur, if they do.)
Nor are we primarily interested in the effects upon the individual and
upon his relationship to others that occur because of the political
manifestations of his sex roles. (Such psychological factors serve
more as an explanation of what we are likely to find than as a theoreti-
cal rationale for our looking for sex differences.) We are not totally
oblivious to the consequences for the individual of his or her being
brought up to expect to play a greater or lesser role in politics.
Nonetheless, our main effort is directed toward understanding what
possible consequences sex differences might have not for allocative
politics but for system politics, especially for the nature of the
child's early response to political authority. Sex enters the analysis
for us only as it affects the relative depth of commitment or the type
of response that is made. When we turn to the data, we shall have this
in mind.

One of the general features of our data — not simply the portion
we analyze in this book — is that relatively small but pervasive sex
differences appear throughout. Boys are generally a bit ahead in the di-
rection of aggregate development. A few of these differences in the
area of political authority are more striking than others, and our em-
phasis in this section will be upon discussing these. We shall proceed
in our discussion of sex differences by selecting from the earlier chap-
ters several of our most important hypotheses in the cognitive realm and
then looking at the kinds of differences that we find for boys and girls
on the items that pertain to these hypotheses. In particular, we shall
focus upon the following hypotheses:

(1) Politicization: The child becomes increasingly politicized
in these years as revealed in his recognition of government
and the public sphere (which becomes separated conceptually
from the private realm). Also as part of his politicization

311

the child distinguishes between public and private authorities and gives much greater weight at least initially to the public ones.

(2) Personalization versus institutionalization: The cognitive image of Government moves from a dominance of personalization to a greater stress upon its institutional aspects.

Given the number of hypotheses that could be brought forth again for consideration in this context (as listed in Chapter XV), the above constitute only a minimal set of key points for illuminating sex differences or similarities. But it is our belief that they serve reasonably well to accomplish our purposes. Let us take each in turn using some key items as indicators of our findings. We will subsequently follow the same procedure for testing for differences among social status groups and cities.

Sex Differences in Cognitive Responses

Politicization

One challenge for the child in coming to grips with the world of political authority is his ability to differentiate the realm of political authority from other aspects of society. Thereby he begins the important process of becoming politicized. In part, this involves attaining some understanding of the concept government as a distinguishable object; in part, it involves recognizing the difference between that which is governmental and that which is not.

Confidence in understanding the idea of government: Let us look first at how readily boys and girls comprehend the idea of government. Table XVI.1. provides relevant information about sex differences in understanding the concept of government.

As we observe, there are more girls than boys who say that they are uncertain about what government means at every age. The difference is especially apparent for the youngest children, suggesting that differences in political sex-role typing are acquired as early as second grade. The young male has a higher probability of becoming politically sensitized from the beginning of the age span. Although, with the compressed variance that we find on this item by the later grades, there is a lessening of the political difference of the sexes over the age span, one might speculate that the young male, more likely to have been sensitized to government early, is then in a position to develop deeper and more lasting orientations of other kinds towards government.

The public and private sectors: Perhaps a more typical set of effects is shown in Table XVI.2 concerning the child's growing capacity to differentiate between the public and private sectors. On balance boys tend to lead and girls to lag in terms of the direction of aggregate development. The most striking difference occurs in the Postman

312

Table XVI.1. Sex Differences in Answering "Not Sure What Government Means"[a]

313

item where the difference over the grades is around 10 percent, or about a grade and a half on the average.

In identifying the public or private status of the milkman, police-man, and (at the younger ages) soldiers, boys are aggregatively somewhat ahead in the direction development is proceeding. This is true even on the Policeman question where the direction shifts in the middle grades. Yet, the boys do not dominate entirely in that girls lead on Judge and Teacher. In general, therefore, the sex differences we find are small, fairly consistent and suggest a slightly faster rate of politicization for boys.

Personalization versus institutional interpretation of government

Image of government: We find a somewhat similar mixed pattern on our question about the two best pictures of our government. A few con-sistent differences appear with boys generally ahead in the aggregate developmental direction. Such differences are presented in Table XVI.3.

The most notable difference in Table XVI 3. is the special but perhaps significant and increasing divergence between girls and boys on the salience of the President as a symbolic representation of Govern-ment. Whereas there is virtually no difference of this kind at grade 2, by grade 8 roughly three times as many girls as boys still pick the President. In this sense, girls remain political "primitives" (relative to the direction of aggregate development) on the average two or more years longer than do boys, if we can project from our figures. Indeed, such a tendency for personalization of authority persists into adolescence (age 13-14) for a significant proportion of females, whereas for males the tendency has declined considerably.

Correspondingly, if not as sharply, boys more often pick Congress as the best representation of government, indicating a greater impetus towards a more impersonal, institutional interpretation. This is not to say that females are always the greatest personalizers (see Uncle Sam) nor is it to assert that other types of institutionalization may not draw equally well from both sexes (see Voting). Yet girls are most distinctive on the President option. The latter suggests a slower rate at shich the female child typically enters into the aggregate conscious-ness of the realm of political authority and incorporates its more ab-stract attributes.

For the recognition of basic functions of government, we might usefully consider two further examples of the greater attraction to young females of the President as a participant in political authority. These are shown in Tables XVI.4. and XVI.5.

On the chief law-maker item, the President is chosen by a larger proportion of girls than of boys at every grade. In the later grades on the item, "Who does the most to run the country?", a similar effect ob-tains. Thus in the instances where a difference is found, the President is more prominent for girls than for boys.

[a]CA-9, page 9, item 41.

Salience; The finding just stated leads naturally to a further
question. How do boys and girls compare on questions that tap the rela-
tive salience of various individual authorities more directly? An item
that we have used for this purpose puts this question: "Who helps you
and your family the most?" The options provided are: policeman, sol-
dier, father, teacher and President.

From Table XVI.6 we see that the President again draws dispropor-
tionately from the female respondents for his support. As on the earlier
questions, he is an especially salient figure of authority for females.
In this respect our earlier hypothesis about the child's early differen-
tiation of family from political authority needs a slight modification
to take account of the greater tendency of girls to prefer the President
as an authority figure.

Summary

The sex differences that we find are small, and, as can be seen
from the above analysis, they do not present a simple pattern. A few
are striking such as the greater response of girls to the President.
This may presage a greater personalized interpretation of authority in
future years. Most, however, are differences too small to be of great
consequences for the operation of the system.

The differentiation thus seen may be suggestive however of possible
marginal effects, particularly in that the politicization of boys starts
on the average a little earlier; thus the political realm is apt ot be-
come a more rooted part of the young male's conceptual and attitudinal
framework. In this we certainly would expect a continuation of the
differentiation already observed in adult political behavior. But such
minor differences may reflect as much a long-term lessening of politico-
cultural differentiation as its continuation. That is to say, sex-
typing is less of a characteristic transmitted from adults to children
than we might have expected, at least for the area of system politics.
A difference is still present; but our data do not show it as likely
to be more than a minor factor in determining the future level of the
child's supportive bonds to political authority.

Socio-Economic Status Differences in Cognitive Responses

Like sex, social class or socio-economic status (SES) has long
occupied a prominent place in political analysis. Students of politi-
cal socialization have reflected this concern in attempting to describe
the differences that appear in childhood and adolescence. Just as for
sex, one of the major sources for stimulating an interest in SES differ-
ences has been the studies of adult voting.[6] This has led perhaps to an
overconcentration upon areas of political learning most related to voting,
particularly upon rate of participation and direction of partisanship.
These and other differences including varying levels of political in-
formation have been widely noted.[7] Let us consider whether SES differences

[a] CA-9, page 13, item 58: "Who helps you and your family the most? Put an X by the two who help you and your family the most." Percentages do not add to 200% because not all children gave two responses; every child did respond at least once.

320

appear in this early period in relation to the systems hypotheses already discussed about sex.

Politicization

Confidence in understanding the idea of government: If we use the same items again as the occasion for testing SES differences in early cognitive response to political authority, then we find a somewhat analogous situation to that for sex differences. There are a number of consistent social status differences—again, not especially large or completely consistent. Table XVI.7. presents one of the cases of clear and persistent status differences.

Those not certain about what government means constitute 31% of the lower status second graders but only 25% of the upper status second graders. These proportions decline to 13% by grade 8 for the lower status children and to 5% for the upper status group. Thus a noteworthy difference of the lead-lag variety exists.

Public and private sectors: When we turn to the items about whether different roles are governmental or not, however, the patterns are less clear. As shown in Table XVI.8. the lower status child is slightly more apt to include the milkman among government workers but a little less likely to exclude the teacher. The most striking of these differences is on the milkman item, and the response pattern for it alone suggests a lead-lag progression. But the lead or lag is by no means uniform across all of these items.

Personalization institutionalization: A somewhat similar picture is obtained when we observe the social status differences shown in Table XVI.9 about the "two best pictures of our government." These data would indicate that there is some tendency for the lower status child to lag as far as the aggregate development is concerned. Such an effect is most prominent on the Voting and Congress options and is present to some extent on the President option. None of these options except Voting shows very marked differences however.

Voting - representative as it is of the child's tendency to depersonalize political authority - is probably of special interest in that the difference is not simply a lead-lag phenomenon but more nearly a matter of increasing differentiation with age, between the lower status children on the one hand and the middle and upper status children on the other. This difference is presented graphically in Figure XVI.1.

The shape of these curves might suggest that the capacity of the child to interpret government as popular participation is more likely

Table XVI.7. Socio-Economic Status Differences in Answering
"not sure what government means"[a]

FIGURE XVI.1.

Socio-Economic Status Differences in Choosing Voting
as One of the Two Best Pictures of Our Government

to be continually reinforced in the patterns of political communica-
tion of the more advantaged child. This would certainly complement
general findings on the relative levels of political participation
of adult members of different social classes.[8] It also corresponds
well to the Almond and Verba findings on differences in adult levels
of participant orientation among people of varying degrees of educa-
tional attainment[9], and with prior research on pre-adult political
socialization.[10]

That such a difference in the institutional interpretation of
government would appear so sharply in childhood would argue strongly
for special attention to this matter in future research. Our own
data are very limited on this question. Yet it is of special inter-
est that in this one case at least, there is an increase in substantive
differentiation. Were the social class context of politics in the
United States more potent, we might have expected a wide range of such
effects in the early reproduction of sub-cultures based on social
strata. As it is, we find this for a very limited type of orienta-
tions, albeit a most interesting and suggestive one.

On the Congress and President options, the finding is not so
clear as for Voting; but differences are present for SES, even though
they are minimal. This suggests that SES differences may have little
bearing upon the future inputs of support for the institutional aspects
of the system.

We obtain a clearer picture of the impact of status differences
when we turn to related items about who does most to "make the laws"
and to "run the country." In Table XVI.10, we find a marked lead-lag
effect for the Congress option. The lower status child becomes able to
relate meaningfully to the impersonal, more abstract objects of govern-
mental authority somewhat later than does the upper status child. In
this case the lead is from a half to more than a grade at every stage.

On Table XVI.11, a somewhat similar effect is presented. The
aggregate development is toward Congress and the upper status child
moves there on the average more quickly. The President or personalized
option might appear to adults to be more appropriate on this question,
but nonetheless the Congress choice becomes increasingly important.
In this movement, the lower status child tends to lag.

Thus, on all three of these items the rate of depersonalization
of government is slowest for the child whom we suspect would have
fewest resources in political communication. But again, these dif-
ferences are so slight, and the trends are so similar, that we would
not expect great differentiation in response to political authority
in adulthood based upon these early leads (or lags) in rate of develop-
ment. There is more of a blanketing effect that erases social status
differences in these terms than forces leading substantially to social
class based subcultures.

Saliency: We might consider one further instance of possible
SES differences in a related context, namely, relative salience among
various individual political or non-political authorities. In Table
XVI. 12, for the item "who helps you and your family the most?" we
do see here minor lead-lag effects, but once again none is very strong.
Thus, we are not apt to project any far-reaching consequences of social
status differences derived from early learning of this kind. This find-
ing is perhaps typical of the many SES differences that appear in our
data in that it is of relatively low magnitude if fairly consistent in
some instances.

Summary

Social status, like sex, shows several modest yet suggestive
differences in how children relate to political authorities. None
of them is so great that we are able to project fundamentally variant
perspectives by the social classes when these children reach maturity.
That we fail to find substantial differentiation in these terms—es-
pecially when borne out in our further analysis in the following chap-
ter—is significant in that it sets some very definite limits upon
how we would foresee the child's social status to affect his "system
political" behavior as an adult.

The effects are likely to be of such relative unimportance,
moreover, that we might usefully question some part of the discussion
that has gone on earlier giving special focus to social class differen-
ces in political socialization. The few effects that we have discovered
thus far suggest only a different rate of development rather than sub-
stantive differentiation in political interpretation among the various
social status groups.

The two caveats to this generalization that we would make how-
ever, are first that these findings pertain only to system politics—
and to that part of it having to do with politicization and personali-
zation. Secondly, we did find a case in which SES differences become
sharper with age (for Voting on the "two best pictures" item). From
either point of view we might project some lasting political conse-
quences. Yet, our overall conclusion would be that none of our sub-
stantial modification in the area of social status. In the next chap-
ter we will reconsider SES for the affective items, together with a
number of other important independent variables.

City Differences in Cognitive Responses

The third major subcultural variable that we have attempted to
give an account of in our research design is city or region. One large
and one medium-sized city in each region were included in order to test
an hypothesis concerning the possibility of a marked difference between
the two Southern and the six non-Southern cities (as well as among other
regions). Our findings include many moderate city differences, but none
fits our major hypothesis in any systematic fashion. We are generally

Table XVI.12. Socio-Economic Differences in Saliency of Authority Figures[a]

[a] CA-9, page 13, item 58.

impressed more by the similarities than by the differences among the cities. Indeed, over any fairly substantial number of items, the differences that do appear seem random.

Let us then take initially an approach opposite from our procedure to this point and look at our data from the standpoint of similarities rather than of differences. First, let us consider as representative, the "two best pictures of our government" item, as shown in Table XVI. 13.

Table XVI. 13.   Geographical Similarity in Development Patterns on "The Best Picture of Government" Item

Grade	Average Correlation Among Sets of Ranks (over the 8 cities)
2	.87
3	.87
4	.71
5	.91
6	.91
7	.91
8	.90

Geographical differences on this key item are not especially noteworthy. By ranking the ten options in each city and grade according to the proportions choosing each option and correlating the rankings, we find indeed high average correlations among sets of ranks. Thus there is substantial similarity among the cities. The magnitude of these correlations would suggest that this set of symbolic associations becomes sorted out in approximately the same way and at the same time in all of the eight cities of the study. Clearly the political subcultures of these metropolitan areas exhibit considerable uniformity.

To show this similarity (and the attendant random variations) more graphically, let us consider Figure XVI.2. which takes the proportion choosing Congress on this item at every grade in each city.

In grades 2-7 there is remarkable similarity in the proportions choosing Congress as one of the best pictures of government in all eight cities. Whatever sharper differentiation occurs does so only at grade 8. Our expectation of South-North differences is not upheld.

We should emphasize that this lack of systematic city difference is usual in our data. We shall have more to say in the next chapter about other possible city differences, but our general conclusion for this portion of our data is clear. The uniformities are again far more impressive than the variations. Indeed, the variations that we do find are essentially random. Thus, the child is likely to begin orientating himself to objects of political authority in about the same way and at

FIGURE XVI.2.
City Differences in Choosing Congress as One of the Two Best
Pictures of Our Government

roughly the same time in all of these eight American metropolitan areas.[11]

Conclusion

We have reviewed our major independent variables that concern subgroup or subcultural variations in patterns of early orientation to the political authorities. The analysis has been confined to what we regard as the most strategic of these differences. From these it is clear that on those social structural variables that we would have expected to yield greatest subcultural divergences--sex, social status, and region--we find only scattered instances of differentiated subgroups, at least in the cognitive orientations about phenomena in the general area of system politics.[14]

This is not to say that we have uncovered no noteworthy variations among subgroups. Indeed we believe that the purposes of political analysis in general and of future political socialization research in particular are best served if we can give more reliable estimates than had previously existed of how much differences these memberships make, in what contexts, and over what periods of development. It is not enough to say that the differences are very small. Our responsibilities go beyond, to show in which respects and to what degree such differences obtain.

We have found some systematic variations for sex and social status. City or region, on the other hand, reveals almost exclusively non-systematic differences. But one searches in vain for some underlying stable pattern of difference across the cities. The political meaning of such non-systematic differentiation may be considerable, for it foreshadows a generally supportive orientation in this realm of basic political orientations. Such similarity among areas may serve as an important source of support which countervalances the more divisive urges of regionalism in certain policy areas like race relations. The young child in North and South and in large and smaller city areas, comes to interpret the political authorities in much the same way as he grows up in the system.

Social status finds its political meaning in these data in the lead-lag phenomenon, wherein the upper status child is usually a step or two ahead of the less advantaged child in what he learns of government. This may mean, if earlier learning takes deeper root <u>ceteris paribus</u> that the upper status child will have a firmer cognitive base for future political behavior and thus he is able to begin putting in support at an earlier age. In addition, in one instance, a substantive difference in interpretation of government also makes its appearance in these years. Were the latter kind of effect more frequent in these data, we would postulate the maintenance in the next generation of a social class based subculture.

Sex differences, though small, are fairly consistent, particularly in the relative prominence of the President as a focus of political authority. We would think that a variety of possibilities could

333

follow from such a marked and increasing difference between girls and boys. One obvious implication would be that few males but a noteworthy block of females might continue to interpret the authorities in such a personalized way even as adults. One might suppose, therefore, that the female political temperament would in many cases be susceptible to charismatic (rather than, say, legal-rational) appeals for legitimacy by a given set of incumbent authorities or by a candidate for office. This certainly would be a factor affecting the persistence of a set of authorities and of a political order based more on one than on the other grounds of legitimacy. Furthermore, that boys also move more readily toward the group norms of aggregate choice on these items would suggest much the same kind of political effect as the lead-lag phenomenon associated with status differences.

All of these possibilities need further inquiry, both to verify the kinds of effects we have found in other contexts and to trace their consequences into adult political life. For the moment we shall have to be content only with an effort at further verification. To this we turn next in the next chapter.

11. A number of other variables might also be considered at this point— for example, I.Q., religion or perhaps political party identification. These and other will be considered in the next chapter as part of a multivariate analysis of predictors of basic affective orientations towards the policeman and President. We omit any analysis of them here for several reasons. First, the differences found are scattered and not very large in the area of basic orientations towards political authority. Second, other analyses of these same data cover many of the findings that we might present. Clues about the effectiveness of I.Q. as a predictor using some of our data can be found in an unpublished doctoral dissertation by E. White, _Intelligence and Political Behavior: A Case Study in Political Socialization_ (University of Chicago, 1966). In general, I.Q. shows approximately the same kinds of lead-lag effects as does SES, with which it overlaps in considerable part. In a doctoral dissertation still in progress, entitled _Title from Dept. Office_ (University of Chicago), D. Leatherman analyzes the effects of religious preferences and extent of religious attendance upon images of political authority as well as upon other orientations from our data. By adding comparable data from children in parochial schools, Leatherman finds that slight religious differences between Catholics and others apparent in our public school children become magnified. Catholics from parochial schools display more idealized images of authority than do the Catholic children in our test group.

    In addition, we have also analyzed but will also not report here the effects of race and of nationality (separating children whose parents were born in the U.S.). These data are, of course, very limited. Our non-white sample comprises only a handful of respondents (N=274). This is largely due to our having sampled exclusively in white public schools. Our "children of immigrants" sample constitutes only 5 percent of the total, moreover. Using these data, we find only a few, very small and non-systematic differences between such children and our white or native born children, respectively. Thus, uniformity of socialization in these terms is again the apparent pattern.

12. Had we used a broader range of subcultural variability in our sampling design — especially small-town children, Negro ghetto children, parochial children, or poverty class rural children — we might have seen much more divergence. Some work has been done on the last of these types of children in relation to the findings for the kinds of children we have studied. See D. Jaros, H. Hirsch and F.J. Fleron, Jr., The Malevolent Leader: Political Socialization in an American Sub-Culture,"

CHAPTER XVII

PREDICTORS OF AFFECTIVE RESPONSES TO POLITICAL AUTHORITIES

In our inquiry into some strategic potential sources of variability in the child's cognitive responses to political authorities (relevant for the processes of politicization and personalization in particular), we have found little systematic variation for sex, social status or region. We may justifiedly ask, however, whether in restricting our attention to these variables and to the hypotheses in Chapter XVI we have narrowed the range of possibilities too severely. We should perhaps consider the effects of these and other independent variables for at least our additional major hypothesis about idealization. In this chapter we shall broaden our inquiry in these ways.

Alternative Explanations of Idealization

One of our major findings has been that the younger the child the more likely is he to idealize authority; even the older child retains on the average a high level regard for most political persons and figures. Can we explain why this should be so from our data?

Numerous plausible reasons may be advanced and on some of these we are able to shed some light. In the first place, as we have already mentioned in Chapter VII, idealization may flow from the feelings of vulnerability we can expect children to have about their environment. Figures such as the policeman and the President could serve as objects of psychological compensation, if they are viewed as powerful and in a commanding position between the child and the unknown dangers of the world. Furthermore, seeing a person as powerful may induce the child, in an intuitive act of appeasement, to construe this person as also helpful, benign and likeable. Fear would seem to case a longer shadow than love.

To be sure, for some children there would be little if any sense of insecurity and thus little need to idealize personal figures of external authority. In addition there will be some children who will visualize these figures as weak, hostile or malevolent. The child's recognition of them would only add to his sense of potential deprivation.[1] In the main, however, we would think that some of the variance in how positively the President or policeman is perceived can be connected to the child's high state of dependence.

In the second place, the child's own favorable response to the political authorities may simply reflect a "rational" judgment on his part from what he knows about them, whatever the source of his knowledge. He may feel that if parents and other adults in his environment are "general positively disposed to these figures they must be worthy of high respect. His evaluation would be nothing more complex than an outcome of his own reality-resting about an area of existence that is in most instances remote from him.

There is a third possibility. If we adopt the normal assumption that adults tend to be critical of government in the United States and really do consider it a necessary evil—and in earlier chapters we have already shown our doubt about the validity of this premise—we might well wonder where the child might get his more benign image. We might speculate that however the agents of socialization may themselves feel about political authority, they would instinctively tend to shelter the child from exposure to unfavorable or disparaging comments. Whatever the child's experiences with the proximate authorities at the tail end of the system and whatever his understanding of the nature of the regime, he would be more likely to absorb positive attitudes directly from adults. It is upon them after all that he must mainly rely for an understanding of the broader world. They might consider it appropriate to instruct him only in the conventional ideals about political authority rather than about the grimmer realities known or suspected.

Finally, the child may approave so highly because he generalizes from his relationship with more familiar figures of authority, especially parents, to the external political authorities. In a Freudian vein, his first and basic orientations towards authority are molded within the family, particularly from experiences with his parents or their surrogates. As he learns about the presence of authority figures outside the family, it has seemed plausible to succeeding generations of students that the child would project his feelings about father authority onto these more remote figures. According to this projection or generalization hypothesis, we should therefore find some relationship between orientations to father and other not-too-dissimilar authorities.

Our own data do not allow us to assign empirical weights to every one of these several lines of explanation to help us explain why the child regards public authorities so favorably in the early school years. As we noted earlier, we have little reliable information in our project materials that bears upon the relative influence of various agents of socialization, for this and other areas of content. The theme we can deal with best perhaps is the generalization hypothesis wherein the child relates and expands his perceptions of proximate (parental) authorities to political ones. Our capacity to assess the hypothesis of "rational" inferences from the nature of prevalent adult sentiments about the regime or the vulnerability hypothesis, on the other hand, is much less direct. Thus, in what follows below, our main attention will be upon generalization as a mechanism of early political attitude formation.

Our operational measures of the attitudes generalized from father (if they are) depend upon the child's various ratings of the policeman and President and upon the same ratings for father. We will compare how the child rates his father and how he rates the two political figures. Our discussion will focus on why children do or do not see these authorities in a highly positive spirit, especially to the extent to which we can gain some insight into the plausibility of the generalization hypothesis.

Furthermore, we shall include in the analysis as independent variables a number of other modifying influences both of the social structure variety discussed in the last chapter—grade, sex, socio-economic status and city—as well as others that have seemed more relevant to the

338

idealization variable: I.Q., religious preference and extent of atten-
dance at religious services, membership and officership in school and
non-school clubs or teams, political party preference, the child's assess-
ment of which parent is more nearly "the boss" in his family, as well as
the child's ratings of his father on the same attributes used for the
political authorities.[2] In part this latter group of independent vari-
ables may help to identify group differences in the way children evaluate
President and policeman. In part they may offer explanations of these
differences that compete with the generalization hypothesis.

Indices of "Power" and "Affect"

In order to relate all of these independent variables to
idealization in a reasonably parsimonious manner, we first reduced the
child's variety of perceptions of political authorities to a few basic
indices. In this way we could represent the core of the affective aspects
of the child's image. This permitted us to guess the influence of each
independent variable, even though in such an analysis we would have to
leave out of account other meaningful aspects of the child's orientations.
We hypothesized, based on earlier factor analyses of our pretest data,
that in this early period at least two dimensions would become stabi-
lized for each authority, one a purely affective response (or simple
liking) and the other an evaluation of the performance attributes of each
authority, especially in relation to his power, leadership, knowledge and
the like. It will be recalled that we have interpreted assessments of
these culturally approved qualities also as reflective of affective orien-
tations, that is, of respect for authority.

The procedure we used to divide indexes was as follows. We
selected the child's ratings of the policeman and the President as most
representative of his early response to political authority. We realize,
of course, that other contact points would be worthy of consideration
in any subsequent analysis. We then intercorrelated the ratings at each
grade 4-8 for each figure--policeman, President, and father. We included
the father ratings so that we could use them later as an indexed indepen-
dent variable. We proceeded next to factor analyse the matrices of
intercorrelations among the ratings for each of the three authorities at
each grade, giving a total of fifteen separate factor analyses.[3] This
series of computations permitted us to describe as simply as possible the
basic attitudinal dimensions that our questions evoked for each of the
three figures of authority at each grade. We were then able--given that
a reasonable degree of stability of these solutions existed across the
grades--to score each child on each attitudinal dimension for the three
authority figures. With such scores, analysis of the relationship between
the child's basic images of the policeman and President and a variety of
independent variables became possible, including in the analysis the simi-
larly derived scores of the child's image of his father.

In Tables XVII.1, XVII.2 and XVII.3 we present an abbreviated
summary of the fifteen factor analyses of the child's ratings of each figure
of authority at each grade. The tables present the factor loadings of the
rotated factor matrices at each grade.

342

In general, these summaries show two highly stable general orientations that appear for each figure at every grade. These we call simply "affect" and "power".

The "affect" dimension is best defined by the two ratings "I like him" and "He is one of my favorites". Given the fact that the two "benevolence" items ("Protects me" and "Would help me if I needed it") also generally load high on this dimension, we could perhaps call the dimension "benevolence", "attachment" or possibly "evaluation". And we could use several different combinations of items to index this dimension, including simply the single term "I like him", the two items "protects" and "would help me", or "like" plus "favorite". Our general procedure has been to use the latter two (the most directly affective items), indexed straightforwardly as a "cluster" or "scale" score. We simply added the numerical ratings the child gave on these two items to form the index score with a range of 1 to 11.[4]

A similar procedure was used for the "power" index, employing "He can make people do what he wants" and "He can punish people" with an identical range in the score. These two items even more sharply and uniquely define the nature of the "power" dimension than do the two affect items best define their dimension.[5]

We proceed, therefore, with four basic dependent variables, "power" and "affect" for President and the same two for policeman, with two corresponding independent variables ("power" and "affect") for the child's father. To use the child's orientations towards his father as the basis for assessing the extent of generalization to political authorities, we assume that these attitudes toward the father become established prior to the development of orientations toward the political authorities. Indeed we found earlier[6]—as partial confirmation of this assumption—that attitudes toward father have already been established by grade 2 or 3 and remain stable thereafter through the elementary school years, whereas the images of the policeman and President shift considerably after the early grades. Our next task, therefore, is to see how our dependent variables—"power" and "affect" orientations toward President and policeman as indicators of idealization—are influenced by (or associated with) the father variables and with other potentially relevant independent variables.

To show the relative explanatory power of so large a number of variables as sex, I.Q., socio-economic status (father's occupation), city, religion, religious attendance, "boss in the family" (child's perception), membership in clubs or teams, grade, party preference, and especially, orientations toward father, we conducted a series of "interaction detection" or "tree analysis" computations. This variety of multivariate analysis attempts, within certain limits, to determine the optimal set of predictors using a non-linear statistical model.[7] The computer program that we used for this series of computations produces, among other things, an ordering of independent variables by relative capacity to account for variance in the dependent variable, an assessment of how much variance each independet variable accounts for, and a summary of the total variance accounted for by all of the independent variables together. These computa-

[a] $\frac{BSS}{TSS}$ = .07   This number refers to the quantity between the sum of squares over total sum of squares and provides a measure of the total variance accounted for in the given interaction detection analysis.

[b] X̄ represents the mean observation for a given group on the dependent variable. On this and subsequent tree diagrams the lower the numerical value of the mean, the higher is the child's evaluation of the authority figure in question.

[c] Information in the top part of these and all other boxes (aside from box #1) defines the dichotomization in the independent variable made in order to maximize the variance accounted for in the dependent variable.

[d] For abbreviations about party preferences, see footnote 2 in this chapter.

344

tional products are extremely voluminous, so that we can provide only the barest sketch of our results here. We will present a few of the more important and representative of our "trees" that show which "splits" were made with what degrees of success in accounting for the variance in each of the dependent variables.[8]

Predictors of Affect for President

In Figure XVII.1 is presented the tree of predictors for "President Affect" index using the five city (see footnote 7), grades 4-8 sample (N=2137). "City" is the first predictor, splitting Chicago and Jackson from Atlanta, Portland and Sioux City. The mean rating (symbolized by $\overline{X}$) in the latter three cities is 5.02, whereas $\overline{X}$=5.75 in Chicago and Jackson. We must bear in mind that the higher the numerical value of the mean (the closer it is to 11), the lower the rating given by the child on the two President Affect items that constitute our index. Thus the children in Chicago and Jackson regard the President less highly in these terms than do their counterparts in the other three cities.

This is not, we should point out, the precise difference that we had expected. We had assumed rather, following the presumed state of mind of their parents, that the children from the two Southern cities would be less approving of the Chief Federal Executive than would the children in the Northern cities, even though the dominant partisan pattern was more Democratic in the South thus matching the partisan identification of the incumbent. But the actual pattern is simply not explainable in such terms. Nor is the split a large city/small city phenomenon. We had supposed that some effect of size of place might enter the picture; but it does not do so in this case. Neither hypothesis was borne out by the data.

From Figure XVII.1 we also find grade, religion and party preference to be of some value in accounting for variance in affect for President. At least in Chicago and Jackson the older children (Group #7) are somewhat less apt to like the President a great deal ($\overline{X}$=5.35). Disenchantment, one could also say, is more acute for the older Chicago or Jackson child than for the younger child from these cities.

Religion comes into the picture for the younger Chicago and Jackson children, splitting the Catholics and those without religious preference away from Jews, Protestants and adherents of other faiths. The former rate the President more highly on the affect dimension (Group #9). We could have anticipated higher Catholic regard for President Kennedy. The greater "affect" mean of non-believers may be attributed perhaps to their having perceived Kennedy to be more liberal politically, thus matching their own probably less conservative outlook.

Party preference also has some predictive value, with Democrats scoring higher (Group #11) and Republicans lower (and with the other party preference options being put in one case with the Democrats and in the other case with the Republicans). Here again, we could expect that the mean rating of Democrats would be higher than that of Republicans, and such is indeed the case.

With all of these predictors together we still account for only 7% of the variance (Figure XVII.1, note a)—which is fairly low. Thus our effort to explain idealization of the President in terms of our best predictors results in low success, although not total failure. The child is somewhat influenced in how he responds affectively to the President by the general impact of the community in which he resides and by his religion, age, and party preference. Mostly, however, he is influenced by factors of other, as yet unspecified, kinds.

We should point out, moreover, that, of the things we do include but which do not appear in the tree, the variables most related to the generalization hypothesis are notable by their absence. We miss here any association among affect for President and affect for father. Indeed none of the father evaluations is related to the child's image of the President in these terms, to any significant degree.

Another way to make the same point more sharply is to consider the simple correlations of the children's ratings of their fathers on the Father Affect index with how they rate the President on President Affect. Table XVII.4 presents these data. Freudian intimations notwithstanding,

---

Table XVII.4. Relationship of President Affect Index to Father Affect Index, by Grade[a]

[a]We used the total samples at each grade for these computations.

---

once again we do not observe a close association between the child's liking for his father and his liking for the President. On this general evaluative dimension, there appears to be little significant generalization of sentiments about the parent to feelings concerning the President. We must therefore use other modes of accounting for this aspect of the child's image of political authority.

Returning to our tree analysis we find that the child who rates the President highest on the affect dimension (Figure XVII.1) is either the Atlanta-Sioux City-Portland Democrat ($\bar{X}=4.36$) or the younger, Catholic or non-believer, from Chicago or Jackson ($\bar{X}=4.39$); and the child who is most apt to rate the President low is a 7th or 8th grader from Jackson or Chicago ($\bar{X}=6.41$) or a younger Republican non-Catholic (and non-agnostic) from Jackson or Chicago ($\bar{X}=6.31$). These differences are not large; but they do serve to show us the limits of our explanatory power in this case. They are sug-

gestive, if perhaps in a negative way, of where we need to go in future investigation of this kind.

City Differences in Patterns of "President Affect" Predictors

In order to probe these patterns of interrelation more deeply before giving up the generalization hypothesis completely, we used the total (grades 4-8) samples in each city for separate A.I.D. analyses. Before we present individual city trees, it might be helpful first to get some more comprehensive perspective by comparing the variance accounted for by each of our independent variables in each of the eight cities. The figures shown in Table XVII.5 make such a comparison, using the separate city computations.

In six of the cities (Chicago, Sioux City, Boston, Portland, Atlanta, and Tacoma) party preference is the best predictor of any on the list, whereas in the other two cities (Jackson and San Francisco) grade is the best predictor. The third variable with modest influence in some of these cities is religious affiliation. It is particularly important in Chicago and Portland. SES shows up somewhat in Chicago and Boston; and "Fater Affect" appears to have some weight in Boston.

None of these predictors accounts for even a modest 5% of the variance on its own, so that none is likely to be a major factor in shifting the course of the child's development of these feelings for the President one way or the other. The fact that the child identifies himself with the party of the President adds a small increment to a perception of benevolence; but this effect is not found in all of the cities. Equally, a religious preference that corresponds to that of the President (as for Catholics and Kennedy) may add a bit of cement to the bond the child establishes with the President; but again it is of minor consequence, and appears only in certain geographical areas.

To display some of these city differences in patterns of association with President Affect more sharply, we present Figures XVII.2 and XVII.3.

Figure XVII.2 shows the tree for the Chicago sample on President Affect. What we find, from the standpoint of a typology of those highest and lowest, is as follows:

(a) For groups with substantial numbers of cases, the child highest in level of President Affect is either a Democrat or one who chooses "don't know what Democrat or Republican means" (Don't understand), and who is in the earlier grades (Group #12, $\overline{X}=4.39$).

(b) Taking into account groups with relatively small numbers of cases, we find that in Chicago the child highest in President Affect is a Republican, Independent, or as yet undecided in party preference (D.K.), who is also either Catholic or a non-believer, and who sees his father to be relatively powerful (Group #14, $\overline{X}=3.32$). In the latter therefore we ob-

b In this and subsequent tree diagrams the word "scores" refers to index score values included for a given dichotomization of the independent variables to which the box refers. In each case such scores range from 1 to 11. The lower the numerical value of the score, the higher the child's evaluation of the authority figure in question.

serve a rather special interaction effect of either Catholicism or religious non-belief together with a perception of high Father Power. This combination of factors accounts for the deviation of this small group of children from the pattern typical of other Republicans or those with no party preference as indicated in Groups #3, 4, 6, and 7.

(c) The child scoring lowest on President Affect is a Republican and a Protestant, Jew or member of some other non-Catholic faith, who sees his father to be less powerful, and who is high in SES (owner or professional). (Group #10, X=8.02.

The gap between these two groups expressed in their respective means is a considerable one. Thus our predictors for Chicago separate various types of children to some degree, and we account for 14% of the total variance.

By contrast, our tree for Jackson (Figure XVII.3) shows a much different and less complex pattern of predictor variables. Whereas grade had been of only secondary importance in Chicago as a predictor, it is best in Jackson. Furthermore, only one of the other Chicago predictors enters (Father Power) and another secondary predictor appears in Jackson—"boss in the family". In comparison with our predictive capacities in Chicago, we are relatively unsuccessful in differentiating among the chiildren of Jackson in how they relate affectively to the President. We account for only 5% of the total variance; and we are able to get very few of our predictors to enter. Several of the variables which, however slightly, begin to show their differentiating effects in Chicago are absent in Jackson. This suggests either a more uniform political subculture in Jackson (in these terms) or else a later development of differentiated orientation to feelings about the President among relevant subgroups.

The little differentiation that we do get in Jackson shows that the most favorable response is given by younger children who perceive the "boss" in their family to be either father or both parents, as against those who perceive mother to be the boss or who say they cannot answer (Group #5, X=5.37). The children in Jackson who are lowest in affect for the President are the older children who perceive their own father not to be especially powerful (Group #7, X=7.02). Thus the patterns of association that appear on President Affect in Jackson and Chicago are somewhat different, with Chicago showing the more varied and extensive set of relationships with our independent variables.

In the other six cities—the tree diagrams for which are not reproduced here—we find other combinations of predictors that form the intermediate cases between Jackson and Chicago. A few other independent variables enter the trees in the other six cities. I.Q. is a predictor in Portland, with those higher in I.Q. showing less affection for the President. I.Q. also appears in Tacoma. In Sioux City, children who have been an officer of a club (among Republicans or those without preference or knowledge of the parties, who rate their father low on power) typically have lower President Affect scores (X=7.17 for club officers, X=5.97 for non-officers). Sex enters as a predictor in Tacoma, with Democratic girls showing higher

average affect ($\overline{X}$=3.74) than Democratic boys ($\overline{X}$=4.23). All of these special effects are relatively low in magnitude, so that the practical impact of any one of them is slight. Some variables appear with greater regularity in the eight trees (for the eight cities) than others, especially party preference, grade, SES, and certain feelings about father. Insofar as we have predictors of measurable consequence for affective orientation towards the President under various geo-cultural conditions, they are these.

Taken as a whole, these variables could suggest that family influences of one kind of another best explain variations in sentiments about President--particularly the social status of the family, and thus possibly its internal communication patterns[9], or other relationships existing between the child and his parents. One senses that we have perhaps caught only the outer edges of these variables; and that more intensive analysis of family variables in this context would yield considerably more explanatory power. That our explanatory power is so slight is perhaps a reflection of the crudity of our measures in relation to the complex and varied environment of the family. Because these variables allow us to explain this orientation so slightly, one could be pessimistic about success in prediction using them; or one could be optimistic, given the fact that a few family variables tend to indicate some underlying pattern of causation amenable to future inquiry.

President Power

When we turn to our second index of feelings concerning the President--which we have labelled "President Power"--we find something a little different however, with relevance this time for the generalization hypothesis. In this case, we again are not notably successful in using our range of predictors to account for a substantial portion of the total variance. But among our predictors, Father Power is fairly prominent. Figure XVII.4 presents the tree using the seven-city sub-sample on "President Power."

What we find is that the Father Power index is the best predictor of scores on the President Power index followed, by city and grade. The child highest in his evaluation of the President's power (Group #5) is high in terms of his father power ratings and he is from the cities other than Chicago and Atlanta (excluding Tacoma, which had been eliminated from the analysis). The child who is lowest in his rating of the President's power is very low in his rating of his own father's power, he is from the higher grades, and he comes from Jackson, Boston, San Francisco, and Portland (Group #11).

Perhaps our key finding here is that the "best" explanatory variable--and one which does better relative to its analogue for President Affect--is how the child rates his father's power. From this perspective we may want to revive the generalization hypothesis even though its area of application may be much narrower than we had originally supposed. The difference here is possibly between generalizing direct affection from one

known individual person (father) to a role personality, the President, (which, apparently, does not operate at all) and perceiving and evaluating an external authority's performance characteristics such as his relative power. One could argue that such analogizing behavior by the child in the latter case is more understandable, given that authority is more likely to be seen as residing in the performance characteristics or the role rather than in the personal qualities. Thus the child, ignoring Freud, may make a not unreasonable connection in the one case but not in the other.

In Chapters VIII, X, and XIII we have already had occasion to comment on this reluctance of the child to rank external authority figures very high on our most directly affective ratings. There we saw in that in comparison with both President and policeman, the children consistently ranked father higher on the direct attachment items ("I like him" and "he is my favorite"). Even where the rating of the authority figures may begin at a fairly high level on these items, in the lower grades, unlike the ratings for father they drop precipitously. The data there gave us the first clue that this kind of direct affect may be specifically related to the particular authority role, one close and personal for the child, rather than to authorities more distant from the nuclear family or others with whom the child may come into more frequent daily contact, such as teachers or policemen perhaps.

Before we leave the subject, therefore, we can take a further test case using the policeman indexes. This should help us to confirm this more differentiated hypothesis.

Policeman Affect and Power

When we turn to the child's basic feelings about the policeman, we see much the same patterns of association as for the President. These are shown in Figures XVII.5 and 6.

Figure XVII.5 shows that grade, sex, father helpfulness (an alternative measure of father affect) and city are related to some extent to the level of affect for the policeman. Thus, relative to the last of these, (although the effect is somewhat marginal), there is a degree of generalization possible on this more affective side of the policeman's image.

We have already hinted at why we might find this relationship for policeman, marginal though it is, but not for President. Although in the aggregate, the children see the President as more likeable and more benevolent than the policeman (Table XIII.1), as we noted long ago there are good reasons for this, independently of the possible projection of their feelings about father. The President is after all a far more prestigious figure than the policeman and we would expect children to express somewhat greater affection for the President if they can do it for any external authorities at all.

However, for the very reason that the policeman is less presti-
gious we would have to account for the child's affect for him in other
terms. Undoubtedly there are a number of factors at work as we noted
in Chapters X and XI. Among them, however, some generalization from the
image of father seems to occur. It could be that the proximity of the
policeman and the frequency of the child's contact with him--at school
crossings and the like--enable the child to see him much more in the way
he does another close-in authority figure, his father, at least on the
protective, helpful side of general affect. In this limited sense then,
our data here may lend some weight to the Freudian theme that the child's
attitude towards political authority may be somewhat shaped by his
feelings about parental authority.

In this same area of policeman affect it is interesting that
we find a sex difference, at least for the older children. Girls rate
the policeman more highly in these terms. If it does not prove, at least
it does add some greater plausibility to the vulnerability hypothesis as
an explanation for the tendency to idealize external authority. The
sexes are undifferentiared for the earlier grades. Thus one might surmise
that they feel equally a regard for the policeman's protective attributes;
but as they grow older the boys take a relatively less favorable view.
Possibly at an earlier age than girls they begin to feel less dependent on
such external authority and they may even become a little restless with
the constraints on their behavior represented by the police. We have
already discussed how the curve of general respect for the police, declining
by grade 8, probably continues to drop to a low point in early adulthood
Chapter XIV).

When we consider Figure XVII.6, we again find some confirmation
for the generalization hypothesis, this time with regard to the index of
evaluation of Policeman Power. Those higher in their evluation of their
own father's power are also more apt to rate the policeman high in power.
Thus, the effect, in this case, is much like that for the President.

In Figure XVII.6 we also have data that could be considered in
relation to the vulnerability hypothesis. A sex difference of a kind simi-
lar to that in Figure XVII.5 is found. On the other hand, our expectation
that the lower status child might feel less secure, therefore more vulnerable
before the outside worldand rate the policeman's power higher than would
the more advantaged child is partially upset (Groups #8 and 9).

Conclusion

Our multivariate analysis yields a complex and inelegant solution
to the question of which of our predictors are of value in accounting for
how the child responds to the President and policeman on our Affect and
Power indexes. The proportion of variance any one of them accounts for
is relatively small, as is the percent of variance explained by all together.
There is some consistency across indexes and cities; but it is not high.
Using Power and Affect indexes as general indicators of the child's regard

357

for political authority--his idealization of it--we have not been too successful therefore in explaining variations in it.

The main hypothesis upon which our data have been able to shed some light, however, concerns the tendency of the child to project his images of parental authority to key figures of authority in the political realm. Our general conclusion is that, although the effect is nowhere very strong, there are several instances in which it would appear to have some potential explanatory power. Possibly the most interesting case however--that of the level of the child's affective response to the President--does not come under this umbrella. Nevertheless, how the child perceives his own father on Affect and Power appears to have at least a selected impact on this area as a whole. The clearest connection comes on the performance dimension of power, both for policeman and President.

Other basic attributes of the child enter marginally into these responses. Sex, I.Q., SES, party and religious affiliation differentiate to a small degree in a few instances. None of these groupings show marked effects, however; nor do they pertain in every one of the eight locales. Several of the differences most expected therefore do not materialize. The period of childhood socialization we must conclude is--on these measures-- not generally one of increasing divergency; it is instead a period of striking similarity of response among children of various basic social categories, just as we found from the cognitive analysis in the preceding chapter.

The terms we have used do of course limit the scope of such differentiation, so that students might do well to continue their search using a broader range of responses relevant to political authority images, reconsidering at least those social categories for which such differences might be most expected. In the one or two cases where we found evidence not inconsistent with the vulnerability hypothesis, for example, we might well have achieved marked success had we had more incisive measures. Thus future research might usefully begin with the questions that we have raised but have been unable to answer to our own satisfaction.

In general, therefore, we have not been able to find large, consistent differences in our data among various salient subcategories of respondents. The differences we observe are scattered, unsystematic and more impressive for their absence than for their presence. Even though we are thus restricted in our ability to account for the child's high positive evaluation of political authority, we can suggest that the lack of any far-reaching differences of these kinds, may well provide an important almost monolithic base of diffuse support for the structure of political authority in the American system. In other words, even the lowest input does not seem to be concentrated in any single identifiable group.

Can we account in any way for this apparent cross-group uniformity, both in cognitive and affective respects, at the system politics level? Here we must turn to more speculative judgments. Regardless of where the children may be acquiring their orientations, it does appear that a strong consensual element appears. Adult socializing agents and agencies may have differences about issues and candidates and may even differ in their general feelings about the importance of politics, but when it comes to feelings about the legitimacy of the authorities, we find a relatively high degree of consensus, among their children at least.

In part, this may be a product of our special sample. It included only children from white, urban and non-economically depressed homes. However even if a more diversified sample had produced the same homogeneous outlook, we would not expect this situation to last. By the middle of the 1960's this consensus may have begun to dissolve under the impact of the urban and racial crisis and the student revolution. Especially is this likely to be the case for the Negro children. Thus future scholarship may need to qualify the finding of uniformity that we have made by recognizing that subcultural forces other than the ones on which we have focussed may be modifying the pre-existing homogeneity of basic political orientations.

But even if this uniformity is breaking up, in the past it might also have been traceable to another peculiarly American phenomenon. Adults in the United States may themselves have had some special feelings about the area of system politics regardless of subgroup; they have managed to get this message across to children with a minimum of ambiguity. In fact, in Chapter XVIII we shall be led to speculate on the possibility that this whole area of system politics may have been the subject of particularly severe efforts in socialization; hence the tendency towards considerable similarity in outlook.

Footnotes

1. See D. Jaros, H. Hirsch, and F.J. Fleron, Jr., "The Malevolent
   Leader: Political socialization in an American Sub-culture".
2. Our measures of these various independent variables were derived
   as follows:

   1. I.Q.: I.Q. scores were available from school records
      for about 85% of our respondents. We used the most re-
      cent score available and we converted various measures
      of I.Q. to a common "stanines" scale using a procedure
      developed by J.C. Flanagan and P.A. Schwarz. See their
      tables in "Development of Procedures for Converting In-
      telligence Test Scores to a Common Scale" (Pittsburgh,
      Penn.: mimeographed publication of the American Insti-
      tute of Research, 1958).
   2. Religious affiliation: CA-9, p. 3, item 19. "Your
      family is: (Choose one) 1. Catholic 2. Jewish 3, Pro-
      testant 4. Other 5. None."
   3. Religious attendance: CA-9, p. 2, item 18. "How often
      do you go to Mass, Church, Temple, or Sunday School?
      (Choose one) 1. Every week 2. Almost every week 3. Only
      once in a while 4. Almost never."
   4. Member or officer of clubs or teams: See Appendix B,
      CA-9, p. 23, items 47-50.
   5. Political party preference: See Appendix B, CA-9, p. 9,
      item 42. On the tree diagrams the options on this ques-
      tion are abbreviated as follows: Sometimes a Democrat
      and sometimes a Republican="Independent", I don't know
      which I would be="D.K.", I don't know what Democrat and
      Republican mean= "I don't understand".
   6. "Boss" in the family: See Appendix B, CA-9, p. 3, item 20.
   7. Ratings of father: See Chapter XII.
3. We used for these computations a principal component analysis of
   Pearson r matrices, with varimax rotation.
4. As each rating ranges from 1 through 6, both ratings in the index
   combine to give an index score of 2 through 12, from which we have
   subtracted 1 for each score to give a resulting range of 1-11.
5. In addition, we find a further dimension or two, depending on how we
   set the eigenvalue necessary for rotation. We present in Table XVII.1,
   XVII.2, and XVII.3 the three-factor rotation solution at each grade.
   Given the fact that the third dimension does not appear for father and
   that it has a somewhat unsteady composition for President and policeman,
   we have chosen to eliminate it from the present analysis and confine
   our attention to the two stable image dimensions common to all three
   figures. We should add that, by lowering the eigenvalue necessary for
   rotation to .90, we were able to obtain at some grades a fourth compo-
   nent on President and Policeman that had an eigenvalue almost equal to
   1. The instability of these fourth components prevented us from using
   them to score children's responses to authorities, however.
6. See Chapter XII.

7. The computer program that we used for our "tree" or "AID" (Automatic Interaction Detection) analysis and its underlying statistical model are described in John A. Sonquist and James N. Morgan, The Detection of Interaction Effects: A Report on a Computer Program for the Selection of Optimal Combinations of Explanatory Variables, Monograph #35, Survey Research Center, Institute for Social Research, (Ann Arbor, Mich.: University of Michigan Press, 1964).

8. The computational routine that we had available places limits on the number of observations and variables that can be used at any one time. In order to use the number of variables that we thought desirable it was necessary for us to take a random sample of 3000 from our total set of respondents. The sample was taken from grades 4-8 in seven of the cities (excluding from the population the children from Tacoma where we lacked the father ratings, grades 2 and 3 where, due to testing restrictions imposed on us, we lacked about half of all the ratings used to devise the indices, and in Figure XVII.1 only, Boston and San Francisco, where for similar reason we lacked religious data). We will present all four of the analyses using the sample. We also carried out the same four basic analyses for each of the eight cities. We will present individual city trees for "Presidential Affect" only.

9. For a suggestive treatment of the influence of the family environment on the child's early political learning, see J.M. McCleod, S.H. Chaffee and D.B. Wackman, "Family Communication and Political socialization", paper presented at the 1966 Convention of the Association for Education in Journalism, Iowa City, Iowa; and "Family Communication: An Updated Report", Paper presented to the Theory and Methodology Division, Association for Education in Journalism, Boulder, Colorado, 1967. Both papers may be obtained from the Mass Communications Research Center, 425 Henry Mall, University of Wisconsin, Madison, Wisconsin.

PART V

CROSS-SYSTEM IMPLICATIONS

Chapter XVIII

THE "MEMBERSHIP" ROLE IN THE POLITICAL SYSTEM

Many implications may be read into our findings. As we have ob-
served on occasion, if we interpret the American political system as
representative of democracies in a mass industrialized society, our
findings may help us to understand how this type of system socializes
its young politically. If we identify the American system as one of a
class of stable political systems, our findings will shed some light
on the sources of stability in this kind of system. If we are interes-
ted in the factors that shape the political attitudes of adults and
wish to designate childhood experiences as a major determinant, we
undoubtedly have much to offer.

Yet none of these implications of our research touches on our
major purposes. They may be considered welcome but only incidental
benefits. The real origins of our purposes lie in theory.

Now that we have covered so much ground, it may be even more
helpful than at the outset to clarify just what it is we have not been
trying to do. Especially because the current assumptions about objec-
tives in the study of political socialization are so seldom questioned,
the greatest danger in the interpretation of our conclusions is that
our own intent will be obscured or seriously misconstrued.

At least one thing should be transparent. As we established from
the beginning, we have not been searching simply for the roots of those
patterns of political behavior that contemporary research has found to
prevail among adults. Just because political science happens to have
certain kinds of political knowledge about adults is no sound reason
in itself for pursuing the source into childhood. To do so without
adequate prior justification would simply have led to adopting the
perspectives of adult research with all the theoretical shortcomings
they might possess. As we have observed, these shortcomings are by no
means irrelevant for the study of primary socialization. Research
about adults has been confined largely to one sector of behavior in
political systems, allocative or partisan politics. It is an impor-
tant area. But for children, concentration on orientations relevant
to allocative politics would have forced us to conclude that little
significant socialization does or could be expected to occur during
so early a phase in the life-cycle.

We have carefully refrained from implying that in childhood
ideological positions begin to take shape, modes of participation first
appear (aside perhaps from party identification), political interest
arises, or aspirations for political office have their roots. Nor
would we contend that even if some slight beginnings in these matters
could be discovered, they would be likely to continue into adulthood
undeflected by adolescent or later experiences. It would be a very
risky business to argue, without far more evidence than a study of chil-
dren could possibly provide, that adult political orientations and
patterns of behavior in areas such as these can be traced directly
back to childhood.

We have found, however, that if we adopt a substantially dif-
ferent theoretical point of departure, one associated with systems
analysis, we automatically open up a whole new area of political ex-
perience to which children may indeed be exposed. This is the area
of system politics. This new approach has invited us to explore the
consequences of primary socialization for the input of diffuse support
to that part of the political system we have identified as the regime,
and within the regime, to that element we have described as the struc-
ture of political authority.

Theoretical Purposes

It is time to refresh our minds about the theoretical underpin-
nings of our inquiry and, therefore, about the reasons for choosing the
growth of diffuse support for political authority as our primary focus.
There are many types of social systems: groups such as societies,
families, or tribes, and analytically separable aspects of behavior
such as cultural, religious or personality systems. Among these we have
been interested in understanding the operations of one special type,
political systems, a kind that we have described as consisting of all
those social interactions through which authoritative allocations are
effected for a society. Initially, at the most general level of theory,
we have considered it important to ask how any and all kinds of political
systems manage to persist in a world both of stability and change. This
is the central puzzle for a systems analytic interpretation of politics.

Every political system is subject to various kinds of stress that
threaten to prevent a society from continuing to allocate values authori-
tatively. One type of stress has concerned us – the possibility that
the members may be unwilling or unable to offer sufficient support for
some kind of structure of political authority. We have postulated that
the regime is a fundamental element in all political systems. Among
other things it identifies the structure, both formal and operative,
through which political authority is organized and exercised. Empiri-
cally men have nowhere been able to resolve all their differences with-
out the intervention, however infrequently or intermittently, of special
persons speaking in the name of society. To these we give the designation
"political authorities". If there is to be any operative political sys-
tem, if a society is to be able to allocate valued things authoritatively,
members of the society will have to accept the decisions of one or another
set of authorities as binding in some areas of social interaction. Other-
wise the Hobbesian state of nature would indeed be likely to prevail.

Without some structure of political authority, we have postulated,
no political system could endure for long. Not that a particular kind
of structure need be inescapable; indeed it may be that prevention of
the disappearance of a political system entirely may entail deep changes
in the structure of political authority, as from a totalitarian to a

democratic one, or from a tribal to a secular representative one.
Transformation of structural type may carry very serious consequences
for many human values. Among these we are concerned for the moment
only with the possibility that a society may be prevented from sustain-
ing some kind of processes and structures for the authoritative allo-
cation of values. As hypothesized in Chapter III, socialization is
interpreted as one kind of response through which political systems
may be able to ward off certain kinds of stress on the structure of
political authority (as well as on other elements of the regime, such
as its norms, with which we do not deal here).

This theoretical starting point has led us to diverge radically
from customary interests in political socialization. It has introduced
a very different set of central questions. If members of a political
system are to accept the decisions of the authorities as binding, how
does this come about? Does the system manage to build up a resevoir
of support upon which the authorities may rely even in periods when
the members may not be able to discern any specific benefits or re-
wards from belonging to the system or when they, the members, may be
called upon to make extraordinary personal sacrifices for advantages
too remote to be perceived clearly?

Speculatively there are many possible sources of support. Among
these, we have argued, primary political socialization will account for
one important type. Taking the American political systems as a case
study, we have sought to explore the way in which socializing processes
could be expected to draw support from its members during the earliest
phases of the life-cycle. Thus, far from simply searching for the roots
of adult behavior intuitively selected as interesting, we have laid
down some theoretical criteria to guide us in our exploration of primary
socialization.

The Earliest Political Role

Where have these theoretical guidelines now led us? They have
brought us to recognize the political void in which past research has
unwittingly placed children. This past neglect virtually defies ra-
tional explanation. From almost time immemorial the great philosophers
have reflected on the importance of early experiences for the political
sphere. Men have always thought that attitudes towards political au-
thority probably get their start in the home; repeatedly the family
has been considered the political system in microcosm.

Strangely, however, in modern times this put research workers off
if not on a false scent at least on one that followed along a secondary
trail. It led to the conviction that if childhood has any meaning for
later political life it could result only from the projection of psycho-
logical predispositions gained within the bosom of the family. It was

assumed that somehow or another personality traits instilled at an early age would later manifest themselves in adult political behavior and thereby affect the operation of political institutions. As we have already noted in Chapter IV, specific political learning seemed non-existent during childhood, or if present, trivial in their consequences for adult behavior. In the end we were driven to the surprising discovery that childhood has been thought of as a political vacuum probably only because to this day so little attention has been given to the <u>specifically political aspects</u> of the socializing processes during that period.

Not that this conclusion need impel us to deny that personality, the underlying structure of learned predispositions, imposes a set of durable constraints on an individual's later political actions. But there is nothing in this assumption that need discourage us from recognizing as a fundamental fact for political research and analysis, that as a person matures he also begins to acquire specifically political orientations and behavior patterns. In the area of diffuse support for the structure of authority these specifically political acquisitions are by no means random. By grade 8 the child has evolved a complex yet predictable pattern of political orientations and these have significant consequences for the American political system.

The "membership" role

How are we now to formulate what happens to the individual by the end of his childhood? We might simply accept the findings as manifestations of a variety of consequential political orientations adding up to a miscellaneous aggregate of attitudes and bits of knowledge and leave it at that. But we might also see in these orientations something more. Through them the maturing individual is introduced to the political system. For the first time he begins to acquire at least a foretaste of a political role in society. Through the process of being recruited as a general supporter (or opponent) of political authority, the child is learning an important ingredient of the meaning of what it is to be a member in a political system.

The role attitudes and behavior patterns about support that he acquires may conform to the expectations among adults about what a person should know and how he should behave. Thereby his political awakening would contribute to the stability of the system. The acquired patterns may however strike out in new directions, a kind which, if carried into adulthood, might produce fundamental transformations in the system. Thereby the newly acquired role might add to the potentialities for change in the system. But regardless of the consequences for the system, in childhood a person begins to absorb a way of looking at the political world, seeing some parts first and others only later, and he even displays distinctive sentiments about things he sees. In short, he will have taken some few firm steps on the way to becoming

a "member" of a political system. Through it a person begins learning about what it means to belong to a political system and to participate in it. If our findings are characteristic, a person is likely to absorb, if only in latent form, some of the most profound feelings human beings are capable of developing about political systems, what we have called diffuse support. Perceptual patterns impress themselves on him so that he has some idea of the nature of his political world, especially about that characteristic part called political authority. Only later in the life-cycle does this first step lead to a variety of differentiated roles. Depending upon the kind of system in which the child grows up, he will gradually learn such separable roles as voter, party member, administrator, headman, political innovator or protester, and the like.

However, most of the specific roles do not and probably cannot evolve very far, if at all, in children. Most children are capable of adopting only the simplest attitudinal and behavioral patterns, those that sum up to the undifferentiated role of being a beginning member of a system. This is but a more precise way of confirming a process known in other areas of socialization as we noted in Chapter IV: that the acquisition of general motives, values, and cognitions precedes the learning of specific skills. The child develops attitudes about support for the regime before he learns those minimal participant skills in politics that membership in a particular system may require.

The kind of role the child assumes may be shaped in part by generalized personality characteristics, as we have observed. About this we have no data. But our research does demonstrate that specifically political experiences are inescapable determinants from the very earliest stages of childhood. We might even turn the tables here and suggest that political orientations might themselves help to form the basic personality.

Research has managed to overlook the existence of a generalized membership role and its early roots. We have tried to explain this neglect in part as a product of an excessively narrow conception of the nature of politics. As long as politics is interpreted in largely controversial or partisan political terms, there was good reason for feeling that the acquisition of major political roles would have to be postponed at least to late adolescence. But once we were able to uncover a deeper level of political experiences in system politics, we were immediately able to identify a broad area in which childhood learning is not only rich and varied; it also has potentially profound consequences for the functioning, indeed for the very persistence, of political systems.

Ingredients of the membership role

In the American political system part of the major outlines of the general membership role is unmistakable; it is best defined by the

specific processes that appear to shape it. We may describe these
processes briefly in the following terms: politicization, personali-
zation, idealization and institutionalization. These concepts merely
sum up what we have already found about some of the ways in which the
maturing member is introduced to the American system by being induced
to lend his support to a set of political authorities. Now, however,
we may look at these processes and outcomes in a new and more general
light, as contributing to the development of the introductory member-
ship role in the political syste.

Politicization is critical for the kind of system we find in the
United States. In general, the most distinctive feature of the member-
ship role is the knowledge and understanding that the child quickly ac-
quires about the presence of a political sphere external to the family
even though he may be unable as yet to give it a name. Without this
recognition it would be difficult to understand how in a mass society
such as the United States, the child could be brought to the point of
extending a minimal level of diffuse support for the structure of au-
thority. In the next chapter, we shall return to this point for its im-
plications about diffuse support for other types of systems. But it
is clear here that becoming a member of the system in the United States
does entail a basic acceptance of the presence, power, and legitimacy
of an authority external and superior to the family.

Processes are at work, as we have seen, that begin to pry the
child away from exclusive bonds to the family and make it possible for
him to reach out to the structure of political authority. He is able
to sort out the public from the private sphere, to recognize the superior
authority of the policeman, and to accept the higher power and perfor-
mance qualities of political institutions when compared with father.
In short, by the time we leave the child in grade 8 he has been thor-
oughly politicized; he has become aware of the presence of an authority
outside of and more powerful than the family.

Personalization of political authority through the head-and-tail
effect has seemed to play a vital part in bringing the child to this
level of political awareness. The President and policeman at the be-
ginning and other figures and some institutions at a later stage represent
the exact points of contact. Some figures, such as the Senator, whom we
would have thought to play some part, are less significant. We have here
the specifically political doors through which children are first able
to move out of the family and into the political sphere, although we
must bear in mind that there are other points of access that we have not
yet explored.[1] Membership in the American system involves, as one of
its role characteristics, moving through these doors and becoming avail-
able for direct mobilization on behalf of (or in opposition to) the
structure of political authority.

Personalization makes possible at a very early stage the virtual
idealization of political authority. We have already pondered the
question as to whether this process does not apply to other systems as

well, a point we shall consider further in the following chapter. But at least for the American system the child finds it easy and natural initially to extend the same kind of feelings to certain objects of political authority if only because they are like the palpable personal beings already familiar to him in the nuclear family. In the American system the authorities draw high positive feelings; hence we have characterized the process as idealization. But in other systems where hostility might represent the first feelings about political authority we might have had to describe the direction of the sentiments as hostile or "hostilization". The important consideration is that through personalization the child is able initially to extend diffuse support, whether positive or negative, to political authority and in this process lies the means through which the child is linked in some way to the structure of political authority.

Furthermore, for at least those systems in which the authorities are represented by organizations and in which the constituent individuals may tend to be overshadowed by the institution itself, somehow or another the maturing member needs to learn to be able to relate himself to de-personalized objects as well. Institutionalization describes the processes in the American system through which the beginning member shifts his early feelings about personalized objects to political institutions. The older the child, the more likely is he to offer a higher evaluation of such institutions of authority as Government or the Supreme Court on our measures of role performance, as against such personal qualities as likeability or benevolence. In this way it would appear that as part of the beginning membership role the child learns to shift his diffuse support to the less personalized elements of the structure of political authority.

Through these four processes, therefore, the child comes to a minimal knowledge of what it means to be a member of the American political system, at least as it involves the structure of political authority. His membership role will include political orientations of many other kinds as well--about regime, goals and norms and about the political community, for example. But the process underlying acquisition of orientations to these is sufficiently different and complex as to merit separate examination. Here we have delineated only those processes relevant to the images of political authority.

The Coherence of the Authority Image

To learn the general values and orientations accompanying early membership in the political system, however, seems to involve more than just being able to identify and relate emotionally to selected objects of authority. To be sure, even this might seem to be asking a lot of a person at so tender an age. Yet there is evidence for believing that the child goes further. From these many facets of authority it appears that the child is well on the way to constructing a more comprehensive and cohesive image of political authority, even if we must recognize it

368

is not one that he could possibly articulate for us under the most subtle interrogation.

In effect we are now raising a question about the validity of speaking not only about the child's orientation to specific authority figures and institutions, separately and discretely, but about the idea of a structure of authority as a set of related roles. Has the child some more comprehensive if latent image of political authority to which, as he matures, he may add new components? Here we need to clarify the relationship, as the child becomes a young member of the system, between the linkages we have necessarily examined in their particularity and the acquisition of the idea of an overall structure of authority through which binding decisions are in face made in a system.

Beyond "egocentricity" in the political system

The establishment of the capacity of the child to orient himself during the early grades to objects far beyond the family, in the national sector of society, is a finding of decisive significance in our understanding of the socialization of children. Piaget, for example, has maintained that "egocentricity" or an awareness of self and immediate surroundings--such as family, neighborhood and town--characterizes the child until about 10 or 11 years of age.[2] Children, he has contended, lack the capacity to give either intellectual content (meaning) or emotional response to large units beyond the self and objects in the immediate environment. If, however, there were no way to overcome this limitation, clearly it would be difficult if not impossible for children to relate themselves to so remote a set of objects as the regime or its set of authority roles.

It is surprising to discover that in the American political system processes have arisen that have succeeded in circumventing these apparent limitations. Not that the child is in the least capable of formally articulating a conception of the regime or the structure of authority. Nevertheless we have discovered that there are specific and well-defined points of contact which do fit in with the child's capabilities. He is not required to orient himself initially to some impersonal and vague set of institutions, even though in fact he is able to do so in some limited degree in his conception of government. Through the personalization of the regime, in the President and policeman, the child is able to find congenial and meaningful content for what he may only later in life, if ever, learn to speak of as political authority. Alternatively, if the authorities presented only an impersonal front to the child, it is difficult to imagine how he would orient himself to them, given the known intellectual and emotional limitations of all children.

Indeed even by ages 10-11, the outer limit of Piaget's period of egocentricity, we have found that the child has already become fairly well politicized, using this term, as we have, to indicate not political interest and participation but only a growing awareness of the political

sector. The children come to recognize the greater potency of some political authorities as agencies outside the family. In thus distinguishing the political from familial authority, the children reveal that they have learned an important lesson, at least in a system in which the political structure is differentiated from other social structures. However inaccurate their image may be from the point of view of the informed adults, the important thing in the political socialization of children is that through the mechanism of personalization they do manage to obtain some awareness of and ideas and feelings about the external agencies of political authority. If our study reveals little else it does establish firmly that, in spite of findings about "egocentricity" in other areas, the average child in our group has a firm cognitive base on which to affix feelings at least about selected political authorities.

The probability of a cohesive image

It is now time, however, to rephrase our findings more meticulously. Although we have repeatedly suggested that we considered the child to be orienting himself to the structure of political authority, this conclusion was somewhat premature. In a strictly nominalistic sense our findings permit us to go no further than to conclude that children are able to grasp specific points in the regime. Aside from the special significance of the child's concept of government, we have only determined that children are able to identify and characterize certain discrete objects in what we identify as the structure of authority. We have not tested the children for their ability to conceptualize this structure as an undifferentiated or cohesive entity, and for obvious reasons. We could not expect children to be able to grasp this abstract and generalized idea. Nonetheless we shall now propose that all these specific linkages probably do add up to a fairly broad and general idea about the presence of some overarching set of political authorities. The child is able only to see and identify limited parts of this set but he has some inchoate idea about the existence of a whole.

On the face of it, this inference may not appear too reasonable. Can we really think of the child as conceiving anything more than a number of isolated objects of authority floating around in his cognitive space? But if this is all children are aware of, can we contend that they are learning to relate to political authority in its general sense or to the whole structure of political authority? Certainly it is not self-evident that just because they are able to establish contact with individual political authorities at some points, the children must necessarily absorb a more comprehensive image of political authority and to profess feelings about it. On the contrary, their transparent inability to comprehend even the verbal symbols, "political authority", would seem to offer proof positive about their ignorance of the broader relationship embodied in the very idea.

Indeed on a priori basis we might well draw the very opposite conclusion. For children--as indeed for many adults--politics in the United States cannot help but present a complex and confusing face even if they had much more information than they do in fact possess. The American system contains some 100,000 governmental units in all, with wide variations in organization and rules. In them we find approximately 500,000 elected officials and over 11,000,000 civilian governmental employees.[3] These are potential ingredients of any image of the political authorities. Added to them are untold numbers of institutions and agencies through which these individuals are organized for action. Moreover all this constitutes only a small part of the political world. It is also populated by an untallied number of aspirants for political office, party officials, and other political and opinion leaders who participate in public affairs at well above the average level of visibility.

For all practical purposes, everyone, adult and child alike, must enter this vast political world selectively. We have indeed seen this to be true of children. They have preferred points of contact with the structure of authority at least. Although with age these linkage points grow in quantity, they are readily numerable, so limited are they. Vast regions even of the formal political structure lie hidden well beyond the child's widest horizons. Although we have not elicited points of contact at the state and local levels, our interviews did indicate that these are less likely to be visible to the child unless there are some special local reasons. The child has scarcely any knowledge of the many administrative offices and agencies at all levels. Just how a maturing person ultimately threads his way through the vast complex of figures and political institutions as he moves well into adulthood we cannot even pretend to guess from our research.

The latency of the overall image of political authority

Does this complex structure mean, however, that there can be no awareness or idea about some general political authority of which the figures and institutions known to the child are only symbolic or representative? A few things are clear about this. Even though we can isolate the objects of authority most salient for the child, we need not conclude that he has a totally fragmentary image of the political authorities. What evidence we do have would indicate just the contrary. It would seem that he has perhaps begun to discern some coherence in the world of political authority; it is a concept latent in his very ability to speak about and characterize discrete objects of political authority.

There are several reasons for this inference. In the first place, from an early stage there is an overarching quality to the child's image of political authority. Even as he grasps the notion of some power beyond the family, he is able to associate it with an amorphous, ill-defined

but nevertheless embracing entity recognized by him as the "government". Even though as he grows older he changes his mind about what might be included in this concept--moving from the President or George Washington and the like to Congress and voting--its very significance is to serve as a container into which he can pour this changing content. The idea of government helps to hold together the discrete elements that go into it.

In the second place, this latent coherence is reinforced by the child's initial hierarchical image of the authorities. When during his early years the child sees the President and policeman and then adds other objects, he attributes to the President the full power to order others about and the full responsibility to care for the country, in much the same way that he might conceive of his parents' power over and obligation to the family. As other objects of authority float into range of the younger child, such as Congress or Senators, our interviews revealed that they were more likely to be interpreted as subordinate to the President, his helpers.

When the child grows a little older, however, the potency of the President recedes although he always remains a prestigious and powerful figure. But now the child considers that this power is shared with Congress, the Supreme Court and even with the people at large.[4] They see little conflict among the political authorities even though the President continues to occupy a position of high status.

The early threads of hierarchy would seem to help to draw together the child's image of authority into some coherent whole. But even when with age the sense of hierarchy is modified, the varied authorities do not become totally unconnected in the child's mind. If they were, there could not be any power-sharing (much less subordination) among the various elements. Thus even though each figure and institution of authority is a discrete unit, the very familiarity of the concept "government", the perception of hierarchical structure, and the later idea of co-operation of power-sharing encourage us to infer that the child is not construing the structure of authority in a totally fragmented or piecemeal fashion. Something larger than any single object of authority seems to permeate the child's thinking even though he would be unable to express this latent concept in discussion.

Finally, if this is not enough to persuade us fully, we can find additional support for this interpretation in what we now know about the nature of the learning process itself. It is a peculiar characteristic of the way children learn that they are often able to grasp an idea well enough to deal with its parts before they can clearly articulate the whole idea itself. An appreciation of the whole may be latent and implicit in the very capacity to handle the parts. This seems to be an integral part of the way the child comes to comprehend broader and more abstract concepts in all spheres of knowledge.

Thus "...in the intuitive phase of concrete operations (approximately ages four to eight), "it has been proposed," [the child] is capable of grasping many of the basic ideas of mathematics, the sciences, the humanities, and the social sciences...The apparent mistake of past generations was to assume that the child had to be able to present a formal structure of thought (for example, the formulation of a proof for a geometric theorem) in order to demonstrate his grasp of the concept. The child in the stage of concrete operations cannot give a formal organization of complex theoretical ideas, but he can solve many problems depending upon such ideas."[5]

We may speculate that the same mode of thought applies to the acquisition of political knowledge. Although the young child especially, is only able to discern discrete parts in the structure of political authority, those that for one reason or another are salient for him, even by grade 2 he would seem to be assuming some larger entity. Through it the individual figures and institutions are somehow interconnected. Even though the child is as yet incapable of formally presenting so complex a theoretical idea as "the structure of political authority" or "the political authorities in toto", he is nonetheless able to react to specific objects of authority as though they are part of the large entity. It is his way of expressing a latent concept. The discreteness of his orientations just reflects his way of grappling with the complexity of his cognitive political space.

This conclusion has an important bearing on our understanding of the way diffuse support emerges. As we now know so well, the children in our test group display a uniformly high respect for the individual components of political authority. We have on occasion proposed that this may be a product of spill-over from their early high regard for the President and policeman. We may now go somewhat further to consider whether the level of approval for all authorities does not represent rather a concrete manifestation of positive feelings that the child is acquiring towards political authority in general. If this is so, we have laid bare the very beginnings of the tap roots of respect for political authority. In the child's respect for the individual objects of authority what we have probably been observing are the lesser shoots of respect that must presuppose this deeper and richer source of nourishment. This conclusion would seem to be as plausible an explanation for the uniformity of regard for all objects of political authority as any hypothesis about spill-over or "halo" effect from early personal figures to later impersonal objects. At the very least both types of processes are probably at work and help to account for the high input of support for political authority.

This conclusion—that the child is learning to orient himself to the structure of authority—is critical for our analysis. It means that in the evolution of the child's general membership role, we need not conceive of the child simply as being linked to the regime in a piecemeal way. He is learning that the idea of political authorities goes beyond any particular objects he may happen to know. As additional

figures or institutions come into view, we can expect that these will elicit a similar response by virtue of the child interpreting them as part of the same set of objects. In other words, in becoming simply a member of a political system one of the first things the child learns is to extend support to (or reject in varying degrees) whatever he considers to represent the political authorities. Theoretically we have already identified this as a condition for the persistence of any and all political systems.

It is clear that an understanding of the origins and development political orientations about diffuse support does more than illuminate one of the sources of regime persistence. It enables us to see this support as part and parcel of the more generalized political role, that of a new member, into which the child is stepping. Membership involves acquiring an early awareness of political authorities in some generalized sense and the acquisition of a set of support responses to these authorities.

BEYOND THE AMERICAN SYSTEM

Now that we have conceptualized our findings more broadly and
have interpreted them as contributing to the delineation of an intro-
ductory membership role, the base of all subsequent behavior in the
American political system, we may ask whether our findings transcend
the particularity of this single case. For our theoretical purposes
it would be rewarding if we could argue without fear of contradiction
that politicization, personalization, institutionalization and ideali-
zation are the fundamental means through which any and all political
systems strengthen their capacity to persist.

Unfortunately this would be putting our inferences in much too
strong a form, ascribing to them a greater generality than they per-
mit. Our sample of children severely limits the validity of any gen-
eralizations. Yet there is good reason for holding that we have ob-
tained some significant clues about the primary socialization of sup-
port applicable to instances over and beyond the American political
systems.

The Limitations of the Sample

There is little question that our sample imposes narrow limits
on any universal generalizations we might hope to obtain. For one
thing, we have after all only one case study—a single political sys-
tem at one moment in time. Our test children represent not a probabili-
ty sample but a group that was selected to bring out divergent patterns
of orientation in the United States towards the political authorities.[1]
Furthermore our test group includes only white children at schools in
metropolitan areas with no significant numbers of children from the
most depressed economic sectors of these cities and no Negroes. Accord-
ingly we have no data on a group in which political socialization might
be proceeding at a very different pace and in which less awareness of
and less positive affect for the political authorities might be present.

Nor do we have definitive evidence that what is learned early in
life will even ameliorate the effects of contradictory experiences
later in life, much less endure in pristine form—even though we have
posited the probability of childhood influence on adult behavior.
Neither have we engaged in a real-time longitudinal study, one in which
we take a set of children and trace through their political development
across the elementary grades. We have only what we have called a synthe-
tic longitudinal design. We assume that because all our test children
fall into one generational group, responses of our seven year olds, for
examples, are probably not very different from the kinds of responses
our thirteen year olds would have given if we had tested them when they
were only seven.

Furthermore, as we pointed out in Chapters XIV and XV, our techniques prevent us from sorting out the differential effects of social maturation, biological growth, and generational experiences. It could possibly be that our findings are valid only for the particular generations adjacent to the one we have tested. Perhaps the saliency of the authorities and their initial idealization are largely products of the modern epoch. In the United States the negative attitudes towards government of the 1920's have yielded, under the impetus of the new role adopted by government during the 1930's, to a more relaxed acceptance of government responsibility for sustaining some minimal level of social welfare and economic activity. The children ot those adults who lived through the Depression could be expected to look more favorably on the actions of the authorities, and limited evidence seems to indicate this to be the case.[2]

It is conceivable too that idealization of the political authorities can be time-bound in another way. They may be representative only of the immediate generations of the past and need not describe those of the immediate future. If critical issues of the 1960's are transforming the attitudes of young people, a residue of their experiences may carry over to later periods. The politically active youth of today --those who man the picket lines protesting against the war in Vietnam and the draft and who actively challenge the disparity between prosperity and poverty and between democratic promise and fulfilment--together with those who stand by quietly but not unsympathetically, will undoubtedly not be able to shake off the memories of these experiences for a long time. If their bitterness towards political authority remains, it could be transmitted to their children. Affect for the authorities among the children of the future might be less enthusiastic, not nearly so idealizing, as it is true of the children we have tested.

Hence, our ability to establish with a reasonable degree of confidence whether our test children, in their idealization of authority are probably representative of the primary socializing process may depend on the time constraints we introduce even within the single system we have examined. For all generations the degree of attachment to the system achieved through personalization need not be as high as we have found nor need affect always move in a positive direction. The intensity and direction (positive or negative) of affect would be likely to depend upon generational influences.

Furthermore when we move beyond the United States to other systems there may even be some question about the universality not only of idealization but of personalization as a vital perceptual and cathecting device in relationship to the most inclusive (national) authorities. The linkage between children and the political system may be contingent on the nature of the regime structure, as we have suggested in Chapter XIV. It could be that at the most inclusive system level, personalization flows only from the prominence of the chief executive under conditions peculiar to the present epoch.

377

As an integral part of the new responsibilities assumed by political authority in modern mass society during the 1930's, the executive arm of government has moved to the forefront of the political stage. It is conceivable that as in the more distant past, perhaps once again in the future, chief executives may recede into a more cooperative, egalitarian structure of authority without nearly the contemporary degree of prominence. If so, for future generations of children, the political chief executive may become less significant in the processes through which linkage to the political system occurs. Also, in those systems where the chief executive plays a more limited role today, as in Switzerland, perhaps other figures or organizations even now come to the fore. In short, the political structure itself may be a critical variable in shaping the nature of the connecting points.

The universality of early politicization is even more questionable than that of personalization. From our one case study it is not at all clear whether politicization may not be limited by the particular characteristics of the American type of system as a whole. This is an important point, and shortly we shall explore it as well as the probability of personalizing processes more fully.

But let us accept the plausibility of drawing only the least interesting kind of implications from our findings. Suppose that our study has indeed described only the profile of one generation and for the United States alone. Would this destroy its utility? Not necessarily. At the very least our study would provide a base line against which other generations might be compared. An analysis of trends would become possible, and for the first time we would be able to sort out significant generational shifts. At the same time it would raise intriguing questions about how identification of and attachment to the structure occurs in other generations and in other systems if not through politicization, and idealization, personalization, the effects of these alternative connective modes, and the reasons for the differences.

However, the likelihood of one aspect of the early membership role--that of personalization--being generational as against age-determined is not too high. Biological as well as social maturational factors would seem to account for early personalization of authority rather than the fact that we are testing children of a certain generation. Regardless of the nature of the structure of political authority, we have suggested more than once, it is difficult to conceive of how a young child especially might apprehend political authority. His emotional and intellectual equipment is too limited to make any other means plausible for perceiving and cathecting authority. Regardless of generation or system, maturing members will probably reach out to the political structure through its most readily personalized aspect, a point that we shall reemphasize shortly in relationship to types of societies other than the American. Furthermore, our conclusions are consistent with what we know about socialization in other areas of behavior, as we have indicated from time to time. But we would not deny that the acid test will come as new generations with new experiences move across the political stage and as replicative research is mounted in the United States as well as in other, dissimilar kinds of system.

The Uniqueness of the American Experience

Even if we had a representative sample, however, and could validly extend our findings to all children in the United States and even if we could assume these findings apply to all recent generations as well, the question could still be raised as to whether our conclusions are not in the end peculiar to the American political system. It is arguable, for example, that adults in the United States have been shown repeatedly to have little interest in politics, and although the level of political concern may slowly be changing under the impact of continuing international and domentic crises, at least during our test period, low political interest is still a dominant characteristic. Politics as an area of great salience and concern for adults has been easily pre-empted by family, job, and leisure.

On these grounds it could be argued plausibly that children might readily construe the lack of adult involvement and concern, for consensus, trust and faith in the political authorities. With no deep and conflicting feelings about political issues, adults might transmit to their children an apparently benign and tolerant political air. The children could interpret this as evidence of the essential benevolence of everything connected with the political sphere. Pursuing this line, it could be pointed out that in other systems, where politics may play a more meaningful role for adults, primary socialization might be different. Among adults in France, for example, the cleavages about politics and the attendant political disillusionment with, if not cynicism about, politics seems to be readily transferred to the maturing children with some dampening effect perhaps on their perception of politics and even on their attachment to the system.[3]

The severity of socialization about system politics

Perhaps it is true that the American political system embodies certain special characteristics relevant to primary socialization, but if so, it is probably not for the reasons just discussed. The fact would seem to be that not all forms of politics are low in salience for the members. To be sure, in comparison with partisan politics other interests have commanded a higher priority. We might expect adults to transmit the same ordering of concerns to children. But for system politics—those matters that relate to identification with and support for the basic aspects of the system and often referred to as patriotism, loyalty, allegiance and the like—we may appropriately doubt whether adults do display the same apathy or indifference.

Rather, the idealization of political authority among our group of children may spring from deep historical roots. In a society such as the United States in which at the turn of the century a vast variety of nationalities came together in an historically very brief period, this

379

emphasis on system politics may mirror a deep anxiety about the diffi-culties of integrating the population and crating a strong sense of political identification. It may represent a typical response to fears of cultural, ethnic and linguistic cleavages.

In the past the influx of immigrants into the United States was accompanied by widespread, conscious policies seeking to blend them into a culturally homogeneous whole in the image of the prior Anglo-Saxon society. This was the dynamics behind the subtle but dominant underlying ideology about America as a melting pot of nationalities. This has constituted a potent belief system. Immigrants were expected to give up their languages and to modify drastically these national iden-tities for the specific bountiful rewards foreseeable upon admission to America. Immigrants arrived anticipating that they would abandon these particularistic identifications. They positively sought to melt into the common pot.

In the schools there was little question that it was the task of education to provide what was considered to be an appropriate kind of civic or citizenship training. "Civic pride" or "patriotism" was to be specifically and directly inculcated. If the curriculum has any signifi cance in the socializing processes, these deliberate policies helped to assimilate or blend the offspring of immigrants to the second and third generations. In fact, the content of the curriculum in the social sciences was seriously crippled by the use of educational insti-tutions in this way, and only in recent years have the elementary and secondary schools just begun to escape the consequences and return to professionally dictated subject matters.

Outside the schools the pressures for conformity and homogeneity in underlying political sentiments were equally intense. Patriotic societies abounded, patriotic oratory rang true to the popular ear even when it rose to hyperbolic heights. The suspicion of disloyalty or un-Americanism defined in monolithic terms appeared to be the most heinous of crimes. McCarthyism of the 1950's revealed these forces in a garish light.

It is not true, therefore, to conclude that in the United States politics has been a matter of low salience and interest. At most this description can apply only to partisan or allocative politics. System attitudes have not been left to chance. Socialization in this sphere has had a great deal of meaning in a system whose ethnic mixture and po-tential for divisiveness might lead it to doubt the strength of its own unity and the unity of its own purposes.

It would appear that system politics is an area of severe socializa-tion. The American system may be exemplary for the low level of politi-cal involvement among its members; it may be equally unique however in placing an extraordinary emphasis on civic or political education for the

380

young. For example, in the Soviet Union, where political education
has been thought to weigh heavily in the school curriculum, surprising-
ly less time seems to be devoted to political matters in the elementary
and secondary schools than in the United States. Political education,
Bereday and Stretch estimates "did not find an unusual amount of politi-
cal exposure on the Soviet side; we found, in fact, that the Americans
demand greater exposure in spite of the American school year being shorter
...In the United States in grades 5 to 12 almost 46% of school time was
devoted to some form of political and social education. In the Soviet
Union the relevant percentage for grades 5 to 11 was only just short of
38%.[4]

It could be that in the United States this concentration on citi-
zenship education has provided a powerful impetus towards the idealiza-
tion of political authorities by children and accounts for the little
cynicism or distrust evident as well as for the surprising consensus
among the children regardless of sex, geographical region and classes.
Children seem to be blended into a common mold with respect to system
attitudes; no glimmering of a critical awareness of the political au-
thorities is apparent.

We know that in other areas of behavior such as toilet training,
sex behavior, or the handling of aggressions, cultures will differ in
the severity of childhood training.[5] We might also suspect that this
is equally true about the political sphere. It may be that the American
system is unique among mass industrialized societies in the severity of
primary socialization about system politics. In this event, generaliza-
tion from it to other systems would need to be handled with extreme care,
especially to those older systems where ethnic integration is not of such
moment, as in Britain or France.[6]

Generalization to multi-ethnic societies

It would appear however that the hypothesis about the severity of
socialization in the United States in the area of system politics might
with some justification be extended to other types of multi-ethnic so-
cieties, especially those still struggling with the development of their
political systems. We say "to other types" because it does seem that the
United States is and has been a multi-ethnic society however unwilling
it has been to conceptualize itself in these terms. For certain histori-
cal reasons, perhaps because the major minority ethnic group rose out of
legal slavery and then has remained in social bondage for almost a cen-
tury, American society has been able to deny the reality.

The racial crisis of the 1960's has vividly revealed that even
though the prevalent white and Anglo-Saxon ideology has been built
around melting-pot aspirations and that this has militated against al-
ternative ways of conceptualizing the American social context, the Uni-
ted States has been unable to escape the strife and turbulence of many

other multi-ethnic societies. American ideology has failed to constrain American reality. Politically this may ultimately force the United States to modify its self-image radically so that it may begin to re-interpret itself for what it really is, a society composed of at least two large and residentially concentrated ethnic groups--Negro and Span-ish-American--in tense juxtaposition to the dominant white, English speaking population.

The same severity of primary socialization at the system politics level found in the United States may therefore turn out to be characteris-tic of other multi-ethnic societies in which assimilation is the prevalent norm. It could be that in other systems like the American, where inter-ethnic tensions have been muted by the unchallenged dominance of the majority group and its assimilative norm, the authorities will also tend to be perceived by children in more personal and idealized terms.

Socialization of Direct versus Mediated Support

Severity of political socialization in the area of system politics therefore would not appear to be necessarily unique to the American system, even though there are probably few other systems in which a melting-pot ideology has prevailed so easily for so many decades. We might also surmise that other aspects of the socializing processes might be found even more generally. As we have already proposed, the burden of our ana-lysis presses us towards the conclusion that wihout some means for politi-cizing children and for coupling them through personalization to the structure of authority, we could scarecely imagine how maturing members in most systems could be brought to accept the legitimacy of the regime. The emotional and cognitive limitations of children would seem to require some high degree of personalization in their younger years and in one way or another, if a system is to persist, the children must become aware of the presence and power of the relevant political authorities. It is highly unlikely that in any political system childhood political sociali-zation would be largely neglected or that most of the burden of apprizing members of the political authorities and of generating responses about them would be left to adolescence and beyond. Personalization and politi-cization during childhood are likely universal cathecting processes.

But the location of these processes need not necessarily be the same in other systems as they are in the American. In the latter the child is withdrawn from the family, as it were, and brought out into the broader society. The political authorities have direct access to him just as he will later have to them. Intermediaries do not bar the child from the authorities. Rather the child sees the structure of authority himself and he responds to it directly in his own terms. The capacity to do this is closely related to the whole personalizing and politicizing processes. In short the input of support in the American system is directly from the child to the authorities.

Need we infer from this that we should expect to find an equally direct input of support in all other political systems? We shall conclude that this is not a necessary or even tenable generalization.

Direct support for the authorities

A peculiarity of the American political system (and probably others of the same type) is that the adult member can and does put in support for the various major political objects (authorities, political community, and the regime) directly. The authorities in turn can and do appeal directly to the members rather than through intermediaries alone. The authorities expect that the outputs they create will frequently have a direct impact on the individual or can be made to do so if they, the authorities, so choose. The system's rules do not provide for a necessary go-between in all cases nor does the nature of the social structure compel such mediation. This is not to say that frequently the authorities and the members may not be related through mediating interest groups, vocational association, regional organizations, or even other formal political units such as states or municipalities. But the authorities do have regular means for direct access to the membership without having to filter communications or administrative actions through others.

Important kinds of consequences for the relationship of the ordinary individual to government and of his exposure to the influence of political authority flow from such direct access. The philosophy of pluralism, from Duguit, Krabbe, Cole, Laski and others, sought to devise an ideology and structural arrangement precisely for the purposes of sheltering the individual from the hazards of this dire exposure to the power and persuasion of the authorities. But aside from the dangers or advantages (and the ameliorating circumstance that the individual in return may have direct access to the authorities through the vote and informal means), the political fact is that in the type of system we find in the United States, under conditions of large-scale, mass industrialized society, such symmetrically direct access between the authorities and the members of the system does exist. Does it begin in childhood? If so, ought we to expect that this will occur with equal prominence in the primary socialization of all political systems?

In the American system our research suggests that the fundamental source of direct access derives from the success with which the socializing processes are able to disengage the child from his primordial ties to the nuclear family and to bring him as a distinct individual under the broader canopy of the political structure. This appears to be the critical starting point in the evolution of direct support in the system.

If the child could not be freed from his initial and exclusive bonds to the family, as we indicated in Chapter XIII, it would seriously embarrass the authorities in their efforts to reach out to him directly, certainly during the early and presumably formative period of childhood.

But we do know that in the American system the child at an early stage
has become fairly well political: he is able to distinguish the public
from the private sphere, he accepts the higher authority of the police-
man, and he recognizes the greater power of the political as against
parental authority. This is strong testimony to the fact that before
the end of grade school the child has moved beyond the narrow confines
of the family to the broader society and has begun to accept the validity
of his own availability to the authorities.

This has many consequences for the system, as we have noted. But
what we now have to recognize is that for the persistence of the system
or for the input of support for the structure of authority, even though
personalization and politicization may indeed be universal processes,
the generation of direct support need not be. This may be a function
rather of the peculiar conditions of the class of systems of which the
United States represents one instance.

It may be critical for the United States, for example, because
the kinds of efforts in which a modernized society is engaged requires
a fairly high level of popular commitment and performance -- through
personal services, payment of taxes, and behavior conforming to a vast
number of legal rules and norms. Without direct access to the members
goal-directed collective action would be enormously complicated, indeed
even impossible. In a mass society, no authorities could afford to bar-
gain and negotiate for compliance through intermediaries representing a
vast network of small units such as heads of nuclear families. The
role-specific, stratified social structure probably makes such direct
access unavoidable, at least in comparison with a lineage structure in
which heads of large kinship segments could act as intermediate level
authorities.

Plural groups do of course exist, and these may serve either to
enhance or diminish the input of support for the authorities depending
on the political circumstances. To the extent that the group leaderships
are conceived to have the backing of their members, the leadership may
act as intermediaries between the political authorities and the individual.
But over and above these groups, the members of the system at times act
simply in their unmediated roles as members of a system, responding dir-
ectly to the political authorities. It is the beginning of this capacity
of the authorities to bypass plural groups that we have detected during
primary socialization. Socialization about the input of mediated support
transparently belongs to another phase of the life-cycle.

Mediation of support for the authorities

However, regardless of the function of direct support in American
type systems, we cannot generalize from this proposition to assert that
socialization must produce a similar pattern of direct input of support
for all systems. Under other conditions a system may have far less

384

opportunity for direct access to the members. Where subsystems exist, such as lineage segments in tribal societies, or cohesive ethnic, linguistic or religious groups in modern and developing societies, or even corporate regional entities (as in a confederal system), these may all present narrow filters or even barriers impermeable to the political authorities. Schools, mass media, and other cultural means may have little penetrative effect. There would thus be little opportunity for the children in these subsystems to perceive distant figures or institutions of authority, much less to acquire sentiments about them, either positive or negative. The accompanying residential and cultural localism and regionalism (communalism so called, in India, for example, of "global society" in French-Canada) tends to disconnect the members from the national symbols and representatives of authority.

Cohesive subsystems like these, however, may but do not necessarily impose stress on the regime of a political system. At times these arrangements may be the only conditions under which a regime may endure and a political system persist. But we would here expect that in these systems children would grow up to look to the lineage, ethnic, linguistic or regional leaders as their authorities. What is of particular significance is that at this level, if our conclusions about socialization of support are correct, children would still go through the personalizing, politicizing, idealizing (or "hostilizing") and institutionalizing processes, except that the relevant authorities would be at the subsystem level. The subsystem authorities would represent gatekeepers who could regulate the flow of support to the authorities of the more inclusive political system.[7] In French-Canada for example, a French child might be aware of the Premier of Quebec sooner than he would be of the Prime Minister of Canada. In much the same way the members of peasant societies, even of an ethno-linguistic homogeneous type, because of lack of comprehensive and penetrative communications, might rely on the village and regional chiefs, headmen, notables and the like to serve as a bridge to some distant and unknown authorities.[8] To some extent there are mediators of supports as pact of the infrastructure of all modern societies as well.

System persistence and indirect support

It is clear that having found early socialization of direct support for the structure of political authority in the United States, we need not postulate that systems persistence is consistent only with this kind of early learning about support. We are only proposing that no system will be possible unless it can support some kind of structure of political authority at the most inclusive system level. In the American system, if our data are not atypical, this seems to be achieved through the initial socialization of direct support for the national authorities as well as a local symbol of political authority. The process of socialization is one that draws the attention of the maturing members to a focus on similar political objects at the polar extremes in the system. These become system symbols and thereby they lend a degree of integration and coherence to the political community that other systems may lack.

Yet we do not suggest that other types of systems have no alter-
native means for breeding this kind of diffuse support for the authori-
ties, even though the process is an indirect one. In those systems in
which local, regional or communal ties are strong, we would expect the
maturing children to be far less aware of the overall system authorities.
But persistence of the system need not be undermined. The strength
of the bond between the members of a subsystem and their immediate au-
thorities on the one hand, and between the latter (now conceived of as
gatekeepers or mediators) and the inclusive (national) system authori-
ties on the other, will establish the level of diffuse support for the
regime. Today we would expect to find Switzerland somewhat closer to
this indirect support input model of socialization than say France,
Great Britain or the United States.

At the very least, it is clear that our data have given us some
understanding of how a stable system goes about providing diffuse sup-
port for the structure of political authority from early childhood.
Our analysis leads us to believe that similar kinds of processes may·
be found in other types of systems even though where localism of various
kinds may prevail, the authorities at the most inclusive level of the
system may play a lesser role in primary socialization than they do in
the United States. Yet we would suspect that the personalizing and
politicizing dynamics of the process through which maturing members
are brought to accept the legitimacy even of the intermediate authori-
ties is probably akin to what we have found for the most inclusive au-
thorities in the American system. It is at least a useful working hy-
pothesis in approaching other types of political systems.

Change, Stability and Persistence

In spite of our arguments to the contrary, it is still possible
that our inferences about the characteristics of socialization with
respect to the structure of political authority are less universal
than we may think but for reasons other than those we have yet advanced.
It could be that however valid our conclusions are about the socializing
processes, at best they apply only to stable political systems. Per-
haps at most we have just discovered the·way in which new members learn
to adapt or conform to existing political patterns. Could we with justi-
fication expect that our findings would have applied equally well if we
had examined a clearly unstable system?

It is readily understandably why our research might be construed
as having implications only for stability. For one thing until the end
of the 1950's at least, the United States has shown all the earmarks of
a relatively stable system. It would have been very surprising indeed
if the children had not reflected this, that is, if we had found that
the children were not positively supportive in their earliest sentiments.
At the same time the theoretical objectives of our inquiry could also

be easily misunderstood as involving us heavily in a search only for the conditions of stability. Misconstruction of this sort represents such a great danger that we might profitably re-examine our theoretical foundations for a moment in order to clear away any lingering ambiguities about the relationship of system stability to our basic purposes. With a substantial body of data and analysis now behind us we shall be able to reassert, at a new level of understanding, the point we made at the outset of the book. There we sought to establish that our theoretical guidelines would lead us towards an understanding of the relationship of socialization to system persistence and not to system-maintenance or stability however much attention the latter subject would of necessity receive in a study of the American system.

Structural legitimacy and stability

On theoretical grounds we had pointed to the need to look for the beginnings of diffuse support in the early growth of a belief in the legitimacy of the authority structure, what we called structural legitimacy. We had contended that over time every system will probably accumulate a large repertoire of responses for coping with stress on the input of support. Among them are typically found efforts to increase the quantity and nature of specific rewards for the members, the use of rational persuasion to arouse favorable sentiments, and the application of coercion in varying degrees. But few systems manage to sustain sufficient diffuse support by these means alone. Efforts are also usually made to cultivate a deeprooted belief in the legitimacy of the authorities and the regime, including the structure of authority as one of its major components. In most systems the members are encouraged to believe that the structure through which the authorities operate is legitimate or valid, that the arrangements for distributing authority in the system are right and proper and as such ought to be accepted.

Promotion of a belief in the structural legitimacy of the regime may be described therefore as a characteristic system response to stimulate the input of support. This response goes beyond seeking the mere approval of a system; it requires a deeper conviction, that the system is ethically acceptable. A belief like this may even constitute a more stable base of support for a regime than a rational culculus of self-interest; in childhood we may suspect from our findings, it is virtually the only foundation that is laid.

On theoretical grounds, therefore, we were deeply sensitive to the desirability of testing whether support in the form of a sense of legitimacy itself makes a start in childhood. But the continuing dialogue over the whole history of political philosophy cautions us that legitimacy is no simple idea, that it may include many elements difficult to break down for empirical research. The limited maturational level of the children made it virtually impossible to examine directly any feelings they might have of this complex sort.

Nevertheless in one instance we did come close to the general idea of legitimacy. We asked our test children, it will be recalled, whom it is most wrong to disobey,--mother, teacher, father or policeman. The policeman was the dominant choice.[9] This encouraged us to believe that the child was beginning to acquire some sense of the legitimacy of this symbol of authority external to the family.

We may now go even further. This question about obedience, we suspect, really reflects the overall implications of our findings about the high level of respect for all authorities and not for the policeman alone. To be sure, esteem and regard for the various figures and institutions of political authority are not identical with a belief in their legitimacy. But it is highly unlikely that children would display such feelings about these authorities without at the same time considering that it was ethically right for them to care for the country. Drawing on Piaget for support, we have already suggested that this is implicit in the child's specific conceptions of the President and policeman.[10] Here we may broaden this to infer that it is also undoubtedly implicit in the very positive images of all the authorities.

This strongly suggests therefore that we have perhaps pinned down one of the earliest sources of that elusive and complex sentiment that we call the belief in legitimacy. It seems reasonable to conclude that if primary socialization can make any contribution to the durability of a system, it must do so through this sentiment at least. With this implication in our findings so prominent, any reader would be fully justified in feeling that perhaps after all, despite our early protests to the contrary, the major emphasis (perhaps unintended) of our research has indeed been upon the determinants of stability and our major findings would probably be relevant only in this context.

Stability and persistence

It should be evident by this time, however, that in fact our interest in the childhood beginnings of feelings of legitimacy derives only from the light it throws on the way in which a maturing member is brought to accept (or reject) the structure of political authority. It helps us to understand how at least a class of political systems, those we call stable, such as the American has been, manages to persist through obtaining support for some structure of political authority. Legitimacy is therefore a kind of sentiment that is relevant both for stability and persistence.

It may appear to be but a quibble thus to attempt to differentiate between these two concepts. But there is a vital theoretical distinction between them. Recognition of this distinction permits us to lift the study of political socialization out of a realm of interpretation in which it is seen largely as a device to perpetuate the status quo.

Persistence refers to the capacity of a society to provide for the making and implementing of binding decisions. Without some kind of regime, including as this concept does the political authorities, such allocations would be impossible.[11] In some systems the preference is of course for stable regimes. But in other systems dissatisfaction (open opposition to) with the regime or the particular way of organizing political authority may be sufficient to force changes in its structure. On occasion, a system may undergo a succession of transformations in the regime. Historically this has been true of France in its shifts through five republics and an equal number of intermediary regimes. In other instances, as in many developing systems in Africa today, the regime may totter on the brink for long periods of time giving all the appearance of instability but never quite collapsing.

Even though a regime may reveal itself as very unstable, however, the members of the system may be able to continue to make and implement binding decisions, even if not with the orderliness or effectiveness implicit in most ideals about good government. But general theory does not seek to measure a system's ethical adequacy; it simply hopes to understand and account for variations in a system's operations. In short, the stability or instability of a system as a whole each represents a condition consistent with the persistence of the system. There are other important relationships between persistence and stability or instability but these do not concern us at the moment. All we need note is that instability does not preclude the persistence of some kind of political system. On occasion it may be a central mechanism for achieving a desired transformation in a regime considered to have outlived its usefulness. Thereby it may contribute to the persistence, in form, of a system for the authoritative allocation of values.

From the point of view of our theoretical objectives it is only a matter of incidental interest that the American system had been stable in the years prior to and coincident with our research. We selected this system not because of its stability but for other reasons already stated. However, the fact that it is stable does limit the scope of our findings. Strictly speaking, if from our study we do learn anything about the input of diffuse support for the structure of political authority, our knowledge should apply in the first instance only to stable systems. Whether similar modes of contact between children and the structure would occur under conditions of rapid or disorderly change in the United States would require research under different conditions or in other types of systems that typically experience unstable regimes.

For theoretical purposes, however, our conclusions would not have been different if in the American system we had discovered that primary socialization conduced to political instability. This might have been the expected outcome, for example, if we had found that children first learned to distrust or hate the President and policeman and, in later grades, ignored or rejected them together with such institutional representatives as the Supreme Court or the government. It may well be that

some segments of the children in the United States, as in the most poverty stricken urban and rural slums, do in fact have feelings closer to these than to the feeling of the children of our group.[12] Even children in the lowest socio-economic status of our group are not so impoverished as to fall into these depressed sections of the population.

But even with these findings and assuming for the moment that children such as these grow up to fight for changes in their regime, our inferences about the socializing processes for the persistence of some kind of regime need not have been different. It could be that for the children to develop hostility towards the authorities, it is also necessary that they become politicized enough to differentiate parental from political authority, that they make personalized contact with figures of authority so as to learn whom to hate, and that they go through a process of depersonalizing authority so that they may transfer their negative affect to institutions. Indeed, as we have observed before, we would find it difficult to visualize some alternative set of politicizing processes.

It should be clear by this time that we are concerned only with the underlying processes through which maturing members in a system acquire supportive orientations about the regime. We have repeatedly cautioned that this support may move in a negative as well as a positive direction. To the present we were compelled to confine our remarks to positive support only because this is the kind we have consistently found to dominate among our group of children. But if we had discovered widespread negative support (hostility), however interesting this might have been for those concerned with sustaining something called stability, for us it would simply have indicated that some shift might be under way in the form of the regime. Instability there would not necessarily be interpreted as contributing to the destruction of the system, although this is always a possible outcome. It might however also represent the beginning of a shift in support to some new kind of regime under which the members of the system could continue to make authoritative allocations. In this event the change would have contributed to the persistence of the system.

In short, in seeking for an understanding of the sources of diffuse support, such as legitimacy, for a regime, we need to realize that negative sentiments need not prevent a system from persisting over time. The change implicit in the input of negative support may well be a major condition for the persistence of a capacity to make authoritative allocations.— We would expect that the presence of negative support among most of our test children would not have changed by very much our inferences about the basic processes through which the children become aware of the structure of authority and learn to relate to it. We have some a priori reasons for believing therefore that politicization, personalization, institutionalization and idealization (or "hostilization") may be universal socializing processes in childhood with regard to the structure of political authority.

APPENDIX A

Methods and Procedures

Design

This study was undertaken when extremely few guidelines
existed for identifying relevant variables or forming working hypotheses.
Indeed, scholarship had advanced very little in the centuries since Plato
and Aristotle first raised the problem of the role of political education
in the political system. Essentially no firm evidence was available con-
cerning when in life new members of a political society typically learned
their most basic lessons. What little empirical data had come to light--
as in Hyman's compilation--seemed to assume that adolescence or early
adulthood were the most politically formative years.

To test this assumption, a pilot study with high school stu-
dents in the Chicago area was carried out in 1959. The finding on this
point was that few if any developmental trends in orientation were de-
tected during these years. Thus, attention turned naturally to the
years before the child reaches high school. And, in the series of studies
that have culminated in this report, investigation moved to considera-
tion of what aspects of fundamental political consciousness come into
being as the child makes his way through elementary and intermediate
school. Our questions then became: "When does the child first begin
to develop his political awareness?" and "At which points in his ma-
turation does his political consciousness become transformed into atti-
tudes and cognitions that begin to approximate those of adults?"

Given such purposes, the ideal research design would have been
to identify a number of representative children who could be questioned
and observed over a broad span of years in order to record the moments
of origination of political orientations and of their subsequent develop-
ment. Given the primitive state of knowledge in this area at that time,
a large investment in longitudinal seemed to be not warranted, however.
Rather, the reasoning was that such an ideal study design could best be
executed only after a more modest series of exploratory studies had been
carried out in which new concepts, methods and hypotheses were generated.
With this necessity in mind plus the usual situation of scarce economic
resources to be used for research, it was thought more appropriate to
undertake a less ambitious, exploratory program, using modal rather than
broadly representative children of elementary and intermediate school age
and a cross-sectional design.

The operational form this design took accorded with the usual
practice of educational and psychological research, namely, purposively
selected respondents from school populations. One important additional
objective of this design was to obtain children at relatively close age
intervals in order to observe year-by-year shifts in political orienta-
tion. Another objective was to begin as early in the grade span as pos-

sible in order to be able to observe the earliest developments, if these began near the time when the child first entered school.

Limitations, of course, were imposed by the nature of the research instruments that we were able to devise, so that in fact, we had to begin with grade 2 children. As we found in pretesting, only at grade 2 were children able to read well enough to follow simple questionnaire items that were read out to them. First grade and kindergarten children appeared almost universally in our pretests to lack this capacity. In the end therefore we have to make a practical compromise by beginning with grade 2 children and obtaining respondents at each successive grade level through grade 8.

Besides grade we decided that three other variables were of sufficient theoretical interest that we ought to make certain that we had relatively even distributions on them. These were sex, socio-economic status and region.

Sex was a relatively straightforward matter in that almost no systematic separation of boys and girls either by schools or classrooms existed in the schools that we were apt to obtain respondents. Thus we were able to rely upon the normal rates of incidence of males and females without further attention in our selection procedures.

Social status was less simple in that public schools tend to be somewhat diverse in terms of the social origins of their pupils; but, by taking equal numbers of what were considered by the local school authorities to be "middle class" and "working class" schools we were able to insure no great preponderance of either one in any given metropolitan area.

For region, our procedure was to divide the country into four major regions--Northeast, North Central, South and West--and then to select a large and a medium sized city in each region for inclusion. In a few cases negotiations with school officials became bogged down, so that alternative cities were chosen and new negotiations were initiated.

For reasons both of economy and political feasibility, we limited our test population therefore to urban children, and, for the same reasons, to white, public school children. The target population was conceived therefore as consisting of modal children in elementary and intermediate schools whose processes of individual political development could serve as a benchmark for future studies. The latter might include especially those types of children deliberately excluded: non-whites, pupils at private and parochial institutions, and those living outside major metropolitan areas. The rationales of exploratory scientific strategy, economy, and feasibility of access therefore suggested a purposely drawn set of subjects (N=12,052 in the main group) that could serve to identify when (and thus potentially, under what circumstances) the child begins to learn his political lessons.

Prior to the selection of this main sample, we also carried out a sizeable series of pilot and pretest investigations with other respondents in Illinois and Indiana. Both the distribution of respondents in the final test group and that for the pilot and pretest groups are reported below.

393

Table A. 1. Number of Respondents by Region, City Size, Socio-Economic Status of the Neighborhood of the School and Grade in School [a]

Region	City Size	Socio-Economic Status	Grade in School 2	3	4	5	6	7	8

[a] The CA-9 questionnaire is reproduced as Appendix B below.

Pilots, pretests and other data

In addition to the main questionnaire, we developed a series of prior instruments, some of which have been referred to above. Two pilots preceded the project reported in this study, both of which were carried out in 1959. One consisted of a questionnaire administered to approximately 1800 ninth through twelfth graders and the second a questionnaire filled out by 366 second through eighth graders--both in the Chicago area.

In the project proper the first series of data collection activities centered around nearly a hundred semi-structured individual interviews with children in grades one through eight in the Chicago area. Secondly, children in other schools were asked to draw pictures concerning such subjects as government and citizenship. Thirdly, a dozen different pencil and paper questionnaires were developed using a variety of content areas and item formats, including a number of picture option items found to be relatively successful in engaging younger children. Finally, two supplementary questionnaires were used--one for teachers of the classrooms where our main instrument was administered, and the second a subsequently developed mail questionnaire to teachers concerning the relative amounts of attention given to various political subjects in the social studies curriculum.

A list of the dozen pretest questionnaires used is as follows:

Table A.2   a. Pretest Instruments

Name of Questionnaire	Where Used	Grades	Number of Respondents
Citizen Attitudes No. 3	Arlington Heights, Ill.; East Chicago, Indiana	2-8	788
Citizen Attitudes No. 4	Homewood, Illinois; Whiting, Indiana	2,3,5,7	345
Citizen Attitudes No. 5	Gary, Mishawaka, Ind.; Winnetka and Homewood, Illinois	3-8	338
Citizen Attitudes No. 6	Hammond, Ind.; Winnetka, Glencoe, Illinois	4,6,7,8	242
Citizen Attitudes No. 7	Park Forest, Illinois; East Chicago, Indiana	3-5,8	314
Citizen Attitudes No. 8 (non CA-9 portion)	Winnetka, Illinois; Gary, Indiana; and Atlanta, Georgia	2-8	1297
In My Opinion No. 1	Homewood, Illinois; Whiting, Indiana	4,6,8	252
In My Opinion No. 2	Gary, Mishawaka, Hammond, Indiana; Winnetka and Glencoe, Illinois	4,6-8	471
In My Opinion No. 3A In My Opinion No. 3B	Waukegan, Bensonville, Matteson and Wilmette, Illinois	3-8	807
G2-NR	Park Forest, Illinois; East Chicago, Indiana	2,3,6,7	235
G2-R		2,4,6,7,	235
Rate the Man No. 1	Hammond, Mishawaka, Ind.; Glencoe, Illinois	3-5,7	333
Rate the Man No. 2		3,5,7	247

b. Teacher Instruments

| Curriculum Questionnaire | Six cities (excluding Jackson and Tacoma | 2-8 | 139 |

396

Administration

Questionnaire administration was in general carried out in regular classrooms under the direction of a member of the project staff. For all grades except seven and eight, the complete questionnaire was normally read out by the staff member while the children marked their answers. In most cases, the teacher remained present and marked his or her own questionnaire. For grades 2 and 3, two former grade school teachers were employed to administer the questionnaire.

At the beginning of the session, the staff member would announce the name of the study, its location and the fact that the questionnaire was an opinion survey rather than examination and that all respondents would remain anonymous and all answers be kept confidential. The latter, of course, were phrased in language the child could readily understand.

Dates of administration

The dates of administration of the pretests and interviews included most of 1961 and early 1962. The main instrument was administered in late 1961 and early 1962.

BEGIN HERE

Print your name

Print your teacher's name

Print the first name and the grade of each brother or sister in grades 2, 3, 4, 5, 6, 7, 8 in this school.

Name   Grade
Name   Grade
Name   Grade
Name   Grade

(16) How old are you? Put an X in the box that tells how old you are today?

1. 6 years old
2. 7 years old
3. 8 years old
4. 9 years old
5. 10 years old
6. 11 years old
7. 12 years old
8. 13 years old
9. 14 years old or older

(17) You are a:
1. Boy
2. Girl

(18) How often do you go to Mass, Church, Temple, or Sunday School? (Choose one)
1. Every week
2. Almost every week
3. Only once in a while
4. Almost never

(19) Your family is: (Choose one)

1. ☐ Catholic
2. ☐ Jewish
3. ☐ Protestant
4. ☐ Other
5. ☐ None

(20) Who is the boss in your family? (Choose one)

1. ☐ Both fairly equal but _father_ more
2. ☐ Both fairly equal but _mother_ more
3. ☐ _Both fairly equal_
4. ☐ I can not answer

(21) Do you have any sisters or brothers?

1. ☐ Yes I have
2. ☐ No I have not

(22) Are you older than all of your sisters and brothers?
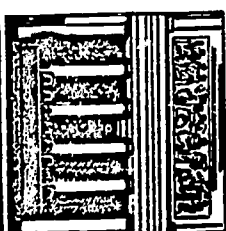

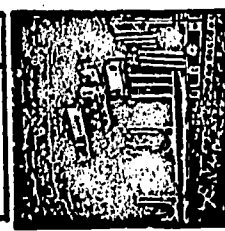

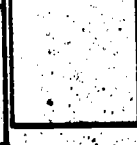

1. ☐ Yes I am
2. ☐ No I am not

(23) Are you younger than all of your sisters and brothers?

1. ☐ Yes I am
2. ☐ No I am not

(24) Here are some pictures that show what our government is. Pick the _two_ pictures that show best what our government is.

1. POLICEMAN
2. WASHINGTON
3. UNCLE SAM
4. VOTING VOTE HERE
5. SUPREME COURT
6. CAPITOL
7. CONGRESS
8. FLAG
9. STATUE OF LIBERTY
X. PRESIDENT
Y. DON'T KNOW

399

(25) If the President came to your school to give a prize to two boys who were the best citizens and the teacher offered him these boys, which two boys would he pick?

Put an X by the two he would choose as the best citizens.
1. ☐ A boy who helps others.

2. ☐ A boy who does what he is told.
3. ☐ A boy who gets good grades.

4. ☐ A boy who is interested in the way our country is run.
5. ☐ A boy who everybody likes.
6. ☐ A boy who works here.
7. ☐ A boy who goes to church.

8. ☐ I don't know what citizen means.

6.
Think of the policeman as he really is . . . .

	1	2	3	4	5	6
Is friendlier than anyone	Is friendlier than almost anyone	Is friendlier than most people	Is friendlier than some people	Is friendlier than a few people	Is friendlier than almost no one
(26) Would always want to help me if I needed it	Would almost always want to help me if I needed it	Would usually want to help me if I needed it	Would sometimes want to help me if I needed it	Would seldom want to help me if I needed it	Would not usually want to help me if I needed it
(27) Makes important decisions all the time	Makes important decisions a lot of the time	Makes important decisions sometimes	Makes important decisions seldom	Almost never makes important decisions	Never makes important decisions
(28) Knows more than anyone	Knows more than most people	Knows more than many people	Knows less than many people	Knows less than most people	Knows less than anyone
(29) Always keeps his promises	Almost always keeps his promises	Usually keeps his promises	Sometimes does not keep his promises	Usually does not keep his promises	Almost never keeps his promises
(30) Can make anyone do what he wants	Can make almost anyone do what he wants	Can make many people do what he wants	Can make some people do what he wants	Can make a few people do what he wants	Can make almost no one do what he wants
(31) Is my favorite of all	Is almost my favorite of all	Is more a favorite of mine than most	Is more a favorite of mine than many	Is more a favorite of mine than a few	Is not one of my favorites

400

(32) When we say the Pledge of Allegiance, we say it: (choose one)

1. ☐ To the Country
2. ☐ To God
3. ☐ To the President
4. ☐ To the Flag

(33) Who makes the laws? Put an X next to the one who does the most to make laws.

1. ☐ CONGRESS

2. ☐ PRESIDENT

3. ☐ SUPREME COURT

4. ☐ I DON'T KNOW

(34) Which do you think is the most true?   (choose one)

1. ☐ If you write to the President he cares a lot what you think.
2. ☐ If you write to the President he cares some what you think.
3. ☐ If you write to the President he cares a little what you think.

---

8. Which of these are laws? Mark an X next to Yes or No to show whether each of these things is a law.
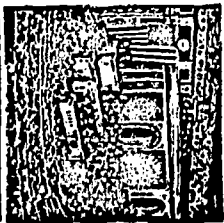

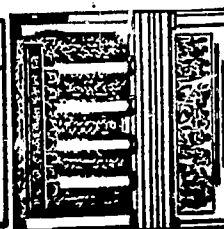

(35) Brush your teeth every morning. Is this a law?
1. ☐ Yes
2. ☐ No

(36) Don't cheat in school. Is this a law?
1. ☐ Yes
2. ☐ No

(37) Cars must stop at stop signs. Is this a law?
1. ☐ Yes
2. ☐ No

(38) Get to school on time. Is this a law?
1. ☐ Yes
2. ☐ No

(39) Always vote. Is this a law?
1. ☐ Yes
2. ☐ No

(40) If you think a policeman is wrong in what he tells you to do, what would you do?
Put an X beside the one that tells what you would do.

1. ☐ Do what he tells you and forget about it.

2. ☐ Do what he tells you but tell your father about it.

3. ☐ Do what he tells you but ask the policeman why.

4. ☐ Do what he tells you but tell the policeman he is wrong.

9.

(41) Who does the most to run the country? Put an X in the box next to the one who does the most to run the country.

1. CONGRESS 2. PRESIDENT 3. SUPREME COURT 4. I DON'T KNOW

(42) If you could vote what would you be? (Choose one)

1. ☐ A Republican.

2. ☐ A Democrat.

3. ☐ Sometimes a Democrat and sometimes a Republican.

4. ☐ I don't know which I would be.

5. ☐ I don't know what Democrats and Republicans mean.

10.

Think of the President as he really is....

	1	2	3	4	5	6
(43)	Would always want to help me if I needed it	Would almost always want to help me if I needed it	Would usually sometimes want to help me if I needed it	Would sometimes want to help me if I needed it	Would usually not want to help me if I needed it	Would not want to help me if I needed it
(44)	Makes important decisions all the time	Makes important decisions a lot of the time	Makes important decisions sometimes	Makes important decisions seldom	Almost never makes important decisions	Never makes important decisions
(45)	Knows more than anyone	Knows more than most people	Knows more than many people	Knows less than many people	Knows less than most people	Knows less than anyone
(46)	Always keeps his promises	Almost always keeps his promises	Usually keeps his promises	Sometimes does not keep his promises	Usually does not keep his promises	Almost never keeps his promises
(47)	Can make anyone do what he wants	Can make almost anyone do what he wants	Can make many people do what he wants	Can make some people do what he wants	Can make a few people do what he wants	Can make almost no one do what he wants
(48)	Is my favorite of all	Is almost my favorite of all	Is more a favorite than most	Is more a favorite of mine than many	Is more a favorite of mine than a few	Is not one of my favorites

Here are some people. Which ones work for the government?

11.

(49) Does the MILKMAN work for the government?
1. ☐ Yes
2. ☐ No

(50) Does the POLICEMAN work for the government?
1. ☐ Yes
2. ☐ No

(51) Does the SOLDIER work for the government?
1. ☐ Yes
2. ☐ No

(52) Does the JUDGE work for the government?
1. ☐ Yes
2. ☐ No

(53) Does the POSTMAN work for the government?
1. ☐ Yes
2. ☐ No

12.

(54) Does the TEACHER work for the government?
1. ☐ Yes
2. ☐ No

(55) Some of you may not be quite sure what the word government means. If you are not sure what government means, put an X in the box below.
1. ☐

(56) Which one of these does most to keep peace in the world? (Choose one)

1. ☐ UNITED NATIONS   3. ☐ I DON'T KNOW   2. ☐ UNITED STATES

(57) What makes you the most proud to be an American? Check the two things that make you most proud.

1. ☐ Americans are the most generous people in the world.
2. ☐ America has beautiful parks and highways.
3. ☐ Americans can vote for their own leaders.
4. ☐ Americans have freed'm.
5. ☐ Our President.

403

(58) Who helps you and your family the most? Put an X by the two who help you and your family the most.

| 1. POLICEMAN | 2. SOLDIER | 3. FATHER | 4. TEACHER | 5. PRESIDENT |

HERE IS A DIFFERENT KIND OF QUESTION. TRY THIS ONE FOR PRACTICE:

Chocolate ice cream tastes good.

1. ☐ YES 2. ☐ yes 3. ○ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(59) The American flag is the best flag in the world.

1. ☐ YES 2. ☐ yes 3. ○ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(60) All laws are fair.

1. ☐ YES 2. ☐ yes 3. ○ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(61) America is the best country in the world.

1. ☐ YES 2. ☐ yes 3. ○ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(62) People in other countries think their country is the best in the world.

1. ☐ YES 2. ☐ yes 3. ○ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(63) Most laws were made a long time ago.

1. ☐ YES 2. ☐ yes 3. ○ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

Think of Your Father as he really is. . . . .

(64)

1	2	3	4	5	6
Would always want to help me if I needed it	Would almost always want to help me if I needed it	Would usually want to help me if I needed it	Would sometimes want to help me if I needed it	Would seldom want to help me if I needed it	Would not usually want to help me if I needed it

(65)

1	2	3	4	5	6
Makes important decisions all the time	Makes important decisions most of the time	Makes important decisions sometimes	Makes important decisions seldom	Almost never makes important decisions	Never makes important decisions

(66)

1	2	3	4	5	6
Knows more than anyone	Knows more than most people	Knows more than many people	Knows less than many people	Knows less than most people	Knows less than anyone

15. Think of *Your Father* as he really is . . .

(67)

1	2	3	4	5	6
Always keeps his promises	Almost always keeps his promises	Usually keeps his promises	Sometimes does not keep his promises	Usually does not keep his promises	Almost never keeps his promises

(68)

1	2	3	4	5	6
Can make anyone do what he wants	Can make almost anyone do what he wants	Can make many people do what he wants	Can make some people do what he wants	Can make a few people do what he wants	Can make almost no one do what he wants

(69)

1	2	3	4	5	6
Is my favorite of all	Is almost my favorite of all	Is more a favorite of mine than most	Is more a favorite of mine than many	Is more a favorite of mine than a few	Is not one of my favorites

(70) Which do you think is the most true? (Choose one)

1. ☐ People who break laws *always get caught*.

2. ☐ People who break laws *usually get caught*.

3. ☐ People who break laws *usually get away*.

4. ☐ People who break laws *always get away*.

16.

(71) How much are you interested in reading or talking about current events, government, or other things going on in our country?   (Choose one)

1. ☐ Very much.

2. ☐ Some.

3. ☐ Only a little.

(72) Voting is the only way that people like my mother and father can have any say about how the government runs things.

		Don't Know		
1. ☐ YES	2. ☐ yes	3. ◯ No Opinion	4. ☐ no	5. ☐ NO

(73) How much difference is there between the Democrats and the Republicans?   (Choose one)

1. ☐ A *very big* difference.

2. ☐ A big difference.

3. ☐ Some difference.

4. ☐ A very small difference.

5. ☐ No difference.

0. ☐ I do not know or I have no opinion.

(74) Sometimes I can't understand what goes on in the government.

		Don't Know		
1. ☐ YES	2. ☐ yes	3. ◯ No Opinion	4. ☐ no	5. ☐ NO

[END DECK 35]

405

17.

(18) What happens in the government will happen no matter what people do. It is like the weather, there is nothing people can do about it.

1. ☐ YES   2. ☐ yes   Don't Know   3. ◯ No Opinion   4. ☐ no   5. ☐ NO

(19) How important do you think it is for grown-ups to belong to either the Republican or Democratic Party? (choose one)

1. ☐ Very important.
2. ☐ Important.
3. ☐ Not too important.
4. ☐ Not important at all.
0. ☐ I do not know or I have no opinion.

(20) Would you like to work for the government?

1. ☐ YES   2. ☐ yes   Don't Know   3. ◯ No Opinion   4. ☐ no   5. ☐ NO

(21) When I heard Kennedy won the election over Nixon: (mark the one which is closest to the way you felt at that time)

1. ☐ I was very happy.
2. ☐ I was happy.
3. ☐ I didn't much care one way or the other.
4. ☐ I felt bad.
5. ☐ I felt so bad I almost cried.

18.

Below are a list of people and things. For each person or thing, circle the number that shows how much they teach you about being a good citizen.

(22) How much does your father teach you about being a good citizen?

1 He teaches me an awful lot	2 He teaches me a lot	3 He teaches me some	4 He teaches me a little	5 He doesn't teach me at all

(23) How much does your teacher teach you about being a good citizen?

1 She teaches me an awful lot	2 She teaches me a lot	3 She teaches me some	4 She teaches me a little	5 She doesn't teach me at all

(24) How much does your mother teach you about being a good citizen?

1 She teaches me an awful lot	2 She teaches me a lot	3 She teaches me some	4 She teaches me a little	5 She doesn't teach me at all

(25) How much do your friends teach you about being a good citizen?

1 They teach me an awful lot	2 They teach me a lot	3 They teach me some	4 They teach me a little	5 They don't teach me at all

(26) How much does your minister, priest, or rabbi teach you about being a good citizen?

1 He teaches me an awful lot	2 He teaches me a lot	3 He teaches me some	4 He teaches me a little	5 He doesn't teach me at all

(27) How much does television teach you about being a good citizen?

1 It teaches me an awful lot	2 It teaches me a lot	3 It teaches me some	4 It teaches me a little	5 It doesn't teach me at all

(28) How much do books, magazines, and newspapers teach you about being a good citizen?

1 They teach me an awful lot	2 They teach me a lot	3 They teach me some	4 They teach me a little	5 They don't teach me at all

406

(29) There are some big powerful men in the government who are running the whole thing and they do not care about us ordinary people.

1. ☐ YES 2. ☐ yes 3. ◯ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(30) After supper I would rather: (choose one)

1. ☐ Read a book.
2. ☐ Watch television.
3. ☐ Talk to my friends.

(31) My family doesn't have any say about what the government does.

1. ☐ YES 2. ☐ yes 3. ◯ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

(32) Many people would like to be President, a Senator, or a Mayor. Why do you think these people would like to have these jobs? (choose one)

1. ☐ They want to change things that are not good in the government.
2. ☐ They want to make a lot of money or be important.
3. ☐ They want to keep things as good as they are in our country.

(33) It is all right for the government to lie to another country if the lie protects the American people.

1. ☐ YES 2. ☐ yes 3. ◯ Don't Know / No Opinion 4. ☐ no 5. ☐ NO

In reading the next few things, you should know that every four years people run for office in our government; this is called an election; and the people running in it are called candidates. Things about government, politics, and candidates that you have done:

(34) I have worn a button for a candidate.

1. ☐ Yes
2. ☐ No

(35) I have helped a candidate by doing things for him -- such as handing out buttons and papers with his name on them.

1. ☐ Yes
2. ☐ No

(36) I have talked with my mother or father about our country's problems.

1. ☐ Yes
2. ☐ No

(37) I have talked with my friends about a candidate.

1. ☐ Yes
2. ☐ No

(38) I have read about a candidate in newspapers or magazines.

1. ☐ Yes
2. ☐ No

(39) I have talked with my mother or father about a candidate.

1. ☐ Yes
2. ☐ No

(40) Why do you think most boys and girls wore buttons in the last important election?
(Choose one)

1. ☐ Because their friends did.

2. ☐ Because their parents did.

3. ☐ Because it was fun.

4. ☐ Because it is a good thing to take sides.

5. ☐ Because they thought it would help their candidate win.

0. ☐ I am not sure what this means.

21.

(41) I think that what goes on in the government is all for the best.

1. ☐ YES   2. ☐ yes   3. ◯ Don't Know   4. ☐ no   5. ☐ NO
                              No Opinion

(42) By the time you are grown-up . . . . .   (Choose one)

1. ☐ All laws will change.

2. ☐ Most laws will change.

3. ☐ Half the laws will change.

4. ☐ A few laws will change.

5. ☐ No laws will change.

0. ☐ I don't know.

22.

(43) I don't think people in the government care much what people like my family think.

1. ☐ YES   2. ☐ yes   3. ◯ Don't Know   4. ☐ no   5. ☐ NO
                              No Opinion

(44) Here are some things that boys and girls have said about what the President's job is.
What do you think the job of the President is? Put an X beside the two things below
that say what you think the job of the President is.

1. ☐ His job is to keep us out of war.

2. ☐ His job is to make friends with other countries.

3. ☐ His job is to help people in our country.

4. ☐ His job is to stand for our country.

5. ☐ His job is to make people obey the laws.

6. ☐ His job is to make sure our country is run well.

(45) Citizens don't have a chance to say what they think about running the government.

1. ☐ YES   2. ☐ yes   3. ◯ Don't Know   4. ☐ no   5. ☐ NO
                              No Opinion

(46) Are your parents interested in current events and what happens in the government?
(Choose one)

1. ☐ Always interested.

2. ☐ Usually interested.

3. ☐ Sometimes interested.

4. ☐ Almost never interested.

0. ☐ I can not answer.

408

(47) Do you belong to a school club, organization, or committee (such as student council, musical organization, or service committee)?

1. ☐ Yes
2. ☐ No

(48) Put an X beside each of the clubs or organizations below which you belong to now, or which you have belonged to for at least a year.

1. ☐ Boy Scouts (or Cub Scouts) 5. ☐ CYO
2. ☐ Girl Scouts (or Brownies) 6. ☐ Boys' Club
3. ☐ Camp Fire Girls 7. ☐ 4-H Club
4. ☐ YMCA, YWCA, YMHA, HI-Y
8. ☐ I do not belong to any club or organization outside of school.

(49) In this school year I belong to some team (which meets after school hours) which plays baseball, basketball, volleyball, or some other sport.

1. ☐ Yes
2. ☐ No

(50) I have held some office in my class or in one of the clubs or organizations mentioned.

1. ☐ Yes
2. ☐ No

(51) It is easy to get a law changed.

1. ☐ YES 2. ☐ yes 3. ◯ Don't Know No Opinion 4. ☐ no 5. ☐ NO

---

(52) The Pledge of Allegiance is like... Put an X beside the one that says what the Pledge of Allegiance is like.

1. ☐ A prayer for our country.
2. ☐ Saying that our flag is best.
3. ☐ Saying that our country is the best.
4. ☐ Saying that we will help our country.

(53) It is better if young people belong to the same political party as their parents. (choose one)

1. ☐ Yes
2. ☐ No
3. ☐ Don't Know

(54) Disobey means to do something someone tells you not to do. Which of these is the most wrong? Put an X beside the one that is the most wrong.

1. ☐ To disobey your mother.
2. ☐ To disobey your teacher.
3. ☐ To disobey your father.
4. ☐ To disobey the policeman.

(55) Which of the following is the best citizen? Put an X beside the sentence that describes the best citizen.

1. ☐ He makes up his mind to be either a Democrat or a Republican and always votes the way his party does.
2. ☐ He doesn't join either the Democrats or the Republicans and votes for the man he thinks is best.
0. ☐ I don't know what the words Democrat and Republican mean.

Think of _Your Father_ as he really is . . . .

(56)	1	2	3	4	5	6
	Almost never makes mistakes	Rarely makes mistakes	Sometimes makes mistakes	Often makes mistakes	Usually makes mistakes	Almost always makes mistakes

(57)	1	2	3	4	5	6
	Always a leader	Usually a leader	More often a leader than a follower	More often a follower than a leader	Usually a follower	Almost always a follower

(58)	1	2	3	4	5	6
	Can punish anyone	Can punish almost anyone	Can punish many people	Can punish some people	Can punish a few people	Can punish no one

(59)	1	2	3	4	5	6

(71) Put an X beside the sentence which comes closest to telling what your father's job is. (If your father is dead or not working now, mark the kind of job he did when he was working.)

1. ☐ He works in a factory or mill; or as a truck driver, janitor or some other job where he works with his hands.

2. ☐ He works with his hands in a job that takes a long time to learn -- like a carpenter, an electrician, a plumber, a TV repairman, a machinist, etc.

3. ☐ He works in an office or store for somebody else. He works as a bookkeeper, salesman, or clerk.
He owns a service station, laundry, or small store.
He is a policeman, fireman, soldier, or works for the government. (He usually wears a uniform or a white shirt and tie to work.)

4. ☐ He works in an office as a manager or executive.

5. ☐ He is a doctor, lawyer, teacher, an engineer, or some job like that. He has a college degree and special training for his job.

6. ☐ He owns a large business, like a factory or a big store.

0. ☐ I don't know what my father does.

(72) If the Democrats and Republicans disagreed on important things: (circle the number that is closest to what you think would happen)

1	2	3	4	5	0
It would be very bad for the country	It would be bad for the country	It would not matter	It would be good for the country	It would be very good for the country	Don't Know

(73) When should a person decide which political party to support?   (Choose one)

1. ☐ Before he goes to high school.

2. ☐ Before he leaves high school.

3. ☐ After high school but before he is old enough to vote.

4. ☐ After he is old enough to vote.

Think of the Policeman as he really is . . . .

(74)	1 Almost never makes mistakes	2 Rarely makes mistakes	3 Sometimes makes mistakes	4 Often makes mistakes	5 Usually makes mistakes	6 Almost always makes mistakes
(75)	1 Always a leader	2 Usually a leader	3 More often a leader than a follower	4 More often a follower than a leader	5 Usually a follower	6 Almost always a follower
(76)	1 Can punish anyone	2 Can punish almost anyone	3 Can punish many people	4 Can punish some people	5 Can punish a few people	6 Can punish no one

(21)	1 Almost always gives up when things are hard to do	2 Usually gives up when things are hard to do	3 Sometimes gives up when things are hard to do	4 Usually does not give up when things are hard to do	5 Almost never gives up when things are hard to do	6 Never gives up when things are hard to do

(END OF DECK 36)

How much do these people help decide which laws are made for our country: Very much, Some, Very Little, or Not At All? Put an X for each person or group of people listed below.

(22) **Rich people**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(23) **Unions**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(24) **The President**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(25) **Newspapers**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(26) **Churches**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(27) **The Average Person**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(28) **Policemen**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

(29) **Big Companies**
1. ☐ Very Much 2. ☐ Some 3. ☐ Very Little 4. ☐ Not at all 0. ◯ Don't Know

31.

(30) How much did you learn from the last election for President? (choose one).

1. ☐ I learned a lot.
2. ☐ I learned some.
3. ☐ I learned very little.

(31) Which is the most important for the policeman to do? (choose one)

1. ☐ Make people obey the law.
2. ☐ Help people who are in trouble.
3. ☐ Catch people who break the law.

Think of the government as it really is. . . . .   (Circle the number of your choice)

	1	2	3	4	5	6
(32)	Almost never makes mistakes	Rarely makes mistakes	Sometimes makes mistakes	Often makes mistakes	Usually makes mistakes	Almost always makes mistakes

1	2	3	4	5	6
I like him more than anyone	I like him more than most people	I like him more than many people	I like him more than some people	I like him more than a few people	I like him less than almost anyone

34.

(49) How important do you think each of these problems is for America today?   (choose one)

Curing sickness (like heart trouble, cancer, and polio).   (choose one)

1. [ ] The most important problem.

2. [ ] One of the most important problems.

3. [ ] More important than many problems.

4. [ ] More important than a few problems.

5. [ ] Not a very important problem.

(50) Communist Russia.   (choose one)

1. [ ] The most important problem.

2. [ ] One of the most important problems.

3. [ ] More important than many problems.

4. [ ] More important than a few problems.

5. [ ] Not a very important problem.

(51) Making our cities beautiful.   (choose one)

1. [ ] The most important problem.

2. [ ] One of the most important problems.

3. [ ] More important than many problems.

4. [ ] More important than a few problems.

5. [ ] Not a very important problem.

414

35.

(52) How important do you think each of these problems is for America today?

People out of work.   (Choose one)

1. ☐ The most important problem.
2. ☐ One of the most important problem.
3. ☐ More important than many problems.
4. ☐ More important than a few problems.
5. ☐ Not a very important problem.

(53) Making sure all Americans have equal rights.   (Choose one)

1. ☐ The most important problem.
2. ☐ One of the most important problem.
3. ☐ More important than many problems.
4. ☐ More important than a few problems.
5. ☐ Not a very important problem.

(54) Most of the boys and girls in my class are: (Choose one)

1. ☐ Republicans.
2. ☐ Democrats.
3. ☐ Neither.
4. ☐ I don't know.

36.

People who try to get elected are . . . .   (circle the number of your choice)

(55)

ABSTRACT

This is an investigation of the child's (ages 7-13) developing images of political authority in the American system and the origins of basic political support. Using questionnaire data collected from 12,0__ white, public school children in eight metropolitan areas (distributed among four major regions of the United States) in 1961-62, plus data from several pilot and pretest questionnaires and interviews, the inquiry has yielded a number of generalizations about the manner in which children come to recognize and evaluate such representatives of political authority as the President, local policeman, Senator, Supreme Court and Government.
